were able to compensate for wind drift, even headwind drift, so as to orient south-westward no matter how the wind changed, and thus the displacement direction was towards the south-west. 4. The duration of flight, estimated from the variation of area density derived from radar data and hourly catches in the searchlight trap through the night, was about 9–10 h. The displacement speed detected using radar was $\sim 5\text{--}11\text{ m s}^{-1}$. Therefore, the dragonflies might migrate 150–400 km in a single flight. 5. The dragonflies were thought to originate in Jiangsu province and they migrated into north-east China to exploit the temporary environment of paddy fields in early summer. Their offspring probably migrated back south during late summer and autumn." 5907. Finch, J.M.; Samways, M.J.; Hill, T.R.; Piper, S.E.; Taylor, S. (2006): Application of predictive distribution modelling to invertebrates: Odonata in South Africa. *Biodiversity and Conservation* 15(13): 4239-4251. (in English). ["The application of distributional modelling techniques to invertebrates has seldom been explored, primarily due to a lack in adequate distributional data for these taxa. Here, we have selected a simple modelling approach for the generation of distribution maps from a limited dataset, as a first step to the atlas-ing of Odonata in South Africa. The BIOCLIM-type ap-

proach was selected for this purpose, as it requires minimal data for model building and validation procedures. BIOCLIM partitions an area climatically prior to survey, and predicts species distributions on a bioclimatic basis. Conservative deterministic models were developed using point presence/absence data for each of the regions' 160 described species. These models were validated by cross-validation, and the Jaccard coefficient of similarity was used as an index of model performance. A sensitivity analysis investigated the influence of extreme values and errors in the data on predictive ability. Models identified disjunct distribution patterns and accurately predicted the restricted ranges of habitat-specialist species. However, models overstated the distribution of habitat generalists and species with distinct outlier records. For accurate predictions of broad-ranging species, it is suggested that a probabilistic approach be adopted. Nevertheless, basic distribution patterns generated through this conservative approach can be further applied to the investigation of species richness and issues relating to conservation, such as reserve design. The BIOCLIM-type approach provided a means of predicting species distributions, allowing for broad-scale atlassing and thereby providing the first step towards Odonata conservation in South Africa." 5908. Fishar, M.R.; Williams, W.P. (2006): A feasibility study to monitor the macroinvertebrate diversity of the River Nile using three sampling methods. *Hydrobiologia* 556: 137-147. (in English). ["The River Nile (Africa) is one of the world's major rivers. Its' catchment in Egypt has a population of 75,000,000. River flow is highly regulated and there are known discharges of pollutants. 1035 km of the river downstream of the Aswan high dam was studied to test the hypothesis that representative qualitative samples can be used to estimate macroinvertebrate biodiversity. Benthic macroinvertebrates are difficult to sample in large rivers and a reliable sampling strategy is required to evaluate their ecological status. Three methods for sampling have been investigated. Ekman Grab, macrophyte sweep netting and Artificial Substrate Samplers (ASS) were used to sample 15 sites from Aswan to Cairo between September 2001 and June 2002. Organisms were identified to species level where possible. Taxon accretion curves indicated that the all taxa present at a site should be collected using either 15 grab samples, 10 macrophyte samples or 5 ASS. The best time to sample was May–June. The biodiversity of macroinvertebrates in the Nile was recorded as 50 taxa with values of 7–31 at individual bank-side sites. Mid-stream biodiversity was much lower (0–19). Lowest biodiversity occurred at sites with known pollution inputs whilst highest occurred at sites with high levels of sedimentation. A regular programme for biomonitoring is recommended which will allow current status to be confirmed and future changes detected." (Authors) The mentioning in table 5 of *Neurocordulia* sp., *Amphiagrion* sp., *Plathemis* sp., *Perithemis* sp., and *Celithemis* sp. indicates that from an odonological point of view this study is not very useful.] Address: Williams, P., Department of Life Sciences, King's College, University of London, Franklin Wilkins Building, 150 Stamford Street, SE1 9NN, UK. 5909. Fleck, G.; Brenk, M.; Misof, B. (2006): DNA Taxonomy and the identification of immature insect stages: the true larva of *Tauriphila argo* (Hagen 1869) (Odonata: Anisoptera: Libellulidae). *Ann. soc. entomol. Fr.* (n.s.) 42(1): 91-98. (in English, with French summary). ["For many insect taxa, larval morphology plays a decisive role in various fields like taxonomy, phylogeny or ecology. However, species identification is usually based on imaginal characters and the identification of larvae depends upon an established link to unequivocally identified imagines. This taxonomic correspondence of larvae and imagines is far from being established in many odonate species. We have employed a molecular approach to link larval and adult specimens in *Tauriphila argo* (Hagen, 1869). The sequenced mt SSU gene fragments of the reared female, supposedly a *T. argo* female, and a clearly identified male specimen of the species were identical. However, the larva of the reared female clearly differed from the described *T. argo* larva, previously matched to the species. From this observation, we conclude that the previously described larva of *T. argo* does not belong to this species because of too many phenotypic differences that far exceed the generally observed intraspecific variation. It can be foreseen that the molecular approach will prove to be effective in identifying unknown larvae in many insect species. Additionally, the discrimination of sibling species or the linkage of allotypes and holotypes will become feasible with this approach." (Authors)] Address: Fleck, G., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: fleck@mnhn.fr

5910. Flenner, I.; Olne, K. (2006): Differences in exocuticle thickness in *Leucorrhinia dubia* (Odonata) larvae from habitats with and without fish. Halmstad University, School of Business and Engineering, Degree project in Biology 10p, Supervisor: Göran Sahlén, 2006-05-31: 14 pp. (in English). ["Many prey species are able to develop different morphological structures as defence against for example predators. Some of these structures are induced only by individuals exposed to a predator. This phenomenon is called phenotypic plasticity. In this paper we examine whether cuticle thickness in *L. dubia* larvae differed between specimens caught in fish containing lakes and fish-free lakes respectively. We measured the thickness of the cuticle from four different parts of the larvae; profemur, pronotum, ninth segment sternite and ninth segment tergite. Our results showed a significantly thicker exocuticle on profemur in larvae with a head width bigger than 4.5 mm caught in lakes with fish. The smaller larvae showed a tendency to have thinner exocuticle on profemur in presence of fish. We discuss the probability that the differences in exocuticle thickness on profemur could be some kind of trade-off situation. The results also showed a tendency among the large larvae; the large individuals from lakes containing fish had a slightly thicker exocuticle on pronotum than the bigger individuals from fish-free lakes." 5913. Garrison, R.W. (2006): A synopsis of the genera *Mnesarete* Cowley, *Bryoplathanon* gen. nov., and *Ormenophlebia* gen. nov. (Odonata: Calopterygidae). *Contributions to Science, Natural History Museum of Los Angeles County* 506: 1-84. (in English, with Spanish summary). ["This synopsis of the exclusively South American genus *Mnesarete* includes keys to both sexes based primarily on morphology of the caudal appendage in males and the posterior margin of the prothorax and intersternite in females, diagnoses, distribution maps, and diagnostic illustrations. Two new genera, *Bryoplathanon* (type species: *Lais globifer* Hagen in Selys) and *Ormenophlebia* (type species: *Lais imperatrix* McLachlan) are described. The following nomenclatural changes are proposed: *M. regina* (Ris), *M. rollinoti* (Martin), and *M. saltuum* (Ris) are transferred to *Ormenophlebia*; and *Hetaerina borchgravi* Selys and *H. fuscibasis* Calvert are transferred to *Mnesarete*. Seven new species (*M. drepane*, *M. epibippium*, *M. lencionii*, *M. loutoni*, *M. machadoi*, *M. rhopalon*, and *M. williamsoni*) are described. A generic key to all New World Calopterygidae and a discussion of the generic concepts of *Hetaerina* and the 24 species of *Mnesarete* are presented, and descriptions for the last larval stadium of *M. grisea* and *O. imperatrix* are provided." 5914. Garrison, R.W.; Ellenrieder, N. von; Louton, J.A. (2006): Dragonfly genera of the New World. An illustrated and annotated key to the Anisoptera. The John Hopkins University Press, Baltimore: vii + 368pp. (in English). [Until now there has been no reliable means to identify the New World genera of Odonata. Now, this volume provides fully illustrated and up-to-date keys for all anisopteran genera with descriptive text for each genus, accompanied by more than 1,600 diagnostic illustrations, including wing patterns and characteristics of the genitalia, and 124 distribution maps, and covering all genera of Anisoptera occurring in North, Middle, and South America. A brief introduction into morphology of Anisoptera with excellent drawings of all morphologically relevant structures necessary to use this book, is followed by a key to the anisopteran families. Following this, each family is briefly characterized by distribution areal, number of known genera and species, and diagnostic characters. The status of family classification is compiled, indicating the current status of the discussion on its phylogenetic position. On the genus basis males and females are keyed separately. Then, each genus is briefly introduced by all information necessary

for nomenclature and taxonomic work, and listing all known species. This is followed by key references, and the distribution of the genus, including a map. The genus is described in detail using morphological structures which are illustrated. This is followed by identifying the "unique characters" of the genus. The current status on phylogenetic classification is outlined, also the potential for new species. The genus section is closed by condensed information on the habitat of the species. The volume ends with an extensive bibliography, a list of the 1626 figures with locality information, and a table with distribution information on genera by country. *Dragonfly Genera of the New World* is a beautifully illustrated and comprehensive guide to the taxonomy and ecology of dragonflies in North, Central, and South America. A reference of the highest quality, this book reveals their striking beauty and complexity. It is a real monumental work on odonate taxonomy and identification, and indispensable for every one working with the Odonata of the Americas. A great book. Congratulation to the authors!!! 5917. Ghose, K.; Horiuchi, T.K.; Krishnaprasad, P.S.; Moss, C.F. (2006): Echolocating bats use a nearly time-optimal strategy to intercept prey. *PLoS Biology* 4(5) (e108): 865-873. (in English). ["Acquisition of food in many animal species depends on the pursuit and capture of moving prey. Among modern humans, the pursuit and interception of moving targets plays a central role in a variety of sports, such as tennis, football, Frisbee, and baseball. Studies of target pursuit in animals, ranging from dragonflies to fish and dogs to humans, have suggested that they all use a constant bearing (CB) strategy to pursue prey or other moving targets. CB is best known as the interception strategy employed by baseball outfielders to catch ballistic fly balls. CB is a time-optimal solution to catch targets moving along a straight line, or in a predictable fashion—such as a ballistic baseball, or a piece of food sinking in

water. Many animals, however, have to capture prey that may make evasive and unpredictable maneuvers. Is CB an optimum solution to pursuing erratically moving targets? Do animals faced with such erratic prey also use CB? In this paper, we address these questions by studying prey capture in an insectivorous echolocating bat. Echolocating bats rely on sonar to pursue and capture flying insects. The bat's prey may emerge from foliage for a brief time, fly in erratic three-dimensional paths before returning to cover. Bats typically take less than one second to detect, localize and capture such insects. We used high speed stereo infra-red videography to study the three dimensional flight paths of the big brown bat, *Eptesicus fuscus*, as it chased erratically moving insects in a dark laboratory flight room. We quantified the bat's complex pursuit trajectories using a simple delay differential equation. Our analysis of the pursuit trajectories suggests that bats use a constant absolute target direction strategy during pursuit. We show mathematically that, unlike CB, this approach minimizes the time it takes for a pursuer to intercept an unpredictably moving target. Interestingly, the bat's behavior is similar to the interception strategy implemented in some guided missiles. We suggest that the time-optimal strategy adopted by the bat is in response to the evolutionary pressures of having to capture erratic and fast moving insects." (in English). ["The life history of *C. erronea* was studied for ten years utilizing field observations of adults and both field and laboratory studies of larvae. The documented adult flight period in Ohio is from 1 June to 3 September. Adult patrolling and larval habitat utilized consists of persistent but very narrow and shallow headwater streams, fed by seeps or springs in densely forested areas. Stream areas utilized have no fish and almost no other Odonata. The only aquatic predators observed were salamander larvae and an occasional very small crayfish. Adult males patrol regular beats during the heat of mid-day, flying low over the streamlets. Multiple males patrol the same streamlets. Adult females are uncommonly seen on the

streams. Oviposition was observed between 18 June and 2 August and females made up to 370 oviposition thrusts in a single event. The author was able to establish criteria to recognize larval instars between F0 and F4 with a 92% confidence level. The larval period appears to be typically three to four years long. Some discussion and tentative hypothesis are made concerning egg development, but there is a need for direct study of the timing of hatching." 5920. Goffart, P.; Paternoster, T. (2006): Redécouverte du Leste verdoyant (*Lestes virens*) en Wallonie. *Gomphus* 20(2): 29-38. (in French, with English and Dutch summaries). ["A small population of *Lestes virens* has been found in the Hainaut county, Belgium during the summer 2005 (July to September), after more than 50 years without certified record of the species in Wallonia. It is established on three oligotrophic and acid pools on a sandy substrate lying within the forest massif to the north of the Haine valley (often called "Campine hennuyère"). Counts' tentatives gave a maximum of 14 males and 7 females, namely 21 individuals, on the 31th of August. All the females were grasped by male in tandem position and where egg-laying in *Juncus effusus* twig tips. One recently emerged male has been observed on the 11th of July. This population might have been present since a long time and been overlooked despite former prospects. Though less probable a priori, it could also result of a recent colonisation event, from populations living in neighbouring regions. The closest known, in Flanders and France, lie however at a distance of one hundred kilometres from the Hainaut site, but other populations could have been overlooked in a shorter radius." (Authors)] Address: Goffart, P., Observatoire de la Faune, de la Flore et des Habitats, Centre de Recherche de la Nature, des Forêts et du Bois, Avenue Maréchal Juin, 23, 5030 Gembloux, Belgium. 5922. Günther, A. (2006): Reproductive behaviour of *Neurobasis kaupi* (Odonata: Calopterygidae). *International Journal of Odonatology* 9(2): 151-164. (in English). ["The reproductive behaviour of *Neurobasis kaupi* was

studied for the first time in Central and South Sulawesi. The species was recorded in a wide variety of clear and fast flowing creeks, streams and rivers, mostly in forested areas. The males were territorial and defended potential oviposition sites, a limited resource. Territory owners demonstrated their presence by brief synchronized flashings of their hindwings as well as by regular inspection flights. Intruders were first driven off by short chasing flights. Longer lasting conflicts led to three different types of threatening flights, depending on the number of males involved and the level of excitation. As in other Calopterygidae males of *N. kaupi* led receptive females to potential oviposition sites. In courtship flight the male presented the upper sides of his stationary, depressed, quivering hindwings, with the hind margins broadly touching the water surface. Oviposition substrates were mostly submerged floating root mats or plants, optimally floating loosely at a depth of 5-15 cm below the water surface. The general patterns of behaviour of *N. kaupi* correspond to the known behaviour of other *Neurobasis* species. However, within this general framework there are clear differences between this species and others, especially *N. chinensis*." [42 species of aquatic insects were recorded from seven sites including 10 odonate species] Address: Hayashi, M., Hoshizaki Green Foundation, Okinoshima, 1659-5, Sono, Izumo, Shimane Pref., 691-0076, Japan
- 5931.** Heckman, C.W. (2006): Encyclopedia of South American Aquatic Insects: Odonata - Anisoptera. ISBN: 978-1-4020-4801-2 : VIII, 725 pp. ["Anisoptera, the first of two volumes on the Odonata in the series Encyclopedia of South American Aquatic Insects, encompasses the large dragonfly species. A brief review of the biology of the group includes illustrations of the main morphological features as well as explanations of alternative systems for naming the wing veins and other structures. The review is then followed by keys to facilitate identification of the adult dragonflies and the known larvae, allowing the user a high probability of identifying his specimens correctly. In addition to anatomical features, the keys include the known ranges of the species, synonyms, and citations of literature in which more information about each individual species can be obtained. These citations are compiled in an extensive bibliography. To provide the user with the best possible opportunity to distinguish the species, the keys are richly illustrated with pen and ink drawings of thousands of individual morphological structures, arranged in 797 figures." - 5933.** Hernandez, K.M.; Reece, B.A.; McIntyre, N.E. (2006): Effects of anthropogenic land use on Odonata in Playas of the southern high plains. *Western North American Naturalist* 66(3): 273-278. (in English). ["Playas are ephemeral wetlands that are the only source of aboveground freshwater in the southern Great Plains, making them of vital importance to aquatic and amphibious animals. Playas are also highly threatened from anthropogenic land use (chiefly agriculture, which decreases hydroperiod through increased sedimentation). We examined community structure of adult odonates (dragonflies and damselflies) in playas differing in the 2 main regional forms of surrounding land use (cropland vs. grassland). Analysis of odonate diversity revealed high overlap between cropland and grassland playas. Traditional species-area theory did not fit observed patterns, as there appears to be a threshold playa size that supports maximal odonate diversity; this nonlinear response may reflect a tradeoff between hydroperiod and availability of emergent vegetation that is required for perching and oviposition. Since agriculture effectively reduces playa depth but not size of the overall playa watershed, this may mean that cropland playas serve as "ecological traps." This property has important implications for regional odonate diversity." - 5934.** Hoang, D.H.; Bae Y.J. (2006): Aquatic insect diversity in a tropical Vietnamese stream in comparison with that in a temperate Korean stream. *Limnology* 7: 45-55. (in English). ["A comparative investigation on aquatic insect diversity was conducted in a tropical stream in Southeast Asia (the Dak Pri stream in southern Vietnam; stream orders II-V, two sites per stream order) with a reference temperate stream in Northeast Asia (the Gapyeong stream in central Korea) in March 2001 and April 2000, respectively. The numbers of aquatic insect taxa in Dak Pri stream (268 species, mostly undescribed, 230 genera, 91 families, and 9 orders; 110.5 ± 17.1 species per site) were about twice those in Gapyeong stream (133 species, 98 genera, 51 families, and 8 orders; 60.3 ± 8.5 species per site). Coleoptera, Trichoptera, Ephemeroptera, and Diptera were the major aquatic insect orders with high taxonomic richness, and Coleoptera, Odonata, and Hemiptera contributed to the higher degree of aquatic insect diversity in Dak Pri stream. The species diversity indices of Dak Pri stream (4.37 ± 0.19) were higher than those of Gapyeong stream (3.73 ± 0.42), whereas the dominance indices of Dak Pri stream (0.195 ± 0.046) were lower than those of Gapyeong stream (0.346 ± 0.113). Collector-gatherers were predominant in both streams; shredders were more abundant in Dak Pri stream while scrapers were more abundant in Gapyeong stream. Factors affecting the higher degree of aquatic insect diversity in Dak Pri stream are discussed." (Authors) Odonata are identified on the genus level.] Address: Bae, Yeon Jae, Department of Biology, Seoul Women's University, 126

(in German, with English summary). [Germany, Nordrhein-Westfalen; A population of *C. pygargus* (Aves) was studied between 1993 and 2002. Only in 2000 a single "Aeshna spec." was among the prey observed.] Address: Hölker, M., Auf'm Alten Garten 17, D-595005 Bad Sassendorf, Germany. E-mail: manfredhoelker@freenet.de

5936. Hooper, I.R.; Vukusic, P.; Wootton, R.J. (2006): Detailed optical study of the transparent wing membranes of the dragonfly *Aeshna cyanea*. *Optics Express* 14(11): 4891-4897. (in English). ["The optical properties of transparent single membranes on the wings of *A. cyanea* have been investigated. These membranes comprise one central thick cuticular layer covered dorsally and ventrally with typical odonatan wax pruinosity. Optical characterisation of individual membranes reveals they can support optical guided modes comprising differential polarisation reflection. We suggest this may offer an intraspecific signalling channel. The guided modes' characteristics depend on membrane thickness and the nature of the wax pruinosity. We accurately modelled multiple optical data sets simultaneously, thereby inaugurally quantifying the roughness of the pruinosity and the complex refractive indices of the wax and the odonatan cuticle." 5937. Hoshizaki Green Foundation (2006): Records on Invertebrate and Vertebrate of Reservoirs in Hirata Area, Izumo City, Shimane Prefecture, Japan. *Bull. Hoshizaki Green Found* 9: 1-12. (in Japanese, with English summary). [Between 2001 and 2003, 214 reservoirs in Hirata Area, Izumo City, Shimane Prefecture, Japan were surveyed. The list includes 35 odonate taxa, 5 of them are briefly commented: *Trigomphus melampus*, *Oligoaeschna pryleri*, *Aeschnophlebia longistigma*, *Aeshna nigroflava*, *Anaciaeschna martini*, and *Epitheca marginata*.] Address: Hoshizaki Green Foundation, Okinoshima, 1659-5, Sono, Izumo, Shimane Pref., 691-0076, Japan

5938. Hottenbacher, N.; Koch, K. (2006): Influence of egg size on egg and larval development of *Sympetrum striolatum* at different prey availability (Odonata: Libellulidae). *International Journal of Odonatology* 9(2): 165-174. (in English). ["Egg size differences might have an important influence on reproductive success because they may lead to different offspring conditions, hatching date or larval size. We presumed that egg size in odonates positively correlates with egg development time, and larger eggs lead to larger larvae. However, we assumed that the size benefit could only be maintained under harsh, but not under good conditions. Harsh and good conditions were simulated by different diets with specific feeding intervals; high prey level fed every day, low prey level fed every second day. The prey organisms used were *Artemia salina* and *Chironomus riparius*. The study was conducted with the libellulid *Sympetrum striolatum*. Our results showed that larger eggs caused a longer development time. Larger eggs resul-

ted in significantly larger first instar larvae. However, larger larvae maintained their size benefit only in the high prey level with *C. riparius*. We found no significant differences between low prey and high prey level within the two prey types. We therefore assume that the differences between the two prey levels in this study were not large enough. In general, *A. salina* seems to be more nutritious than *C. riparius* for the first larval stadia." 5939. Hovmöller, R. (2006): Molecular phylogenetics and taxonomic issues in dragonfly systematics (Insecta: Odonata). Doctoral thesis. Stockholm University, Department of Zoology. ISBN: 91-7155-282-0: VI, 59 pp. (in English, with Swedish summary). ["Dragonflies (Odonata) are one of the ancestral groups of extant insects. They represent one of the three most basal branches in the phylogeny of winged insects. The other two groups are the Ephemeroptera, mayflies, and Neoptera, the latter which covers the remaining winged insects. The first paper is about the phylogenetic position of Odonata in relation to the other basal insect clades using 18S and 28S rDNA sequences. It was demonstrated that there are under certain parameters a strong statistical support for a sister-group relationship between Odonata and Neoptera forming the group Palaeoptera. The second paper is about the phylogeny of the Holarctic dragonfly *Leucorrhinia*. Dragonfly larvae are frequently equipped with spines on the abdomen, with great variation in spinyness between species. From an analysis of sequences of ITS and 5.8S rDNA it was found that spines have been lost at least twice in *Leucorrhinia*, in the European *L. rubicunda* and again in a clade of North American species. The third paper is on the subfamily Ischnurinae (Odonata: Coenagrionidae), a group dominated by the two larger genera *Ischnura* and *Enallagma* along with several mono- or oligotypic genera. From the presented molecular study, using mitochondrial 16S rDNA and COII sequences, it is demonstrated that Ischnurinae, and *Ischnura* are monophyletic. *Enallagma* is not monophyletic, and the genus name *Enallagma* should be restricted to the *E. cyathigerum* clade. The fourth paper is a catalogue of the genus *Coenagrion*, with full information on synonymy, type material and bibliographical data. The fifth paper is an appeal to the International Commission on Zoological Nomenclature to suppress the genus group name *Agrion*. The letter of appeal elucidates the priority of *Agrion*, and demonstrates why it has fallen out of use. A case if made for why *Agrion* should be placed on the list of unavailable names, and *Calopteryx* given full validity." 5940. Hunger, H.; Schiel, F.-J. (2006): Rote Liste der Libellen Baden-Württembergs und der Naturräume, Stand November 2005 (Odonata). *Libellula Suppl.* 7: 3-14. (in German, with English summary). ["The herewith presented Red List of the Odonata of Baden-Württemberg, Germany and its biogeographic regions is based on digital data analyses of about 80.700 data sets and the classification method of the German Federal Agency for Nature Conservation. Compared to the previous version of the Red List, the number of species

listed has declined considerably. The reasons for this have to be discussed carefully and can be contributed to three main factors: First, the classification method has become more objective and more concise; second, increased knowledge about some species leads to a more optimistic evaluation of their population vulnerability; and third, the improved water quality of rivers has simultaneously led to an improved habitat quality. Nevertheless, the Red List of Odonata of Baden-Württemberg still includes more than half of the species, with two species being extinct, 12 critically endangered and 11 endangered." (Authors)] Address: Hunger, H., Institut für Naturschutz und Landschaftsanalyse (INU-LA), August-Ganther-Straße 16, D-79117 Freiburg, Germany. E-mail: holger.hunger@inula.de

5945. Johansson, F.; Englund, G.; Brodin, T.; Gardfjell, H. (2006): Species abundance models and patterns in dragonfly communities: effects of fish predators. *Oikos* 114(1): 27-36. (in English). ["We investigated if dragonfly larvae community composition and species abundance curves are sensitive to variation in predation intensity, and whether the fit to a particular niche partitioning model could be used to make inferences about mechanisms structuring communities. The approach taken was to compare communities in lakes either having or lacking fish predation. Dragonfly species classified as active, strongly dominated the dragonfly communities in fishless lakes, and low active species dominated fishless lakes. As activity level is known to correlate with susceptibility to fish predation this indicates that these communities are structured by fish predation. Fitting relative abundance data to five niche partitioning models showed that the same model fitted data from both types of habitats (fish/no fish). This means that the observed differences in relative abundances were substitutive, i.e. the relative abundance of a rank stayed constant, even though the identity of the species having this rank changed. The best fit to data from both types of lakes was found for the random assortment model, which is usually interpreted as an indication that the community is not structured by within-guild interactions. This interpretation for fishless lakes did not seem to agree with other community measures (i.e. lowered diversity and evenness and no relationship between species richness and dragonfly biomass), which indicate that the community is structured by within-guild interactions. Moreover, a detail in the fitting procedure, the number of species included in the analysis, affected which model that fitted data best. Thus, we question if fitting niche partitioning models to data can provide mechanistic understanding of how resources are partitioned in natural communities." 5948. Juillerat, L.; Wildermuth, H. (2006): Landmilben als Libellenparasiten: Befall von *Orthetrum coerulescens* mit *Leptus* sp. (Odonata: Libellulidae; Parasitengona: Erythraeidae). *Libellula* 25(3/4): 171-184. (in German, with English and French summaries). ["During the 2001 flying season 110 mites of the genus *Leptus* were recorded on adults in five of six local populations of *O. coerulescens* in the Swiss Jura mountains. Of the host individuals 72.8 % were teneral, 24.3 % immature, and 2.9 % mature. On average 29 % of the tenerals bore mites, this proportion varying between 0 and 53 % within six local populations. The parasite load amounted to one to five mites per individual; it averaged 1.57 and did not differ significantly between sexes. Almost two thirds of the host individuals bore a single mite. Most parasites were attached to the host's legs. Infested hosts survived an average of 18.1 days from emergence and non-infested hosts 28.0 days. The observed infestation of *O. coerulescens* by terrestrial mites may reflect the superposition of the host's and parasite's preferred habitats, namely spring mires comprising mosaics of tiny seepages and streams intimately intermingled with extensively grazed fen vegetation." 5952. Kasangaki, A.; Babaasa, D.; Efitre, J.; McNeillage, A.; Bitariho, R. (2006): Links between anthropogenic perturbations and benthic macroinvertebrate assemblages in Afromontane forest streams in Uganda. *Hydrobiologia* 563: 231-245. (in English). ["Relationships between environmental variables and benthic macroinvertebrate assemblages were investigated among several sites that varied in disturbance history in Bwindi Impenetrable National Park, an Afromontane site in East Africa. Environmental variables were correlated with the level of past catchment disturbance – logging, agricultural encroachment, and present tourism activity. For example, sites in medium and high disturbance categories had higher values of specific conductance and lower water transparency than low disturbance category sites, these environmental variables may therefore act indicators of ecological quality of rivers. Environmental variables such as conductivity and water transparency were found to be good predictors of benthic macroinvertebrate assemblages, with anthropogenically stressed sites having lower diversity than the reference sites. Impacted sites were dominated by tolerant taxa such as chironomid and leeches, while 'clean water' taxa such as Ephemeroptera, Plecoptera and Trichoptera dominated at minimally impacted sites. Comparison of sites with different disturbance histories provided evidence for differences in benthic macroinvertebrate communities that reflect the state of forest restoration and recovery. We recommend quarterly monitoring of water quality to act as an early warning system of deterioration and tracking ecological recovery of previously impacted sites." (Authors) Odonata are treated on the family level.] Address: Kasangaki, A., Institute of Tropical Forest Conservation, Mbarara University of Science & Technology, PO Box 44, Kabale, Uganda. 5955. Khodabandeh, S. (2006): Na⁺,K⁺-ATPase in the gut of larvae of the zygopteran, *Ischnura elegans*, and the Anisoptera, *Libellula lydia*, (Odonata): Activity and immunocytochemical localization. *Zoological Studies* 45(4): 510-516. (in English). ["Na⁺,K⁺-ATPase activity and immunolocalization were demonstrated in the gut of *Ischnura elegans* and *Libellula lydia* larvae. Localization was performed through immunofluorescence light microscopy using the IgGa5 mouse monoclonal antibody. The Na⁺,K⁺-ATPase activity was significantly higher in the hindgut than in the foregut-midgut in both species. In *I. elegans*, Na⁺,K⁺-ATPase activities were 29.44 and 5.12 iM Pi/mg/protein/h in the hindgut and foregut-midgut, while in *L. lydia*, the activities were 16.24 and 1.98 iM Pi/mg/protein/h in the hindgut and foregut-midgut, respectively. No specific fluorescence staining was observed in the cells of the foregut or midgut regions in either species. Na⁺,K⁺-ATPase was found in the malpighian tubules and rectal pad epithelium in *I. elegans*, and in the epithelium of the basal pads of the rectal gill lamellae in *L. lydia*. A consistently high immunoreactivity was observed in the sides of the lumen of malpighian tubule cells, and a positive and strong fluorescence signal was found in the basolateral sides of the pads of epithelium cells. These findings show that as in crustaceans, this antibody is useful for locating of Na⁺,K⁺-ATPase and ionocytes in insect osmoregulatory tissues. A high concentration of Na⁺,K⁺-ATPase activity in these tissues confirms their participation in osmoregulation through active ion exchange." (Author)] Address: Khodabandeh, Saber, Department of Marine Biology, Faculty of Marine Sciences, University of Tarbiat Modarres, Mazandaran, Noor, PO Box 46414-356, Iran. E-mail: surp78@yahoo.com

5956. Khrokalo, L. A.; Sheshurak, P. M. (2006): Flight seasonality of dragonflies (Insecta, Odonata) in northeastern Ukraine. *Vestnik Zoologii* 40(2): 145-154. (in English, with summary). [Data on seasonal flight periods of Odonata in Northeastern Ukraine (Kyiv, Chernigiv, Sumy, Chekasy and Kharkiv administrative regions) based on field observations and a review of material collected during 1992–2004 are provided. Field data by the authors (numbers of species occurring during the six seasons as adults) were compared with literature data. The study resulted in new resp. amended insights into the regional phenology of *Chalcolestes parvidens*, *Coenagrion armatum*, *Brachytron pratensis*, *Aeshna affinis*, *Anax imperator*, *Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Cordulia aenea*, *Epitheca bimaculata*, *Sympetrum danae*, *Leucorrhinia rubicunda*, and *L. caudalis*. Flight seasonalities are depicted of 13 frequently occurring species. The regional total of 55 species can be grouped in six phenological groups.] Address: Khro-

5958. Kishida, O.; Nishimura, K. (2006): Flexible architecture of inducible morphological plasticity. *Journal of Animal Ecology* 75: 705-712. (in English). ["Predator-induced morphological defences are produced in response to an emergent predator regime. In natural systems, prey organisms usually experience temporal shifting of the composition of the predator assemblage and of the intensity of predation risk from each predator species. Although, a repetitive morphological change in response to a sequential shift of the predator regime such as alteration of the predator species or diminution of the predation risk may be adaptive, such flexible inducible morphological defences are not ubiquitous. We experimentally addressed whether a flexible inducible morphological defence is accomplished in response to serial changes in the predation regime, using a model prey species which adopt different defensive morphological phenotypes in response to different predator species. *Rana pirica* (Matsui) tadpoles increased body depth and tail depth against the predatory larval salamander *Hynobius retardatus* (Dunn); on the other hand, they only increased tail depth against the predatory larval dragonfly *Aeshna nigroflava* (Martin). *Rana pirica* tadpoles with the predator-specific phenotypes were subjected to removal or exchange of the predator species. After removal of the predator species, tadpoles with each predator-specific phenotype changed their phenotype to the nondefensive basic one, suggesting that both predator-specific phenotypes are costly to maintain. After an exchange of the predator species, tadpoles with each predator-specific phenotype reciprocally, flexibly shifted their phenotype to the now more suitable predator-specific one only by modifying their body part. The partial modification can effectively reduce time and energy expenditures involved in repetitive morphological changes, and therefore suggest that the costs of the flexible morphological changes are reduced." 5959. Kraft, P.G.; Franklin, C.E.; Blows, M.W. (2006): Predator-induced phenotypic plasticity in tadpoles: extension or innovation? *Journal of Evolutionary Biology* 19(2): 450-458. (in English). ["Phenotypic plasticity, the ability of a trait to change as a function of the environment, is central to many ideas in evolutionary biology. A special case of phenotypic plasticity observed in many

organisms is mediated by their natural predators. Here, we used a predator-prey system of dragonfly larvae and tadpoles to determine if predator-mediated phenotypic plasticity provides a novel way of surviving in the presence of predators (an innovation) or if it represents a simple extension of the way noninduced tadpoles survive predation. Tadpoles of *Limnodynastes peronii* were raised in the presence and absence of predation, which then entered a survival experiment. Induced morphological traits, primarily tail height and tail muscle height, were found to be under selection, indicating that predator-mediated phenotypic plasticity may be adaptive. Although predator-induced animals survived better, the multivariate linear selection gradients were similar between the two tadpole groups, suggesting that predator-mediated phenotypic plasticity is an extension of existing survival strategies. In addition, nonlinear selection gradients indicated a cost of predator-induced plasticity that may limit the ability of phenotypic plasticity to enhance survival in the presence of predators." 5960. Krauss, V.; Fassl, A.; Fiebig, P.; Patties, I.; Sass, H. (2006): The evolution of the histone methyltransferase gene *Su(var)3-9* in metazoans includes a fusion with and a re-fission from a functionally unrelated gene. *BMC Evolutionary Biology* 2006, 6:18: 15 pp. (in English). ["Background: In eukaryotes, histone H3 lysine 9 (H3K9) methylation is a common mechanism involved in gene silencing and the establishment of heterochromatin. The loci of the major heterochromatic H3K9 methyltransferase *Su(var)3-9* and the functionally unrelated α subunit of the translation initiation factor eIF2 are fused in *Drosophila melanogaster*. Here we examined the phylogenetic distribution of this unusual gene fusion and the molecular evolution of the H3K9 HMTase *Su(var)3-9*. Results: We show that the gene fusion had taken place in the ancestral line of winged insects and silverfishes (Dicondylia) about 400 million years ago. We cloned *Su(var)3-9* genes from a collembolan and a spider where both genes ancestrally exist as independent transcription units. In contrast, we found a *Su(var)3-9*-specific exon inside the conserved intron position 81-1 of the eIF2 α gene structure in species of eight different insect orders. Intriguingly, in the pea aphid *Acyrtosiphon pisum*, we detected only sequence remains of this *Su(var)3-9* exon in the eIF2 α intron, along with an eIF2 α -independent *Su(var)3-9* gene. This reveals an evolutionary re-fission of both genes in aphids. *Su(var)3-9* chromo domains are similar to HP1 chromo domains, which points to a potential binding activity to methylated K9 of histone H3. SET domain comparisons suggest a weaker methyltransferase activity of *Su(var)3-9* in comparison to other H3K9 HMTases. Astonishingly, 11 of 19 previously described, deleterious amino acid substitutions found in *Drosophila Su(var)3-9* are seemingly compensable through accompanying substitutions during evolution. Conclusion: Examination of the *Su(var)3-9* evolution revealed strong evidence for the establishment of the *Su(var)3-9/eIF2 α* gene fusion in an ancestor of dicondylid insects and a re-fission of this fusion during the evolution of aphids. Our comparison of 65 selected chromo domains and 93 selected SET domains from *Su(var)3-9* and related proteins offers functional predictions concerning both domains in *Su(var)3-9* proteins." (Authors) The study includes *Enallagma cyathigerum*.] Address: Krauss, V.,

5961. Kumar, R.; Hwang, J.-S. (2006): Larvicidal efficiency of aquatic predators: A perspective for mosquito biocontrol. *Zoological Studies* 45(4): 447-466. (in English). ["Biological control of mosquito larvae with predators and other biocontrol agents would be a more-effective and eco-friendly approach, avoiding the use of synthetic chemicals and concomitant damage to the environment. Manipulating or introducing an auto-reproducing predator into the ecosystem may provide sustained biological control of pest populations. The selection of a biological control agent should be based on its self-replicating capacity, preference for the target pest population in the presence of alternate natural prey, adaptability to the introduced environment, and overall interaction with indigenous organisms. In order to achieve an acceptable range of control, a sound knowledge of various attributes of interactions between a pest population and the predator to be introduced is desirable. Herein, we qualitatively review a wide range of literature sources discussing the ability of different aquatic predators to control mosquito larval populations in environments where mosquitoes naturally breed. Different predators of mosquito larvae include amphibian tadpoles, fish, dragonfly larvae, aquatic bugs, mites, malacostracans, anostracans, cyclopoid copepods, and helminths. The most widely used biocontrol agents of mosquito populations are the western mosquito fish, *Gambusia affinis*, and the eastern mosquito fish, *G. holbrooki*. The effect of these fishes on native faunal composition and their inability to survive in small containers, tree holes etc., which are ideal breeding sites of vectorially important mosquitoes, make them inefficient in controlling mosquito populations. On the basis of larvicidal efficiency, the ability to produce dormant eggs, the hatchability of dormant eggs after rehydration, faster developmental rates, and higher fecundity, various tadpole shrimp can be considered to mosquito ideal control agents in temporary water bodies and rice paddy fields. Among various predators of mosquito larvae, the cyclopoid copepods are efficient, found naturally, are safe for human beings, and are also economical in their application. The mosquito larval selectivity patterns of many cyclopoids, their adaptability to variable aquatic environments which are ideal breeding sites for mosquitoes, their resistance to starvation, and their day-night prey detection ability using hydromechanical signals make them an ideal biocontrol agent. Therefore, there is a need to test the feasibility of cyclopoid copepods by putting them into operational use as ecocompatible means of biocontrol." 5965. Kunz, B.; Ober, S.V.; Jödicke, R. (2006): The distribution of *Zygonyx torridus* in the Palaearctic (Odonata: Libellulidae). *Libellula* 25(1/2): 89-108. (in English, with German summary). ["*Z. torridus* is an Oriental-Afrotropical species, whose range also covers the southern margin of the Palaearctic. All known records from the latter region are listed, mapped and discussed. Records from single localities covering a longer period of time are available for the Canary Islands, the Jordan Valley, and Spain. The known occurrence in northern Africa is restricted to Morocco and Tunisia. In southern Europe the species is rare, and several populations seem to have been lost recently. Records are known from Portugal, Spain and Italy. One visual observation originates from southwestern Turkey. A record from Iran indicates a bridge to the population on the Indian subcontinent. The species is new to the fauna of Italy, Tunisia and Turkey." (Authors)] Address: Kunz, B., Hauptstr. 111, D-74595 Langenburg, Germany. E-mail: libellen@berndkunj.de

5966. Lambrechts, J.; Guelinckx, R. (2006): De balans na het natuurherstel in Het Vinne te Zoutleeuw (Vlaams-Brabant): in één jaar van 7 naar 27 libellensoorten. *Gomphus* 20(2): 3-12. (in Dutch, with English and French summaries). ["The results after the restoration of the Vinne at Zouleeuw (province of Vlaams-Brabant) as a natural lake in Flanders: in 1 year from 7 to 27 of Odonata species. This contribution gives an overview of the dragonfly fauna (Odonata) of Het Vinne, a site in the extreme south eastern part of the province of Vlaams-Brabant (Belgium). Het Vinne was the only natural lake (> 100 hectares) in Flanders, but disappeared completely 150 years ago due to land reclamation. A nature restoration project has been undertaken by the Flemish land Agency (VLM) in 2004. As a result, the species poor plantations of poplar disappeared in fa-

vor of open water and reed marshes. The dragonfly survey undertaken in 2005 resulted in a list of 27 species for this site. The most interesting species are *Lestes dryas*, *Sympecma fusca* and *Orthetrum coerulescens*. Because of its relatively isolated location in the dry loamy region of Belgium many more species are unexpected. Worth mentioning are the big populations of *Ischnura pumilio* and *Libellula quad-rimaculata*. Also the following southern species were notified: *Lestes barbarus*, *Erythromma lindenii* and *Crocothemis erythraea*." (Authors)] Address: Lambrechts, J., Zuurbemde 9, B-3380 Glabbeek, Belgium. 5967. Lambrechts, J.; De Knijf, G. (2006): Libellen in het Nationaal Park Hoge Kempen. *Likona* jaarboek 2005 – n°15: 50-57. (in Dutch, with English summary). ["Since 1990, 50 dragonfly species (with populations of 45 species) or 83% of all recent Flemish species have been observed in the National Park Hoge Kempen. 14 from the 17 Red List species have been noted, and with populations of 9 species. Also all the 3 species belonging to the category 'rare' are present. We can conclude that this National Park is a real biodiversity hotspot for dragonflies in Flanders. Nearly all Red List species characteristic for oligotrophic and running waters (brooks and rivulets) are present in high numbers. Only the species typical for meso-eutrophic standing waters are lacking, due to the nearly complete absence of this habitat type in the Park. The Park is also of international importance due to the presence of *Leucorrhinia pectoralis*, a species mentioned in the Annexes II and IV of the Habitat Directive. Within the Park, the Vallei van de Zijpbeek is the most important site for dragonflies. Gravel pits can be of great importance for Odonata, also for Red List species, if they were reshaped after exploitation." 5968. Landwer, B.; Sites, R.W. (2006): Variability in larval characters states used to distinguish between species of *Pantala* Hagen (Odonata: Libellulidae). *Florida Entomologist* 89(3): 354-360. (in English). ["Despite widespread distributions and abundance, previously published diagnoses of the larvae of the two species of the dragonfly genus *Pantala* often were contradictory or confusing. Morphometric analysis of mensural characters and qualitative analysis of relative character states were used to determine the ability of previously published characterizations to accurately distinguish larvae of the two species. We found that many published characterizations were inaccurate or insufficient, and their use in making species level determinations would result in frequent misidentifications. In distinguishing between the two species, the most useful and reliable characteristic was the palpal setal count. However, in specimens where this count is intermediate, other characteristics may need to be evaluated." 5969. Latty, T.M. (2006): Flexible mate guarding tactics in the dragonfly *Sympetrum internum* (Odonata: Libellulidae). *Journal of Insect Behavior* 19(4): 469-477. (in English). ["Mate guarding—a behaviour prevalent in odonates—is a post copulatory association during which males prevent females from re-mating. Some species

use two forms of guarding: contact mate guarding, which is energetically costly but highly effective and non-contact mate guarding, which is less costly but less effective. This study aimed to determine if male *S. internum* adjust the duration of contact mate guarding according to environmental, temporal and physiological factors. There was a significant interaction between male density and season on duration of contact mate guarding. Early in the season males increased the duration of contact guarding as the density of rivals increased. Later in the season males guarded mates longer irrespective of male density. Wind and temperature did not detectably alter the duration of contact mate guarding, suggesting that the trade-off between current and future reproductive success was more important than were physiological costs." (Author)] Address: Latty, Tany, Department of Biological Sciences, University of Calgary, 2500 University drive, Calgary, Alberta, Canada T2N 1N4. E-mail: tmlatty@ucalgary.ca.

5970. Laurila, A.; Pakkasmaa, S.; Merilä, J. (2006): Population divergence in growth rate and antipredator defences in *Rana arvalis*. *Oecologia* 147(4): 585-595. (in English). ["Growth and development rates often differ among populations of the same species, yet the factors maintaining this differentiation are not well understood. We investigated the antipredator defences and their efficiency in two moor frog *Rana arvalis* populations differing in growth and development rates by raising tadpoles in outdoor containers in the nonlethal presence and absence of three different predators (newt, fish, dragonfly larva [*Aeshna*']), and by estimating tadpole survival in the presence of free-ranging predators in a laboratory experiment. Young tadpoles in both populations reduced activity in the presence of predators and increased hiding behaviour in the presence of newt and fish. Older tadpoles from the slow-growing Gotland population (G) had stronger hiding behaviour and lower activity in all treatments than tadpoles from the fast-growing Uppland population (U). However, both populations showed a plastic behavioural response in terms of reduced activity. The populations differed in induced morphological defences especially in response to fish. G tadpoles responded with relatively long and deep body, short tail and shallow tail muscle, whereas the responses in U tadpoles were often the opposite and closer to the responses induced by the other predators. U tadpoles metamorphosed earlier, but at a similar size to G tadpoles. There was no evidence that growth rate was affected by predator treatments, but tadpoles metamorphosed later and at larger size in the predator treatments. G tadpoles survived better in the presence of free-ranging predators than U tadpoles. These results suggest that in these two populations, low growth rate was linked with low activity and increased hiding, whereas high growth rate was linked with high activity and less hiding. The differences in behaviour may explain the difference in survival between the populations, but other mechanisms (i.e. differences in swimming speed) may also be involved. There appears to be considerable differentiation in antipredator responses between these two *R. arvalis* populations, as well as with respect to different predators." - 5978.** Longcore, J.R.; McAuley, D.G.; Pendelton, G.W.; Reid Bennatti, C.; Mingo, T.M.; Stromborg, K.L. (2006): Macroinvertebrate abundance, water chemistry, and wetland characteristics affect use of wetlands by avian species in Maine. *Hydrobiologia* 567: 143-167. (in English). ["Our objective was to determine use by avian species (e.g., piscivores, marsh birds, waterfowl, selected passerines) of 29 wetlands in areas with low (<200 $\mu\text{eq l}^{-1}$) acid-neutralizing capacity (ANC) in southeastern Maine. We documented bird, pair, and brood use during 1982-1984 and in 1982 we sampled 10 wetlands with a sweep net to collect invertebrates. We related mean numbers of invertebrates per wetland to water chemistry, basin characteristics, and avian use of different wetland types. Shallow, beaver (*Castor canadensis*)-created wetlands with the highest phosphorus levels and abundant and varied macrophyte assemblages supported greater densities of macroinvertebrates and numbers of duck broods (88.3% of all broods) in contrast to deep, glacial type wetlands with sparse vegetation and lower invertebrate densities that supported fewer broods (11.7%). Low pH may have affected some acid-intolerant invertebrate taxa (i.e., Ephemeroptera), but high mean numbers of Insecta per wetland were recorded from wetlands with a pH of 5.51. Other Classes and Orders of invertebrates were more abundant on wetlands with pH>5.51. All years combined use of wetlands by broods was greater on wetlands with pH \leq 5.51 (77.4%) in contrast to wetlands with pH>5.51 that supported 21.8% of the broods. High mean brood density was associated with mean number of Insecta per wetland. For lentic wetlands created by beaver, those habitats contained vegetative structure and nutrients necessary to provide cover to support invertebrate populations that are prey of omnivore and insectivore species. The fishless status of a few wetlands may have affected use by some waterfowl species and obligate piscivores." (Authors) Odonata are treated on the family level.] Address: Longcore, J., U.S. Geological Survey, Patuxent Wildlife Research Center, 5768 South Annex A, Orono, ME 04469, USA. - 5979.** Luo, G.; Sun, M. (2006): The effects of corrugation and wing planform on the aerodynamic force production of sweeping model insect wings. *Acta Mechanica Sinica* 21(6): 531-541. (in English). ["The effects of corrugation and wing planform (shape and aspect ratio) on the aerodynamic force production of model insect wings in sweeping (rotating after an initial start) motion at Reynolds number 200 and 3500 at angle of attack 40° are investigated, using the method of computational fluid dynamics. A representative wing corrugation is considered. Wing-shape and aspect ratio (AR) of ten representative insect wings are considered; they are the wings of fruit fly, cranefly, dronefly, hoverfly, ladybird, bumblebee, honeybee, lacewing (forewing), hawkmoth and dragonfly (forewing), respectively (AR of these wings varies greatly, from 2.84 to 5.45). The following facts are shown. (1) The corrugated and flat-plate wings produce approximately the same aerodynamic forces. This is because for a sweeping wing at large angle of attack, the length scale of the corrugation is much smaller than the size of the separated flow region or the size of the leading edge vortex (LEV). (2) The variation in wing shape can have considerable effects on the aerodynamic force; but it has only minor effects on the force coefficients when the velocity at r^2 (the radius of the second moment of wing area) is used as the reference velocity; i.e. the force coefficients are almost unaffected by the variation in wing shape. (3) The effects of AR are remarkably small: when AR increases from 2.8 to 5.5, the force coefficients vary only slightly; flow-field results show that when AR is relatively large, the part of the LEV on the outer part of the wings sheds during the sweeping motion. As AR is increased, on one hand, the force coefficients will be increased due to the reduction of 3-dimensional flow effects; on the other hand, they will be decreased due to the shedding of part of the LEV; these two effects approximately cancel each other, resulting in only minor change of the force coefficients." - 5980.** Machida, K.; Oikawa, T.; Shimanuki, J. (2006): The effect of the costal vein configuration of the wings of a dragonfly. *Key Engineering Materials* 326-328: 819-822. (in English). ["In generally, it is known that structures of living thing are optimized. The wings of a dragonfly are thin and light. Although it is having the structure of bearing the load produced in the case of an advanced flight such as "Flapping flight", "Glide", and "Hovering". The wings of a dragonfly are made by veins and membranes. In addition, the wings of a dragonfly have some characteristic structures, such as "Nodus". Thus, the wings of dragonfly have many complicated structures. The configuration of costal vein of the wings is different from them of other insects. So, we paid attention to the configuration of costal vein of the wings. Therefore, in this study, we researched about the effect

of costal vein. As a result, it was showed that the configuration of costal vein became bending and torsional deformation small. In addition, it was showed that the configuration of costal vein related to nodus. In this study, several 3-D models of the dragonfly's wing were made and calculated by the 3-D finite element method." 5982. Marshall, J.C.; Steward, A.L.; Harch, B.D. (2006): Taxonomic resolution and quantification of freshwater macroinvertebrate samples from an Australian dryland river: the benefits and costs of using species abundance data. *Hydrobiologia* 572: 171-194. (in English). ["In studies using macroinvertebrates as indicators for monitoring rivers and streams, species level identifications in comparison with lower resolution identifications can have greater information content and result in more reliable site classifications and better capacity to discriminate between sites, yet many such programmes identify specimens to the resolution of family rather than species. This is often because it is cheaper to obtain family level data than species level data. Choice of appropriate taxonomic resolution is a compromise between the cost of obtaining data at high taxonomic resolutions and the loss of information at lower resolutions. Optimum taxonomic resolution should be determined by the information required to address programme objectives. Costs saved in identifying macroinvertebrates to family level may not be justified if family level data can not give the answers required and expending the extra cost to obtain species level data may not be warranted if cheaper family level data retains sufficient information to meet objectives. We investigated the influence of taxonomic resolution and sample quantification (abundance vs. presence/absence) on the representation of aquatic macroinvertebrate species assemblage patterns and species richness estimates. The study was conducted in a physically harsh dryland river system (Condamine-Balonne River system, located in south-western Queensland, Australia), characterised by low macroinvertebrate diversity. Our 29 study sites covered a wide geographic range and a diversity of lotic conditions and this was reflected by differences between sites in macroinvertebrate assemblage composition and richness. The usefulness of expending the extra cost necessary to identify macroinvertebrates to species was quantified via the benefits this higher resolution data offered in its capacity to discriminate between sites and give accurate estimates of site species richness. We found that very little information (<6%) was lost by identifying taxa to family (or genus), as opposed to species, and that quantifying the abundance of taxa provided greater resolution for pattern interpretation than simply noting their presence/absence. Species richness was very well represented by genus, family and order richness, so that each of these could be used as surrogates of species richness if, for example, surveying to identify diversity hot-spots. It is suggested that sharing of common ecological responses among species within higher taxonomic units is the most plausible mechanism for the results. Based on a cost/benefit analysis, family level abundance data is recommended as the best resolution for resolving pat-

terns in macroinvertebrate assemblages in this system. The relevance of these findings are discussed in the context of other low diversity, harsh, dryland river systems." (2006): Verbreitung und Phänologie des Zweiflecks, *Epitheca bimaculata* Charpentier, 1825 (Odonata, Corduliidae), im Norden Brandenburgs. *Entomologische Nachrichten und Berichte* 50(1-2): 45-53. (in German). [Germany; "The author recorded *E. bimaculata* at 551 occasions in the study area between Prenzlau, Schwedt, Eberswalde and Rheinsberg (about 3500 km²), at 140 localities listed in this paper. From 1987 to 2006, breeding was observed in 88 water bodies in this lake landscape shaped during the Pleistocene. It represents the centre of distribution of the species in Germany. At the lake with the largest breeding colony, up to 394 exuviae in a year were found. The greatest recorded abundance of the species in this region was 193 exuviae along 80 meters of lake shore. *E. bimaculata* reaches a frequency of at least 29 % in 216 lakes with a water surface of more than one hectare existing in the UNESCO-biosphere reserve „Schorfheide-Chorin“ in the eastern part of the study area. The cornerstone data of adult phenology in the period 1992-2004 were as follows: earliest emerging adults, 11 May; peak emergence, 16 May; first males appearing in their territory over the water surface, 25 May; last living specimens, 24 June." 5986. McCauley, S.J. (2006): The effects of dispersal and recruitment limitation on community structure of odonates in artificial ponds. *Ecography* 29(4): 585-595.

(in English). [“I examined the effects of isolation on the structure of both adult and larval dragonfly (Odonata: Anisoptera) communities forming at physically identical artificial ponds over two years. Isolation, whether measured by distance to the nearest source habitat or by connectivity to multiple sources, was significantly negatively related to the species richness of dragonflies observed at and collected in these ponds. These results indicate that dispersal and recruitment limitation acted as filters on the richness of communities at these artificial ponds. The richness of larval recruits in artificial ponds was lower than the richness of adult dispersers observed at ponds, and distance from a source habitat explained a greater fraction of the variation in larval than adult richness (83 and 50%, respectively). These results and a male biased sex-ratio in adults observed at artificial ponds suggest that isolated habitats may be more recruitment limited than observations of dispersers would suggest. A Mantel test indicated there was a spatial component to the composition of communities forming in tanks, and that distance between tanks and community dissimilarity (1-Jaccard's) were significantly positively related ($r=0.52$). This pattern suggests that their position with respect to alternative source environments influenced the composition of the communities that recruited into these ponds. These results provide further evidence of recruitment limitation in this system. Results from this study highlight the importance behaviorally limited dispersal may have in taxa morphologically capable of broad dispersal and suggest that the role of dispersal and recruitment limitation may be critical in shaping community structure across habitat gradients that include variation in habitat duration.” (Author)] Address: McCauley, S. 5987. McGuffin, M.A.; Baker, R.L.; Forbes, M.R. (2006): Detection and avoidance of fish predators by adult *Enallagma damselflies*. *Journal of Insect Behavior* 19(1): 77-91. (in English). [“Reproductive success of iteroparous insects depends on their own survival as well as that of their offspring and thus adults should consider risk of predation to both themselves and their offspring when selecting a suitable place to lay eggs. We surveyed species composition of *Enallagma damselflies* from sites in eastern Ontario and found that, similar to studies in Michigan, USA, *Enallagma boreale* does not co-exist with fish, whereas *E. signatum* is apparently restricted to sites with fish. *E. ebrium* is found at fish and fishless sites. Laboratory experiments on these species showed no effect of chemical cues of fish presence on propensity to oviposit or number of eggs released. By using field enclosures, we found adult *E. ebrium* could detect and avoid fish during visits to a site, but females visiting fish sites did not significantly reduce oviposition duration.” (Authors)] Address: Baker, R.L., Dept Zoo], Erindale Coll., Univ. 5988. McMillan, V.E. (2006): Preliminary observations of reproductive behavior in *Arigomphus villosipes* (Selys) (Anisoptera: Gomphidae). *Bulletin of American Odonatology* 10(1): 19-22. (in English). [“I studied the behavior of the *A. villosipes* (Unicorn Clubtail) at a small artificial pond in New York State from 6 June-8 July 2002. Throughout the day males adopted perch sites

along the shoreline, typically 3 m or farther apart. Most of their time was spent perching, interrupted by brief patrols or chases of other males. Marking records showed that most males (79%) returned to the pond on one or more subsequent days. Individual males displayed only weak attachment to perch sites, often occupying two or more different areas along the shoreline over several hours on a given day. Female visits to the pond were brief and infrequent; pair formation occurred at the water, whereupon the pair left the pond to mate. Females oviposited by flying slowly over shallow water, dipping the abdomen once or twice at multiple sites; mate-guarding was never observed. Suggestions are given for future studies of this species.” (Author)] Address: McMillan, Vicky, Colgate Univ., Dept. Biol., 13 Oak Dr. Hamilton, NY 13346-1398, USA . 5994. Meurgey, F. (Coord. & Red.) (2006): Les Odonates des Départements et Collectivités d'Outre-mer français. Société française d'odonatologie. ISBN: 2950729169: 144 pp. (in French, with English summary). ["France counts 10 overseas territories distributed around the world. Mainly located in the Tropics, these territories relate to a great diversity of habitats and species. In 1999, the "Société Française d'Odonatologie" created a study group on dragonflies fauna of the French overseas territories. This group is in charge to contribute to the advance of knowledge on faunas still imperfectly known, as well from a systematic point of view as of biology and ecology. The level of knowledge of each department or territory of Overseas is not equal, since is subjected to various constraints such as the surface, accessibility and also number of species to be considered. The Nantes Museum of Natural History takes part in these studies in various manners, such as conservation of collections, missions in West Indies, publications. Since the creation of this group, 42 papers were published (31 in *Martinia* review), solely or included in a supplement (2001), and two thematic issues (2002, 2004). 179 new species could be added to the lists of the geographical areas by the members of this Group. The French Overseas departments and territories currently gather 363 species. France gathers 8% of world dragonfly fauna, and thus has an important responsibility as regards conservation of the species and their habitats." 5996. Mikolajewski, D.J.; Johansson, F.; Wohlfahrt, B.; Stoks, R. (2006): Invertebrate predation selects for the loss of a morphological antipredator trait. *Evolution* 60(6): 1306-1310. (in English). ["Antagonistic selection by different predators has been suggested to underlie variation in morphological antipredator traits among and within species. Direct empirical proof is equivocal, however, given the potential interrelationships of morphological and behavioral traits. Here, we tested whether

spines in larvae of the dragonfly *Leucorrhinia caudalis*, which are selected for by fish predators, are selected against by invertebrate aeshnid predators. Using a manipulative approach by cutting spines instead of making comparisons among species or inducing spines, we were able to decouple the presence of spines from other potentially covarying morphological antipredator traits. Results showed survival selection for the loss of spines imposed by invertebrate predation. Moreover, spined and nonspined larval *L. caudalis* did not differ in the key antipredator behaviors, activity level, and escape burst swimming speed. The observed higher mortality of spined larvae can therefore be directly linked to selection by aeshnid predation against spines." 6005. Ott, J. (2006): Die Arktische Smaragdlibelle - *Somatochlora arctica* (Zetterstedt, 1840) - in der Pfalz: übersehen oder kurz vor dem Aussterben? (Insecta: Odonata: Corduliidae). Fauna Flora Rheinland-Pfalz 10 (4): 1323-1338. (in German, with English summary). ["*S. arctica* is one of the rarest dragonflies in the Palatinate and presently only one autochthonous population south of Trippstadt (near Kaiserslautern / Rhineland-Palatinate, Germany) is known to be existing. Several former breeding sites of the species were degraded or destroyed in the past but there is still in principal the possibility of a resettlement from populations of the French sites in the Northern Vosges; presently however the biotope conditions for the species in most of the waters are not adequate due to the lack of water and also effects of climatic changes. As the species could have been overlooked in some areas due to not being conspicuous an intensive mapping in the remaining 'good' biotopes is recommended which should take place as part of a special species protection programme for mooreland dragonflies in the Palatinate." (Author)] Address: Ott, J., Friedhofstr. 28, D-67705 Trippstadt, Germany. E-mail: L.U.P.O.-GmbH@t-online.de

6006. Ott, J. (2006): Die Südliche Binsenjunger – *Lestes barbarus* (Fabricius, 1798) - erobert den Pfälzerwald (Insecta: Odonata: Lestidae). Fauna Flora Rheinland-Pfalz 10(4): 1315-1321. (in German, with English summary). ["In 2005 *L. barbarus* was discovered for the first time in the central Palatinate forest at the nature reserve „Pfälzerwoog“ near Fischbach/Dahn (Rhineland-Palatinate, Germany), where the species meanwhile is breeding, as in 2006 a big population was registered. The reasons for settling at the water are the new and extensive open shores with a scarce *Juncus*-vegetation as a consequence of the decrease of the water table in the lake and general climatic changes in the area. The origin of the population is probably the „Bienwald“, a nature reserve situated east of the area in a distance of 20 kilometers, separated by more or less dense forests. Another new locality of *Lestes barbarus* was recently discovered near Kaiserslautern, which is located about 35 km north of the Fischbach population and 30 km west of the „Haardtrand“ or „Donnersberg“ populations." 6009. Peacor, S.D. (2006): Behavioural response of bullfrog tadpoles to chemical cues of predation risk are affected by cue age and water source. *Hydrobiologia* 573: 39-44. (in English). ["When confronted by signals of predators presence, many aquatic organisms modify their phenotype (e.g., behaviour or morphology) to reduce their risk of predation. A principal means by which organisms assess predation risk is through chemical cues produced by the predators and/or prey during predation events. Such responses to predation risk can directly affect prey fitness and indirectly affect the fitness of species with which the prey interacts. Accurate assessment of the cue will affect the adaptive nature, and hence evolution, of the phenotypic response. It is therefore, important to understand factors affecting the assessment of chemical cues. Here I examined the effect of the age of chemical cues arising from an invertebrate predator, a larval dragonfly (*Anax junius*), which was fed bullfrog tadpoles, on the behavioural response (activity level and position) of bullfrog tadpoles. The bullfrog response to chemical cues declined as a function of chemical cue age, indicating the degradation of the chemical cue was on the order of 2–4 days. Further, the decay occurred more rapidly when the chemical cue was placed in pond water rather than well water. These results indicate a limitation of the tadpoles to interpret factors that affect the magnitude of the chemical cue and hence accurately assess predation risk. These findings also have implications for experimental design and the adaptation of phenotypic responses to chemical cues of predation risk." 6012. Petzold, F. (2006): Parasitierung von Libellen durch Wassermilben an einem Moorsee in Nordbrandenburg (Odonata; Hydrachnidia). *Libellula* 25(3/4): 185-198. (in German, with English summary). ["All those odonate species of which numerous individuals from the locality were investigated proved to be infested by

water mite larvae. The infestation rate of the different species amounted to 0.24 to 0.98 (mean: 0.65). In all species half of the infested individuals bore less than 15 mites. Occasionally, heavy parasite load was found, the maximum value per individual being 278 for Zygoptera (*Pyrrhosoma nymphula*) and 1136 for Anisoptera (*Corulia aenea*). With respect to the attachment sites of the mites on the dragonfly body clear differences between Zygoptera and Anisoptera were found. While in the former the parasites clung to the underside of the thorax and abdomen, in the latter they were attached ventrally to the abdomen, preferentially to S7-S9. Both, non-infested and infested as well as formerly heavily parasitized individuals participated in tandem formation in a proportion corresponding to that in the whole population. Compared with non-infested individuals, infested individuals exhibited no impairment of their reproductive behaviour." (Author)] Address: Petzold, F., Pappelallee 73, D-10437 Berlin, Germany. 6017. Reece, B.A. (2006): Growth and development of a model research organism (*Enallagma civile*, Insecta: Odonata) in Playa lakes of the southern high plains, TX. Texas Tech University, Department of Biological Sciences. Graduate Student Forum. Program and Abstracts. April 10-14, 2006: (in English). [Verbatim: Cropland agriculture and grazing grassland represent the two major land uses for the Southern High Plains of Texas. These different land uses have varying impacts on surrounding biological systems. Playa lakes (the only source of aquatic habitat in a region over 100,000 km² in area) are greatly affected by these forms of land use. In particular, hydroperiod has been shown to be significantly shortened in cropland regions due to increased sedimentation. The impacts of this disturbance have been hypothesized to affect the rate of growth of larval damselflies in playa lakes surrounded by cropland. Like many other amphibious organisms, damselflies exhibit phenotypic plasticity in growth rate in response to environmental cues about habitat longevity or quality, resulting in a tradeoff between rapid growth and large body size at adult emergence. However, this tradeoff has not been examined as a function of anthropogenic land use surrounding playas. The impacts of different surrounding forms of land use were investigated using a model organism (*Enallagma civile*) placed in field enclosures in a transfer experiment in a replicated series of playa lakes. Growth and development parameters were estimated as well as various environmental correlates such as temperature, turbidity, pH, dissolved oxygen, and prey availability. Results to date suggest that growth and development are influenced by at least some these environmental correlates. Because various population and community parameters are dictated by adult body size (such as fitness), an understanding of how human land use affects individual ontogeny can shed light on higher-order ecological properties.] Address: <http://www.orgs.ttu.edu/biologistassociation/TTUABGradForum2006.pdf>

6018. Reels, G.T.; Dow, R. (2006): Underwater oviposition behaviour in two species of Euphaea in Borneo and Hong Kong (Odonata: Euphaeidae). *International Journal of Odonatology* 9(2): 197-204. (in English).

["Submerged oviposition behaviour by female *Euphaea decorata* and *E. subcostalis* is reported. *E. decorata* descended to within 10 cm of the stream bottom and oviposited endophytically for a total of 59 min. An *E. subcostalis* female descended 3 cm to dead leaves at the stream bottom and stayed submerged for 20-25 s. Noncontact guarding by the male was observed in both cases. Submerged oviposition into substrates near to the stream bottom may be common behaviour for members of the Euphaeidae." 6019. Rollinger, F. (2006): Feuchtgebiete und Rote Listen: *Gomphus flavipes* und *Libellula fulva*. *Regulus* 11: 9. (in German). [*Stylurus flavipes* is reported as extinct in Luxembourg. In 2006, *L. fulva* established along the rivers Alzette and Kiemelbach near Schiffingen a quite strong population.] Address: Rollinger, Françoise, c/o *Regulus*-Redaktion, Kräizhaff, route de Luxembourg, L-1899 Kockelscheuer, Luxemburg

6020. Rouquette, J. (2006): Itchen Navigation Odonata & Butterflies Survey 2006. <http://www.hwt.org.uk/files/odonata%20and%20butterfly%20survey%202006.pdf>: 32 pp. (in English). ["The Itchen Navigation Heritage Trail Project is a major Lottery funded scheme to restore and enhance the historic, cultural and wildlife value of this historic waterway. Major engineering works will shortly be undertaken to improve the structural integrity and the wildlife value of the Navigation. This study was therefore commissioned to carry out a comprehensive survey for Odonata (dragonflies and damselflies) and butterflies. The main aims were to provide information on the existing status of the Navigation and to make recommendations on habitat enhancement to guide the engineering works. The survey has focussed particular attention on the Southern Damselfly (*Coenagrion mercuriale*), a BAP priority species that is listed on the EC Habitats Directive. The Itchen valley contains an internationally important population of this endangered species and much of the valley has been designated as an SAC with the Southern Damselfly as a key interest feature. The entire length of the Navigation was divided into 500m sections and surveyed in July 2006. The key findings are: • The Southern Damselfly was recorded at one location on the Navigation (Section 22) and a review of previous surveys has revealed that it has been recorded in low numbers at 3 further locations (Sections 14, 16 and 20). • 9 other species of Odonata were recorded, with *Calopteryx splendens* (the Banded Demoiselle) the most common species present. • 20 species of butterfly were seen. None of these are restricted to habitat in or around the Navigation, but the Navigation still has an important role to play in providing nectar sources, shelter and foodplants. None of the Itchen Navigation provides optimal habitat for the Southern Damselfly at present, but many sections could be improved with sympathetic management works. Furthermore, the Navigation can act as a corridor providing vital links between existing colonies, and as a water source for rewetting the surrounding meadows. Detailed management recommendations for the Southern Damselfly and other species are provided. Principally this involves the creation of wide shallow margins at the edge of the Navigation where broad leaved emergent vegetation can flourish. Re-profiling of the banksides is required in many places, along with tree and scrub clearance in some areas to reduce the amount of shading."] Address: Rou-

6021. Ryazanova, G.I. (2006): Habitat choice as the defensive behavior of *Calopteryx splendens* Harris larvae (Odonata, Calopterygidae): Impact of the predator species and of the population density of damselflies. *Entomological Review* 86(4): 383-388. (in English). ["Laboratory experiments have demonstrated that the change in the height of dispersal of *Calopteryx splendens* Harris larvae on perches is a protective strategy in the presence of fish. Specificity of protective behavior of damselflies in the presence of pelagic or bottom-dwelling fishes, or of a complex of both types of fishes is described. The effectiveness of the habitat choice is reduced in the presence of the complex of fishes. The use of an optimal protective strategy by all the larvae was observed only in the case when their population density was the lowest. The increase in the population density resulted in the increased importance of intraspecific competition (cannibalism) and decreased effectiveness of protective behavior against heterospecific predators. Original Russian Text published in *Entomologicheskoe Obozrenie*, 2006, Vol. 85, No. 2, pp. 281-288." (Author)] Address: Ryazanova, G.I., Biological Faculty, Moscow Lomonosov State University, Moscow, 119992, Russia

6024. Schiel, F.-J.; Hunger, H. (2006): Bestandssituation und Verbreitung von *Ophiogomphus cecilia* in Baden-Württemberg (Odonata: Gomphidae). *Libellula* 25 (1/2): 1-18. (in German, with English summary). ["From 2003 to 2005, 185 sections of 81 running waters in Baden-Württemberg, Germany were surveyed for the presence of *O. cecilia*. Prior to 2003, only 19 waters were known to harbour this species. In 2005, this number had risen to 35. In at least 28 (80 %) of these waters with a total length of 188 km, *O. cecilia* was indigenous. Larger populations existed exclusively in a few waters in the region of Nordbaden, at altitudes of less than 150 m above sea level, where the density of colonised waters was also the highest in Baden-Württemberg, and in the High Rhine. All other populations were small and more or less isolated. The positive trend of the species coincides with an improvement of water quality since the 1970s. With the exception of the High Rhine

upstream of the mouth of River Aare, 'moderately contaminated' and 'critically contaminated' waters were colonised equally well. In spite of this positive population trend, the sp. is still subject to various threats: intensive management as well as inappropriate restoration of water courses, especially establishment of dense woody vegetation along the shores, and eutrophication." (Authors)] Address: Schiel, F.-J., Inst. Naturschutz und Landschaftsanalyse, Turenenweg 9, D-77880 Sasbach, Germany. E-mail: Franz-Josef.Schiel@INULA.de

6025. Schiel, F.-J. (2006): Nachweis einer zweiten Jahresgeneration von *Erythromma najas* (Odonata: Coenagrionidae). *Libellula* 25(3/4): 159-164. (in German, with English summary). ["At a pond southwest of Karlsruhe (Upper Rhine valley, Germany), which was created in December 2005, eight exuviae of *E. najas* were recorded on 19-VII and 03-VIII-2006. Exuviae of *E. lindenii*, *Ischnura elegans*, *Anax imperator*, *Crocothemis erythraea* and *Sympetrum fonscolombii* were also found at this site in 2006. The pond was created in December 2005, had no connection with other waterbodies and no hydrophytes were introduced. Therefore, the exuviae collected could only have originated from eggs laid in May and June 2006. So this is the first record of bivoltine development of *E. najas* under natural conditions and the first central European record of a bivoltine life cycle of *E. lindenii* and *A. imperator*. Probably part of the population of central European coenagrionids has two generations per year, while the main cohort emerges one year after oviposition." (Author)] Address: Schiel, F.-J., Inst. Naturschutz und Landschaftsanalyse, Turenenweg 9, D-77880 Sasbach, Germany. E-mail: Franz-Josef.Schiel@INULA.de

6026. Schneider, T.; Müller, O. (2006): Der Endemit *Boyeria cretensis*: Beobachtungen zur Verhaltensbiologie der Imagines (Odonata: Aeshnidae). *Libellula* 25 (3/4): 135-146. (in German, with English summary). ["Because of its very restricted distribution and its high level of stenotopy, *B. cretensis* belongs to one of the most threatened European dragonfly species. The distribution of this endemic dragonfly is restricted to rivulets with permanent water and pronounced gallery vegetation in a narrow belt between 50 and 400 m a.s.l. belonging to the thermomediterranean and mesomediterranean zone of the island of Crete. The behaviour of the species was studied at several rivulets in Crete and interpreted in connection with the biotope. The species shows a clear preference for shaded rivulets. Different strategies during patrolling, hunting and oviposition were described. The current agricultural policy of the European Community by reducing the survival of *B. cretensis* by changing the water regime of rivulets and by destruction of their gallery vegetation is discussed." 6029. Srivastava, D.S. (2006): Habitat structure, trophic structure and ecosystem function: interactive effects in a bromeliad-insect community. *Oecologia* 149 (3) : 493-504. (in English). ["Although previous studies have shown that ecosystem functions are affected by either trophic structure or habitat structure, there has been little consideration of their combined effects. Such interactions may be particularly important in systems where habitat and trophic structure covary. I use the aquatic insects in bromeliads to examine the combined effects of trophic structure and habitat structure on a key ecosystem function: detrital processing. In Costa Rican bromeliads, trophic structure naturally covaries with both habitat complexity and habitat size, precluding any observational analysis of interactions between factors. I therefore designed mesocosms that allowed each factor to be manipulated separately. Increases in mesocosm complexity reduced predator (damselfly larva) efficiency, resulting in high detritivore abundances, indirectly increasing detrital processing rates. However, increased complexity also directly reduced the per capita foraging efficiency of the detritivores. Over short time periods, these trends effectively cancelled each other out in terms of detrital processing. Over longer time periods, more complex patterns emerged. Increases in mesocosm size also reduced both predator efficiency and detritivore efficiency, leading to no net effect on detrital processing. In many systems, ecosystem functions may be impacted by strong interactions between trophic structure and habitat structure, cautioning against examining either effect in isolation."(Author)] Address: Srivastava, Diane S., Department of Zoology and Biodiversity Research Centre, University of British Columbia, 6270 University Blvd., Vancouver, BC, Canada, V6T 1Z4. Contents: Introduction; Species guide - Zygoptera, Species guide - Epiproctophora/Anisoptera; illustrated glossary; keys to adults; keys to larvae; checklist of species; references and further reading; index of scientific names; index of common names.] Address: Theischinger G., 2A Hammerley Road, Grays Point, NSW 2232, Australia
- 6035.** Torralba-Burrial, A.; Ocharan, F.J. (2006): Dispersión y proporción sexual en la emergencia en una población de *Sympecma fusca* (Odonata, Lestidae) en Huesca (NE de España). *Bol. R. Soc. Esp. Hist. Nat. (Sec. Biol.)*, 101 (1-4): 29-36. (in Spanish, with English summary). ["Dispersal is a life-history key trait, which is usually due to the adult flight in Odonata. A population of *S. fusca*, inhabiting a temporary pond in the NE of Iberian Peninsula, was analysed by mark-recapture methods. 236 individuals (101 males, 135 females) were marked between July and October of 2000. Sex ratio at emergence was not significantly different from 1:1 and both sexes dispersed equally. They left the pond upon emergence, and returned neither to it nor its surrounding area in summer. Any marked individual was found neither in the nearest ponds (< 3 km) nor in other ponds of the shire. Overwintering individuals were observed amid the vegetation at pond edge, however there was not any marked one among them. This suggests a total absence of philopatry in this species, unlike behaviour observed in other lestid damselflies, what is discussed." - 6036.** Tsubaki, Y.; Kato, C.; Shintani, S. (2006): On the respiratory mechanism during underwater oviposition in a damselfly *Calopteryx corneria* (Selys). *Journal of Insect Physiology* 52: 499-505. (in English). ["*C. cornelia* females oviposit almost exclusively underwater in forest streams. Field observation showed that the duration of uninterrupted submerged oviposition ranged between 20 and 120 min and the number of eggs laid was linearly related to the time spent underwater. By holding a damselfly under water in a small jar, we measured the maximum 'submergence potential', which was defined as the time elapsed between placing the insect underwater and asphyxiation. A series of experiments showed that there was no gender difference in the submergence potential. This was about 120 min if a damselfly was allowed to change its position while under water. The submergence potential was shorter if the damselflies were kept motionless, if air bubbles trapped on the wing surfaces were removed by coating with Vaseline or if the water was hypoxic. By contrast, submergence potential was longer if a part of the wings were kept above the water surface, or if the water was agitated using a magnetic stirrer. These results suggest that ovipositing *C. cornelia* females depend for oxygen on the physical-gill action of the thin air layer trapped on the body and wing surfaces. Respiration capacity under water is not likely to be a limiting factor for ovipositing females during the production of a single clutch." - 6037.** Tsuyuki, K.; Sudo, S.; Tani, J. (2006): Morphology of insect wings and airflow produced by flapping insects. *Journal of Intelligent Material Systems and Structures* 17(8-9): 743-751. ["This article describes the results of some experiments concerning wing morphology and flight performance of some flying insects: cicadas, dragonflies, and gadflies. First, the wing structures of these insects are measured down to the minutest detail by a three-dimensional curve-shaped measuring system. The surface shapes of the insect wings are mapped by distinct three-dimensional images. From the three-dimensional images, correlation coefficients are calculated by comparisons of the distribution of undulation on the wings. The surface shapes and the correlation coefficients show a difference in functions for flapping flight between each wing. Second, the distribution of velocity fields around a flapping cicada and a flapping dragonfly are visualized with a PIV system to identify the airflow generated by the wings. The distribution of velocity vectors for one stroke of a dragonfly wing is explained in the article. Additionally, the difference of airflow around the wings of a dragonfly and a cicada are revealed. It is found that the flapping forewing of the dragonfly carries out an important motion in its highly efficient flight." - 6038.** Wallace, I.D.; Lawson, N.J.; Harvey, A.R.; Jones, J.D.C.; Moore, A.A.J. (2006): High-speed photogrammetry system for measuring the kinematics of insect wings. *Applied Optics* 45(17): 4165-4173. (in English). ["We describe and characterize an experimental system to perform shape measurements on deformable objects using high-speed close-range photogrammetry. The eventual application is to extract the kinematics of several marked points on an insect wing during tethered and hovering flight. We investigate the performance of the system with a small number of views and determine an empirical relation between the mean pixel error of the optimization routine and the position error. Velocity and acceleration are calculated by numerical differencing, and their relation to the position errors is verified. For a field of view of 40 mm x 40 mm, a rms accuracy of 30 µm in position, 150 µm/s in velocity, and 750 µm/s² in acceleration at 5000 frames/s is achieved. This accuracy is sufficient to measure the kinematics of hoverfly flight." (Authors) The paper contains many references to Odonata.] Address: Moor, A.J., School of Engineering and Physical Sciences, Heriot-Watt University, Edinburgh, EH14 4AS, United Kingdom. - 6039.** Wang, Y.P.; Wang, Y.H.; Lu, P.; Zhang, F.; Li, Y. (2006): Diet composition of post-metamorphic bullfrogs (*Rana catesbeiana*) in the Zhoushan Archipelago, Zhejiang Province. *Biodiversity Science* 14(5): 363-371. (in Chinese, with English summary). ["Bullfrogs are listed as one of the 100 worst invasive alien species in the world. They are generalist predators and thus may affect native species through predation. However, in previous diet studies, the food contents of bullfrogs were mostly examined at a single site. From June 30 to August 11 in 2005, we examined the diet composition of post-metamorphic bullfrogs on eight islands (Daishan, Liheng, Xiushan, Fodu, Taohua, Xiashi, Cezi, and Putuoshan) in the Zhoushan Archipelago, Zhejiang Province, with the stomach flushing method. A total of 391 bullfrogs were measured during the study period, including 113 adults and 278 juveniles. Analyses of stomach contents showed that, for adult bullfrogs, the most important prey items (by diet volume) overall were Decapoda, Coleoptera, Odonata, Mesogastropoda, Raniformes, and Cypriniformes; while for juvenile bullfrogs, they were Decapoda, Coleoptera, Cypriniformes, Odonata, Orthoptera, Hymenoptera, Lepidoptera larvae, Mesogastropoda, and Raniformes. Moreover, prey size and diet volume increased with the body size of both adult and juvenile bullfrogs. The diet composition of primary preys of bullfrogs was significantly different among different islands. The results indicate that bullfrogs exert different predatory influences on native fauna at different sites, and that bullfrogs are generalist predators with extensive ecological impacts on native fauna." - 6040.** Weihrauch, F. (2006): Der Zahnkärppling *Gambusia holbrooki* als Prädator von Libelleneiern (Teleostei: Poeciliidae; Odonata: Libellulidae). *Libellula* 25 (3/4): 209-214. (in German, with English summary). ["At an irrigation ditch NE of El Rocío, Huelva province, Andalusia, Spain, on 18 and 21-IX-2006 repeated egg predation by swarms of *C. holbrooki* was observed during the exophytic oviposition of two *Crocothemis* erythraea females and seven *Sympetrum fonscolombii* tandems into open water. Other, endophytically ovipositing Odonata species were not bothered, as well as *C. erythraea* females that were hidden from the fish by carpets of algae or duckweed during oviposition. During all observed interactions, swarms of approximately 20-30 *C. holbrooki* chased the dragonflies immediately after the first dips, attacking the tip of the female's abdomen in a number of cases, and obviously struggling for each sinking egg. The dragonflies responded to these attacks by changing their behaviour from a chain of subsequent dips into the water to single or, at most, triple dips that were followed by rapid changes of oviposition sites. In one exactly noted case, a *S. fonscolombii* tandem performed 42 dips and 25 changes of place in almost two minutes. However, this avoidance behaviour was not successful due to the high fish density in the ditch. Judging from swallowing movements and other reactions of the fish, most eggs seen to be laid were consumed." (Author)] Address: Weihrauch, F., Jägerstr. 21A, D-85283 Wolnzach, Germany. - 6042.** Wennemann, L. (2006): Kulturelle Entomologie: Insektenterminologie in der deutschen Sprache. *Mitt. dtsh. Ges. allg. angew. Ent.* 15: 435-438. (in German, with English summary). ["German articles in newspapers (Ruhr Nachrichten, Westdeutsche Allgemeine Zeitung, Frankfurter Allgemeine Zeitung, Die Zeit) and general journals (Audimax, Bunte, DB Mobil, Focus, DLG Mitteilungen etc.) were analyzed for their colloquial language containing entomological terms and phrases. Some examples are given here: The German term 'Fliegenfänger' (fly catcher) is used when a goalkeeper has a bad day allowing the opponent team to score avoidable goals. This example is put into the category 'Diptera' whereby the second example 'einmotten' (to put in mothballs) is put into the category 'Lepidoptera'. 'Moskitos Essen' is the name of an ice hockey team from the town Essen (Germany) and is categorized under 'Diptera'. Results show that sayings and entomological terms are often used and found in printed matters. It is obvious that terms associated with the holometabol insect orders such as Hymenoptera, Lepidoptera und Diptera are most frequently used in contrary to hemi- or paurometabol insect orders such as Blattodea, Orthoptera and Odonata. Preliminary explanations are given why certain insect orders are more frequently used than others. This paper should be a new approach to put cultural entomology into focus and to advertise for his diverse, interesting and fascinating scientific topic within the field of entomology." 6046. Westermann, K. (2006): Strategien frisch geschlüpfter *Lestes viridis* zur Vermeidung von Regenschäden (Odonata: Lestidae). *Libellula* 25(1/2): 47-60. (in German, with English summary). ["In detailed daily studies of the emergence of *L. viridis* it was found that newly emerged imagines use several strategies to minimize damage from rain. The most effective one is the ability of the larvae to postpone emergence during rainy or cool weather for up to 14 hours at the emergence site, or by at least one day in the water. In early and late stages of emergence, imagines are relatively insensitive to rain. Larvae attach to the emergence support at angles between 90 and 180 degrees, which frequently provides the imagines with a degree of protection from rain under leaves and oblique stems. In case of sudden onset of heavy rain, imagines are able to climb, flutter

or fly to more protected sites. It is remarkable that in case of rain most larvae choose better protected sites for emergence. Losses caused by rain were approximately 1 % of the total number of imagines emerging." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

6047. Westermann, K.; Westermann, E. (2006): Zur Phänologie der Gebänderten Heidelibelle (*Sympetrum pedemontanum*) im NSG „Elzwiesen“ in den Jahren 2003 bis 2005. *Naturschutz am südlichen Oberrhein* 4(2): 251-257. (in German, with English summary). ["Our results show that the periods of emergence and flight activity of *S. pedemontanum* in Baden-Württemberg, Germany are much more extended than formerly known. In most cases, emergence was not notably synchronised. Reproductive activities lasted almost until the end of the flight period. The maximum life span of imagoes of *S. pedemontanum* was determined as at least 56 days." (Authors)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

["Every year billions of butterflies, dragonflies, moths and other insects migrate across continents, and considerable progress has been made in understanding population-level migratory phenomena. However, little is known about destinations and strategies of individual insects. We attached miniaturized radio transmitters (ca 300 mg) to the thoraxes of 14 individual dragonflies (common green darners, *Anax junius*) and followed them during their autumn migration for up to 12 days, using receiver-equipped Cessna airplanes and ground teams. Green darners exhibited distinct stopover and migration days. On average, they migrated every 2.9G0.3 days, and their average net advance was 58G11 km in 6.1G0.9 days (11.9G2.8 kmdL1) in a generally southward direction (186G528). They migrated exclusively during the daytime, when wind speeds were less than 25 km hL1, regardless of wind direction, but only after two nights of successively lower temperatures (decrease of 2.1G0.6 8C in minimum temperature). The migratory patterns and apparent decision rules of green darners are strikingly similar to those proposed for songbirds, and may represent a general migration strategy for long-distance migration of organisms with high self-propelled flight speeds." (Authors)] Address: Wikelski, M., Department of Ecology and Evolutionary Biology, and 4Woodrow, Wilson School, Princeton University, Princeton, NJ 08544, USA. E-mail: wikelski@princeton.edu

6049. Wildermuth, H. (2006): Reciprocal predation involving Odonata, Asilidae and Saltatoria. *International Journal of Odonatology* 9(2): 225-234. (in English). ["A singular observation of an adult *Tettigonia viridissima* (*Tettigoniidae*) that captured a female *Eutolmus rufibarbis* (*Asilidae*) sucking a male *Lestes sponsa* (*Lestidae*) is reported. The reciprocal predation of Odonata, Asilidae, and Saltatoria (*Ensifera*, *Caelifera*) hitherto recorded in Europe is compiled and augmented by unpublished data on asilids as predators of odonates. Heavy predation by robberflies may occur only on grasshoppers and dragonflies; all other reciprocal predation events are occasional." (Author)] Address: Wildermuth,

6050. Wildermuth, H. (2006): Verhaltensgesteuerte Thermoregulation bei *Somatochlora flavomaculata* (Odonata: Corduliidae). *Libellula* 25(1/2): 31-46. (in German, with English summary). ["The species is a 'flier' that typically regulates its body temperature by physiological means. In a field study on the Alpine foothills it was shown that it also thermoregulates behaviourally. The flight activity ranged from 19 to 35°C ambient temperature. Below 28°C males patrolled exclusively in the sun, and basking individuals achieved optimal incident insolation by adopting an appropriate posture. Above 32.5°C active males stayed completely in the shade of trees and bushes. Between 28 and 32.5°C all transitions existed: more than half of the males patrolled partly in the shade, while the others flew either completely in the sun or entirely in the shade. As ambient temperatures rose, on their patrol stretches, males had a tendency to stay longer in the shade than in the sun. At high temperatures they often perched on the shaded side of a plant stem with their body axis pointing towards the sun. The results are discussed in the context of the relation between physiological and behavioural thermoregulation by 'fliers', especially Corduliidae." (Authors)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

6051. Worthen, W.B.; Jones, C.M. (2006): Relationships between body size, wing morphology, and perch height selection in a guild of Libellulidae species (Odonata). *International Journal of Odonatology* 9(2): 235-250. (in English). ["Ten common libellulid species perch along the shoreline of lakes and ponds in South Carolina, USA. We collected individuals at five ponds throughout summer 2005, weighed them in the field, and calculated wing loading ($N \cdot m^{-2}$) and wing aspect ratios from digital photographs. We measured the perch-height preferences of these species in 'low perch' (10, 20, 30, and 40 cm) and 'high perch' (20, 40, 60 and 80 cm) experiments. Flywheel anemometers recorded wind speeds at each perch height. Species differed significantly in mean body mass, spanning nearly an order of magnitude from *Perithemis tenera* (67 mg) to *Libellula vibrans* (633 mg). There were also significant differences in wing morphology that correlated with mean mass; larger species had greater wing loadings and greater wing aspect ratios than smaller species. Species also differed significantly in their perch-height preferences in both experiments, in a manner correlating with body mass and hindwing aspect ratios. *Erythemis simplicicollis* and *P. tenera* preferred short perches, *Celithemis fasciata*, *Pachydiplax longipennis* and *Platthemis lydia* used perches of intermediate height, and *Libellula auripennis*, *L. cyanea*, *L. incesta*, *L. luctuosa*, and *L. vibrans* preferred the tallest perches. Because mean wind speed and maximum wind speed also increased with perch height, larger species may prefer taller perches to experience greater wind speed and generate more compensatory lift to offset their larger wing loadings. However, it is also possible that correlations between body mass and perch height are the result of large species competitively restricting smaller species to lower perches." 6055. Xu J.; Zhao C.; Zhang, Y.; Zhang, Y. (2006): Effect of flapping trajectories on the dragonfly aerodynamics. *Chinese Science Bulletin* 51(7): 777-784. (in English). ["The effects of translational, figure-eight and double-figure-eight flapping trajectories on the dragonfly aerodynamics were numerically studied by solving the Navier-Stokes equations. There is a common characteristic regarding the lift/drag force coefficients that the downstroke flapping provides the lift forces while the upstroke flapping creates the thrust forces for different flapping trajectories. The maximum lift force coefficient exceeds five for the translational trajectory. It is greater than six for the figure-eight and double-figure-eight flapping trajectories, which is sufficiently larger than unity under the steady state flight condition. The ellipse and double-figure-eight flapping trajectories yield the decrease of the lift force, while the figure-eight flapping trajectory yields higher lift force as well as the thrust force than the translational flapping one. During the insect flight, the wing flapping status should be changed instantaneously to satisfy various requirements. Study of the flapping trajectories on the insect aerodynamics is helpful for the design of the Micro-air-vehicles (MAVs)." - 6058.** Yusa, Y.; Sugiura, N.; Wada, T. (2006): Predatory potential of freshwater animals on an invasive agricultural pest, the apple snail *Pomacea canaliculata* (Gastropoda: Ampullariidae), in southern Japan. *Biological Invasions* 8: 137-147. (in English). ["The apple snail *Pomacea canaliculata* is an invasive species and a serious pest of rice in many Asian countries. We studied predatory activities of various animals living in Japanese freshwater habitats, by keeping each individual of a potential predator species with 36 snails of various sizes for three days in the aquarium. Forty-six species were tested, and 26 in eight classes fed on small snails. A species of leech, crabs, the common carp, turtles, the mallard duck and the Norway rat attacked even adult snails of 20–30 mm in shell height. These findings will be helpful in identifying effective predators for biological control of the pest snail. In addition, most of the animals attacking snails are reported to be common in rivers or ponds, but few live in modernized paddy fields having little connections with natural water systems. This may be a reason why this snail maintains large populations in paddy fields but not in other freshwater habitats." (Authors) *Sieboldius albardae*, *Anotogaster sieboldii*, *Anax parthenope*, *Macromia amphigena*, and *Pantala flavescens* were tested for their predatory potential. They seem to be of minor importance as predators of the snails, and if, only for early stages of the snails.] Address: Yusa, Yoichi, Faculty of Science, Nara Women's University, Kitaouya-Nishimachi, Nara 630-8506, Japan. 6064. Živic, I.; Markovic, Z.; Brajkovic, M. (2006): Influence of the temperature regime on the composition of the macrozoobenthos community in a thermal brook in Serbia. *Biologia, Bratislava* 61(2): 179-191. (in English). ["In contrast to cold and eurythermal waters, benthic communities of warm brooks in temperate regions have been inadequately studied. In order to investigate the effects of water thermal regime on the benthic communities of warm waters and their relationships with those of cold and eurythermic ones, the macrozoobenthos was studied at eight sites in the Toplica River, and at four sites in its tributary, the Termalni brook. Investigations were carried out seasonally from April 2000 to January 2001. Warm waters of the Termalni brook were characterized by specific macrozoobenthos assemblages that exhibited significant differences to the populations of eurythermal and cold waters of the Toplica River. The dominant taxa in the macrozoobenthos community of warm waters were mainly Gastropoda species. Moreover, benthic communities of warm waters were characterized by lower diversity and greater biomass in comparison with those of cold and eurythermal waters. The gradient of average annual temperatures represented the main ecological factor influencing changes of diversity and biomass along the course of the investigated Termalni brook. Inflow of warm waters at site T6 lead to a decrease in macrozoobenthos abundance and changes in qualitative and quantitative composition of the benthocoenosis of a highland stream, but did not significantly alter diversity." (Authors) Odonata are referred on the order-level at several occasions. In the appendix are documented records of *Cordulegaster boltonii*, *Gomphus vulgatissimus*, *Onychogomphus forcipatus*, and *Orthetrum albistylum*.] Address: Zivic, Ivana, Faculty of Biology, University of Belgrade, 11000 Belgrade, Serbia and Montenegro. 6066. Zuellig, R.E.; Kondratieff, B.C.; Schmidt, J.P.; Durfee, R.S.; Ruitter, D.E.; Prather, I.E. (2006): An annotated list of aquatic insects of Fort Sill, Oklahoma, excluding Diptera with notes on several new state records. *Journal of the Kansas Entomological Society* 79(1): 34-54. (in English). ["Qualitative collections of aquatic insects were made at Fort Sill, Lawton, Oklahoma, between 2002 and 2004. Ephemeroptera, Plecoptera, Trichoptera, Odonata, Coleoptera, aquatic Heteroptera, Neuroptera, and Megaloptera were targeted. Additional records are included from a survey that took place in 1999. More than 11,000 specimens from more than 290 collections were examined. Based on the current understanding of aquatic insect systematics, 276 taxa distributed over 8 orders, 46 families, and 141 genera were identified. Twenty-three of the 276 taxa [...] are reported from Oklahoma for the first time. The three most diverse orders included Coleoptera (86 species), Odonata (67 species) and Trichoptera (59 species), and the remaining taxa were distributed among Heteroptera, (30 species), Ephemeroptera (21 species), Plecoptera (6 species), Megaloptera (4 species), and Neuroptera (3 species). Based on previous published records, many of the species collected during this study were expected to be found at Fort Sill; however, 276 taxa of aquatic insects identified from such a small geographic area is noteworthy, especially when considering local climatic conditions and the relatively small size of Fort Sill (38,300 ha). Despite agricultural practices in Oklahoma, the dust bowl days, and the development of water-based recreation at Fort Sill, a high percentage of the total known aquatic insect fauna of Oklahoma can be found in a small geographic area." 6067. Clarke, G.M.; Spier-Ashcroft, F. (2006(?)): A review of the conservation status of selected Australian non-marine invertebrates. <http://www.deh.gov.au/biodiversity/threatened/action/non-marine-invertebrates/index.html>: III, 142 pp. (in English). [This review represents a first attempt to objectively assess the conservation status of a selected suite of the over 300000 Australian non-marine invertebrates. Any attempt to provide a detailed and comprehensive overview of the conservation status of such a large and diverse group is obviously impractical. The authors have taken a selection of 25 taxa (including 'Petalura species': *P. gigantea* and *P. litorea* on pages 90-94) that are representative of the diversity of our invertebrate fauna, their geographic distribution, different habitat requirements and associations and potential threats. For each selected species the following information is provided: General taxonomic status of the species, including an illustration; 2. Species survival status; 3. Species distribution – a map of current distribution is provided at the end of each synopsis overlaid with Conservation and Protected Areas; 4. Ha-

bitat details; 5. Biological overview; 6. Significance – details of the biological, ecological, and scientific significance of the species which have contributed to its inclusion in the plan; 7. Threats; 8. Conservation objectives; 9. Conservation actions already initiated for the taxon; 10. Conservation actions required for long-term conservation of the species. This section is subdivided into research and management needs. 11. A list of relevant experts who provided information. Available at: <http://www.deh.gov.au/biodiversity/threatened/action/non-marine-invertebrates/index.html>]

6069. Burgmer, T.; Hillebrand, H.; Pfenninger, M. (2007): Effects of climate-driven temperature changes on the diversity of freshwater macroinvertebrates. *Oecologia* 151: 93-103 (in English) ["Increasing temperatures due to climate change were found to influence abundance and timing of species in numerous ways. Whereas many studies have investigated climate-induced effects on the phenology and abundance of single species, less is known about climate-driven shifts in the diversity and composition of entire communities. Analyses of long-term data sets provide the potential to reveal such relationships. We analysed time series of entire communities of macrozoobenthos in lakes and streams in Northern Europe. There were no direct linear effects of temperature and climate indices (North Atlantic Oscillation index) on species composition and diversity, but using multivariate statistics we were able to show that trends in average temperature have already had profound impacts on species composition in lakes. These significant temperature signals on species composition were evident even though we analysed comparatively short time periods of 10–15 years. Future climate shifts may thus induce strong variance in community composition." [...] "Species correlated with high Trend-Temp, and thus likely to increase both in abundance and range, were: ... *Coenagrion* sp./Zygoptera, Libellulidae indet./Anisoptera, ..."] (Authors) Address: Burgmer, Tanja; Aquatic Ecology, Institute for Botany, University of Cologne, Gyrhofstr. 15, 50931 Köln, Germany. 6070. Cordero Rivera, A. (Ed.) (2007): Forests and Dragonflies (4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005). Pensoft Series Faunistica 61, ISSN 1312-0174: 300pp. (in English). ["Over the world, forests provide diverse habitats for a range of organisms, including dragonflies and other animals, that at a first sight seem not to depend on forests. For instance, *Macromia splendens*, one of Europe's most endangered dragonflies, uses forest roads as hunting places, and larvae are sometimes found amongst tree roots. As the authors of this book show, dragonflies are highly dependent on forest cover and composition, and this is true from the boreal forests to the tropics. The aim of this book is therefore to explore the ways in

which forests affect dragonfly life, and to show that forests are much more than places where timber is produced." 6071. Dallas, H.F.; Day, J.A. (2007): Natural variation in macroinvertebrate assemblages and the development of a biological banding system for interpreting bioassessment data—a preliminary evaluation using data from upland sites in the south-western Cape, South Africa. *Hydrobiologia* 575: 231-244 (in English): ["The variability of macroinvertebrate assemblages - (including Odonata on the family level) - was investigated at 27 upland reference sites in the south-western Cape, South Africa. Multivariate analyses showed that sites did not group on the basis of geomorphological zonation, i.e. mountain stream and foothill-cobble bed. When separate analyses were undertaken for mountain stream (n = 21) and foothill-cobble bed sites (n = 6), assemblages formed three and two groups, respectively. Similarity amongst groups ranged from 47% to 52%, while within-group similarity was between 54% and 67%. Environmental variables shown to contribute to this variability included distance from source, cation ratio ($([Na^+]+[K^+])/([Na^+]+[K^+]+[Ca^{2+}]+[Mg^{2+}])$), pH, longitude and stream width. Whilst overall variability in the metrics of the biotic index, SASS (South African Scoring System), is high at reference sites, the interpretation of monitoring-site data using biological bands derived from a range of reference sites, ensured that variability was taken into account and that detection of disturbance at a monitoring site was not impeded. A biological banding system has been developed for upland sites in the south-western Cape, together with a list of reference or expected SASS-taxa. This list includes details pertaining to seasonality and biotope preferences. The ability to define reference conditions that take

intrinsic variability amongst reference sites into account is important for the accurate interpretation of bioassessment data." 6072. Groeneveld, L.F.; Clausnitzer, V.; Hadrys, H. (2007): Convergent evolution of gigantism in damselflies of Africa and South America? Evidence from nuclear and mitochondrial sequence data. *Molecular Phylogenetics and Evolution* 42(2): 339-346 (in English) [Extreme large body size is rare in modern Zygoptera (damselflies). Only the South and Central American damselfly family Pseudostigmatidae and one African species, *Coryphagrion grandis*, share the morphological trait of gigantism. By means of phylogenetic analyses using two mitochondrial markers (16S rDNA and ND1) and one nuclear marker (EF1) in combination with an existing morphological data set, we trace the evolution of gigantism in damselflies. Individual and combined data sets were analyzed using the maximum parsimony, minimum evolution and maximum likelihood algorithms. Regardless of the algorithm used and the data set analyzed all principal tree topologies support a monophyly of the damselfly taxa displaying giant body size. This supports the view that the evolution of gigantism in damselflies from Africa and South America is not the result of convergent evolution due to strikingly similar habitat preferences, but rather the result of close genealogical relationship. Because modern odonates evolved before the split of Africa from Gondwanaland, the proposed phylogeny suggests that *C. grandis* represents a Gondwana relict.] Address: Hadrys, Heike, ITZ, Ecology and Evolution, TiHo Hannover, Bünteweg 17d, D-30559, Hannover, Germany. 6073. McCauley, S.J. (2007): The role of local and regional processes in structuring larval dragonfly distributions across habitat gradients. *Oikos* 116(1): 121-133. (in English). ["Despite the importance of community-structuring processes operating at both local and regional scales, there is relatively little work examining both forces within a single system. I used a combination of observational and experimental approaches to examine the processes structuring larval dragonfly distributions in lentic habitats that encompass a gradient of both permanence and top predator type. I compared the relative vulnerability of species to predators from different portions of this gradient to assess the role of predation as a local force structuring communities. I also assessed the role of regional processes on species' distributions by examining species' propensity to disperse to and colonize artificial ponds distributed across a landscape. In both studies I contrasted habitat specialist species, which had larvae restricted to permanent lakes, with habitat generalist species, which had larvae that occur broadly across the habitat permanence and top predator transition. Results from this work suggest that dispersal and colonization behavior were critical mechanisms restricting the distributions of habitat specialist species, but that predation may act to reinforce this pattern. The habitat specialists dispersed less frequently, colonized artificial ponds less often when they did reach them, and most moved shorter distances than the habitat generalist species. Habitat specialists were also more vulnerable than habitat generalists to an invertebrate top predator with which they do not co-exist.

Results from these studies suggest that species distributions can be shaped by processes operating at both regional and local spatial scales. The role of dispersal and recruitment limitation may be generally underestimated as a force shaping species distributions and community structure across habitat gradients in which there is a transition in both the biotic interactions and the disturbance interval across that gradient." 6074. Moseley, M. (2007): Acadian biospeleology: composition and ecology of cave fauna of Nova Scotia and southern New Brunswick, Canada. *International Journal of Speleology* 36(1): 1-21. (in English) ["The vertebrate and invertebrate fauna, environment and habitats of caves and disused mines in Nova Scotia and southern New Brunswick are provisionally catalogued and described, based on field collections made over many years. The area was glaciated and the subterranean fauna consists of non-troglobites all of which have arrived and colonised the caves during or following final recession of the Pleistocene glaciers. The statistical composition of the fauna at the higher taxonomic level is similar to that in Ontario, but is less species rich and there are some notable ecological and other differences. Porcupine dung accumulations are an important habitat in the region, constituting a cold-temperate analogue of the diverse guano habitats of southern and tropical caves. Parietal assemblages are, as in other cold temperate regions, an important component of the invertebrate fauna but here include species derived directly from dung communities: another parallel with tropical guano caves. An unanticipated finding is the number of non-indigenous species now utilising local caves. These appear to have colonised unfilled ecological niches, suggesting that post-glacial recolonisation of the subterranean habitat in Nova Scotia has been relatively delayed. Finally the general and regional significance of the subterranean fauna is briefly discussed." (Author) *Aeshna umbrosa* nymphs, *Aeshna* sp. indet. nymphs, *Cordulegaster maculata* imago, and *Macromia illinoensis* nymphs are compiled as records from the surveyed caves.] Address: Moseley, M., Research Associate, Nova Scotia Museum of Natural History, 1747 Summer Street, Halifax, Canada B3H 3A6. 6075. Munyuli, M.B.T.; Luther, G.C.; Kyamanywa, S. (2007): Effects of cowpea cropping systems and insecticides on arthropod predators in Uganda and Democratic Republic of the Congo. *Crop Protection* 26(2): 114-126 (in English) ["Knowledge of the distribution, abundance, species diversity and effectiveness of indigenous natural enemies of cowpea pests in Uganda and the Democratic Republic of the Congo (DRC) is poor. Similarly, effects of insecticides commonly used by cowpea farmers on arthropod predators are not well documented in these countries, so effects of insecticides on these natural enemies were monitored in field trials with cowpea grown solely and in association with sorghum or greengram. The abundance of predators (Coccinellidae, Staphylinidae, Syrphidae, Anthocoridae, Mantidae, Dermaptera, ground beetle, predatory mite, lygaeid bugs, Anthocoridae, dragonflies and spiders) were considerably affected by insecticides and the cropping system. Polyculture had a higher index of di-

versity than monocultures. In terms of species diversity supported, there was no significant difference between cowpea/greengram and cowpea/sorghum. There was a seasonal variation in similarity (MS=0.71, long rains; MS=0.77, short rains) of the predator community supported by the cowpea cropping system, between Mulungu (DRC) and Kumi (Uganda) habitats. Lower pests pressure on cowpea crop, higher abundance of predators and higher cowpea yields were observed to be associated with cowpea/greengram cropping systems. Therefore cowpea/greengram should be promoted among other biological control conservation strategies, aiming at enhancing natural enemies in cowpea systems, through habitat manipulation. This study indicated that generalist predators, through their activities might be important natural enemies of cowpea pests in Uganda and in DRC." 6076. Nummelin, M.; Lodenius, M.; Tulisalo, E.; Hirvonena, H.; Alanko, T. (2007): Predatory insects as bioindicators of heavy metal pollution. *Environmental Pollution* 145(1): 339-347 (in English) ["Heavy metal concentrations of different predatory insects were studied near by a steel factory and from control sites. Waterstriders (Gerridae), dragon fly larvae (Odonata), antlion larvae (Myrmeleontidae) and ants (Formicidae) were analyzed by AAS. In most cases the metal concentrations were higher near the factory, but e.g. waterstriders had higher cadmium concentrations in control area. Discriminant analysis clearly reveals that all these insect groups can be used as heavy metal indicators. However, the commonly used ants were the least effective in indicating the differences between the factory and control sites. Waterstriders are good in detecting differences in iron and manganese, but seem to be poor in accumulating nickel and lead. Antlions are efficient in detecting differences in iron. Antlions and ants are effective in accumulating manganese; as well antlions are efficient in accumulating cadmium. Waterstriders are poor in accumulating lead, but antlions and ants are effective." 6079. Salur, A.; Kiyak, S. (2007): Additional records for the Odonata fauna of South-Western Anatolia - Part I: Anisoptera. *Munis Entomology & Zoology* 2(1): 63-78.

(in English). [43 species and subspecies of Anisoptera were collected in the provinces of Antalya, Aydın, Burdur, Denizli, Isparta and Muğla in South-Western Anatolia, April-September between 2000 - 2002. These records are documented in detail.] Address: Salur, A., Hitit University Arts and Sciences Faculty Department of Biology, 19030, Corum, Turkey. E-mails: alosalur@gmail.com

6080. Shostell, J.M.; Williams, B.S. (2007): Habitat complexity as a determinate of benthic macroinvertebrate community structure in cypress tree reservoirs. *Hydrobiologia* 575: 389-399 (in English). ["We analyzed benthic samples (n = 128) collected from four cypress-tree population areas within a large, shallow Arkansas reservoir over a 2-year period to investigate macroinvertebrate community distribution patterns and their relation to physical and chemical parameters. The calculated biomass, abundance and diversity of the benthic macroinvertebrate community varied significantly both temporally and spatially. Variations of these variables are most likely explained by significant differences in the concentration of carbon and nitrogen in sediments across lake sites, and on a smaller scale, the presence or absence of cypress trees. Benthic macroinvertebrate abundance, biomass, and diversity significantly decreased with distance from tree." (Authors) Tab. 2 lists as an odonate species "Cynacantha sp." (sic). Address: Shostell, J.M., Department of Biology, Penn State University-Fayette, Route 119N, Uniontown, PA 15401, USA. E-mail: jms88@psu.edu

6081. Anholt, B.R. (1997): Sexual size dimorphism and sex-specific survival in adults of the damselfly *Lestes disjunctus*. *Ecological Entomology* 22(2): 127-132. (in English). ["(1.) A population of adult *Lestes disjunctus* (Odonata: Lestidae) was studied in eastern Ontario, Canada. Mass at sexual maturity and activity rates of individuals were measured. Population density was estimated on transects, while survival rates and population size were estimated using mark-recapture methods. (2.) There was no difference in mass of mated and unmated males. Females were more than 50% heavier than males, and were also more active than males. (3.) Males were almost eight times more abundant on transects than females, but Manly-Parr estimates of male population size were only a maximum of 2.5 times larger than estimates for females. (4.) Males were 2.5 times more likely to be resighted after marking than were females. This accounts for much of the discrepancy between transect estimates and mark-recapture estimates of relative population size. (5.) Daily survival rates of sexually mature females were not significantly less than those of males, and therefore cannot account for a change in sex-ratio from 1 : 1 at emergence to more males than females in sexually mature adults. (6.) Differences in mortality must occur prior to sexual maturity, coincident with the time during which differences in mass gain are also taking place." 6082. Asahina, S. (1997): Records of Northern Vietnamese Odonata taken by the expedition members from the National Science Museum, Tokyo. 6. Platystictidae, Megapodagrionidae, Lestidae and Synlestidae. *Bull. natn. sci. mus. Tokio Ser. A.* 23(2): 107-113. (in English). ["Seven species of northern Vietnamese damselflies are classified into four families, Platystictidae (1 new species and 1 new subspecies), Megapodagrionidae (1 new species and 1 species previously known from Lower Burma and Laos), Lestidae (1 common South Asiatic species), and Synlestidae (2 species pre-

viously known from Southwest China, etc.)." (Author) *Drepanosticta vietnamica*, *Rhipidolestes owadai*] Address: Asahina, S., 4-4-24 Takadanobaba, Shinjuku-ku, Tokyo 169, Japan

6083. Beschovski, V.L.; Gashtarov, V. (1997): *Selysiotthemis nigra* (Vander Linden, 1825) - a new genus and species for the Bulgarian fauna (Odonata: Anisoptera: Libellulidae). *Ent. Zschr.* 107(7): 309-310. (in English, with German summary). [First record of *S. nigra* in Bulgaria. One male specimen on 4-VI-1996 in the small floodplain of the river Melnishka, a left affluent of the river Struma near the town of Melnik.] Address: Beschovski, V.L., Inst. Zool., Bulgarian Acad. Sci., Boul. Tzar Osvoboditel 1, 1000 Sofia, Bulgaria

6084. Goutner, V.; Furness, R.W. (1997): Mercury in feathers of Little Egret *Egretta farzetta* and Night Heron *Nycticorax nycticorax* Chicks and in their prey in the Axios Delta, Greece. *Archives of environmental contamination and toxicology* 32(2): 211-216. (in English). ["Mercury concentrations were measured in feathers of little egret and night heron chicks and in their prey in the Axios Delta, Greece. Significantly higher concentrations occurred in night heron than in little egret in 1993. In the night heron the mercury content of feathers was negatively correlated to the size of chicks, possibly due to inhibition of growth. Mercury concentrations were higher than reported for heron feathers in seriously polluted sites in North America and Japan, but the toxic hazard is unclear. Diets differed considerably between the two species due to use of different foraging habitats and this seems responsible for different mercury contents of feathers. Mercury concentrations in the pumpkinseed sunfish *Lepomis gibbosus*, goldfish *Carrassius auratus*, and in dragonfly Odonata larvae were the highest among the prey categories. Frogs and water beetles *Dytiscidae* had moderate concentrations whereas saltwater fish and terrestrial prey had very low mercury concentrations. The implication is that the deltaic marshes are the habitat most polluted with mercury. Night heron chick feathers, freshwater fish and dragonfly larvae could be used to monitor mercury contamination in this region, but use of bird feathers alone could give misleading results if changes in diet occurred." 6088. Saugestad, T. (1997): Stor torvlibelle *Leucorrhinia pectoralis* (Charpentier, 1825) funnet i Hordaland. *Insekt-Nytt* 22(4): 15-17. (in Norwegian, with English summary). [The genus *Leucorrhinia* is represent in Norway with five species, of which only *L. dubia* is common. Two males of the endangered *L. pectoralis* were recorded on 19.07. and 22.07.1997, at Leirvikvatn, Tysnes, HOY. This is the first record from West-Norway. In addition, 10 taxa also recorded at the locality are listed.] Address: Saugestad, T., Gamle Kalvedalsvei 12B, N-5019 Bergen, Norway

6089. Tani, J.; Qu, J.; Yamaguchi, E. (1997): Rhythmic movement of dragonfly wing model. *Transactions of the Japan Society of Mechanical Engineers*. C 63 (No. 614): 3390-3395. (in Japanese, with English summary). ["This paper describes the model for insect wing movement with the non-linear oscillator. Living things have flexibility for various environments and on the whole structures keep a function even if a part of them is out of order. Recently, biological properties of living things which are autonomous distributed-systems become the focus of attention. The synchronous phenomenon of the system is applied to insect wing model. The equations of motion for insect wings are derived at first, and then Van del Pol equation is used to produce a non-linear rhythmic force. By solving these equations a rhythmic movement of insect wing model is obtained. It is found that various autonomous vibration can be generated using this model." (Authors) For an English version see Tani et al 1998 (OAS 855).] Address: Tani, J., Tohoku Univ., Inst. Fluid Sci., Katahira 2-1-1; Sendai; Miyagi 9808577; Japan

1998

6091. Flaspohler, D. (1998): A technique for sampling flying insects. *J. Field Ornithol.* 69(2): 201-208. (in English). ["I describe a procedure for sampling flying insects. Using binoculars, a stopwatch, and a hand-held counter, an observer counts insects passing through a measurable focal volume for a set time. No insect identification skills are needed. I tested the accuracy and repeatability of the procedure under controlled conditions and found that with known limitations, it is a reliable way to sample flying insect abundance. I used the procedure to describe daily activity pattern of flying insects using a clearing adjacent to a neotropical lowland forest reserve. While flycatcher and flying insect activity patterns were not strongly correlated, similarities in activity were noted." (Author) The paper contains some references to Odonata.] Address: Flaspohler, D., Department of Wildlife Ecology, A229 Russell Labs, University of Wisconsin-Madison, Madison, Wisconsin 53706 USA

6092. Sudo, S.; Tsuyuki, K.; Ikohagi, T.; Ohta, F.; Shida, S.; Tani, J. (1998): Wing structure of dragonfly: 2nd report, wing and flight. *Transactions of the Japan Society of Mechanical Engineers*. C 64(No.625): 3526-3533. (in Japanese, with English summary). ["This paper is concerned with the wing structure and the aerodynamic characteristics of a flying dragonflies. The structural properties of dragonfly wings were studied through the measurements of some morphological parameters. The scanning electron microscopic observation showed the morphological characteristics of the dragonfly wing. Dragonflies (*Sympetrum infuscatum*, *S. kunkeli*) were examined in a small low-turbulence wind tunnel. In the experiment on the measurements of wing flapping, an optical displacement detector was used to measure the displacement of the dragonfly wing. In the experiment on the measurements of the velocity fluctuation, a hot-wire anemometer was used to measure the velocity field. The spectrum of dragonfly flight was revealed by the measurement of velocity fluctuation." (Authors)] Address: Sudo, S., Faculty of Systems Science and Technology, Akita Prefectural University, Yurihonjo 015-0055 Japan

1999

6093. Ellington, C.P. (1999): The novel aerodynamics of insect flight: applications to micro-air vehicles. *J. exp. Biol.* 202: 3439-3448. (in English). ["The wing motion in free flight has been described for insects ranging from 1 to 100 mm in wingspan. To support the body weight, the wings typically produce 2-3 times more lift than can

be accounted for by conventional aerodynamics. Some insects use the fling mechanism: the wings are clapped together and then flung open before the start of the downstroke, creating a lift-enhancing vortex around each wing. Most insects, however, rely on a leading-edge vortex (LEV) created by dynamic stall during flapping; a strong spanwise flow is also generated by the pressure gradients on the flapping wing, causing the LEV to spiral out to the wingtip. Technical applications of the fling are limited by the mechanical damage that accompanies repeated clapping of the wings, but the spiral LEV can be used to augment the lift production of propellers, rotors and micro-air vehicles (MAVs). Design characteristics of insect-based flying machines are presented, along with estimates of the mass supported, the mechanical power requirement and maximum flight speeds over a wide range of sizes and frequencies. To support a given mass, larger machines need less power, but smaller ones operating at higher frequencies will reach faster speeds." (Author) The paper deals mainly with Diptera, Hymenoptera and Lepidoptera, and contains only passing references to Protodonata and Odonata.] Address: Ellington, C.P., Dept of Zoology, University of Cambridge, Downing Street, Cambridge CB2 3EJ, UK. E-mail: c.ellington@zoo.cam.ac.uk

6094. Morse, D.H. (1999): Choice of hunting site as a consequence of experience in late-instar crab spiders. *Oecologia* 120(2): 252-257. (in English). ["Earlier experiences may play an important role in the choice of hunting sites, but their effects on the foraging repertoire of most animals remain poorly understood. I tested the role of previous flower choices (hunting sites) by penultimate-instar female crab spiders *Misumena vatia* in making subsequent patch-choice decisions. *M. vatia* is a sit-and-wait predator, and the two flower species used, ox-eye daisy *Chrysanthemum leucanthemum* and common buttercup *Ranunculus acris*, are important hunting sites. Spiders with different immediate experience showed similar abort-term (<1 day) giving-up times on the two flower species, independent of their previous substrate. However, four-fifths of the individuals that remained a day or longer tended to leave buttercups sooner than daisies, especially if they had previously occupied daisies. Thus they may directly assess the quality of a potential hunting site, perhaps in response to prey abundance, but previous experience may play a minor role as well. Of spiders that made several consecutive choices of hunting sites, those on daisies often confined these runs to daisies (one of two years); those on buttercups did not exhibit comparable fidelity. Spiders molting into the adult stage almost always subsequently chose the same flower species (either daisy or buttercup) as the one on which they molted. Thus, juvenile experiences may influence adults, the critical stage when virtually all of the spiders' reproductive resources are gathered, even if this resulted from imprinting on their molt sites rather than carrying information over the molt." 6096. Ishii, M.; Kanata, T.; Kobayashi, K.; Michishita, Y. (2000): Vegetation and species diversity of aquatic insects in the Ziou marsh, northern Osaka. Scientific report of the College of Agriculture, Osaka Prefecture University 52: 29-41. (in Japanese, with English summary). ["Vegetation and species diversity of aquatic insects were investigated in the Ziou Marsh in Nose Town, northern Osaka Prefecture, central Japan from April to November, 1998. A total of 60 species of vascular plants belonging to 40 families were found in the marsh. Dominant species were *Isachne globossa*, *Scirpus fuirenooides*, *Potamogeton fryeri*, *Juncus effusus* var. *decipiens*, *Haloragis micrantha*, etc. A total of 52 species of aquatic insects were observed in the water. In 20 (39%) and 22 (42%) out of the 52 species, only larvae and adults were observed respectively. Dominant species were *Notonecta triguttata*, Chironomidae sp.1, *Sigara* spp., *Gerris latiaabdominis*, and Chironomidae sp.2, *Cloeon* sp., and *Aeshna nigroflava*, representing about 80% of the total number of aquatic insects observed in this marsh. As for adult Odonata, a total of 29 species from 9 families were found in this marsh. Dominant species were *Sympetrum kunkeli*, *Nannophya pygmaea*, *Indolestes peregrinus*, *S. darwinianum*, and *Cercion calamorum*, representing about 60% of the total individuals found. Adults of the tiny dragonfly, *N. pygmaea*, were observed from May to August in this marsh, though females disappeared about half a month earlier." (Authors)] Address: Ishii, M., College of Agriculture, Osaka Prefecture University, Japan

2001

6098. Bernath, B.; Szedenics, G.; Molnar, G.; Kriska, G.; Horvath, G. (2001): Visual ecological impacts of "shiny black anthropogenic products" on aquatic insects: oil reservoirs and plastic sheets as polarized traps for insects associated with water. *Archiv für Naturschutz und Landschaftspflege* 40: 89-109. (in English). [The waste oil lake in Budapest (Hungary) deceived, attracted and killed insects in large numbers and acted as a huge insect trap for 50 years from 1951. Records of insects made between August 1997 and September 1998 also included Odonata, namely *Aeshna mixta*, *Anax imperator*, and *Sympetrum vulgatum*.] Address: Horvath, G., Biooptics Laboratory, Department of Biological Physics, Loránd Eötvös University, 1117 Buda-

pest, Pázmány Péter sétány 1, Hungary. E-mail: gh@arago.elte.hu

6099. Bönsel, A. (2001): Hat *Aeshna subarctica* (Walker 1908) in Nordostdeutschland eine Überlebenschance? Die Entwicklung zweier Vorkommen im Vergleich zum gesamten Bestand in Mecklenburg-Vorpommern. *Natur und Landschaft* 76(6): 257-261. (in German, with English summary). [Exuviae of *A. subarctica* have been recorded since 1995 in the Göldenitzer Moor mire in the German regional state of Mecklenburg/Western Pomerania. The abundance declined from 322 to 12 emerged individuals within 6 years. This was associated with the simultaneously observed disappearance of *Sphagnum* species. The loss of *Sphagnum* plants is due to intensive drainage and elevated nutrient availability. In the Horster Moor mire, a presumably extinct population re-established itself after restoration measures as an abundant and autochthonous population. Restoration of the Horster Moor site, where peat had previously been extracted industrially, commenced in 1986 by waterlogging of this ombrogenous bog. At first, *Sphagnum* cover developed slowly. However, a stand of *Eriophorum* species developed in shallow flooded areas with mossy bog ponds. In areas where manual peat-digging was practised, flooded *Sphagnum* grew again after the water level rose. Consequently, after 14 years of re-vegetation, *A. subarctica* has re-established itself with a major autochthonous population. However, this population remains endangered by eutrophication of its larval waters. In Mecklenburg/Western Pomerania there are currently 9 further occurrences of *A. subarctica*. These are all similarly severely endangered. Therefore, medium-term extinction of this dragonfly in north-eastern Germany appears likely.] Address: Bönsel, A., Vasenbusch 15, D-18337 Gresenhorst, Germany. E-mail: andre.boensel@gmx.de

6100. Derka, T.; Kováčová, J.; Bulánková, E. (2001): Substrate importance for selected macrozoobenthic communities in Rudava river. *Folia faunistica Slovaca* 6: 59-68. (in Slovakian, with English summary). ["The macroinvertebrate communities inhabiting different substrate types were investigated in a small sandy bottom river in SW Slovakia. Special attention was paid to macroinvertebrates associated with wood debris and submersed root mats of riparian trees. A total of 57 taxa of temporal fauna were recorded at two sites; the lowest number of taxa was found on the sandy substrate. The muddy substrate with detritus was also inhabited relatively poorly, whereas the most diverse was the community on the woody debris (35 taxa collected). At all substrate types, the highest biomass values were found in amphipods. Trichoptera were important on debris and the habitats associated with roots. Densities were highest on muddy habitats with detritus but the biomass was lower than that on the roots and debris. Sandy bottom showed the lowest values of densities and biomass. Woody debris and submersed roots were found to be essential for the maintenance of diversity and abundance of macroinvertebrate community." (Authors) The paper includes notes on *Calopteryx splendens*.] Address: Bulankova, Eva, Institute of Ecology, Faculty of Natural Sciences, Comenius University, Mlynská dolina B-II, SK-84215 Bratislava., Slovakia; tel.+ 421-7-728 922, e-mail: Bulankova@fns.uniba.sk

6104. Pliuraite, V. (2001): Seasonal changes of the abundance, biomass, species composition of macrozoobenthos in the rivers Merkys and Svventoji. *Ekologija* 2001(4): 16-30. (in Lithuanian, with English summary). [Lithuania, *Calopteryx splendens*, *Gomphus vulgatissimus*, and *Libellula quadrimaculata* are listed from different stretches of the rivers.] Address: Pliuraite, V., Ekologijos institutas, Akademijos g.2, LT-2600 Vilnius, Lietuva

6105. Ramos Elorduy, J.; Pino, J.M. (2001): Contenido de vitaminas de algunos insectos comestibles de México. *Revista de la Sociedad Química de México* 45(2): 66-76. (in Spanish, with English summary). ["The concentrations of Vitamins A, C, D, and B (thiamine, riboflavin and niacin) in 35 species of edible insects were determined. It is noted the role of these substances for the development and growth of the human organism, as well as for health. The concentrations obtained for the edible insects studied were compared with those of conventional edible products rich in these micronutrients, noting that in many cases certain species surpass the vitaminic content of various common edible products, therefore, some edible insects species can be considered as a good vitaminic source. This is the case of *Periplaneta americana* (adults) in vitamin A, *Latebraria amphipyrioides* (larvae) in vitamin C, *Achea domestica* (nymphae) in vitamin D, and *Copestylum anna* and *C. haggi* (larvae) in thiamine, riboflavin, and niacin. It is observed that the insects species studied possess more content in vitamins of the B group, It is pointed out the importance of the presence of these vitamins for the diet of peasants of the rural area of Mexico, who regularly consume insects, and even store and commercialize them." (Authors) Exclusively vitamin B was found - in low concentrations - in the larvae of *Anax* sp.] Address: Ramos-Elorduy, Julieta, Instituto de Biología, Universidad Nacional Autónoma de México. Circuito Exterior, Ciudad Universitaria, Ap. Postal 70-153, Mexico 04510, D.F.

The habitat selection of the species is stressed.] Address: Schlüpmann, M., Hierseier Weg 18, D-58119 Hagen, German. E-mail: martin-schluemann@t-online.de

6107. Sibl, J. (2001): Contribution to the knowledge of dragonflies (Insecta: Odonata) of the National Park Muránska planina (Slovakia). *Folia faunistica Slovaca* 6: 53-58. (in Slovakian, with English summary). ["The dragonfly fauna at 36 localities was studied in the national park Muránska planina (central Slovakia) and its surroundings. The occurrence of 16 dragonfly species was recorded, or 27 when including literature records. The occurrence of *Leucorrhinia pectoralis*, which is considered rare in Slovak republic, as well as in some other European countries, was confirmed in the study area. 8 species - *Pyrrhosoma nymphula*, *Ischnura pumilio*, *Sympecma fusca*, *Leucorrhinia pectoralis*, *Crocothemis erythraea*, *Orthetrum cancellatum*, *Cordulia aenea*, *Aeshna cyanea* - were for the first time recorded from the study area." (Author)] Address: Sibl, J., J. Stanislava 15, SK 84105 Bratislava, Slovakia. E-mail: sibl@changenet.sk

6108. Torres, L.; Onore, G. (2001): Diversidad de Odonata en ríos del bosque nublado Otonga y sus alrededores. In: Nieder, J. & W. Barthlott (Eds.): *Epiphytes and canopy fauna of the Otonga rain forest (Ecuador). Results of the Bonn - Quito epiphyte project, funded by the Volkswagen Foundation (Vol. 2 of 2)*. ISBN: 3-8311-1858-2: 275-300. (in Spanish, with English summary). ["Ten rivers were selected at similar altitudes: six located within the Otonga Reserve and four in agricultural areas. One semi-quantitative sampling of aquatic macro-invertebrates, in winter and summer, was undertaken, and physical and chemical parameters were measured for each river. A qualitative sampling of Odonata nymphs and adults was carried out for each river. All adult specimens were captured. Six nymphs genera and five adults genera were collected in or close the rivers studied. No correlation among the river characteristics, aquatic macro-invertebrates, and species and families of Odonata found in the rivers was observed. Although human activity exists around the rivers, this study demonstrated that those in agricultural regions were not sources of contamination that affect the macro-invertebrate fauna. The paucity of taxa in the rivers is probably due to a low percentage of organic matter." 6110. Armbruster, P.; Hutchinson, R. A.; Cotgreave, P. (2002): Factors influencing community structure in a South American tank bromeliad fauna. *Oikos* 96: 225-234. (in English). ["We examined factors influencing the structure of naturally replicated, taxonomically unrestricted communities inhabiting South American tank bromeliads. We measured aspects of plant physical structure and collected the entire macroscopic fauna of 209 bromeliads from the Yasuní Scientific Reserve in lowland eastern Ecuador. We collected a total of 11 219 individuals of 354 morphospecies. The morphospecies abundance distribution of our sample was approximated by a log-series distribution dominated by rare morphospecies (57% of the morphospecies were represented by a single individual). Six methods for estimating the total number of bromeliad associated morphospecies in our study area gave results which varied by a factor of three, illustrating that caution should be exercised in interpreting the results of any single estimator. Variation in plant volume, number of leaves, detritus content, and water volume explained 62% of the variation in morphospecies richness among plants. Finally, there was a quadratic relationship between body mass and both individual abundance and morphospecies richness in our sample. These results illustrate an important role of both biotic and abiotic factors influencing the structure of taxonomically unrestricted, ecologically defined natural communities." (Authors) 16 Odonata specimens from 8 morphospecies have been collected.] Address: Armbruster, P., Dept of Biology, 321 Marsh Life Sciences Bldg., Uni of Vermont, Burlington, VT 05405-0086, USA. (in German, with English summary). [The visually controlled ambush behaviour of *Libellula quadrimaculata* (Linnaeus, 1758) (Libellulidae, Odonata): *L. quadrimaculata* belongs to a group of dragonflies which

"employ a special hunting strategy, exhibiting the so-called „perching" behaviour. The males perch in the sun on vegetation near the shore, waiting in ambush for potential mates or items of prey. Initial findings indicated that males settling on the perch in the morning oriented the longitudinal axes of their bodies in such a way as to have the sun behind them, and accordingly were looking away from the sun. This also happened in the afternoon. A central topic of the investigation were visual factors significant for the dragonfly when perching. In order to ascertain this, the dragonfly's line of vision relative to the sun and to the visual environment was investigated." (Authors)] Address: Sauseng, Manuela Institut für Zoologie und Institut für Histologie und Embryologie, Karl-Franzens—Universität Graz, Universitätsplatz 2, 8010 Graz, Austria. 6114. Tsuyuki, K.; Sudo, S. (2002): Three-dimensional structure of a wing and flow field around a flapping dragonfly with the PIV system. Transactions of the Japan Society of Mechanical Engineers. B 68 (No.676) : 3392-3399. ["In the present paper, studies of dragonfly wing revealed the structural morphology and the aerodynamic characteristics. Some experimental studies on dragonfly wings were performed with a scanning electron micrograph, a three-dimensional curved shape measuring system and a Particle Image Velocimetry (PIV) system. Firstly, the scanning electron micrograph observed the cross section shape of a dragonfly wing. Secondly, the system for the measurement of surface shape measured the surface roughness of a dragonfly wing with μm order accuracy. The results of surface shape measurement revealed there are three regions on a dragonfly wing, which had different function for a wing. Lastly, the PIV system measured the flow characteristics around the dragonfly wing and the flapping dragonfly. The analysis of two-dimensional velocity fields with the PIV system clarified the existence of the large velocity areas over a dragonfly wing and the specific flows around a flapping dragonfly." 6115. Clausnitzer, V. (2003): Ecology and biogeography of the dendrolimnetic *Coryphagrion grandis*. 2. Symposium der A. F. W. Schimper-Stiftung: 1-13. (in English). ["A study on the ecology of the dendrolimnetic damselfly *C. grandis* was undertaken in coastal forests of East Africa. The results are compared with other dragonfly species, known to breed in phytotelmata as well. These ecological and additional morphological and genetic results of this study show, that the monotypic *Coryphagrion grandis*, which was placed for conveniences within the Megapodagriidae, belongs to the otherwise South and Central American Pseudostigmatidae. Although the separation from the neotropical Pseudostigmatidae occurred at least 100 million years ago, the morphology and biology *Coryphagrion grandis* is still very similar to the former. These findings support biogeographical considerations about historical forest distribution in Africa, stability of East African coastal forests and the species loss due to extinctions in West and Central Africa. Since the future of *Coryphagrion*

grandis depends on the survival of the last coastal and lower Eastern Arc forests in East Africa, a short conservation chapter is added in the end." (Author)] Address: Clausnitzer, Viola, Graefestr. 17, D-06110 Halle/Saale, Germany. E-mail: violacl@t-online.de

6116. Davis, S.; Golladay, S.W.; Vellidis, G.; Pringle, C.M. (2003): Macroinvertebrate biomonitoring in intermittent coastal plain streams impacted by animal agriculture. J. Environ. Qual. 32: 1036-1043. (in English). ["Little attention has been given to the ecology of intermittent coastal plain streams in the southeastern United States, and it is not known whether available macroinvertebrate biomonitoring methods reliably detect degradation in these streams. This study compared differences in biomonitoring metrics between reference and agricultural streams, and between the flow period (January–April) and the intermittent flow period (May–December). Percentages of crustaceans, isopods, and Ephemeroptera–Plecoptera–Trichoptera (EPT) were significantly higher at the reference site than the two most impacted sites during the flow period, probably resulting from the abundance of leaf litter and lower temperatures. During this same period, the agriculturally impacted sites had a significantly higher percentage of dipterans—a group that thrives in the silty, nutrient-rich waters. Four metrics (percent Crustacea, Isopoda, Diptera, and EPT) had no overlap between values for the most impacted and the least impacted sites during the flow period, but no metrics were able to detect more discrete differences among sites. Sites were physically and biologically similar during the intermittent period when natural stresses (i.e., stagnant water, high temperatures, low dissolved oxygen) were high, with many metrics such as percentages of dominant family, burrowers, chironomids and dipterans becoming similar at all sites. Our findings indicate that development of a better understanding of invertebrate fauna in reference conditions and of the natural variation in intermittent streams is necessary to develop effective biomonitoring programs for these systems." (Authors) The study includes a passing reference to "Odonata".] Address: S.W. Golladay, J.W. Jones Ecological Research Center, Route 2, Box 2324, Newton, GA 31770, USA. E-mail: sgollada@jonesctr.org

Kagoshima University Research Center for the Pacific Islands Occasional Papers No.39, Section 2, Report 7. The Progress Report of the 2000 and 2001 Survey of the Research Project "Social Homeostasis of Small Islands in an Island-zone": 73-75. (in English). ["Ulithi Atoll in Yap State is located in the western zone of the Federated States of Micronesia and comprises 49 islets. In a survey of Ulithi Atoll, we visited its four inhabited islands, Asor, Falalop, Fassarai, and Mogmog. Insects were collected both by day and night, and 262 species of insects from nine orders were recorded. In order to estimate the species richness and natural environment of each island, the number of species in each taxonomic order was considered. Fassarai had the greatest species richness of the four islands, while Mogmog had the least. This suggests that human inhabitation affects insect species richness, because most of Mogmog Island was used as living space." (Authors) A total of 6 odonate taxa are labelled but without any details with the exception of the number of taxa recorded on each island.] Address: Tsuda, K., Faculty of Agriculture, Kagoshima University, Kagoshima 890-0065, Japan

["Motion camouflage is a strategy whereby an aggressor moves towards a target while appearing stationary to the target except for the inevitable change in perceived size of the aggressor as it approaches. The strategy has been observed in insects (including Odonata), and mathematical models using discrete time or neural-network control have been used to simulate the behaviour. Here, the differential equations for motion camouflage are derived and some simple cases are analysed. These equations are easy to simulate numerically, and simulations indicate that motion camouflage is more efficient than the classical pursuit strategy ('move directly towards the target')."] (Author)] Address: Glendinning, P., Department of Mathematics, UMIST, PO Box 88, Manchester M60 1QD, UK. 6129. Matsui, A.; Satoh, M. (2004): Distribution of aquatic animals in the drainage systems created by paddy farmland consolidation in Shimodate City, Ibaraki Prefecture, Japan. *Japanese journal of conservation ecology* 9: 153-163. (in Japanese, with English summary). ["Conventional paddy farmland consolidation in Japan, which aims to increase farming efficiency by improving the drainage conditions of paddy fields and independently creating irrigation and drainage canals, is thought to have negative impacts on biodiversity in rural areas. The Land Improvement Act of Japan was amended in June 2001 and requires agricultural and rural development projects to be harmonized with the environment. It is widely recognized that transforming concrete irrigation and drainage canals into earthen canals and minimizing the differences in elevation between paddy plots and drainage canals aid in the preservation of aquatic animals. However, most paddy fields that have been consolidated using conventional standards will inevitably remain intact, thus continuing to have a substantial influence on the regional environment. Therefore, at least the minimum environmental measures should be effectively implemented in consolidated paddy fields. To this end, the distribution of the aquatic animals associated with these fields requires clarification. In addition, this knowledge will be useful in determining how to effectively distribute water during the non-

irrigation season. The purpose of this study was to clarify the distribution of aquatic animals in the canal systems of main, lateral, and farm drains in the consolidated paddy fields, with a special focus on canal structure and year-round water flow in the canals. A field survey at six sites, which were selected for their different canal levels, was carried out in Shimodate City, Ibaraki Prefecture, Japan (36°21'N, 139°59'E). Sampling was conducted at monthly intervals from April 2001 to March 2002. A survey of fishes revealed that *Zacco platypus* (Oikawa) was concentrated in the main drains, while *Misgurnus anguillicaudatus* (Dojou) was found mainly in the lateral and farm drains. Among aquatic insects, *Calopteryx atlata* (Hagurotombo) was concentrated in the lateral drains, while *Onhetrum albistylum speciosum* (Shiokaratombo) was observed primarily in the farm drains. *Z. platypus* preferred gravel-bottom main drains to those made of concrete. *C. atlata* and *O. albistylum speciosum* preferred year-round water flow to seasonal flow in lateral and farm drains, respectively. In contrast, *Sympetrum infuscatum* (Noshimetombo) preferred seasonal water flow to year-round flow in farm drains. The drainage systems in the consolidated paddy fields are clearly composed of different levels of drains with peculiar physical conditions, e.g., water depth and flow velocity, each of which attracts certain aquatic animals. To enrich the biodiversity of the paddy fields, our results suggest the importance of year-round water flow and natural materials for canal beds." (Authors)] Address: Masayoshi Satoh, M., Graduate School of Life and Environmental Sciences, University of Tsukuba, I-1-I, Tennodai, Tsukuba City, Ibaraki 305-8572, Japan. 6130. Matsu'ura, S.; Watanabe, M. (2004): Dynamics of reed community artificially established for conservation of the endangered damselfly *Mortonagrion hirosei* and odonate larvae inhabiting the community. *Japanese Journal of Conservation Ecology* 9: 165-172. (in Japanese, with English summary). ["To conserve the brackish water damselfly *Mortonagrion hirosei*, a reed community was artificially established adjacent to a small natural habitat in Mie Prefecture, Japan, in 2003. From April to November, we measured the dynamics of the reed community as well as the changes in abiotic factors in the understory of the community in which *M. hirosei* adults were active. Reeds that emerged in the artificial community were thinner and shorter than those in the natural habitat, however reed density did not differ between the two habitats. Therefore, the established reed community provided a more open habitat for *M. hirosei* adults compared to the natural habitat. Although adults of many odonate species were observed flying over both reed communities, only larvae of *Ischnura senegalensis* were collected in November in addition to those of *M. hirosei*. Because a predator of *M. hirosei* is *I. senegalensis* that should be excluded from the community, maintaining a dense reed community must be important for the conservation of *M. hirosei*." 6133. Relyea, R.A. (2004): Fine-tuned phenotypes: tadpole plasticity under 16 combinations of predators and competitors. *Ecology* 85(1): 172-179. (in English) ["It is now well appreciated that most organisms can alter their phenotypes when faced with environmental variation. Decades of empirical investigations have documented hundreds of examples of phenotypic plasticity, yet most studies have focused on the presence or absence of a single environmental factor. As a result, we know little about how organisms respond to gradients of environmental factors (i.e., threshold responses vs. continuous responses), nor do we understand how organisms respond to combinations of environmental variables. I examined how larval wood frogs (*Rana sylvatica*) altered their behavior, morphology, and growth in response to combined gradients of predation and competition. Increased predation risk induced lower activity, deeper tails, and shorter bodies, which collectively caused slower growth. Increased competition caused slower growth which induced higher activity, shallower tails, and longer bodies. For both environmental gradients, the responses were frequently continuous rather than threshold responses. Moreover, predation and competition had interactive effects. Responses to predators were always larger under low competition than under high competition. Responses to competition were larger under low predation risk when predation and competition induced traits in the same direction, but larger under high predation risk when predation and competition induced traits in opposite directions. The results demonstrate that responses to phenotypically plastic traits can be fine-tuned to a wide variety of environmental combinations." 6137. Schulz, R. (2004): Field studies on exposure, effects, and risk mitigation of aquatic nonpoint-source insecticide pollution: a review. *J. Environ. Qual.* 33: 419-448. (in English). ["Recently, much attention has been focused on insecticides as a group of chemicals combining high toxicity to invertebrates and fishes with low application rates, which complicates detection in the field. Assessment of these chemicals is greatly facilitated by the description and understanding of exposure, resulting biological effects, and risk mitigation strategies in natural surface waters under field conditions due to normal farming practice. More than 60 reports of insecticide-compound detection in surface waters due to agricultural nonpoint-source pollution have been published in the open literature during the past 20 years, about one-third of them having been undertaken in the past 3.5 years. Recent reports tend to concentrate on specific routes of pesticide entry, such as runoff, but there are very few studies on spray drift-borne contamination. Reported aqueous-phase insecticides concentrations are negatively correlated with the catchment size and all concentrations of 10 g/L (19 out of 133) were found in smaller-scale catchments (100 km²). Field studies on effects of insecticide contamination often lack appropriate exposure characterization. About 15 of the 42 effect studies reviewed here revealed a clear relationship between quantified, non-experimental exposure and observed effects in situ, on abundance, drift, community structure, or dynamics. Azinphos-methyl, chlorpyrifos, and endosulfan were frequently detected at levels above those reported to reveal effects in the field; however, knowledge about effects of insecticides in the field is still sparse. Following a short overview of various risk mitigation or best management practices, constructed wetlands and vegetated ditches are described as a risk mitigation strategy that have only recently been established for agricultural insecticides. Although only 11 studies are available, the results in terms of pesticide retention and toxicity reduction are very promising. Based on the reviewed literature recommendations are made for future research activities." (Author) The study also refers to some studies of insecticide exposures on Odonata in rice fields, but they are said to have not provided clear evidence for a relationship between population parameters and insecticide exposures.] Address: Schulz, R., Zoological Institute, Technical University, Fasanenstrasse 3, D-38092, Germany. - 6139.** Abro, A. (2005): The accessory glands of the female genital tract in *Aeshna juncea* (L.) and *A. grandis* (L.) (Anisoptera: Aeshnidae). *Odonatologica* 34(2): 103-110. (in English). ["The micro-anatomy of the female accessory glands in adult *A. juncea* and *A. grandis* is similar but the size of the *A. grandis* glands is clearly larger than that of *A. juncea*. The secretory cells constitute a simple columnar epithelium surrounding a cuticle-lined lumen. The glandular epithelium is provided with a peculiar system of deep, narrow, intercellular crypts bordered with microvillar cell membranes. Lipids released to the crypt lumen are presumably forced into the central gland lumen by contractions of the muscular network attached to the outside of the gland. The efferent duct of each gland that opens to the distal part of the vagina has a complicated muscular apparatus, probably serving as a pump. The secreted substances accumulate in the central gland cavity mainly during the pre-reproductive phase, which the dragonflies spend away from water. The secretion contains substances with wax-like properties and becomes darkened by osmication. Secretory cells appear to possess a limited life span; scattered cells in process of dying occur already during the early reproductive phase. In the late reproductive phase most of the glandular epithelium presents a disintegrated appearance. There is no cell renewal in the gland in the course of adult life. The pattern of cell death indicates a decomposition by apoptosis. Besides contributing to investment of the eggs, the glands presumably intervene also in other aspects of the reproductive processes." (in English). ["Live mass was recorded for over 290 adult Odonata during peak flight season in Mississippi. Total live mass is reported for 19 species, along with a quantitative species subset analysis of inter- and intraspecific sex partitioned mass. Fresh mass was significantly correlated with species and sex in Anisoptera ($p = 0.021$) and Zygoptera ($p = 0.001$), based on separate species-level analyses of the Libellulidae ($n = 6$ species) and Coenagrionidae ($n = 4$ species), respectively. Total live mass also was correlated with total body length in the libellulid dragonflies ($r^2 = 0.59-0.94$, $p < 0.0001-0.03$) and length-mass slopes were not significantly different among species. Limitations and cautions of mass prediction via proportionate size dimension(s) are discussed, some advantages of working with adults as opposed to larvae and measuring fresh mass as opposed to dry mass are described, and further study of length-mass relationships in adult Odonata is encouraged." - 6143.** Canales-Lazcano, J.; Contreras-Garduno, J.; Cordoba-Aguilar, A. (2005): Fitness-related attributes and gregarine burden in a non-territorial damselfly *Enallagma praevarum* Hagen (Zygoptera: Coenagrionidae). *Odonatologica* 34(2): 123-130. (in English). ["Odonata are usually infected with intestinal gregarines. Using *E. praevarum* adults, it was investigated whether: (a) both sexes differed in the degree of parasitism and immune ability (as shown by melanization of artificial, nylon-based implants in the thoracic region); and, (b) gamete production, survival and fat reserves correlated with gregarine burden. 2 sets of in-copula (to control for age) animals were used. One was used for estimation of egg and sperm, and the other for fat reserves. Survival was monitored as the time that field-captured insects survived under laboratory conditions in the absence of food. Gregarines were counted by dissection of the gut. Despite the case that females had more parasites than males, both sexes did not differ in immune ability. Eggs, but neither sperm nor fat reserves in both sexes, correlated negatively with parasite number. Survival in both sexes also correlated inversely with gregarine burden. This, however, held only for males when the analysis was performed by sex. These results are discussed in terms of the detrimental effects of gregarine on Zygoptera hosts." 6157. Fenoglio, S.; Bo, T.; Cucco, M. (2005): Winter prey preference of *Perlodes microcephalus* (Pictet, 1833) (Plecoptera, Perlodidae) nymphs in an Apenninic creek, northwestern Italy. *Entomological news* 116(4): 245-252. (in English). [The feeding habits of *P. microcephalus* nymphs have been investigated in Caramagna. "This large species is one of the most representative carnivorous stonefly nymphs in this area, where it is a top-bottom predator in many fishless creeks. Despite its ecological importance, little is known about its trophic ecology. In this study, we examined the gut contents of 35 nymphs during the winter of February 2005. We detected an evident trophic preference for the following taxa: Chironomidae (Diptera) as well as Psychomidae, Glossosomatidae, Hyporhyacophila sp., and other Trichoptera. This preference appears to be independent of the prey's availability in the substratum. Rheostenic taxa, also abundant and widespread in the substratum, were almost absent or seldom found in the diet of *P. microcephalus*. These results suggest that the trophic preferences of *P. microcephalus* are more dependent on prey microhabitat preference than on prey abundance." (Authors) Odonata are not represented as prey while they ("*Calopteryx* sp., *Onychogomphus* sp., *Orthetrum* sp.") are co-occurring with *P. microcephalus*.] Address: Fenoglio, S., University of Piemonte Orientale, Dipartimento di Scienze dell'Ambiente e della Vita, Via Bellini n. 25, 15100 Alessandria, Italy. 6161. Gonzalez-Soriano, E.; Cordoba-Aguilar, A. (2005): Male behaviour in the male dimorphic damselfly *Paraphlebia quinta* Calvert (Zygoptera: Megapodagrionidae). *Odonatologica* 34(4): 379-385. (in English). ["*P. quinta* is a tropical species with 2 male morphs: the black-winged (BW) male and the hyaline-winged (HW) male; here their sexual behaviour is described. In general, males seem to spend relatively little time in flying activities. This may be explained either by the inability to recognise conspecifics and, hence, engage in social interactions, or by the reduced energetic reserves that prevent them from engaging in expensive activities. BW males were more aggressive and site-faithful than HW males. BW defended spaces containing debris (plant and wood) against conspecifics while HW did not. BW-BW, BW-HW and HW-HW aggressive encounters were common. Despite their non-aggressive nature toward BW males, HW males behaved aggressively when faced by HW males. The distance flown by each morph from male grasping of the male until she started oviposition was measured: HW flew longer distances than BW. These differences between male morphs are compared to those found in *Mnais p. pruinosa*, another male dimorphic zygopteran. Similar to what happens in that species, both tactics in *P. quinta* are possibly maintained due to the similar reproductive and energetic costs accrued by and benefits paid to each morph." 6163. Hofmann, T.A.; Mason, C.F. (2005): Competition, predation and microhabitat selection of zygoptera larvae in a lowland river. *Odonatologica* 34(1): 27-36. (in English). ["The microdistribution of 4 lotic species was investigated in the field. Microhabitat selection of *Calopteryx splendens* and *Erythromnia najas* was further examined in the laboratory, individually at different larval densities and in the presence of the other species and a predator. *E. najas*, *Ischnura elegans* and *Platycnemis pennipes* showed significant preferences

for particular aquatic macrophytes compared to others in the field, whereas *C. splendens* did not discriminate between the investigated plant species. Only limited spatial separation was apparent between the larvae of different species, as preferences for the same macrophyte species were found. When kept separate and at low densities, larvae of *C. splendens* and *E. najas* inhabited significantly different microhabitats in the laboratory. At high intraspecific abundances, spatial overlap between the two species became apparent as both increasingly occupied less preferred substrata, which is in concurrence with the ideal free distribution model of habitat selection. *E. najas* showed no change in perch selection in the presence of *C. splendens* at high densities. In this instance, intraspecific competition therefore appeared to be more important than interspecific competition with other Zygoptera in determining the microdistribution of *E. najas*. In the field, the niches of the two species may be more adequately separated on the basis of prey selection or hunting behaviour. *E. najas* also actively reacted to the presence of a predator, indicating some flexibility of response regarding perch selection." 6166. Ishida, K. (2005): Reclassification of *Rhipidolestes okinawanus* Asahina, 1951, Occurring in the Ryukyus (Odonata, Megapodagrionidae). *Japanese journal of systematic entomology* 11: 167-181. (in English). ["*Rhipidolestes okinawanus* Asahina, 1951 is reclassified into 3 species, *R. okinawanus*, *R. shozoi* sp. nov., and *R. amamiensis* sp. nov.. *R. amamiensis* inhabiting the Amami Islands is divided into 2 subspecies, *R. amamiensis amamiensis* occurring in Amami-Oshima and *R. amamiensis tokunoshimensis* subsp. nov. in Tokunoshima." (Author)] Address: Ishida, K., Seisho High-school, Gifu, Japan

6167. Jaletzke, M.; Walter, B. (2005): Zur Flora, Vegetation und Fauna von Karpfenzuchtanstalten in Westfalen. *Abhandlungen aus dem Westfälischen Museum für Naturkunde* 67(3): 75-90. (in German, with English summary). [A total of 27 odonate species is said to oc-

cur at two carp breeding water body complexes in Westfalia, Germany, but no details are given (for details see: Schmidt, E. (1993): Die ökologische Nische von *Sympetrum depressiusculum* (Selys) im Münsterland (Naturschutzgebiet Heubachwiesen). *Libellula* 12(3/4): 175-198.] Address: Jaletzke, Martina, Klinkenhagen 52, D-48653 Coesfeld, Deutschland

6168. Kandibane, M.; Raguraman, S.; Ganapathy, N. (2005): Relative abundance and diversity of Odonata in an irrigated rice field of Madurai, Tamil Nadu. *Zoos' Print Journal* 20(11): 2051-2052. (in English). [Nine Anisoptera and three Zygoptera were recorded during 2000 in an irrigated rice field of Madurai India. *Pantala flavescens*, *Diplocodes trivialis*, *Crocothemis servilia*, *Tramea limbata*, and *Agriocnemis femina femina* were the dominant species recorded in weeded and partially weeded ecosystems. They were more abundant in partially weeded rice ecosystem than in weeded rice ecosystem. Rare species like *Orthetrum sabina*, *Rhyothemis variegata*, *Neurothemis tullia*, *Anax guttatus*, and *Trithemis* sp. occurred only at the tillering stage of crop growth.] Address: Kandibane, M., Krishi Vigyan Kendra, Vriddhachalam, Tamil Nadu 606001, India

6169. Kikuchi, R.M.; Uieda, V.S. (2005): Composition and distribution of macroinvertebrates in different types of substrate of a stream in the Municipal District of Itatinga, São Paulo, Brazil. *Entomol. Vect.* 12(2): 193-231. (in Portuguese, with English summary). [Relationships between habit, physical conditions of the habitat (substrate, flow, turbulence) and food availability of the fauna of a tropical stream were surveyed in a tributary of the Basin of Paranapanema, located in the municipal district of Itatinga, São Paulo. Comparing substrates dominated by vegetation, rocky and sandy structures the authors found a larger density of fauna in the rocky substrate and larger diversity in the vegetation substrate. In all substrates, Insecta, and mainly Diptera, prevailed in abundance and diversity of species. In most cases, Odonata are treated on the family level.] Address: Kikuchi, Regina Mayumi, Programa de Pós-graduação em Ecologia e Recursos Naturais, Universidade Federal de São Carlos, Caixa postal 676, Rodovia Washington Luís, Km 235, CEP: 13565-905, São Carlos, SP, Brasil. E-mail: rmkikuchi@yahoo.com.br

6170. Koch, H.-M. (2005): Herbstschlupf von *Lestes sponsa*. *mercuriale* 5: 41-42. (in German). [A record of late emergence at *L. sponsa* near Reutlingen, Baden-Württemberg, Germany is documented. The possibility of a bivoltine development in 2005 is discussed] Address: Koch, H.-M., Krämerstr. 40, D-72764 Reutlingen, Germany. E-mail: koch.druckerei@t-online.de

6171. Konogaya, S.; Kobayshi, H (2005): An effect of irrigation and cultivation system on food chain in paddy water environment. *Journal of rural planning association* 24(special issue): S49-S54. (in Japanese, with English summary). ["For the purpose of examining on role of irrigation and cultivation system to paddy ecosystem, we study species and number of Odonata larvae and analyze the stable isotope ratios of the Odonata larvae and the plankton/detritus in water of paddy fields and irrigation ponds. As a results, cultivation system clearly effects to composition of species and number of Odonata larvae. $\delta^{13}C$ indicates that *Orthetrum albistylum speciosum* larvae and *Coenagrionidae* spp. larvae which are dominant species in paddy water, de-

pend on specified food sources, each other. $\delta^{15}N$ shows that the trophic level of Odonata larvae is higher than that of the plankton/detritus in paddy water. It is considered that analyze the stable isotope ratios application is effective to examine water ecosystem and food web in paddy." (Authors)] Address: Konogaya, S., Graduate School of Agriculture, IBARAKI Univ., Japan

6172. Kosterin, O.E. (2005): Western range limits and isolates of eastern odonate species in Siberia and their putative origins. *Odonatologica* 34(3): 219-242. (in English). ["*Macromia amphigena*, *Shaogomphus postocularis*, and *Sympetrum croceolum*, ranging in NE China, Korea and Japan, have isolates at the NE margins of the Altai-Sayan mountain system: all 3 in SE West Siberia, *M. amphigena* and *S. postocularis* also in southern Central Siberia and *M. amphigena* in E Kazakhstan and W Mongolia. *Ophiogomphus obscurus*, *Nihonogomphus ruptus*, and *Calopteryx japonica* have continuous ranges protruding to the West from E. Asia to the Ob ' River basin and to 60 degrees N latitude. *Coenagrion ecornutum* has a similar range but extends N in Siberia to 65 degrees N and has an isolate in the S Ural Mts. *C. lanceolatum*, *C. hylas* and *Somatochlora graeseri* reach 70 degrees N and also extend westward to the Ob ' River basin, but *C. hylas* has isolates in the Polar Urals and Bavaria, while *S. graeseri* is probably isolated in the Ural Mts. Of 4 other eastern spp. in Siberia, 2 reach 70 degrees N, but *Somatochlora exuberata* extends westwards only to the sources of the Yenisey River and *Coenagrion glaciale* to Lake Baikal, while *Cercion v-nigrum* and *Anisogomphus maacki* just penetrate into SE Transbaikalia. Thus, 11 eastern odonate species have their western limits in Siberia (defined in a narrow sense, not including the Far East). In addition, 4 have more westerly isolates, 3 in the Urals and 1 in Bavaria. Siberia also includes the eastern limits of 21 western species 24 transpalaeartic species spread far to the N and 10 species occupy S Siberia only (or just occur locally), 2 Central Asian species barely penetrate into S. Siberia. *Aeshna viridis* is a doubtful amphipalaeartic species. Numerous palaeopalynological reconstructions suggest that during the Holocene climatic optimum, a continuous belt of broad-leaved forest was restored in Siberia, providing conditions for a recolonization of Siberia by Odonata. Westward migrations of eastern species were favoured by the optimum occurring earlier in the east than in the west. Hence, many western species had no time to occupy all of Siberia and today the eastern limits of their ranges lie within the region. *M. amphigena*, *S. postocularis* and *S. croceolum* perhaps were the most stenotopic of those E. Asian species that colonized Siberia during the Holocene, and after the optimum, their ranges shrank to the peri-Altaian refugium. Their isolates there should be dated no earlier than 5-6 thousand yrs ago. *C. v-nigrum* and *A. maacki* are perhaps the least mobile of the eastern species in Siberia." (Author)] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. E-mail: kosterin@bionet.nsc.ru

- 6180.** Matsubara, K.; Hironaka, M. (2005): Postcopulatory guarding behaviour in a territorial damselfly, *Pseudagrion p. pilidorsum* (Brauer), for submerged ovipositing females (Zygoptera: Coenagrionidae). *Odonatologica* 34(4): 387-396. (in English). ["The postcopulatory mate guarding behaviours by territorial and non-territorial males for submerged ovipositing females were investigated in the field. After copulations, females in tandem began to oviposit at the water surface and thereafter they usually submerged completely underwater. The female often repeated the submergence and emergence at several oviposition sites. When the female submerged completely, the male released her without submergence and rested above the water surface during oviposition (non-submerged guarding), or the male submerged completely and remained in tandem, whether only at first or for the duration of the oviposition (submerged guarding). Territorial males always performed non-submerged guarding when the female oviposited inside their territories. The non-submerged guarding inside the territory might allow the territorial male both to guard the ovipositing female and to maintain his territory. On the other hand, when the female oviposited inside another male's territories, territorial and non-territorial males exhibited both non-submerged guarding and submerged guarding. Thus, *P. p. pilidorsum* males may adopt either submerged guarding or non-submerged guarding in response to change in the probability of a takeover of the emerged female by rival males inside another male's territory." (Authors)] Address: Matsubara, K., Department of Applied Biological Sciences, Faculty of Agriculture, Saga University, Honjo 1, Saga, 840-8502, Japan
- 6181.** McBean, M.C.; White, S.A.; MacGregor, J.A. (2005): Foraging behaviour of the damselfly larva *Pyrrhosoma nymphula* (Sulzer) in response to predator presence (Zygoptera: Coenagrionidae). *Odonatologica* 34(2): 155-164. (in English). ["The trade of between foraging and predator avoidance was studied. In the presence of a larva of the predatory *Aeshna juncea*, *P. nymphula* was found to reduce foraging activity significantly reduced foraging activity in response to chemical stimuli from *P. nymphula*. *A. juncea* but not in response to visual stimuli. Foraging activity was further reduced when the diet of *A. juncea* was changed from chironomid larvae to *P. nymphula*. This suggests that predators are detected chemically and are chemically labelled by their diet. Foraging activity was found to increase with starvation level after 48 h without access to food, with a further increase after 72 h of starvation. The presence of chemical stimuli from conspecific fed predators delayed the increase in foraging activity until 72 h of starvation. These results have implications for larval survival and adult reproductive fitness." (Authors)] Address: White, S.A., Division of Environmental and Evolutionary Biology, Inst. Biomed. & Life Sciences, Univ. Glasgow, Glasgow G12 8QQ, Scotland. E-mail: s.white@bio.gla.ac.uk
- 6182.** McKee, D.; Harvey, I.F.; Thompson, D.J.; Sherratt, T.N. (2005): Frequency of female colour morphs in populations of four coenagrionid damselflies (Zygoptera: Coenagrionidae). *Odonatologica* 34(1): 37-49. (in English). ["Knowledge of naturally occurring andromorph and gynomorph frequencies in populations of

coenagrionid damselflies is important for understanding the evolution of female-limited polymorphism. Here are reported the frequencies of andromorphs and gynomorphs in populations of *Coenagrion puella*, *C. mercuriale*, *Xanthocnemis zealandica* and *Ischnura fluviatilis* and a review is presented of the literature for other coenagrionid spp. It is shown that ratios of andromorphs to gynomorphs are often unequal with andromorphs generally being the uncommon morph. Significant inter- and intra-population variation in morph frequency sometimes occurs but is of low magnitude. No evidence was found for spatial segregation of andromorphs and gynomorphs. Andromorph frequency could not be significantly related with sex ratio or male density.] Address: Thompson, D.J., Population Biology Research Group, School of Biological Sciences (Nicholson Building), University of Liverpool, P.O. Box 147, Liverpool, L69 3BX, UK. E-mail: d.j.thompson@liv.ac.uk

6183. Mitchell, A.; Samways, M.J. (2005): The morphological 'forms' of *Palpopleura lucia* (Drury) are separate species as evidenced by DNA sequencing (Anisoptera: Libellulidae). *Odonatologica* 34(2): 173-178. (in English). ["*P. lucia* is a widespread African species with a checkered taxonomic history. Currently 2 'forms' or subspecies, *P.l. lucia* and *P.l. portia* are recognized, although debate over the taxonomic status of these taxa has hardly let up over the last 230 years. The 2 'forms' show distinctive wing pattern differences although other aspects of their morphology are very similar. They can occur highly sympatrically at some localities in southern Africa, as well as elsewhere, thus raising the question of whether they are two species or one perhaps with balanced polymorphism. DNA sequence data from the ITS2 and COI genes were collected from specimens of both these 'forms' to assess more rigorously the taxonomic status of these taxa. The closely related *P. deceptor* (Calvert) and *P. jucunda* (Rambur) were included in the data set to provide a baseline for comparisons. Specimens from all 4 taxa were from pools of the flood plain of the Sabie R., Kruger National Park, South Africa, and were potentially able to interbreed. Both phylogenetic analyses and comparisons of sequence divergence levels strongly support the hypothesis that the 2 'forms' of *P. lucia* are reproductively isolated and should be accorded full species status as *P. lucia* (Drury, 1773) and *P. portia* (Drury, 1773)."] (Authors)] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

Abhandlungen aus dem Westfälischen Museum für Naturkunde 67(3): 163-190. (in German, with English summary). ["Since the end of the 1970s in the Westphalian Bay (in the north of North Rhine-Westphalia, Germany) a lot of ponds had been built or reconstructed mainly for biotope and species protection purposes. In the years between 1989 and 2003 hydrochemistry, flora and vegetation of 14 ponds were examined to estimate biotope development of man made ponds and the efficiency of biotope management measures. Furthermore one or two times amphibians, dragonflies, water beetles, water bugs, mussels and water snails were recorded to get a better idea of biotope qualities. The results clarify, that every pond is an individual habitat with its special species inventory and nature protection importance, which needs individual concepts for management. On the other hand some general guidelines for management and building of ponds as nature protection areas were deduced. The comparison of data of different years makes clear, that eutrophication leads to an acceleration of succession and therefore to decreasing numbers of plant species and species of the red data list. Because of these facts the management of ponds will be a permanent task of nature protection activities." (Authors) A total of 24 odonate species was observed.] Address: Conze, K.-J., Listerstr. 13, D-45147 Essen, Germany. E-mail: Klaus-Juergen.Conze@t-online.de

and the mating of *O. cecilia* are described and discussed.] Address: Rackow, H., Hohenstoffelstraße 73, D-78224 Singen, Germany. E-mail: HartmutRackow@web.de

6194. Relyea, R.A (2005): The heritability of inducible defenses in tadpoles. *J. Evol. Biol.* 18: 856-866. (in English) ["The evolution of plastic traits requires phenotypic trade-offs and heritable traits, yet the latter requirement has received little attention, especially for predator-induced traits. Using a half-sib design, I examined the narrow-sense heritability of predator-induced behavior, morphology, and life history in larval wood frogs (*Rana sylvatica*). Many of the traits had significant additive genetic variation in predator (caged *Anax longipes*) and no-predator environments. Whereas most traits had moderate to high heritability across environments, tail depth exhibited high heritability with predators but low heritability without predators. In addition, several traits had significant heritability for plasticity, suggesting a potential for selection to act on plasticity per se. Genetic correlations confirmed known phenotypic relationships across environments and identified novel relationships within each environment. This appears to be the first investigation of narrow-sense heritabilities for predator-induced traits and confirms that inducible traits previously shown to be under selection also have a genetic basis and should be capable of exhibiting evolutionary responses." - 6200.** Schoeppner, N.A.; Relyea, R.A. (2005): Damage, digestion, and defence: the roles of alarm cues and kairomones for inducing prey defences. *Ecology Letters* 8: 505-512. (in English). ["Inducible defences are widely used for studying phenotypic plasticity, yet frequently we know little about the cues that induce these defences. For aquatic prey, defences are induced by chemical cues from predators (kairomones) and injured prey (alarm cues). Rarely has anyone determined the separate and combined effects of these cues, particularly across phylogenetically diverse prey types. We examined how tadpoles (*Hyla versicolor*) altered their defences when 10 different prey were either crushed by hand or consumed by predators. Across all prey types, crushing induced only a subset of the defences induced by consumption. Consuming vs. crushing produced additive responses for behaviour but synergistic responses for morphology and growth. Moreover, we discovered the first extensive evidence that prey responses to different alarm cues depends on prey phylogeny. These results suggest that the amount of information available to the prey affects both the quantitative and qualitative nature of the defended phenotype." - 6201.** Sipkay, C.S.; Hufnagel, L.; Gaal, M. (2005): Zoocoenological state of microhabitats and its seasonal dynamics in an aquatic macroinvertebrate assembly (Hydrobiological case studies on Lake Balaton No. 1). *Applied ecology and environmental research* 3(2): 107-137. (in English). ["In the years 2002, 2003 and 2004 we collected samples of macroinvertebrates on a total of 36 occasions in Badacsony bay, in areas of open water (in the years 2003 and 2004 reed-grassy) as well as populated by reed (*Phragmites australis*) and cattail (*Typha angustifolia*). Samples were taken using a stiff hand net. The sampling site includes three microhabitats differentiated only by the aquatic plants inhabiting these areas. Our data was gathered from processing 208 individual samples. The quantity of macroinvertebrates is represented by biovolume value based on volume estimates. We can identify taxa in abundant numbers found in all water types and ooze; as well as groups associated with individual microhabitats with various aquatic plants. We can observe a notable difference between the years in the volume of invertebrate macrofauna caused by the drop of water level, and the multiplication of submerged macrophytes. There are smaller differences between the samples taken in reeds and cattail stands. In the second half of 2003 – which was a year of drought – the *Najas marina* appeared in open waters and allowed to support larger quantities of macroinvertebrates. In 2004 with higher water levels, the *Potamogeton perfoliatus* occurring in the same area has had an even more significant effect. This type of reed-grass may support the most macroinvertebrates during the summer. From the aspect of diversity relations we may suspect different characteristics. The reeds sampling site proved to be the richest, while the cattail microhabitat is close behind, open water (with submerged macrophytes) is the least diverse microhabitat." (2005): Possible settlement benefits related to site fidelity for the territorial dragonfly, *Perrithemis tenera* (Say) (Anisoptera: Libellulidae). *Odonatologica* 34(4): 397-405. (in English). ["Site fidelity, the tendency to return to a previously occupied breeding location, is commonly observed in animals and yet often the benefit to such behavior is unclear. In this study, possible settlement benefits to site fidelity for *P. tenera* are examined. Males defend small mating territories on ponds and lakes to which they typically, but not always, return the following day. In an observational study, it was found that males did not become territorial earlier in the day when site-faithful than when switching territories. However, males switching territories were more likely to be seen examining oviposition sites (other than the site they ultimately defended) prior to becoming territorial than site-faithful males. In an experimental study, it was controlled for differences in territory and oviposition site structure, time of day, evictions and disturbance, and found that site-faithful males spent significantly less time settling on a territory prior to defending that territory than males settling at a site for the first time. Because males examining sites are probably more at risk from predators, this study suggests that site-faithful males may experience lowered settlement costs than males returning to their original territory." 6207. Tynkkynen, K. (2005): Interspecific interactions and selection on secondary sexual characters in damselflies. *Jyväskylä Studies in Biological and Environmental Science* 151: 26 pp. (in English). ["Interspecific interactions related to species recognition can cause selection and affect the evolution of secondary sexual characters. Such interactions include for example avoidance of maladaptive hybridization and interspecific aggression. In this thesis, I focus especially on interspecific aggression and on selection which it may cause on sexual characters of the damselfly, *Calopteryx splendens*. Males of *C. splendens* have pigmented wing spot as a sexual character in the middle of their wings. Large-spotted *C. splendens* males resemble another species *Calopteryx virgo*, males of which have almost completely pigmented wings. I observed character displacement in *C. splendens* males such that the wing spot size decreased with increasing relative abundance of *C. virgo*. Territorial *C. virgo* males reacted more aggressively and from greater distance towards large- than small-spotted *C. splendens* males. This suggests that the character displacement may have evolved because of the interspecific aggression arising from mistaken species recognition. Interspecific aggression causes negative survival selection on wing spot size of *C. splendens* males. In addition, interspecific aggression leads to interspecific territoriality in which large-spotted *C. splendens* males seem to have reduced ability to obtain or keep a territory. Reduced territory holding ability may have negative effects on mating success of large-spotted *C. splendens* males. This is because in contrast to other studies with *Calopteryx* species, in wild sympatric populations females did not mate with large-spotted males. My results clearly show that interspecific aggression is able to cause selection on sexual characters and thus has potential to affect the evolution of secondary sexual characters." 6211. Watanabe, M.; Matsuoka, H.; Susa, K.; Taguchi, M. (2005): Thoracic temperature in *Sympetrum infuscatum* (Selys) in relation to habitat and activity (Anisoptera: Libellulidae). *Odonatologica* 34(3): 271-283. (in English). ["The thoracic temperature of adults in a forest-paddy field complex in the cool temperate zone of Japan was measured. After emergence, individuals moved into the forest gaps, where all sexually immature adults remained on perches. Both males and females controlled their thoracic temperatures against a radiant heat load in a similar manner. After maturation, some of the individuals were seen to fly in tandem over the rice paddy fields under direct sunlight for oviposition. This study evaluated the impact of the thermal environment on the perching behaviour in the forest gaps and flying behaviour in tandem in the rice paddy fields. Mean thoracic temperatures of adults were consistently higher than ambient temperatures. The difference between the high thoracic and low ambient temperature was lower among flying individuals in the rice paddy fields than in perching individuals living in the forest gaps. The control of thoracic temperature in response to ambient and radiant temperature in perching mature adults was similar to that in immature adults. In the rice paddy fields, the flying in tandem resulted in a smaller difference

rence between thoracic over radiation temperature in females than in males in tandem. The high degree of thermoregulation clearly allowed mature adults to be active under direct sunlight. The role of perching in the forest gaps is discussed with regard to thermoregulation." (2006): Diversity, abundance, and disturbance response of Odonata associated with breeding sites of *Anopheles pseudopunctipennis* (Diptera: Culicidae) in southern Mexico. *Environmental Entomology* 35 (6): 1561-1568. (in English). ["Odonate nymphs are important predators of the immature aquatic stages of mosquitoes. Populations of the malaria vector *Anopheles pseudopunctipennis* Theobald (Diptera: Culicidae) can be efficiently reduced by extraction of filamentous algae from river pools in southern Mexico. Here, we examined the influence of this intervention on the diversity of odonates associated with mosquito breeding pools after annual extractions of algae from river pools in a 3-km section of the Coatán River, over a period of 2 yr. Odonate sampling was performed at monthly intervals in control and treated sections of the river for 4-5 mo after extraction in both years and before extraction in 1 yr. In total, 16 species, 10 genera, and 6 families of odonates were collected. Shannon diversity index values declined significantly during a period of 1 mo in 2001 and >5 mo in 2002. However, the abundance of odonates captured was not affected by algal extraction. In contrast, year-to-year variation in the diversity and abundance of the odonate community was strongly influenced by precipitation and river volume. Despite the importance of algae in river ecology, we conclude that the mosquito control intervention resulted in minimal impact on the odonate community in southern Mexico." 6222. Buczyńska, E.; Buczyński, P. (2006): Aquatic insects (Odonata, Coleoptera, Trichoptera) of the central part of the "Krowie Bagno" marsh: the state before restoration. *Annales Universitatis Mariae Curie-Skłodowska Lublin - Polonia LXI, 2 Sectio C*: 71-88. (in English, with Polish summary). ["In 2003 the assemblages

of selected aquatic insects (dragonflies, beetles, caddisflies) were studied within two lakes surrounded by a transitional peat bog» and a canal and ditches situated in the meliorated fen» The influence of melioration and peat bog degradation on entomofauna, its present status and the role of "Krowie Bagno" as a refugium of special care species were analysed. Thirty-seven dragonfly species, 75 beetle species, 21 caddisfly species were found. 12 special care and 8 indicator species were recorded. The fauna of lakes was typical of polyhumic ones, however, the changes associated with drying out and early stage of eutrophication were clearly seen in case of caddisfly assemblages. Melioration ditches turned out to be a refuge for the species connected with completely vanished at the study area sedge bogs. Deep and rich in vegetation canal was the main habitat for lacustrine caddisfly species. Such fauna is the result of natural water recession» transformation of the remaining ones as well as creating anthropogenic waters. "Krowie Bagno" is still the refuge of many valuable species and assemblages typical of dystrophic waters. Nevertheless, they are still endangered, some of them are partially on the wane. The aim of the «naturalization activities like free cutting, raising the level of irrpoundage conducted after 2003 is to prevent the fauna, In several years, the next planned inventory of entomofauna will discover whether such activities improve ecological relationships of the studied area or not." In addition, *Liogomphus yixianensis* Ren et Gao, 1996 is described in detail. All the insect fossils are collected from the lower part of the Yixian Formation (uppermost Jurassic" lower Cretaceous) in Huangbanjigou of Beipiao, western Liaoning, China.] Address: Chang, J.-p., College of Earth Sciences, Jilin University, Changchun 130061, Jilin, China

6228. Clausnitzer, V. (2006): Dragonflies (Odonata) of Rufiji district, Tanzania with new records for Tanzania. *Journal of East African Natural History* 95(2): 139-162. (in English) ["The dragonfly fauna of the Rufiji District was studied during several field trips in 2001–2003 covering the rainy and the dry season. A total of 73 species was recorded by capture with net and visual identification of imagos. *Ceriagrion mourae* was seen for the first time since its description from Mozambique in 1969. *Ceriagrion mourae*, *Teinobasis alluaudi*, *Gynacantha immaculifrons*, *Paragomphus magnus* and *Paragomphus sabcicus* are first records for Tanzania. *Coryphagrion grandis*, *Ceriagrion mourae*, *Teinobasis alluaudi* and *Hadrothemis scabrifrons* are globally endangered habitat specialists confined to coastal forests of Eastern Africa. The majority of the species are common and widespread and inhabits the Rufiji River and its floodplains, while a smaller proportion are only found in permanent streams draining into the Rufiji or in forest habitats. The high overall species richness is a result of the variety of habitats and their connectivity, combined with the dynamics of the floods. The habitat specialists found in Ngumburuni forest and in the forests of the Kichi and Kiwengoma Hills are globally endangered species and require special attention with regard to conservation." (Author)] Address: Clausnitzer, Viola, Graefestr. 17, D-06110 Halle/Saale, Germany. E-mail: violacl@t-online.de

6229. Corbet, P.S. (2006): Forests as habitats for dragonflies (Odonata). In: Rivera, AC (Ed). 2006. Forests and Dragonflies. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. Pensoft Series Faunistica 61: 13-36. (in English). ["The ways in which forests can be inferred, or shown, to meet the habitat requirements of dragonflies are reviewed globally. The relationship between dragonflies and forests is examined along a latitude spectrum in the Northern Hemisphere, from the Arctic Circle to the equator, a tran-

sect along which species diversity progressively increases, and the microclimate within forest becomes steadily more permissive for occupancy by the several stages in the dragonfly life history. In mid-temperate latitudes dragonflies use forests mainly for aestivation as pre-reproductive adults, a strategy functionally similar to the siccation exhibited by tropical dragonflies in seasonal-rainfall regions. Tropical rainforest is the planet's most diverse terrestrial ecosystem, with regard to species and habitats. It provides habitats for many species of dragonflies, for some or all of their life- history stages. Many such species, and their behaviour and ecology, remain undescribed. For biologists, including odonatologists, the foremost challenge of our time is that this irreplaceable storehouse of biological information faces imminent threat of destruction before its contents can be placed on record." 6231. Dijkstra, K.D.; Clausnitzer, V. (2006): Thoughts from Africa: how can forest influence species composition, diversity and speciation in tropical Odonata?. Forests and Dragonflies. Fourth WDA International Symposium of Odonatology, Pontevedra (Spain), July 2005: 127-151. (in English). ["We introduce tropical African forests and their Odonata, and speculate how climatic oscillations and associated large-scale habitat shifts may have governed speciation across the forest-savanna ecotone, presenting several hypothetical scenarios. Ecological traits of forest species and possible reasons for their disappearance when forest is opened up are

discussed. We believe that low insolation in forest habitats and interspecific competition are key factors segregating forest and non-forest species. While openland species cannot cope with low insolation inside the forest, forest species have evolved a slow lifestyle to cope with the forest environment, but are out-competed by more aggressive non-forest species beyond forest borders. Casual field observations support this hypothesis, although the reality is likely to be more complex. Phylogenetic reconstruction of groups that straddle the habitat divide, linked to ecological observations, may elucidate evolutionary reactions to landscape change. The reaction of odonate assemblages to forest loss is studied easily in Africa's imperilled forests. Because many of these forests are believed to be relatively young and highly forest-adapted species may have very low dispersal capacities, comparative ecological research of 'forest-dependent' odonate assemblages inside and outside ancient forest refugia is recommended." 6235. Faucheux, M.J. (2006): Les organes sensoriels des antennes larvaires de Libellules: les propriocepteurs et les vibrorécepteurs d'*Erythromma lindenii* (Sélys, 1840) (Odonata Zygoptera: Coenagrionidae). *Bull. Soc. Sc. Nat. Ouest de la France, nouvelle série* 28(3): 153-159. (in French, with English summary). ["The larval antennae of *E. lindenii* are short and made up of a scape, a pedicel and a fourth-segmented flagellum. They bear four types of aporous and exclusively

mechanoreceptive sensilla: spatula-shaped sensilla chaetica, curved sensilla chaetica, sensilla filiformia and sensilla campaniformia. The curved sensilla chaetica are proprioceptors which monitor the relative position of the 3rd and 4th flagellomeres. Sensilla filiformia are vibration receptors which play the major role in prey detection. The unique sensillum campaniformium on the pedicel is a proprioceptor which informs the larva of the position of the flagellum relative to the pedicel. Spatula-shaped sensilla chaetica are tactile receptors distributed on the scape and the pedicel. No chemoreceptive sensilla has been observed on the antennae." (Author) Address: Faucheux, M.J., Laboratoire d'Endocrinologie des Insectes Sociaux, Université de Nantes, 2 rue de la Houssinière, B.P. 92208, F-44322 Nantes Cedex 03, France. Nat. Ouest de la France, nouvelle série* 28(3): 160-167. (in French, with English summary). ["The larval antenna of *C. viridis* is made up of a scape, a pedicel and a flagellum comprising 5 segments. It bears two types of aporous sensilla: the sensilla filiformia and the curved sensilla chaetica. The sensilla filiformia appear with the scape; they are numerous on the two surfaces of the pedicel and the 5 flagellomeres. These mechanoreceptive sensilla, of different lengths, react to the slightest vibrations produced in the water by the appearance of prey; they are vibrorécepteurs. It is the second time that the curved sensilla chaetica, whose role is proprioceptive, are observed in the zygopteran larvae, these sensilla being unknown in other insects, whether larvae or adults. In *C. viridis*, they are located on the distal parts of flagellomères 1,2,3 and 4, and they record the relative position of the flagellomere with regard to one another. A comparison is carried out with the larval sensory equipment of *Erythromma lindenii* which has been previously studied." 6240. Fincke, O.M. (2006): Use of forest and tree species, and dispersal by giant damselflies (*Pseudostigmatia*): future prospects in fragmented forests. In: Rivera, AC (ED). 2006. *Forests and Dragonflies*. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. *Pensoft Series Faunistica* 61: 103-125. (in English). ["Phytotelmata, or water-filled plant containers, provide an important aquatic habitat in tropical forests typically depauperate of permanent ponds and lakes. As top predators in these microhabitats, species of *Pseudostigmatidae* offer a rare opportunity to measure the effects of forest plant species on the abundance and distribution of their aquatic occupants. Like the specialists of bromeliads, which depend on the presence of a small group of epiphytic plants, odonates ovipositing in water-filled tree holes and fruit husks require a non-random assortment of tree sizes and species. The size and density of microhabitats ultimately affect larval abundance, although, for most species, it remains unclear how closely adult recruitment tracks larval survivorship. Within its geographic range, *Megaloprepus* relies more heavily on primary forests than do species of *Mecistogaster* that are adapted to dryer conditions and hence are more tolerant of secondary and highly disturbed forests. An experiment with *Megaloprepus* revealed that it exhibited relatively low flight endurance, particularly in females, which rarely dispersed across open areas. Recent comparative work challenges the status of *Megaloprepus* as a monospecific genus, and suggests that many *pseudostigmatid* populations may be highly structured genetically. The larval ecology and adult behavior of *Megaloprepus* suggest that its populations should be more highly structured than those of the more vagile tree-hole aeshnids. Collectively, the data reviewed here suggest that forest fragmentation, exacerbated by less predictable threats from global warming, may pose a greater threat to *Megaloprepus* and similar species such as *Microstigma rotundatum*, than to species of *Mecistogaster*. The fate of all *pseudostigmatids* is intimately tied to that of the plant species harboring them. As predators of phytotelm mosquito larvae, some of which are disease vectors, the demise of pseudo-

stigmatids may affect not only forest food chains, but also human health." (Author)] Address: Fincke, O.M., Dept Zool., Univ. Oklahoma, 730 Van Vleet Oval, Room 314, Norman, OK 73019, USA. E-mail: fincke@ou.edu

["*Mnais costalis* males exist in 2 forms specialised for the demands of 2 distinct strategies, territorial fighters and non-territorial sneaks, which give approxi-

mately equal fitness payoffs. Territorial males have orange wings, whereas typical non-territorial males are clear-winged. By simulating agonistic encounters between males it is shown that the 2 morphs showed distinct responses to the signal from orange wings: territorial orange-winged males always tried to enter contests, while clear-winged males always avoided them. On the other hand, the 2 morphs showed similar responses to the signal from clear wings: both morphs tried to attack models. Also presented are 'painted clear models' which were clear-winged males whose wings had been painted orange, and both morphs responded as if they were orange-winged models. These observations indicate that males discriminate between fighter and sneaker morphs using the colour of wings, and shows different styles of agonistic responses toward fighter and sneaker morphs. It is likely that non-territorial sneaks may gain an advantage from non-signalling because clear wings increase crypsis on another male territory, increasing their success in stealing copulations. No indication was found that clear-winged males are female mimics, or that having clear wings reduced the level of aggression directed towards them by territorial orange-winged males.] Address: Tsubaki, Y., Biodiversity Conservation Research Group, National Institute for Environmental Studies, Tsukuba 305-0053, Japan. Biol. Sci., Belgrade* 58 (2): 115-119. (in English). ["Results of investigating the community of aquatic invertebrates in the Ribnica and Lepenica Rivers (Kolubara River drainage area) are given in the present work. Forty-three taxa are recorded. In relation to other studied streams in Serbia, the investigated rivers are characterized by high diversity of macroinvertebrates. Cluster analysis indicates that the locality on the Lepenica stands apart from those on the Ribnica, which is a consequence of the difference of habitats found at them. Results of saprobiological analysis of the macrozoobenthos in the given rivers indicate that their waters belong to quality classes I and II." (Authors) Three odonate taxa are listed: *Gomphus vulgatisimus*, *Calopteryx virgo*, and *Calopteryx* sp.] Address: Jovic, A., Siniša Stankovic Institute for Biological Research, 11060 Belgrade, Serbia and Montenegro

6251. Knijf, G. de (2006): Libellen in België. Nieuwe kennis voor een beter beheer van hun leefgebieden. *Natuur.focus* 5(4): 129-134. (in Dutch). ["In this contribution we report on some results of the recently published book on Belgian Odonata, which is based on >65.000 observations. After setting the historical context, we first present some general results for the 69 Belgian species, e.g. the overall coverage and some changes in species composition. Especially the strong increase in several southern species is striking. The Campine region is the area with the highest species density and the only region in Flanders where nearly all Red List species occur. This list contains 17 species (or 26%) which fit into the categories 'endangered by extinction', 'endangered', and 'vulnerable'. Most Red list species live either in moderately base-rich or meso-eutrophic waters and in poor or oligotrophic fens. In a next part we give some recommendations for a better proper management of aquatic habitats. Finally we stress on the urgent necessity to start with a monitoring scheme for dragonflies in Flanders." These are also the highest known occurrences in Baden-Württemberg, Germany." (Authors)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

6253. Kosterin, O.E.; Vikhrev, N.E. (2006): Odonata seen for three days in a populated lowland part of Cambodia. *Malangpo* 21: 212-217. (in English). ["A report about Odonata met during three day long trips to the Siem Reap area of Cambodia on January 7-9, 2006 is given in a form of field notes. 24 species were met with, of which *Heliocypha biforata* (Selys, 1859), *Lestes concinnus* Hagen in Selys, 1862, *Aciagrion borneense* Ris, 1911, *Agriocnemis minima* Selys, 1877, *A. nana* (Laidlaw, 1914), *Ceriagrion praetermissum* Lieftink, 1929, *Diplacodes trivialis* (Rambur, 1842), *Brachydiplax chalybea* Brauer, 1868, *Brachythemis contaminata* (Fabricius, 1793), *Crocothemis servilia* (Drury, 1770), *Neurothemis tullia* (Drury, 1773), *Rhodothemis rufa* (Rambur, 1842) have not been reported for Cambodia in literature (although the published records are very scarce per se)."] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. E-mail: kosterin@bionet.nsc.ru

6254. Kriska, G.; Csabai, Z.; Boda, P.; Malik, P.; Horvath, G. (2006): Why do red and dark-coloured cars lure aquatic insects? The attraction of water insects to car paintwork explained by reflection-polarization signals. *Proc. R. Soc. B* (2006) 273: 1667-1671. (in English). ["We reveal here the visual ecological reasons for the phenomenon that aquatic insects often land on red, black and dark-coloured cars. Monitoring the numbers of aquatic beetles and bugs attracted to shiny black, white, red and yellow horizontal plastic sheets, we found that red and black reflectors are equally highly attractive to water insects, while yellow and white reflectors are unattractive. The reflection-polarization patterns of black, white, red and yellow cars were measured in the red, green and blue parts of the spectrum. In the blue and green, the degree of linear polarization p of light reflected from red and black cars is high and the direction of polarization of light reflected from red and black car roofs, bonnets and boots is nearly horizontal. Thus, the horizontal surfaces of red and black cars are highly attractive to redblind polarotactic water insects. The p of light reflected from the horizontal surfaces of yellow and white cars is low and its direction of polarization is usually not horizontal. Consequently, yellow and white cars are unattractive to polarotactic water insects. The visual deception of aquatic insects by cars can be explained solely by the reflection-polarizational characteristics of the car paintwork." (Authors) The paper includes references to Odonata.] Address: Horvath, G., Biooptics Laboratory, Department of Biological Physics, Loránd Eötvös University, 1117 Budapest, Pázmány Péter sétány 1, Hungary. E-mail: gh@arago.elte.hu

6255. Leroy, T. (2006): *Coenagrion lunulatum* (Charpentier, 1825) en France: répartition, abondance, élé-

ments d'écologie et de conservation (Odonata, Zygoptera, Coenagrionidae). *Martinia* 22(4): 151-166. (in French, with English summary). ["Based on a bibliographical analysis and field work realized between 2000 and 2005, this article describes what we know about *C. lunulatum* in France. This mountaneous, shy and rare species is mostly present in Auvergne region, with a short and precocious flight period. The conservation state of these populations, which are of European importance, seems reasonable, although this is a very fragile species and a number of threats remain." (Author)] Address: Leroy, T., Le Bourg, F-63210 Heumeil-Eglise, France. E-mail: thierry-leroy@caramail.com

6256. Levasseur, M. (2006): Découverte d'un *Paragomphus* sp. sur l'île d'Anjouan Archipel des Comores (Odonata, Anisoptera, Gomphidae). *Martinia* 22(4): 183-186. (in French, with English summary). ["During a short consulting mission on behalf of the Comorian government (form. Islamic Federal Republic, now Comorian Union), the author had the opportunity to prospect several communal water intakes. One of them located at a small dam on a "mro" (little stream) in Anjouan, supported 3 exuviae, 2 of them being immediately attributable to gomphids. After bibliographical search and inquiry to dragonfly specialists of the region, it appears that these exuviae belong to a *Paragomphus* sp. and are the first data concerning gomphids in the Comorian archipelago. To date, these exuviae are still not identified and could be those of a new species for science." (Author)] Address: Levasseur, M., 11 rue du Pont Colbert, F-78000 Versailles, France. E-mail: levasseur@magic.fr

6257. Lingenfelder, U. (2006): Beobachtung der Arktischen Smaragdlibelle - *Somatochlora arctica* (ZETTERSTEDT, 1840) - im südlichen Pfälzerwald (Odonata: Corduliidae). *Fauna Flora Rheinland-Pfalz* 10(4): 1211-1218. (in German, with English summary). ["In 2003, *S. arctica* has been recorded in the southern part of the Palatinate Forest for the first time. Two males of the species could be observed at a valleycomplex southwest of Eppenbrunn near the border to France. The observation is described and locality and date of the observation are briefly discussed." (Author)] Address: Lingenfelder, U., Seebergstraße 1, D-67716 Heltersberg, Germany. E-mail: u.lingenfelder@vr-web.de

6258. Lingenfelder, U. (2006): Nachweise des Zweifelflecks - *Epiptera bimaculata* (CHARPENTIER, 1825) - im Pfälzerwald (Odonata: Corduliidae). *Fauna Flora Rheinland-Pfalz* 10(4): 1219-1247. (in German, with English summary). ["*E. bimaculata* [...] has been recorded at six localities in the Palatinate Forest since 2001. Reproduction evidences were provided at two waters. At one of these localities *E. bimaculata* is established for at least six years. Additional observations of the species in the Palatinate were reported recently from the natural areas „Nördliche Oberrheinebene“ and „Kaiserslauterner Senke“. All known recordings in Rhineland-Palatinate are compiled, findings in the Palatinate region are shown in a distribution map. A short survey of the distribution of the species in adjoining regions is also given here. In conclusion, habitats, distribution and status in the Palatinate Forest are discussed shortly as well as problems in recording the species, of dispersal and threats." (Author)] Address: Lingenfelder, U., Seebergstraße 1, D-67716 Heltersberg, Germany. E-mail: u.lingenfelder@vr-web.de

(in English). ["The larval antennae of *E. lindenii* are short and made up of a scape, a pedicel and a fourth-segmented flagellum. They bear four types of aporous and exclusively mechanoreceptive sensilla: spatula-shaped sensilla chaetica, curved sensilla chaetica, sensilla filiformia and sensilla campaniformia. The curved sensilla chaetica are proprioceptors which monitor the relative position of the 3rd and 4th flagellomeres. Sensilla filiformia are vibration receptors which play the major role in prey detection. The unique sensillum campaniformium on the pedicel is a proprioceptor which informs the larva of the position of the flagellum relative to the pedicel. Spatula-shaped sensilla chaetica are tactile receptors distributed on the scape and the pedicel. No chemoreceptive sensilla has been observed on the antennae." ry St. Edmunds, Suffolk IP29 5BX, UK. E-mail: Adrian.parr@bbsrc.ac.uk

6273. Parr, A.J. (2006): Migrant and dispersive dragonflies in Britain during 2005. J. Br. Dragonfly Society 22(1): 13-18. (in English). ["The 2005 season was a rather mixed one for migrant and dispersive dragonflies, with the autumn in particular being relatively uneventful. There were, however, several highlights during the main part of the year. Most notably, *Anax parthenope* appeared in record numbers and, with ovipositing reported from at least three sites in England (as well as one in Ireland), the species is perhaps now starting to reliably colonize our area. Following a quiet season in 2004, *Sympetrum fonscolombii* was once again recorded quite widely and a limited amount of oviposition was observed, although no observations of the autumn emergence of locally-bred individuals following rapid larval development took place. In addition to sightings of unusual species, there was also evidence of the continuing range expansion of a number of our resident species such as *Aeshna mixta*, *Libellula depressa*, *L. fulva*, and *Orthetrum cancellatum*. On the negative side, following sightings during 2002—2004, there were no reports of the *Lestes barbarus* during the season, suggesting that the possible colonization of Britain by this species has been temporarily halted." (Author)] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK. E-mail: Adrian.parr@bbsrc.ac.uk

6274. Perotti, M.G.; Fitzgerald, L.A.; Moreno, L.; Puenta, M. (2006): Behavioral responses of *Bufo arenarum* tadpoles to odonate naiad predation. Herpetological Conservation and Biology 1(2): 117-120. (in English). ["In the presence of predators (*Pantala* sp.), anuran tadpoles often exhibit behavioral plasticity, which in turn reduces predation risk. We evaluated indirect effects of odonate larva predation on activity of *Bufo arenarum* tadpoles. We reared intact and tail-damaged larvae in three different predator treatments: (1) caged predators fed tadpoles; (2) caged predators that were starved; and (3) no predators. Both intact and damaged tadpoles were significantly less active when exposed to predator cues. There were no differences in activity between tadpoles with damaged and intact tails, however significant differences were observed between fed and starved predator treatments. Our results are consistent with other studies that have shown bufonid tadpoles reduce activity when exposed to predator cues and Address a novel contribution of southern-hemisphere bufonid, expanding the knowledge of that family in ecological experiments." Qual. 35: 61-67. (in English). ["Increasing development of historic farmlands raises questions regarding the fate of pesticides applied when these land were in cultivation. We quantified As and Pb budgets in field soils in two orchards where arsenical pesticides were applied in the early 20th century and a third uncontaminated control field. Sequential extractions and X-ray analyses also were used to determine mineral phases. In addition, we measured metal loads in drainages adjacent to the fields and in two common macroinvertebrate (Chironomidae, Libellulidae) taxa within the wetland at the outlet of the drainages. We find that the applied As and Pb have undergone little vertical redistribution; concentrations of As and Pb in the top 25 cm of contaminated orchard soils are higher than in the uncontaminated control field. However, none of the applied lead arsenate (PbHAsO₄) remains in its original mineral phase. Instead, the metals are now primarily adsorbed onto fine silt and clay-sized amorphous oxides and organic matter. Further, physical erosion associated with tilling and replanting appears to have mobilized the fine-particulate-bound As and Pb in one orchard. The remobilized metals are found in sediments in the stream channel draining the tilled orchard. It is unclear if the As and Pb transported sediments are biologically active; average macroinvertebrate metal burdens in the wetland are not elevated above those observed elsewhere in the region. However, little of the mobilized metals may have reached the wetland. These results demonstrate that land use change can significantly impact the retention of arsenical pesticides." - 6279.** Robb, T.; van Gossum, H.; Forbes, M.R. (2006): Colour variation in female *Lestes disjunctus* Selys: a second example of a polymorphic lestad (Zygoptera: Lestidae). Odonatologica 35(1): 31-39. (in English) ["Coexistence of discrete female colour morphs is a common characteristic of many odon. species. Surveys have found that for some North American and European genera, half or more of the spp. show female-limited polymorphism, while in other genera, female polymorphism appears far less common among spp. One such genus is *Lestes* with reportedly only one species (*L. sponsa*) being polymorphic. Here are described andromorphs and heteromorphs for *L. disjunctus*. Female-limited polymorphism might be more common, even in this genus, than is perceived currently. female morph frequencies were estimated for 4 consecutive years: andromorphs constitute approximately 16% of mature females sampled and this proportion is fairly consistent between years. Similar to other published reports on other species, andromorphs and heteromorphs in this study population did not differ in wing length or mass. Seasonal patterns in representation of different morphs suggest that further research should be done on timing of emergence of andromorphs versus heteromorphs in this and perhaps other species." - 6284.** Saito, Y.; Owada, M.; Kato, S.; Inoue, S. (2006): Monitoring Survey (2001-2005) of Dragonflies (Odonata) of the Imperial Palace, Tokyo, Central Japan. *Memoirs of the National Science Museum* 43: 383-406. (in Japanese, with English summary). ["Monitoring investigations on the fauna of Odonata were made at the gardens of the Imperial Palace, Tokyo, ca. 115 ha, central Tokyo, from 2001 to 2005. A total of 33 species belonging to 8 families were recorded. Similar research were carried out at the same place from 1996 to 2000, and 27 species in 8 families were recorded (Tomokuni & Saito, 2000). The following six species are recorded from the Imperial Place for the first time: *Aeschnophlebia anisoptera* Selys, *Polycanthagyna melanictera* (Selys), *Anaciaeschna martini* (Selys) (Fig. 30) and *Anax nigrofasdatus nigrofasciatus* Oguma (Fig. 31), *Libellula quadrimaculata asahinai* Schmidt (Fig. 35) and *Sympetrum kunckeli* (Selys). Three endangered species in Tokyo urban areas, *Ceriagrion nipponicum* Asahina (Figs. 9-10), *Trigomphus melampus* (Selys) (Figs. 19-21) and *Aeschnophlebia longistigma* Selys (Figs. 27-29) were discovered by the former study (Tomokuni & Saito, 2000), and they are still abundant in the Palace. *Rhyothemis fuliginosa* Selys (Fig. 41), which had also been very scarce in the urban Tokyo, was gradually increase its number from 2002-2004, and we were able to observe its outbreak in the summer of 2005." - 6288.** Stoks, R.; McPeck, M.A. (2006): A tale of two diversifications: Reciprocal habitat shifts to fill ecological space along the pond permanence gradient. *The American Naturalist* 168: 50-72. (in English). ["The *Enallagma* and *Lestes* damselflies have both diversified and adapted over the past 1015 million years to the various ecological milieus found along the pond permanence gradient among North American ponds and lakes. Previous articles have explored this diversification process for *Enallagma*. In this article, we present a phylogenetic hypothesis for the North American *Lestes*, use this hypothesis to reconstruct *Lestes* diversification, and compare the diversification processes inferred for *Lestes* and *Enallagma*. The results of this study suggest that *Lestes* began in temporary ponds where large dragonflies are the top predators, while *Enallagma* began in permanent lakes where fish are the top predators. Starting from these different ancestral habitats, both genera have invaded and adapted to habitats already occupied by the other genus. Moreover, these adaptive habitat shifts involved substantial convergence on the behaviors used to deal with fish and dragonfly predation in both genera and a major life-history shift from diapausing to directly developing eggs in *Lestes*. However, in *Lestes* lineages invading fish lakes, swimming speed and morphology did not change to match those of *Enallagma* species, illustrating that reciprocal shifts between alternative selection regimes are not necessarily evolutionary opposites. Also, the greater sizes and growth rates of *Lestes* species compared to *Enallagma* species, which should impart substantial ecological advantages in competition between the genera, were shown to result from phylogenetic inheritance and not from adaptive diversification. This historical analysis of diversification raises new questions about the relationship between the macroevolutionary mechanisms driving lineage diversification and the ecological mechanisms structuring local food webs and regional species assemblages." - 6289.** Takahara, T.; Kohmatsu, Y.; Maruyama, A.; Yamaoka, R. (2006): Specific behavioral responses of *Hyla japonica* tadpoles to chemical cues released by two predator species. *Current Herpetology* 25(2): 65-70. (in English). ["We experimentally examined the anti-predator behaviors of tadpoles of the Japanese tree frog, *Hyla japonica*, to chemical cues released by a cyprinid fish, *Gnathopogon elongatus elongatus*, and a dragonfly nymph, *Anax parthenope julius*. Tadpoles exposed to these chemical cues exhibited a similar reduction in activity level. In the presence of the fish chemical cues, however, the tadpoles spent more time in the bottom water layer compared to controls, but did not change their microhabitat choice in the presence of dragonfly nymph chemical cues. These findings suggest that tadpoles of *H. japonica* have predator-specific behaviors in response to chemical cues from different predators with differential foraging strategies." (Authors)]

6290. Takemon, Y.; Yamamoto, A.; Nakashima, M.; Tanida, K.; Kishi, M.; Kato, M. (2006): Isolation of sperm vesicles from adult male mayflies and other insects to prepare high molecular weight genomic DNA samples. *Molecular Biology Reports*, Volume 33, Number 1: 65-70. (in English). ["We describe here a simple and efficient protocol for genomic DNA isolation from adult males of insects: e.g., Ephemeroptera, Odonata, Orthoptera and Dictyoptera. To minimize contamination of external DNA source, the sperm vesicles were isolated from male individuals from which high molecular weight genomic DNA was extracted. According to this protocol, the genomic DNA samples obtained were high quality (intact), and abundant enough for genotyping analyses and molecular cloning. The protocol reported here enables us to process a huge number of individuals at a time with escaping from cross-contamination, and thus it is quite useful for conducting genetic studies at least in some species of insects. The large yield of high molecular weight DNA from single individual may be advantageous for non PCR-based experiments. As a case study of the protocol, partial coding sequences of histone H3 and EF-1a genes are determined for some insects with PCR-amplified DNA fragments." 6292. Thorne, A.D.; Pexton, J.J.; Dytham, C.; Mayhew, P.J. (2006): Small body size in an insect shifts development, prior to adult eclosion, towards early reproduction. *Proc. R. Soc. B* 273: 1099-1103. (in English). ["Life-history theory has suggested that individual body size can strongly affect the allocation of resources to reproduction and away from other traits such as survival. In many insects, adults eclose with a proportion of their potential lifetime egg production that is already mature (the ovigeny index). We establish for the solitary parasitoid wasp *Aphaereta genevensis* that the ovigeny index decreases with adult body size, despite both initial egg load and potential lifetime fecundity increasing with body size. This outcome is predicted by adaptive models and is the first unequivocal intraspecific demonstration. Evidence suggests that a high ovigeny index carries a cost of reduced longevity in insects. Our results therefore contribute to the emerging evidence that small body size can favour a developmental shift in

juveniles that favours early reproduction, but which has adverse late-life consequences. These findings are likely to have important implications for developmental biologists and population biologists." 6293. Tsubaki, Y.; Tsuji, N. (2006): Dragonfly habitat maps based on landcover and habitat relation models. In: Rivera, AC (ED). 2006. *Forests and Dragonflies*. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. *Pensoft Series Faunistica* 61: (in English). ["We constructed dragonfly distributional models (logistic regression models) based on occurrence records collected in the national recording scheme of Japan. Such occurrence records have several shortcomings in that they only record what is present and not what is absent, and sampling efforts are highly variable among recording grid-squares (about 10x10 km). Moreover, the accuracy of logistic regression models is strongly influenced by the presence/absence prevalence. We developed two data screening methods to select 'reliable' species presence/absence data sets from presence-only species assemblage records: exclusion of grid-squares without enough survey efforts, and exclusion of grid-squares out of temperature range in each species. Then we tried to find out landcover-occurrence relationships within the temperature range based on logistic regression models. We obtained statistically significant models for 98 species among all dragonflies inhabiting the main four islands of Japan (128 species). Goodness-of-fit tests showed that some landcover types significantly affected the occurrence of each species. Area of broad-leaved forests within a grid-square (10x10 km) had positive effects on the occurrence of 57 species, indicating that at least 50% of dragonflies depend on forests. Our analysis also showed that landcover heterogeneity (Shannon-Wiener's H') had positive effects on the occurrence of most species (73 among 98 species). We showed three examples of habitat maps generated by the logistic model together with actual occurrence records. We discussed how the model performance might change in relevance to the data screenings we applied." 6295. Van Swaay, C.A.M., Groenendijk, D. & Plate, C. (2006): Vlinders en libellen geteld. Jaarverslag 2005. Rapport VS2006.020, De Vlinderstichting, Wageningen.: 31 pp. (in Dutch). [Monitoring butterflies and dragonflies in the Netherlands in 2005 De Vlinderstichting (Dutch Butterfly Conservation) and CBS (Statistics Netherlands) coordinate the monitoring schemes for butterflies and dragonflies in the Netherlands. The butterfly scheme started in 1990, the dragonfly scheme in 1997. Method: Butterflies and dragonflies are counted using a line-transect method. Butterfly transects are visited every week, dragonfly transects once every fortnight. The length of the transects is variable and depends on habitat quality and availability. In addition, single species transects are exclusively counted for a specific threatened butterfly or dragonfly. Indices were calculated using the computer program TRIM (Trends and Indices for Monitoring Schemes). This program was developed by CBS for the analysis of time series of counts with missing observations. The butterfly indices are calculated using a weighting procedure and 1992 is now used as the first year in the trend calculation and set to a reference value of 100. The dragonfly indices are not weighted yet and 1999 is used as the first year in the trend calculation and, therefore, set to a reference value of 100. Results of 2005: [...] Again, also in 2005 dragonflies were counted every fortnight between May and September at 328 sites (figure 5). The average number of dragonflies per transect was a bit higher than in most previous years (table 2; figure 10). Like in most other years *Enallagma cyathigerum* was the most common species (over 70,000 individuals). *Ischnura elegans*, with nearly 20,000 individuals, was the most widespread species. It was seen on about 90% of the plots (table 2). For some species indices are presented (chapter 8). Again, an alarming decreasing trend was detected for *Aeshna viridis* and *Coenagrion hastulatum*. Another Red List species, *Calopteryx virgo*, still shows a positive trend. Scientific names and the Dutch vernacular names for all dragonfly species are given in chapter 10." 6297. Ward, L.; Mill, P.J. (2006): Diel activity patterns in the adult Banded Demoiselle, *Calopteryx splendens* (Harris), and the effect of weather variables. *J. Br. Dragonfly Society* 22(2): 58-63. (in English). ["Diel activity patterns of the territorial zygopteran *C. splendens* were studied in a well-established breeding population on the River Wharfe in northeast England. The effect of weather on the activity of the species was investigated. A bimodal activity curve was observed in both males and females, albeit rather more pronounced in the males. Male activity was largely influenced by reproductive behaviour, more specifically territory selection and defence, with short feeding flights within the immediate vicinity of the perch. Conversely, the activity patterns of the females incorporated more defined periods of foraging activity, quite distinct from periods of reproductive activity. The activity of the species significantly increased with increase in ambient air temperature and solar energy, whereas a significant negative relationship was found between the number of *C. splendens* in flight and increase in cloud cover, rainfall and wind speed. The observed activity patterns are discussed with reference to maximum profitability of specific activities, the physical condition of an individual and the recorded weather variables. There are implications for the long-term reproductive success of individuals where weather conditions suppress activity." (Authors)] Address: Mill, P.J., Fac. Biol. Sciences, University of Leeds, Leeds, West Yorkshire LS2 9JT, UK. E-mail: p.j.mill@leeds.ac.uk

6301. Yanoviak, S.P.; Lounibos, L.P., Weaver, S.C. (2006): Land use affects macroinvertebrate community composition in phytotelmata in the Peruvian Amazon. 1172: 1181. (in English, with Spanish summary). ["Patches of forest in the western Amazon often are converted to small-scale subsistence plantations (chacras), which become early successional forest (purma) when abandoned. Differences in abiotic conditions and phytotelm characteristics among chacras, purmas, and adjacent forest likely influence the distribution of phytotelm colonists. We sampled the contents of natural water-filled tree holes in the three habitat types and quantified differences in the abundance, species richness and composition of their macroinvertebrate communities. We additionally placed experimental tree-hole analogs (water-filled bamboo [*Guadua* sp.] internodes) in each of the habitat types and sampled their macroinvertebrate communities over 110 d. The species composition of macroinvertebrates in both tree holes and bamboo sections differed among habitats. Larvae of damselflies and crane flies, both important predators of mosquitoes, were replaced by larvae of the predatory mosquito *Toxorhynchites* spp. in chacras. Several mosquito species were relatively more abundant in chacra habitat. Macroinvertebrate abundance and species richness were correlated with water volume in tree holes and varied over time in bamboo sections. Species richness in bamboo did not differ among the three focal habitat types, but forest tree holes contained more species than tree holes in chacras. Differences in species composition between the two types of phytotelmata largely were attributed to the short duration of the bamboo experiment." (Authors)] Address: Yanoviak, S.P., Center for Biodefense and Emerging Infectious Diseases, University of Texas Medical Branch, 301 University Blvd., Galveston, TX 77555. USA.

6304. Zhang, D.; Yang G.; Zheng, Z. (2006): Phylogenetic relationship of some species of Libellulinae inferred from sequences of mitochondrial cytochrome b gene (Odonata: Libellulidae). *Journal of Ningxia University (Natural Science Edition)* 27(3): 255-259. (in Chinese, with English summary). ["Partial nucleotide sequences of mitochondrial DNA cytochrome b gene from 7 species of 3 genera of Libellulinae in China were amplified by PCR and directly sequenced by silver-staining sequencing technique. The sequences were parts of Cyt b gene of mtDNA (576 base pairs in length), and in the obtained sequences, the average of A + T was about 70.2%. From every amino acid codon, the average of A + T in the third site was higher (85.4%) than the other two sites. The sequence data revealed considerable variation in 180 nucleotide sites (about 31.25%) among the analyzed individuals from 3 genera, *Orthetrum*, *Lyriothemis* and *Libellula*. We obtained homologous nuclear sequence of *Mnais maclachlani* for outgroup. The phylogenetic trees were constructed with neighbour-joining method, maximum parsimony method and Bayesian inference. The confidence of nodes in the trees was evaluated by 1 000 replicates bootstrap. The phylogenetic relationship of mitochondrial DNA suggested that *Orthetrum* was more evolutionary than *Lyriothemis* and *Libellula*. The phylogenetic relationships of the 3 genera was *Libellula* -> *Lyriothemis* -> *Orthetrum*." (Authors)] Address: Zhang, Dazhi, School of Life Science, Ningxia University, Yinchuan 750021, China

6305. Zhang, D.-z.; Dai, J.-x.; Zheng, Z.-m. (2006): Phylogeny of Libellulidae based on mitochondrial cytochrome b nucleotide sequences (Odonata: Anisoptera). *Sichuan Journal of zoology* 25(4): 695-699. (in Chinese, with English summary). ["In this study, fragments of mitochondrial DNA cytochrome b gene (each 576 base pairs in length) have been characterized from twenty individuals belong to 9 species from 6 genera of Libellulidae in China. These sequences were parts of Cyt b gene of mtDNA, and in the obtained sequences, A % + T % was about 69.12 %. From every amino acid codon, A % + T % in the third site was higher (86.15 %) than the other two sites. The sequence data revealed considerable variation in 216 nucleotide sites (about 37.15 %) among the analyzed individuals from 6 genera. We obtained homologous nuclear sequence of *Megalestes m aai* (damselfly) for outgroup. The phylogenetic trees were constructed with neighbour-joining method, maximum likelihood method and maximum parsimony method. The confidence of nodes in the trees was evaluated by 1000 replicates bootstrap. The phylogenetic relationship of mitochondrial DNA suggested that the Libellulidae was a monophyletic group. *Orthetrum* was more evolutionary than other genera. The phylogenetic relationships of the 6 genera was : *Pantala* and *Sympetrum* -> *Lyriothemis* -> *Acisoma* and *Crocothemis* -> *Orthetrum*." 6307. Baker, R.L.; McGuffin, M.A. (2007): Technique and observer presence affect reporting of behavior of damselfly larvae. *Journal of the North American Benthological Society* 26(1): 145-151. (in English). ["We experimentally tested for systematic biases in techniques commonly used to study behavior of larval aquatic insects. We determined whether larval Zygoptera responded to the presence of an observer and whether live observation missed some behaviors. We found significant differences between behaviors recorded during live observations and behaviors videotaped in the absence of an observer. All behaviors, except Rotate, were exhibited less frequently in the presence of an observer. These results suggest that larvae respond to the presence of observers as if they were predators. Live observation also missed some behaviors. The duration of Crawl Forward, which can be very subtle, and the frequency of Rotate, which can be very rapid and is easily missed, were greater when recorded from the videotape than by a live observer. Wherever possible, use of video recording systems is preferable over reliance on live observations." (Authors)] Address: Baker, R.L., Dept Zoo], Erindale Coll., Univ. Toronto, Mississauga, ON, L6L 2C6. Canada. e-mail: rbaker@credit.erin.utoronto.ca

6308. Baptista, D.F.; Buss, D.F.; Egler, M.; Giovanelli, A.; Silveira, M.P.; Nessimian, J.L. (2007): A multimetric index based on benthic macroinvertebrates for evaluation of Atlantic Forest streams at Rio de Janeiro State, Brazil. *Hydrobiologia* 575: 83-94. (in English). ["This study describes the application of a protocol for biological assessment of water quality at first to third order streams at Serra dos Órgãos, an area covered by Atlantic Forest in Rio de Janeiro State, Brazil. Major impacts in the region are domestic effluents and deforestation. Our main objective is to establish biocriteria for the establishment of the Serra dos Órgãos Multimetric Index (SOMI) based on benthic macroinvertebrates. We used data from previous studies, sampled by experienced biologists, from 1999 through 2002. The benthic macroinvertebrate community was sampled in 12 reference sites and seven impaired sites in three river basins: Guapimirim, Macaé and Grande, all from the same bioregion. From the 22 tested metrics, 6 were included in the SOMI (% Diptera, % Coleoptera, Family Taxa, EPT Taxa, BMWP-CETEC and % Shredders). Scores (5, 3 or 1) were developed for these metrics to allow for aggregation into the index. Seven intermediately impaired sites were used for evaluating the applicability of the multimetric index. We concluded that the SOMI is a robust easy-to-apply tool for biomonitoring programs in the Serra dos Órgãos region, south-east Brazil." (Authors) Odonata are included into the study at several parts.] Address: D. F. Baptista, D.F., Laboratório de Avaliação e Promoção da Saúde, Ambiental – FIOCRUZ/IOC, Av. Brasil, 4365, Manguinhos, Rio de Janeiro, RJ, Brasil. E-mail: darcilio@ioc.fiocruz.br

6310. Beattie, R. (2007): The geological setting and palaeoenvironmental and palaeoecological reconstructions of the Upper Permian insect beds at Belmont, New South Wales, Australia. *African Invertebrates* 48 (1): 41-57. (in English). ["The entomofauna of the Tatarian insect beds within the Newcastle Coal Measures at Belmont, north of Sydney, was described many years ago. A new collection contains some undescribed species, particularly beetles; a new exposure of the fossiliferous deposits is now documented. The Newcastle Coal Measures consist of sandstones, conglomerates, shales, coal and tuffs, which were deposited in the Hunter Trough. The depositional environment consisted of a series of very shallow, stagnant freshwater pools along a gravel river channel system within a regional coal swamp. A volcanic event produced a volcanic ash dump, causing a "snapshot" kill of insects, validating possible interpretation of percentages of insect fossils in ecological modelling. The pool community included Conchostraca, Permosyne beetles and extremely rare insect larvae. A community on swamp banks adjacent to the water courses was comprised of Glossopteris-dominated flora and Phyllothea, with an insect-dominated, first-level consumer community of phloem-feeding Hemiptera and possibly pollenivorous Mecoptera. A leaf-litter and bark-dwelling community included Pro-

telytroptera, Psocoptera and archostematan Coleoptera. Neuroptera, extremely rare Trichoptera, and ancestors of the Orthoptera were also present in small numbers. Adult Neuroptera fossils suggest the presence of their predatory larvae and this group, along with the Odonata, are considered to have been the predatory components within this environment. No chelicerates, tetrapods or other potential top predators have been found in this, or proximal, facies. Disruptive colour patterns in some of the insects may indicate predator-prey relationships. Of interest also is the identification of a number of Glossopteris leaves with chewed margins. If these observations are correct, they would represent one of the earliest records of this kind of ichnofossil in Australia." (Author)] Address: Beattie, R., Dept of Earth & Marine Sciences, The Australian National University, Canberra, ACT 0200 Australia, P.O. Box 320, Berry, NSW 2535 Australia. 6311. Beckemeyer, R.J.; Hall, J.D. (2007): The entomofauna of the Lower Permian fossil insect beds of Kansas and Oklahoma, USA. *African Invertebrates* 48(1): 23-39. (in English). ["The Lower Permian Wellington Formation fossil beds of mid-continent North America are known best for the famous Elmo, Kansas locality. The Elmo site has produced tens of thousands of specimens from which more than 150 species of insects have been described. Equally productive and more widespread geographically, but less well-known, are the Midco, Oklahoma beds located some 270 km south of Elmo. The Midco beds have also yielded tens of thousands of specimens, but the material has been less well studied, and only half as many species have been identified from there. Renewed attention has been given in recent years to both the geology and palaeontology of the Wellington Formation. The history of these insect beds is recounted and the insect faunal composition is briefly reviewed. There are nearly 200 species in 106 genera, 53 families and 21 orders. Sizes (as measured by mean forewing length) range from 1.9 mm to 330 mm, with a mean of 22 mm and a median of 12 mm. Ten of 13 species with fore wings greater than 50 mm in length are Protodonata. Most species are known from one or a few specimens (abundance ranges from 1 to just under 400 specimens per species). Of ten species for which 50 or more specimens are known, eight are Grylloblattida (and six of these Grylloblattida: Lemmatophorina), indicating that these taxa were either quite abundant or were preferentially preserved, or both. When reviewing the holotype/neotype specimens used to describe the Wellington Formation species, we find that 62% consist of fore wings, while 9% are complete specimens. However, when considering all known specimens, 48% of the species are known only by their fore wings, while 13% are now represented by complete specimens, indicating the importance of continued collecting and review of Wellington Formation insect fossils." 6312. Beukema, J. (2007): Are the observed dispersal capacities in damselfly species sufficient to cope with the ongoing rapid shift of climate zones?. In: Tyagi, B.K. (Ed.): *Odonata : Biology of Dragonflies*. Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 175-182. (in English). ["To keep up with present polewards shifts in climate zones, species have

to expand their distribution areas in polewards direction with an average speed of several kilometers per year. Therefore, their dispersal capacities and the use they make of these deserve special interest. Both results of mark-recapture studies as well as records of the time course of colonization of new water bodies would point to remarkably small proportions of populations of Zygopteran species actually moving over such distances within a flying season. Reasons are given why these observations may underestimate true dispersal capacities. Records of range shifts reveal that most Odonate species appear to be able to the present speed of polewards climate shift." (Author)] Address: Beukema, J., Royal Netherlands Institute for Sea Research, P. O. Box 59, 1790AB Den Burg, Texel, The Netherlands. E-mail: janb@nioz.nl

6313. Blaustein, L.; Chase, J. (2007): Interactions between mosquito larvae and species that share the same trophic level. *Annual Review of Entomology* 52: 489-507. (in English). [Ecological theory predicts, and empirical research shows, that species sharing the same trophic level as a target species (hereafter controphic species) can have large direct and indirect effects on the target species by sharing resources and/or by serving as alternative prey to predators. Yet, the roles of controphic species of mosquito larvae in affecting mosquito populations have received little attention. Published empirical evidence, although scarce, suggests that controphic species such as zooplankton and anuran larvae compete with mosquito larvae, can positively affect mosquito larvae by consuming bacteria that are pathogenic to mosquito larvae, reduce predation on mosquito larvae by serving as alternative prey, and ultimately cause increased predation on mosquito larvae by causing a numerical response in the predator. We conclude that more extensive theoretical and empirical studies in elucidating the roles of controphic species will better allow us to predict mosquito population dynamics and allow for better management of mosquitoes." (Author) The review includes data on Odonata.] Address: Blaustein, L., Community Ecology Laboratory, Institute of Evolution, Faculty of Sciences, University of Haifa, Haifa 31905, Israel. 6314. Boano, G.; Sindaco, R.; Riservato, E.; Fasano, S.; Barbero, R. (2007): *Atlante degli odonati del Piemonte e della Valle d'Aosta*. Memorie della Associazione Naturalistica Piemontese 6: 160 pp. (in Italian, with English summary). [Italy; "Atlas of the Odonata of Piedmont and Valle d'Aosta. Based on an exhaustive review of the literature, the study of several local entomological collections, and extensive unpublished data, we have written an atlas of the Odonata of Piedmont and Valle d'Aosta which presents up-to-date information on the geographic (using a 10km UTM grid) and altitudinal distribution, ecological preferences, and phenology of these insects in the two regions in question. We have analysed and mapped over 6200 records, of which about 2000 were already published in approximately fifty different sources, while the remaining 4200 (87.5%) were unpublished; these were for the most part gathered by the authors over the last 15 years. Bibliographical data is quite scattered: only 6 publications contain more than 50 records, and of these only 3 were published after Capra and Galletti's (1978) fundamental reference work. We confirmed the presence of 63 species (72 % of the national total), all of which have been recorded in the last 15 years except for Erythromma na-

jas. We report the first records of *Coenagrion coerulescens* for the well-investigated region of Piedmont, along with 14 new records for Valle d'Aosta: *Calopteryx splendens*, *Ischnura pumilio*, *Erythromma lindenii*, *Coenagrion tenellum*, *Aeshna mixta*, *Anax parthenope*, *Cordulia aenea*, *Libellula depressa*, *Orthetrum cancellatum*, *Crocothemys erythraea*, *Sympetrum fonscolombii*, *S. sanguineum*, *S. striolatum* and *S. vulgatum*. The rarest species (< 10 UTM squares) are (in parenthesis we indicate the ratio of total UTM squares / post-1990 UTM squares): *Erythromma najas* (1/0), *Coenagrion caerulescens* (2/2), *Leucorrhinia dubia* (3/3), *Sympetrum flavolum* (4/2), *Brachytron pratense* (4/1), *Somatochlora meridionalis* (5/3), *Aeshna grandis* (4/4), *Sympetrum vulgatum* (5/2), *Coenagrion mercuriale* (5/5), *Gomphus flavipes* (8/6), *Sympecma paedisca* (8/1), *Somatochlora alpestris* (9/9), *Oxygastra curtisii* (10/6), *Onychogomphus uncatatus* (9/9). Given the importance of protecting suitable habitats for the conservation of Odonates, we have felt it useful to provide an overview of the knowledge related to the Odonates present in Sites of Community Interest and in the protected areas of Piedmont and Valle d'Aosta." 6316. Bots, J.; De Bruyn, L.; Adriaens, T.; Dumont, H.; Stoks, R.; Van Gossum, H. (2007): Seasonal and diurnal variation in the proportions of female morphs of the damselfly *Enallagma cyathigerum*. *Animal Biology* 57(2): 217-230. (in English). ["In many damselfly species a female-limited colour polymorphism is encountered which is assumed to be the result of sexual conflict. Typically, one morph resembles the male's body colouration (andromorph), while the other is dissimilar (heteromorph). Little is known about the extent of temporal variation in female morph proportions at the water where mating occurs. Knowledge about such variation should help to identify the factors that affect female morph proportion and the scales at which these factors operate. The objective of this study is to assess the occurrence of diurnal and seasonal variation in female morph proportions at the water for the damselfly *Enallagma cyathigerum*. Diurnal variation was evaluated at six nearby populations, while seasonal variation was examined at one of these populations. Furthermore, we considered temporal variation in female morph proportion in relation to proxies of male harassment (i.e., male density and operational sex ratio). Our findings indicate that female morph proportion varies throughout a day but is uniform on a seasonal scale. Variation in female morph proportions could not be explained by concomitant variation in male density or operational sex ratio. We suggest future study of male mate choice may consider temporal variation in female morph proportions at the water." 6320. Buden, D.W.; Paulson, D.R. (2007): Odonata of Yap, Western Caroline Islands, Micronesia. Pacific Science 61(2): 267-277. (in English). [“Fifteen species of Odonata are recorded from Yap, Micronesia—two Zygoptera and 13 Anisoptera. None is endemic to Yap. *Hemicordulia lulico* occurs elsewhere only in Palau, whereas most of the other species are widespread in the western Pacific and Indo-Australian regions. *Macrodiplox cora* and *Tramea loewi*, both recorded by Lief-tinck in 1962, were the only species not encountered during this study; *Tramea loewi* remains known in Micronesia only from a single male collected in Yap by R. J. Goss in 1950. Six of the breeding species in Yap that are widespread in Indo-Australia occur no farther east in the Caroline Islands except possibly as unusual extralimital records in the cases of *Agriocnemis femina* and *Neurothemis terminata*; the four other species reaching only as far east as Yap are *Anaciaeschna jaspidea*, *Agrionoptera insignis*, *Orthetrum serapia*, and *Rhyothemis phyllis*. *Orthetrum serapia* is reported from Micronesia for the first time, although a very old single specimen record of *O. sabina* from Tobi Island may possibly pertain to *O. serapia*. The odonate fauna of the outer islands of Yap State is poorly known; only six species have been recorded from among four of the 15 island groups. In addition, *Tramea transmarina euryale* rather than *T. t. propinqua* was found to be the subspecies occurring in the Chuuk Islands, contrary to earlier publications.” (Authors)] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. 6321. Cannings, R.A.; Ramsay, L.R.; Cannings, S.G. (2007): Odonata inventories in British Columbia, Canada: determining the conservation status of odonata species. In: Tyagi, B.K. (Ed.): Odonata : Biology of Dragonflies. Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 137-151. (in English). [“The Order Odonata in British Columbia, Canada, is reasonably well known but, before 1996, systematic inventories were confined to small areas or even single localities. From 1996 to 2006, concentrated surveys were conducted annually throughout much of the province. The main goals of these surveys were to determine the status and habitat needs of Odonata, with an emphasis on the species considered to be at risk; to increase public awareness of dragonflies, their ecology

and conservation; and to encourage interest in dragonfly monitoring and research in the various regions. Each year, public lectures about dragonflies were given in local communities around the province and volunteer collectors from these places participated in the project. To demonstrate how such inventory provides information for assigning conservation status ranks to dragonfly species, the changes in these ranks over a nine-year period were examined. Preliminary conservation status ranks were assigned to British Columbia's Odonata species in 1993. Subsequently, inventory efforts focused on those species considered rare or at risk in order to determine more accurately their status and habitat requirements. During these surveys, the geographical distributions of many species were expanded, our knowledge of habitat preferences increased and five species were added to the provincial list. Many of the targeted species were found to be more abundant than previously thought and their conservation ranks were changed accordingly. Others were recorded only rarely or not at all. Accurately ranking poorly known species is challenging, particularly if samples are small or if much of their range is inaccessible. By increasing our knowledge of these dragonflies and their habitats, we can assign species ranks more with more confidence, thus ensuring that conservation efforts will target the species and habitats that truly require them.” (Authors)] Address: Cannings, R.A., Royal British Columbia Museum, 675 Belleville Street Victoria, British Columbia V8W 9W2. 6323. Carballa, O.L.; Giere, S.; Cordero, A.; Hadrys, H. (2007): Isolation and characterization of microsatellite loci to study parthenogenesis in the citrine forktail, *Ischnura hastata* (Odonata: Coenagrionidae). Molecular Ecology Notes (OnlineEarly Articles). : (in English). [“The citrine forktail, *Ischnura hastata*, is an American damselfly species, widely distributed, with only-female populations also found at the Azores islands. Here we report the development of nine microsatellite loci for this species. The number of alleles per locus ranged from six to 11, with an observed heterozygosity ranging from 0.245 to 0.737. Eight of the nine loci successfully amplified in a sample of parthenogenetic females from the Azores. The developed microsatellite system will be a useful tool to investigate population structure, as well as the number of clones, the type of parthenogenesis and the origin of the parthenogenetic populations of this species.” (Authors)] Address: Carballa, Olalla Lorenzo, Evolutionary Ecology Group, Department of Ecology and Animal Biology, Universidad de Vigo, EUIT Forestal, Campus Universitario, 36005, Pontevedra, Spain. 6324. Chang, X.; Zhai, B.; Liu, X.; Wang, M. (2007): Effects of temperature stress and pesticide exposure on fluctuating asymmetry and mortality of *Copera annulata* (Slys) (Odonata: Zygoptera) larvae. Ecotoxicology and

Environmental Safety 67(1): 120-127. (in English). ["Although there have been some investigations into the effects of insecticide on the level of fluctuating asymmetry (FA) of adult damselflies, the cooperative effects of environmental factors on FA of larval damselflies were known little. This paper explored effects of exposure to temperature and pesticide on larval development of the damselfly *Coperla annulata* (Selys). A conventional life history trait (mortality) and developmental instability (estimated by calculating fluctuating asymmetry of bilaterally symmetrical structures) were used to measure stresses in this paper. The results showed that temperature and different concentrations of pesticide produced significant effects only on developmental stability of some characters. The FA values of three traits decreased at lower concentrations, then increased slowly with increased insecticide doses. The FA values of four traits decreased slowly with increased temperatures. However, the interaction between different concentrations of insecticide and temperature was complicated and only produced significant effects on five traits. Insecticide treatment did not significantly affect mortality of the larvae of damselfly. However, mortality was significantly positively associated with temperature. There were significantly negative associations between mortality and the FA values of three traits. These results may be caused by higher mortality and short rearing time although we did not find the significant effects of concentrations on mortality. Therefore, we speculate FA may be induced if larval damselflies were treated during longer term and FA has potential as a more specific bioindicator of stresses if we guarantee enough longer rearing time without higher mortality under stressful environment." 6325. Crick, K. (2007): Observations on final instar damselfly caudal lamellae with little or no evidence of secondary tracheae. *J. Br. Dragonfly Society* 23(1): 10-13. (in English). ["In the summer of 2006, 457 exuviae were collected from localities in Hampshire, and they produced an anomaly that occurred in four species, *Enallagma cyathigerum*, *Coenagrion puella*, *Erythromma najas* and *Pyrrhosoma nymphula*. Thus samples collected from three sites before the first week in June produced 29 exuviae that exhibited little or no evidence of secondary tracheae in their caudal lamellae. [...] One of the sites did suffer a significant increase in phosphate, which caused a dropping of dissolved oxygen level. "The apparent cause of the phosphate increase was due to slurry from cows entering the water. The cows are used as a grassland management tool and had remained on site longer than planned, resulting in the need to import feed. This feed was laid out adjacent to the polluted area of water, resulting in a prolonged concentration of cattle in a confined area of the reserve." (Author)] Address: Crick, K., 29 Village Way, Yateley, Hampshire GU46 7SE, UK

6326. Cuffney, T.F.; M. D. Bilger, M.D.; Haigler, A.M. (2007): Ambiguous taxa: effects on the characterization and interpretation of invertebrate assemblages. *J. N. Am. Benthol. Soc.* 26(2): 286-307. (in English). ["Damaged and immature specimens often result in macroinvertebrate data that contain ambiguous parent-child pairs (i.e., abundances associated with multiple related levels of the taxonomic hierarchy such as *Baetis pluto*

and the associated ambiguous parent *Baetis* sp.). The choice of method used to resolve ambiguous parent-child pairs may have a very large effect on the characterization of invertebrate assemblages and the interpretation of responses to environmental change because very large proportions of taxa richness (73–78%) and abundance (79–91%) can be associated with ambiguous parents. To Address this issue, we examined 16 variations of 4 basic methods for resolving ambiguous taxa: RPKC (remove parent, keep child), MCWP (merge child with parent), RPMC (remove parent or merge child with parent depending on their abundances), and DPAC (distribute parents among children). The choice of method strongly affected assemblage structure, assemblage characteristics (e.g., metrics), and the ability to detect responses along environmental (urbanization) gradients. All methods except MCWP produced acceptable results when used consistently within a study. However, the assemblage characteristics (e.g., values of assemblage metrics) differed widely depending on the method used, and data should not be combined unless the methods used to resolve ambiguous taxa are well documented and are known to be comparable. The suitability of the methods was evaluated and compared on the basis of 13 criteria that considered conservation of taxa richness and abundance, consistency among samples, methods, and studies, and effects on the interpretation of the data. Methods RPMC and DPAC had the highest suitability scores regardless of whether ambiguous taxa were resolved for each sample separately or for a group of samples. Method MCWP gave consistently poor results. Methods MCWP and DPAC approximate the use of family-level identifications and operational taxonomic units (OTU), respectively. Our results suggest that restricting identifications to the family level is not a good method of resolving ambiguous taxa, whereas generating OTUs works well provided that documentation issues are Addressed." (Authors) The analysis contains some data on "*Argia* sp.".] Address: Cuffney, T.F., US Geological Survey, 3916 Sunset Ridge Rd., Raleigh, North Carolina 27607 USA. E-mail: tcuffney@usgs.gov

6329. Dijkstra, K.-D.; Groeneveld, L.F.; Clausnitzer, V.; Hadrys, H. (2007): The Pseudagrion split: molecular phylogeny confirms the morphological and ecological dichotomy of Africa's most diverse genus of Odonata (Coenagrionidae). *International Journal of Odonatology* 10(1): 31-41. (in English) ["The continental African representatives of the genus *Pseudagrion* fall into two groups (A and B) based on their ecology and larval and adult morphology. While the B-group species are found in generally warmer habitats, which are more sunny, lentic or low-lying, the A-group representatives occur more in cooler habitats. We compared molecular genetic and ecological data of twelve species representing both groups. Mitochondrial DNA sequence analyses strongly support their segregation into two major clades and suggest the monophyly of each. High bootstrap support confirms the deep phylogenetic split. Overall, only a minority of species have been studied for each group. However, genetic distances of the species within each clade indicate that they are significantly more closely related to each other than to species of the opposite clade. We conclude that the observed ecological and morphological similarities are due to common ancestry, suggesting two independent radiations within the continental African *Pseudagrion* species. The biogeographic and palaeoecological history of the two clades remains unresolved." (Authors)] Address: Clausnitzer, Viola, Graefestr. 17, D-06110 Halle/Saale, Germany. E-mail: violacl@t-online.de

6330. Dijkstra, K.D.; Samways, M.J.; Simaika, J.P. (2007): Two new relict *Syncordulia* species found during museum and field studies of threatened dragonflies in the Cape Floristic Region (Odonata: Corduliidae). *Zootaxa* 1467: 19-34. (in English). ["Red List assessments often require the verification of records and taxonomy in museum collections and the field. Such research during an assessment of threatened dragonflies in the Cape Floristic Region (CFR) biodiversity hotspot, led to the discovery of two new narrow-range endemic *Syncordulia* species, bringing the known total to four in the genus. The new species, *Syncordulia legator* and *S. serendipator*, are described with emphasis on their identification, ecology and biogeography. Morphological diversity within the genus and the absence of obvious close relatives suggest an ancient and isolated presence in the CFR, emphasizing the uniqueness and conservation importance of the region's endemic odonate fauna." (Authors)] Address: Simaika, J.P., Centre for Invasion Biology, Dept of Conservation Ecology and Entomology, Stellenbosch University, P Bag X1, Matieland 7602, South Africa. E-mail: simaika@sun.ac.za

6331. Dijkstra, K.D.; Clausnitzer, V.; Martens, A. (2007): Tropical African *Platycnemis* damselflies (Odonata: Platycnemididae) and the biogeographical signifi-

cance of a new species from Pemba Island, Tanzania. *Systematics and Biodiversity* 5(2): 187-198. (in English). ["The damselfly, *Platycnemis pembipes* sp. nov., is described from Pemba Island (Ngezi Forest, Tanzania) and its affinities with Guineo-Congolian and Malagasy congeners are examined. For this purpose the identity and distribution of Afrotropical *Platycnemis* is reviewed, especially the taxonomically confused continental species. The Pemba species is nearly identical to some species of the Malagasy radiation of *Platycnemis*, but distant from the Guineo-Congolian species that have tropical Asian affinities. It is argued that the species is a long-distance wind-borne arrival from Madagascar, which survived due to favourable climatic conditions on Pemba. Habitats on the mainland, only 50 km further, are or have been drier and therefore seem unsuitable. The new species, living proof of a remarkable colonisation event, is under immediate threat, confined to a single stream in an imperilled forest, over 1000 km from its nearest relatives. The holotype of the enigmatic *P. mauriciana*, not recorded on Mauritius after its description, cannot originate from the island as it pertains to the European *P. latipes*. Five species recalling the Asian genus *Copera* are known in the male sex from central and western Africa; all were confused to some degree with *P. congolensis* and a key is given. The lectotype of *P. congolensis* is designated and its identity is clarified. *Platycnemis flavipes* and *P. xanthopus* are junior synonyms of *P. nyansana*. Discovery of the *P. rufipes* female showed that *P. escherichi*, known only from the female holotype, is a junior synonym of it. The generic classification of *Platycnemis* and *Copera* is not resolved, but data and hypotheses that should aid future analysis are provided." (Authors)] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.

6332. Dijkstra, K.-D. (2007): The name-bearing types of Odonata held in the Natural History Museum of Zimbabwe, with systematic notes on Afrotropical taxa. Part 1: introduction and Anisoptera. *International Journal of Odonatology* 10(1): 1-29. (in English). ["Orthographic details of 118 name-bearing types of Odonata are provided in two parts: the first and present paper deals with Anisoptera, the second with Zygoptera. 58 types pertain to good species, although the taxonomy of at least four is problematic. The details of 11 'holotypes' of forms are also provided, although these and their names have no nomenclatory status. The taxonomy of the Afrotropical members of *Microgomphus* is discussed, as are the supinus-group of *Onychogomphus*, the fritillarius-group of *Paragomphus*, the genus *Tragomomphus*, and the basitinctagroup of *Trithemis*. *Microgomphus bivittatus* is transferred to *Lestinogomphus*, and *Tragomomphus seydeli* to *Onychogomphus*. *Heliaeschna longfieldae* is a junior synonym of *H. sembe*; *Microgomphus mozambicensis* and probably *M. schoutedeni* of *M. nyassicus*; *Onychogomphus quirikii* and *O. septemflavum* of *O. seydeli*; *Paragomphus dicksoni* of *P. cognatus*; *Aethiothemis watulikii* of *A. basilewskyi*; *Eleuthemis quadrigutta* of *E. buettikoferi*; *Malgassophlebia aequatoris*, *M. longistipes* and *M. nigeriae* of *M. bispina*; *Tetrathemis bifida* and *T. sulci* of *T. camerunensis*; *Trithemis jacksoni* of *T. arteriosa*. It was confirmed that *Gynacantha ochraceipes* is a junior synonym of *G. vesiculata*; *Macromia paludosa* of *Phyllomacromia overlaeti*; *Trithemis falconis* of *T. aequalis*; *Zygonyx ikomae* of *Z. natalensis*." 6333. Dijkstra, K.D. (2007): Gone with the wind: westward dispersal across the Indian Ocean and island speciation in Hemicordulia dragonflies (Odonata: Corduliidae). *Zootaxa* 1438: 27-48. (in English). ["The taxonomy and biogeography of the western representatives of the largely Papuan-Australian genus Hemicordulia are discussed and compared with other alate fauna including butterflies, birds, bats and other dragonflies. Specimens from Malawi, Mozambique, Réunion, South Africa, Tanzania and Uganda were compared with Indian specimens of *H. asiatica*, with which they were previously regarded conspecific. They are found to be distinct and are described as the continental *H. africana* n. sp. and those from Réunion as *H. atrovirens* n. sp. The three species were compared with *H. similis* of Madagascar and *H. virens* of Mauritius. Insufficient material of the Seychelles taxon *H. similis delicata* was available; it may represent another insular endemic species. The distribution of Hemicordulia is discussed in the light of the dispersal capacity of Odonata and the biogeography of taxa with similar distributions in the region, with an emphasis on the survival of 'oceanic' species on the continent. Recent (i.e. in the last few million years) trans-oceanic airborne dispersal aided by westward storms, is the most likely explanation for the distribution of the genus in Africa and the Indian Ocean islands, as well as for other winged animals of Asian affinities in the region. The world range of Hemicordulia is largely insular, broadly excluding continents, and *H. africana* n.sp. demonstrates 'inverted insularity': all continental sites are in proximity to large water bodies, such as the great African lakes. This pattern may be related to the climatological instability of these sites, which offer suitable cool habitat where competition is (temporarily) reduced. Hemicordulia prefer cool conditions, but may be vulnerable to overheating and competition with more warm-adapted species." (Author)] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

6334. Dijkstra, K.D.; Pilgrim, E.M. (2007): Trithetrum, a new genus of African dragonflies formerly placed in Sympetrum (Odonata, Libellulidae). *Journal of Afrotropical Zoology* 3: 77-81. (in English). ["Based on many morphological differences, the genus Trithetrum is described as distinct from Sympetrum Newman. The genus contains Trithetrum congoense (Aguesse) and T. navasi (Lacroix), both formerly placed in Sympetrum. Two males from Congo-Kinshasa constitute the first records of T. congoense since its description from Congo-Brazzaville." 6335. Dmitriew, C.; Cooray, M.; Rowe, L. (2007): Effects of early resource-limiting conditions on patterns of growth, growth efficiency, and immune function at emergence in a damselfly (Odonata: Coenagrionidae). *Can. J. Zool.* 85(3): 310-318. (in English, with French summary). ["Periods of restricted growth during early development are expected to have detrimental effects on subsequent metrics of fitness, most prominently increases in age and decreases in size at maturity. However, in some cases, animals may compensate by altering foraging effort, growth efficiency, or patterns of re-

source allocation between critical traits prior to maturation. Yet, even when compensation for age and size is complete, brief periods of restricted growth may carry costs persisting in the long term, and compensatory tactics may themselves be costly. We investigated the long-term costs of early growth restriction and mechanisms of compensatory growth in the damselfly *Ischnura verticalis* (Say, 1839). Larvae were temporarily exposed to one of three feeding regimes in the early stages of development, after which food levels were restored. In the period of unrestricted growth prior to emergence, partial compensation for structural size in the lowest food treatment was observed, while both resource-limited groups accelerated mass gain relative to controls. Changes in food consumption and food conversion efficiency were ruled out as mechanisms for accelerating growth following diet restriction. We tested for changes in resource allocation patterns that could explain the observed compensatory growth and found that adult body shape may depend on early growth conditions in females. There was no evidence of detrimental effects on immune function at emergence, although males tended to have higher phenoloxidase activity (a measure of immunocompetence) than females." (Authors)]

6336. Dumont, H.J. (2007): Dragonflies from the Okavango swamps (Botswana, Southern Africa) in winter. In: Tyagi, B.K. (Ed.): *Odonata : Biology of Dragonflies*. Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 45-50. (in English). ["Geographic situation and altitude of the Okavango swamps combine to create a distinctly seasonal climate, with an outspoken cool season. The local dragonfly fauna in winter is distinctly less species-rich than in summer. Although low abundances (rare species) may slightly complicate the situation, it is probably fair to estimate the faunal impoverishment at a factor 2 to 4 (17 species were censused in July 2006, against c. 70 known from all seasons combined). The composition of the winter fauna is dominated by wide-ranging species, tolerant of strong variations in environmental conditions, but at least two Pseudagrion species (*P. deningi*, *P. coelestis*) appear to have taken advantage of the void created by the austral winter, and have their adult population peak in winter." 6337. Fincke, O.M.; Fargevielle, A.; Schultz, T.D. (2007): Lack of innate preference for morph and species identity in mate-searching Enallagma damselflies. *Behav. Ecol. Sociobiol.* 61: 1121-1131. (in English). ["Insect mate recognition is often viewed as stereotypic, innate, and species-specific. However, male damselflies can learn to identify female-specific color morphs as potential mates. A suite of male mimicry hypotheses assume that heteromorphic females, which differ from males in color pattern, are more easily recognized as "female" and thus lack the inherent, anti-harassment advantage that the more male-like signal provides for andromorphs. Using two measures of male preference, we investigated whether naïve males have a preexisting sensory bias for a given morph color in *Enallagma civile*, a species that appeared to exhibit extreme plasticity in morph expression across generations within a breeding season. *E. civile* males raised in the absence of females exhibited no preference for either morph, whereas males raised with one female type ex-

hibited a learned sensory bias for that morph. Male *Enallagma* also lacked a bias toward conspecific females over a congeneric sister species. In a naturally naïve population of *Enallagma ebrium*, males reacted sexually to both morphs of *Enallagma hageni* as often as they did to conspecific females, whose thoracic spectra were nearly identical with those of *E. hageni*. Moreover, despite the similar thoracic spectra of males and andromorphs, both of which reflected UV, males rarely reacted sexually to other males. Our results falsified implicit assumptions of male mimicry hypotheses, supported learned mate recognition, and suggested a scenario for speciation via sexual conflict." 6341. Gonzalez Soriano, E.; Novelo Gutierrez, R. (2007): Odonata of Mexico revisited. In: Tyagi, B.K. (Ed.): *Odonata : Biology of Dragonflies*. Jodhpur, Scien-

tific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 105-136. (in English). ["Odonata of Mexico, comprising one of the greatest biodiversity regions in the world, is discussed with as many as 19 species, including also one of the hitherto unrecorded genus *Ophiogomphus*, enlisted since 1996. A large number of taxonomic, geographic and other features associated with many of these species in different ecosystems are also elaborated." (Authors)] In an appendix, all taxa are listed according the Mexican states] Address: Gonzalez-Soriano, E., Depto Zoologia, Inst. Biol., Universidad Autonoma, Apartado Postal 70-153, 04510 Mexico, D.F., Mexico. E-mail: esoriano@mail.ibiologia.unam.mx

6342. Grand, D.; Boudot, J.-P. (2007): *Les Libellules de France, Belgique et Luxembourg*. ISBN : 2 - 914817 - 05 - 3: 480 pp. [This remarkable book presents in six chapters a sound introduction to the phylogeny, morphology, biology, and biogeography of Odonata, as well as information on predators, parasites, ecology, habitats and the relationship of Odonata to human beings and their culture. All these texts are illustrated with excellent photographs, which holds true also for the rest of the book. Chapter 5 deals with the identification of imagos and exuviae, presenting full keys for the 100 taxa treated in the book. These keys are remarkable from the didactical point of view: Important and significant morphological characters are highlighted in the drawings or photographs. The key to the imagines is definitively a genuine contribution and improvement to identification of European dragonflies and will, enable even beginners to make correct identifications. An important feature is the key to the exuviae of all species. In most cases morphological relevant structures are presented as black and white photographs, a few lacking contrast (due to poor printing quality?). Structures relevant for identification are marked with arrows, and structural/morphometric relationships ("ratios") are documented by bars. In some cases, drawings are added to help in identification. This new key will certainly improve and facilitate the identification of dragonfly exuviae. Chapter 6, providing monographs of all species treated, is the most voluminous of the book. All chapters include brilliant photographs, notes on morphological characters, possible confusions with related species, distribution maps (Europe; France on the basis of the Départements, and regions in Belgium and Luxembourg), as well information on ethology, habitat, and phenology. The appendix contains plates with the wings of the species, and a selected bibliography. This remarkable book is a must in the library of every European odonatologist. At the same time, being a concise introduction to one of Europe's most interesting faunal regions, it is of major importance to odonatologists worldwide. 6343. Grant, P.B.C.; Samways, M.J. (2007): Montane refugia for endemic and red listed dragonflies in the Cape floristic region biodiversity hotspot. *Journal Biodiversity and Conservation* 16(3): 787-806. (in English). ["One of the features of many endemic organisms is that they are highly spatially restricted, and habitat specialists. The Kogelberg Biosphere Reserve (KBR) is a major centre of plant endemism within a global hotspot, the Cape Floristic Region (CFR). Dragonflies in this botanical hotspot have a range of habitat specialization from narrow-range specialists to widespread genera-

lists, with an unusually strong bias towards the specialists. A huge 53% of dragonfly individuals and 26% of taxa recorded are national endemics, and three species are Red Listed. Thus, a group of predatory insects, which are largely not dependent on plant composition, mirrors the level of habitat specialization and restricted distributions of the plants at the spatial scale of the whole reserve. Although some studies caution the use of one taxon as a surrogate for another, the results here show that at the reserve scale in this global hotspot there can be remarkable concordance, suggesting further studies on other taxa should be carried out to determine the full extent of taxonomic concordance in this irreplaceable area." 6344. Grozeva, M.; Marinov, M. (2007): Cytogenetic study of *Somatochlora borisi* Marinov, 2001 (Odonata: Corduliidae), and three relative species. *Acta zool. bulg.* 59(1): 53-56. (in English, with Bulgarian summary). ["The recently described species *Somatochlora borisi* Marinov, 2001 (Odonata: Corduliidae), combines morphological characters of two relative corduliide genera, *Somatochlora* and *Cordulia*. In the present study its karyotype was studied for the first time. Routine and differential (C-banding and DNA binding fluorochrome staining) cytogenetic techniques were applied. The chromosome formula of *S. borisi* includes $2n=20+XX/XY$. For comparison, the male karyotype of *S. metallica* (from Finland), *S. meridionalis* and *C. aenea* (from Bulgaria) were also examined. In a larva of *S. meridionalis*, the spermatogonial metaphases showed 25 chromosomes confirming $2n=24+X$ reported earlier for the species. Some polymorphism of the chromosome size had been observed in the populations examined, but this problem needs a special study. For *S. metallica* and *C. aenea* previously reported for these species the karyotype $2n=24+X$ and the telomeric localization of C-heterochromatin were confirmed. All the data obtained are discussed in comparison to literature cytogenetic data on the genera *Somatochlora* and *Cordulia*. The cytogenetic data confirm that *S. borisi* deviates widely from the other *Somatochlora* and *Cordulia* species and provide an additional argument to separate it in a new genus." (Authors)] Address: Grozeva, Snezana M., Institute of Zoology, 1 Tsar Osvoboditel Blvd., BG-1000 Sofia, Bulgaria. E-mail: sgrozeva@yahoo.com

6345. Hannon, E.R.; Hafernik, J.E. (2007): Reintroduction of the rare damselfly *Ischnura gemina* (Odonata: Coenagrionidae) into an urban California park. *Jour. Insect. Conserv.* 11(2): 141-149. (in English). ["Habitat degradation led to local extinction of the San Francisco forktail damselfly (*Ischnura gemina*) in Glen Canyon Park, San Francisco, California. In this study, we reintroduced *I. gemina* into Glen Canyon after the damselfly's habitat was restored. Upon release, we carried out a mark-release-recapture study to monitor the damselfly's population dynamics. Our data were compared to two "baseline" studies on *I. gemina*, conducted in the park prior to the damselfly's demise. Our recapture rates were significantly lower than the prior studies due to a large initial decline in marked individuals upon release. Despite a lower recapture rate, the reintroduction was initially successful since the damselflies reproduced throughout the summer and the following year. However, the population failed to persist during the se-

cond year when the habitat became degraded with excess vegetation. Future success is contingent on the continual management and upkeep of the habitat." 6347. Haritonov, A.Y. (2007): The composition and history of Siberian odonate fauna. In: Tyagi, B.K. (Ed.): *Odonata : Biology of Dragonflies*. Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 73-87. (in English). ["Based on literature analysis and the latest special researches the more precise list of dragonflies taxons of Asian part of Russia, counted 129 species, is presented. The species are distributed among 7 geographical regions: Ural and Transural, West-Siberian Plain, Altai and Sayan, North of East Siberia, South of East Siberia, North of Far East, South of Far East. The ancient autochthonous odonate fauna of south part of Russian Far East is the most rich of species and is a member of Subholarctic faunistic region. The rest of territory is a member of Holarctic faunistic region and to divide into two parts: Euro-Siberian and Siberian subregions. Their odonate fauna is not rich, young and allochthonous." (Author) The paper contains the results of several taxonomic studies (dissertations in Russian language) resulting in synonymies of several taxa.] Address: Haritonov, A.Y., Institute of Animal Systematics and Ecology, Siberian Division of Russian Academy of Sciences, Frunze str. 11, Novosibirsk 630091, Russia e. mail: pc@eco.nsc.ru

6348. Harris, W.; Parry, G.S.; Forman, D.W. (2007): Predation of odonate larvae by Otters (*Lutra lutra*). *J. Br. Dragonfly Society* 23(1): 20-24. (in English). ["The occurrence of odonate larval remains in the faeces (spraints) of Eurasian otters (*Lutra lutra*) was assessed between March and April 2006 in two Welsh rivers. Spraints were collected individually during detailed field surveys every two weeks. Odonate remains identified as *Aeshna mixta* and *Cordulegaster boltonii* were found in 61 % (11/18) of the spraints analysed and a minimum number of 66 individual larvae (45 *Aeshna mixta* and 21 *Cordulegaster boltonii*) were estimated in these spraints. This study clearly illustrates that vertebrate predators such as otters have the potential to consume large numbers of odonate larvae and highlights the need for applied research in this neglected area of odonate and otter ecology." 6349. Hartley, M.K.; Rogers, W.E.; Siemann, E. (2007): Responses of prairie arthropod communities to

fire and fertilizer: balancing plant and arthropod conservation. *Am. Midl. Nat.* 157: 92-105. (in English). ["Fire is an important tool for limiting woody plant invasions into prairies, but using fire management to maintain grassland plant communities may inadvertently reduce arthropod diversity. To test this, we established twenty-four 100 m² plots in a tallgrass prairie in Galveston County, Texas, in spring 2000. Plots were assigned a fire (no burn, one time burn [2000], two time burn [2000, 2001]) and fertilization treatment (none, NPK addition) in a full factorial design. Fertilization treatments allowed us to examine the effects of fire at a different level of productivity. We measured plant cover by species and sampled arthropods with sweep nets during the 2001 growing season. Path analysis indicated that fertilization reduced while annual fires increased arthropod diversity via increases and decreases in woody plant abundance, respectively. There was no direct effect of fire on arthropod diversity or abundance. Diptera and Homoptera exhibited particularly strong positive responses to fires. Lepidoptera had a negative response to nutrient enrichment. Overall, the negative effects of fire on the arthropod community were minor in contrast to the strong positive indirect effects of small-scale burning on arthropod diversity if conservation of particular taxa is not a priority. The same fire regime that minimized woody plant invasion also maximized arthropod diversity." (Authors) Odonata are represented, but have been excluded from analysis.] Address: Siemann, Eviann, Department of Ecology and Evolutionary Biology, Rice University, 6100 Main St., Houston, Texas 77005 USA. 6350. Hassall, C.; Thompson, D.J.; French, G.C.; Harvey, I.F. (2007): Historical changes in the phenology of British Odonata are related to climate. *Global Change Biology* 13(5): 933-941. (in English). ["Responses of biota to climate change take a number of forms including distributional shifts, behavioural changes and life history changes. This study examined an extensive set of biological records to investigate changes in the timing of life history transitions (specifically emergence) in British Odonata between 1960 and 2004. The results show that there has been a significant, consistent advance in phenology in the taxon as a whole over the period of warming that is mediated by life history traits. British odonates significantly advanced the leading edge (first quartile date) of the flight period by a mean of 1.51 ± 0.060 (SEM, $n = 17$) days per decade or 3.08 ± 1.16 (SEM, $n = 17$) days per degree rise in temperature when phylogeny is controlled for. This study represents the first review of changes in odonate phenology in relation to climate change. The results suggest that the damped temperature oscillations experienced by aquatic organisms compared with terrestrial organisms are sufficient to evoke phenological responses similar to those of purely terrestrial taxa." 6351. Hedström, I.; Sahlen, G. (2007): The dry season governs the reproduction of three pseudostigmatid zygopterans in Costa Rica (Odonata: Pseudostigmatidae). *International Journal of Odonatology* 10(1): 53-63. (in English). [*Megaloprepus caerulatus*, *Mecistogaster linearis*, and *M. ornata* "were surveyed during five

years, and striking differences in their reproduction patterns were shown: (1) At two study sites in seasonal, tropical semi-dry forests in Pacific Costa Rica, adult *M. ornata* could be observed throughout the year, occasionally during the dry season up to 24 individuals at one time. Larvae were found from the middle to the end of the wet season suggesting a generation time of one year. (2) At two other study sites in aseasonal tropical wet forest in Caribbean Costa Rica, adults of *M. caerulatus* were observed year round, often in rather low numbers. Larvae of this species as well as *M. linearis* appeared throughout the year. While dry periods and rainfall certainly are key factors in governing the reproductive patterns of these species in relation to the climatic regimes of their preferred life zones, it is also concluded that competition from other container dwellers, including tadpoles of poison arrow frogs, may be additional factors in explaining their seasonal variation. It is also argued that all three species seem to have a high plasticity in their life cycles and hence are able to adapt to local conditions rather than displaying the same behaviour throughout their range." 6353. Horrigan, N.; Dunlop, J.E.; Kefford, B.J.; Zava-hir, F. (2007): Acute toxicity largely reflects the salinity sensitivity of stream macroinvertebrates derived using field distributions. *Marine and Freshwater Research* 58(2): 178-186. (in English). ["Two types of salinity tolerance information are commonly used for assessing salinity risk to freshwater organisms. These are data from laboratory experiments, usually acute (=96-h LC50) values, and field distributions. Both approaches have advantages and limitations, and their applicability to the formation of guidelines and assessment of risks is not clear. In the present study, the acute lethal tolerances (72-h LC50) and acute tolerance scores (ATS) of 37 macroinvertebrate families from Queensland, Australia, were compared with maximum field conductivities and previously derived salinity sensitivity scores (SSS). LC50 values were significantly correlated with maximal field conductivities and SSS. To investigate this relationship further, the changes in community structure related to an increase in salinity were assessed. A salinity index (SI) (based on cumulative SSS) and acute salinity index (ASI) (based on cumulative ATS) were calculated using an independent data set from south-east Queensland (429 samples) and compared with each other and actual conductivity levels. Both indices were significantly correlated with each other and followed a similar trend when plotted against actual conductivity. These results support the notion that salinity sensitivity of mac-

roinvertebrates derived from acute toxicity experiments reflects sensitivities derived using field distributions. Definition of this relationship will allow the two sources of salinity sensitivity to be combined in a weight-of-evidence approach, resulting in a more robust data set with which to estimate safe salinity concentrations." (Authors) The paper also includes data on Odonata.] Address: Dunlop, J.E., Department of Natural Resources and Water, 120 Meiers Road, Indooroopilly, Qld 4068, Australia. ["684 *S. fonscolombii*, 94 mature adults and 590 second generation adults, were recorded at the Lound gravel pits complex, Nottinghamshire, from 25 June to 23 October 2006. All except 20 were recorded from around a shallow pit." (Author)] Address: Hursthouse, D., 22 Rose Avenue, Clowne, Derbyshire S43 4NU, UK

6355. Irusta, J.B.; Araujo, A. (2007): Adaptationist approach of reproductive behaviour in Libellulidae: a case report on *Diastatops obscura* Fabricius. In: Tyagi, B.K. (Ed.): *Odonata : Biology of Dragonflies*. Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 223-240. (in English). ["In this chapter we discuss three topics related to reproductive behaviour in Libellulidae, specifically theoretical aspects based on data obtained from the species *Diastatops obscura* (Fabricius, 1775) in its natural environment in Northeast Brazil. First, we studied reproductive strategies, with emphasis on intrasexual competition among males in territorial areas and the interconnection and synchronism of the behaviours of both sexes. Second, we analysed the females' choice of mate, a subject of lively discussion today among odonatologists throughout the world. Finally, we studied the possible relation between male body size and reproductive success. It was shown that males compete for areas of greatest access to sexually mature females, and that females select dominant males over the satellites. In competition among males, it was observed that larger individuals are more likely to achieve more copulations than smaller and medium-size males. It was also shown that larger individuals accomplish oviposition of the females inseminated by them more often and in greater numbers, and are territorial for more days than their smaller counterparts. Accordingly, we discuss aspects related to female choice and stabilizing selection." 6356. Irusta, J.B.; Araújo, A. (2007): Reproductive tactics of sexes and fitness in the dragonfly, *Diastatops obscura*. *Journal of Insect Science* 7:24, available online: insectscience.org/7.24: 10 pp. (in English). ["The sexual selection strategies of territorial Odonata that do not present courtship behavior is still not completely understood, especially the role of the females. *Diastatops obscura* Fabricius (Odonata: Libellulidae) females participate in mate selection in a passive manner, allowing copulation with the first male that captures them and afterwards choosing whether to oviposit or not. This study introduces the idea of female passive choice as an adaptative tactic in intersexual selection. Also

discussed is the adaptative value of this tactic and its flexibility according to environmental conditions and reproductive strategies adopted by the males. A natural population of *Diastatops obscura* was observed in the Pitimbu River of northeast Brazil. Focal continuous and ad libitum techniques were used to record attempted copulation, copulation, and oviposition behavior, in addition to registering male territoriality. An estimate of individual reproductive success (IRS) was obtained by recording 187 reproductive events. Territorial males, mainly occupying areas near the river margin, achieved greater copulation and oviposition success (IRS = 0.371) than did satellite males (IRS = 0.028). Females that copulated with territorial males experienced, for the most part, only one copulation and oviposition event, while those that copulated with satellite males fled or performed a second copulation with a territorial male. Thus, the best tactic adopted by the *D. obscura* males was to occupy a territory providing the greatest access to females, while the females used passive choice for fitness optimization." 6357. Joop, G.; Gillen, A.; Mikolajewski, D.J. (2007): Colour polymorphism in female *Coenagrion puella*: differences in egg shape (Odonata: Coenagrionidae). *International Journal of Odonatology* 10(1): 71-80. (in English). ["The maintenance of female colour polymorphism in coenagrionids is still an open issue. Here we ask if the three different female morphs of *C. puella* represent different reproductive traits in terms of clutch and egg size. Therefore clutch size and egg morphometry of the three female colour morphs were examined. We found that female colour morphs did not differ in clutch or egg size. However, we also found that the female morphs differ in egg shape, with the intermediate morph having more elongated eggs compared to the hetero- and andromorphic females. Our results are discussed in terms of potential different preferences in oviposition substrate." 6359. Juen, L.; Ramos Cabette, H.S.; De Marco, P. (2007): Odonate assemblage structure in relation to ba-

sin and aquatic habitat structure in Pantanal wetlands. *Hydrobiologia* 579: 125-134. (in English). ["Structural properties of aquatic habitats are the basis of several theories produced to explain the functioning of aquatic environments. We predicted a longitudinal change of ecosystem properties along the river, and also that potamal areas of the river are similar to lakes. In rivers with periodic floods we also expect a high degree of similarity due to increased environmental similarity and increase dispersal of component species. Otherwise, rivers must be conceived as a landscape element with an intrinsic hierarchical nature and dispersal among its parts are constrained by this structure. Under this view, we also could expect that different basin or different "micro-basin" could present communities that are historically different in their general properties. Here, we aimed to describe odonate larval communities in the Pantanal Mortes-Araguaia river basin in Brazil comparing the composition, species richness and community structure between lakes and rivers, and also the possible differences among river basins. The field work was done in three rivers and three lakes chosen to conform to a paired experiment, each pair in a different river basin. An aggregated sampling unit was used based on Ekman dredge and D-nets replicated on each site. We sampled 936 individuals distributed in 30 genera and a total of 34 morphotypes. There was no difference in species richness among lakes and rivers, but a marked difference among basins. Samples from the same basin present a higher similarity of the species abundance relations than among river or lake samples. We also did not observed differences in composition and community structure between large rivers and lakes, in the same basin. The results supported the concept of structural similarity between large rivers and lakes and the differences observed among basins could indicate historical events in colonization that are shaping communities characteristics." 6360. Khodabandeh, S. (2007): Ultrastructure and osmoregulatory function of the branchial chamber in the larvae of dragonfly, *Libellula lydia* (Odonata). *Journal of agricultural science and technology* 9(2): (in English). ["The ultrastructure of the cells, Na⁺, K⁺-ATPase activity and immunolocalization were examined in the branchial chamber of *L. lydia* larvae. Na⁺,K⁺-ATPase activity and localization were performed through biochemical techniques and immunofluorescence light microscopy using a mouse monoclonal antibody IgGa5, respectively. The branchial chamber possesses six pair gills lamellae that extend into the rectal lumen. A thickened epithelial layer and a modified fat body cells layer are present at the base of the each gill lamella. Epithelial cells covered by a thin cuticle and they possess apical microvilli and baso-lateral membrane infoldings associated with mitochondria. The cytoplasm of the modified fat body cells is filled with mitochondria, glycogen and a few lipid droplets. The Na⁺,K⁺-ATPase activity was significantly higher (15.36 μM Pi mg⁻¹ protein h⁻¹) in the branchial chamber. Na⁺,K⁺-ATPase immunofluorescence staining was observed in the epithelial layer cells of the basal pads of the rectal gill lamellae, with a consistently high immunoreactivity. These findings show that the epithelial cells present cytological features of the ionocytes, a high activity and concentration

of Na⁺,K⁺-ATPase, confirming their participation in osmoregulation through active ion exchanges." (Author)] Address: surp78@yahoo.com

["*Papuagrion carcharodon*, a new coenagrionid from the rainforest of Papua New Guinea's Simbu Province, is described (holotype: 06°43'S, 145°05'E; 900 m a.s.l., 27 March 2004, to be deposited at Naturalis, Leiden). This new species is similar to *P. ekari* and *P. pesechem* but may be distinguished from both by the tooth-shaped lower branch of the male cerci, and the position of the tubercles on the female pronotum." (Authors)] Address: Michalski, J., 223 Mount Kemble Avenue, Morristown New Jersey 07960, USA. E-mail: jmichalski@easthanoverschools.org

6373. Mikolajewski, D.J.; Joop, G.; Wohlfahrt, B. (2007): Coping with predators and food limitation: testing life history theory for sex-specific larval development. *Oikos* 116(4): 642-649. (in English). ["For animals with complex life cycles, recent models of sexual size-dimorphism at maturity assume three key variables to optimise larval life history: activity in the larval stage, development time, and size at maturation. However, model predictions remain largely untested. In the territorial dragonfly *Libellula depressa* (Odonata) exhibiting a flexible development time we tested for male-biased sexual size-dimorphism and sex differences in larval activity, development time, and growth rate. Based on models we predicted that males achieved their larger size compared to females by a longer development rather than being more active. Results revealed that males took longer to develop and achieved a larger size than females but were not more active. Compared to males, females exhibited a higher growth rate which was not achieved by an activity-mediated increased food intake. We conclude that sexual size-dimorphism in species with a flexible development time is mediated by differences in developmental length but not activity. Furthermore, sexes differ in their plastic responses to food availability and predator presence making it necessary to consider sex-specific differences in testing further life history responses." 6374. Miller, P.L. (2007): Dragonflies of the Madurai Kamaraj University Campus (Tamil Nadu, India). In: Tyagi, B.K. (Ed.): *Odonata : Biology of Dragonflies*. Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 273-322. (in English). ["Twenty five odonate species were observed on the Madurai Kamaraj University campus during the periods September 1987 and February 1988. Of these, proof of breeding on the campus was obtained for sixteen species and there was strong, circumstantial evidence of breeding in at least a further two species. Five bred only in permanent habitats and seven only in temporary habitats, the remainder probably doing so in both types. Sixteen species were sexually active at the largest habitat, a seasonal lake. Five further species, although commonly present, showed no sexual activity at campus sites." (Author) Special emphasis is given to oviposition behaviour.] Address: author diseased

6375. Mitra, A. (2007): Larval and adult behavioural patterns of some odonata species from Dehradun Valley. In: Tyagi, B.K. (Ed.): *Odonata : Biology of Dragonflies*. Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 323-341. (in English). ["Different behavioural patterns of five odonata species have been studied in and around Asan reservoir, Dehradun, India from May 1995 to April 1997. The odonate imago feeds only on living prey and predominantly on flying insects. *Orthetrum s. sabina* has been seen to detect the perching prey more accurately. The mature males of all the five species arrive at the rendezvous earlier in the season during the day than females and form the territory. Only except *Brachythemis contaminata*, the males of other four species either show aggressive behaviour and chase display (in Anisoptera) or show threat display by 'abdomen raising' or 'wing opening' (in Zygoptera). Before wheel tandem lasts for a few seconds in *Crocothemis s. servilia* and *Brachythemis contaminata* while it lasts from 2-5 minutes in *Orthetrum s. sabina*. Comparatively, in zygoptera, before wheel tandem lasts longer and intramale sperm translocation occurs at that time. The copulatory wheel generally lasts for 6-22 seconds in *Crocothemis s. servilia*; 4-15 seconds in *Brachythemis contaminata*; 15-25 minutes in *Orthetrum s. sabina*; 10-15 minutes in *Ischnura a. aurora* and 35-45 minutes in *Ceriagrion coromandelianum*. All the three anisoptera oviposit by frequent dipping of their abdomen under water surface, whereas, the two zygopterans oviposit endophytically. Among the five species, only *Ceriagrion coromandelianum* oviposits in tandem. The duration of oviposition varies from 20-30 seconds in *Crocothemis s. servilia*; 3-6 minutes in *Orthetrum s. sabina*; 4-6 minutes in *Brachythemis contaminata*; 20-25 minutes in *Ischnura a. aurora* and 20-30 minutes in *Ceriagrion coromandelianum*. Odonata larvae are generalized predators and early instars prefer *Paramoecium* spp., *Daphnia* spp., diatoms etc., while later instars prey on chironomid larvae and pupae, mosquito larvae, ephemeropteran nymphs, *Branchiura* spp., *Limnodrilus* spp. and some nematodes. *Orthetrum s. sabina* larvae shows cannibalism. The last instar of all the five species stop feeding 2-3 days before emergence. Emergence occurs in *Crocothemis s. servilia* and *Orthetrum s. sabina* during 5.00 to 7.00 hours at a height of 6-25 cm and 10-30 cm from the water level, respectively. In *Brachythemis contaminata* emergence occurs during 12.30 to 2.00 hours at a height of 2.5-10 cm. Emergence occurs in *Ischnura a. aurora* during 12.00-2.00 hours and in *Ceriagrion coromandelianum* during 3.00-5.00 hours at a height of 8-12 cm and 10-15 cm from the water level, respectively." 6376. Mola, L.M. (2007): Cytogenetics of American Odonata. In: Tyagi, B.K. (Ed.): *Odonata : Biology of Dragonflies*. Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 153-173. (in English). ["The current knowledge of the cytogenetics of American odonates is reviewed. Chromosome studies have been performed in nearly 830 species and subspecies of 9 Zygoptera and 6 Anisoptera families. The species analysed were collected in 15 countries: Canada, the US and Mexico from North America; Guatemala and Costa Rica from Central America; Dominica and Jamaica from the Caribbean; and Venezuela, Surinam, Brazil, Peru, Bolivia, Chile, Argentina and Uruguay from South America. The proportion of species ana-

lysed differs from one country to another. Although the most frequent haploid numbers are 12, 13 and 14, there is a wide variation from $n=3$ in *Macrothemis hemichlora* from Bolivia and Brazil to $n=21$ in *Orthemis nodiplaga* from Argentina. Two distinctive characters of the order are the presence of holokinetic chromosomes and the post-reductional type of meiosis. The most frequent sex chromosome mechanism is XX/XO (female/male), the derived neo-XY system occurs in approximately 5.5% of the species, and the X1X1X2X2/X1X2Y multiple system is only present in *Micrathyrina unguolata*. The presence of a small pair of chromosomes, the m-chromosomes, is found in nearly 80% of the species. Studies of the distribution and composition of the heterochromatin are scarce. C-banding showed that autosomes usually have heterochromatic blocks in the telomeric regions, and that, in general, the sex chromosome in males is completely expositive, or shows an intermediate staining. In the few species analysed with fluorochromes, the heterochromatin seems to have a heterogeneous molecular composition. Odonata shows a high degree of karyotypic constancy at both intra- and inter-specific levels. However, polytypisms for the number of autosomes, the sex chromosome mechanism, and the size of the m-chromosomes were described in some species. Inter-specific variation in the chromosome number and/or in the sex chromosome mechanism were seen in some genera. Fusions and, less frequently, fragmentations are the main chromosome rearrangements involved in karyotype evolution." 6377. Monroy, L.P.D.; Realpe, E. (2007): Local assemblage patterns of odonates in Central Choco, Colombian Pacific. In: Tyagi, B.K. (Ed.): Odonata : Biology of Dragonflies. Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 183-199. (in English). ["The dragonfly community in Central Chocó region was sampled with the aim of detecting patterns of local distribution and its relationship with the habitats' configuration. The Chocóan odonatofauna shows strong relationship with the presence of pluvial forest and it is postulated as a landscape condition for this ecological distribution pattern. The community shows relationship with variables like vegetation architecture associated to classified habitats, characteristics of aquatic environment, habitat's maturity and human impact. The species adaptability categorization is presented and features of specificity related to the habitats. Pluvial forest fragmentation, technified mining, the excessive logging constitute the main threats for the stenotopic species (*Archilestes nov. sp.*, *Leptobasis sp.*, *Metaleptobasis sp.*, *Philogenia cristallina*, *Palaemnema dentata*, *Heteragrion erythrogastrum*, *Perissolestes emotus*, *Neocordulia batesi*). These species were related with the presence of mature forest, and their abundances were always the lowest. The eurytopic species (*Erythrodiplax andagoya*, *E. famula lativittata*, *Micrathyrina dictynna*, *Zenithoptera americana*, *Ischnura hastata*) are related with lentic systems with strong anthropic intervention and their abundances showed to be much higher. For the first time, a preliminary list of 38 species for the odonatofauna of Central Chocó is presented." (Authors)] Address: Monroy, L. P.D. Zoology and Eco-

logy Aquatic Laboratory LAZOEIA Biologie Sciences Department, Universidad de los Andes Bogota, Colombia. E-mail: le-perez@uniandes.edu.co

6391. Rouquette, J.R.; Thompson, D.J. (2007): Roosting site selection in the endangered damselfly, *Coenagrion mercuriale*, and implications for habitat design. *Jour. Insect. Conserv.* 11(2): 187-193. (in English). ["A successful conservation strategy for an insect species should Address the habitat requirements of all life stages and all activities performed by those life stages. In

this paper the night-time roosting habitat and behaviour of the endangered damselfly *C. mercuriale* was investigated by marking damselflies with UV fluorescent paint. Night-time observations revealed that individuals did not roost together and those that were recorded on more than one occasion did not return to the same spot each night. There was no apparent preference for roosting close to the watercourses. *C. mercuriale* roosted towards the top of the vegetation and this vegetation was considerably taller than the mean height of the vegetation in the study area. Adults were strongly associated with two tussock-forming monocots, *Juncus inflexus* and *Deschampsia cespitosa*. Differences in the abundance of these plants were shown to result in large differences in the numbers of *C. mercuriale* roosting in different parts of the site. The importance of providing these structural elements of habitat as part of a wider conservation strategy for this species is discussed." 6392. Rundle, S.D., Bilton, D.T.; Abbott, J.C.; Foggo, A. (2007): Range size in North American *Enallagma* damselflies correlates with wing size. *Freshwater Biology* 52(3): 471-477. (in English). ["(1.) Cross-species macroecological comparisons in freshwater invertebrates have been restricted by a lack of large-scale distributional data, and robust phylogenies. Here, we use data from the Odonata Central database to explore body length-range size and wing length-range size relationships in damselflies from the genus *Enallagma*; the recent publication of a phylogeny for this group meant that, as well as a cross-species analysis, we were able to assess relationships in a phylogenetically controlled manner. (2.) For cross-species comparisons, only wing length showed significant (positive) regression relationships with range size and occupancy, although the inclusion of body length in multiple regressions increased the fit of the models. Damselflies with larger wings relative to their body length had larger distributions, a result confirmed by a significant positive relationship between range size and residuals from the regression of wing size on body size. (3.) For the phylogenetically controlled analyses, only wing length contrast scores were significantly related to distribution patterns and entered into regression models; the significant positive relationships between wing length contrasts and both range size and occupancy contrasts suggested that evolutionary increases in wing length had occurred alongside range expansions. (4.) Together these results suggest that species of *Enallagma* with larger wings (both absolute and relative to body length) tend to be more widely distributed in North America and that the evolution of wing size may have played a role in range expansion. No such relationships were evident for body size. We discuss the potential importance of wing morphometrics for studying the evolutionary ecology of freshwater insects." 6395. Seidenbusch, R.; Heidemann, H. (2007): An experimental key for the differentiation of the exuviae of the Southern Darter *Sympetrum meridionale* (Sélys) and the Common Darter *S. striolatum* (Charpentier), with notes on the Ruddy Darter *S. sanguineum* (Müller). *J. Br. Dragonfly Society* 23(1): 25-32. (in English). ["A study was carried out to develop a diagnostic key for identification of the exuviae of [...] *S. meridionale* and *S. striolatum*. Until now, no reliable key has existed to differentiate the exuviae of these very similar species. Previous keys have suggested that they can be discriminated using dorsal and lateral spines, features which in our experience have proved to be very variable and unreliable. Therefore, we propose an experimental key which separates these species without reference to such spines. About two thirds of the exuviae of *S. meridionale* and *S. striolatum* can be separated by the ratio of the width of the submentum to the length of the mentum. The remaining third fall into an intermediate section but can be separated by using further ratios of morphological measurements. In our experience, using all the diagnostic features presented in this paper will allow exuviae of these species to be separated reliably." 6397. Stav, G.; Kotler, B.P.; Blaustein, L. (2007): Direct and indirect effects of dragonfly (*Anax imperator*) nymphs on green toad (*Bufo viridis*) tadpoles. *Hydrobiologia* 579(1): 85-93. (in English). ["We conducted an artificial pond experiment to assess the direct and indirect effects of predation on *Bufo viridis* tadpoles. We ran

three treatments: free Anax (unrestrained predatory dragonfly nymph Anax imperator), caged Anax (non-consumptive effects), and control (no Anax). Anax showed both strong consumptive and non-consumptive effects on Bufo tadpoles. Free Anax eliminated all of the tadpoles within six days. Tadpoles preferred the shady side of the ponds. Caged Anax caused tadpoles to increase their spatial preferences. Tadpoles avoided the center of the pond, and in the presence of the caged predator, they were found in the center even less. Tadpoles also showed a strong preference for crowding together, and in the presence of a caged Anax, they tended to crowd more. Moreover, Bufo metamorphosed earlier and at a larger size in the caged Anax ponds, possibly by providing extra food resources due to the extra organic matter excreted by the predators." 6398. Stoks, R.; De Block, M. (2007): Causes and costs of lamellae autotomy in damselfly larvae: a review. In: Tyagi, B.K. (Ed.): Odonata : Biology of Dragonflies. Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 241-255. (in English). ["Autotomy, the amputation of a body part at a breakage plane, is a well-known escape mechanism when animals are caught by a predator. Here, we review the ecological causes, field occurrence, and costs of lamellae autotomy in damselfly larvae. Lamellae autotomy is widespread in nature and is an important escape mechanism when caught by invertebrate predators and small fish, but has no survival advantage against large fish. However, associated with the other functions of lamellae, autotomy carries short-term costs in the form of a reduced ability to withstand low oxygen levels and high temperatures, and an increased vulnerability to conspecific and heterospecific predation. To deal with the latter, larvae show threat-sensitive antipredator behaviour after autotomy. The resulting reduced food intake together with their increased predator-induced stress, may explain negative effects on mass and size at emergence and wing asymmetry. Based on the known short-term costs, long-term costs on adult fitness and a regulatory role of autotomy in population regulation are likely, but await experimental proof." Jodhpur, Scientific Pub., 2007, xx, 368 pp., tables, figs., ISBN 81-7233-482-6: 257-271. (in English). ["The habitat distribution of endemic odonates of Western Ghats is studied based on field work and published literature. One hundred and seventy six species of odonates with 68 endemics are reported from the Western Ghats. The breeding habitats of 50 endemic species are known. The current field survey discovered new populations of three monotypic species from the region. Most of the endemic species are restricted to riverine habitats as compared to non-endemics. Streams flowing through evergreen forests and Myristica swamps support high diversity of endemics. Draining of Myristica swamps, diversion of streams for agricultu-

re and structural alterations are major threats to the conservation of endemic species of the region. Long term conservation of endemic odonate fauna of region should focus on conservation of riverine habitats of the region." 6402. Toms, R.B. (2007): Rooting the phylogenetic tree for winged insects: independent adaptations to terrestrial life. African Invertebrates 48(1): 203-211. (in English). ["Although numerous articles have been published on insect phylogeny using a great variety of techniques, there is no consensus on the nature of the first winged insects, the ancestors of holometabolous insects or the causes for the origin of metamorphosis. This discord has resulted in the lack of secure foundations within entomological theory. However, several recent articles provide key information which may help to resolve some of the long-standing disputes. Some biologists have argued that the first winged insects might have been amphibiotic rather than terrestrial and that metamorphosis might have originated as an adaptation to amphibiotic life. Thus entomological theory may now be passing through a paradigm shift where, for the first time, the phylogenetic tree for all insects may be firmly rooted." 6406. Ward, L.; Mill, P.J. (2007): Long range movements by individuals as a vehicle for range expansion in *Calopteryx splendens* (Odonata: Zygoptera). Eur. J. Entomol. 104(2): 195-198. (in English). ["(1.) Flight activity in zygopterans is generally restricted to short-range movements associated with foraging, reproductive activity and escape. Indeed, previous studies have suggested that *Calopteryx* species, including *C. splendens*, are relatively sedentary species, with a low tendency for long distance movements. (2.) Recent observations suggest that *C. splendens* is expanding its northern range in the UK; in the northeast the species is now well established in Northumberland and, in the northwest, has recently spread into south-west Scotland. The current study aimed to investigate the mobility and dispersal tendency of *C. splendens* in a well-established breeding population in NE England. (3.) A mark-release-recapture study was carried out on a population of *C. splendens* along a section of the River Wharfe, West Yorkshire, UK. 831 adult *C. splendens* were marked uniquely for individual identification in order to monitor the day-to-day, and overall, distance and direction of movement for each individual. Of these 381 were recaptured at least once. (4.) The majority of males (85%) and females (88%) moved a distance of 100 m or less and only five of the recaptured individuals (1.3%) moved a minimum distance in excess of 500 m. Although the median distance moved by males was greater than that for females, this was not significant. In addition, there was no significant difference in the number of either males or females moving upstream as opposed to downstream. (5.) The results are compared with those from other studies on calopterygid movement. Although most individual *C. splendens* stay within a suggested home range of approximately 300 m, clearly individuals have the potential to cover relatively long distances, and it is these latter movements that play a fundamental role in increasing the range of the species." 6407. Watts, P.C.; Rousset, F.; Saccheri, I.J.; Leblois, R.; Kemp, S.J.; Thompson, D.J. (2007): Compatible genetic and ecological estimates of dispersal rates in insect (*Coenagrion mercuriale*: Odonata: Zygoptera) populations: analysis of 'neighbourhood size' using a more precise estimator. *Molecular Ecology* 16(4): 737-751. (in English). ["Genetic and demographic estimates of dispersal are often thought to be inconsistent. In this study, we use *C. mercuriale* as a model to evaluate directly the relationship between estimates of dispersal rate measured during capture-mark-recapture fieldwork with those made from the spatial pattern of genetic markers in linear and two-dimensional habitats. We estimate the 'neighbourhood size' (N_b) - the product of the mean axial dispersal rate between parent and offspring and the population density - by a previously described technique, here called the regression method. Because *C. mercuriale* is less philopatric than species investigated previously by the regression method we evaluate a refined estimator that may be more applicable for relatively mobile species. Results from simulations and empirical data sets reveal that the new estimator performs better under most situations, except when dispersal is very localized relative to population density. Analysis of the *C. mercuriale* data extends previous results which demonstrated that demographic and genetic estimates of N_b by the regression method are

equivalent to within a factor of two at local scales where genetic estimates are less affected by habitat heterogeneity, stochastic processes and/or differential selective regimes. The corollary is that with a little insight into a species' ecology the pattern of spatial genetic structure provides quantitative information on dispersal rates and/or population densities that has real value for conservation management." (Authors)] Address: Watts, P. C.; School Biological Sciences, The Biosciences Building, Crown Street, University of Liverpool, Liverpool, L69 7ZB, UK. E-mail: p.c.watts@liv.ac.uk

6408. Watts, P.C.; Thompson, D.J.; Allen, K.A.; Kemp, S.J. (2007): How useful is DNA extracted from the legs of archived insects for microsatellite-based population genetic analyses?. *Journal of Insect Conservation* 11(2): 195-198. (in English). ["DNA obtained from museum specimens provides a historical perspective on levels of genetic diversity. Archived samples are irreplaceable so it is desirable that only parts of the specimens are used, which constrains the amount of DNA obtained from small taxa. However, at present there are no quantitative data on yields of DNA from such samples. In this paper we determine the amount of DNA that may be extracted from the legs of museum-archived specimens of the damselfly *Coenagrion mercuriale* (Charpentier) and the suitability of this DNA for PCR-amplification of nuclear genetic loci (microsatellites). We find that (i) the yield of DNA correlates with the genotyping success rate and (ii) the amount of DNA obtained from the legs decreases with time since sample collection until 1954, before which no DNA could be detected (although DNA may be present in very low quantities). This cut-off point for successful DNA extraction corresponds with the date until reliable genotypes could be obtained by routine PCR. Thus, air-dried insect legs more than 50 years old appear to have limited usefulness for studies that seek to amplify many nuclear loci without the use of other techniques that may be used to increase the possible low-quantities of template DNA present." This study quantified patterns of macroinvertebrate secondary production and stored benthic organic matter along a gradient of pollution and habitat channelisation over a 3-km reach of Goosefare Brook, a first-order stream in southern Maine (U.S.A.). 2. Whole-community invertebrate production decreased from 26.4 g ash-free dry mass (AFDM) m⁻² year⁻¹ at the reference station to 1.1 g AFDM m⁻² year⁻¹ at stations with the greatest levels of pollution. Production decreased along the pollution gradient for most taxa, although decreases were partly offset by production increases in tolerant taxa. Biomass turnover rates (P/B) were less affected by the stresses than was production. 3. Differences in functional characteristics of the community were evident at stations with channelised habitat, but overall production declined in a linear pattern that mirrored the pollution gradient. Stored organic matter showed a decline along the gradient, but was also lower at channelised stations. Populations of taxa with documented pollution tolerance were more likely to maintain or increase production and P/B. 4. Decreasing biomass because of decreasing stored organic matter and lethal effects of pollutants resulted in shifts in the pathways of energy flow observed at stations exposed to moderate physical or chemical stress, to the loss of most taxa and an extreme (96%) decrease in production at the stations receiving the highest levels of metal pollution. 5. The shifting prominence of different taxa along a continuum of stress in Goosefare Brook shows that describing the nature of an impairment in a functional context requires consideration of chemical stressors, habitat alterations and food resources." (Authors) The study includes data on "*Cordulegaster*" and "*Lanthus*".] Address: Woodcock, T.S., Dept of Biology, N3022 Science Building, Wilfrid Laurier University, 75 University Ave. W., Waterloo, Ontario, Canada, N2L 3C5. 6414. Wildermuth, H. (1997): Phänologie und Larvenhabitate von *Somatochlora flavomaculata* (VdL) in einem voralpinen Moorkomplex (Anisoptera: Corduliidae). *Libellula* 16(1/2): 17-32. (in German, with English summary). ["Based on sight observations, quantitative collections of exuviae and habitat analyses the emergence and flight period as well as the larval waters were investigated during a 13 year study near Zurich in the Swiss midlands. The emergence period lasted from the middle of May to the end of July, the flight period from the end of May to the end of September. Puddles, peat diggings and ditches revealed suitable larval habitats. These are shallow water bodies rather densely overgrown by emergent vegetation comprising different plant associations. The visual cue for the recognition of the various oviposition sites may consist of the homogeneous structure of the larval habitat indicating shallow water with organic mud ground and free of fish. The significance of male extraaquatic territories is shortly discussed with respect to habitat selection." (Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rütli, Switzerland. [Sachsen, Germany; remnant wings of *Calopteryx splendens* were found at a site the lizard *L. agilis* escaped from the approaching person.] Address: Brockhaus, T., An der Morgensonne 5, D-09387 Jahnsdorf, Germany. E-mail: T.Brockhaus@t-online.de

6416. Mason, W.T. (1998): Macrobenthic monitoring in the Lower St. Johns River, Florida. *Environmental Monitoring and Assessment* 50(2): 101-130. (in English). ["The macrobenthos in the oligohaline 132 km reach of the Lower St. Johns River, Florida, is an unusual blend of freshwater and marine organisms within the annelid, mollusc, aquatic insect, and crustacean groups. During 1993-1994, the community composition was freshwater oriented in the 47 km (seg I) and estuarine dominated in the lower 85 km (seg II). Of the total 146 taxa (including Odonata) collected, 89% were euryecious 'eutrophic' and 'pollution tolerant' organisms. Densities ranged between 5000 and 20 000 individuals/m² ann av and maximum densities (85 000 individuals/m²) occurred in the muck substrate at the confluence of major tributaries and embayments. Throughout the lakelike seg II, benthic hypoxia existed during much of summer through fall. Biotic index values for grab, artificial substrate, and sled trawl samples reflected greatest stresses to the macrobenthos then. Both low taxonomic diversity and densities of organisms at the most downriver stations nearest the port of Jacksonville indicated that toxic substances also adversely affected the macrobenthos. Maintenance of the narrow band of littoral submerged aquatic vegetation (SAV) and adjacent shoreline riparian vegetation is important to sustain macrobenthic communities and other kinds of aquatic life in the river." (Author)] Address: Mason, W.T., Southeastern Biological Science Center, National Biological Service, U.S. Department of the Interior, Gainesville, Florida, U.S.A.

6417. Watanabe, M.; Taguchi, M.; Ohsawa, N. (1998): Field study on population of the damselfly *Calopteryx japonica* (Odonata) using mark-release-and-recapture method as a technique for environmental education. Bulletin of the Faculty of Education, Mie Univ, Natural Science 49: 29-37. (in Japanese, with English summary). ["In order to clarify the population dynamics of *C. japonica*, the mark-release-and-recapture method was used for the population inhabiting in a small river in cool temperate zone of Japan, 1989 and 1990. The survey on the distribution of each adult perching was also carried out. The estimated daily number of males was 500 (1989), while that of females was 480 (1989). Then the operational sex ratio in each year was likely unity. The daily estimate number of immigrants in each year was low, and the daily survival rate was high. Therefore, the populations in both years were considered to be a closed population. The perching site of the damselfly depended upon the sunlit area on the shore line of the river. Along the shore line the perching site of males was shown as a clear random distribution, due to the territorial behaviour. The survey curriculum provided the basic understanding of concepts on mark-release-and-recapture method for high school students as well as undergraduate students. The damselfly used in this study allowed for the application and extension of the skills and knowledge of field ecology. These results were discussed as a teaching material for the damselfly in view point of the environmental education." 6423. Che Salmah, M.R.; Hassan, S.T.S.; Abu Hassan, A. (2000): Local movement and feeding pattern of adult *Neurothemis tullia* (Drury) (Odonata: Libellulidae) in a rain fed rice field. Tropical Ecology 41(2): 233-241. (in English, with Spanish and Portuguese summaries). ["The movements of *N. tullia* adults were studied in a rain fed rice field using the mark-release-recapture technique. Both male and female dragonflies were widely distributed within their home range of approximately 30 m radii. Adult movements were highly localized and the longest distance travelled was about 130 m. Diurnal feeding pattern was studied by examining gut contents. Some individuals had taken preys as early as 0730 hr. Feeding activity however, peaked at 1030 hr and at 1730 hr. Daily food intake was highly variable between sexes and within hours of the day. Females fed more actively in the morning and their body weights were heavier than that of males at all hours of the day. Active feeding activity of both sexes reflected effective predation." (Authors)] Address: Che Salmah, M.R., School of Biological Sciences, Universiti Sains Malaysia, 11800 Minden, Penang, Malaysia

6427. Sanchez, M.I.; Green, A.J.; Dolz, J.C. (2000): The diets of the White-headed Duck *Oxyura leucocephala*, Ruddy Duck *O. jamaicensis* and their hybrids from Spain. Bird Study 47: 275-284. (in English). ["We studied the gut contents of 17 White-headed Ducks, 25 North American Ruddy Ducks and 26 hybrids between the two species collected from 14 Spanish wetlands. This is the most detailed study to date of *Oxyura* diet in the Palearctic region. Food items from at least 27 families of invertebrates (including Odonata) and at least ten families of aquatic plants were identified. The method of collection of ducks and rapid digestion of soft-bodied invertebrates may have overestimated the importance of plant matter. However, animal foods were more important, constituting 73% of aggregate volume of gullet contents. In both duck species and their hybrids, benthic chironomid larvae and pupae were the most important food item, present in 69% of gullets and 75% of gizzards, and constituting 35% of aggregate volume and 26% of aggregate percentage in gullets. Angiosperm seeds were the next most important dietary component, and crustaceans (mainly Amphipoda, Cladocera and Isopoda) and green plant material were of secondary importance. No significant differences in diet were detected between duck species, sex or age classes. Birds sampled in the breeding season had more nematodes, but these may have been parasitic. Chironomids were less abundant in Ruddy Ducks collected from northern Spain outside of the range of the White-headed Duck." (Authors)] Address: Sanchez, Marta, Estación Biológica de Doñana, Avenida de María Luisa s/n, Pabellón del Perú, 41013 Sevilla, Spain

6428. Hlasek, J. (2001): Dragonflies of the Trebonsko PLA and BR. Ochrana Přírody 56(3): 71-74. (in Czech, with English summary). ["More than 50 dragonfly species have been recorded in the Trebonsko Protected Landscape Area and Biosphere Reserve. Although the area includes more than 465 fishponds larger than one hectare, species richness reflects mainly the high number of different types of water reservoirs. There are more than 500 permanent pools and remainders of meanders in the nature reserves in the Luznice and Nezárka river system. Dragonflies can be found also in the watered sandpits and peatbog mines. Various types of running waters are also very important, including both rivers and the extensive network of drains between fishponds. Last but not least, many reservoirs have been created by the PLA Administration as a part of conservation programmes. In the year 1999, 23 reservoirs were built. Dragonfly fauna of the Trebonsko region includes important populations of *Coenagrion lunulatum*, *Nehalennia speciosa*, *Lestes virens*, *Ophiogomphus cecilia*, *Cordulegaster boltonii*, *Aeshna subarctica*, *A. juncea*, *Brachytron pratense*, *Leucorrhinia dubia*, *Orthetrum albistylum* and *Sympetrum danae*." 6442. Roque, F.O.; Trivinho-Strixino, S.; Strixino, G.; Agostinho, R.C (2003): Benthic macroinvertebrates in streams of the Jaragua State Park (Southeast of Brazil) considering multiple spatial scales. *Journal of Insect Conservation* 7(2): 63-72. (in English). ["The study of the distribution of macroinvertebrates, considering multiple hierarchic scales and incorporating different spatial dimensions to assess the role of disturbance in aquatic environments, can contribute to conservation, environmental evaluation and improvement of analytical tools in ecology. The object of this study was to evaluate the diversity of macroinvertebrates in streams of the Jaraguá State Park (SP-Brazil), considering three spatial scales: mesohabitats, segments, and hydrographic basins with different land use parameters (forest, mixed agriculture, organic pollution and deforestation). The samples, collected with a Surber collector, were taken

in the beginning of the dry season of 1998. Analysis of data through multiple correspondence analysis showed the importance of variables in macroscale (land use) for the distribution of the fauna in general and the relevance of variability in mesoscale for some taxa in particular. The work points to the necessity of considering different levels of spatial heterogeneity for the conservation of biodiversity in the streams of the park." (Authors) Odonata are considered on the genus level.] Address: Roque, F.O., Programa de Pós Graduação em Ecologia e Recursos Naturais UFSCar, Brazil. E-mail: pfor@iris.ufscar.br

6445. Akamatsu, F.; Toda, H.; Okino, T. (2004): Food source of riparian spiders analyzed by using stable isotope ratios. Ecological Research 19: 655-662. (in English). ["We analyzed the food source of riparian spiders in a middle reach of the Chikuma River, Japan, by using stable isotope ratios of carbon and nitrogen. The carbon and nitrogen isotope ratios of attached algae were higher than those of terrestrial plants, reflecting a large carbon isotope fractionation in terrestrial plants and a difference in nitrogen sources. The carbon isotope ratios of terrestrial insects were similar to those of the terrestrial plants, and the ratios of aquatic insects were scattered between those of the terrestrial plants and the attached algae. The carbon and nitrogen isotope ratios of spiders were intermediate between those of the terrestrial and aquatic insects. The two-source mixing model using the carbon isotope ratio showed that the web-building spiders utilized both the terrestrial and aquatic insects, with large contribution by the aquatic insects (54% on average with a maximum of 92% among spider's taxa collected in each zone), in the riparian area in a middle reach of the Chikuma River. The large contribution of the aquatic insects was often observed for the spiders collected near river channel (<5 m) and for the horizontal web-building spiders collected across the riparian area. The relative contribution of the aquatic insects might be related with food availability (distance from river channel) and spider's food preference reflected in their web types (horizontal vs. vertical). Our results showed that organic materials produced in the river channel, in the riparian area, and in the

terrestrial area surrounding the riparian area were mixed at the carnivorous trophic level of riparian spiders." (Authors) "The $\delta^{13}\text{C}$ of Odonata (*Calopteryx japonica*) were lower than the average $\delta^{13}\text{C}$ of the other aquatic insects."] Address: Toda, H., Department of Environmental Sciences, Faculty of Science, Shinshu University, 3-1-1 Asahi, Matsumoto 390-8621, Japan. 6449. Colon-Gaud, J.-C.; Kelso, W.E.; Rutherford, D.A. (2004): Spatial distribution of macroinvertebrates inhabiting Hydrilla and Coontail beds in the Atchafalaya basin, Louisiana. J. Aquat. Plant Manage. 42: 85-91. (in English). ["Hydrilla [*Hydrilla verticillata* (L.f.) Royle] became established in the Atchafalaya River Basin (ARB) in south central Louisiana during the 1970s, and now dominates the submergent macrophyte community. We examined the potential effects of this shift in macrophyte composition on the distribution of phytomacrofauna by comparing water quality and macroinvertebrate assemblage structure in canopy and sub-canopy habitats at edge and interior locations within hydrilla and native coontail (*Ceratophyllum demersum* L.) beds during the latter stages of the 2001 flood pulse. Both plant species exhibited similar water quality characteristics during the study, with significantly higher temperature, dissolved oxygen, and pH levels in canopy habitats. Principal components analysis of log-transformed macroinvertebrate densities identified four assemblages that together accounted for 63.5% of the variation in the density data. The Gastropoda-Hydrachnida assemblage exhibited higher densities in coontail during May-June (declining river stages), and was more abundant at interior locations in both macrophyte beds during July (stable river stages). The Hemiptera-Amphipoda as-

semblage exhibited higher densities in the canopies of the two plants during both sampling periods, as did the Decapoda-Odonata assemblage in July. The Diptera-Coleoptera assemblage showed a similar trend in vertical distribution, as well as marginally higher densities in hydrilla beds. The continued spread of hydrilla throughout the ARB has reduced the diversity of macrophyte habitats available to phytophilous macroinvertebrates, and has resulted in pervasive hypoxia in the macrophyte sub-canopy over large portions of available littoral habitat, with significant impacts on the vertical distribution of littoral macroinvertebrates." 6450. De Armas, L.F. (2004): Nuevo registro de *Ceclithemis eponina* (Drury, 1773) para Cuba (Odonata: Libellulidae). Boln Soc. ent. aragon. 34: 228-229. (in Spanish, with English summary). [1 male, Bacunayagua, Matanzas prov., 9-III-2004. This is the 7th record of the N. American *C. eponina* for Cuba, and the 2nd for the province.] Address: De Armas, L.F., P.O. Box 4327, San Antonio de los Baños, La Habana-32500, Cuba

6451. Dogan Bora, N.; Gül, A. (2004): Feeding biology of *Silurus glanis* (L., 1758) living in Hirfanli Dam lake. Turk. J. Vet. Anim. Sci. 28: 471-479. (in English). [Stomach contents and feeding features of the European catfish, *S. glanis* living in Hirfanli Dam Lake were investigated. Recognizable organisms were found in the stomachs of 91 *S. glanis* out of 162 caught between September 1996 and August 1997. The following prey items were found: Gammarus (21.87%), Odonata (19.79%), Sander lucioperca (19.79%), Tinca tinca (18.76%), *Silurus glanis* (1.04%), and Gastropoda (1.04%). In addition, it was noted that 1.04% of the organisms found in the stomachs of *S. glanis* were Homoptera and 2.08% were the parasite Platyhelminthes.] Address: Gül, A., Department of Biology Education, Gazi Faculty of Education, Gazi University, 06500 Teknik Okullar, Ankara, Turkey.

6452. Hadrys, H.; Melber, A. (2004): Biodiversität und Artenschutz: Paradebeispiel Libellen. TiHo - Forschung fürs Leben. Das Forschungsmagazin der Stiftung Tierärztliche Hochschule Hannover. 2004: 32-34. (in German, with English summary). ["Biodiversity and conservation biology: dragonflies, the classic example." [...] One of the most important groups of insects used for developing conservation strategies and as a bioindicator for quality and stability of environments is the order Odonata. Due to the odonates' complex reproduction behaviour and very specific habitat preferences, progressive anthropogenic changes to the environment have severe consequences on many odonates. For example, numerous species exist only in small isolated populations. The genetic diversity, i.e. adaptability, of a species and the survival of single populations is much more rapidly detectable at the genotypic level than by phenotypical methods. Based on genetic information, it is also possible to quickly identify isolation processes that threaten a population. Molecular genetic methods are becoming increasingly important for animals conservation in that they provide essential information on the condition of populations, species and habitats. This is demonstrated by the following study on the biodiversity of African dragonflies." (Authors)] Address: Hadrys,

Heike, Institut für Tierökologie und Zellbiologie, Bunteweg 17, D-30559 Hannover, Germany. E-Mail: heike.hadrys@tiho-hannover.de

6453. Iwata, S.; Watanabe, M. (2004): Saline tolerance of young zygopteran larvae inhabiting the emergent plants community established in estuaries. Japanese journal of entomology. New series 7(4): 133-141. (in Japanese, with English summary). ["Eggs and young larvae of the endangered brackish water damselfly, *Mortonagrion hirosei*, were reared under various concentration of saline water, comparing with those of *Ischnura senegalensis*, *I. asiatica* and *M. selenion*, all of which inhabited the abandoned rice paddy fields near the habitat of *M. hirosei*, reed community. The hatchability of each species under high concentration of saline was low, and 20.PERMIL. of saline water did not allow to hatch in *I. asiatica* and *M. selenion*. The mortality of young larvae of each species was also increased with the concentration of saline, and 15.PERMIL. of saline water was harmful to survive for both *I. asiatica* and *M. selenion*. Saline seemed to affect the moulting of the young larvae. On the other hand, *M. hirosei* and *I. senegalensis* had similar saline tolerance at egg and young larval stages. Both species were considered to survive under brackish water, and then *M. hirosei* might be a prey of *I. senegalensis* when they co-existed in the fields. The conservation strategy for *M. hirosei* was discussed in view point of the artificially established reed community for the larval habitat." 6454. Langheinrich, U.; Tischew, S.; Gersberg, R.M.; Lüderitz, V. (2004): Ditches and canals in management of fens: opportunity or risk? A case study in the Drömling Natural Park, Germany. Wetlands Ecology and Management 12: 429-445. (in English). ["Up until the present, canals and ditches in Europe have been used to drain and thus devastate fens (lowland moors). However, in many cases, their function can be changed from drainage to irrigation and re-wetting of previously drained areas. These systems of canals and ditches are characteristic elements of the historically developed cultural landscape. Therefore, management and development plans should be oriented towards their continual maintenance. Despite the density of canals and ditches in many regions of Germany, especially of Eastern Germany, there are only a few studies to evaluate these systems of waterways, and an integrated approach towards their assessment has been totally absent. Existing approaches for typology and assessment of flowing waterbodies have been investigated in the Drömling Natural Park with regard to their applicability to such artificial canals and ditches. Special attention is given to the composition of macroinvertebrate fauna and the assessment of factors that determine it. Surprisingly, most water sectors have a high conservation value. High total numbers of species correlated well with the occurrence of endangered species. Among the macroinvertebrates, limnophilic and phytophilic species were dominant, but rheophilic fauna were also commonly present. This was caused by the intermediate status of canals and ditches, since they are neither completely flowing nor completely stagnant waterbodies. Habitat quality of these waters is determined by a small number of morphological parameters: bank

steepness, depth of bottom, substrate diversity, hydraulic structures, and the structure of surroundings. In the framework of management and development measures, they should be maintained and improved for the future. To assess water quality, the Saprobic index and the Chemical index were appropriate, but for indication of trophic status, the Macrophyte-trophic index was adequate. Estimation of ecological integrity by a multi-metric index using macroinvertebrates indicates that waterbodies are in a good status according to the demands of the European Water Framework Directive." (Authors) The study includes a regional checklist of Odonata..] Address: Langheinrich, Uta, Dept of Water Management, University of Applied Sciences Magdeburg, Breitscheidstr. 2, D-39114 Magdeburg, Germany. 6455. Maeto, K.; Sato, S. (2004): Odonata habitats in the Shimanto River Basin - *Aquabiology* 26(6): 522-527. (in Japanese, with English summary). ["We studied the habitat of Odonata in the Shimanto River basin in Shikoku, Japan. We conducted a correspondence analysis (CA) of 88 species observed at 455 grid sites (ca. 0.5km*0.5km). Multiple regression analyses of the two main axes of the CA ordination on the geographical features (altitude, relief) and vegetation of grid sites indicated that the degree of relief and the areal proportion of paddy fields were the main determinants of the species distribution of Odonata. The Odonata species appearing in the Red Data Book of Kochi Prefecture were evaluated based on their recent tendency of occurrence. Several indicator species for environmental monitoring were selected on three landscapes (i.e. mountain, hill foot and plain) according to the endangered level and the requirement of water quality of each species. 6456. Nakagawa, M.; Motobayashi, T.; Arai, Y.; Nishimura, T. (2004): Ecology of eggs of *Gynacantha japonica* Bartenev in paddy fields. *Transactions of the Japanese Society of Irrigation, Drainage and Reclamation Engineering* 72(1): 71-77. (in Japanese, with English summary). ["*G. japonica* often inhabits paddy fields and passes the winter at the egg stage in soil of paddy fields. It had been seen often, but a marked decrease in density has been reported. In this paper, dormancy and hatching conditions were studied in eggs of *G. japonica*. Diapause eggs showed relatively high tolerance against drying condition, while post-diapause eggs in spring were sensitive to drying history. Hatching of the post-diapause eggs was promoted by receiving light stimulus under ponding condition. It was considered that changes in physical conditions, especially moisture condition, of paddy fields by farm land consolidation and increase in number of fallow paddy fields may result in decrease of number in *G. japonica*." 6457. Pankratius, U. (2004): Moosjungfern im Aischgrund und im Nürnberger Reichswald. *Galathea* 20(2): 75-110. (in German, with English summary). [Bavaria, Germany; *Leucorrhinia dubia*, *L. pectoralis*, and *L. rubicunda* were studied at more than 120 water bodies. Special emphasis was given to records of exuviae. The results are compared to older published regional records. Conservation measures are discussed ex-

tensively.] Address: Pankratius, U., Allensteiner Straße 6, D-90766 Fürth, Germany

6458. Penalver, E.; Delclos, X. (2004): Insectos del Mioceno inferior de Ribesalbes (Castellón, España). *Interacciones planta-insecto*. *Treb. Mus. Geol. Barcelona* 12: 69-95. (in Spanish, with English summary). ["This paper carries out the study of ichnofossils originated by insects found in the Lower Miocene locality of "La Rinconada", near Ribesalbes (Province of Castellón, Spain). The main fossil record is integrated by plant-insect interactions that are observed in leaves and leaflets: ovipositions, mines and a chew mark. The insect ovipositions, on leaves of *Laurophyllum*, *Caesalpinniaceae* and *Populus*, show ovate to oblong eggs with 0.9-1.1 mm length and 0.2-0.3 mm width. They occur in eccentric arcs, sometimes with a zigzagged pattern. These ovipositions were produced by damselflies of the family *Coenagrionidae*. Insect mines are reported in leaves of *Laurophyllum* and *Celtis?*, and show a blotch shape in *Laurophyllum* sp., with a channel-structure, and a linear shape in *Celtis* sp.? Insect larvae, which were endophytophagous, i.e. internal plant parasites, produced these channel marks of leaf-mines. The mine patterns observed in *Laurophyllum* leaf are similar to those produced by the recent larvae of the *Nepticulidae* (Lepidoptera). Such a diverse set of plant-insect interactions are uncommon in the fossil record. In addition, one level with bioturbation, possibly produced by aquatic larval chironomids, is also described here." 6462. Zivic, I.; Markovic, Z.; Brajkovic, M. (2004): Impact of waste-waters from mind „Lece“ on diversity of macrozoobenthos in the Gazdarska Reka River, right-hand tributary of the Jablanica Reka River. *Proceedings of the 2nd Congress of Ecologists of the Republic of*

Macedonia with International Participation, 25-29.10.2003, Ohrid. Special issues of Macedonian Ecological Society, Vol. 6, Skopje: 247-251. (in English). ["Investigations of impact of wastewaters from mind „Lece“ on diversity of macrozoobenthos in the Gazdarska reka River (a right-hand tributary of the Jablanica reka River) were conducted during years 2001 and 2002. The bottom fauna was composed of 14 groups of macroinvertebrates with 73 determined taxa. The most varied groups were the insect orders Trichoptera (17 taxa), and Diptera (13), Plecoptera (11), Coleoptera (10) and Ephemeroptera (9), while the most uniform were insects belonging to classes Hirudinea, order Odonata and family Ancilidae Larvae belonging to insect orders Ephemeroptera, Plecoptera and Trichoptera were dominant in benthocenosis at first and second localities. These localities were characterized by highest values of diversity index, 3.2 and 3.0 respectively. Due to emptying of wastewater from mind „Lece“ at third locality value of diversity index abruptly dropped to 0.1 due to capacity of the river for self-purification, the variety of benthocenosis increases at localities downstream from locality 3." 6468. Cicort-Lucaciu, A.-S.; Ardeleanu, A.; Cupsa, D.; Naghi, N.; Dale (2005): The trophic spectrum of a *Triturus cristatus* (Laurentius 1768) population from Plopiis Mountains area (Bihor County, Romania). *North-Western Journal of Zoology* 1(1): 31-39. (in English). [Crested newts eat mainly invertebrates, but may also ingest vegetal particles, amphibian eggs or shed skins. Besides the shed skins of conspecific individuals, we have also identified shed skins of *Bombina variegata*, and even of *Lacerta agilis*. Due to the particular morphology of the habitat, the warm season brings about differences in the accessibility of different prey categories from one part to another of the Sinteu pond. This difference in the potential food spectrum alters the newts' diet, leads to a change into the "sit-and-wait"

feeding strategy, increase the number of hungry individuals, and indicates a decrease in the preying capacity of newts that prepare to leave the aquatic environment. Quantitatively, the most important prey taxa to the studied population are tadpoles and Nematocera larvae." (Authors) Larvae of Odonata account up to 16.75% of food items.] Address: Cicort-Lucaciu, A.-S.; University of Oradea, Faculty of Science, Romania, alfredcicort@yahoo.com

6469. DeWalt, R.E.; Favret, C.; Webb, D.W. (2005): Just how imperiled are aquatic insects? A case study of stoneflies (Plecoptera) in Illinois. *Ann. Entomol. Soc. Am.* 98(6): 941-950. (in English). ["Nearly 5,000 historical and contemporary specimen records of stoneflies (Plecoptera) from Illinois demonstrated that this fauna is highly imperiled, boding poorly for aquatic insect communities in North America and elsewhere. Losses include two extinctions of endemics and 20 extirpations of 77 total species, a rate of loss that is higher than for either mussels or fish in Illinois. Another 19 species (24.7%) were designated as critically imperiled, being known from five or fewer locations. Two families, Perlidae and Perlodidae, experienced the greatest number of losses. Species lost were mostly those with longer life cycles and direct egg hatch. Three historically hyperdiverse regions were identified and losses in all 14 natural divisions were documented. Large river habitats and historically prairie regions have experienced the greatest proportional losses of species. This scenario probably follows for Ephemeroptera, Trichoptera, and Odonata in the Midwest and in other areas with similar glacial and cultural histories." (Author) The paper contains some references to the Odonata.] Address: DeWalt, R.E., Illinois Natural History Survey, Center for Biodiversity, 607 E. Peabody Drive, Champaign, IL 61820

lish summary). ["Between 1999 and 2001, the first part (36 ha) of the former Heerenveen fenland area in the De Hamert national park was restored. This fenland lies between old river dunes along the river Meuse and old sediments deposited by the river Rhine. It was part of an extensive fenland area along the Dutch-German border between the towns of Venlo and Genneep. Reclamation for agricultural purposes started about a century ago by drainage and peat harvesting. Opportunities for restoration seemed favourable because groundwater flows from the Rhine terrace are largely intact. Problems of water pollution from nearby agricultural fields were not to be expected because of the upstream position of the area. The Heerenveen fen was restored by removing the top layer of fertilised soil. Drainage was stopped by filling in ditches. The flora and fauna in the restoration area were surveyed between 2000 and 2003. Typical plants of soft water habitats, like the rare *Ranunculus ololeucos*, returned. Many amphibian species benefited from the large area of new wetland." (Authors) At least 23 Odonata species could be found. Species of early succession states of habitat development as *Ischnura pumilio* and *Sympetrum fonscolombii* are stressed.] Address: Kurstjens, G., Ecologisch adviesbureau, Col. Ekmanstr. 15, NL-6573 BM Beek-Ubbergen, The Netherlands

6476. Nagy, B.; Székely, A.; Szállassy, A. (2005): Site fidelity and fluctuating asymmetry in males of *Libellula fulva* (Odonata: Libellulidae). *Entomol. rom.* 10: 59-64. (in English, with Romanian summary). ["During two seasons (2002-2003), a closed *Libellula fulva* (Müller, 1764) population was studied along a small, canalized creek in Eastern Hungary. The territorial behaviour of males was observed with the mark-recapture method. A number of 169 males were marked in 2002, and 186 males in 2003. The movement of marked males was observed with binoculars, and was recorded along a 350 meter natural section of the stream that was marked every five meters with numbered sticks. The site fi-

delity of males was studied with the localisation index (LI) and site fidelity index (SFI). We found that the SFI of males that simultaneously defended three territories was high, while the LI was highest in the case of males that protected only one area. The purpose of the study was to see if male's site fidelity is related to wing asymmetry and body size. There was no correlation between male's site fidelity and the measure of wing asymmetry in 2002. In 2003, however, a significant correlation was found in the case of males which defended only one territory. There was no correlation between body size and SFI." 6478. Quiroz-Martinez, H.; Rodriguez-Castro, V.A.; Solis-Rojas, C.; Ma (2005): Predatory capacity and prey selectivity of nymphs of the dragonfly *Pantala hymenaea*. *J. Am. Mosq. Control. Assoc.* 21(3): 328-330. (in English). ["Predatory capacity and prey selectivity of nymphs of *P. hymenaea* were evaluated on larvae of the mosquito *Culex quinquefasciatus* (Diptera: Culicidae) and larvae of the midge *Chironomus plumosus* (Diptera: Chironomidae) as prey. With functional response methodology, 7 larval densities were exposed to predator individuals in a glass jar under laboratory conditions. The study was performed in 2 experiments. The 1st was a test system with each prey species alone. The 2nd tested a mixture of both prey species in a 1:1 ratio. Prey selectivity and prey capacity were significantly greater on midge larvae than on mosquito larvae." 6479. Robb, T.; Forbes, M.R. (2005): Success of ectoparasites: how important is timing of host contact?. *Biology Letters* 1: 118-120. (in English). ["Hosts often differ in their degree of parasitism and their expression of resistance. Yet very little is known about how the availability (and allocation) of resources to parasites at pre-infective stages influences their success in initiating parasitism, or in inducing and succumbing to resistance from hosts. We studied a damselfly-mite association to address how experimental variation in the age of first contact with hosts (timing) influenced subsequent parasite fitness. We demonstrate that timing influenced the ability of larval mites to make the transition to parasitism, but was not associated with measures of physiological resistance by hosts. Timing presumably relates to the availability of resources remaining for individuals to exploit their hosts. More research is needed on the importance of such factors, from variation in host resistance and parasite success and, ultimately, to the numbers and distributions of parasites on hosts." 6482. Szymkowiak, P.; Tryjanowski, P.; Winięcki, A.; Grobelny, S.; Kon (2005): Habitat differences in the food composition of the wasp-like spider *Argiope bruennichi* (Scop.) (Aranei: Araneidae) in Poland. *Belg. J. Zool.*, 135(1): 33-37. (in English). ["During the last few decades the wasp-like spider *Argiope bruennichi* Scopoli, 1772 expanded its wide geographical distribution in Europe. In this paper we describe and test differences in the diet composition of the wasp-like spider inhabiting a river valley (traditional habitat) and xerothermic grassland (new habitat) in Poland. From a total of 163 webs of *A. bruennichi*, 430 prey items were found, mainly insects: Coleoptera, Diptera, Homoptera, Heteroptera, Hymenoptera, Lepidoptera, Mecoptera, Odonata, Orthoptera and Neuroptera. Moreover, a semi digested specimen of the common frog *Rana temporaria* was recorded. Habitats differed significantly in the percentage distribution of eleven general food categories. Among potential influencing factors the number of caught prey was correlated only with the height of the web hub above the ground. The wasp-like spider is ecologically flexible in the use of novel food spectra and this probably allows the colonisation of new localities, as well as habitats." (Authors) The most numerous spe-

cies caught in the webs of the river valley population of *A. bruennichi* was *Ischnura elegans*. *Sympetrum sanguineum* was also among the prey of the spider.] Address: Szymkowiak, P., Department of Animal Taxonomy and Ecology, Adam Mickiewicz University, Umultowska 89, 61-614 Poznań, Poland. 6483. Thomas, J.A. (2005): Monitoring change in the abundance and distribution of insects using butterflies and other indicator groups. *Phil. Trans. R. Soc. B* (2005) 360: 339–357. (in English). ["Conservative estimates suggest that 50–90% of the existing insect species on Earth have still to be discovered, yet the named insects alone comprise more than half of all known species of organism. With such poor baseline knowledge, monitoring change in insect diversity poses a formidable challenge to scientists and most attempts to generalize involve large extrapolations from a few well-studied taxa. Butterflies are often the only group for which accurate measures of change can be obtained. Four schemes, used successfully to assess change in British butterflies, that are increasingly being applied across the world are described: Red Data Books (RDB) list the best judgements of experts of the conservation status of species in their field of expertise; mapping schemes plot the changing distributions of species at scales of 1–100 km²; transect monitoring schemes generate time series of changes in abundance in sample populations of species on fixed sites across the UK; and occasional surveys measure the number, boundaries and size of all populations of a (usually RDB) species at intervals of 10–30 years. All schemes describe consistent patterns of change, but if they are to be more generally useful, it is important to understand how well butterflies are representative of other taxa. Comparisons with similarly measured changes in native bird and plant species suggest that butterflies have declined more rapidly than these other groups in Britain; it should soon be possible to test whether this pattern exists elsewhere. It is also demonstrated that extinction rates in British butterflies are similar to those in a range of other insect groups over 100 years once recording bias is accounted for, although probably lower than in aquatic or parasitic taxa. It is concluded that butterflies represent adequate indicators of change for many terrestrial insect groups, but recommended that similar schemes be extended to other popular groups, especially dragonflies, bumblebees, hoverflies and ants. Given institutional backing, similar projects could be employed internationally and standardized. Finally, a range of schemes designed to monitor change in communities of aquatic macro-invertebrates is described. Although designed to use invertebrates as a bio-indicator of water quality for human use, these programmes could be extended to monitor the 2010 biodiversity targets of the World Summit on Sustainable Development." (Author)]. Address. not stated.

6484. van Buggenum, H.J.M.; Hannen, J.; Hermans, J.T.; Heijligers, H.W (2005): Fauna and water table drawdown in Limburg. *Natuurhistorisch maandblad* 94 (11): 253–258. (in Dutch, with English summary). ["Water table drawdown is one of the main causes of the extinction and decline of animal species in wet environments. Paradoxically, however, raising water levels to combat drawdown is currently causing a further decline of several species. For a long time, it was thought that re-establishment of the former vegetation would auto-

matically lead to a return of the original fauna. Unfortunately, the relation between the environment and the presence of animal species seems much more complex than was thought. The restoration of areas that had become desiccated in the past has often involved measures being taken over a large area and within a short time. An example is the Mariapeel, a wetland in the west of the province of Limburg, where drastic large-scale restoration measures have caused breeding and foraging areas for birds to disappear. Fortunately, fauna is now beginning to receive more attention. The article discusses the relation between measures to combat water table drawdown and water-dependent shrews, birds, dragonflies, amphibians, reptiles and land snails." (Authors) The article stresses on *Cordulegaster boltonii*, and gives a map with distribution data of *C. boltonii*, *Calopteryx virgo*, and *Orthetrum coerulescens* in the Limburg province, The Netherlands.] Address: Hermans, J.T.; Hertestraat 21, NL-6067 ER Linne, The Netherlands

6485. van Schaik, V.A.; Geraeds, R.P.G. (2005): Yellow-legged clubtail along the river Roer. The settlement of a new population in the province of Limburg. *Natuurhistorisch maandblad* 94(2): 33–36. (in Dutch, with English summary). ["Dragonflies along the river Roer have been monitored since 1999. Surveys in 2000 resulted in three sightings of *Stylurus flavipes*. The first exuviae of the species were found during a survey by boat in 2002. This was the first time that this species was proved to have reproduced in the river Roer. During 2002 and 2003, 46 exuviae were collected. These results show that the species has established itself along the river Roer. The dispersion of *S. flavipes* is associated with the lower reaches of larger streams. Since the river Roer is a small river, the habitat is different from those where this species is usually found in the Netherlands." 6486. Verbeek, P.J.M.; Scherpenisse-Gutter, M.C. (2005): Restoration of flora and fauna at the Haselaarsbroek Nature Reserve. *Natuurhistorisch maandblad* 94(11): 232–237. (in Dutch, with English summary). ["Restoration measures taken in 1996 have transformed the Haselaarsbroek, a nature reserve in the province of Limburg, The Netherlands from an artificially forested woodland to a very rich nature reserve, whose appearance resembles its original state before the afforestation. The measures have led to a highly valuable vegetation. The seepage zone is especially interesting, featuring several hectares of newly developed peatland. Many red-listed plant species have colonised the new area. Because of its many types of water body, the area is now very rich in dragonfly species. It is probably among the richest dragonfly areas in the Netherlands, and the seepage zone is particularly important for several endangered species. Further management of the area will be crucial. A major problem is that of encroachment by tree saplings. Management in the coming years will be improved by increasing the number of grazing cattle and cutting down trees and shrubs." (Authors) 44 Odonata species are listed in Table 2.] Address: Verbeek, P.J.M., Bureau Natuurbalans-Limes divergens BV, Postbus 31070, NL-6503 CB Nijmegen, The Netherlands

6487. Wang, J.Z. (2005): Dissecting insect flight. *Annual Review of Fluid Mechanics* 37: 183–210. (in

English). ["What force does an insect wing generate? Finding answers to this enduring question is an essential step toward our understanding of interactions of moving objects with fluids that enable most living species such as insects, birds, and fish to travel efficiently and us to follow similar suit with sails, oars, and airfoils. We give a brief history of research in insect flight and discuss recent findings in unsteady aerodynamics of flapping flight at intermediate range Reynolds numbers (10–104). In particular, we examine the unsteady mechanisms in uniform and accelerated motions, forward and hovering flight, as well as passive flight of free-falling objects. The results obtained by "taking the insects apart" helped us to resolve previous puzzles about the force estimates in hovering insects, to elucidate basic mechanisms essential to flapping flight, and to gain insights about the efficiency of flight." (Author). This review article includes many notes on dragonflies.] Address: Wang, Z. Jane, Theoretical and Applied Mechanics, Cornell University, Ithaca, New York 14853, USA. E-mail: z.jane.wang@cornell.edu

6488. Williams, D.D. (2005): Temporary forest pools: can we see the water for the trees?. *Wetlands Ecology and Management* 13: 213-233. (in English). ["Temporary waters, in general, are fascinating habitats in which to study the properties of species adapted to living in highly variable environments. Species display a remarkable array of strategies for dealing with the periodic loss of their primary medium that sets them apart from the inhabitants of permanent water bodies. Survival of individuals typically depends on exceptional physiological tolerance or effective migrational abilities, and communities have their own, distinctive hallmarks. This paper will broadly overview the biology of temporary ponds, but will emphasize those in temperate forests. In particular, links will be sought between aquatic community properties, the nature of the riparian vegetation, and forestry practices. Quite apart from their inherent biological interest, temporary waters are now in the limelight both from a conservation perspective, as these habitats come more into conflict with human activities, and a health-control perspective, as breeding habitats for vectors of arboviruses. Traditionally, many temporary waters, be they pools, streams or wetlands, have been considered to be 'wasted' areas of land, potentially convertible to agriculture/silviculture once drained. In reality, they are natural features of the global landscape representing distinct and unique habitats for many species – some that are found nowhere else, others that reach their maximum abundance there. To be effective, conservation measures must preserve the full, hydroseral range of wetland types." (Author) The study includes Odonata.] Address: Williams, D.D., Surface & Groundwater Ecology Research Group, Department of Life Sciences, University of Toronto at Scarborough, 1265 Military Trail, Scarborough, Ontario, Canada M1C 1A4. 6489. Abellán, P.; Sánchez-Fernández, D.; Millán, A.; Botell, F.; Sánc (2006): Irrigation pools as macroinvertebrate habitat in a semi-arid agricultural landscape (SE Spain). *Journal of Arid Environments* 67(2): 255-269. (in English). ["The intensification of agriculture has

resulted in the loss of many aquatic ecosystems in southern Europe. Despite this, the construction of irrigation pools and reservoirs to retain the water necessary for intensive cultivation may also provide new habitats for macroinvertebrates. The biotic and abiotic attributes of 40 such reservoirs in south-eastern Spain were studied to determine the presence of macroinvertebrates, and to discover if there is such a thing as an optimal design of an artificial pond for maximizing macroinvertebrate richness. A total of 72 macroinvertebrate taxa (including Odonata) belonging to 38 families were recorded from the pools examined. Pools constructed with low-density polyethylene covered with sand and stones contained a significantly greater species richness, abundance and diversity of macroinvertebrates than those constructed with high-density plastic materials. The treatment with algicide, and the presence of emergent and submerged vegetation, accounted for most of the deviance when modelling species richness by means of logistic regression." 6491. Alvarez, D.; Nicieza, A.G. (2006): Factors determining tadpole vulnerability to predators: can prior experience compensate for a suboptimal shape?. *Evolutionary Ecology* 20(6): 523-534. (in English). ["We investigated the role of constitutive morphology and previous experience in predator avoidance in two anuran species associated with different larval habitats. In *Rana temporaria*, deeper tails and larger body size conferred selective advantage against dragonfly (*Aeshna cyanea*) predation. Previous experience with predators had a positive influence on the survival of *R. temporaria* tadpoles equivalent to predator selection. By contrast, survival in *Bufo bufo* seems unrelated to tail shape or experience. This suggests that *B. bufo* lacks constitutive morphological defenses against insect predators, and that morphological and behavioral defenses could result more effective than chemical deterrents for these insect predators. A key novelty of this study is the observation that *Rana* tadpoles having prior experience with predators have an enhanced success in further encounters, and this occurs before the morphological induced defense has been established. This induced modification for *R. temporaria*, and its lack of for *B. bufo*, may be an important determinant of larval survival." - 6496.** Anteau, M.J.; Afton, A.D. (2006): Diet shifts of lesser scaup are consistent with the spring condition hypothesis. *Canadian Journal of Zoology* 84(6): 779-786. (in English). ["We compared diets of lesser scaup (*Aythya affinis* (Eyton, 1838)) in the springs of 2000 and 2001 to those reported in the 1970s and the 1980s to determine whether forage quality has declined as predicted by the spring condition hypothesis. In Minnesota, we found that the current aggregate percentage of Amphipoda (an important food item) in lesser scaup diets was 94% lower than that reported from the same locations in the 1980s. Current mean individual prey mass of Amphipoda and *Bivalvia* in Minnesota were 86.6% and 85.1% lower than historical levels, respectively. In Manitoba, current aggregate percentages of Trichoptera and Chaoboridae in lesser scaup diets (1% and 0%, respectively) were lower than those reported from the same location in the 1970s (14% and 2%, respectively), whereas the percentage of Chironomidae (40%) was higher than that of historical levels (19%). Current mean individual prey mass of all insects, seeds, Chironomidae, and Zygoptera in Manitoba were 63.5%, 65.4%, 44.1%, and 44.9% lower than those of historical levels, respectively. The observed dietary shift from Amphipoda to less nutritious prey in Minnesota, coupled with lower mean individual prey mass in both locations, likely constitutes lower forage quality in lesser scaup diets, which is consistent with the spring condition hypothesis." - 6497.** Baixeras, J. (coord.) (2006): *Les Libèl·lules de la comunitat Valenciana*. Generalitat Valenciana. ISBN 84-482-4248-3: 170 pp. (in Spanish, with English, Portuguese and Catalan summaries). [This book "is the result of a two years study funded by the Conselleria de Territori i Habitatge of the Valencian Government in Spain. The main research institutions involved have been the Cavanilles Institute of Biodiversity and Evolutionary Biology of the University of Valencia, the Iberoamerican Center for Biodiversity of the University of Alicante and the Department of Biology of Organisms and Systems of the University of Oviedo as well as a remarkable number of external collaborators. The aims of the project have been to produce a checklist of the Valencian insects of the order Odonata, study the distribution and detect problems of conservation that may be affecting the populations. The first data of odonates of the Valencian Community correspond to works by Boscá (1916), Navás (1922) and Pardo (1942). Some species of great interest are recorded for the first time in some of these works. It is the case of *Macromia splendens*, just recorded in 1923 and *Lindenia tetraphylla*, never recorded since 1965. Later works by Docavo Alberti (1983), Navarro et al. (1988), Bonet Betoret (1990) and Domingo Calabuig (2002) gather a total number of 42 species, whose records are mainly concentrated in the province of Valencia. The present work increases the list in 16 species, completing a catalogue of 58 species that presumably will be increased in the future. During the years 2003 and 2004, 225 localities of the three Valencian provinces (Castellon, Valencia and Alicante) were visited. More than 3.000 specimens of 53 species were examined; five species known from the area were not found. Different habitats were targeted for the selection of the sampling localities, from high mountains to lowlands, from streams to lakes. Some of the species deserved some attention. It is the case of protected or scarce species like *Calopteryx virgo*, *Coenagrion mercuriale*, *C. puella*, *Gomphus simillimus*, *G. graslini*, *Oxygastra curtisii*, *Orthetrum nitidinerve* and *Zygonyx torridus*. Two interesting species, previously recorded from the area have not been found, it is the case of *Lindenia tetraphylla* and *Macromia splendens*. Some sections devoted to habitat and conservation problems in the species have been included in the book. The habitats of low altitude, mainly represented by marshes and river mouths are the aquatic ecosystems more polluted and

the occurring fauna is composed by poorly demanding species. The study confirms the expansion of *Trithemis annulata* and *Selysiothemis nigra*, at present two relatively frequent species. The conservation of the middle courses of the rivers is much better. This is the Level that shows the highest degree of transitions. Typical species associated to this habitat are *Calopteryx haemorrhoidalis*, *C. xanthostoma*, *C. caerulescens*, *Ischnura elegans*, *Ceragrion tenellum*, *Platycnemis iatipes*, *Pyrrhosoma nymphula*, *Cordulegaster bottonii*, *Onychogomphus forcipatus*, *O. uncutus*, *G. graslinii*, *G. similimus* and *Orthetrum coerulescens*. It is also possible to find a wide range of species in connection with inland pools or stagnant waters. Typical species of this group are: *Enallagma cyathigerum*, *Coenagrion caerulescens*, *C. scitulum*, *Lestes virens*, *L. barbarus*, *L. viridis*, *L. dryas*, *Ischnura graellsii*, *I. pumilio*, *Libellula depressa*, *Orthetrum cancellatum*, *Crocothemis erythraea*, *Symptetrum meridionale* and *S. striolatum*. Finally the best preserved area is found between 500 and 1.000 m altitude. This is a range only found in deep inland areas, and includes species like *I. graellsii*, *C. mercuriale*, *C. xanthostoma*, *C. virgo*, *P. latipes*, *P. nymphula*, *O. uncutus*, *O. forcipatus*, *A. affinis*, *A. cyanea*, *O. curtisii*, *O. brunneum* and *Boyeria irene*. The core of this work is represented by a collection of files devoted to the 58 species occurring in the Valencian Community. The inclusion of the species in red books and the legal status is indicated for every species. Every species includes some comments on morphology and biology, distribution, habitat and present situation of the populations, threats and conservation actions recommended by the authors when necessary. A distribution map in UTM squares of 100 km² (10x10 km) is given for every species. The records based in bibliographical data are indicated by a blue dot, the records based in our own material are indicated by a red square. The text finished with an exhaustive list of references on the theme." 6498. Bal, D.; Groenendijk, D. (2006): Consequences of the Habitats Directive for the legal protection of dragonflies in The Netherlands. *Brachytron* 9(1-2): 38-48. (in Dutch, with English summary). ["The European Habitats Directive offers an import framework for national legislation concerning nature conservation. Several species of dragonflies (Odonata) have been incorporated in the annexes of this directive. Of the twelve dragonfly species of Annex IV eight species are indigenous in The Netherlands. In accordance with the directive these eight species are protected by the Dutch Flora Fauna Act. Of the nine dragonfly species of Annex II, four species are indigenous in The Netherlands, but only two have populations at the moment: *Leucorrhinia pectoralis* and *Ophiogomphus cecilia*. Therefore, only for these two species Special Protection Areas will be assigned under the Nature Conservation Act, as part of the European Natura 2000 network. The conservation status of both species is 'unfavourable - bad', so measures have to be taken to ensure that the status will become 'favourable'. Several other dragonfly species will be selected as 'typical species' of habitat types and, therefore, will become an important indicator for the quality of many Dutch Nature 2000 sites." 6499. Balik, I.; Cubuk, H.; Karasahin, B.; Ozkok, R.; Uysal, R.; Alp, (2006): Food and feeding habits of the pikeperch, *Sander lucioperca* (Linnaeus, 1758), population from Lake Egirdir (Turkey). *Turkish Journal of Zoology* 30(1): 19-26. (in English, with Turkish summary). ["The stomach contents of 986 pikeperch, collected from Lake Egirdir in Turkey were investigated between March 2001 and February 2002. Thirteen taxonomic categories were identified from the 1745 prey items analysed. It was determined that the diet of pikeperch in Lake Egirdir consisted of some fish species (*Knipowitschia* sp., *Aphanius anatoliae* *anatoliae*, *Gambusia affinis*, *Nemacheilus lendli*, *Carassius gibelio*, and *Sander lucioperca*), odonats (*Calopteryx splendens*), mysids (Mysis), amphipods (*Gammarus*) and dipterans (*Chironomus*). Of these prey categories, fish was more important than the others. In particular, *Knipowitschia* sp. and *A. a. anatoliae* were the primary prey for the pikeperch. The proportions of vertebrates and invertebrates in the diet composition of pikeperch in the 150-190 mm length class were found roughly equal. The importance of vertebrates (especially prey fish) in the diet of the pikeperch in Lake Egirdir increased with increasing body size of fish, but, at the same time, the importance of invertebrates decreased. Pikeperch longer than 300 mm consumed only fish, frogs and odonats. The cannibalism rate was 0.6%. In addition, it was found that the diet of the pikeperch in Lake Egirdir considerably changed from season to season." 6501. Bonada, N.; Rieradevall, M.; Prat, N.; Resh, V.H. (2006): Benthic macroinvertebrate assemblages and macrohabitat connectivity in Mediterranean-climate streams of northern California. *Journal of the North American Benthological Society* 25(1): 32-43. (in English). ["Drought leads to a loss of longitudinal and lateral hydrologic connectivity, which causes direct or indirect changes in stream ecosystem properties. Changes in macrohabitat availability from a riffle-pool sequence to isolated pools are among the most conspicuous consequences of connectivity loss. Macroinvertebrate assemblages were compared among 3 distinct stream macrohabitats (riffles [R], pools connected to riffles [Pc], disconnected pools [Pd]) of 19 Mediterranean-climate sites in northern California to examine the influence of loss of habitat resulting from drought disturbance. At the time of sampling, 10 sites were perennial and included R and Pc macrohabitats, whereas 9 sites were intermittent and included only Pd macrohabitats. Taxa richness was more variable in Pd, and taxa richness was significantly lower in Pd than in Pc but not R. These results suggested a decline in richness between Pc and Pd that might be associated with loss of connectivity. Lower Ephemeroptera, Plecoptera, and Trichoptera (EPT) richness relative to Odonata, Coleoptera, and Heteroptera (OCH) richness was observed for Pd than

R and Pc macrohabitats. Family composition was more similar between R and Pc than between R or Pc and Pd macrohabitats. This similarity may be associated with greater connectivity between R and Pc macrohabitats. Correspondence analysis indicated that macroinvertebrate composition changed along a gradient from R to Pc and Pd that was related to a perennial-intermittent gradient across sites. High variability among macroinvertebrate assemblages in Pd could have been related to variability in the duration of intermittency. In cluster analysis, macroinvertebrate assemblages were grouped by macrohabitat first and then by site, suggesting that the macrohabitat filter had a greater influence on macroinvertebrate assemblages than did local site characteristics. Few taxa were found exclusively in Pc, and this macrohabitat shared numerous taxa with Rand Pd, indicating that Pc may act as a bridge between R and Pd during drought. Drought is regarded as a ramp disturbance, but our results suggest that the response of macroinvertebrate assemblages to the loss of hydrological connectivity among macrohabitats is gradual, at least in Mediterranean-climate streams where drying is gradual. However, the changes may be more dramatic in and and semiarid streams or in Mediterranean-climate streams if drying is rapid." 6502. Borisov, S.N. (2006): Adaptations of dragonflies (Odonata) under desert conditions. *Zoologicheskii Zhurnal* 85(7): 820-829. (in Russian, with English summary). ["Different types of adaptation in dragonflies directed to the selection of optimal habitats in the desert zone in the southern part of central Asia were revealed. The most favourable habitats for the development of larval phases are flowing and semi-flowing water bodies of irrigation systems. The life cycles in dragonflies are synchronous with seasonal climatic changes; their reproductive period is restricted to the time of optimal hygrothermal conditions. The time of flying in monovoltine species may be reduced and shifted to spring time (*Libellula q. quadrimaculata*, *Anaciaeschna isocles antehumeralis*) or, on the contrary, it becomes longer due to the prereproductive diapause, when dragonflies fly away to mountains (*Sympetrum arenicolor*, *Aeshna m. mixta*, *Sympecma gobica*, *S. paedisca*, and *S. fusca*). The vernal and autumnal peaks in the number with its significant decrease in mid-summers are characteristic of bivoltine species (*Ischnura elegans* and *I. evansi*). Species with the long imaginal state due to the asynchronous seasonal development of populations are numerous only in spring (*Anax p. parthenope* and *Lindenia tetraphylla*). The labile diurnal rhythms in the activity of dragonflies allow to avoid effects of unfavourable weather conditions. Emergence for many species takes place at night." 6504. Bouwman, J.H.; Kalkman, V.J. (2006): Status of the Odonata of the habitat directive in The Netherlands. *Brachytron* 9(1-2): 3-13. (in Dutch, with English summary). ["In 2004 special attention was given to the distribution of five species of Odonata - *Sympecma paedisca*, *Aeshna viridis*, *Ophiogomphus cecilia*, *Leucorrhinia pectoralis* and *Gomphus flavipes* - present on the Habitat Directive of the EU. Of the first four species all square kilometres where the species was found between 1980-2000 but not after 2000 were revisited. For *Gomphus flavipes* a search was conducted in each 5 km squares in the flood plains. The work resulted in up to date information on the distribution of the species. *Sympecma paedisca*: The reproduction takes place in the Weerribben and Kuinderplas. In the provinces of Friesland and Drenthe the individuals are seen at many different sites each autumn but until now no successful reproduction is proven. *Aeshna viridis*: The distribution of this dragonfly overlaps with that of Water soldier (*Stratiotes aloides*). In The Netherlands there are two core-areas where large stands of this plant occur and where *A. viridis* is found: in the western and northern part of the country. *A. viridis* disappeared from a few localities, but it was discovered at several new localities. The overall impression is that the species is stable. *Gomphus flavipes*: After an absence of more than 90 years the species was rediscovered in 1996. Since then the species colonised all larger rivers in the Netherlands. It is especially common along the Waal and Merwede and less so along the Lek and Nederrijn. Prior to 2004 the species was known from a few records along the IJssel. During fieldwork in 2004 it was shown that it is present along the full length of the IJssel though in low numbers. The species is largely absent from the river the Maas. This river lacks the groynes and the adjacent sandbanks which are deposited behind the groynes and which probably form the larval habitat in other rivers. Remarkable a small population is present along the Roer, a small river, which runs into the Maas. *Ophiogomphus cecilia*: The only reproduction site in The Netherlands is the river Roer. In 2002 and 2003 in total 105 exuviae were found making clear that this population is well established. Searches along the Geleenbeek, where the species was seen in 1995 and 1996 were not successful. *Leucorrhinia pectoralis*: This species is rare in most of Europe but relatively common in parts of The Netherlands. Large populations occur in the lowland peat marshes of De Weerribben and De Wieden and the Lonnerkermeer (all in the province of Overijssel). A small population is found in the lowland peat marshes in the province of Utrecht and Noord-Holland (nature reserve Het Hol). Apart from these populations the species is found at several localities in the east and south of the Netherlands and at one locality in the dunes. However, none of these localities seem to hold stable

populations." (Authors)] Address: Bouwman, J.H., Vlinderstichting, Postbus 506, NL-6700 AM Wageningen, The Netherlands. E-mail: jaap.bouwman@vlinderstichting.nl

6507. Butler, S.G.; Chelmick, D.G.; Vick, G.S. (2006): Descriptions of the last instar larvae of *Neodythemis hildebrandti* Karsch and *N. afra* (Ris) with comments on the status of the genus and subfamily (Anisoptera : Libellulidae, Tetrathemistinae). Odonatologica 35(3): 233-241. (in English). ["The larvae of *N. hildebrandti* (from Nosy Be, Madagascar) and *N. afra* (from Mt Kupe, Cameroon) are described, illustrated from exuviae, and compared with the larva of *N. (Allorrhizucha) klingi* (Karsch) from W Africa. Differences between the larva of *Neodythemis* and that of other known African Tetrathemistinae genera (*Malgassophlebia*, *Notiothemis* and *Tetrathemis*) are highlighted, and it is suggested that this provides support for the view that *Neodythemis* (including *Allorrhizucha*) and *Micromacromia* form a natural group, the 'neodythemistines', and that they are only distantly related to other genera in the subfamily. This provides additional evidence for the view that Tetrathemistinae is not a phylogenetically homogenous grouping within the Libellulidae." 6508. Calle, P.; Kurstjens, G.; Peters, B. (2006): Dragonflies of the Gelderse Poort. Natural river landscape richer in biodiversity than expected. Brachytron 9(1-2): 49-57. (in Dutch, with English summary). ["In 2003 fieldwork was carried out to learn about the dragonfly biodiversity in the Gelderse Poort. In this area floodplain restoration projects were realised on a large scale (ca. 800 ha) since 1990. The nature reserves in the Gelderse Poort consists of floodplains with some alluvial forests and river dunes, as well as (reed) marshes in former floodplains. In total 43 species have been observed since 2000 of which 37 have populations in the area. Seven Dutch Red Listed species occur in the Gelderse Poort: *Aeshna isocelis*, *Brachytron pratense*,

Gomphus flavipes, *G. vulgatissimus*, *Lestes virens*, *Libellula fulva* and *Sympetma fusca*. This investigation shows the high species richness in dragonflies of natural floodplains. Recently this phenomenon was not well known in The Netherlands. The popular opinion was a rather low biodiversity in dragonflies due to regular flooding and bad water quality. Also the presence of Beavers (*Castor fiber*) has positive effects on the habitats of some species, for example on *Libellula fulva*. Males of this species use dead branches cut by Beavers as perches." (Authors)] Address: Kurstjens, G., Ecologisch adviesbureau, Col. Ekmanstr. 15, NL-6573 BM Beek-Ubbergen, The Netherlands

6509. Chazal, A.C. (2006): Lepidoptera and Odonata Surveys of Colonial National Historic Park, James City, Surry, and York Counties, Virginia. Technical Report NPS/NER/NRTR-2006/063: 102 pp. (in English). ["In 2003, the United States Department of the Interior, National Park Service contracted with the Virginia Department of Conservation and Recreation, Division of Natural Heritage (DCR-DNH) to conduct an inventory of the diurnal Lepidoptera and Odonata on Colonial National Historical Park (COLO), located in James City, Surry, and York counties, Virginia. Between May-July 2003 and April-October 2004, DCR-DNH conducted surveys over 18 days covering 17 different habitats, which were categorized into six habitat types: developed areas, fields, forested uplands, forested wetlands, marshes, and water (i.e. freshwater ponds). 75 species of Lepidoptera and 42 species of Odonata were observed. The field habitat, primarily classified as Planted / Cultured / Cultivated Herbaceous Vegetation, had the highest species diversity and highest total numbers for Lepidoptera. The field habitats also had the highest species diversity and second highest totals (forested wetlands had higher totals) for Odonata. The globally rare skipper, *Problemata bulenta* (Rare Skipper G2G3 S1), was reconfirmed at an existing site on COLO, but no further occurrences were found during targeted surveys for that species. Five watchlisted species were observed: Aaron's Skipper (*Poanes aaroni*), *Anax longipes*, *Sympetrum ambiguum*, *Ischnura prognata*, and *Telebasis byersi*. All of these watchlisted species are considered common to very common and secure across their global ranges. The results of this survey represent 37 new county records for Lepidoptera and 26 for Odonata. Species accumulation curves indicate that further surveys for Lepidoptera and Odonata may increase the known fauna of COLO." (Author)] Address: Chazal, Anne, Virginia Department of Conservation and Recreation, Division of Natural Heritage, 217 Governor Street, Richmond, VA 23219, USA

6510. Chazal, A.C. (2006): Lepidoptera and Odonata Surveys of George Washington Birthplace National Monument, Westmoreland County, Virginia. Technical Report NPS/NER/NRTR--2006/062: 82 pp. (in English). ["In 2003, the United States Department of the Interior, National Park Service contracted with the Virginia Department of Conservation and Recreation, Division of Natural Heritage (DCR-DNH) to conduct an inventory of the diurnal Lepidoptera and Odonata on George Washington Birthplace National Monument (GEWA), Westmoreland County, Virginia. Between May-July 2003 and April-September 2004, DCR-DNH conducted surveys over 13 days covering thirteen habitats which were categorized into six habitat types: beach/shoreline, developed areas, field, forest, marsh, and water (i.e., fresh-

water ponds). Fifty-one species of Lepidoptera and 37 species of Odonata were observed. The field habitats, primarily classified as Planted/Cultured/Cultivated Herbaceous Vegetation, had the highest species diversity and highest total numbers for Lepidoptera. The marsh habitats, primarily comprised of Tidal Oligohaline Marsh, had the highest species diversity and totals for Odonata. No rare, threatened, or endangered species were observed. Three watchlisted species were observed: Aaron's Skipper (*Poanes aaroni*), *Anax longipes*, and *Lestes inaequalis*. All of these species are considered common to very common and secure across their global ranges. The results of this survey represent 24 new county records for Lepidoptera and 23 for Odonata. The species accumulation curve for Lepidoptera indicates that further surveys may increase the known fauna of GEWA; however, the same type of curve for Odonata leveled off by the eighth survey indicating that further surveys may have low probability of recording new species." (Author)] Address: Chazel, Anne, Virginia Department of Conservation and Recreation, Division of Natural Heritage, 217 Governor Street, Richmond, VA 23219, USA

6513. Contreras-Garduno, J.; Canales-Lazcano, J.; Cordoba-Aguilar, A. (2006): Wing pigmentation, immune ability, fat reserves and territorial status in males of the rubyspot damselfly, *Hetaerina americana*. *Journal of Ethology* 24(2): 165-173. (in English). ["An explanation for courting traits is that they convey information about the bearer's condition to conspecifics, more specifically immune ability. Here we test a series of immune-based assumptions in the territorial damselfly *H. americana*, whose males bear wing pigmentation patterns,

which are maintained via male-male competition. *H. americana* males emerge and take some time to mature sexually, after which, depending on their fat reserves, may start defending territories where females arrive at for copulation. Territorial males are eventually defeated and lose their territories. This loss is a consequence of a reduction in muscular fat reserves. We tested whether: (a) territorial males had more pigmented wings, more intense melanine-based immune response (encapsulation response to a nylon filament implant) and higher fat reserves than non-territorial males; (b) pigmentation is related to immunity and fat reserves; (c) the immune response held constant in two different episodes (3 days between each) in the same male during territorial tenure; and (d) immune response and fat reserves decreased after experimentally simulated fighting event. Our results agree with current views of immune ability and courting traits: (1) territorial males had more wing pigmentation, higher immune responses and fat reserves than non-territorial males; (2) pigmentation was also correlated with immunity and fat reserves; and (3) immune response was similarly intense in the two episodes during territorial tenure. However, this response and fat reserves were considerably lower after fighting compared to that of territorial males and non-territorial males. Our work points out a link between fat reserves and immune ability which agree with previous studies in insects. Given, however, that in this species the use of wing pigmentation via male-male competition is more likely to provide information about current fat reserves than immunity, it is suggested that immune ability is only indirectly selected and may not be the information that pigmentation would convey to conspecifics." (Authors)] Address: Cordoba-Aguilar, A., Centro de Investigaciones Biologicas, Universidad Autonoma del Estado de Hidalgo, Apdo. 6514. Cordoba-Aguilar, A.; Contreras-Garduno, J.; Peralta-Vazquez, H.; (2006): Sexual comparisons in immune ability, survival and parasite intensity in two damselfly species. *Journal of Insect Physiology* 52(8): 861-869. (in English). ["Recent evolutionary studies have suggested that females have a more robust immune system than males. Using two damselfly species (*Hetaerina americana* and *Argia tezpi*), we tested if females produced higher immune responses (as phenoloxidase and hydrolytic enzymes) had a higher survival (using a nylon implant inserted in the abdomen and measuring survival after 24 h) and fewer parasites (gregarines and water mites) than males. We also tested whether immune differences should emerge in different body areas (thorax vs. abdomen) within each sex with the prediction that only females will differ with the abdomen having a higher immune response than their thorax since the former area, for ecological and physiological reasons, may be a target zone for increased immune investment. Animals were adults of approximately the same age. In both species, females were more immunocompetent than males, but only in *H. americana* females were immune responses greater in the abdomen than in the thorax. However, there were no differences in survival and parasite intensity or the probability of being parasitised between the sexes in either of the two species. Thus, this study]ends partial support to the principle that females are better at defending than males despite the null difference in parasitism and survival." (Authors)] Address: Cordoba-Aguilar, A., Centro de Investigacio-

nes Biologicas, Universidad Autonoma del Estado de Hidalgo, Apdo. P. 69-1, Plaza Juarez, Pachuca, Hidalgo 42001, Mexico E-mail: acordoba@uaeh.reduaeh.mx

6515. Cordoba-Aguilar, A.; Mendez, V. (2006): Immune melanization ability and male territorial status in *Erythemis vesiculosa* (Fabricius) (Anisoptera: Libellulidae). *Odonatologica* 35(2): 193-197. (in English). ["Using a nylon filament implant inserted in the thorax, it was tested whether there were immune ability and size differences between territorial and nonterritorial male male that gather in lentic aquatic sites. It was found that territorial male male mounted a larger melanin-based immune response than nonterritorial male male. This is coherent with current results in other odon. and is interpreted as territorial male male being in better condition than nonterritorial male male - However, there was no size difference between the territorial and nonterritorial individuals. This suggests that size may be a poor predictor of immune ability." (Authors)] Address: Cordoba-Aguilar, A., Centro de Investigaciones Biologicas, Universidad Autonoma del Estado de Hidalgo, Apdo. 6519. Creed, R.P. (2006): Predator transitions in stream communities: a model and evidence from field studies. *Journal of the North American Benthological*

Society 25(3): 533-544. (in English). ["The role of predators (particularly top predators such as fish) in structuring stream communities has been debated for 2 decades. Much of the debate may have been caused by the lack of a conceptual framework for evaluating predator effects in stream communities. First, I propose a general conceptual model of the factors (abiotic, such as stream permanence and disturbance regime; biotic, such as predation) that can influence community structure, and the conditions in which these various factors would be expected to be important. Hydrologic permanence and disturbance transitions separate streams where abiotic factors are most important in determining community structure from streams with relatively benign disturbance regimes where predation may be more important. Second, I focus on the potential effect of predators in perennial streams with relatively benign disturbance regimes. Such streams are divided longitudinally into sections where different types of predators might be important in determining community structure. Large invertebrates (stoneflies, dragonflies, shrimp, and crayfish) and salamanders may be the dominant benthic predators affecting species composition in small perennial fishless streams. A transition from invertebrate. and amphibian-dominated to fish-dominated systems may occur in larger, downstream sections (predator transition 1). In addition, longitudinal transitions in fish-assemblage structure from upstream tributaries to downstream main-channel fish assemblages (predator transition 2) may affect community structure. I present evidence supporting the above model and suggest experimental approaches to test the model. This conceptual framework may help in understanding the role of specific predators in determining prey distributions in many stream communities." (Author)] Address: Creed, R.P., Appalachian State Univ, Dept Biol, Boone, NC 28608 USA. E-mail: creedrp@appstate.edu

6520. Crumrine, P.W. (2006): Age specific behavioral responses of odonate larvae to chemical and visual cues from predators. *Journal of Freshwater Ecology* 21(1): 9-16. (in English). ["Many aquatic organisms possess the ability to detect and respond to visual and chemical cues from predators and injured conspecifics, but relatively few studies have investigated if those responses change during development in odonates. In a laboratory experiment, I exposed 8(th) and 12(th) instar larvae of the dragonfly *Anax junius* to (1) the presence of a free-swimming fish predator (*Lepomis macrochirus*); (2) water that recently contained *L. macrochirus*; (3) water that contained crushed conspecifics; (4) water that recently contained living conspecifics; and (5) charcoal filtered tap water that contained no visual or chemical stimuli. The 12(th) instar *A. junius* moved more often, spent more time moving and spent less time perched on artificial aquatic vegetation than did 8(th) instar *A. junius*. *A. junius* moved less in the presence of fish chemical cues relative to the control. Although 8(th) and 12(th) instar *A. junius* differed in their responses to stimuli from predators, the overall response of *A. junius* to predators was not strong. The characteristic high activity level of *A. junius*, which is an advantage in fishless habitats, may limit success of this species in habitats with insectivorous fish." (Author)] Address: Crumrine, P.W., Department of Natural Sciences, Longwood University, Farmville, VA 23909, USA. E-mail: crumrinepw@longwood.edu

- 6521.** Das, P.K.; Sivagnaname, N.; Amalraj, D.D. (2006): Population interactions between *Culex vishnui* mosquitoes and their natural enemies in Pondicherry, India. *Journal of Vector Ecology* 31(1): 84-88. (in English). ["Population interactions among mosquitoes in the *Culex vishnui* subgroup, which are vectors of Japanese Encephalitis, and their natural enemies were studied in Pondicherry, India. We tested the hypothesis that the breakdown of interactions between the larvae and their natural enemies due to drought followed by rain was responsible for the sudden increase in the vector population above the threshold for disease transmission during the heavy rainy period. We randomly sampled mosquito larvae and their predators in different breeding habitats and subjected the mean densities of prey, predator, and mosquito larvae infected with parasites/pathogens to covariate analysis to understand the interaction between prey and their natural enemies in relation to environmental factors. In rice fields, neither prey nor predator showed any positive correlation with temperature, RH, or the number of rainy days. However, the pathogen/parasite of mosquito immatures showed a positive correlation with RH. Among the mosquito predators, notonectids exhibited a significant positive correlation with *Cx. vishnui* larvae. The parasitic *Romanermis iyengari* and pathogenic *Coelomomyces anopheliscus* also showed positive correlations with immatures. No parasites and pathogens of mosquito larvae were recorded in shallow water pools (SWP) or cement tanks (CT) during the study period. Important predators recorded in SWP were notonectids, damselfly nymphs, *Diplonychus indicus*, and hydrophilids. Dragonfly nymphs, Gerrids, and tadpole shrimps were recorded in CT. In CT, prey and their predators were positively correlated with RH and rainy days. In SWP, there was a highly significant correlation between prey, predators and environmental factors. We conclude that rice fields are a stable ecosystem where regular interaction occurs between larvae and their natural enemies and a sudden increase in mosquito populations is uncommon. In transient habitats, no such stability is present and they become more important as breeding habitats in terms of seasonality and number. Shallow water pools should be seriously considered for the control of these vectors." (Author)] Address: Das, P.K., Indian Council Med Res, Vector Control Res. Ctr, Indira Nagar, Pondicherry 605006, India
- 6522.** de Boer, E.P.; Wasscher, M.T. (2006): Rediscovery of *Leucorrhinia albifrons* in The Netherlands. *Brachytron* 9(1-2): 14-20. (in Dutch, with English summary). ["In late June 2005, several specimens of *Leucorrhinia albifrons* were seen on the Dellebuursterheide, a nature reserve in the province of Friesland, The Netherlands. This rare species was thought to be extinct in the Netherlands. The last record dates from 1994, also in Friesland. In the days following the rediscovery a suitable reproduction site was found where the species was seen regularly until July 12, with a maximum number of ten individuals on a single day. In addition to the sighting of several ovipositing females, a larval skin was found, thus proving successful reproduction at this site. The habitat of the reproduction site consists of a shallow oligotrophic lake of 200x100 meter in a lightly wooded heath landscape. Except for a submerged blanket of peat moss (*Sphagnum*, sp.) the vegetation is rather poor in species and indicates moderately acid circumstances. Before the nineties, this site was completely cleared of overgrown vegetation and the enriched soil was removed by the local conservation body within the framework of a recovery program. It is therefore likely that *L. albifrons* has not colonised the lake until after 1990, since the habitat previous to the undertaken recovery measurements, is considered to have been unsuitable for the species. Therefore, the origin of this population still remains unclear. In 2006 further investigation will take place to discover possible other reproduction sites, and to provide a species protection program." - 6533.** Foster, S.E.; Soluk, D.A. (2006): Protecting more than the wetland: The importance of biased sex ratios and habitat segregation for conservation of the Hine's emerald dragonfly, *Somatochlora hineana* Williamson. *Biological conservation* 127: 158-166. (in English). ["Within species habitat use may depend on age, season or sex of an individual. The distribution of males and females may vary both temporally and spatially due to differences in the costs of reproduction and the distribution of critical resources. Conservation of a species requires knowledge of the habitat use of both sexes in order to predict the population size and protect all habitats that a species requires. Adult dragonfly populations often have highly male-biased sex ratios at the breeding habitat. This bias has been attributed to females using alternative habitats to avoid male harassment, or to high female mortality. We monitored adult *S. hineana* populations, in breeding and non-breeding habitats in Door County, Wisconsin and found significant differences in habitat use between males and females. Males primarily used wetland habitats, while females primarily used dry meadows and marginal breeding habitats, only coming into wetlands to lay-eggs or find mates. We assessed food resources in the different habitats and found that high quality insect prey (primarily adult Diptera) were more available in the wetland habitat, indicating that these areas were likely a more productive foraging area for adult dragonflies. The fact that females appear to avoid the wetland habitat is consistent with the hypothesis that male harassment alters female distribution patterns. Consideration of the patterns of habitat use by *S. hineana* indicates the need to develop a broader understanding of the importance of non-wetland areas in the conservation of wetland species." - 6535.** Geraeds, R.P.G.; van Schaik, V.A. (2006): The skimmers of the Blankwater Reserve. A survey of the emergence of three species of skimmer. *Natuurhistorisch maandblad* 95(6): 141-146. (in Dutch, with English summary). ["The Blankwater is a nature reserve located

east of the town of Roermond, The Netherlands near the German border, which includes two large pools. In 2004, a 20 m transect on the north bank of the southern pool was surveyed for the emergence of three skimmer species, *Orthetrum cancellation*, *O. coerulescens* and *O. brunneum* in this still water body. The presence of three skimmer species in the same habitat is rare in the Netherlands. In the period of May 11 to September 4, all exuviae of emerged skimmers were collected two to three times a week. This resulted in 176 exuviae of *O. cancellation*, 246 *O. coerulescens* and 5 of *O. brunneum*. Exuviae were found on 22 different plant species, most of them on Jointed rush (*Juncus articulatus*). *O. cancellation* mostly emerged at low height in the land vegetation, with exuviae found up to 10 m from the waterline. *O. coerulescens* also emerged at low heights in the land vegetation, but nearer the waterline. The five exuviae of *O. brunneum* were found in the water vegetation, again at low heights. In total, 25 dragonfly species were observed during the survey. Exuviae of seventeen species were found along the transect." (Authors)] Address: Geraeds, R.P.G., Bergstraat 70, NL-6131 AW Sittard, The Netherlands

6536. Geraeds, R.P.G.; van Schaik, V.A. (2006): Dragonflies in the valley of the river Roer. Part II, true dragonflies (Anisoptera). *Natuurhistorisch maandblad* 95(11): 246-253. (in Dutch, with English summary). ["In the 2000-2005 period, the river Roer and 80 stagnant water bodies in the valley of the Roer were surveyed for the presence of dragonflies.[...]. The survey revealed the presence of 25 true dragonfly species. Very common species included *Gomphus vulgatissimus*, *Orthetrum cancellation*, *Anax imperator*, *Sympetrum sanguineum* and *S. striolatum*. *G. vulgatissimus* bred only in flowing water, while the other very common species bred in still waters. One larva of *O. cancellation* was caught in the river Roer. Common species included *Ophiogomphus cecilia*, *Stylurus flavipes*, *Gomphus pulchellus*, *Aeshna grandis*, *A. cyanea*, *A. mixta* and *Libellula depressa*. *O. cecilia* and *S. flavipes* bred only in flowing water, while exuviae of *G. pulchellus* were found at both streaming and still water bodies. The other common dragonfly species bred only in still waters. Rare species in the valley included the *Onychogomphus forcipatus*, *Somatochlora metallica*, *Cordulia aenea*, *Orthetrum coerulescens*, *Crocothemis erythraea*, *Libellula quadrimaculata*, *S. danae* and *S. vulgatum*. The river Roer is the only place where *O. forcipatus* breeds. *S. metallica* bred in slow flowing and still waters. Although no exuviae were found, it is likely that *S. metallica* breeds in a former meander of the Roer. The species was observed by this water body in several years. *C. aenea*, *C. erythraea*, *L. quadrimaculata* and *S. vulgatum* bred only in a few still waters. It is likely that *O. coerulescens* breeds in the Holsterbeek, as mating behaviour was observed there. It is uncertain whether *S. danae* is breeding in the valley of the river Roer. It is likely that the occasionally observed animals were migrants from the nearby Meinweg nature reserve. Very rare species in the survey included *Sympetrum flaveolum*, *Brachytron pratense*, *Somatochlora flavomaculata*, *Orthetrum brunneum* and *Cordulegaster boltonii*. Except for *C. boltonii* exuviae of these species were never found. A few imagos of *S. flaveolum* were spotted almost every year. *B. pratense* was spotted twice. A male (2003) and a female (2005) were seen at two different former meanders of the Roer, water bodies which look like suitable habitats for this species. *S. flavomaculata*

was also observed twice, near a stagnant water body and along the Holsterbeek brook. *O. brunneum* was observed only once along the Roer, in 2003. This was most likely a migrant from the Blankwater nature reserve. In 2005, an exuvium of *C. boltonii* was found along the Roer near Roermond. Since the river is not a suitable habitat for this species, it is most likely that this was a larva that had drifted in from upstream sections of the river in Germany. Over the 2000-2005 period, a total of 40 Odonata species were observed in the valley of the river Roer. Twenty-nine of these were observed along the river, while 26 species were mostly observed at stagnant water bodies. The largest water bodies (the former meanders of the river Roer) generally hosted the most dragonfly species. Nevertheless the stagnant water body with the largest number of species was a small pond. The Roer hosts the only population of *O. forcipatus* and one of the two populations of *O. cecilia* in the Netherlands, making this river one of the most important dragonfly habitats in the country." (Authors)] Address: Geraeds, R.P.G., Bergstraat 70, NL-6131 AW Sittard, The Netherlands

6537. Geraeds, R.P.G.; van Schaik, V.A. (2006): Dragonflies in the valley of the river Roer. Part I, damselflies (Zygoptera). *Natuurhistorisch maandblad* 95(9): 197-203. (in Dutch, with English summary). ["Between 2000 and 2005, the valley of the river Roer was surveyed for the presence of dragonflies. [...]. The Dutch part of the river Roer is a meandering stream with a length of 21 km, its valley including 91 stagnant water bodies. The six-year dragonfly survey covered the river and 80 of these stagnant waters. A total of 15 species of damselfly were found in the area. Very common species included *Calopteryx splendens*, *Platycnemis pennipes*, *Erythromma lindenii*, *Coenagrion puella*, *Ischnura elegans* and *Pyrrhosoma nymphula*. *C. splendens* bred only in flowing water, while *P. pennipes* and *E. lindenii* bred in flowing and still waters. The other very common damselfly species bred in still waters. Common species included *Chalcolestes viridis*, *Erythromma najas* and *E. viridulum*. Although *E. najas* and *E. viridulum* were frequently observed along the river, all three species bred only in still waters. Rare species in the Roer valley included *Sympetma fusca*, *Lestes sponsa*, *Coenagrion pulchellum* and *Enallagma cyathigerum*; they were only observed along still waters. Although a breeding site was found only for *L. sponsa*, breeding by the other three rare species is likely because they were observed at the same location in different years, or their mating and oviposition behaviour was observed. *Lestes virens* and *Ceragrion tenellum* were very rare. *L. virens* was observed at three locations, being seen at the same two ponds in 2004 and 2005. During these years, mating and oviposition behaviour were observed. The *C. tenellum* was seen only once during the survey period; two males were found by a former meander of the river Roer." (Authors)] Address: Geraeds, R.P.G., Bergstraat 70, NL-6131 AW Sittard, The Netherlands

6538. Gonzalez-Soriano, E.; Novelo-Gutierrez, R. (2006): *Elasmothermis aliciae* spec nov, a new dragonfly from Mexico, Belize and Costa Rica with a description of its larva and a key to the known larvae of the genus (Anisoptera : Libellulidae). *Odonatologica* 35(3): 243-253. (in English). ["The new species and its larva are described and illustrated from specimens collected in Mexico (states of San Luis Potosi and Veracruz), Belize (Toledo distr.) and Costa Rica (Heredia prov.). Holotype

male and allotype female (in copula): Mexico, Veracruz state, Rio La Palma, 25 km N of Catemaco, 28-VIII-1988; deposited at UNAM, Mexico. The species is closely related to *E. cannacrioides* Calv. with which it was formerly confused. Adults of the former are larger than those of the latter. The larva is also easily distinguished from *E. cannacrioides* by its larger size and differences in the shape of the dorsal protuberances. Notes on biology and distribution are provided and the known larvae of the genus *Elasmothemis* Westfall are keyed." (Authors)] Address: Gonzalez-Soriano, E., Depto Zoologia, Inst. Biol., Universidad Autonoma, Apartado Postal 70-153, 04510 Mexico, D.F., Mexico. E-mail: esoriano@mail.ibiologia.unam.mx

6539. Haas, F. (2006): Evidence from folding and functional lines of wings on interordinal relationships in Pterygota. *Arthropod Systematics & Phylogeny* 64(2): 149-158. (in English). ["The fundamental difference between palaeopteran (*Aeshna* sp., Odonata) and neopteran (*Perla* sp., Plecoptera) Pterygota is exemplified with by two recent representatives. When sitting, the *Aeshna* sp. needs quite some space, neither fore nor hind wing are protected and its silhouette is perfectly visible from all directions. The plecopteran protects its hind wings with the fore wings and may completely disappear behind a plant stalk. Evidently, neopteran insects need less space when at rest." - 6550.** Iwamoto, H.; Inoue, K.; Yagi, N. (2006): Evolution of long-range myofibrillar crystallinity in insect flight muscle as examined by X-ray cryomicrodiffraction. *Proc. R. Soc. B* 273: 677-685. (in English). ["Insect flight muscle is known for its crystal-quality regularity of contractile protein arrangement within a sarcomere. We have previously shown by X-ray microdiffraction that the crystal-quality regularity in bumble-bee flight muscle is not confined within a sarcomere, but extends over the entire length of a myofibril (O1000 sarcomeres connected in series). Because of this, the whole myofibril may be regarded as a millimetre-long, natural single protein crystal. Using bright X-ray beams from a synchrotron radiation source, we examined how this long-range crystallinity has evolved among winged insects. We analysed O4600 microdiffraction patterns of quick-frozen myofibrils from 50 insect species, covering all the major winged insect orders. The results show that the occurrence of such long-range crystallinity largely coincides with insect orders with asynchronous muscle operation. However, a few of the more skilled fliers among lower-order insects apparently have developed various degrees of structural regularity, suggesting that the demand for skilful flight has driven the lattice structure towards increased regularity." (in Japanese, with English summary). ["The study was conducted in no-till, no-puddling and conventional cultivation method rice field, respectively. We investigated larval development, emergence species and emergence patterns of *Sympetrum* in each rice field. The following results were obtained: 1. larval dragonfly populations in no-till and no-puddling rice field were higher than those in conventional rice field. 2. During 5 year period, the number of exuviae collected per 50m² in no-till, conventional, no-puddling cultivation methods were 751, 4,422, 4,272 respectively. Especially *Sympetrum frequens* was the most abundant species in no-puddling rice field. 3. Larval composition of each dominant species (*S. infuscatum*, *S. frequens*, *S. darwinianum*) in conventional and no-puddling cultivation method was characterized by a constant percentage throughout 5 years. *S. frequens* were dominant species in no-till cultivation rice field at first year, but after two years *S. infuscatum* became the most abundant species. We have shown that disturbance for puddling decreased larvae of *Sympetrum* and individuals of *S. frequens* decrease in no-till cultivation rice field." - 6552.** Jinguji, H.; Tsuyuzaki, H.; Sato, T. (2006): Effect of temperature and light on egg hatching of *Sympetrum frequens*. *Transactions of the Japanese Society of Irrigation, Drainage and Reclamation Engineering* 74(3): 79-84. (in Japanese, with English summary). ["The aim of the present study is to obtain quantitative information on egg hatching with respect to temperature and light to clarify the effect of cultivation methods on *Sympetrum frequens*. Eggs of the species were collected on October in 2004 at Akita prefecture located at north of Japan, and the eggs had been laid on soil surface of paddy field till April in 2005. The eggs (3 trays with 30 eggs each) were held under four constant temperature (5°C., 10°C., 15°C. and 20°C.) with a photoperiod (L:D, 14:10; relative light intensity, 3000 Lux) and 20°C. in the dark. Cumulative hatching percentage under 20°C. with and without light was 98.9% and 95.6% respectively. The percentage under 15°C., 10°C. and 5°C. were 95.6%, 88.9% and 84.4%, respectively. These results suggest that the dragonfly do not require light for hatching, and hatching is suppressed by low temperature such as 5°C. Mean hatching days with light under 20°C., 15°C., 10°C. and 5°C. were 3.5, 4.8, 11.6 and 41.0 respectively. Reciprocal of variance of hatching day under these conditions were 0.15, 0.09, 0.03 and 0.02 respectively. These results indicate that the eggs under 20°C. and 15°C. hatched faster and more uniformly than those under 10°C. and 5°C. Based on these results, theoretical lower thermal threshold and thermal constants for hatching were estimated at 4.9°C. and 54.6 degree-days. According to these results, the effects of cultivation methods on hatching of this species were discussed." ["On March 27 2006 a larva of *C. boltonii* was caught at the brook Aalsbeek (also called Molenbeek), just east of Belfeld (AC: 207-368). This is the fifth Dutch locality where *C. boltonii* is known to reproduce. The species was already known from this locality from records made by Maus Lieftinck in 1921, 1922, 1923, 1924, 1926 and 1951 and from a record by Dirk Geijskes in 1967. It is likely that the species has been present ever since but has been overloo-

ked." (Authors)] Address: Kalkman, V.J., Oude Rijnsburgerweg 28, NL-2342 BC Oegstgeest, The Netherlands. E-mail: Kalkman@naturalis.nnm.nl

6558. Kalnins, M. (2006): The distribution and occurrence frequency of Gomphidae (Odonata: Gomphidae) in river Gauja. *Acta Universitatis Latviensis* 710, Biology: 17-28. (in English, with Latvian summary). ["The article contains data on four gomphid dragonfly species known in Latvia – *Gomphus flavipes*, *G. vulgatissimus*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia* and the latest data on their distribution, occurrence frequency and density of individuals. Gomphidae were obtained from macrozoobenthos samples in 1998. In total 280 quantitative and 65 qualitative samples were collected in the River Gauja from the town Taurene upstream to below Carnikava. For complete analyses, observations of adults individuals were also used based on a bibliography, unpublished (personal) observations and data from 1933 to 2005. Three species of Gomphidae, *G. vulgatissimus*, *O. forcipatus* and *O. cecilia* were recorded. Data with regard to observations of larvae / exuviae / imago stages showed that all gomphid species are encountered throughout Latvia. *G. flavipes* is infrequent for Latvia and this species has been recorded only in the Gauja. Gomphids occurred in 13.2% of obtained samples, *G. vulgatissimus* in 10%, *O. forcipatus* in 5% and *O. cecilia* in 0.7%. Ecological analysis of bottom substrate showed that *O. forcipatus* prefers a hard substrate situated in the rhithral stretches or in the rapids. The density of *G. vulgatissimus* reached 0.919 ind. m⁻², and *O. forcipatus* 0.514 ind. m⁻²." (2006): Validating species sensitivity distributions using salinity tolerance of riverine macroinvertebrates in the southern Murray-Darling Basin (Victoria, Australia). *Canadian Journal of Fisheries & Aquatic Sciences* 63(8): 1865-1877. (in English). ["Species sensitivity distributions (SSDs) are commonly used in risk assessment and in setting water quality guidelines, yet their predictions have not been validated against loss of species with increasing pollutant concentrations in nature. We used a rapid toxicity testing method to determine the acute salinity tolerance (72 h LC50 values (concentration of salinity lethal to 50% of individuals)) of 110 macroinvertebrate taxa from the southern Murray-Darling Basin in central Victoria, Australia, and con-

struct an SSD. This SSD was compared with loss of riverine macroinvertebrates species from increasing salinity in Victoria. Macroinvertebrate species richness per individual sample, when salinity was < 9.9 mS center dot cm(-1), was invariant of salinity. However, when species richness was calculated across multiple samples above about 0.3-0.5 mS center dot cm(-1), it declined with increasing salinity. This decline was predicted from the SSD after application of a variable safety factor calculated from an exponential or quadratic equation. Our findings confirm that SSDs can predict the loss of freshwater macroinvertebrate species from increases in salinity. This suggests that SSDs may be useful more generally for other aquatic organisms, other stressors, and toxicants." (Authors) The study includes Odonata.] Address: Kefford, B.J., RMIT Univ., Sch. Appl. Sci., POB 71, Bundoora, Vic 3083, Australia. E-mail: ben.kefford@rmit.edu.au

6561. Ketelaar, R. (2006): Pattern and rapidity of the colonisation of *Erythromma viridulum* in The Netherlands. *Brachytron* 9(1-2): 33-37. (in Dutch, with English summary). ["*E. viridulum* is one of the southern Odonata quickly colonising large parts of Europe. The species was a very rare damselfly in The Netherlands until 1970. After 1980 it rapidly colonised The Netherlands and has become one of the most common species. It is suggested in this article that the expansion of *E. viridulum* took place via three routes an expansion northwards from Belgium, an expansion north-westwards via the Rhine valley and a possible expansion from an outpost in the north of The Netherlands. The first two routes can be tested by a close examination of German and Belgian records; the latter will probably remain suggestive." [Atypical tandems among six species of Lestidae from Na Plachtí (Eastern Bohemia, Czech Republic) are presented: The following interspecific tandems were noticed during 2004-2005: male *Lestes barbarus* + female *L.*

dryas, male *L. sponsa* + female *L. virens*, male *L. viridis* + female *L. dryas*, and male *L. sponsa* + female *Erythromma najas*. Moreover tandems among conspecific males were confirmed in *L. viridis*, in *Sympetma fusca*, and among heterospecific males in *L. sponsa* + *L. dryas*, *L. dryas* + *L. sponsa*, and *L. sponsa* + *L. barbarus*. In addition a tandem formed by a male of *L. sponsa* and a dead immature male of *L. viridis* is described. A triplicate tandem (male *L. sponsa* with the tandem *L. viridis*) was observed, too.] Address: Mikát, M., Pekařova 670, CZ-500 09 Hradec Králové, Czech Republic. E-mail: marmulak.hk@tiscali.cz

6564. Mirza, R.S.; Ferrari, M.C.O.; Kiesecker, J.M.; Chivers, D.P. (2006): Responses of American toad tadpoles to predation cues: behavioural response thresholds, threat-sensitivity and acquired predation recognition. *Behaviour* 143(7): 877-889. (in English). ["Predation is one of the most important selective forces acting on prey animals. To respond adaptively to predation threats and increase their chances of survival, prey animals have to be able to recognize their potential predators. Even though a few studies demonstrated innate predator recognition, the vast majority of animals have to rely on learning to acquire this information. Often aquatic prey animals can learn to recognize predators when they detect conspecific alarm cues associated with cues from a novel predator. In this study, we exposed American toad (*Bufo americanus*) tadpoles to varying concentrations of chemical alarm cues (cues from injured conspecifics). We identified a concentration of cues which caused an overt antipredator response (supra-threshold concentration) and a lower concentration for which the prey failed to exhibit a response (sub-threshold concentration). In a second experiment, we attempted to condition the tadpoles to recognize the odour of larval dragonflies (*Anax* sp.) by pairing the dragonfly odour with either the sub-threshold concentration or the supra-threshold concentration of alarm cues. In both cases, the tadpoles learned to recognize the predator based on this single pairing of alarm cues and predator odour. Moreover, the intensity of the learned response was stronger for tadpoles conditioned with the supra-threshold concentration of alarm cues than the sub-threshold concentration. This is the first documented case of this mode of learning in anuran amphibians. Learned recognition of predators has important implications for survival." 6567. Niba, A.S.; Samways, M.J. (2006): Development of the concept of 'core resident species' for quality assurance of an insect reserve. *Biodiversity & Conservation* 15(13): 4181-4196. (in English). ["Awareness in the eyes of the public is important for involving the wider community in conservation. A dragonfly awareness trail was developed and implemented in the year 2000 at a national botanical garden in South Africa. Such a trail is not likely to always have the same number of dragonfly species either throughout the year or from one year to the next. The aim was to assess dragonfly assemblage changes that occurred along the trail over 3 years, so as to fine-tune expectations that the public may have as regards species to be seen at any particular time. A cumulative species variance for species and species-environmental relations, strongly indicated that certain measured site variables were responsible for the main variation in dragonfly species patterns over time. Habitat requirements of an odonate species may be defined primarily in terms of marginal grasses, floating and submerged vegetation, marginal herbs, sedges and reeds, and pH. Additional variables were percentage shade, exposed rock, marginal forest and water flow characteristics. Both dragonfly species richness and abundance changed over the 3 years. One of the reasons for this was a single, major disturbance, in the form of dredging the reservoir site to reverse ecological succession in 2002. Despite an impact such as this, and after accounting for vagrancy, there were in all 24 'core resident species' still to be seen along the trail from January to May. Another 11 species, including two migrants and one species lost temporarily to dredging disturbance, can be considered only as 'possibilities' on any one visit. Assurance that the 24 core species can be seen in the summer months (although only three in winter) is essential for maintaining the bona fide of such a trail, and hence conservation awareness, in the eyes of the public." (Authors)] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

6568. Niba, A.S.; Samways, M.J. (2006): Remarkable elevational tolerance in an African odonata larval assemblage. *Odonatologica* 35(3): 265-280. (in English). ["The spatial patterns in species richness and abundance were investigated here at a series of reservoirs at different elevations, to establish which factors

determine species distributions along this topographic gradient. Larvae of 18 species were sampled in small reservoirs across a 1250 m elevational gradient at one latitude. Most species occurred throughout all elevations indicating that this subtropical odonate assemblage as a whole is remarkably tolerant of elevational changes. Although Anisoptera larval species richness and abundance increased significantly with increasing elevation, there was no change in Zygoptera species richness, while Zygoptera abundance decreased significantly. Species-site-variable triplots for Anisoptera and Zygoptera larvae indicated that no measured site variable on an individual basis clearly accounted for larval species assemblage distribution patterns. Nevertheless, canonical axes and their respective intra-set correlation coefficients showed that some measured site variables e.g. floating/submerged vegetation, turbidity, pH, water temperature (resulting from sunny or shade habitat conditions), marginal grasses, water depth as well as elevation to some extent, explained the main variation in species assemblage composition/distribution in a broadly similar manner for both suborders. Generally, the reservoirs recruited species from the regional pool, irrespective of the elevation of the pool. These species were all geographically widespread species that took advantage of the presence of these man-made reservoirs, and included only one national endemic. Although these artificial water bodies are not increasing the 'extent of species occurrence', they play a major role in increasing 'area of occupancy'. Furthermore, these species are remarkably vagile, habitat-tolerant, as well as elevationally-widespread. A reasonable explanation is that this assemblage is the historical survivor over many millennia of oscillating wet/dry periods and natural selection. The present-day species are those that readily recolonise pools after drought has been broken, and are pioneering residents of new water bodies over a wide elevational range." (Authors)] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

6569. Nicieza, A.G.; Álvarez, D.; Atienza, E.M.S. (2006): Delayed effects of larval predation risk and food quality on anuran juvenile performance. *Journal of Evolutionary Biology* 19: 1092-1103. (in English). ["Metamorphosis can disrupt the correlation structure between juvenile and adult traits, thus allowing relatively independent evolution in contrasting environments. We used a multiple experimental approach to investigate how diet quality and larval predation risk affected the rates of growth and development in painted frogs (*Discoglossus galganoi*), and how these changes influence post-metamorphic performance. A high-energy diet entailed growth advantages only if predation risk did not constrain energy acquisition, whereas diet quality affected primarily the extension of the larval period. Predation risk influenced juvenile shape, most likely via the effects on growth and differentiation rates. Juvenile frogs emerging from predator environments had shorter legs and longer bodies than those from the nonpredator tanks. However, these morphological changes did not translate into differences in relative jumping performance. Neither size-adjusted lipid storage nor fluctuating asymmetry was significantly influenced by food quality or predation risk. Our data suggest that the post-metamorphic costs of predator avoidance during the larval phase are mostly a consequence of small size at metamorphosis." (Authors)] The experimental design

6571. Novelo-Gutierrez, R.; Che Salmah, M.R. (2006): The larva of *Macromia cincta* Rambur, with a key to the known *Macromia* larvae of the Malaysian Peninsula (Anisoptera : Macromiidae). *Odonatologica* 35(1): 61-66. (in English). ["A female final instar larva (reared) from the Malaysian Peninsula is described and illustrated in detail. A comparison to other larvae of the genus inhabiting this Peninsula is made, and a key is provided. The unique features in the larva of *M. cincta* are: premental setae 4+2 or 4+3, dorsal protuberances on abdominal segments 3-10, increasing gradually to the rear but suddenly reduced on 10, and the presence of a basal tubercle on the inner margin of the galeolacina." 6573. Oppel, S. (2006): Site fidelity and dispersal of adult *Neurobasis awamena* Michalski in tropical rainforest streams in Papua New Guinea (Zygoptera: Calopterygidae). *Odonatologica* 35(4): 331-339. (in English). ["The species inhabits swift mountain streams at montane elevations of southern Papua New Guinea. In this study the duration for which adult male and female remained at a given site in rainforest streams was determined, and the dispersal distance and direction of marked individuals leaving the site of initial observation was assessed. Territorial defence was non-exclusive and male held territories for up to 45 days. On average, male remained 9 days, female 11 days at a given site. Both sexes stayed significantly longer at sites with suitable oviposition substrates than at a site without. Mating occurred only twice during the study period, and the scarcity of mating events might explain long territory holding times. On a

daily basis male moved larger distances than female, suggesting that female remain at a site for a longer period before moving a long distance. Both sexes showed similar lifetime dispersal distances (1000-1300m), and dispersal was predominantly directed upstream. It is concluded that this unidirectional dispersal of adults may compensate for downstream drift of larvae in rapid flowing streams." 6574. Pass, G.; Gereben-Krenn, B.-A.; Merl, M.; Plant, J.; Szucsich, N (2006): Phylogenetic relationships of the orders of Hexapoda: Contributions from the circulatory organs for a morphological data matrix. *Arthropod Systematics & Phylogeny* 64(2): 165-203. (in English). ["Discussions of phylogenetic studies based on morphological data focus mainly on results of the cladistic analysis while selection and evaluation of characters themselves are often underrepresented. Our paper seeks to address this with a survey of characters of the circulatory organs to contribute to the analysis of phylogenetic relationships of hexapod orders. The survey is based on examination of literature and includes, in addition, numerous unpublished data. Of 38 variable traits of the dorsal vessel and the various accessory circulatory organs, we selected 11 which are potentially informative at supraordinal level. They are critically discussed and coded as characters for use in comprehensive future cladistic analyses employing greater sets of morphological data. It must be stated that many features of circulatory organs for higher systematic categories are still based on one or few species for most orders of hexapods; this deficiency is due to the great methodological effort required to investigate internal organs. In general, circulatory organs of hexapods are simply organized making it difficult to discriminate homology from convergence. In addition to phylogeny, general aspects of the evolution of the circulatory system are outlined. In an appendix we provide comprehensive information on the traits, characters and the species in which they occur." (in English). ["The present immunocytochemical study reveals the presence of well-defined endocrine cells, intermingled with the columnar cells of the epithelium in the midgut region of the alimentary canal of *T. virginia*. The midgut endocrine cells are of 2 types, the open-type midgut endocrine cells (OMEC) with a long tubule opening into the lumen of the midgut and close-type midgut endocrine cells (CMEC) which are spherical in shape and devoid of extending tubules. Various gastrointestinal hormone-like substances are localized in respective types of midgut endocrine cells in different regions of the midgut i.e. anterior, middle and posterior. The NPY, FMRFamide and P-endorphin were localized in the open-type while substance P, gastrin, CCK and VIP in the close-type midgut endocrine cells. The midgut endocrine cells in *T. virginia* differ from each other in their location, cytomorphological and immunocytochemical cha-

racteristics representing different types of endocrine cells. Functional significance of these myotropic and vertebrate gastrointestinal hormone-like substances in the midgut endocrine cells of *T. virginia* is discussed." 6577. Phoenix, J.; Hentschel, W. (2006): Neue Nachweise von *Aeshna subarctica elisabethae* Djakonov, 1922 und *Somatochlora alpestris* (Selys, 1840) aus dem Böhmischem Teil des Erzgebirges [Krušné hory]. *Vážky 2005: Sborník referátu VIII. celostátního semináře odonatologu ve Žďárských vrších, ZO CSOP Vlašim, 2006: 167-174.* (in German, with Czech summary). [New records of *Aeshna subarctica elisabethae* Djakonov, 1922 and *Somatochlora alpestris* (Selys, 1840) from the Bohemian part of the Erzgebirge mountains. "The two bogdwelling dragonfly species *Aeshna subarctica elisabethae* and *Somatochlora alpestris* occur as well in the Saxonian as in the Bohemian part of the Erzgebirge [Krušné hory]. As far as we know today, the only reproductive habitats of *Aeshna s elisabethae* are restricted to a small, cross-border area in the western part of the Erzgebirge (bogs north of the village Prebuz [Frühbuss]). Concerning the distribution of *S. alpestris* in the bohemian part of the Erzgebirge there are only records from the bogs near the village Boží Dar [Gottesgab] and the bog Malé jerábí jezero [Kleiner Kranichsee] known. Because of more extended occurrence in the saxonian part (actually 16 localities, some of them in cross-border habitats) some additional still undetected localities are supposed in the bohemian part too. Therefore a special search for *S. alpestris* in suitable habitats in the higher mountain region of the Erzgebirge is suggested." 6578. Pintor, L.M.; Soluk, D.A. (2006): Evaluating the non-consumptive, positive effects of a predator in the persistence of an endangered species. *Biological Conservation* 130(4): 584-591. (in English). ["Failure to consider both the consumptive and non-consumptive effects of predators on prey can lead to erroneous conclusions about the net effect of the relationship. The predatory devil crayfish, *Cambarus diogenes* Girard functions as an ecosystem engineer constructing extensive burrow systems through aquatic habitats. Despite crayfish posing a serious predation threat, preliminary data indicate that the federally endangered Hines Emerald dragonfly larvae, *Somatochlora hineana* Williamson regularly inhabit crayfish burrows. During late summer, *S. hineana* larval habitat dries up; leaving crayfish burrows as some of the only wetted habitats. Thus, *C. diogenes* can affect *S. hineana* through both direct, negative and indirect positive effects. We examined the positive role of crayfish burrows as drought refuges, and the threat of predation by *C. diogenes* on *S. hineana* larvae.

Monthly field sampling indicated that *S. hineana* use open channel areas in spring and early summer moving into burrow systems in mid summer when channel areas normally dry. Laboratory experiments and field observations confirmed that crayfish prey on *S. hineana* larvae. Adult crayfish were a larger predation threat than juvenile crayfish. Despite their negative predatory impact, removal of crayfish from burrows in the field did not enhance densities of *S. hineana* larvae. Although *S. hineana* may face the threat of predation in burrows, they face a greater risk of desiccation if they remain in the open channel. These results lead to the counterintuitive conclusion that the maintenance of a predator is important for conserving an endangered prey species." (Authors)] Address: Pintor, Lauren, Univ. Calif. Davis, Dept Environm. Sci. and Policy, 1 Shields Ave, Davis, CA 95616 USA. E-mail: Impintor@ucdavis.edu

6579. Poopathi, S.; Tyagi, B.K. (2006): The challenge of mosquito control strategies: from primordial to molecular approaches. *Biotechnology and Molecular Biology Review* 1(2): 51-65. (in English). ["Mosquito control programs worldwide have been evaluating the feasibility to implement biological control strategies by using *Bacillus sphaericus* (Bs) and/or *B. thuringiensis* serovar israelensis (Bti). A comprehensive review is presented here to assess the potentiality of biological control agents in mosquito control operation. Vector control is primordial and very essential means for controlling transmission of filariasis, malaria, Japanese encephalitis and dengue in human society. Over the last few decades, there is growing realization that alternate methods to synthetic chemical control needs to be studied and perfected. In the last decade the bacilli based mosquito larvicides popularly known as biological larvicides are becoming more popular in vector management program the world over. The toxicity to mosquito larvae is due to crystal toxins encoded by specific genes. The major advantages of these biolarvicides are reduced application cost, safety to environment, human beings, animals and other non-target organisms. This special review paper explores the importance of bacterial toxin in controlling vector mosquitoes and the tactics for managing resistance to the mosquitocidal bacteria which include rotating different mosquitocidal strains and using genetic engineering to produce new combinations of toxins. This paper also provides a focus on continuous research toward identification of novel mosquitocidal toxins suitable for use if resistance to existing toxins." 6580. Rabosky, D.L. (2006): LASER: A maximum likelihood toolkit for detecting temporal shifts in diversification rates from molecular phylogenies. *Evolutionary Bioinformatics Online* 2006: 257-260. (in English). ["Rates of species origination and extinction can vary over time during evolutionary radiations, and it is possible to reconstruct the history of diversification using molecular phylogenies of extant taxa only. Maximum likelihood methods provide a useful framework for inferring temporal variation in diversification rates. LASER is a package for the R programming environment that imple-

ments maximum likelihood methods based on the birth-death process to test whether diversification rates have changed over time. LASER contrasts the likelihood of phylogenetic data under models where diversification rates have changed over time to alternative models where rates have remained constant over time. Major strengths of the package include the ability to detect temporal increases in diversification rates and the inference of diversification parameters under multiple rate-variable models of diversification. The program and associated documentation are freely available from the R package archive at <http://cran.r-project.org>." (Author) Example: Holarctic Damselfly Radiation; Turgeon et al. (2005). 6584. Richardson, J.L. (2006): Novel features of an inducible defense system in larval tree frogs (*Hyla chrysoscelis*). *Ecology* 87(3): 780-787. (in English). ["Organisms in aquatic ecosystems must often tolerate variable environmental conditions, including an uncertain risk of predation. Individuals that can maintain plastic defenses against predation will increase their survival when predators are present, but will not incur the costs of these defenses when the risk of predation is low and the defense is not induced. Larvae of the pond-breeding anuran *Hyla chrysoscelis* develop a conspicuous phenotype in the presence of predators consisting of a brightly colored tail and a deeper tail fin. In this study, I attempted to identify the source of the chemical signal that induces this defensive morphology in this species. I tested whether metabolites alone, originating from the prey but passing through the predator, were able to induce the same morphological response as the combination of alarm signals released directly by at-

tailed conspecifics, and metabolites. I used morphometric and tail conspicuousness data to assess tadpole response to the perceived risk of predation by larval odonate predators (*Anax junius*). I also tested whether this inducing cue could be recognized across species by measuring the morphological response of *H. chrysoscelis* tadpoles exposed to cues emitted when tadpoles of a closely related genus (*Pseudacris crucifer*) were consumed. Tadpoles exhibited a clean morphology in response to all cues corresponding to their relative reliability as indicators of a risk of predation. *H. chrysoscelis* tadpoles were also able to respond to cues emitted when tadpoles of a closely related genus were consumed by predators. These results illustrate that tadpoles of this species are able to respond to metabolites alone without alarm signals, and that interspecific chemical communication is a primary mechanism for predator avoidance in this inducible defense system." (Author)] Address: Richardson, J.L., Univ. Washington, Dept Biol. Struct., Box 357420, Seattle, WA 98195 USA

6585. Richardson, J.M.L.; Gunzburger, M.S.; Travis, J. (2006): Variation in predation pressure as a mechanism underlying differences in numerical abundance between populations of the poeciliid fish *Heterandria formosa*. *Oecologia* 147(4): 596-605. (in English). ["We explored whether a variation in predation and habitat complexity between conspecific populations can drive qualitatively different numerical dynamics in those populations. We considered two disjunct populations of the least killifish, *Heterandria formosa*, that exhibit long-term differences in density, top fish predator species, and dominant aquatic vegetation. Monthly censuses over a 3-year period found that in the higher density population, changes in *H. formosa* density exhibited a strong negative autocorrelation structure: increases (decreases) at one census tended to be followed by decreases (increases) at the next one. However, no such correlation was present in the lower density population. Monthly census data also revealed that predators, especially *Lepomis* sp., were considerably more abundant at the site with lower *H. formosa* densities. Experimental studies showed that the predation by *Lepomis gulosus* occurred at a much higher rate than predation by two other fish and two dragonfly species, although *L. gulosus* and *L. punctatus* had similar predation rates when the amount of vegetative cover was high. The most effective predator, *L. gulosus*, did not discriminate among life stages (males, females, and juveniles) of *H. formosa*. Increased predation rates by *L. gulosus* could keep *H. formosa* low in one population, thereby eliminating strong negative density-dependent regulation. In support of this, changes in *H. formosa* density were positively correlated with changes in vegetative cover for the population with a history of lower density, but not for the population with a history of higher density. Our results are consistent with the hypothesis that the observed differences among natural populations in numerical abundance and dynamics are caused in part by the differences in habitat complexity and the predator community." zed by stomach flushing technique. *Mauremys rivulata* is an omnivorous species, with food items including aquatic insects and their larvae, amphibians and plants. Juvenile turtles were strictly carnivorous and larger ones shifted to a more herbivorous diet. Animal remains found in juveniles were more diverse, consisting of at least six different species of insects and amphibians, while larger animals consumed at the most three different animal species." (Authors) Odonata, preferably Anisoptera, Libellulidae represent approximately 25% of food items in adult *M. rivulata*. Juvenile terrapins also consumed adult Zygoptera.] Address: Amr, Zuhair S., Jordan Univ. Sci. & Technol., Dept Biol., POB 3030, Irbid, Jordan. E-mail: amrz@just.edu.jo

6587. Robb, T.; Forbes, M.R. (2006): Sex biases in parasitism of newly emerged damselflies. *Ecoscience* 13(1): 1-4. (in English, with French summary). ["There are several examples of sex-biased parasitism of invertebrate hosts. Sex biases in parasitism could be explained by differences between males and females either in exposure to or susceptibility to parasites. Our results show that for the common spreadwing damselfly, *Lestes disjunctus*, there was a female bias in mean intensity of parasitism by larval *Arrenurus pollictus* mites for newly emerged individuals sampled over emergence periods in both 2002 and 2003. This bias could not be explained by host body size and timing of emergence, factors thought to influence exposure of host larvae to larval mites. We suggest a novel explanation for sex-biased parasitism based on differences in developmental trajectories of larval male and female hosts, which should influence frequency of contact by larval mites. This explanation may help explain female-biased parasitism in other lestad damselflies, which should be exaggerated for early emerging species with compressed emergence periods. Further work is needed to test this novel explanation and determine whether it is applicable to other invertebrate host-parasite associations where parasites first come into contact with immature stages of hosts." 6588. Robb, T.; Forbes, M.R. (2006): Age-dependent induction of immunity and subsequent survival costs in males and females of a temperate damselfly. *BMC Ecology* 6: 13 pp. (in English). ["Background: To understand variation in resistance to parasites within host populations, researchers have examined conditions under which immunity is induced and/ or is costly. Both host sex and age have been found to influence immune expression and subsequently are likely factors influencing the costs of resistance. The purpose of this study was to examine immune expression and associated survival costs for two age groups (newly emerged and sexually mature individuals) of the damselfly, *Enallagma boreale* Selys. Survival was assessed for experimentally challenged and control damselflies, housed initially at 22°C and then subjected to low temperatures (15°C) associated with reduced foraging activity and food deprivation. Experimental conditions emulated natural local variation in bouts of good weather followed by inclement weather (successions of days with hourly mean temperatures around 15°C and/ or rainy weather). Results: At least one of three immune traits was induced to higher levels for both newly emerged and mature *E. boreale* challenged by Lippopolysaccha-

ride (LPS) relative to saline-injected controls, when housed at 22°C. The immune traits assayed included haemocyte concentration, Phenoloxidase activity and antibacterial activity and their induction varied among ages and between males and females. For matures, those injected with LPS had lowered survivorship compared to saline-injected controls that were housed initially at 22°C and subsequently at 15°C. Newly emerged LPS-injected damselflies did not show reduced survivorship relative to newly-emerged controls, despite showing immune induction. Conclusion: Reduced longevity following induction of immunity was observed for reproductively mature damselflies, but not for newly emerged damselflies. Costs of resistance depend only partly on the immune trait induced and more on the age (but not sex) of the host. In four years, we often observed bouts of inclement weather following good days and these bouts occurred primarily during the emergence periods, but also during the flight periods, of *E. boreale*. The duration of these bouts appear sufficient to compromise survival of mature damselflies that responded immunologically to LPS challenge. We further suggest the environmental conditions likely experienced by different ages of damselflies, following resistance expression, has influenced optimal immune investment by individuals in different age classes and the likelihood of detecting costs of resistance." 6591. Samways, M.J. (2006): Open and banded wings: Hypotheses on damselfly wing position (Zygoptera). *Odonatologica* 35(1): 67-73. (in English). ["Zygoptera species either perch with their wings open or closed. The alternatives do not appear to be phylogenetically constrained, as there are sexual differences in *Ecchlorolestes peringueyi*, and population variation and individual variation in *Pseudagrion sublacteum*. Open wings would appear to be more conspicuous to predators (Shiny Wing Hypothesis). Yet there is a difference between clear and coloured, banded wings in *Chlorolestes* species. Clear wings appear to be associated with crypsis, either in open or forest habitats. For species that have banded wings (and banded bodies), those individuals that are banded are aggressively territorial to clear-winged conspecifics and are sexually more attractive to female female. Open-winged perching behaviour is associated with perching on tips of shoots and rapid escape from ground predators, supporting the Quick Takeoff Hypothesis. Conspicuous open-winged perching for banded-wing individuals appears to be a tradeoff between territorial superiority on the one hand and predation from aerial predators, particularly birds, on the other. Predation however, appears to be minor relative to the advantages gained by conspicuousness." (Author)] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

6592. Samways, M.J. (2006): National red list of South African Odonata. *Odonatologica* 35(4): 341-368. (in English). ["Using the IUCN categories and criteria, the conservation status of the South African dragonfly fauna has been assessed. IUCN recommendations for adjusting the global categories and criteria for national red listing have been taken into consideration. A total of 40 taxa are listed as threatened or near-threatened, which is 25% of the national total (160 species and subspecies). The precautionary rather than evidentiary approach is taken throughout, especially as many sp. are marginal and although not threatened globally are highly threatened locally. Nevertheless, it is clear that locally the South African odonate fauna is under severe threat, especially the stream sp. Many of the threats are synergistic, both with natural drought/flood cycles, and with other threats. Restoration of hydrological regimes and riparian conditions are promoting conservation of this odonate assemblage." (Author)] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

6593. Schilder, R.J.; Marden, J.H. (2006): Metabolic syndrome and obesity in an insect. *Proc. Natl. Acad. Sci. USA* 103(4): 18805-18809. (in English). ["Dragonflies infected with noninvasive gregarine gut parasites (Microsporidia, Apicomplexa) have reduced flight-muscle performance, an inability to metabolize lipid in their muscles, twofold elevated hemolymph carbohydrate concentrations, and they accumulate fat in their thorax in a manner analogous to mammalian obesity. Gregarine infection is associated with inappropriate responses of hemolymph carbohydrate concentration to insulin and with chronic activation in the flight muscles of p38 MAP kinase, a signaling molecule involved in

immune and stress responses. Short-term exposure to gregarine excretory/secretory products caused elevated blood carbohydrate and p38 MAPK activation in healthy individuals. These characteristics comprise a set of symptoms and processes that are known in mammals as metabolic syndrome but which have not previously been described in other animal taxa. In addition to expanding the known taxonomic breadth of metabolic disease, these results indicate that insects may be useful experimental models for studying its underlying biology and mechanisms." 6596. Steffens, W.P.; Smith, W.A. (2006): Description of the larva of *Somatochlora incurvata* Walker (Anisoptera: Corduliidae). *Odonatologica* 35(4): 379-383. (in English). ["The last larval instar is described and illustrated from material collected in central and southeast Wisconsin, United States, and the larval habitat is described. The larva differs from related species in the arctica group of *Somatochlora* in having a greater head width and in the dorsolateral setal patterns on abdominal tergites VI-IX. Segment IX has distinct paired dorsolateral tufts, and VIII, VII, and VI have progressively less defined to absent paired tufts. These characters distinguish the species from the most similar species, *S. forcipata*, and all others of the arctica group." 6597. Stoks, R.; De Block, M. (2006): Physiological costs of compensatory growth in a damselfly. *Ecology* 87(6): 1566-1574. (in English). ["Little is known about physiological costs of rapid growth. We successfully generated compensatory growth to time stress and transient food stress in the damselfly *Lestes viridis* and studied the physiological correlates of the resulting reduced ability to cope with starvation. We found evidence for both mechanisms proposed to underlie the physiological trade-off: compensatory growth was associated with (1) a higher metabolic rate, as indicated by a higher oxygen consumption and a faster depletion of energy storage molecules (glycogen and triglycerides), and (2) a smaller investment in energy storage. The former may also explain why storage molecules after emergence were negatively affected by time stress and

food stress, despite the successful compensation before emergence. These deferred physiological costs of rapid growth have the potential to couple larval stresses to adult fitness irrespective of age and size at emergence, and they may partly explain why many animals do not show their maximum achievable growth rate." 6598. Stoks, R.; De Block, M.; Slos, S.; Van Doorslaer, W.; Rolff, J. (2006): Time constraints mediate predator-induced plasticity in immune function, condition, and life history. *Ecology* 87(4): 809-815. (in English). ["The simultaneous presence of predators and a limited time for development imposes a conflict: accelerating growth under time constraints comes at the cost of higher predation risk mediated by increased foraging. The few studies that have addressed this tradeoff have dealt only with life history traits such as age and size at maturity. Physiological traits have largely been ignored in studies assessing the impact of environmental stressors, and it is largely unknown whether they respond independently of life history traits. Here, we studied the simultaneous effects of time constraints, i.e., as imposed by seasonality, and predation risk on immune defense, energy storage, and life history in lepid damselflies. As predicted by theory, larvae accelerated growth and development under time constraints while the opposite occurred under predation risk. The activity of phenoloxidase, an important component of insect immunity, and investment in fat storage were reduced both under time constraints and in the presence of predators. These reductions were smaller when time constraints and predation risk were combined. This indicates that predators can induce sublethal costs linked to both life history and physiology in their prey, and that time constraints can independently reduce the impact of predator-induced changes in life history and physiology." 6600. Svensson, E.I.; Eroukhmanoff, F.; Friberg, M. (2006): Effects of natural and sexual selection on adaptive population divergence and premating isolation in a damselfly. *Evolution* 60(6): 1242-1253. (in English). ["The relative strength of different types of directional selection has seldom been compared directly in natural populations. A recent meta-analysis of phenotypic selection studies in natural populations suggested that directional sexual selection may be stronger in magnitude than directional natural selection, although this pattern may have partly been confounded by the different time scales over which selection was estimated. Knowledge about the strength of different types of selection is of general interest for understanding how selective forces

affect adaptive population divergence and how they may influence speciation. We studied divergent selection on morphology in parapatric, natural damselfly (*Calopteryx splendens*) populations. Sexual selection was stronger than natural selection measured on the same traits, irrespective of the time scale over which sexual selection was measured. Visualization of the fitness surfaces indicated that population divergence in overall morphology is more strongly influenced by divergent sexual selection rather than natural selection. Courtship success of experimental immigrant males was lower than that of resident males, indicating incipient sexual isolation between these populations. We conclude that current and strong sexual selection promotes adaptive population divergence in this species and that premating sexual isolation may have arisen as a correlated response to divergent sexual selection. Our results highlight the importance of sexual selection, rather than natural selection in the adaptive radiation of odonates, and supports previous suggestions that divergent sexual selection promotes speciation in this group." 6601. Tarkowska-Kukuryk, M. (2006): Water soldier *Stratiotes aloides* L. (Hydrocharitaceae) as a substratum for macroinvertebrates in a shallow eutrophic lake. *Pol. J. Ecol.* 54(3): 441-451. (in English). ["The importance of water soldier (*Stratiotes aloides* L.) as a colonization substratum for epiphytic and mining fauna has been investigated in the shallow, eutrophic lake in East Poland. Samples were taken in May, July and October in 2000–2001. Studies focused on abundance and species diversity of phytophilous fauna of *Stratiotes aloides*, in particular on the relation between epiphytic and mining organisms and their seasonal changes. The studied zoocenosis differed significantly in terms of density and taxa number. In all studied seasons fauna inhabiting *Stratiotes aloides* showed higher abundance and species diversity than mining invertebrates. Both zoocenosis were predominated by Chironomidae larvae. The percentage of midges in epiphytic fauna decreased slightly during vegetation period, the mining fauna showed the opposite pattern. Epiphytic Chironomidae were dominated by four taxa (*Dicrotendipes* sp., *Glyptotendipes* sp., *Paratanytarsus austriacus*, *Psectocladus* sp.). The mining fauna was represented mainly by *Glyptotendipes* sp. larvae. Density and biomass of epiphytic fauna showed the positive correlation with water soldier biomass." 6605. Thomas, E.J.; John, J. (2006): Diatoms and macroinvertebrates as biomonitors of mine-lakes in Collie, Western Australia. *Journal of the Royal Society of Western Australia* 89(3): 109-117. (in English). ["Several voids created through open-cut coal mining occur near the town of Collie in the south-west of Western Australia. After mining, the voids fill with fresh water and form mostly acidic wetlands. Five of these mine-lakes were monitored in 1999 using macroinvertebrates and diatoms. On the basis of acidity and water chemistry two groups of wetlands were identified using multivariate analyses; wetlands with low pH (< 4.5), and those with comparatively higher pH (> 4.8). Distinct macroinvertebrate and diatom assemblages were characteristic of each of the wetland groups. Macroinvertebrates including *Orthetrum caledonicum* and *Megaporus solidus* were associated with the Group 1 wetlands (pH < 4.5) while *Sternopriscus browni* and *Micronecta* sp. were two of the most abundant macroinvertebrates in the Group 2 wetlands (pH > 4.8). In the Group 1 wetlands *Nitzschia paleaeformis* and *Pinnularia microstauron* were among the dominant diatom species. *Eunotia curvata* and *Tabellaria flocculosa* were two of the diatom species commonly found in the Group 2 waterbodies. While pH was one of the factors primarily responsible for the distribution of both biomonitors, diatoms appeared to be more sensitive than macroinvertebrates to acidity." 6606. Thompson, D.J.; Watts, Ph.C. (2006): The structure of the *Coenagrion mercuriale* populations in the New Forest, southern England. In: Rivera, AC (ED). 2006. Forests and Dragonflies. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. *Pensoft Series Faunistica* 61: 239-258. (in English). [UK; *C. mercuriale* "is a poor disperser and susceptible to habi-

tat fragmentation/loss. It is protected by European legislation. An analysis of Capture-Mark-Recapture (CMR) data indicated that the population network on Beaulieu Heath in the New Forest comprised some 40 000 individuals. A nationwide genetic study indicates that the New Forest is a principal reservoir of genetic diversity for UK *C. mercuriale*. The New Forest is, however, presently best characterised as five genetic units. We found that several small, isolated populations of *C. mercuriale* in the New Forest showed substantial genetic differentiation from the principal populations on Beaulieu Heath, Setley Plain and Mill Lawn Brook. Isolation is brought about by preventing dispersal across intervening areas of unsuitable habitat such as forest, farmland or road. Although habitat loss is a principal concern for the persistence of this species, the pattern of limited movement to proximate sites highlights the need for a network of suitable habitat patches. This will also help to slow the rate of genetic erosion at peripheral sites." 6608. Van de Meutter, F.; Stoks, R.; De Meester, L. (2006): Rapid response of macroinvertebrates to drainage management of shallow connected lakes. *Journal of Applied Ecology* 43(1): 51-60. (in English). ["1. Shallow lakes throughout the world are subject to drainage, either for fish harvesting or lake restoration. Lake drainage of fish lakes is known to improve macrophyte and zooplankton diversity, but the effect on the macroinvertebrate community is poorly known. 2. In the present study, we investigated temporal trends in the macroinvertebrate community following drainage of six shallow connected lakes. Diversity increased for all macroinvertebrates (family level). Recolonization of the lakes occurred within the first year after the drainage and was supplemented with a set of species that were previously rare or did not occur in the lakes. Changes in the abiotic conditions of the lakes were small and transient, except for the decline in fish. The rapid recolonization by the species occurring before drainage is attributed to the high connectivity of our system. The appearance of supplementary species may relate to lowered fish predation, suggesting that fish were a dominant factor in shaping the communities. 3. Synthesis and applicati-

ons. Lake drainage has a positive effect on the diversity and richness of macroinvertebrates in shallow connected lakes. This positive effect may be due to a decline in fish predation following lake drainage in combination with a high rate of recolonization among others via connections to non-drained lakes. Lake drainage, therefore, is probably the most cost-effective lake restoration tool in shallow connected lakes. Other restoration tools may be preferable in isolated lakes where recolonization is constrained." (Authors) The analysis includes Odonata.] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

6611. Walsh, E.J.; Salazar, M.; Ramirez, J.; Moldes, O.; Wallace, R.L. (2006): Predation by invertebrate predators on the colonial rotifer *Sinantherina socialis*. *Invertebrate Biology* 125(4): 325-335. (in English). ["Colonies of the freshwater colonial rotifer *Sinantherina socialis* (Monogononta, Flosculariidae) have been shown to be unpalatable to a variety of small-mouthed, zooplanktivorous fishes. To test whether invertebrate predators ingest the rotifer *S. socialis*, we conducted two types of experiments: (1) Microcosm experiments-in separate experiments, four invertebrate predators (i.e., dragonfly nymphs, damselfly nymphs, notonectids, and Hydra) were offered prey either singly or in combination. Prey were comprised of *S. socialis*; *Epiphanes senta*, a solitary, free-swimming rotifer; and *Daphnia magna*, a microcrustacean. In each experiment, the percent of prey surviving after 12, 18, and 24 h was recorded. (2) Paired-feeding experiments-in separate experiments, predators were offered prey in a pairwise fashion, in which members of *D. magna* were alternated with a rotifer, either *S. socialis* or *E. senta*. The results of the microcosm experiments showed that, after 24 h, 60-100% prey items of *S. socialis* survived the predators, but significantly fewer individuals of *E. senta* (6-89%) and *D. magna* (< 25%) survived. When offered rotifers and individuals of *D. magna* simultaneously, predators tested consistently consumed more specimens of *Daphnia*. However, predators significantly reduced percent survival in *E. senta* but not in *S. socialis*. Preda-

tors, given a choice between the two rotifer species, all consumed significantly more specimens of *E. senta* than *S. socialis* after 24 h. In the paired-feeding experiments, three of the four predators captured members of *S. socialis*, but these colonies were frequently released rather than ingested, although in some cases colony structure was seriously disrupted. Our results suggest that the unpalatable nature of members of *S. socialis* to certain fishes extends to several invertebrate predators, but the nature of the putative factor(s) responsible for this remains unknown." (Authors)] Address: Walsh, Elizabeth J., Univ. Texas, Dept Biol. Sci., El Paso, TX 79968 USA. E-mail: ewalsh@utep.edu

6612. Wasscher, M.T. (2006): From NLO to NVL, 35 years of organized dragonfly study in The Netherlands. *Brachytron* 9(1-2): 21-32. (in Dutch, with English summary). ["Before 1970 some people in The Netherlands were studying dragonflies, but there was no higher organisation with newsletters and/or meetings. Since the start of the NLO on 7 March 1970, three periods of 'official' dragonfly activity can be recognised. These periods were separated by intervals of lesser activity, where no meetings were organised and few, if any, official newsletters were published. In those intervening periods, there were always youth federation members studying dragonflies, and those dragonfly lovers would then start the next period of official dragonfly study in The Netherlands. The first period commenced with the formation of the NLO during 1970, under the leadership of Bastiaan Kiauta. This period ended with the foundation of the international SIO in 1974. The second period lasted from 1979 to 1992 and was started by Marian Verdonk, with Marcel Wasscher gradually taking over her tasks. The final period, which is still on-going, started in 1994, though already in 1992 youth federation members of the NJN had started a 'Dragonfly Project' which would result in increased interest in dragonflies in The Netherlands. In 1997 both the NLO and the Dragonfly Project merged into a new dragonfly organisation, the NVL. In 2002 the Dutch Atlas was published, a milestone in dragonfly study in The Netherlands. Over the last decade, dragonflies have become an important group for nature study and nature management. This is illustrated by an official Red List, two field guides in Dutch, 22 regional and provincial study groups and over 400 members of the NVL, some of whom are also professional dragonfly workers." 6615. Yanybaeva, V.A.; Dumont, H.J.; Haritonov, A.Yu.; Popova, O.N. (2006): The Odonata of south ural, Russia, with special reference to *Ischnura aralensis* Haritonov, 1979. *Odonatologica* 35(2): 167-185. (in English). ["The odonate fauna of S. Ural (Russia), as known from literature data and new collections, is composed of 59 species. *Coenagrion ecornutum*, *Ischnura pumilio*, *Somatochlora graeseri* and *Selysiothemis nigra* are first records for S. Ural; the presence of *Ischnura aralensis* Haritonov, 1979 (syn. *I. haritonovi* Dumont, 1997), *Aeshna cyanea*, *Anax imperator* and *Libellula depressa* is confirmed, but that of *Pyrrhosoma nymphula*, *Sympetma fusca*, *Cordulegaster boltonii* and *Libellula fulva* is not. *Aeshna undulata* Bartenev, 1909 is a probable synonym of *A. juncea* Linnaeus, 1758. *I. aralensis*, *C. ecornutum*, *Enallagma cyathigerum risi* and *S. graeseri* were found W as well as E of the Ural River, and thus are part of the fauna of Europe. Several western species reach their limit of eastward extent in S. Ural and, conversely, several eastern (Siberian) species reach their limit of westward extent there too. The range of *I. aralensis* is discussed in the light of the contractions and expansions of the Caspian-Aral lakes during the Late Pleistocene. The current disjunct positions of its colonies is understood as the result of the present phase of aridity in middle Asia." (Authors)] Address: Yanybaeva, V. A., Bashkirian State Nat Reserve, RUS-453592 Sargaya, Bashkortostan R, Russia. E-mail: bashart@bashnet.ru

6616. Yuan, H.-W.; Burt, D.B.; Wang, L.-P.; Chang, W.-L.; Wang, M.-K.; (2006): Colony site choice of blue-tailed bee-eaters: influences of soil, vegetation, and water quality. *Journal of Natural History* 40(7-8): 485-493. (in English). ["All bee-eaters (Family Meropidae) are cavity nesters, excavating terrestrial burrows in sites ranging from flat ground, to small mounds of soil, steep earthen banks seen in road clearings, eroded cliff faces, and river gorges. However, very little is known concerning the environmental factors that influence nest site selection in bee-eaters. We addressed abiotic and biotic issues associated with colony site choice in blue-tailed bee-eaters (*Merops philippinus*) nesting on Kin-

men Island, off mainland China, from 2000 to 2002. About 89% of the colonies were located on slopes with soils of sandy loam and the other 11% on sandy clay loam. No colony was found on clay loam, which covered 20% of the island. The sandy loam and sandy clay loam had lower soil pressure, density and moisture, which, presumably, were easier for bee-eaters to excavate and provided better drainage and ventilation for nest cavities. Bee-eaters avoided placing nest cavities in areas with dense vegetation and abandoned colony sites when they became overgrown. Vegetation would impede excavation and decrease the detectability of predators. Bee-eaters may prefer colony sites near water bodies showing water chemistries indicative of more biological productivity, especially in relation to the diversity and abundance of their major prey, dragonflies." (Authors) 13 Odonata species are listed in table 3.] Address: Ding, Tzung-Su, Natl Taiwan Univ, Sch Forestry and Resource Conservat, Taipei, Taiwan. E-mail: ding@ntu.edu.tw

6617. Yutaka, Y.; Sato, N. (2006): The influences of the application of organic matters as the substitution of chemical fertilizers and the reduction of agricultural chemicals on the growth and yield of rice plant and the frowning wings of Red dragonflies. *Bulletin of the Fukushima Prefecture Agricultural Experiment Station* 37: 28-39. (in Japanese, with English summary). ["The influences of the chemical fertilizers, the agricultural chemicals and the organic matters on the growth and yield of rice plant and the growing wings of red dragonflies were investigated in the cold and highland areas, especially Inawashiro Town, where the resident has an interest in the environment. The yield of brown rice in the use of organic matters, such as cattle or chicken manures and strained lees of rapeseed oil, as the substitution chemical fertilizers decreased around 10% compared with those of the popular cultivation. The reduction of yield was associated with a lower number of ears, which was caused by the suppression of tiller number on the initial growing stage. The reduction of agricultural chemicals did not affect the growth and yield of rice plant except to herbicide. However, the yield of brown rice in the field not applied herbicide was almost 30% less than that of the popular cultivation by the propagation of weed on the 3 years later. Red dragonflies grew wings from the beginning to end in July, and the peak of the number of growing wings was shown in the mid-July. The number of red dragonflies grown wings evidently decreased by the midterm drainage, and it decreased by the surface spread of the dried cattle manure used for the purpose of the constraint of weed. Then, it was suggested that the growing wings of red dragonflies was not affected by the application of chemical fertilizer and agricultural chemicals except to insecticide, but decreased by the application of an insecticide." (Author)] Address: Yutaka, Y., Fukushima Prefecture Agricultural Experiment Station, Japan

6618. Zawal, A. (2006): Phoresy and parasitism: water mite larvae of the genus *Arrenurus* (Acari: Hydrachnidia) on Odonata from Lake Binowskie (NW Poland). *Biological Letters* 43(2): 257-276. (in English). ["Larvae of the genus *Arrenurus* parasitize Odonata, Diptera and Coleoptera. This work describes relationships between *Arrenurus* larvae and Odonata (imagines, larvae and exuviae) in a Polish lake. The mites examined were found on 2349 adult odonates (277 female and 872 male), 805 larvae (356 female and 449 male) and 395 e-

xuviae of 34 species from Lake Binowskie and its vicinity. In total, 1128 larval water mites were collected from adult odonates, 556 from larvae, and 165 from exuviae. Water mite larvae were found on imagines of 9 species, on larvae of 12 species, and on exuviae of 9 species. Among adult of odonates only damselflies (Zygoptera) were parasitized, and a high prevalence (up to 77.8%) and intensity (up to 195 parasites per host) of parasitism were recorded. Adult females were more frequently infested than males, the preferred body parts being the thorax and the ventral side of the middle segments of the abdomen. Both phoretic and parasitic larvae of water mites were found on odonate larvae. Phoretic larvae constituted 25.8% of the total number of water mite larvae on odonate larvae. The occurrence of water mite larvae on exuviae shows their mortality when mites fail to move onto the eclosing adult odonate or when mites do not get detached from odonate larvae before their emergence from water." 6621. Abdel-Salam Shaalan, E.; Canyon, D.V.; Muller, R.; Wagdy Faried (2007): A mosquito predator survey in Townsville, Australia, and an assessment of *Diplonychus* sp. and *Anisops* sp. predatorial capacity against *Culex annulirostris* mosquito immatures. *Journal of Vector Ecology* 32 (1): 16-21. (in English). ["A twelve-month survey for mosquito predators was conducted in Townsville, Queensland, Australia, which is located in the arid tropics. The survey revealed the presence of five predaceous insects but only *Anisops* sp. (backswimmers) and *Diplonychus* sp. were common. Predatorial capacity and factors influencing this capaci-

ty were then assessed for adult *Anisops* sp. and adult and nymph stages of *Diplonychus* sp. against *Culex annulirostris* mosquito immatures under laboratory conditions. Predatorial capacity bioassays showed that adult *Diplonychus* sp. preyed upon both larval and pupal stages of *Cx. annulirostris* quite successfully. Nymphs of *Diplonychus* sp. proved to be more successful with smaller prey immatures, and *Anisops* sp adults did not prey successfully on any prey pupae. Increasing the foraging area and introducing aquatic vegetation significantly reduced the predatorial capacity of *Diplonychus* sp. nymphs, while only vegetation and not foraging area had a significant effect on adult *Diplonychus* sp. predation capacity. Overall, adult *Diplonychus* sp. proved to be a more efficient predator than *Anisops* sp., and field trials are now recommended to further assess the potential of *Diplonychus* sp. as a biocontrol agent." (Authors) Odonata are treated on the order resp suborder level.] Address: Abdel-Salam Shaalan, E., Zoology Department, Aswan Faculty of Science, South Valley University, Aswan, Egypt

6623. Araujo, Y.; Beserra, P. (2007): Diversity of invertebrates consumed by the Yanomami and Yekuana communities from the alto Orinoco, Venezuela. *Inierciercia* 32(5): 318-323. (in Spanish, with English and Portuguese summaries). ["Invertebrates represent a rich and tempting food for the indigenous people and play an important role in the diet of these populations. The aim of this work was to make the taxonomic identification of the invertebrate species consumed by the indigenous communities Yanomami and Yekuana from the Alto Orinoco region, Amazonas State, Venezuela. Open interviews were carried out and behavioral observation made of 27 males and 9 females from 12 to 70 years old. Larvae and adult specimens of invertebrates indicated and validated as eatable were collected alive and later identified. The Yanomami consume 20 and the Yekuana 28 species of invertebrates. The Yanomami eat mainly caterpillars, larvae of scarabs and wasps, termites, ants and spiders, while the Yekuana consume earthworms, shrimps, oysters and a variety of aquatic insects. The proximity of the Yekuana communities to rivers and streams has possibly contributed to the specialization of their rich diet in aquatic insects "(including Odonata)", unlike the Yanomami communities that consume mainly terrestrial invertebrates of forest origin. The strategy of the natives in the consumption of these small animals indicates that they have a detailed knowledge of their environment and of the use and manipulation of the forest resources, to provided food to the human populations without affecting biodiversity." 6624. Armstrong, R.H.; Hudson, J.; Hermans, M. (2007): *Dragons in the Ponds*. Nature Alaska Images (Juneau, Alaska). ISBN 978-1-57833-362-2: 32 pp.. (in English). [This book is directed towards encouraging a child's interest in Odonata. It provides a general overview of the adult and nymphal morphology, outlines the number of species, and introduce all the major North American families providing examples. This is followed by presenting the dragonflies, which were chosen as Official State Insects: Alaska - *Libellula quadrimaculata* and Washington - *Anax junius*. The majority of the book is dedicated to the life history of Anisoptera. It is full of colour photos showing nymphs feeding, adults emerging, mating, laying eggs, being preyed upon, and a number of flight shots as well (including Zygoptera). Some of these photos are really impressive. (Martin Schorr)] Address: www.alaskabooksandcalendars.com

6625. Baker, R.A. (2007): What was the British list like 120 years ago? Robert McLachlan's 1884 list of Odonata compared with today's lists. *J. Br. Dragonfly Society* 23(2): 52-57. (in English). ["A comparison is made between the list of Odonata from Britain recorded in 1884 and those published recently. Robert McLachlan, who published the nineteenth century list, relied on his own observations and earlier accounts, together with records of museum and private collections. The species which have become extinct and those recorded for the first time in Britain since McLachlan's paper was published, are of particular interest." 6627. Beaton, G. (2007): *Dragonflies and Damselflies of Georgia and the Southeast*. Wormsloe Foundation Nature Book. University of Georgia Press. ISBN-13: 978-0820327952 : 355 pp. (in English). ["... Organized for easy use in the field, this abundantly illustrated guide, with more than 400 color photographs, is the first to cover Georgia's Odonata. It details more than 150 species - species that are also the ones most likely to be seen throughout the U.S. Southeast north of Florida. The guide first explains dragonfly and damselfly body parts, taxonomy, life cycles, and habitats; discusses conservation issues; and offers tips on observing and photographing odonates. Later chapters, organized according to the ten odonate families, such as spreadwings, darners, spiketails, and emeralds, provide general family information followed by accounts of individual species. The beautifully illustrated species accounts

describe general appearance and key identification features, distribution, habitats, life history and behavior, and conservation. Supplementary materials include suggestions for the best places to watch odonates in Georgia, a comparative listing of species' level of endangerment, and the date range during which each species can be seen... - Included in species accounts are: beautiful, detailed photos that show odonates from angles important to determining species, sex, or age; common and scientific names; important features for field identification, with tips on distinguishing between similar-looking species; typical behavior of the species, including breeding and feeding habits; occasional commentary on taxonomy or other notable features; and, colorful quick guide, with a range map, incidence information, sizing graphics, and flight period information. Additional features include: listing of twenty ideal sites around the state for odonate watching; notes on infrequently sighted species; ratings for each odonate's conservation status, from most critically imperiled to most stable species; chronological listing of flight dates; listing of additional resources: books, organizations, Web sites, and equipment suppliers; and, a glossary and index. 6628. Berry, R.; van Kleef, J.; Stange, G. (2007): The mapping of visual space by dragonfly lateral ocelli. *Journal of Comparative Physiology A: Neuroethology, Sensory, Neural, and Behavioral Physiology* 193: 495-513. (in English). ["We study the extent to which the lateral ocelli of dragonflies are able to resolve and map spatial information, following the recent finding that the median ocellus is adapted for spatial resolution around the horizon. Physiological optics are investigated by the hanging-drop technique and related to morphology as determined by sectioning and three-dimensional reconstruction. L-neuron morphology and physiology are investigated by intracellular electrophysiology, white noise analysis and iontophoretic dye injection. The lateral ocellar lens consists of a strongly curved outer surface, and two distinct inner surfaces that separate the retina into dorsal and ventral components. The focal plane lies within the dorsal retina but proximal to the ventral retina. Three identified L-neurons innervate the dorsal retina and extend the one-dimensional mapping arrangement of median ocellar L-neurons, with fields of view that are directed at the horizon. One further L-neuron innervates the ventral retina and is adapted for wide-field intensity summation. In both median and lateral ocelli, a distinct subclass of descending L-neuron carries multi-sensory information via graded and regenerative potentials. Dragonfly ocelli are adapted for high sensitivity as well as a modicum of resolution, especially in elevation, suggesting a role for attitude stabilisation by localization of the horizon." (Authors)] Address: Berry, R., Research School of Biological Sciences, Australian National University, PO Box 475, Canberra, ACT 2601, Australia. E-mail: rberry@rsbs.anu.edu.au

6629. Berry, R.P.; Stange, G.; Warrant, E.J. (2007): Form vision in the insect dorsal ocelli: An anatomical and optical analysis of the dragonfly median ocellus. *Vision Res.* 2007: 1394-1409. (in English). ["Previous work has suggested that dragonfly ocelli are specifically adapted to resolve horizontally extended features of the world, such as the horizon. We investigate the optical and anatomical properties of the median ocellus of *Hemicordulia tau* and *Aeshna mixta* to determine the ex-

tent to which the findings support this conclusion. Dragonfly median ocelli are shown to possess a number of remarkable properties: astigmatism arising from the elliptical shape of the lens is cancelled by the bilobed shape of the inner lens surface, interference microscopy reveals complex gradients of refractive index within the lens, the morphology of the retina results in zones of high acuity, and the eye has an exceedingly high sensitivity for a diurnal terrestrial invertebrate. It is concluded that dragonfly ocelli employ a number of simple, yet elegant, anatomical and optical strategies to ensure high sensitivity, fast transduction speed, wide fields of views and a modicum of spatial resolving power." 6631. Blanke, A. (2007): The dragonfly assemblage of Santa Teresa – patterns of behaviour and habitat use in a tropical environment. Diplomarbeit. Mathematisch-Naturwissenschaftlichen Fakultät der Rheinischen Friedrich-Wilhelms-Universität Bonn: V, 124 pp. (in English, with German summary). [Brasil; "This study has focused on the role of several factors for behaviour of four Neotropical dragonfly assemblages close to each other. It was shown that in areas with identical climate, the microhabitat severely influences the diel activity pattern of some species. Theories stating interspecific changes of behaviour in relation to body size, failed to explain the great behavioural changes observed for the same species. Every species has behaved differently in each area. Some behavioural differences were significant, and lead to the assumption that microhabitat changes (i.e. spatial structure) sometimes superpose the influences of body size and species assemblage. Some observed species even showed the typical activity patterns expected from the other group, that is perching or flight respectively. A wide perceptive horizon, which is stated for the larger species in this study, seems to demand flexible behaviour, enabling the species to adapt to as many habitats as possible. Species with a narrow perceptive horizon (i.e. generalists) are also able to colonize many areas, because their requirements to the environment allow a wider spectrum of habitats. A stricter and perch-orientated behaviour pattern is supposed to be characteristic for these species." 6632. Bönsel, A.; Matthes, J.; Matthes, H.; Runze, M. (2007): Erfolgskontrollen nach Revitalisierungen von Feldsöllen in Mecklenburg-Vorpommern. Auswirkungen auf Rotbauchunke, Laubfrosch und Libellen. *Natur und Landschaft* 82: 129-136. (in German, with English summary). [The article reports on measures taken from 2001 to 2004 to revitalize 19 kettle ponds in north-eastern Germany. After revitalization measures, a zone designed to sequester nutrients was set up around each kettle pond, and partly planted with woody plants. Recolonization by *Bombina bombina*, *Hyles arborea* (both Amphibia) and dragonflies was recorded in the first vegetation period immediately after the measures, and again in 2005. The documentation shows that the nutrient sequestration zone did not prevent eutrophication. Only the revitalized ponds surrounded with peaty soil were protected sufficiently from non-point nutrient inputs, and remained mesotrophic. *B. bombina* and *H. arborea* colonized ponds regardless of eutrophication processes. Species losses were recorded between initial and follow-up monitoring only when there had been anthropogenic fish stocking, or if ponds were temporary. "Of the 34 dragonfly species recorded, most were autochthonous, and their numbers high in mesotrophic waters. Pioneer species disappeared quickly or remained only in the mesotrophic waters, with small numbers of individuals. Such dynamics were recorded in a range of rural areas. If filtering capacity and thus groundwater protection and the promotion of the two amphibian species listed in Annexes II and IV of the Habitats Directive are the targeted functional utility of kettle ponds, then the revitalization measures were a success. If, however, the goal is to maintain species-rich dragonfly populations over several years, it is essential to prevent non-point nutrient inputs via drainage water. Establishing protective planted zones did not prove successful in this regard. While this measure did prevent erosion, drainage always introduces unfiltered, nutrient-rich water. Targeted filtration of drainage water is the key requirement for kettle pond revitalization in rural landscapes." (Authors)] Address: Bönsel, A., Vasenbusch 15, 18337 Gresenhorst, Germany. 6633. Bolek, M.G.; Janovy, J. Jr. (2007): Small frogs get their worms first: The role of nonodonate arthropods in the recruitment of *Haematoloechus coloradensis* and *Haematoloechus* complexus in newly metamorphosed Northern Leopard frogs, *Rana pipiens*, and Woodhouse's toads, *Bufo woodhousii*. *Jour. Parasitol.* 93(2): 300-312. (in English). ["Studies on the life cycles and epizootiology of North American frog lung flukes indicate that most species utilize odonates as second intermediate hosts; adult frogs become infected by ingesting odonate intermediate hosts. Newly metamorphosed frogs are rarely infected with these parasites, predominantly because they are gape-limited predators that cannot feed on large intermediate hosts such as dragonflies. We examined the role of the frog diet and potential intermediate hosts in the recruitment of the frog lung fluke, *Haematoloechus coloradensis*, to metamorphosed *Rana pipiens*, *Bufo woodhousii*, and bullfrogs (*R. catesbeiana*) from western Nebraska. Because of the uncertain validity of *H. coloradensis* as a distinct species from *Haematoloechus* complexus, morphological characters of both species were reevaluated.

ated and the life cycles of both species were completed in the laboratory. The morphological data on *H. coloradensis* and *H. complexus* indicate that they differ in their oral sucker to pharynx ratio, uterine loop distribution, and placement of vitelline follicles. However, in terms of their life cycles, both species are quite similar in their use of physid snails as first intermediate hosts, a wide range of nonodonate and odonate arthropods as second intermediate hosts, and leopard frogs and toads as definitive hosts. These results indicate that *H. coloradensis* and *H. complexus* are generalists at the second intermediate host level and might be able to infect newly metamorphosed leopard frogs and toads by using small nonodonate arthropods more commonly than other frog lung fluke species. Comparisons of population structure of adult flukes in newly metamorphosed leopard frogs indicate that the generalist nature of *H. coloradensis* metacercariae enables it to colonize young of the year leopard frogs more commonly than other *Haematoloechus* spp. that only use odonates as second intermediate hosts. In this respect, the generalist nature of *H. coloradensis* and *H. complexus* at the second intermediate host level is an avenue for the colonization of young of year frogs." (Authors) The paper contains fascinating pictures of the *H. coloradensis* cercarial attachment, creeping, and penetration behaviour on *Ischnura verticalis*.] Address: Bolek, M.G., School of Biological Sciences, University of Nebraska-Lincoln, Lincoln, Nebraska 68588, USA. E-mail: mbolek@unlserve.unl.edu

6634. Bolek, M.G.; Janovy, J. Jr. (2007): Evolutionary avenues for, and constraints on, the transmission of frog lung flukes (*Haematoloechus* spp.) in dragonfly second intermediate hosts. *Jour. Parasitol.* 93(3): 593-607. (in English). ["Metacercariae survival patterns and their distribution in second intermediate odonate hosts were examined for 4 species of frog lung flukes. Surveys of aquatic larvae and recently emerged teneral dragonflies and damselflies indicated that prevalence and mean abundance of *Haematoloechus* spp. metacercariae were significantly lower in teneral dragonflies than larval dragonflies, while there was no significant difference in prevalence or mean abundance of *Haematoloechus* spp. metacercariae among larval and teneral damselflies. Experimental infections of dragonflies indicated that metacercariae of *Haematoloechus coloradensis* and *Haematoloechus complexus* were located in the head, thorax, and branchial basket of dragonflies, whereas metacercariae of *Haematoloechus longiplexus* and *Haematoloechus parvipleus* were restricted to the branchial basket of these hosts. Metacercariae of *H. coloradensis*, *H. complexus*, and *H. longiplexus* infected the head, thorax, and abdomen of damselflies, but these insects were resistant to infection with *H. parvipleus*. Subsequent metamorphosis experiments on experimentally infected dragonflies indicated that most metacercariae of *H. longiplexus* were lost from the branchial basket during metamorphosis, but most metacercariae of *H. coloradensis*, *H. complexus*, and *H. parvipleus* survived dragonfly metamorphosis. These observations suggest that the observed ecological host specificity of *H. longiplexus* in semiterrestrial leopard frogs may be due to few metacercariae of *H. longiplexus* reaching these frogs in a terrestrial environment. Because of the uncertain validity of *Haematoloechus variopleus* as a distinct species from its synonym *H. parvipleus*, their morphological characters were reevaluated. The morphological data on *H. variopleus* and

H. parvipleus indicate that they differ in their acetabulum length and width, ovary shape, testes length, and egg length and width. Experimental infections of plains leopard frogs, northern leopard frogs, and bullfrogs with worms from bullfrogs indicate that the synonymy of *H. parvipleus* with *H. variopleus* is not warranted, and that these flukes are distinct species, i.e., *H. parvipleus* in bullfrogs and *H. variopleus* in plains leopard frogs and northern leopard frogs." (Authors)] Address: Bolek, M.G., School of Biological Sciences, University of Nebraska-Lincoln, Lincoln, Nebraska 68588, USA. E-mail: mbolek@unlserve.unl.edu

6635. Bouwman, J.; Groenendijk, D. (2007): New records of *Somatochlora arctica* in northwestern Lower Saxony (Odonata: Corduliidae). *Libellula* 26(1/2): 35-40. (in German, with English summary). ["During two visits to the German side of the borderland of the Province Groningen (Netherlands) and the Emsland district (western Lower Saxony, Germany) in June and July 2006 we recorded *S. arctica* at three new localities. All records pertain to adult males, up to seven at a time. These findings point to the possibility that this enigmatic and regionally rare dragonfly may be present at more sites in the northwest of Germany and the northeast of the Netherlands than hitherto supposed." 6636. Braccia, A.; Voshell, J.R.; van Christman, D. (2007): The Odonata of newly constructed ponds with life history and production of dominant species. *Aquatic Insects* 29(2): 115-130. (in English). ["The species composition of an odonate assemblage from six new ponds in Virginia, USA, was documented, and life histories and production of three dominant odonate taxa (*Anax junius*, *Gomphus exilis*, and *Enallagma civile*) were determined. The assemblage consisted of 19 species and was numerically dominated by *A. junius*, *G. exilis*, *E. civile*, and libellulids. Production of *A. junius*, *G. exilis*, and *E. civile* was 795 mg DW m⁻² yr⁻¹, 27 mg DW m⁻² yr⁻¹, and 236 mg DW m⁻² yr⁻¹, respectively. Coefficients of variation for production of each species were 50.77%, which suggests that variance should be considered in production estimates, especially if results are to be compared across studies or habitats. Low density and production of the dominant species in this study may be a result of inadequate densities of food items and limited availability of preferred habitat in the newly created ponds." (Authors)] Address: Braccia, Amy, Department of Entomology, Blacksburg, Virginia, USA; E-Mail rvoshell@vt.edu

6637. Brauner, O. (2007): Winterbeobachtungen von Libellen auf La Gomera und La Palma, Kanarische Inseln (Odonata). *Libellula* 26(3/4): 213-232. (in German, with English summary). ["In February of the years 2001, 2004 and 2007 Odonata were observed in La Gomera, and in February 2000 and November/ December 2005 in La Palma. During these journeys, ten species were recorded at 49 sites in La Gomera, and nine species at 26 sites in La Palma. Compared to the published literature, in La Palma the first records of *Ischnura saharensis*, *Anax ephippiger*, *Sympetrum nigrifemur* and *Trithemis arteriosa* were taken. In addition, the first record of *Anax parthenope* from this island taken in June 2006 is presented. Concerning La Gomera, two new sites of *Zygonyx torridus* in the island are presented, inc-

cluding the first observations of larvae and exuviae, and *A. ephippiger* is recorded from there also for the first time. With the exception of *Z. torridus*, all recorded Odonata species were observed during February in the adult stage. In six species emergence was observed between December and February. Annotations on the phenology of the species are given." (Authors)] Address: Brauner, O., R.-Breitscheid-Straße 62, D-16225 Eberswalde, Germany. E-mail: oliver.brauner@gmail.com

6638. Bried, J.T.; Herman, B.D.; Ervin, G.N. (2007): Umbrella potential of plants and dragonflies for wetland conservation: a quantitative case study using the umbrella index. *Journal of Applied Ecology* 44(4): 833-842. (in English). [" 1. Shortcuts to measuring biodiversity enable prioritization of conservation effort in the face of limited time, personnel and funding. The conservation umbrella approach focuses management effort according to individual species that may confer protection to a larger community. This approach can help guide the management agenda towards attainable goals by maximizing conservation returns per unit effort. The development of the umbrella index has shown promise in identifying umbrella species in terrestrial ecosystems but has received little attention with respect to the management of wetland ecosystems. 2. We used the umbrella index to assess the umbrella potential of vascular plants and dragonflies (Odonata) from 15 wetland impoundments in northern Mississippi, USA. The presence of adult odonates was determined by repeated visual surveys and plant lists were compiled from 50 plots per site. 3. Umbrella schemes, or the sites occupied by top umbrella species, missed large numbers of beneficiary species and occurrences. With one exception, umbrella schemes failed to optimize conservation returns relative to randomized schemes in both assemblages. Also, umbrella schemes approximately equalled the performance of non-umbrella schemes both overall and for species with a low rate of occurrence. Low occurrence rates in both assemblages may have hindered umbrella index performance because the index assumes that species with moderate occurrence rates have the most umbrella potential. 4. Cross-taxon analyses (Mantel tests and McNemar tests) suggested transferability of plant and dragonfly umbrella schemes, and non-random association between the plants and dragonflies in these wetlands. 5. Synthesis and applications. Despite the questionable performance of umbrella schemes in our study, the use of a quantitative ecological tool such as the umbrella index instead of political or popularity criteria is strongly recommended for future selection of umbrella species. The results of cross-taxon analyses supported growing evidence for spatial and functional relationships between wetland macrophytes and adult odonates. We suggest that the more easily measured assemblage can be used to set priorities for wetland conservation planning in circumstances where human resources are constrained." 6640. Brockhaus, T. (2007): Überlegungen zur Faunengeschichte der Libellen in Europa während des Weichselglazials (Odonata). *Libellula* 26(1/2): 1-17. (in German, with English and Swedish summary). ["In contrast to other aquatic insect groups, no relevant discussion on the faunal history of the Odonata during the Ice Age exists. In the present paper I examine previous hypotheses regarding the postglacial settlement of dragonflies in Europe. I include a short overview of the processes during the Ice Age. Especially I write about the present state of knowledge of the climate, countryside and habitats during the Weichsel Glacial Stage. There are in East Germany extensive findings from about 33,000 years ago. But there is no fossil evidence of dragon flies from that time. In addition, in the context of present knowledge of the ecology, morphology, physiology and dispersal of Odonata, I develop a hypothesis regarding the possible dragon fly fauna of the tundra of that time. It is possible that both coldstenothermic

and eurythermic species belong to this periglacial fauna. I offer further suggestions regarding the treatment of this question that may contribute to a better understanding of ecological findings and to the history of dispersion and zoogeography of Palaearctic dragonflies." (Authors)] Address: Brockhaus, T., An der Morgensonne 5, D-09387 Jahnsdorf, Germany. E-mail: T.Brockhaus@t-online.de

6641. Buczyński, P.; Zawal, A. (2007): Dragonflies (Odonata) of the "Szare Lake" nature reserve. *Parki Narodowe i Rezerваты Przyrody* 26(4): 79-91. (in Polish, with English summary). [28 species of Odonata were recorded in 2004 in the "Szare Lake" nature reserve (NW Poland, West Pomeranian Lake District). Dragonfly assemblages of aquatic habitats in the reserve were analysed. Particular attention was paid to Szare Jake which is a well preserved representative of lobelian lakes. The importance of lobelian lakes for dragonfly conservation in Poland and Europe is discussed.] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. 6644. Calle, P.; Knijf, G. de; Kurstjens, G.; Peters, B. (2007): Actuele en historische libellenfauna van de grensmaas. *Natuurhistorisch maandblad* 96(10): 269-277. (in Dutch, with English summary). ["Present and historic biodiversity of dragonflies in the Grensmaas floodplain: The stretch of the river Meuse between Maastricht (NL) and Maaseik (B), known as the Grensmaas, is unique to the Netherlands and Flanders because of its rapidly flowing water, gravel banks and islands. This article discusses the historic and present value of this floodplain for dragonfly species. In 2006, extensive research was done in several nature reserves along the river and in the summer streambed of the river itself, to assess the consequences for flora and fauna of 10-15 years of habitat restoration work in this floodplain. In this context, the dragonfly fauna was also surveyed, with special attention being paid to the strictly protected *Gomphus flavipes*. Data are presented for

four different periods. Before 1950, about 28 species occurred, including several typically rheophile species, like *Gomphus vulgatissimus*, *Ophiogomphus cecilia* and *Onychogomphus forcipatus*. Between 1950 and 1989, the diversity of dragonflies fell severely, due to water pollution and habitat destruction (canalisation and agricultural activities). From 1990 onwards, the dragonfly diversity increased again, due to floodplain restoration, reduced pollution and climate change. In the most recent period (1998-2006), more than 38 species were recorded in the Grensmaas floodplain, including several Red List species like *Libellula fulva* and *Sympecma fusca*. Currently, *G. stylurus* does not have a stable population in the river, but occurs as a summer migrant. Another 11 species are currently also most likely to be migrants, since their specific breeding habitat is lacking. It is expected that the dragonfly diversity will increase slightly and population sizes will grow as a result of a new large-scale floodplain restoration project, in which the width of the river bed will be enlarged to the size it had around 1850. Another major improvement will be the smaller amounts of silt in the riverbed, as silt has a negative impact on the habitat of larvae of rheophile species. Most of the silt originates from these waste which was until recently discharged untreated by the city of Liège in Belgium." (authors)] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. E-mail: geert.deknijf@inbo.be

6645. Carchini, G.; Della Bella, V.; Solimini, A.G.; Bazzanti, M. (2007): Relationships between the presence of odonate species and environmental characteristics in lowland ponds of central Italy. *Ann. Limnol... Int. J. Lim.* 43(2): 81-87. (in English). ["A set of 21 ponds was sampled three times for odonate larvae during spring 2002. At the same time 17 environmental variables were recorded including area, wet phase duration, total nitrogen, total phosphorus, aquatic macrophytes and land use. A total of 16 odonate species belonging to Lestidae, Coenagrionidae, Aeshnidae and Libellulidae were recorded, and the total number of species per pond varied from zero to six. The relationships between species richness, assemblages and environmental variables were studied by simple and multiple correlation and by Canonical Correspondence Analysis (CCA). The results showed that permanent ponds were larger, deeper, had more macrophyte species, had more extensive macrophytes cover and lower concentrations of nitrogen and phosphorus than temporary ponds. Multiple regression analysis showed that the number of odonate species was positively affected firstly by the number of macrophyte species, and then by pond depth. However, pond depth appeared to be interchangeable with several others variables, such as pond area and water duration and negatively correlated with nitrogen concentration, variables which are all linked with the permanent or temporary status of the ponds. CCA analysis indicated that odonate species presence was linked with a few environmental variables, showing a tendency of Odonata to avoid ponds with higher nitrogen concentrations, with the exception of *Lestes barbarus*, a species typical of temporary water in central Italy. At the same time, the majority of species were linked with longer water phase duration and with greater macrophyte species richness. A comparison with previous studies, and in particular with those carried out in central Italy, confirmed the positive influence of macrophytes, water duration, and also the negative effect of nutrient load. However, several other variables,

in particular land use, shade, presence of fish, which were influential in other studies, were not significant in this study." (Authors)] Address: Carchini, G., Dipartimento di Biologia, Università "Tor Vergata", Viale della Ricerca Scientifica, I-00133 Roma, Italy. E-mail: archini@utovrm.it

6646. Carvalho, A.L. (2007): Recomendações para a coleta, criação e colecionamento de lavras de Odonata. Arquivos do Museu Nacional, Rio de Janeiro 65(1): 3-15. (in Portuguese, with English summary). ["Recommendations for collecting, rearing, and storing larvae of Odonata. The taxonomy of the dragonfly larvae of Neotropical Region is still very poor. Manuals or guides about this subject are not available yet. So, it is necessary to breeding unknown larvae for their correct identification, based on the related emerged adults, and posterior description. Methods for all the steps of the work related to the manipulation of these forms in the field and in the laboratory, specially the rearing, are presented in detail. Each procedure is discussed and associated with biological data. Alternative materials, cheap and easy to find, are preferentially indicated." (Author)] Address: Carvalho, A.L., Museu Nacional / UFRJ, Departamento de Entomologia. Quinta da Boa Vista, São Cristóvão, 20940-040, Rio de Janeiro, RJ, Brasil.

6647. Catling, P.M. (2007): Variation of hind-wing colour and length in *Sympetrum internum* (Odonata: Libellulidae) from the Canadian prairie provinces. Canadian Entomologist 139(6): 872-880. (in English, with French summary). ["Amber coloration, called saffroning, extends from 1 to 15 mm across the hind-wing base in females of *S. internum* from the prairie provinces but extends only from 2 to 3 mm in males. There are no substantial differences in hind-wing length between the sexes. A significant correlation was found between hind-wing length and the extent of saffroning for both males and females. Regressions of these characters against latitude and longitude revealed that (1) there is a significant decrease in hind-wing length northward for both sexes; (2) there is a significant decrease in saffroning northward that is more significant for females; (3) there is no significant effect of longitude on hind-wing length; and (4) saffroning in females significantly increases westward but there is no similar effect in males, and the trend in females is much less significant than the latitudinal trend. Within the prairie provinces, extensive saffroning is confined to the Prairie Ecozone and moderate saffroning occurs around the edges of this ecozone. The surrounding Boreal Plains Ecozone is characterized by females with very limited saffroning. There is generally extensive variation in the extent of saffroning within some Prairie Ecozone locations, ranging from limited to moderate or extensive, but limited and moderate saffroning were more frequent at most locations in the Prairie Ecozone. Various explanations for saffroning are considered. Since limited, moderate, and extensive saffroning occur together throughout an extensive area, and occur within many populations and within a group emerging at the same time, formal taxonomic recognition of individuals with moderate or extensive saffroning seems unwarranted." 6649. Chang, X.; Zhai, B.; Wang, M.; Wang, B. (2007): Relationship between exposure to an insecticide and fluctuating asymmetry in a damselfly (Odonata, Coenagrionidae). Hydrobiologia 586(1): 213-220. (in English). ["In this study, we explored the effects of pesticide on fluctuating asymmetry (FA) levels and mortality of *Ceriagrion* sp. larvae. The results showed that the mortality of larval damselflies treated with pesticide was significantly higher than that treated with tap water which had been aerated for 48 h, but there were no significant differences among mortality of larvae treated with different concentrations of pesticide. Meanwhile, we found that the level of FA of the first tibia length, one of the seven bilaterally symmetrical traits (First femur length, First tibia length, Second femur length, Second tibia length, Third femur length, Third tibia length and Prementum width), differed significantly with different treatments, whereas the others did not show any significant differences. The Bonferroni (Dunn) *t* Tests revealed that FA of the first tibia length at 15×10^{-9} mg l⁻¹ was significantly higher than that at 1.5×10^{-9} mg l⁻¹ and control. There was no significant relationship between trait size and the absolute difference between their right and left sides. There was also no significant relationship between body size and the absolute difference between right and left sides. Trait size was significantly positively correlated with body size. FA was not associated with mortality. Therefore, we concluded that FA of the first tibia length of *Ceriagrion* sp. larvae may be induced by sublethal doses of pesticides. That is to say, its FA may be regarded as an indicator of reflecting the level of pesticide stress." (Authors)] Address: E-mail: bpzhai@njau.edu.cn

6651. Chaput-Brady, A.; Pays, O.; Lodé, T.; Secondi, J. (2007): Morphological clines in dendritic landscapes.

Freshwater Biology 52(9): 1677-1688. (in English). ["1. In complex landscapes such as river networks, organisms usually face spatio-temporal heterogeneity and gradients in geomorphological, water, ecological or landscape characteristics are often observed at the catchment scale. These environmental variables determine developmental conditions for larval stages of freshwater insects and influence adult phenotypic characteristics. Environmental clines are therefore expected to generate morphological clines. Such a process has the potential to drive gradual geographical change in morphology-dependent life history traits, such as dispersal. 2. We studied the influence of aquatic and terrestrial environmental factors on morphological variations in *Calopteryx splendens* across the Loire drainage. To investigate these effects we took explicitly into account the hierarchical structure of the river network. 3. We analysed eight morphological traits. Results showed significant body size variation between tributaries and the presence of a morphological cline at the drainage scale. We observed an effect of pH and water temperature on body size. Individuals in downstream sites were larger than individuals in upstream sites, and adults whose larval stages were exposed to alkaline pH and high temperatures during summer were larger. 4. Body size affects flight abilities in insects. Thus, our results suggest that morphological clines may generate an asymmetric dispersal pattern along the downstream-upstream axis, downstream populations dispersing farther than upstream ones. Such a process is expected to influence population genetic structure at the drainage scale if larval drift and floods do not balance an asymmetrical dispersal pattern of adults along the downstream-upstream gradient. To assess the influence of environmental gradients on the variation of life history traits it is important to understand the population biology of freshwater insects, and more generally of riverine organisms. It is also essential to integrate such data in conservation or restoration programmes." 6652. Chatterjee, S.N.; Ghosh, A.; Chandra, G. (2007): Eco-friendly control of mosquito larvae by *Brachytron pratense* nymph. *Journal of Environmental Health* 69(8): 44-48. (in English). ["The study reported here revealed the biocontrol efficacy of aquatic nymphs of the dragonfly *Brachytron pratense* against larvae of the mosquito *Anopheles subpictus*. It was found that during a 24-hour study period, a nymph of *B. pratense* would consume (mean value of three observations) 66 fourth-instar *An. subpictus* larvae released in a water bowl containing 3 liters of pond water. The consumption rate was significantly higher ($p < .05$) during the lights-on phase of the experiment than during the lights-off phase ($t = 2.15$). Under field conditions, a significant decrease ($p < .05$) in larval density in dipper samples was observed 15 days after the introduction of dragonfly nymphs (10 individuals) in concrete tanks. The biocontrol potential of the nymphs under field conditions was also indicated by a significant increase ($p < .05$) in the density of mosquito larvae 15 days after the removal of nymphs. In the control tanks (where no nymphs were introduced), mean larval-mosquito density did not differ significantly throughout the study period ($p > .05$)."] (Authors).] Address: Chatterjee, S.N., Department

of Zoology, University of Burdwan, Mosquito Research Unit, Rajbati, Bardhaman, West Bengal, India

6653. Chelmick, D. (2007): Further observations of *Macromia splendens* (Pictet) in Andalusia, Spain (Anisoptera: Macromiidae). *Notul. odonatol.* 6(10): 109-112. (in English). ["Chelmick (2006, *Notul. odonatol.* 6: 69-72) provided information on the status of *M. splendens* in Andalusia. This paper outlines further information on the distribution, habitat and behaviour of this species in southern Spain. The paper concludes with discussion on the conservation and threats to the habitat of this internationally important species." (Author) In addition, records are documented of *Oxygastra curtisii* and *Gomphus graslinii*, species likewise protected by law.] Address: Chelmick, D.G., 31 High Beech Lane, Haywards Heath, West Sussex, RH16 1SQ, UK. 6654. Cicek, K.; Kermer, A. (2007): Food composition of the Marsh Frog, *Rana ridibunda* Pallas, 1771, in Thrace. *Turkish Journal of Zoology* 31(1): 83-90. (in English, with Turkish summary). [An analysis of the stomach contents of 53 (19 males, 34 females) adult individuals of *Rana ridibunda* was performed. The frog diet consisted of a wide variety of arthropods; Diptera (42.62%) and Coleoptera (21.84%) were especially prominent. Aquatic forms did not contribute much to the frog diet; Odonata were represented with less than 1% of all prey items. The prey items identified indicate that individuals of this species, like other ranids, are generalist opportunistic predators whose diet is most strongly influenced by prey availability.] Address: Cicek, K., Ege University, Faculty of Science, Biology Department, Zoology Section, TR-35100, Üzmir, Turkey

6655. Clausnitzer, H.-J.; Clausnitzer, C.; Hengst, R. (2007): Ergänzungen zur Ökologie von *Ceriagrion tenellum* in der südlichen Lüneburger Heide (Odonata: Coenagrionidae). *Libellula* 26(3/4): 157-160. (in German, with English summary). ["After the mild winter of 2006/2007 featuring only very few days with temperatures below 0°C, during summer 2007 *C. tenellum* was found in numbers at several ponds without flowing water, even emerging from a garden pond. The absence of frost during the preceding winter apparently enabled the development to take place in these waters." (Authors)] Address: Clausnitzer, H.-J., Eichenstraße 11, D-29348 Eschede, Germany. E-mail: H.-J.Clausnitzer@t-online.de

6656. Clausnitzer, H.-J.; Clausnitzer, C.; Hengst, R. (2007): Zur Ökologie von *Ceriagrion tenellum* im Bereich der nordöstlichen Verbreitungsgrenze in Niedersachsen (Odonata: Coenagrionidae). *Libellula* 26(1/2): 19-34. (in German, with English summary). ["*C. tenellum* has a south-western European distribution; hence the populations in Lower Saxony are near its north-eastern limit. These populations were surveyed from 1990 to 2006. The species lives mainly in primary habitats heathy peatlands and creeks with paludification but there are also some populations in artificial habitats. It was found in 60 localities, but not throughout the period. In the last 15 years 19 new cases of colonisation of bogs and ponds were observed. This positive trend coincided with the renaturation of the small rivers Lutter and Lachte, and with moderately cold winters. The larvae are susceptible to frost and therefore large populations are associated with running water. After the winter

of 2005/2006 that had led to a longer freezing up of many waters, there were strong losses in ponds without, or with only very small, water current up to the total extinction of a local population. Winter cold forms the limiting factor for this species in the northeastern part of its range." (Authors)] Address: Clausnitzer, H.-J., Eichenstraße 11, D-29348 Eschede, Germany. E-mail: H.-J.Clausnitzer@t-online.de

6657. Conn, A.T.; Burgess, S.C.; Ling, C.S. (2007): Design of a parallel crank-rocker flapping mechanism for insect-inspired micro air vehicles. Proceedings of the Institution of Mechanical Engineers, Part C: Journal of Mechanical Engineering Science 221(10): 1211-1222. (in English). ["In the current paper, a novel micro air vehicle (MAV) flapping mechanism for replicating insect wing kinematics is presented. Insects flap their wings in a complex motion that enables them to generate several unsteady aerodynamic mechanisms, which are extremely beneficial for lift production. A flapping wing MAV that can reproduce these aerodynamic mechanisms in a controlled manner is likely to outperform alternative flight platforms such as rotary wing MAVs. A biomimetic design approach was undertaken to develop a novel flapping mechanism, the parallel crank-rocker (PCR). Unlike several existing flapping mechanisms (which are compared using an original classification method), the PCR mechanism has an integrated flapping and pitching output motion which is not constrained. This allows the wing angle of attack, a key kinematic parameter, to be adjusted and enables the MAV to enact manoeuvres and have flight stability. Testing of a near-MAV scale PCR prototype using a high-speed camera showed that the flapping angle and adjustable angle of attack both closely matched predicted values, proving the mechanism can replicate insect wing kinematics. A mean lift force of 3.35 g was measured with the prototype in a hovering orientation and flapping at 7.15 Hz." (Authors) Fig. 2 presents a simplified two-dimensional rigid-body linkages representing the mechanics of the Odonata wing joint.] Address: Burgess, S.C., Department of Mechanical Engineering, University of Bristol, Queen's Building, University Walk, Bristol BS8 1TR, UK. 6658. Cordero-Rivera, A.; Sánchez-Guillén, R.A. (2007): Male-like females of a damselfly are not preferred by males even if they are the majority morph. *Animal Behaviour* 74(2): 247-252. (in English). ["Animals searching for prey and males searching for mates share similar problems of detection if their targets are diverse in colour or physical appearance. There is good evidence for predators switching their preferences for prey in a frequency-dependent way; predators focus on the most common form, and the decreased predation on rarer forms allows multiple forms to survive. Frequency-dependent mate selection has also been proposed to explain the maintenance of several female colour morphs in damselflies. However, the fact that one of the female morphs is coloured like a male (androchrome) and behaves similarly to males suggests the phenomenon of male mimicry in this system as an alternative explanation for the polymorphism. We compared androchrome frequencies in populations and mating pairs in *Ischnura elegans*, over a range of androchrome frequencies (8–90%). In 22 of 23 samples androchromes mated less often than expected (significantly in 13 samples). We found no evidence for males switching their preferences in a frequency-dependent way. A test

of male preference for female morphs in a population with 85% androchromes indicated that males behaved indiscriminately and did not prefer the commonest (male-like) morph. Our results support androchrome male mimicry rather than learned mate recognition by males (a purely frequency-dependent model) as the main mechanism behind the maintenance of this sex-limited colour polymorphism." 6664. Dehghani, R.; Miranzadeh, M.B.; Yosefzadeh, M.; Zaman, S. (2007): Fauna aquatic insects in sewage maturation ponds of Kashan University of Medical Science 2005. *Pakistan Journal of Biological Sciences* 10(6): 928-931. (in English). [9 samples in 2005 resulted in 1032 specimens of diverse taxa. Dominance was as follows: Diptera (52%), Hemiptera (24%), Ciclopodidae (12%), Hydroacarinae (9.5%), Coleoptera (0.77%), Aranidae (0.67%), Hymenoptera (0.58%), and Odonata (0.48%).] Address: Dehghani, R., Kashan Medical Sciences University, Iran department of Environmental Health, Kashan Medical Sciences University, Kashan, Iran

6665. Dijkstra, K.-D. (2007): Dragonflies and Damselflies (Odonata) of Lokutu. *RAP Bulletin of Biological Assessment* 46: 21-36. (in English). [68 mostly Guineo-Congolian running-water species were found, with remarkable range extensions, as well as new species of *Platycypha*, *Elatoneura* and *Mesocnemis*. The results indicate a healthy watershed in the Lokutu surroundings, with limited degrees of pollution and streambed erosion. If forest cover and natural stream morphology are retained, the rich dragonfly fauna will be as well. The obtained species list is especially long considering the paucity of stagnant water species and the absence of certain Congolian endemics. This is explained by the absence of their habitat and possibly by the barrier that the extensive forest surrounding Lokutu (still) poses to the dispersal of open land species. The observed richness is probably typical of the Congo Basin as a whole and other areas are expected to be even richer. Therefore the Lokutu area does not require specific conservation action. Unlike other groups traditionally surveyed in RAPs, Odonata are invertebrates, strongly tied to freshwater, that are not actively exploited by humans. This RAP proved that it is possible to rapidly obtain a clear picture of Odonate diversity, even allowing a partial description of their ecology. The rich and apparently largely natural Odonate fauna found contrasts with the impoverished and imperiled status of the other groups studied. Therefore it is recommended to use Odonata more frequently to supplement biodiversity assessments of traditional groups, especially in the Congo Basin, where sampling Odonata may show whether existing conservation priorities also protect watersheds and freshwater biodiversity." (Author)] Address: Dijkstra, K. D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

6666. Dijkstra, K.D. (2007): The name-bearing types of Odonata held in the Natural History Museum of Zimbabwe, with systematic notes on Afrotropical taxa. Part 2: Zygoptera and descriptions of new species. *International Journal of Odonatology* 10(2): 137-170. (in English). [Orthographic details of 118 name-bearing types of Odonata and 11 'holotypes' of forms, without nomenclatural status, are provided in two parts: the second and present paper deals with Zygoptera. The taxonomy of the gracilis-group of *Chlorocypha* and the Afrotropical members of *Prodasineura* and *Aciagrion* are discussed. *Chlorocypha fabamacula* is removed from synonymy with *C. wittei*; *Pseudagrion superbum* from *P. serrulatum*. *Chlorocypha basilewskyi* and possibly *C. hasta* are junior synonyms of *C. tenuis* – their treatment as a subspecies of *C. jacksoni* and *C. molindica* respectively is rejected; *Elatoneura tropicalis* of *E. cellularis*; *Agriocnemis dissimilis* of *A. palaeforma*; *Pseudagrion quadriculatum* of *P. superbum*; *Pseudagrion williamsi* of *P.*

kersteni; *Teinobasis malawiensis* of *T. alluaudi*. It was confirmed that *Chlorocnemis rossii* is a junior synonym of *C. flavipennis*; *Aciagrion congoense* of *A. africanum*; *Agriocnemis aligulae* of *A. maclachlani*; *Agriocnemis umbargae* of *Ceriagrion annulatum*; *Ischnura hilli* of *I. abyssinica*. *Africocypha ntaali* is definitely a junior synonym of *A. greyi*, but their synonymy with '*Libellago*' *lacuselephantum* must be investigated. *Chlorocnemis montana maccleeryi* is nearer *C. abbotti* than nominotypic *C. montana*, and is raised to species level. *Aciagrion heterosticta karamoja* is nearer *A. gracile* than nominotypic *A. heterosticta*, and is raised to species level pending further revision. *Aciagrion dondonsense* sp. nov., a species formerly confused with *A. zambiensis* and *A. congoense* (see above) is described. *Africallagma sinuatum* f. *fugax* pertains to a good species and is described as *A. pallidulum* sp. nov. The possible specific status of *Platycypha caligata* f. *lacus* requires further study. *Trithemis integra* sp. nov., a species formerly confused with *T. basi tincta* (see Part 1), is described. The spelling *Pseudagrion sjoestedti* (versus *P. sjostedti*) is advocated." (Author)] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

6667. Dijkstra, K.-D. (2007): Dragonflies and damselflies (Odonata) of the Atewa Range. In: McCullough, J., L.E. Alonso, P. Naskrecki, H.E. Wright & Y. Osei-Owusu (Editors). A rapid biological assessment of the Atewa Range Forest Reserve, Eastern Ghana. *RAP Bulletin of biological assessment* 47: 50-54 (report),-137-142 (appendix). (in English). [Ghana; "A total of 72 species were found in the streams and rivers that have their headwaters within the reserve (and associated standing water habitats), although only 31 (43%) were found strictly within the reserve's boundaries. Eight species were recorded in Ghana for the first time, of which six (75%) were recorded inside the reserve. Of these, *Atoconeura luxata* is the most significant discovery because: (1) it had not been described at the time and material taken during the RAP was included in its recently published description; (2) it is the only regionally threatened odonate found, being Red-listed as Vulnerable in western Africa; and (3) it confirms the nationally unique 'montane' character of the site. The results indicate a healthy watershed in the forest reserve and the surrounding area, with limited pollution and streambed erosion. This is confirmed by the presence of forest species even in more disturbed landscapes. If forest cover and natural stream morphology are retained, the present dragonfly fauna is expected to persist. However, if development activities were to entail the removal of vegetation or mineral deposits from the range, its capacity to store, buffer and filter rainwater would be seriously compromised, jeopardizing the reliable discharge of freshwater into the region's rivers; an essential resource for millions of Ghanaians and a rich biodiversity." (Author) Appendix 3 provides a checklist of Odonata recorded from Ghana.] Address: Dijkstra, K.D., Curator of invertebrates, National Zoological Collection of Suriname, University of Suriname, P.O. Box 9212, Paramaribo, Suriname. E-mail: Dijkstra@naturalis.nnm.nl

6668. Dijkstra, K.-D. (2007): Rapid survey of dragonflies and damselflies (Odonata) of North Lorma, Gola and Grebo National Forests, Liberia. *RAP Bulletin of Biological Assessment* 44: 25-28-79-85. (in English). [During a rapid survey of the North Lorma, Gola and Grebo National Forests, 93 species of dragonflies and

damselflies were found. Seven species (*Paragomphus nigroviridis*, *Phyllogomphus moundi*, *Nesciothemis minor*, *Palpopleura deceptor*, *Tetrathemis polleni*, *Tramea limbata* and *Trithemis monardi*) were recorded in Liberia for the first time. Numbers of species and individuals seemed low, probably because the survey was at the end of the wet season, rather than towards the start. The results nonetheless indicate a healthy watershed in each forest, with limited pollution and streambed erosion. If forest cover and natural stream morphology are retained, the present dragonfly faunas are expected to persist. The most interesting species assemblage was recorded in Gola National Forest, including two species (*Sapho fumosa*, *Trithemis africana*) of conservation concern. Gola National Forest is a major diamond mining area, and the possible beneficial and detrimental impacts of these activities are discussed. Harboring typical examples of a rich Upper Guinea fauna, each forest, and especially Gola National Forest, deserves to be conserved." (Author) Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

6669. Dolný, A.; Pavlík, P. (2007): A phenologically interesting record of *Sympetrum striolatum* (Charp.) (Anisoptera: Libellulidae). *Notul. odonatol.* 6(9): 108. (in English). [6 January 2005, active adult *S. striolatum* female in Stramberk Botanical Garden and Arboretum (alt. 353 m), Czech Republic (49°35'20"N, 18°07'29"E)] Address: Dolný, A., Katedra biologie a ekologie, Přírodovědecká fakulta Ostravské univerzity, Bráfova 7, 701 03, Ostrava 1, Czech Republic. 6670. Donath, H. (2007): Die Entwicklung der Odonatenfauna im Gebiet des früheren Braunkohlentagebaus Schlabendorf-Süd (Land Brandenburg, Niederlausitz) über drei Jahrzehnte (Odonata). *Entomologische Nachrichten und Berichte* 51(1): 7-14. (in German, with English summary). [Germany; "From 1977 to 1991, the brown coal mine South Schlabendorf covered an area of 3269 hectare in the Lower Lusatia. The dragonfly fauna in the water-rich western part was studied before devastation from 1976 until 1982. Of the 31 species found 28 were autochthonous, 8 of which are included in the Red List of Brandenburg. Recolonisation was surveyed since 1992. Presently, 22 species reproduce in the area, among which 5 to 7 from the Red List. Before mining, summer-cool brooks and moorland were important habitats, but today springs and littoral zones of lakes in areas of open-cast mining are valuable dragonfly habitats. Compared to the situation before mining, the share of Mediterranean species rose from 2 % to 32 %, while the Eurosiberian group decreased from 54 % to 32 %." (Authors)] Address: Donath, H., Caule Nr. 1, D-15926 Zieckau, Germany

6671. Dow, R.A.; Choong, C.Y.; Orr, A.G. (2007): Two new species of *Chalybeothemis* from Malaysia, with a redefinition of the genus (Odonata: Libellulidae). *International Journal of Odonatology* 10(2): 171-184. (in English). ["*Chalybeothemis chini* sp. nov. from Pahang, Peninsular Malaysia, and *C. pruinosa* sp. nov. from Sarawak, Malaysian Borneo, are described from the male sex. The new species necessitate some redefinition of the previously monotypic genus, which is provided. The quiescent penis of *Chalybeothemis* is illustrated for the first time. Differences between *C. chini*, *C. fluviatilis* and *C. pruinosa* are discussed and tabulated. *C. fluviatilis* is

reported from Sarawak for the first time. Relationships of *Chalybeothemis* within the Libellulidae are discussed." 6676. Ellenrieder, N. von; Garrison, R.W. (2007): Dragonflies of the Yungas (Odonata). A Field Guide to the Species from Argentina. Libelulas de las Yungas (Odonata) Una guía de campo para las especies de Argentina. Pensoft Series Faunistica 67, ISSN 13120174, Pensoft Publishers, Sofia-Moscow: 168 pp.. (bilingual in English and Spanish). [The Yungas are highly biodiverse cloud forests extending from Venezuela south through NW Argentina, and are considered one of the biodiversity 'hot spots' in South America. This bilingual (Spanish/English) pocket field guide, the first of its kind for any region in South America, is accompanied by 280 illustrations including detailed diagnostic drawings and numerous colour photos of live Odonata. It covers 102 taxa found in the Argentine Yungas (a relative small part of the bioregion Yungas), representing over a third of all species known from the country. The species are treated monographically providing information on identification (description of the taxa, sometimes with advise to sibling species), distribution and habitat, and behaviour. It is a little bit confusing to find in a book for identification Odonata of a relative small area five unidentified taxa: *Argia* sp. (later described as *A. yungensis*), *Triacanthagyna* sp., *Limnetron* sp., *Micrathyria* sp., and *Erythrodiplax* sp. Following the illustrations of the book "Dragonfly genera of the New World" by the same authors, *Micrathyria* sp. should be *M. divergens*. It would be very useful to untangle these shortcomings by a leaflet added to the book. My personal opinion is that many of the colour pictures are reproduced in a scale insufficiently for an identification book, or the intended didactic information. Even using a magnifying glass it is nearly impossible to see what you should see indicated by arrows! (e.g. fig. 8, differences in male and female genitalia). In general the type size of the settings is too small for odonatologists getting older and older, and whose eyes getting more worse and worse. The effectiveness of some of the pictures is quite limited (e.g. *Rhinoaeschna pallipes*, *Tramea calverti*). The numerous black & white drawings are fine. In spite of shortcomings the book is very welcome because it will help to enlarge interest in our favourite beasts among the people in South America. To stimulate dragonfly research, Pensoft offers a free shipment of the book to any private customer in South America. (Martin Schorr)] Address: Pensoft Publishers, Geo Milev Str., No 13a, 1111 Sofia, Bulgaria. www.pensoft.net

6677. Ellenrieder, N. von; Garrison, R.W. (2007): Untangling some taxonomic riddles on damselfly genera (Zygoptera) from the neotropical region. IDF-Report 11: 1-34. (in English) ["Examination of type material deposited in the IRSNB (Royal Belgian Institute of Natural Sciences, Brussels, Belgium) and in the BMNH (British Museum of Natural History, London, Great Britain) allowed us to solve taxonomic riddles regarding several damselfly (Zygoptera) genera from the neotropical region. We provide notes on the status of several types, and introduce the following new synonymies: *Argia huallaga* Fraser, 1946 = *A. adamsi* Calvert, 1902; *Argia makoka* Fraser, 1946 = *A. kokama* Fraser, 1946; *Argia mollusca* Fraser, 1946 = *A. collata* Selys, 1865; *Argia trifoliata* Fraser, 1946 = *A. variegata* Förster, 1914; *Argia umbriaca* Fraser, 1946 = *A. indicatrix* Calvert, 1902; *Amphiagrion amphion* Selys, 1876 = *Ischnura verticalis* (Say, 1840); a new combination: *Oxyagrion cardinalis* Fraser, 1946 to *Leptobasis cardinalis* (Fraser, 1946); and three lectotype designations (for *Acanthagrion gra-*

cile race? *lancea* Selys, 1876, *Acanthagrion trimaculatum* Selys, 1876, and *Leptagrion flammeum* Selys, 1876)." (Authors). Address: Ellenrieder, Natalia von, Museo de Ciencias Naturales, Universidad Nacional de Salta, Mendoza 2, Salta 4400, Argentina. E-mail: odo_nata@hotmail.com

6678. Englund, R.; Polhemus, D.A. (2007): *Argiolestes kula*, a new species of damselfly from eastern New Guinea (Odonata: Megapodagrionidae). Journal of the New York Entomological Society 114(3): 95-107. (in English). ["*Argiolestes kula* n. sp. is described from eastern new Guinea and nearby offshore islands (Sariba, Basilaki, Fergusson), and a comparison is provided to the closely related species *Argiolestes sidonia* Martin. Figures of the male abdominal appendages, wing venation and breeding habitat are provided, accompanied by a distribution map. A checklist of *Argiolestes* species is also included." 6681. Flenner, I. (2007): Forest lakes affected by forestry - how resilient are dragonfly communities to logging in Central Sweden? Halmstad University. School of Business and Engineering. Masters project 20p. Supervisor: Göran Sahlén. 2007-05-30: 16 pp. (in English). ["The main cause of environmental disturbance in the Fennoscandian boreal forests today is forestry. Natural disturbances are important to maintain diversity, but anthropogenic disturbance, such as forestry, differs

in many ways from the natural ones. Forestry is a big industry in Sweden and only a small remnant of old-growth forest is left. Several studies have shown an initial decrease in e.g. dragonfly diversity a few years after logging, followed by an increase up to numbers comparable with the original species number. In this study I examined whether the new, quite diverse, species composition is similar to the one present before the logging or if some species are disappearing and are replaced with other, maybe opportunistic species. Other factors such as ongoing changes in climate also will be considered. A resampling of 34 (and an additional 4) lakes that also were sampled in 1996-97 was done during summer of 2006. Analyses of data from the two sampling occasions were done. I found that even if the diversity is just temporarily affected (or not affected at all), it is not always the same species involved. This means that the diversity in a single lake can appear to be high, but the total diversity in Sweden, or Scandinavia, is declining. I also found some interesting new species for the area, such as *Nehalennia speciosa*, *Sympetma fusca* and *Aeshna mixta*." 6685. Fulan, J.A.; Henry, R. (2007): Temporal distribution of immature Odonata (Insecta) on *Eichhornia azurea* stands in the Camargo Lake, Paranapanema River, São Paulo. *Revista Brasileira de Entomologia*

51(2): 224-227. (in Portuguese, with English summary). ["This study aimed to record the abundance and richness of Odonata on *E. azurea* stands, from March 2004 to March 2005, in the Camargo Lake, lateral to the Paranapanema River, São Paulo, Brasil after an extreme flood pulse, and also to investigate the controlling environmental factors on the distribution of Odonata abundance. The greatest abundance and richness occurred in the dry period, and Coenagrionidae was the most abundant and with greater genus richness during the whole study period. This high abundance possibly occurred due to its behavior, as endophytic posture and climbing behavior. Aeshnidae and Libellulidae presented low abundance especially in the dry period. The main environmental factors that affected the distribution of Odonata abundance were water surface temperature, pluviosity, and *Eichhornia azurea* biomass." 6686. Fuselier, L.; Decker, P.; Lunski, J.; Mastel, T.; Skolness, S. (2007): Sex differences and size at emergence are not linked to biased sex ratios in the common green darner, *Anax junius* (Odonata: Aeshnidae). *Journal of Freshwater Ecology* 22(1): 107-117. (in English). ["Many species of dragonflies exhibit sexual dimorphism and biased sex ratios in adult populations. It is predicted that, in species with territorial adults, males should be larger than females at emergence. Larger male size should elevate foraging rate and lead to increased predation risk and higher male mortality during the larval stage. We tested these predictions for a territorial dragonfly, *A. junius*, using laboratory and field experiments. We measured differences in growth and foraging activity between the sexes, determined sex ratios at emergence, and measured size at emergence for female and male dragonflies. Males gained more mass than females and males spent more time in motion and moved longer distances than females in foraging trials. Males were larger than females at emergence in natural populations, but sex ratios at emergence were not significantly different from 1:1. Sex-specific growth strategies in the larval stage did not result in biased sex ratios at emergence but may be important to the reproductive success of this territorial dragonfly." (Authors)] Address: Fuselier, Linda, Biosciences Department, 1104 7th Ave South, Minnesota State University, Moorhead, Moorhead, MN, 56563, USA. E-mail: fuselier@mnstate.edu

6687. Gaino, E.; Piersanti, S.; Reborja, M. (2007): Ultrastructural organization of the larval spiracles in *Libellula depressa* L. (Anisoptera: Libellulidae). *Odonatologica* 36(4): 373-379. (in English). ["In the last larval instar (F-0) of *L. depressa*, 2 paired spiracles, in the form of elongated eye-shaped structures, are located in the anterior region of the mesothorax segment. A fine structural analysis of these spiracles under the scanning and electron microscopes reveals that each spiracle consists of a well-developed cuticular peritreme with a dorsal-anterior lip bearing a thin laminar coat and a ventral-posterior lip bearing a filter apparatus. The filter apparatus derives from a series of folds forming discrete groups adhering to one another to delimit empty spaces and producing a honeycomb-like structure. This structure is coherent with the need to avoid entry of water when the larva is submerged. The function of these spi-

racles during the insect development is discussed, noting that in anisopteran larvae the rectal epithelium, forming the so called branchial basket, is the main respiratory organ." (2007): Die rezente Verbreitung von *Aeshna viridis* und *Leucorrhinia pectoralis* in Schleswig-Holstein – Ergebnisse einer vierjährigen Untersuchung (Odonata: Aeshnidae, Libellulidae). Libellula 26(1/2): 41-57. (in German, with English summary). ["During 2003 to 2006 the distribution and status of *L. pectoralis* and *A. viridis* in Schleswig-Holstein, Germany were surveyed. Within the framework of an obligatory monitoring protocol that has been set by the European Habitat Directive, the research was carried out by authority of the Minister for Agriculture, Environment and Rural Areas. As a result, localities of both species were found in each natural landscape. Furthermore, with respect to the two biogeographical regions, the records were almost equally distributed. Throughout Schleswig-Holstein 27 recent sites were discovered for *L. pectoralis* and 36 for *A. viridis*. So far threats for *L. pectoralis* could not be detected, whereas the loss of Water-soldier, *Stratiotes aloides*, poses the main threat for *Aeshna viridis*. However, the preconditions to conserve habitats of *A. viridis* by the protection and introduction of *S. aloides* are promising." 6697. Hammond, J.I.; Luttbeg, B.; Sih, A. (2007): Predator and prey space use: dragonflies and tadpoles in an interactive game. *Ecology* 88(6): 1525-1535. (in English). ["Predator and prey spatial distributions have important population and community level consequences. However, little is known either theoretically or empirically about behavioral mechanisms that underlie the spatial patterns that emerge when predators and prey freely interact. We examined the joint space use and behavioral rules governing movement of freely interacting groups of odonate (dragonfly) predators and two size classes of anuran (tadpole) prey in arenas containing two patches with different levels of the prey's resource. Predator and prey movement and space use was quantified both when they were apart and together. When apart from predators, large tadpoles strongly preferred the high resource patch. When apart from prey, dragonflies weakly preferred the high resource patch. When together, large prey shifted to a uniform distribution, while predators strongly preferred the high resource patch. These patterns qualitatively fit the predictions of several three trophic level, ideal free distribution models. In contrast, the space use of small prey and predators did not deviate from uniform. Three measures of joint space use (spatial correlations, overlap, and co-occurrence) concurred in suggesting that prey avoidance of predators was more important than predator attraction to prey in determining overall spatial patterns. To gain additional insight into behavioral mechanisms, we used a model selection approach to identify behavioral movement rules that can potentially explain the observed, emergent patterns of space use. Prey were more likely to leave patches with more predators and more conspecific competitors; resources had relatively weak effects on prey movements. In contrast, predators were more likely to leave patches with low resources (that they do not consume) and more competing predators; prey had relatively little effect on predator movements. These results highlight the importance of investigating freely interacting predators and prey, the potential for simple game theory models to predict joint spatial distributions, and the utility of using model choice methods to identify potential key factors that govern movement." 6698. Hardersen, S. (2007): Telemetry of Anisoptera after emergence – first results (Odonata). *International Journal of Odonatology* 10(2): 189-202. (in English). ["The behaviour of Anisoptera during the period between emergence and the onset of sexual activity is poorly known, mainly because freshly emerged adults are hard to follow. In the present study the system

RECCO[®] Transmitter/Receiver and custombuilt tags made from Schottky diodes and copper wire were used to monitor freshly emerged Anisoptera. The system had an average maximum detection distance of ca 85 m. Ten individuals of *Libellula fulva* were successfully tracked for up to five consecutive days. They almost exclusively utilized trees or shrubs as perches at heights ranging from 1.8 to ca 31 m. Open meadows or open river bank vegetation, which were present close to the release site, were never used for perching. Considering that human observers can reasonably detect adult anisopteran up to a height of 3 m, 92.5% of all registered perch sites were "out of reach". The maximum distances covered on the first day averaged 37.7 m and 31.1 m for males and females, respectively. Two individuals, followed for four and five days respectively, remained in relatively small areas of 480 m² - 2,500 m² for three and four consecutive days. Five tagged individuals of *Aeshna mixta* showed a very different behaviour from *L. fulva*. Already in the first hours after release, all flew distances of more than 200 m and were lost. The telemetry system used was not suitable to study this species immediately after emergence." 6700. Hilfert-Rüppell, D.; Rüppell, G. (2007): *Juwelenschwingen / Geheimnisvolle Libellen. Gossamer Wings / Mysterious Dragonflies*. Splendens-Verlag. ISBN-13: 9783000203893: 168 pp. (Bilingual in English and German). [In the past years, we have seen some brilliant books on Odonata, many of them furnished with impressive photography. I am tempted to write none of them is as brilliant and eye catching as this book. 264 detailed digital photos (and a few illustrations) demonstrate the life history of dragonflies with focus on the imaginal stage, and the damselflies (Calopterygidae). Hereby the authors use the didactic concept to comment on each of the pictures with brief but precise biological information, remembering a little bit of information provided to comment documentation films. The chapters are covering the following topics: Appearance, From Water to Air, Flight, Prey Capture, Threatening and Fighting, Courting, Mating Tactics, Danger, Mating, Oviposition, Larvae, Roosting. The book is written both

in German and English. Ola Fincke has written the preface, giving some insight into her odonatological vita. This book is far more than a coffee table book, nevertheless it would be very useful as gift to persons you want to convince that dragonflies are beasts worth to settle this earth. 6705. Hope, P. (2007): The Dragonflies of Eastern Mugla Province, Southwest Turkey. ISBN-13: 9789750196317: 232 pp. (in English). ["The province of

Mugla is situated in Southwest Turkey. 56 species of dragonfly have been recorded for this area. This book describes the species, their habitats and locations, and includes colour photos, hand-drawn location maps and distribution maps." (Publisher)]

6706. Horvath, G.; Malik, P.; Kriska, G.; Wildermuth, H. (2007): Ecological traps for dragonflies in a cemetery: the attraction of *Sympetrum* species (Odonata: Libellulidae) by horizontally polarizing black gravestones. *Freshwater Biology* 52: 1700-1709. (in English). ["1. We observed that the dragonfly species *Sympetrum flaveolum*, *S. striolatum*, *S. sanguineum*, *S. meridionale* and *S. danae* were attracted by polished black gravestones in a Hungarian cemetery. 2. The insects showed the same behaviour as at water: (i) they perched persistently in the immediate vicinity of the chosen gravestones and defended their perch against other dragonflies; (ii) flying individuals repeatedly touched the horizontal surface of the shiny black tombstones with the ventral side of their body; (iii) pairs in tandem position frequently circled above black gravestones. 3. Tombstones preferred by the dragonflies were in the open and had an area of at least 0.5 m² with an almost horizontal, polished, black surface and with at least one perch in their immediate vicinity. 4. Using imaging polarimetry, we found that the black gravestones, like smooth water surfaces, reflect highly and horizontally polarized light. 5. In double-choice field experiments with various test surfaces, we showed that the dragonflies attracted to shiny black tombstones display positive polarotaxis and, under natural conditions, detect water by means of the horizontally polarized reflected light. This, and the reflection-polarization characteristics of black gravestones, explain why these dragonflies are attracted to black tombstones. 6. If females attracted to the black gravestones oviposit on them, the latter constitute ecological traps for dragonflies that are not close to water." 6708. Ishizawa, N. (2007): Energy expenditure in patrolling males of *Cordulia aenea amurensis* Selys (Anisoptera: Corduliidae). *Odonatologica* 36(4): 381-397. ["The males hover frequently during patrolling flight, and fiercely chase rival males. Their patrolling flight was videotaped and analyzed. The average net-patrol flight speed (except hovering) was 161.6±30.6 cm/s faster in the morning and the evening than during the day. Also, hovering frequency was more frequent and the duration

of hovering bouts was longer in the morning and the evening than during the day. and was synchronized with patrolling flight speed. However, chasing flight was not related to patrolling or hovering and the duration of chasing bout was about 4-5 seconds with an average flight speed of 274.6±64.7cm/s. The body temperatures of patrolling flight and chasing flight were significantly different; the former, 39.8±1.4°C, the latter was 40.4±1.0°C. The time budget of patrolling males based upon video pictures was calculated and the relative energy expenditure of patrolling males was estimated by standardizing the average net-patrolling flight speed as 1. Energy expenditure of the males was greater in the morning and the evening than during the day. It is assumed that energy expenditure was affected by ambient temperatures, with males changing the flight speed and duration of hovering. The males are inferior in their sex recognition and it is assumed that their frequent hovering with concurrent large energy expenditure is to enable males to distinguish females.] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozavva City, Saitama Pref., Japan. 6709. Ishizawa, N. (2007): Morphological variations in relation to maturation in *Pantala flavesens* (Fabricius) in central Japan (Anisoptera: Libellulidae). *Odonatologica* 36(2): 147-157. (in English). ["*P. flavesens* was investigated in open fields in a deciduous forest in an inland part of the Kanto region for 3 months from late June 2003. The sp. was estimated to be bivoltine from summer to late autumn. The size of the adults was unchanged throughout the season. The sex ratio of the population skewed towards females. Maturity degree (MD), shown as the value of body weight divided by the cube of wing length, shifted upwards until the second half of August, after which it decreased sharply. Similarly the wing loading (WL) (calculated by dividing body weight by wing area) increased until the second half of August, and decreased from September, and in early October it was not significantly different between males and females. As the relationship of body temperature to ambient temperature showed no difference between mature and immature individuals, or between sexes, with both correlation coefficients and regression coefficients being large for a flyer type species, they seemed to be easily affected by the ambient temperature." (Author)] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozavva City, Saitama Pref., Japan. E-mail: isizawa7@rivo.mediatti.net

6710. Iwami, T.; Kishida, O.; Nishimura, K - (2007): Direct and indirect induction of a compensatory phenotype that alleviates the costs of an inducible defense. *PLoS ONE* 2(10): e1084. doi:10.1371 / journal.pone.0001084: (in English). ["Organisms often exhibit phenotypic plasticity in multiple traits in response to impending environmental change. Multiple traits phenotypic plasticity is complex syndrome brought on by causal relations in ecological and physiological context. Larvae of the salamander *Hynobius retardatus* exhibit inducible phenotypic plasticity of two traits, when at risk of predation by dragonfly larvae (*Aeshna nigroflava*). One induced phenotype is an adaptive defense behaviour, i.e., stasis at the bottom of water column, directly triggered by the predation risk. Another one is a compensatory phenotype, i.e., enlarged external gills, for an unavoidable cost (hypoxia) associated with the induced defense. We identified two ways by which this compensa-

tory phenotype could be induced. The compensatory phenotype is induced in response to not only the associated hypoxic conditions resulting from the induced defense but also the most primary but indirect cause, presence of the predator." 6711. Jödicke, R. (2007): Die Verbreitung von *Ceragrion tenellum* in Deutschland, mit Hinweisen auf sein aktuelles Vorkommen in Westniedersachsen (Odonata: Coenagrionidae). *Libellula* 26(3/4): 161-188. (in German, with English summary). ["A compilation of all known records of *C. tenellum* from Germany up to 1997 demonstrated a main area of distribution in the north-western part of the country. In the Weser-Ems region of western Lower Saxony the species currently proved to be widely distributed and very abundant. NW Germany is, in connection with the adjacent Netherlands and N Belgium, the main centre of distribution under the Atlantic climate. Here *C. tenellum* prefers peatland bogs and heathy lakes, which are common habitats in this region. With the tendency towards milder winter temperatures, population density and abundance increased. New colonizations and the presence at waters unsuitable for the species' reproduction demonstrated a high potential of expansion. There was a record of individuals dispersing as far as 780 m away from the nearest reproductive site. The flying season in 2007 began in the last third of May and lasted until mid October. In western Lower Saxony, the most frequent female colour morph was *f. erythrogastrum* at frequencies between 70.0% and 97.5%. It is argued that the species is not endangered in the northwestern parts of Germany and should therefore be removed from the Red Lists of Lower Saxony, North Rhine-Westphalia and BRD." (Author)] Address: Jödicke, R., Am Liebfrauenbusch 3, D-26655 Westerstede, Germany. E-mail: reinhard.joedicke@ewetel.net

6712. Jonsson, M.; Johansson, F.; Karlsson, C.; Brodin, T. (2007): Intermediate predator impact on consumers weakens with increasing predator diversity in the presence of a top-predator. *Acta Oecologica* 31 (1): 79-85. (in English). ["Adding or removing a top-predator is known to affect lower trophic levels with potentially large, indirect effects on primary production. However, little is known about how predator diversity may affect lower trophic levels, or how adding or removing a top-predator influences the effects of predator diversity. Using aquatic mesocosms containing three and four trophic levels, we tested whether intermediate predator diversity affected predation on consumers and if top-predator presence influenced such effects. We found that the presence of intermediate predators suppressed the consumer population and that this suppression tended to increase with increased intermediate predator diversity when the top-predator was absent. However, with the top-predator present, increased intermediate predator diversity showed the opposite effect on the consumers compared to without a top-predator, i.e. decreased suppression of consumers with increased diversity. Hence, in our study, the loss of intermediate predator species weakened or strengthened predator-prey interactions depending on if the top-predator was present or not, while loss of the top-predator only strengthened the predator-prey interactions. Therefore, the loss of a predator species may render different, but perhaps predictable effects on the functioning of a system depending on from which trophic level it is lost and on

on the initial number of species in that trophic level." (Authors)] Address: Johansson, F., Department of Ecology and Environmental Science, Animal Ecology Group, Umea University, 90187 Umea, Sweden. E-mail: frank.johansson@eg.umu.se

6713. Jordan, S.; Barluet, E.; Olaf, M.; Parsons, B.; Simon, C. (2007): Blue hawaiiense and beyond: conservation genetics and comparative phylogeography of four Hawaiian Megalagrion damselfly species (Odonata: Coenagrionidae). Proceedings of the Symposium on the Biology of Hawaiian Streams and Estuaries: Bishop Museum Bulletin in Cultural and Environmental Studies 3: 247-260. (in English). ["Hawaii's endemic Megalagrion damselflies are rivaled in their beauty and diversity only by the degree of threat posed to them by anthropogenic disturbance. In this preliminary study of phylogeography and conservation genetics, we have sequenced about 660 base pairs (bp) of the mitochondrial COII gene from 191 damselflies from four species, including 31 populations that span a gradient of endangerment. We applied phylogeographic analyses in order to understand their biogeographic history. Unlike Megalagrion xanthomelas and *M. pacificum*, *M. calliphya* and *M. hawaiiense* rarely share haplotypes between populations and between islands, even within the larger Maui Nui superisland, suggesting that these latter two species do not disperse as well across land or water. Their phylogenies also better reflect the geological history of the islands. We applied conservation genetic analyses in order to understand their genetic health. Under a conservation genetic paradigm, populations with low genetic diversity are generally considered to be at greater risk of decline and extinction than populations with high genetic diversity. Applying this principle to Megalagrion populations gave both expected and surprising results. Expected results included measurements of high diversity in most populations of *M. calliphya*, *M. hawaiiense*, and Hawaii'i Island populations of *M. xanthomelas*. Low diversity was observed in populations known to be bottlenecked or relictual, including O'ahu and Maui *M. xanthomelas*, and *M. pacificum*. Surprising results included low genetic diversity in O'ahu Ko'olau and Hawaii'i Onomea *M. hawaiiense*, Moloka'i *M. pacificum*, and West Maui *M. calliphya*. We propose that these latter three populations be monitored and managed to maximize their long-term genetic health." 6715. Jung, K.-S. (2007): Odonata of Korea. Dragonflies. ISBN: 978-89-958060-3-6: 512 pp. (in Korean). [Regrettably, this opulent handbook on the Odo-

nata of Korea is completely written in Korean language. Thus, for those uninitiated to the Korean language, there is rarely more to use than the brilliant colour photos of species and habitats, and the excellent pictures of freshly killed specimens for identification. Significant morphological characters are shown by arrows, and the Korean names of the species are accompanied by the Latin ones. I suppose, this part of the book is considering exclusively the species from South-Korea, while the monographic chapter covers all Korean species, but providing no pictures from those North-Korean species not available for photographing and not occurring in South-Korea (e.g. *Leucorrhinia dubia*). The book is completed by chapters on morphology with brilliant figures, fascinating histological sections, biology, and stunning flight studies. The monographic part of the books covers 125 species on approximately 300 pages. The photography is a kind of art work, with some really great photographs. It is a pity that I can't read this book. Definitely, and in spite of this: I am really happy to have it in my library. (Martin Schorr) Copies can be purchased from the author.] Address: Jung, Kwangsu, 102-601., Dalvitmaul apt., Hwajung-dong, Koyangsi, 412-270, Gyunggido, Korea. E-mail: tootootoo@korea.com

6716. Kalcounis-Rueppell, M.C.; Payne, V.H.; Huff, S.R.; Boyko, A.L. (2007): Effects of wastewater treatment plant effluent on bat foraging ecology in an urban stream system. Biological Conservation 138(1-2): 120-130. (in English). ["Wastewater treatment plant (WWTP) effluent in the Cape Fear River Basin headwaters in North Carolina, USA, has influenced stream water quality and aquatic components of the stream food web. To examine effects of WWTP effluent on terrestrial predators in this system we determined prey availability, bat community structure, and bat foraging and commuting behavior at sites above and below WWTPs. We predicted an effect of effluent in the riparian habitat specialist *Perimyotis subflavus* but not the habitat generalists *Eptesicus fuscus*, *Lasiurus borealis*, or *Nycticeius humeralis*. Nocturnal insect abundance was higher upstream of the WWTPs. There were more Diptera, Coleoptera, and Lepidoptera upstream of the WWTPs whereas there were more Odonata downstream of the WWTPs. There were more *E. fuscus* upstream of the WWTPs and more *P. subflavus* downstream of the WWTPs. Despite the difference in bat community structure up-and downstream of the WWTPs, bat commuting and foraging activity levels were the same; there was no difference in the total number of echolocation sequences we recorded per night up. and downstream of the WWTPs nor was there a difference in the proportion of those sequences that contained a feeding buzz. Our results suggest the effect of anthropogenic nutrients in the stream persists through higher food web trophic levels as we found impacts on nocturnal flying insects as well as two common species of insectivorous bats. *Perimyotis subflavus* and *E. fuscus* may serve as easily tractable terrestrial bioindicators of water quality as influenced by WWTP effluent in this, and other, urban watersheds." 6717. Kaller, M.D.; Kelso, W.E. (2007): Association of macroinvertebrate assemblages with dissolved oxygen concentration and wood surface area in selected subtropical streams of the southeastern USA. Aquatic

Ecology 41: 95-110. (in English). ["Woody debris (CWD) is an important habitat component in northern Gulf of Mexico coastal plain streams, where low gradients and low flows allow accumulation of CWD and promote low dissolved oxygen (DO) concentrations. We tested the influences of CWD and DO on stream macroinvertebrates experimentally by placing two surface area CWD treatments each in three concentrations of ambient DO in two streams in Louisiana, USA, with macroinvertebrates collected from ambient woody debris used as a control. We also sampled macroinvertebrates in benthic and woody debris habitats in three streams twice yearly over 2 years to examine the applicability of the experimental results. Total abundance, richness (generic), and Shannon–Wiener diversity were all higher in lower DO conditions during the experiment, and total abundance was higher in the larger CWD treatment. Stream sampling corroborated the relationship between higher diversity and low DO in both benthic and woody debris habitats, but the relationship between richness and low DO only was supported in benthic habitats. Few taxa correlated with DO or CWD in the experiment (5 of 21 taxa) or stream survey (2 of 54 taxa). Whereas most taxa were uncorrelated with experimentally manipulated and in-stream measured variables, we suggest these taxa respond as generalists to stream habitat and physicochemistry. Based on this experiment and stream sampling, we believe the majority of macroinvertebrates in these streams are tolerant of seasonally low DO conditions." (Authors) The taxa list includes *Argia* spp. and *Dromogomophus* spp.] Address: Kaller, M.D., School of Renewable Natural Resources, Louisiana Agricultural Experiment Station, LSU Agricultural Center, Louisiana State University, Baton Rouge, LA 70803, USA. 6718. Kandibane, M.; Raguraman, S.; Mahadevan, N.R. (2007): Diversity and community structure of aquatic arthropods in an irrigated rice ecosystem of Tamil Nadu, India. *Asian Journal of Plant Sciences* 6(5): 741-748. (in English). ["Inventory, diversity and community structure of aquatic arthropods between weeded and partially weeded rice ecosystems were studied in a field experiment under irrigated condition during Rabi, 2000. The research revealed that a total of 12, 2, 6 and 3 species of Odonata, Ephemeroptera, Hemiptera and Coleoptera aquatic insects were recorded, respectively. *Agriocnemis femina femina*, *Pantala flavescens*, *Crocothemis servilia*, and *Diplocodes trivialis* were the dominant species in both the ecosystems, but were significantly more dominant in partially weeded rice ecosystem. *Trithemis* sp., *Rhyothemis variegata*, *Anax guttatus* and *Lethocerus indicus* (Heteroptera) were absent in weeded rice ecosystem and rest of the species occurred in both the ecosystems. Aquatic beetles, water strider and water scorpion evinced perfect similarity through out the season. But, damselfly, backswimmer and mayfly expressed more than 0.80 similarity and perfect similarity (1.00) during early and maturity stages of crop and showed less stability during the 2nd, 3rd and 4th week. The guild of aquatic arthropods revealed the dominance of predatory groups in partially weeded rice ecosystem through out the season. Same group of aquatic arthropods had not dominated in all the weeks of crop growth, but the group of aquatic arthropods changed during various stages of crop. A total of 18 weed species were recorded in partially weeded plots." (Authors)] Address: Kandibane, M., Dept Agricult. En-

tomol., Tamil Nadu Agricultural Uni., Coimbatore. 641003, Tamil Nadu, India

6719. Keats, R.A.; Osher, L.J. (2007): The macroinvertebrates of *Ruppia* (Widgeon Grass) beds in a small Maine estuary. *Northeastern Naturalist* 14(3): 481-491. (in English). ["Little information exists on macroinvertebrate community composition in small, micro-tidal, *Ruppia maritima* (widgeon grass)-dominated Maine estuaries. Qualitative and quantitative assessments of the macroinvertebrate fauna of widgeon grass beds in Northeast Creek estuary (Acadia National Park, ME) are presented here. The community was dominated by euryhaline freshwater invertebrates including midge larvae (Chironomidae: *Dicrotendipes*, *Cricotopus*, *Chironomus*), oligochaetes, damselfly larvae (Coenagrionidae: *Enallagma*), amphipods (Gammaridae: *Gammaurus*), gastropods (Hydrobiidae: *Hydrobia*), ostracods (Cytheridae: *Cyprideis*), and water boatmen (Corixidae: *Trichocorixa*). Macroinvertebrate abundances at the sampled sites were 35,100 individuals/m² in both August and September, and 22,200 individuals/m² in October. This study provides baseline faunal-community data that can be used in future monitoring studies." 6720. Kishida, O.; Trussell, G.C.; Nishimura, K. (2007): Geographic variation in a predator-induced defense and its genetic basis. *Ecology* 88(8): 1948-1954. (in English). ["Predator-induced morphological defenses are a well-known form of phenotypic plasticity, but we continue to have a limited understanding of geographic variation in these responses and its genetic basis. Here we examine genetic variation and geographic differentiation in the inducible defenses of tadpoles (*Rana pirica*) in response to predatory salamander larvae (*Hynobius retardatus*). To do so, we crossed male and female frogs from a "mainland" Japanese island having predaceous salamanders and a more isolated island not having predaceous salamanders and raised resulting offspring in the presence and absence of *H. retardatus*. Mainland tadpoles exhibited a higher capacity to express the inducible morphology (a more bulgy body) than those from the predator-free island, and expression of the bulgy morph in mainland–island hybrids produced phenotypes that were intermediate to those produced by pure crosses. In addition, parental sex had no effect on expression of the bulgy morph. Our results support the hypothesis that geographic variation in inducible defenses is linked to the additive effects of autosomal alleles that are shaped by differences in historical exposure to the inducing predator." (Authors) Odonata are referred on several times in introduction.] Address: Kishida, O., Graduate School of Fisheries Sciences, Hokkaido University, Hakodate 041-8611, Hokkaido, Japan. 6724. Laister, G. (2007): Die Libellenfauna der Linzer Donauauen. Entwicklung und aktuelle Situation. *Berichte f. Ökologie u. Naturschutz der Stadt Linz* 1: 65-123. (in German, with English summary). ["The dragonfly fauna of the Danube floodplains of Linz, Austria was investigated in the first half of the 1990s (Laister 1994, 1996a, 1998). This study was repeated in 2002/2003 to ascertain the current status of the populations and to detect any changes. Although the floodplains of Linz are "old" and now only manifest weak hydrodynamics, their dragonfly fauna must be regarded as very valuable. In a current mapping 39 dragonfly species could be shown to occur there, of which 32 are considered long-established. In relationship to the first mapping clear improvements could be demonstrated in regard to the species that inhabit the stretches of running water as well as in respect to those which are bound to silted up areas covered by reeds. The metapopulation concept as expanded by Sternberg (1995, 1999) for dragonflies might enable us to enhance our understanding of the high turnover rates which were registered." 6725. Larison, B. (2007): Environmental heterogeneity and alternative mating tactics in the damselfly *Protoneura amatoria*. *Behavioral Ecology* 18: 1021-1028. (in English). ["Conditional male mating strategies have been studied extensively in relation to male attributes, such as size and resource-holding potential, but few studies have considered the effects of environmental heterogeneity on the use of alternative mating tactics. In some systems, environmental heterogeneity may be the key to understanding the evolution and maintenance of such polyphenisms. I examined the influence of the physical environment on the use of alternative tactics by the damselfly *Protoneura amatoria*. Male *P. amatoria* reversibly use 2 tactics to gain matings: 1) sit and wait in the canopy for passing females or 2) hover over the water and attempt to grab females that are ovipositing in floating debris. Observations in 3 streams indicated that the use of the hovering tactic was greater under high-light than low-light conditions and at higher densities of ovipositing females. The density of ovipositing females was correlated with both the light conditions and the availability of oviposition substrate, indicating that physical factors exert indirect as well as direct influences on tactic use. Experimental manipulations showed that both males and females responded directly to light conditions and suggested that males responded directly to the density of ovipositing females. These results can be explained largely in terms of the cues and constraints inherent in different light environments. Thus, the conditional mating strategy of *P. amatoria* appears to have evolved in response to, and been maintained by, fine-scale variation in the physical environment. These findings are discussed in relation to flight dynamics and predation risk." 6727. Lingenfelder, U.; Ott, J.; Schorr, M.; Trockur, B. (2007): Die Libellenfauna (Odonata) der Our zwischen Dasburg und Wallendorf (Rheinland-Pfalz / Luxemburg). *Mainzer naturwissenschaftliches Archiv* 45: 283-311. (in German, with English summary). [In the course of a species protection programme for the Orange-spotted emerald (*Oxygastra curtisii*) ordered by the federal state of Rhineland-Palatinate, the dragonfly fauna of the river Our, which forms the border between Germany and Luxembourg, was investigated in the years 2005 and 2006 between the villages of Dasburg and Wallendorf. Altogether 26 species were found, including *O. curtisii* which currently is known in Germany and Luxembourg only at this river section of the Our. Out of these 26 dragonflies in total 12 were autochthonous in the river, for seven other species it is very likely. As one more dragonfly species was found along the Our in the 1980ies, in total 27 species have been recorded in this river section until today.] Address: Lin-

genfelder, U., Seebergstr. 1, D-67716 Heltersberg, Germany. E-mail: u.lingenfelder@vr-web.de

6728. Liria, J. (2007): Fitotelmata fauna on the bromeliads *Aechmea fendleri* André y *Hohenbergia stellata* Schult of the San Esteban Nacional Park, Venezuela. Rev. peru. biol. número especial 14(1): 33-38. (in Spanish, with English summary). ["In the present work, we characterize the associations of mosquitoes species and other invertebrates on bromeliads from San Esteban Nacional Park in Carabobo State, Venezuela. Eighteen plants of *Aechmea fendleri* (11) and *Hohenbergia stellata* (7) were sampled in rainy (September 2004) and dry (March 2005) seasons. A total of 2020 macroinvertebrates were collected. The most important was the Diptera Order, with the Families Chironomidae (43%), Chaoboridae (25%) and Culicidae (6%), and the Coleoptera, Scyrtidae (5%). In Culicidae the most abundant species were *Culex consolator* (31%), *C. neglectus* (27%) and *Wyeomyia celaenocephala* (17%). The highest abundance and richness was in dry season, when Culicidae diversity increases. The diversity and evenness was similar among season and it was highest in *H. stellata*." (Author) "Coenagrionidae" counted for 1% of total athropod abundance.] Address: Liria, J., Departamento de Biología, Facultad de Ciencias y Tecnología, Universidad de Carabobo. Campus Barbuja, Valencia, Estado Carabobo, Venezuela. E-mail: jliria@uc.edu.ve

6729. Lockwood, M. (2007): Rediscovery of *Symptetrum pedemontanum* (Müller in Allioni) and *S. vulgatum* (L.) in Catalonia, NE Spain (Anisoptera: Libellulidae). Notul. odonatol. 6(10): 115-118. (in English). ["The 2 species were rediscovered in an area of irrigated hay meadows in La Cerdanya (Catalonia, NE Iberian Peninsula) in August 2005, the first confirmed record for the former species from the Iberian Peninsula since 1959 and the first ever record for the latter for Catalonia. In 2006, a much fuller survey of the whole potential breeding area of the 2 species was carried out and in the whole area only one small breeding colony (of both species) was located. This is thought to be the only known population of *S. pedemontanum* in the Iberian Peninsula. Details of the habitat and threats to the species are given." 6738. Matushkina, N.; Gorb, S. (2007): Mechanical properties of the endophytic ovipositor in damselflies (Zygoptera, Odonata) and their oviposition substrates. *Zoology* 110(3): 167-175. (in English). ["Damselfly females use their ovipositor valves to saw aquatic plants in order to insert their eggs into the plant tissues. Stiffness of the plant substrata is therefore an important parameter for oviposition substrate choice by females. Using a force transducer combined with a motorised micromanipulator, the bending stiffness of the ovipositor at the axial compressional load was studied in seven European damselfly species and compared to the local stiffness of seven preferred plant substrates. The puncture force of tested plant samples ranged from 105 to 1500 mN, and their local stiffness ranged from 208 to 1776 N/m. The bending stiffness of the ovipositor was estimated as 173–409 N/m depending on the damselfly species. Using original and literature data, a significant positive correlation between mechanical properties of the ovipositor and preferred oviposition substrates was demonstrated. Possible behavioural adaptations to overcome high stiffness of plant tissues during oviposition are discussed." (2007): Zum aktuellen Vorkommen der Hauben-Azurjungfer *Coenagrion armatum* westlich Vilhelmina/Asele Lappmark in Schwedisch Lappland (Odonata). *Entomologische Nachrichten und Berichte* 51(2): 128-130. (in German). [16.06.1999 and 07.06.2002, Malgoviken near Malgovik, approximately 10 km west of Vilhelmina, Sweden. Some diagnostic key factors are outlined.] Address: Müller, J., Frankefelde 3, 39116 Magdeburg, Germany. E-mail: FaunOek.JMueller@t-online.de

6744. Müller, J.; Steglich, R. (2007): Gehören *Coenagrion armatum* und *Onychogomphus forcipatus* (Odonata) zur Libellenfauna Sachsen-Anhalts? *Entomol. Mitt. Sachsen-Anhalt* 15(1): 28-30. (in German). [The paper stresses the historical development of the Federal State Sachsen-Anhalt, Germany as prerequisite of proper localisation of ancient odonate records, some of which may be hidden in the files of adjacend Federal

States and resulting from collections prior the corrections of the frontiers between the states. A focus is set on the long lasting wrong interpretation of a "record" of *Coenagrion armatum* in Sachsen-Anhalt and the unknown status of *Onychogomphus forcipatus*. A few notes on records of *O. forcipatus* along the river Jagst, Baden-Württemberg are added.] Address: Müller, J., Frankefelde 3, 39116 Magdeburg, Germany. E-mail: FaunOek.JMueller@t-online.de

6745. Nakahara, M.; Tsubaki, Y. (2007): Function of multiple sperm-storage organs in female damselflies (*Ischnura senegalensis*): Difference in amount of ejaculate stored, sperm loss, and priority in fertilization. *Journal of Insect Physiology* 53(10): 1046-1054. (in English). ["We studied changes in the number of sperm within two kinds of female sperm-storage organ in the damselfly *Ischnura senegalensis* (Odonata: Coenagrionidae): the bursa copulatrix and the spermatheca. We counted the number of sperm within each storage organ and tested their viability after a single copulation in female damselflies kept for seven days with and without oviposition. We also counted sperm and tested their viability in females that underwent an interrupted second copulation after the sperm-removal stage, and after subsequent oviposition. Our results showed that the bursa copulatrix and spermatheca have different sperm storage roles. Immediately after copulation, most eggs appear to have been fertilized with bursal sperm, which were positioned near the fertilization point. By seven days after copulation, a greater proportion of spermathecal sperm were used for fertilization, as the number of bursal sperm had decreased. We hypothesize that female damselflies use the spermatheca for long-term storage and the bursa copulatrix for short-term storage: bursal sperm are more likely to be used for fertilization but may have a higher risk of mortality due to sperm removal by a competing male and/or sperm expelling by the female, whereas spermathecal sperm are safer but will be used for fertilization only after their release from the spermatheca." 6748. Olberg, R.M.; Seaman, R.C.; Coats, M.I.; Henry, A.F. (2007): Eye movements and target fixation during dragonfly prey-interception flights. *Journal of Com-*

parative Physiology A: Neuroethology, Sensory, Neural, and Behavioral Physiology 193: 685-693. (in English). ["The capture of flying insects by foraging dragonflies is a highly accurate, visually guided behavior. Rather than simply aiming at the prey's position, the dragonfly aims at a point in front of the prey, so that the prey is intercepted with a relatively straight flight trajectory. To better understand the neural mechanisms underlying this behavior, we used high-speed video to quantify the head and body orientation of dragonflies (female *Erythemis simplicicollis* flying in an outdoor flight cage) relative to an artificial prey object before and during pursuit. The results of our frame-by-frame analysis showed that during prey pursuit, the dragonfly adjusts its head orientation to maintain the image of the prey centered on the "crosshairs" formed by the visual midline and the dorsal fovea, a high acuity streak that crosses midline at right angles about 60° above the horizon. The visual response latencies to drifting of the prey image are remarkably short, ca. 25 ms for the head and 30 ms for the wing responses. Our results imply that the control of the prey-interception flight must include a neural pathway that takes head position into account." 6749. Olias, M.; Weihrauch, F.; Bedjanic, M.; Hacet, N.; Marinov, M.; (2007): *Lestes parvidens* and *L. viridis* in southeastern Europe: a chorological analysis (Odonata: Lestidae). *Libellula* 26(3/4): 243-272. (in German, with English summary). ["In order to clarify the actual distribution and the overlap of ranges of *Lestes parvidens* and *L. viridis* in Europe, all available and credible information from records of the two species in southern and southeastern Europe was compiled. This compilation includes all literature references that clearly distinguish between the two species, which usually was not the case prior to the mid-1990s, records taken personally by the authors, and the review of museum specimens. The hitherto researched distributional range of *L. parvidens* in Europe extends from Asia minor to Corsica and Sicily in the west, and to Austria, Slovakia and the Ukraine in the north. On the other hand, the range of *L. viridis* extends from western, central and southern Europe, where it is common, to the southeast as far as the southern Greek mainland and the Black Sea coast. The first records of *L. viridis* from Turkey are documented from Turkish Thrace. In the area of overlapping ranges, which from north to south extends over more than 1,000 km in Italy as well as the Pannonian lowlands and the Balkans, numerous cases of syntopic occurrences were recorded. Although in these hybridization is not uncommon, the reproductive isolation between *L. parvidens* and *L. viridis* has reached an extent that does not allow a complete amalgamation of the two taxa any more. In conclusion, the results of our chorological analysis substantiate the status of *L. parvidens* and *L. viridis* as clearly separated, good species." 6750. Osterwalder, R. (2007): Gomphiden-Exuvienfunde an renaturierten Uferabschnitten und neu angelegten Seitenarmen zweier Schweizer Flüsse (Odonata: Gomphidae). *Libellula* 26(1/2): 77-92. (in German, with English summary). ["Along the rivers Reuss and Aare the colonization of recently revitalized sections and newly created side branches by dragonflies, was in-

vestigated in the first years after the completion of the construction works. The study focussed on the evidence of development by exuviae findings of gomphids on eight stretches between 140 and 900 m in length where the bank reinforcements were removed or new watercourses were built in the period from 1998 to 2005 and on corresponding unchanged river sections for comparison. Exuviae of *Onychogomphus forcipatus*, *Ophiogomphus cecilia* and *Gomphus vulgatissimus* were found in varying numbers and distribution on the different sections. From these findings it is concluded that the revitalized and regenerated areas were rapidly colonized by gomphid larvae that drifted or moved actively into these habitats." 6751. Ott, J. (2007): The expansion of Mediterranean dragonflies in Europe as an indicator of climatic changes — Effects on protected species and possible consequences for the NATURA 2000 web. In: Secretariat of the Convention on Biological Diversity (2007). Emergins issues for biodiversity conservation in a changing climate. Abstracts of Poster Presentations at the 12th Meeting of the Subsidiary Body on Scientific, Technical and Technological Advice of the Convention on Biological Diversity. Montreal, Technical Series no. 29, i - viii + 112pp: 32-34. (in English). ["The invasion of southern and eurytopic species becomes obviously a general process in Germany and Middle and Northern European countries indicating the disturbance of the waters, as well as the lack of water in many countries and regions (Italy, Spain – Germany: e.g. the federal state of Brandenburg). Consequently strong changes within the European dragonfly fauna could be expected. Especially the species of moorland biotopes, springs, small brooks and alpine regions will face a strong decrease and in some regions also extinction. In the longer term this process will lead more to a decrease of biodiversity than to an increase and to a devaluation of the web NATURA 2000." 6753. Parr, A.J. (2007): Migrant and dispersive dragonflies in Britain during 2006. *J. Br. Dragonfly Society* 23(2): 40-51. (in English). ["The 2006 season saw some of the most spectacular movements of migrant dragonflies ever recorded in Britain, perhaps even exceeding those of the famous summer of 1995. In terms of sheer numbers, the highlight of the year was the profusion of *Sympetrum fonscolombii* that were reported. Approaching a thousand individuals — the highest annual total for Britain by some long way — were observed during the summer months, with many staying to

breed. Autumn emergents were later noted at over a dozen sites, some as far north as Lancashire and East Yorkshire. *Anax parthenope* also had a record-breaking year, with some 90 individuals being observed and oviposition being noted from five different areas. *Erythromma viridulum* similarly had an eventful season, showing a very major expansion of range, at least some of which seemed to involve fresh immigration. Other notable events included a major influx of *S. flaveolum* and the discovery of a female *Lestes barbarus* at an inland site on the Somerset/ Gloucestershire border. No less than four *Aeshna* affinis were also reported from southern England, there having only ever been one previous confirmed British record of this species." 6755. Petrovicová, K.; David, S. (2007): Dragonflies (Odonata) of the upper reaches of the Kysuca river (NW Slovakia). 8. vedecká konferencia doktorandov a mladých vedeckých pracovníkov, 18.-19. 4. 2007, FPV UKF Nitra: 391-403. (in Slovakian, with English summary). ["The dragonfly fauna of the typical water habitats of the Kysuca River was characterised based on a three-year field study (2003-2005). We collected 873 dragonfly specimens (703 imagoes, 65 larvae and 5 exuviae and so confirmed the presence of 39 species at 16 sample sites in the study area. We distinguished 3 types of water habitats inside the Kysuca inundation area: epipotamal, hyporithral and temporary small lakes in inundated area. Taxon richness and Shannon diversity (H') did not differ between localities different part of stretches of the Kysuca River. There was an average of 4 dragonfly species per locality. The value of diversity was low $H' = \pm 1.4$, but the upper limit of $H_{max} = \pm 1.9$. Upper limits of evenness of samples were $e = \pm 0.9$. Total abundance, taxon richness and H' of the small lakes in flood plane of the dragonflies were significantly higher. Taxon diversity of the dragonflies was significantly higher from the habitats with vegetation. Ordination of the species composition revealed that the fauna of the River Kysuca is clearly separated from the temporary small lakes water bodies. The lotic species assemblages from the Kysuca River *Calopteryx splendens*, *C. virgo*, *Onychogomphus forcipatus* and

virgo, *Onychogomphus forcipatus* and *Platycnemis pennipes* can be regarded as streams dragonfly communities *Gomphus - Calopteryx splendens* (virgo) although the cenobiotic species *Gomphus vulgatissimus* was not recorded by the authors." (Authors)] Address: Petrovièová, Kornélia, Hlavná 83; 95195 Obyce, Slovakia. E-mail: mefik@post.sk

6756. Petrulevicius, J.F.; Nel, A. (2007): Enigmatic and little known Odonata (Insecta) from the Paleogene of Patagonia and Northwest Argentina. *Ann. Soc. Entomol. fr. (N.S.)* 43(3): 341-347. (in English, with French summary). ["The findings of new specimens of Latibalsaliidae and Frenguelliidae in Northwest and Patagonia Argentina are noteworthy for the knowledge of these little known families and the explanation of their systematic position. The new findings confirm the phylogenetic position of these families. The morphology of the discoidal cell in both fore and hind wings of *Frenguelia* corresponds to the most basal epiproctophoran damsel-dragonflies, implying a Triassic age for the particular lineage of this family. The absence of any fossil record between Triassic and Eocene could be related to a highly specialized biology for these animals, maybe related to mountain rainforests as for *Epiophlebia*, unique surviving damsel-dragonfly. Lastly, the middle Eocene Italian dragonfly family Bolcathemidae Gentilini 2002 is considered as a junior synonym of the Paleocene Argentinean family Palaeomacromiidae Petrulevicius et al. 1999 supporting faunistic contact between Europe and South America during the late Cretaceous." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrs1.mnhn.fr

6757. Petrulevicius, J.F.; Nel, A.; Rust, J.; Bechly, G.; Kohls, D. (2007): New Paleogene Epallagidae (Insecta: Odonata) recorded in North America and Europe. Biogeographic implications. *ALAVESIA* 1: 15-25. (in English). ["Three new fossil Epallagidae: *Eodichrominae* are described, viz. *Labandeiraia* n. gen. with the two species *L. americaborealis* n. sp. (Eocene of USA), and *L. europae* n. sp. (Paleocene/Eocene of Denmark), and *Litheuphaea coloradensis* n. sp. (Eocene of USA). The pattern of distribution of this damselfly group in the Paleogene of North America and Europe is the same as for the damselfly subfamily *Thaumatoneuridae*: *Dysagrioninae* and the neuropteran *Polystoechotidae*. This pattern could correspond to Paleocene/Eocene land bridges between these continents via Greenland or Bering or to ancient Late Cretaceous groups." (Authors)] Address: Petrulevicius, J.F., Div. Cient. Paleozoología Invertebrados, Museo de La Plata, Fac. Cs. Nat., UNLP and CONICET Argentina. E-mail: levicius@museo.fcnym.unlp.edu.ar

6758. Piersanti, S.; Rebor, M.; Salerno, G.; Gaino, E. (2007): Behaviour of the larval dragonfly *Libellula depressa* (Odonata Libellulidae) in drying pools. *Ethology Ecology & Evolution* 19: 127-136. (in English). ["Numerous papers report that dragonfly larvae are able to survive dry periods in temperate areas. In this study, we investigated, in experimental field conditions in woodland, the behaviour of the larvae of *L. depressa*, belonging to the penultimate stadium (F-1), in a drying pond and the ability of these larvae to seek for water in dry conditions. Larval behaviour in a drying pond was studied using a small artificial pond that enabled water to flow out. Most of the larvae left the pond and, of the-

se, a higher percentage left the pool after the formation of puddles. The ability of the dragonfly larvae to move towards a nearby pond was investigated by placing them 5 m away from a natural pond, with the freedom to walk on the ground. More of the larvae released nearest the low edge of the pond, where a humidity gradient was present, were able to reach water than of those released nearest the high edge, where no humidity gradient was present. The ecological significance of the behaviour of the larvae of *L. depressa* is discussed in relation to the typical habitat of this species, represented by small, shallow ponds, and to the presence of hygrosensors in dragonfly larvae." (Authors)] Address: Rebor, Manuela, Dipartimento di Biologia Cellulare e Ambientale, Università di Perugia, 06123 Perugia, Italy. E-mail: rebor@unipg.it

6759. Pilgrim, E.M.; Dohlen, C.D., von (2007): Molecular and morphological study of species-level questions within the dragonfly genus *Sympetrum* (Odonata: Libellulidae). *Annals of the Entomological Society of America* 100(5): 688-702. (in English). ["This study combines morphological and molecular data to address several questions of species validity within the dragonfly genus *Sympetrum*. We compared morphological characters (genitalia and other putatively diagnostic characters) and DNA sequences from mitochondrial cytochrome oxidase I (COI) and nuclear internal transcribed spacer (ITS) regions between these disputed taxa and their close relatives. Specimens of *Sympetrum nigrescens* Lucas shared COI haplotypes with *Sympetrum striolatum* (Charpentier), and no morphological characters consistently diagnosed *S. nigrescens*, which therefore becomes a junior synonym of *S. striolatum*. Similarly, *Sympetrum occidentale* Bartenev shared identical COI and ITS sequences with *Sympetrum semicinctum* (Say), and the supposed diagnostic morphological characters overlapped with the intraspecific variation within *S. semicinctum*. *Sympetrum occidentale* becomes a junior synonym of *S. semicinctum*. In a third case, the genetic distance between *Sympetrum signiferum* Cunnings & Garrison and *Sympetrum vicinum* (Hagen) was lower than that found between most undisputed species. However, the morphological characters that distinguish *S. signiferum* from *S. vicinum* were distinct and consistent, and they supported the retention of *S. signiferum* as a valid species. In the fourth case, neither morphological nor genetic data were able to distinguish *Sympetrum janeae* Carle consistently from *Sympetrum internum* Montgomery, or *Sympetrum rubicundulum* (Say); in addition, genetic distances between individuals of *S. internum* and *S. rubicundulum* were small or nonexistent. Further studies are necessary to test the species status of *S. janeae* and its close relatives." (Authors)] Address: Pilgrim, E., NERL Student Services Contractor, Molecular Ecology Research Branch, US EPA, 26 Martin Luther King Drive Cincinnati, OH 45268, USA. E-mail: Pilgrim.Erik@epamail.epa.gov

6760. Rebor, M.; Piersanti, S.; Salerno, G.; Gaino, E. (2007): Water deprivation tolerance and humidity response in a larval dragonfly: a possible adaptation for survival in drying ponds. *Physiological Entomology* 32: 121-126. (in English). ["Water deprivation tolerance is investigated in the last larval stadium of *Libellula depressa* under various conditions of relative humidity (60 – 100% relative humidity; RH). Most of the larvae maintained at 100% RH emerge and, at lower RH levels

show some resistance to dehydration because they die after a mean period ranging from 1.4 days at 60% RH up to 6.7 days at 90% RH. In dual-choice chambers with humidity gradients from 63–74% RH and from 68–84% RH, larvae spend most of the time in the moist side of the chamber. In a Y-tube olfactometer, the larvae reveal a positive hygrotaxis to two airstreams carrying different amounts of water vapour (98% vs. 50%) and spend most of their time in the 'humid' arm. The ecological significance of desiccation tolerance and hygropositive response in the last larval stadium of *L. depressa* is discussed in relation to the presence of hygroreceptors in dragonfly larvae." (Authors)] Address: Rebor, Manuela, Dipartimento di Biologia Cellulare e Ambientale, Università di Perugia, 06123 Perugia, Italy. E-mail: rebor@unipg.it

6761. Rebor, M.; Piersanti, S.; Almaas, T.J.; Gai, E. (2007): Hygroreceptors in the larva of *Libellula depressa* (Odonata: Libellulidae). *Journal of Insect Physiology* 53: 550-558. (in English). ["Ultrastructural and electrophysiological (single-cell recordings) investigations were carried out on the coeloconic sensilla borne by the apical antenna of the larvae of *L. depressa*. These sensilla appear as pegs located in pits. One of them is a compound sensillum constituted of two fused pegs in a common pit and the other two are single pegs located in separated pits close to each other. Coeloconic sensilla show position and ultrastructural details very similar to those described in insect hygroreceptors. The electrophysiological recordings on the apical antennae of the last larval instar of *L. depressa* clearly show the presence of moist and dry cells responding antagonistically to humidity changes. This study gives the first evidence of hygroreceptors in dragonfly larvae and represents the first electrophysiological approach to larval sensilla of aquatic insects. The presence of hygroreceptors in *L. depressa* larvae is in agreement with the hygropositive response shown by these insects in laboratory and field behavioural experiments." 6762. Roddis, S. (2007): Southern Hawker *Aeshna cyanea* attracted to light. *Atropos* 32: 59. (in English). [The same (?) female was caught by a moth-trap on 7 and 15-VIII-2006.] Address: Roddis, S., The Hollies, Station Road, Darley Dale, Matlock, Derbyshire, DE4 2EQ, UK

6763. Rouquette, J.R.; Thompson, D.J. (2007): Patterns of movement and dispersal in an endangered damselfly and the consequences for its management. *Journal of applied ecology* 44(3): 692-701. (in English). ["1. *Coenagrion mercuriale* is one of Europe's rarest and most threatened damselflies. It is listed in the European Community (EC) Habitats and Species Directive and is the only odonate currently given priority status in the UK Biodiversity Action Plan. Information regarding patterns of movement and dispersal in this species is required to guide conservation and management programmes. Management is currently geared towards habitat restoration of isolated subpopulations, with little attention paid to the metapopulation and landscape context. 2. A multisite mark–release–recapture project was carried out in the valley of the River Itchen in southern England to determine the extent of movement and the factors affecting movement of mature adults of this

endangered damselfly. A total of 8708 individuals was marked. 3. The species was found to be extremely sedentary, with dispersal limited to an area of contiguous habitat. The median net lifetime movement was 31.9 m and 66% of individuals moved less than 50 m in their lifetime. Movements of greater than 500 m were rare and the longest recorded movement was 1.79 km. This makes it the most sedentary odonate that has been studied in the UK. 4. The highest recapture rates and the lowest movement distances were recorded at the most isolated site. Time between capture and recapture, and day in season had an effect on movement, and individuals travelled further on their first than on subsequent moves. There was no consistent effect of age or sex on distance moved. 5. There was strong evidence for inverse density-dependent movement, with individuals moving further in low-density than high-density populations. This is the first time that inverse density-dependent movement has, to our knowledge, been observed in a natural population of odonates. 6. Synthesis and applications. *Coenagrion mercuriale*, along with many other invertebrate species of conservation concern, lives in a management-dependent mid-successional habitat. However, the species is highly sedentary. Furthermore, patterns of movement and dispersal are strongly affected by landscape structure and population density. This means that it is unable to recolonize isolated sites and requires 'stepping stone' habitats to improve its chances of survival in the medium to long term. Suitable habitat management between sites that are beyond the dispersal distance of individuals can be used to connect or reconnect populations. Within existing sites only small sections of habitat should be managed in any one year and new areas should be created close to existing populations. The long-term persistence of *C. mercuriale* and other invertebrate species requires a landscape approach to management, with connectivity an important part of management planning. It is clear that carefully conducted studies of movement and dispersal are key components in guiding invertebrate conservation strategies." 6765. Samways, M.J.; Grant, P.B.C. (2007): Honing Red List assessments of lesser-known taxa in biodiversity hotspots. *Biodiversity and Conservation* 16(9): 2575-2586. (in English). ["Red Listing organisms is an iterative process involving two variables. First, the conservation status of a taxon becomes clearer as more information becomes available, and secondly, the actual status changes as the taxon becomes more threatened or less threatened. Using a 20-year database of South African dragonflies has enabled us to hone conservation assessments and to arrive at a realistic appraisal of their true conservation status. Changes in the evaluati-

on of taxa came about through improved knowledge of habitat and particularly from information on the exact flight period. This background improved the apparency of the taxa so enabling accurate conservation assessments. The temporal shortcoming was addressed in detail by focusing on the core of the Cape Floristic Region global biodiversity hotspot, and recording the phenology of species. We found that there were large differences in emergence times. While flight times may not be a source of error in the temperate northern hemisphere, they can be a major issue in low and southern latitudes. Indeed, the error can be so great that species thought to be extinct were effectively resurrected. Temporal shortcomings can only be overcome by first undertaking a presence/absence survey over time to determine the appropriate time of year for making rigorous Red List assessments. This is not a criticism of the Red Listing process per se, which, for this taxon, we found to be largely sound. However, the results do emphasize that a critical approach to methodology is a necessary foundation when searching for trend indicators from the Red List with regards to lesser-known taxa." 6766. Schilder, R.J.; Marden, J.H. (2007): Parasites, proteomics and performance: effects of gregarine gut parasites on dragonfly flight muscle composition and function. *Journal of Experimental Biology* 210(24): 4298-4306. (in English). ["In previous work, we found that dragonflies infected with gregarine gut parasites have reduced muscle power output, loss of lipid oxidation in their flight muscles, and a suite of symptoms similar to mammalian metabolic syndrome. Here, we test the hypothesis that changes in muscle protein composition underlie the observed changes in contractile performance. We found that gregarine infection was associated with a 10-fold average reduction in abundance of a 155 kDa fragment of muscle myosin heavy chain (MHC; 206 kDa intact size). Insect MHC gene sequences contain evolutionarily conserved amino acid motifs predicted for calpain cleavage, and we found that calpain digestion of purified dragonfly MHC produced a peptide of 155 kDa. Thus, gut parasites in dragonflies are associated with what appears to be a reduction in proteolytic degradation of MHC. MHC155 abundance showed a strong negative relationship to muscle power output in healthy dragonflies but either no relationship or a weakly positive relationship in infected dragonflies. Troponin T (TnT) protein isoform profiles were not significantly different between healthy and infected dragonflies but whereas TnT isoform profile was correlated with power output in healthy dragonflies, there was no such correlation in infected dragonflies. Multivariate analyses of power output based on MHC155 abundance and a principal component of TnT protein isoform abundances explained 98% of the variation in muscle power output in healthy dragonflies but only 29% when data from healthy and infected dragonflies were pooled. These results indicate that important, yet largely unexplored, functional relationships exist between (pathways regulating) myofibrillar protein expression and (post-translational) protein processing. Moreover, infection by protozoan parasites of the midgut is associated with changes in muscle protein composition (i.e. across body compartments) that, either alone or in combination with other unmeasured changes, alter muscle contractile performance." (in German, with English summary). [5-VII-2006, S. arctica was found in the nature reserve "Rote Auen", Austria, and

for the first time in Upper Austria north of the Danube ("Mühlviertel"). Additional species of Odonata found at the same site are listed.] Address: Schwarz, M., Eben 21, A-4202 Kirchschlag, Austria. E-Mail: schwarz-entomologie@utanet.at

6772. Scoggins, M.; McClintock, N.L.; Gosselink, L. (2007): Occurrence of polycyclic aromatic hydrocarbons below coal-tar-sealed parking lots and effects on stream benthic macroinvertebrate communities. *J. N. Am. Benthol. Soc.* 26(4): 694-707. (in English). ["Parking-lot pavement sealants recently have been recognized as a major source of polycyclic aromatic hydrocarbons (PAHs) in urban stream sediments in Austin, Texas. Laboratory and field studies have shown that PAHs in sediments can be toxic to aquatic organisms and can degrade aquatic communities. After identifying increases in concentrations of PAHs in sediments below seal-coated parking lots, we investigated whether the increases had significant effects on stream biota in 5 Austin streams. We sampled sediment chemistry and biological communities above and below the point at which stormwater runoff from the parking lots discharged into the streams, thus providing 5 upstream reference sites and 5 downstream treatment sites. Differences between upstream and downstream concentrations of total PAH ranged from 3.9 to 32 mg/kg. Analysis of the species occurrence data from pool and riffle habitats indicated a significant decrease in community health at the downstream sites, including decreases in richness, intolerant taxa, Diptera taxa, and density. In pool sediments, Chironomidae density was negatively correlated with PAH concentrations, whereas Oligochaeta density responded positively to PAH concentrations. In general, pool taxa responded more strongly than riffle taxa to PAHs, but riffle taxa responded more broadly than pool taxa. Increases in PAH sediment-toxicity units between upstream and downstream sites explained decreases in taxon richness and density in pools between upstream and downstream sites." 6774. Serrano-Meneses, M.A.; Azpilicueta-Amorin, M.; Szekely, T.; Cord (2007): The development of sexual differences in body size in Odonata in relation to mating systems. *Eur. J. Entomol.* 104(3): 453-458. (in English). ["Adult body size is the result of important environmental, maternal and/or genetic effects acting on

animals during development. Here we investigate how sexual size dimorphism (SSD) develops in seven species of Odonata: *Anax imperator*, *Cordulegaster boltonii*, *Onychogomphus uncatas*, *Oxygastra curtisii* (Anisoptera), *Cercion lindeni*, *Ischnura graellsii* and *Platycnemis acutipennis* (Zygoptera). SSD of both the last larval and adult stages of the same individuals, which were reared under laboratory conditions, was measured. The aims were to investigate (i) whether SSD develops during the larval stage, (ii) the direction of larval and adult SSD, and (iii) whether the direction of adult SSD can be predicted by the mating system of a given species (e.g. males of territorial species being larger than females and the opposite for non-territorial species). We found that although larval differences in size may be present between the sexes, these are not necessarily shown in the adult stage (they may change or disappear). Also, the mating system was not related to patterns of adult SSD. Differences in SSD in larvae may be caused by differential use of resources via differential niche-utilisation or sex-specific growth patterns. We highlight the fact that sexual selection favouring large male size and fecundity selection, which selects for large females may be acting on the observed patterns in SSD in adults." 6775. Serrano-Meneses, M.A.; Córdoba-Aguilar, A.; Méndez, V.; Layen, S. (2007): Sexual size dimorphism in the American rubyspot: male body size predicts male competition and mating success. *Animal Behaviour* 73 (6): 987-997. (in English). ["Sexual differences in body size are widespread among animals, and various explanations for the evolution and maintenance of sexual size dimorphism have been proposed. We investigated the effects of sexual selection and fecundity selection on the sizes of males and females, respectively, in American rubyspots, *Hetaerina americana*. Males are larger than females and have large red spots at the base of each wing that are sexually selected via male-male contests. Mating success is determined by the ownership of a territory. Large males held territories for longer and sustained longer territorial fights than small males. Territorial males obtained more copulations than nonterritorial ones. Large males also had more wing pigmentation and mated with large females. Large territorial males had high energy reserves, whereas nonterritorial males appeared to have depleted reserves. Selection analyses of body size showed disruptive selection acting on male body size, suggesting that both small and large males may be favoured in terms of mating success. We also tested whether fecundity selection acts on female size. However, female body size was unrelated to the number of eggs carried. Taken together, our results suggest that in this territorial damselfly species male-biased size dimorphism is driven by large male size in male-male competition being selectively advantageous in territory acquisition and/or maintenance. We also suggest that small size is advantageous in nonterritorial males to improve their agility in courting (or subduing) females." - 6777.** Shieh, S.-H.; Hsu, C.-B.; Wang, C.-P.; Yang, P.-S. (2007): Leaf breakdown in a subtropical stream riffle and its association with macroinvertebrates. *Zoological Studies* 46(5): 609-621. (in English). ["The relationships between the quality of leaves of 3 trees (*Machilus thunbergii*, *Schefflera octophylla*, and *Ficus erecta*) and the assemblages of macroinvertebrates were studied at a riffle section of a 3rd-order subtropical forest stream in northern Taiwan. Macroinvertebrate taxon richness and density that colonized bags of leaves of the 3 tree species did not significantly differ. Macroinvertebrate assemblages were dominated by collectors, such as non-Tanyponinae Chironomidae, Prosimulium spp., and Baetis spp., which constituted > 79% of the total fauna. Results of a principal component analysis (PCA) showed that the macroinvertebrate assemblages were associated with the incubation time of the litter bags in the stream and the fine particulate organic matter (FPOM) trapped by the leaf bags, but not with the variables of leaf litter quality. Shredders, predominantly small nemourids, accounted for only 5.7%, 7.1% and 10.8% of the total macroinvertebrate assemblages on *M. thunbergii*, *S. octophylla*, and *F. erecta*, respectively, suggesting that macroinvertebrates played only a minor role in leaf litter breakdown in this subtropical 3rd-order stream. However, the density of shredders on *F. erecta*, as a function of the weight of the leaf litter remaining, was significantly higher than that of *M. thunbergii*, possibly because of the preference of shredders for high-quality food resources. In a comparison with the temperate zone systems, the dominant taxa of shredders that colonized the leaf litter were similar, but their relative abundances were much less in this subtropical forest stream riffle." - 6778.** Smith, J.; Samways, M.J.; Taylor, S. (2007): Assessing riparian quality using two complementary sets of bioindicators. *Biodivers. Conserv.* 16: 2695-2713. (in English). ["Biological indicators are being increasingly used to rapidly monitor changing river quality. Among these bioindicators are macroinvertebrates. A shortcoming of macroinvertebrate rapid assessments is that they use higher taxa, and therefore lack taxonomic resolution and species-specific responses. One subset of invertebrate taxa is the Odonata, which as adults, are sensitive indicators of both riparian and river conditions. Yet adult Odonata are not necessarily an umbrella taxon for all other taxa. Therefore, we investigated whether the two metrics of aquatic macroinvertebrate higher taxa and adult odonate species might complement each other, and whether together they provide better clarity on river health and integrity than one subset alone. Results indicated that both metrics provide a similar portrait of large-scale, overall river conditions. At the smaller spatial scale of parts of rivers, Odonata were highly sensitive to riparian vegetation, and much more so than macroinvertebrate higher taxa. Odonate species were more sensitive to vegetation structure than they were to vegetation composition. Landscape context is also important, with the odonate assemblages at point localities being affected by the neighbouring dominant habitat type. Overall, benthic macroinvertebrates and adult Odonata species provide a highly complementary pair of metrics which together provide large spatial scale (river system) and small spatial scale (point localities) information on the impact of stressors such as riparian invasive alien trees. As adult Odonata are easy to sample and are sensitive to disturbance at both small and large spatial scales, they are valuable indicators for rapid assessment of river condition and riparian quality." - 6780.** Song, D.; Wang, H.; Zeng, L.; Yin, C. (2007): Microstructure and nanomechanical properties of the wing membrane of dragonfly. *Materials Science and Engineering A* 457: 254-260. (in English). ["Detailed investigations on the microstructure and the mechanical properties of the wing membrane of the dragonfly were carried out. It was found that in the direction of the thickness the membrane was divided into three layers rather than as traditionally considered as a single entity, and on the surfaces the membrane displayed a random distribution rough microstructure that was composed of numerous nanometer scale columns coated by the cuticle wax secreted. The characteristics of the surfaces were accurately measured and a statistical radial distribution function of the columns was presented to describe the structural properties of the surfaces. Based on the surface microstructure, the mechanical properties of the membranes taken separately from the wings of living and dead dragonflies were investigated by the nanoindentation technique. The Young's moduli obtained here are approximately two times greater than the previous result, and the reasons that yield the difference are discussed." 6786. Svensson, E.I.; Friberg, M. (2007): Selective predation on wing morphology in sympatric damselflies. *The American Naturalist* 170: 101-112. (in English). ["Although predation is thought to affect species divergence, the effects of predator-mediated natural selection on species divergence and in nonadaptive radiations have seldom been studied. Wing melanization in *Calopteryx* damselflies has important functions in sexual selection and interspecific interactions and in species recognition. The genus *Calopteryx* and other damselfly genera have also been put forward as examples of radiations driven by sexual selection. We show that avian predation strongly affects natural selection on wing morphology and male wing melanization in two congeneric and sympatric species of this genus (*Calopteryx splendens* and *Calopteryx virgo*). Predation risk was almost three times higher for *C. virgo*, which has an exaggerated degree of wing melanization, than it was for the less exaggerated, sympatric congener *C. splendens*. Selective predation on the exaggerated species *C. virgo* favored a reduction and redistribution of the wing melanin patch. There was evidence for nonlinear selection involving wing patch size, wing patch darkness, and wing length and width in *C. splendens* but weaker nonlinear selection on the same trait combinations in *C. virgo*. Selective predation could interfere with species divergence by sexual selection and may thus indirectly affect male interspecific interactions, reproductive isolation, and species coexistence in this genus." (Authors) *Motacilla flava* *Motacilla alba* *Motacilla cinerea* as predators] Address: Friberg, M., Department of Zoology, Stockholm University, SE-106 91 Stockholm, Sweden E-mail: magne.friberg@zoologi.su.se

6787. Switzer, P.V. (2007): Using dragonflies as common, flexible and charismatic subjects for teaching the scientific process. *American Biology Teacher* 69(3): 158-164. (in English). ["Biology laboratories are usually designed around convenient and available subjects. For example, for animal laboratories "*Daphnia magna*," "*Drosophila melanogaster*," frogs, rats, and mice are common animals that are relatively easy to obtain, relatively cheap, and consequently lend themselves well to laboratory experimentation. On many campuses, however, a body of water exists - either in the form of a creek or small pond - and this water attracts numerous animals that have tremendous potential as subjects for teaching and learning. Chief among these animals are the dragonflies and damselflies. In this paper, focusing primarily on dragonflies, the author explains why dragonflies make great subjects, gives some practical advice for using them in teaching, and provides a few

specific examples of how he has used them in his introductory zoology, upper-division animal behaviour, and non-majors environmental life science classes." (Author)] Address: Switzer, P.V., Eastern Illinois Univ., Dept Biol, Sci., Charleston IL 61920; USA. E-mail: cfpvs@eiu.edu

6788. Tol, J. van (2007): The Platystictidae of the Moluccas and Misool (Odonata). *Deutsche Entomologische Zeitschrift* 54(1): 3-26. (in English). ["The Platystictidae of the Moluccas and Misool (Indonesia) are revised. All species are assigned to *Drepanosticta* Laidlaw. Representatives of this genus are known from the larger islands in the region, viz. Halmahera, Bacan, Obi, Ambon, Buru, Seram, and from the Kai island group. Aru is poorly studied for odonates, and no platystictids are known. Nine new species are described, viz. *Drepanosticta halmahera* sp. n., *D. rudicula* sp. n., *D. sembilanensis* sp. n. and *D. siu* sp. n., all from Halmahera; *D. bifida* sp. n. and *D. psygma* sp. n. from Bacan; *D. misoolensis* sp. n. from Misool; *D. amboinensis* sp. n. from Ambon and *D. obiensis* sp. n. from Obi. Two previously described species, *D. robusta* Fraser (Kai) and *D. moluccana* Lieftinck (Buru), are redescribed and illustrated. A key to all species is provided, as well as preliminary notes on phylogenetic relationships and biogeography. Halmahera platystictids show sister-group relationships with species from Bacan or, remarkably, Misool. The Moluccan *Drepanosticta* species are assigned to the *D. lymetta* and *D. megametta* species groups, which are also known from the Philippines and the Papuan region, and the *D. moluccana* group, presumably confined to the southern Moluccas. The role of the middle Eocene South Caroline Arc in the distributional history of the *Drepanosticta* species is discussed. (Author)] Address: Tol, J. van, National Museum of Natural History, P.O. 6792. Trigal, C.; García-Criado, F.; Alaez, C.-F. (2007): Macroinvertebrate communities of mediterranean ponds (North Iberian Plateau): importance of natural and human-induced variability. *Freshwater Biology* 52(10): 2042-2055. (in English). ["1. The effects of natural and human-induced variability on the composition of macroinvertebrate communities of 28 ponds located in the North Iberian Plateau (Spain) were studied to determine the best predictors of community structure. 2. Constrained ordination was used to identify the main factors explaining the among-pond variance in abundance (as catch per unit effort) of total macroinvertebrate and Chironomidae assemblages and trophic structure (functional feeding groups). 3. Variance partitioning showed that human disturbance (represented by a pond condition index, total phosphorus concentration and pesticides) was the best predictor of macroinvertebrate community structure, whereas factors, such as habitat and biotic variables were of secondary importance. Factors controlling the chironomid community were broadly similar to those acting on the whole community of macroinvertebrates. In contrast, trophic structure was mainly determined by habitat and biotic variables. 4. Our results show that macroinvertebrates may be used as effective indicators of the ecological status of Mediterranean ponds. The Chironomidae deserve special attention because they were the dominant group in the study ponds and the strongest explanatory variable for their distribution was degradation." 6793. Turner, A.M.; Chislock, M.F. (2007): Dragonfly predators influence biomass and density of pond snails. *Oecologia* 153: 407-415. (in English). ["Studies in lakes show that fish and crayfish predators play an important role in determining the abundance of freshwater snails. In contrast, there are few studies of snails and their predators in shallow ponds and marshes. Ponds often lack fish and crayfish but have abundant insect populations. Here we present the results of field surveys, laboratory foraging trials, and an outdoor mesocosm experiment, testing the hypothesis that insects are important predators of pulmonate snails. In laboratory foraging

trials, conducted with ten species of insects, most insect taxa consumed snails, and larval dragonflies were especially effective predators. The field surveys showed that dragonflies constitute the majority of the insect biomass fishless ponds. More focused foraging trials evaluated the ability of the dragonflies *Anax junius* and *Pantala hymenaea* to prey upon different sizes and species of pulmonate snails (*Helisoma trivolvis*, *Physa acuta*, and *Stagnicola elodes*). *Anax junius* consumed all three species up to the maximum size tested. *Pantala hymenaea* consumed snails with a shell height of 3 mm and smaller, but did not kill larger snails. *P. acuta* were more vulnerable to predators than were *H. trivolvis* or *S. elodes*. In the mesocosm experiment, conducted with predator treatments of *A. junius*, *P. hymenaea*, and the hemipteran *Belostoma flumineum*, insect predators had a pronounced negative effect on snail biomass and density. *A. junius* and *B. flumineum* reduced biomass and density to a similar degree, and both reduced biomass more than did *P. hymenaea*. Predators did not have a strong effect on species composition. A model suggested that *A. junius* and *P. hymenaea* have the largest effects on snail biomass in the field. Given that both pulmonate snails and dragonfly nymphs are widespread and abundant in marshes and ponds, snail assemblages in these water bodies are likely regulated in large part by odonate predation." 6794. Tyrrell, M. (2007): Maintenance of the female androchrome colour polymorph in the Blue-tailed Damselfly *Ischnura elegans* (Vander Linden). *J. Br. Dragonfly Society* 23(2): 33-39. (in English). ["In order to explain the maintenance of the male-like androchrome colour form in female Zygoptera, a form that would otherwise suffer severe disadvantages through lack of recognition by males, a number of theories have been developed. Cordero & Andres (1996) reviewed these theories and concluded that a "Density Dependence" theory offered the most likely explanation. This paper reports on research into the implications for female androchrome colour forms in both low and high density populations as a test of the Density Dependence theory, and was applied to the Blue-tailed Damselfly *Ischnura elegans* (Vander Linden) in Northamptonshire. For the low and high density populations studied, mating success was found to be directly related to the proportion of each colour form in the population as a whole, with no one colour form exhibiting preferential advantages or disadvantages. Similarly there was found to be no significant difference between the mating frequencies in the two populations. These observations suggest that the female androchrome in *Ischnura elegans* is not a perfect male mimic and that the male is readily able to recognize this colour form as female." 6798. Van Gossum, H.; Beatty, C.D.; Charlat, S.; Waqa, H.; Markwell, (2007): Male rarity and putative sex-role reversal in a Fijian Islands community of damselflies (Odonata). *Journal of Tropical Ecology* 23: 591-598. (in English). ["Behavioural sex-role reversal occurs when males and females exchange their standard roles in territorial defence or parental care. One circumstance under which sex-role reversal may occur is when males are a limiting resource, so that females have to compete for access to mates. Here we report on male rarity and male and female behaviour of species within the damselfly genus *Nesobasis*, endemic to Fiji. Earlier reports suggested that, in some members of this genus, males were seldom observed and that females of these species were consequentially territorial, a phenomenon described as 'sex-role reversal'. Quantitative estimation of the ratio of adult males to females at 15 localities in 13 *Nesobasis* species (1489 individuals) indicated that males were extremely rare in some species, yet common in others. This interspecific variability in male rarity cannot be explained by elevation or habitat. Formal observations of three species with abundant males revealed that males of these species were highly territorial: they physically challenged intruders while remaining within a confined area. By contrast, in three species where males were consistently rare or absent, females were not territorial: instead, they moved widely and were primarily engaged in oviposition. While we do not know the underlying reason for the unusual rarity of males at oviposition sites in some species, it is clear that this rarity has not provided sufficient selection pressure to generate genuine sex-role reversal." 6799. Van Gossum, H.; Beirinckx, K.; Forbes, M.R.; Sherratt, T.N. (2007): Do current hypotheses explain continental and seasonal variation in female morph frequencies of the damselfly, *Nehalennia irene*? *Biological Journal of the Linnean Society* 90(3): 501-508. (in English). ["Female-limited colour polymorphism occurs in many damselfly species, where one morph re-

sembles the male (andromorph) and the other is dissimilar (gynomorph). Explanations for this phenomenon vary, but most assume that andromorphism has arisen in odonates, as a response to excessive male harassment. Here, we quantify the extent of continental and seasonal variation in female morph frequencies in a widely-distributed damselfly and ask whether the spatiotemporal patterns in andromorph frequency can be understood on the basis of sexual harassment theory. We sampled the damselfly, *Nehalennia irene* (Hagen) among regions across Canada, and at several sites, over the reproductive season, within Central Canada. Andromorph frequencies ranged from 0 to > 90% across Canada. In particular, sites in Western Canada had consistently high andromorph frequencies, whereas andromorph frequencies among Central sites were lower and variable and, among Eastern sites, were lower still (except one site) and relatively invariant. For populations in Central Canada, both andromorph frequencies and population densities varied significantly over time, reaching a peak mid-season. As expected, morph frequency covaried significantly with estimates of male harassment in some cases, but estimates of male harassment did not consistently account for variation in morph frequencies within all regions. Additional factors such as genetic drift may influence morph frequency at the edge of a species' range. Future work also should test, and attempt to explain causation, for seasonal variation in morph frequency." 6801. Van Gossum, H.; Beirinckx, K.; Forbes, M.R.; Sherratt, T.N. (2007): Reproductive interference between *Nehalennia* damselfly species. *Ecoscience* 14: 1-7. (in English, with French summary). ["We tested the hypotheses that reproductive interference between 2 congeneric damselfly species influences their local population densities and the female morph ratios in one of the species. *Nehalennia irene* has 2 female types (andromorph and gynomorph), whereas *N. gracilis* exhibits only one female type. Andromorphic *N. irene* females not only resemble conspecific males in body coloration, but also resemble heterospecific females of *N. gracilis*. We predicted male *N. irene* to be most attracted to gynomorphs of *N. irene* and male *N. gracilis* to be least attracted to them. Further, if *N. gracilis* males harass andromorphic *N. irene* females excessively, then they may reduce andromorph frequencies of *N. irene* locally. Our results indicate hybridization to be prevented by a "lock-and-key" mechanism, but male *N. irene* often attempt mating with female *N. gracilis*. Contrary to prediction, andromorph frequency in *N. irene* did not depend on whether *N. irene* populations were in sympatry or allopatry with *N. gracilis*. As predicted, *N. irene* males attempted tandem formation most frequently with conspecific gynomorphs, while *N. gracilis* males made most heterospecific tandem attempts on *N. irene* andromorphs. Collectively, our results suggest that *N. gracilis* females may be frequently harassed by *N. irene* males, and that this may help explain the relative rarity of *N. gracilis*." 6804. Wang, Z.J.; Russell, D. (2007): Effect of forewing and hindwing interactions on aerodynamic forces and power in hovering dragonfly flight. *Physical Review Letters* 99(148101): 1-4. (in English). ["Dragonflies are four-winged insects that have the ability to control aerodynamic performance by modulating the phase lag (ϕ) between forewings and hindwings. We film the wing motion of a tethered dragonfly and compute the aerodynamic force and power as a function of the phase. We find that the out-of-phase motion as seen in steady hovering uses nearly minimal power to generate the required force to balance the weight, and the in-phase motion seen in takeoffs provides an additional force to accelerate. We explain the main hydrodynamic interaction that causes this phase dependence." (Authors)] Address: Wang, Jane, Itasca Consulting Group, Inc., Minneapolis, MN 55401, USA. E-mail: zw24@cornell.edu

6805. Wappler, T.; Petrulevicius, J.F. (2007): *Priscalestidae*, a new damselfly family (Odonata: Lestinoidea) from the Middle Eocene Eckfeld maar of Germany. *ALAVESIA* 1: 69-73. (in English). ["We describe *Priscalestes germanica* Petrulevicius & Wappler, a new genus and species of Lestinoidea Calvert (1901) (sensu Bechly 1996) from the Eocene of Germany. The new genus represents a new family, *Priscalestidae* Petrulevicius & Wappler fam. nov., with close relationship to *Megalestidae*, *Lestidae* and the genus *Promegalestes* Petrulevicius & Nel 2004 from the late Paleocene of Argentina. The new family seems to be in a basal position with respect to the *Lestidae* because of the lack of their synapomorphies, i. e. MA strongly zigzagged and the area between IR2 and RP3/4 distally strongly widened with three rows of cells between these two veins instead of only one. The new family differs also from *Lestidae* and *Megalestidae* in the presence of two autapomorphies, i.e. (1) all secondary longitudinal veins (except IR1 and IR2) suppressed, resulting in presence of unicellular rows between IR1 and RP2, RP2 and IR2, RP3 and MA; and (2) the midfork closer to the subnodus than to the arculus. The sharing of last character with *Promegalestes* let us thinking in a close relations-

hip of these two genera." (Authors)] Address: Wappler, T., Institut für Paläontologie, Nussalle 8, 53115, Bonn, Germany. E-mail: twappler@uni-bonn.de

6806. Ward, L.; Mill, P.J. (2007): Spacing behaviour in larval Banded Demoiselle *Calopteryx splendens* (Harris). *J. Br. Dragonfly Society* 23(2): 58-62. (in English). ["The widely held view is that *C. splendens* larvae tend to inhabit aquatic vegetation growing on a silt substrate where they use the roots and stems for shelter and as emergence supports. However, considering the patchy distribution of aquatic vegetation in a river and the semivoltine nature of the larval life cycle this could potentially result in serious overcrowding of larvae at oviposition sites. In the current study the spacing behaviour of *C. splendens* larvae was investigated, under experimental conditions, with regard to the density of an emergent support. ... A shift in *C. splendens* from a random, approaching contagious, distribution towards a more regular pattern with increased density of dowels was observed in the current study." (Authors)] Address: Ward, Louise, Askham Bryan College, Askham Bryan, York, YO23 3FR, UK

6807. Ware, J.; May, M.; Kjer, K. (2007): Phylogeny of the higher Libelluloidea (Anisoptera: Odonata): An exploration of the most speciose superfamily of dragonflies. *Molecular phylogenetics and evolution* 45(1): 289-310. (in English). ["Although libelluloid dragonflies are diverse, numerous, and commonly observed and studied, their phylogenetic history is uncertain. Over 150 years of taxonomic study of Libelluloidea Rambur, 1842, beginning with Hagen (1840), [Rambur, M.P., 1842. *Neuropteres. Histoire naturelle des Insectes*, Paris, pp. 534; Hagen, H., 1840. *Synonymia Libellularum Europaeorum. Dissertation inauguralis quam consensu et auctoritate gratiosi medicorum ordinis in academia albertina ad summos in medicina et chirurgia honores.*] and Selys (1850), [de Selys Longchamps, E., 1850. *Revue des Odonates ou Libellules d'Europe* [avec la collaboration de H.A. Hagen]. Muquardt, Bruxelles; Leipzig, 1-408.], has failed to produce a consensus about family and subfamily relationships. The present study provides a well-substantiated phylogeny of the Libelluloidea generated from gene fragments of two independent genes, the 16S and 28S ribosomal RNA (rRNA), and using models that take into account non-independence of correlated rRNA sites. Ninety-three ingroup taxa and six outgroup taxa were amplified for the 28S fragment; 78 ingroup taxa and five outgroup taxa were amplified for the 16S fragment. Bayesian, likelihood and parsimony analyses of the combined data produce well-resolved phylogenetic hypotheses and several previously suggested monophyletic groups were supported by each analysis. *Macromiinae*, *Corduliidae* s. s., and *Libellulidae* are each monophyletic. The corduliid (s.l.) subfamilies *Synthemistinae*, *Gomphomacromiinae*, and *Idionychinae* form a monophyletic group, separate from the *Corduliinae*. *Libellulidae* comprises three previously accepted subfamilies (*Urothemistinae*, a very restricted *Tetrathemistinae*, and a modified *Libellulinae*) and five additional consistently recovered groups. None of the other previously proposed subfamilies are supported. Bayesian analyses run with an additional 71 sequences obtained from GenBank did not alter our conclusions. The evolution of adult and larval morphological characters is discussed here to suggest areas for future focus. This study shows the inherent problems in using poorly defined

and sometimes inaccurately scored characters, basing groups on symplesiomorphies, and failure to recognize the widespread effects of character correlation and convergence, especially in aspects of wing venation." 6808. Watts, P.C.; Saccheri, I.J.; Kemp, S.J.; Thompson, D.J. (2007): Effective population sizes and migration rates in fragmented populations of an endangered insect (*Coenagrion mercuriale*: Odonata). *Journal of Animal Ecology* 76: 790-800. (in English). ["1. Effective population sizes (N_e) and migration rates (m) are critical evolutionary parameters that impact on population survival and determine the relative influence of selection and genetic drift. While the parameter m is well-studied in animal populations, N_e remains challenging to measure and consequently is only rarely estimated, particularly in insect taxa. 2. We used demographic and genetic methods to estimate N_e and m in a fragmented population of the endangered damselfly *C. mercuriale* to better understand the contrast between genetic and field estimates of these parameters and also to identify the spatial scale over which populations may become locally adapted. 3. We found a contrast between demographic and genetic-based estimates of these parameters, with the former apparently providing overestimates of N_e , owing to substantial underestimation of the variance in reproductive success, and the latter overestimating m , because spatial genetic structure is weak. 4. The overall N_e of sites within the population network at Beaulieu Heath, the largest *C. mercuriale* site in the UK, was estimated to vary between approximately 60 and 2700. 5. While N_e was not correlated with either the total numbers of adults (N) or the area of habitat, this parameter was always less than N , because of substantial variance in reproductive success. The ratio N_e / N varied between 0.006 and 0.42 and was generally larger in smaller populations, possibly representing some 'genetic compensation'. 6. From a simple genetic model and these data on N_e and m , it seems that populations of *C. mercuriale* have the potential to respond to localized spatial variation in selection and this would need to be considered for future genetic management of this endangered species." (Authors)] Address: Thompson, D.J., Population Biology Research Group, School of Biological Sciences (Nicholson Building), University of Liverpool, P.O. Box 147, Liverpool, L69 3BX, UK. 6809. Webb, T.J.; Freckleton, R.P. (2007): Only half right: Species with female-biased sexual size dimorphism consistently break Rensch's Rule. *PLoS ONE* 2(9): e897. doi:10.1371/journal.pone.0000897. (in English). ["Background: Most animal species display Sexual Size Dimorphism (SSD): males and females consistently attain different sizes, most frequently with females being larger than males. However the selective mechanisms driving patterns of SSD remain controversial. 'Rensch's rule' proposes a general scaling phenomenon for all taxa, whereby SSD increases with average body size when males are larger than females, and decreases with body size when females are larger than males. Rensch's rule appears to be general in the former case, but there is little evidence for the rule when females are larger than males. Methodology/Principal

Findings: Using comprehensive data for 1291 species of birds across 30 families, we find strong support for Rensch's rule in families where males are typically larger than females, but no overall support for the rule in families with female-biased SSD. Reviewing previous studies of a broad range of taxa (arthropods, reptiles, fish and birds) showing predominantly female-biased SSD, we conclude that Rensch's conjecture is the exception rather than the rule in such species. Conclusions/Significance: The absence of consistent scaling of SSD in taxa with female-biased SSD, the most prevalent direction of dimorphism, calls into question previous general evolutionary explanations for Rensch's rule. We propose that, unlike several other ecological scaling relationships, Rensch's rule does not exist as an independent scaling phenomenon." (Authors) The study also includes "dragonflies and damselflies".] Address: Webb, T.J., Department of Animal and Plant Sciences, University of Sheffield, Sheffield, United Kingdom. 6810. Wildermuth, H. (2007): *Leucorrhinia pectoralis* in der Schweiz – aktuelle Situation, Rückblick und Ausblick (Odonata: Libellulidae). *Libellula* 26(1/2): 59-76. (in German, with English summary). ["The species was recorded from 1835 to 2006 at 64 localities of which 61 are situated in the Central Plateau, mainly between 400 and 600 m a.s.l., and three in the Jura mountains. It does not occur in the Alpine region. From 2000 to 2006 *L. pectoralis* was still found at twelve localities, but only four vigorous populations existed in this period: three in the canton Zürich and one in the canton Fribourg. Primary cause for the decline was the destruction of bogs by peat extraction and reclamation of agricultural land. From ca 1950 onwards the species disappeared successively in many remaining and currently protected mires because the peat cuttings became increasingly overgrown. The future existence of *L. pectoralis* in Switzerland depends on the management of small water bodies in partly exploited mires. It is necessary to regenerate overgrown peat cuttings and to maintain them at early and medium succession stages. Regeneration of partly destroyed bogs by raising the water table can also be helpful." (Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rütli, Switzerland. E-mail: hansruedi@wildermuth.ch

6811. Wildermuth, H. (2007): Anheftung der parasitischen Landmilbe *Leptus* sp. an *Orthetrum coerulescens* (Parasitengona: Erythraeidae; Odonata: Libellulidae). *Libellula* 26(3/4): 207-212. (in German, with English summary). ["In north-eastern Switzerland a population of *O. coerulescens* was found in which four individuals were infested with terrestrial mite larvae. One freshly emerged dragonfly bore 15 mites. Their attachment and behaviour was studied in the laboratory. Some mites were attached on peripheral body parts that are hardly supplied with hemolymph, and no growth could be noted in any individual during three days of observation. It is discussed to what extent the mite's object of attachment is alimentary or possibly mainly phoretic." (Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rütli, Switzerland. 6812. Wildermuth, H. (2007): Polarotaktische Reaktionen von *Coenagrion puella* und *Libellula quadrimaculata* auf Erdbeerkulturen als ökologische Falle (Odonata: Coenagrionidae, Libellulidae). *Libellula* 26(3/4): 143-

150. (in German, with English summary). ["In north-eastern Switzerland, *C. puella* and *L. quadrimaculata* were found in numbers in July 2006 away from water bodies on a large strawberry field that was covered with shiny black plastic sheets between the plant rows. Both sexes exhibited typical elements of the species-specific reproduction behaviour including oviposition attempts. Obviously, they took the plastic sheets for ponds because such surfaces attract dragonflies like the similarly polarized light reflected from water surfaces. As the dragonflies lost time, energy and possibly also genetic material by their maladaptive habitat choices, they got caught in an ecological trap. In 2007 only few individuals of *C. puella* and no *L. quadrimaculata* were found on the same strawberry field. During sporadic checks of other fields with plastic sheets in the region no dragonflies were observed. Hence, such surfaces obviously attract reproductively active individuals in numbers only under special conditions, perhaps at high population densities. It is assumed that the negative effects of black shiny surfaces on dragonfly populations in a man-modified landscape is probably negligible." 6813. Wildermuth, H.; Martens, A. (2007): The feeding action of *Forcipomyia paludis* (Diptera: Ceratopogonidae), a parasite of Odonata imagines. *International Journal of Odonatology* 10(2): 249-255. (in English). ["Females of *Forcipomyia paludis* were studied microscopically during their feeding action on Odonata wings where they were mostly attached to main veins in the basal half of the wings. In some individuals rhythmic nodding of the head was noted. Conspicuously many midges lifted the abdominal tip every one or two minutes and from the anus fast growing gas bubbles appeared that burst after about half a second. We suppose that the insects, having punctured the host's veins with their stout proboscis, sucked much air (as well as haemolymph) from the tracheae which they had to get rid of afterwards. From these observations, combined with further indications, it is inferred that *F. paludis* acts as a true parasite of Odonata and that the association is not only phoretic as previously assumed." 6814. Willigalla, C. (2007): Zusammensetzung der Libellenfauna der Stadt Mainz im Zeitraum der letzten 30 Jahre (Insecta: Odonata). *Fauna Flora Rheinland-Pfalz* 11(1): 175-190. (in German, with English summary). [Rheinland-Pfalz, Germany; "In 2006 the NABU-project "Biomonitoring" researched the dragonfly species of the lentic and lotic waters in the city of Mainz. The 18 waters studied served as habitats for 36 dragonfly species. Until now, 23 species had been found in Mainz. Most of the newly detected species can be classified as mediterranean. As representatives of this group *Aeshna affinis*, *Crocothemis erythraea*, *Orthetrum brunneum*, *Sympetrum fonscolombii* and *Sympetrum meridionale* were found in 2006. Whereas there are known populations of the first four species from other regions in Rhineland-Palatinate the record of the Southern Darter is the first rediscovery of this species in Rhineland-Palatinate since 1993. Mediterranean species contribute the main proportion to the dragonfly coenosis (60%). *Aeshna affinis* and *Crocothemis erythraea* also showed the highest abundance at some waters studied. In addition to the mediterranean group, species

typical of lotic waters were observed, e. g. *Gomphus vulgatissimus*, *Gomphus flavipes* and *Onychogomphus forcipatus*. The increased number of species found in 2006 was probably caused by the improved quality of the river Rhine in terms of structure and water chemistry, climatic change and increased intensity of data collection." 6815. Wojtal, A.; Frankiewicz, P.; Andziak, M.; Zaleski, M. (2007): The influence of invertebrate predators on *Daphnia* spatial distribution and survival in laboratory experiments: Support for *Daphnia* horizontal migration in shallow lakes - *Internat. Rev. Hydrobiol.* 92(1): 23-32. (in English). ["The behavioural response of *Daphnia cucullata* to the presence of the pelagic invertebrate predator *Leptodora kindtii*, and the predation rate of littoral dragonfly nymphs on this species were investigated under laboratory conditions. Results of this study revealed a strong hiding response of *Daphnia cucullata* in the presence of the predatory cladoceran, *L. kindtii*, which was similar to the response of *Daphnia* in the presence of juvenile perch. This suggests that pelagic invertebrate predators may cause *Daphnia* to hide in the littoral zone which could result in increased exposure to predation by littoral invertebrates. A strong influence of dragonfly nymphs on *D. cucullata*, both in the presence and absence of macrophytes, was found. The average predation rate of Odonata larvae was about 5 prey ind⁻¹h⁻¹ and did not differ significantly between treatments. Quantification of dragonfly pressure on *Daphnia* populations will require cross-verification with field experiments since in the natural conditions *Daphnia* seeks a shelter in the vegetation stands against predation by *Leptodora*, despite the occurrence of odonates." 6816. Worthen, W.B. ; Jones, C.M. (2007): The effects of wind speed, competition, and body size on perch height selection in a guild of Libellulidae species (Odonata). *International Journal of Odonatology* 10(2): 257-272. (in English). ["For eleven species of sympatric libellulids, male mean mass was positively correlated with wing aspect ratio, wing loading, and mean perch height. We tested the hypotheses that perch height selection was governed by interspecific competition or biomechanical responses to increased wind speed at higher perches. Although larger odonates might prefer higher perches to offset their increased wing loading, species' mean perch height did not correlate with changes in mean or maximum wind speeds. Rather, perch height selection is best explained by competitive interactions. Mean mass (log10 transformed) of these species are distributed in a significantly non-random manner, consistent with community-wide character displacement. Also, observations of aggressive interactions and the response to decoys of three abundant species revealed a competitive hierarchy based on body size. *Libellula luctuosa*, the largest species, avoided stations with conspecific decoys but was attracted to stations with the decoys of two smaller species. *L. incesta* avoided stations with larger *L. luctuosa* decoys, but was attracted to stations with smaller *Pachydiplax longipennis* decoys. *P. longipennis* avoided stations with conspecific and *L. incesta* decoys. *L. luctuosa* was also more successful in displacing perchers (82.4%) than *L.*

incesta (68.9%) and *P. longipennis* (46.6%). In pairwise contrasts, the larger species was always more successful at displacing the smaller species. Finally, *P. longipennis* was attacked at significantly higher rates when it perched on high perches than when it perched at lower perches. We conclude that interspecific competition causes niche partitioning of perch height in this community." (in Chinese, with English summary). [Type specimens are deposited in the Dali College, Dali, Yunnan, 671000, China. *Perissogomphus asahinai*, sp. nov.: "The new species is allied to *P. stevensi*, but differs in the following characters: 1) occiput black and with a middle yellow spot; 2) prothorax with the middle lobe black and the yellow spots at middle and side; 3) synthorax grass-green on dorsum and with a black middle stripe, but without a broad M-shaped marking; 4) abdominal segment 10 yellow and with the basal half black on dorsum; 5) superior anal appendages terminal armed with 7-8 small black spines. Length of abdomen: male: 43.0 mm, female: 42.0 mm; length of hind wing: male: 36.5 mm, female: 40.0 mm. Holotype: male, Yang-bi river, Dali City, Yunnan Province, 07-VIII-1999, leg. Yang, Zi-zhong; Paratype: 1 female: Cangshan Mountain, Dali City, Yunnan Province, 03-VI-1998, leg. No. 6. Etymology. The new species is named asahinai in honour of Dr. Syoziro Asahina." (Authors)] Address: Zhu, H.-q., Shanxi University, 42-38, Taiyuan, Shanxi 030006, China

6824. Braune, E.; Richter, O.; Sönderath, D.; Suhling, F. (2008): Voltinism flexibility of a riverine dragonfly along thermal gradients. *Global Change Biology* 14: 1-13. (in English). ["Potential effects of future warming should be reflected in life history patterns of aquatic organisms observed in warmer climates or in habitats that are different in ambient temperature. In the special case of the dragonfly *Gomphus vulgatissimus* (L.) (Odonata: Gomphidae) previous research suggests that voltinism decreases from south to north. We analysed data on voltinism from 11 sample sites along a latitudinal gradient from about 44°N to 53°N, comprising small streams to medium-sized rivers. Furthermore, to simulate different conditions and to allow projections for future climate change scenarios, we developed a population dynamic model based on a projection matrix approach. The parameters of the model are dependent on temperature and day length. Our field results indicate a decrease in voltinism along the latitudinal gradient from southern to northern Europe and a corresponding increase of voltinism with higher temperatures. An increase in voltinism with width of the running water implies an effect of varying habitat temperature. Under the impact of global warming, our model predicts an increased development speed, particularly in the northern part of the latitudinal gradient, an extension of the northern range limit and changes in phenology of *G. vulgatissimus*, leading to an extension of the flight season in certain regions along the gradient." (Authors)] Address: Suhling F., Inst. Geoökologie, TU Braunschweig, Langer Kamp 19c, D-38102 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

6825. Butler, R.G.; deMaynadier, P. (2008): The significance of littoral and shoreline habitat integrity to the conservation of lacustrine damselflies (Odonata). *J. Insect Conserv.* 12(1): 23-36 (in English) ["Human development of pond and lake shorelines may significantly impact native lacustrine biota including a variety of aquatic macroinvertebrate groups. In an effort to better understand the habitat associations and sensitivities of lacustrine damselflies, we sampled adults in littoral macrophyte habitat during two flight periods at 35 randomly selected pond and lake sites in southern Maine during 2000 and 2001. Data were also collected to help characterize water body, shoreline disturbance, and aquatic vegetation at each study site. Nonmetric multidimensional scaling was used for ordination of damselfly assemblages, and coordinates from the most stable solution were related to site variables using forward stepwise multiple regression. Our results suggest that the diversity and composition of damselfly assemblages is related to the abundance and richness of littoral zone macrophytes, extent of riparian disturbance, benthic substrate granularity, and lake productivity; all variables subject to anthropogenic degradation on excessively developed waterbodies. Additionally, we developed a Habitat Tolerance Index useful for distinguishing between relative habitat specialists and generalists from among a diverse assemblage of 19 lacustrine species. Finally, species-specific damselfly associations with multiple genera of floating and emergent macrophytes were assessed using both nonparametric correlation and multiplicative regression yielding significant relationships for 17 species, including two damselflies of

global conservation concern (*Enallagma laterale* and *E. pictum*). We conclude that the protection of littoral and shoreline habitat integrity, with special emphasis on emergent and floating macrophytes, is critical to the conservation of lacustrine biodiversity." (Authors)] Address: Butler, R.G., Department of Natural Sciences, University of Maine at Farmington, 173 High Street, Farmington, Maine 04938, USA. E-mail: butler@maine.edu

6826. Campero, M.; De Block, M.; Ollevier, F.; Stoks, R. (2008): Correcting the short-term effect of food deprivation in a damselfly: mechanisms and costs. *Journal of Animal Ecology* 77(1): 66-73. (in English). ["1. Mass at emergence is a life-history trait strongly linked to adult fitness. Therefore, when faced with transient food shortage in the larval stage, mass-correcting mechanisms are common. 2. These correcting mechanisms may carry costs with them. On one hand, these costs may be overestimated because they can be confounded with the direct effects of the transient food shortage itself. On the other hand, costs may be underestimated by ignoring physiological costs. Another largely neglected topic is that correcting mechanisms and costs may critically depend upon other stressors that often co-occur. 3. Here, we identify the mass-correcting mechanisms and their associated costs at emergence in the damselfly *Coenagrion puella*, after being stressed by a transient period of starvation and a subsequent exposure to pesticide stress during the larval stage. We introduce path analysis to disentangle direct costs of starvation and the mass-correcting mechanisms in terms of immune response. 4. As predicted, we found no differences in mass at emergence. Starvation directly resulted in a costly delayed emergence and a decreased immune response at emergence. Mass-correcting mechanisms included a prolonged post-starvation period, reduced mass loss at emergence and compensatory growth, although the latter only in females under pesticide stress. 5. The mass-correcting mechanisms were associated with beneficial effects on investment in immune response, but only in the absence of pesticide stress. Under pesticide stress, these beneficial effects were mostly undone or overruled, resulting in negative effects of the mass-correcting mechanisms in terms of immune response. 6. Our results stress the importance of and introduce a statistical way of disentangling direct costs of starvation and the mass-correcting mechanisms themselves, and the importance of including physiological endpoints in this kind of studies." (Authors)] Address: Campero, Melina, Laboratory of Aquatic Ecology, University of Leuven, Ch. Debériotstraat 32, B-3000 Leuven, Belgium. E-mail: melina.campero@gmail.com

6827. Chaves, M.L.; Rieradevall, M.; Chainho, P.; Costa, J.L.; Costa, M.J.; Prat, N. (2008): Macroinvertebrate communities of non-glacial high altitude intermittent streams. *Freshwater Biology* 53(1): 55-76 (in English) ["1. Macroinvertebrate assemblages of five non-glacial intermittent high altitude headwater streams (above 1400m - Serra da Estrela, Portugal), with dry periods of different lengths (0-3?months), were investigated in nearly undisturbed conditions to (i) examine spatial differences and identify environmental variables responsible for the observed invertebrate patterns, (ii) assess the association of dry period length with invertebrate community structure and (iii) determine the influence of using different taxonomic identification levels

(order, family and genus) to assess invertebrate community patterns. 2. More than 100 macroinvertebrate genera were identified. Insects clearly dominated these communities with more than 95% of total captures and around 95% of the total richness. Diptera were the most rich and abundant group with chironomid occurrences comprising over 70% of macroinvertebrate captures. 3. The highest taxon richness, diversity, EPT (Ephemeroptera+Plecoptera+Trichoptera) and OCH (Odonata+Coleoptera+Heteroptera) genus richness, the greatest number of exclusive and characteristic taxa identified by the Indicator Value (IndVal), and a distinct community structure shown by Canonical Correspondence Analyses (CCA), were found in the only stream that was never totally dry, with pools lasting over summer. Environmental gradients that spatially structured the macroinvertebrate communities were always related to flow variations. 4. Over time, the highest abundances found in these systems were also related to flow variations and maximum genus richness occurred in the connected pools or in isolated pools. Streams with longer dry periods presented a distinct recolonization phase, with higher abundance of the stonefly larvae *Nemoura* sp. and the presence of the chironomid larvae *Krenosmittia* sp., possibly arriving from the hyporheos. 5. Taxonomic level of invertebrate identification was vital for recognizing the characteristic taxa (IndVal) of streams yet was not critical for identifying streams with the highest macroinvertebrate richness/diversity or structuring environmental gradients. 6. Overall, this study emphasizes the variability of high altitude intermittent streams macroinvertebrate communities, despite spatial proximity. This variability was probably related to flow intermittency and hydrologic permanence, different vegetation covers and riverbed substrata. Consequently, the establishment of reference conditions should involve long-term data collections and more detailed physical characterization. Also, these findings have significant implications for accurately predicting the ecological consequences of future climate change in high altitude scenarios." (Authors)] Address: Chaves, M.L., Universidade de Lisboa, Faculdade de Ciências, Instituto de Oceanografia, Lisboa, Portugal 2: Departament d'Ecologia, Universitat de Barcelona, Barcelona, España

As sister group of the *Neobrachystigmata* in the new clade *Paraneobrachystigmata*, it demonstrates the presence of this relatively much derived subclade in the Middle Ju-

assic, suggesting a great antiquity for the Cavilabiata." (Authors)] Address: Nel, A., Lab. Ent., Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrs1.mnhn.fr

6830. Kadoya, T.; Suda, S.; Tsubaki, Y.; Washitan, I. (2008): The sensitivity of dragonflies to landscape structure differs between life-history groups. *Landscape Ecology* 23(2): 149-158 (in English) ["Contrasting life-history strategies of long versus short pre-reproductive phases are known in adult dragonflies of temperate regions. Because the long-phase species spend a longer time in terrestrial habitats such as grasslands or woodlands during their pre-reproductive phase, we hypothesized that long-phase species would be more sensitive to landscape structure than short-phase species. To test this hypothesis, we conducted periodic censuses of adult dragonflies at small man-made ponds. We compared the two above functional groups in terms of the degree to which species occurrence depended on landscape structure. The difference among the two groups was not significant, but occurrence of long-phase species tended to depend on landscape structure. Long-phase species responded to landscape structure at larger spatial scales and showed stronger spatial autocorrelation in their occurrence among sampling ponds than short-phase species." (Authors)] Address: Kadoya, T., Department of Ecosystem Studies, Institute of Agriculture and Life Science, The University of Tokyo, 1-1-1 Yayoi, Bunkyo-ku, Tokyo 113-8657, Japan. 6831. Kalkman, V.; Clausnitzer, V.; Dijkstra, K.D.; Orr, A.G.; Paulson, D.R.; Tol, J. van (2008): Global diversity of dragonflies (Odonata) in freshwater. *Hydrobiologia* 595(1): 351-363 (in English) ["Larvae of almost all of the 5,680 species of the insect order Odonata are dependent on freshwater habitats. Both larvae and adults are predators. The order is relatively well studied, and the actual number of species may be close to 7,000. Many species have small distributional ranges, and are habitat specialists, including inhabitants of alpine mountain bogs, seepage areas in tropical rain forests, and waterfalls. They are often successfully used as indicators for environmental health and conservation management. The highest diversity is found in flowing waters in rain forests of the tropics, the Oriental and Neotropical regions being the most speciose. This paper discusses diversity, summarises the biogeography of dragonflies in the different biogeographical regions and gives the total number of species and genera per family per biogeographical region. Examples are given of areas of particular diversity, in terms of areas of endemism, presence of ancient lineages or remarkable recent radiations but no well-based review of areas with high endemism of dragonflies is available so far. The conservation status of dragonflies is briefly discussed. Species confined to small remnants of forest in the tropics are most under threat of extinction by human activities." (Authors)] Address: Kalkman, V.J., Oude Rijnsburgerweg 28, NL-2342 BC Oegstgeest, The Netherlands. E-mail: Kalkman@naturalis.nnm.nl

6832. McCauley, S. (2008): Slow, fast and in between: habitat distribution and behaviour of larvae in nine species of libellulid dragonfly. *Freshwater Biology* 53(2): 253-263. (in English). ["1. Activity and microhabitat use are important factors determining species performance in habitats that differ in permanence and spe-

cies composition of top predators. This study examined the relationship between the distribution across a gradient of habitat permanence and an associated transition in the composition of top predators and the behaviour of species of larval dragonflies. It also assessed the relationship between larval behaviour, body size and the duration of the larval stage. In laboratory mesocosms the mobility of the different species was measured, as was the extent to which they associated with artificial vegetation. 2. Species mobility was positively related to their natural occurrence in habitats in which invertebrates or small-bodied fish were the top predators, and negatively related with the frequency with which species co-existed with large-bodied fish, the permanence of the habitat and the length of the larval stage. 3. Rather than falling into strict low and high mobility categories, habitat generalists that occurred across the habitat gradient, co-existing with different top predators, had variable mobility levels. In these generalists, mobility was positively related to how frequently they were found in natural habitats in which invertebrates were the top predators. 4. The extent to which species utilized the artificial vegetation in mesocosms was associated with the length of the larval period but was not associated with mobility or species habitat distribution in the field." 6833. Mellado Diaz, A.; Suarez Alonso, M.L.; Vidal-Abarca Gutierrez, M.R. (2008): Biological traits of stream macroinvertebrates from a semi-arid catchment: patterns along complex environmental gradients. *Freshwater Biology* 53(1): 1-21 (in English) ["1. The relationships between biological traits of macroinvertebrates and environmental characteristics were investigated in streams with contrasting physical, chemical or landscape level attributes. We used an ordination technique, RLQ analysis, which links an environmental table (R) with traits table (Q) through an abundance table (L) to investigate the relationship between habitat characteristics and biological traits. 2. A major environmental axis explaining the distribution of species and their distinctive biological features was obtained. This axis included variables of anthropogenic pressure (agricultural and urban uses) and natural variability (climatic and geologic) that are strongly intercorrelated in the study area, with a clear spatial component. 3. The attributes of species from frequently disturbed systems (small size, multivoltinism, diapause, ovoviviparity, etc.) were associated with semi-arid areas whereas traits common in more stable and favourable environments (large body size, semi-voltinism, isolated eggs, etc.) were found in upland forested areas. 4. The natural climatic variation was proposed as a disturbance axis of a theoretical habitat templet (driven by the intense hydrological disturbances typical of semi-arid streams), while anthropogenic pressure (mainly intensive agriculture) and high salinity, a natural consequence of geology, was proposed as an adversity axis. Different life-histories associated with contrasting environmental features were superimposed in this habitat templet. 5. The ecological–evolutionary scenario in which stream macroinvertebrates have evolved and by which their communities are organized, is closely linked to disturbance, environmental harshness and human pressure." 6835. Nakahara, M.; Tsubaki, Y. (2008): Sperm mortality, insemination and fertilization in the damselfly *Ischnura senegalensis*: comparisons between wild and inbred populations. *Journal of Ethology* 26(1): 145-151 (in English) ["Inbreeding can have deleterious effects on individual or population fitness. To avoid fitness reduction, individuals may adopt behavioral or physiological mechanisms to reduce their investment in the production of offspring with genetically similar mates. We examined whether insemination by inbred males introduced more dead sperm than insemination by wild males by counting sperm in female *Ischnura senegalensis* (Rambur) sperm storage organs. If inbred males inseminated fewer or lowerquality sperm, females would avoid inferior sperm. Our results revealed three features of damselfly inbreeding: insemination failed in a larger proportion of inbred pairs than in wild pairs, inbred pairs showed significantly reduced fertility, and the numbers of live and dead sperm in an inbred female's sperm storage organs did not differ from those in wild females. These results suggested that neither sperm quantity nor sperm quality was responsible for low fertility to a significant extent, but some kind of female quality, such as sperm usage or storing ability, was. Although inbred pairs had lower fertility, there were no significant differences between inbred and wild pairs in the total numbers of live or dead sperm. It thus seemed that female choice at the insemination stage was responsible for low fertility rather than sperm quantity or quality measured by live-to-dead ratio." 6837. Pilgrim, E.M.; von Dohlen, C.D. (2008): Phylogeny of the Sympetrinae (Odonata: Libellulidae): further evidence of the homoplasious nature of wing venation. *Systematic Entomology* 33(1):159-174 (in English) ["Sympetrinae is the largest subfamily of the diverse dragonfly family Libellulidae. This subfamily, like most libellulid subfamilies, is defined currently by a few wing venation characters, none of which are synapomorphies for the taxon. In this study, we used DNA sequence data from the nuclear locus elongation factor-1a and the mitochondrial loci 16S and 12S rRNA, together with 38 wing venation characters, to test the monophyly of the Sympetrinae and several other libellulid subfamilies. No analysis recovered Sympetrinae as monophyletic, partly because of the position of Leucorrhinia (of the subfamily Leucorrhiniinae) as a strongly supported sister to Sympetrum (of Sympetrinae) in all analyses. The subfamilies Brachydiplactinae, Leucorrhiniinae, Trameiinae and Trithemistinae were also found not to be monophyletic. Libellulinae was the only subfamily supported strongly as monophyletic. Consistency indices and retention indices of wing venation characters used to define various subfamilies were closer to zero than unity, showing that many of these characters were homoplasious, and therefore not useful for a classification scheme within Libellulidae." 6839. van Gossum, H.; Sherratt, T.N. (2008): A dynamical model of sexual harassment in damselflies and its implications for female-limited polymorphism. *Ecological Modelling* 210:1/2: 212-220. (in English). ["Female-limited polymorphism is a widespread phenomenon in damselflies. Typically, one female morph resembles the male (the andromorph), while the alternative morph(s) does not (the gynomorph(s)). Contemporary explanations for the phenomenon vary, but they generally assume that the polymorphism has arisen as a consequence of frequency-dependent selection on females to avoid excessive male harassment. Here, we quantitatively characterise two hypotheses, the learned-mate recognition hypothesis (LMR) and the male mimicry (MM) hypothesis. The LMR proposes that males learn more quickly to attack the more commonly encountered female morph in the population, so that rarer female phenotypes are harassed relatively less. By contrast, the MM proposes that when andromorphs are initially rare compared to males, then they are harassed

less than gynomorphs, due to their morphological similarity to males. We present a parameterised dynamical model of the mating system as a way of quantifying the rate of male harassment of females. We then use this information in a multi-generational model that includes selection via the differential harassment of morphs and genetic drift, as well as between-year variability in damselfly density and sex ratio. The proportions of andromorphs at selective equilibria were analytically identified. While both the LMR and the MM versions of the model predict no consistent change in the equilibrium proportion of andromorphic females with increasing damselfly density, only the MM predicts that the equilibrium proportion of andromorphs should increase with sex ratio. Under low harassment rates (e.g. low population densities and/or low male search rates) selection is absent and female morph frequencies are free to drift. The potential applications of this form of dynamical model for other systems involving sexual harassment are discussed." 6842. Clark, T.E.; Samways, M.J. (1997): Sampling arthropod diversity for urban ecological landscaping in a species-rich southern hemisphere botanic garden. *Journal of insect conservation* 1: 221-234. (in English). ["Arthropods were sampled using pitfall traps, sticky traps, sweep netting, Malaise traps and visual sampling at a national botanic garden, KwaZulu-Natal, South Africa, where the taxonomic impediment is great. The aims were to compare two sites, one of native vegetation and the other of mainly exotic plants, to determine the possible localized extent of biodiversity change across the land mosaic, and to test and compare methodologies and indicator taxa and to make recommendations for ecological landscaping of a botanic garden. Species richness and evenness varied considerably with sampling technique used. From results of a single replicate of data from all trapping methods including 821 arthropod species and 3831 individuals, a number of conclusions could be drawn. Trapping procedures such as sweep netting and pitfall traps, which focus on species with restricted mobility and/or host plant requirements, indicated greatest differences in diversity between two closely located sites. Taxa varied in sensitivity to microlandscape, again depending on the extent of their mobility. Cicindelid and carabid beetles were particularly good indicators of habitat disturbance and type. The management recommendations are that in a species-rich urban botanic garden such as this, as many ecotopes as possible should be preserved or created. These should vary in topography, landscape characteristics and vegetation composition, with as much connectivity as possible. This is a feasible blanket approach to give home to a large number of nameless species and morphs. Patches of different ecotopes should not be separated by more than a few metres by expanses of mown lawn which isolates much of the fauna." 6844. Forbes, M.; Leung, B.; Schalk, G. (1997): Fluctuating asymmetry in *Coenagrion resolutum* (Hagen) in relation to age and male pairing success (Zygoptera: Coenagrionidae). *Odonatologica* 26(1): 9-16. (in English). ["Recent evidence suggests that fluctuating asymmetry (FA) of characters may index either stress during development of organisms, or be related to fitness of individuals following development. The Authors tested whether wing FA of *C. resolutum* was related to damselfly age and to male pairing success. It was predicted younger individuals should have higher FA on average as compared to older individuals if FA was related to damselfly survival. It was found that younger individuals had higher FA than older individuals over all sampling dates combined. However, this relation was due to the inclusion of one of three comparisons between pre-reproductive and mature insects, and was not a general phenomenon. Wing FA was not related to male pairing success. The results suggest that character FA can be related to fitness measures of damselflies, but not in a highly repeatable way. Data are also provided on seasonal changes in mite parasitism and body size that may relate to our finding FA-fitness relations restricted to one period of the flight season." 6845. Forbes, M.R.; Schalk, G.; Miller, J.G.; Richardson, J.M.L. (1997): Male-female morph interactions in the damselfly *Nehalennia irene* (Hagen). *Can. J. Zool.* 75(2): 253-260. (in English, with English and French summaries). ["Several hypotheses concerning factors that favour coexistence of female morphs in damselflies invoke differential attraction to (or harassment of) female morphs from mate-searching ♂♂. We designed experiments to determine whether ♂♂ were differentially attracted to either of two discrete female morphs in *N. irene*. One female morph was similar in colour and pattern to the conspecific male ("androchrome") and the other was dissimilar ("gynochrome"). ♂♂ were indiscriminate in their mating attempts. Overall, ♂♂ were more attracted to gynochrome ♀♀; however, ♂♂ that showed high response intensity to model ♂♂ were

equally likely to grasp models of the gynochrome and androchrome ♀♀. During male–female encounters in the field, androchrome ♀♀ were more likely to chase ♂♂, whereas gynochrome ♀♀ showed more refusal displays. Other direct and indirect evidence suggests that gynochrome ♀♀ may be greater targets of sexual aggression than androchrome ♀♀ while at the pond's edge, but that androchrome ♀♀ more often frequent the pond's edge. Whether or not these differences in behaviour translate into differential costs and benefits of being a particular morph is unknown." 6851. Matsura, T.; Nomura, K.; Komatsu, K. (1998): Ecological studies of odonate larvae living in artificial ponds in an urban area: Occurrence of larval *Sympetrum striolatum imitoides* and its life history in primary school swimming pools. *Japanese Journal of Ecology* 48(1): 27-36. (in Japanese, with English summary). ["As a part of a research program on the ecology of odonate larvae inhabiting artificial ponds, we surveyed outdoor swimming pools of primary schools in Kyoto City every late spring. During a 4 year period, 11 species of odonate larvae (*Libellulidae*, *Aeshnidae*, *Gomphidae* and *Coenagrionidae*: 7, 1, 1 and 2 species, respectively) were collected. Only larval *Sympetrum striolatum imitoides* predominated at most swimming pools. We took samples from 4 schools every late spring for 4 years and obtained the annual changes in the numbers of their larvae. This survey revealed that while larval *S. striolatum imitoides* was common in the school pools in Kyoto City, density varied from year to year. To clarify why only larvae of *S. striolatum imitoides* were dominant in the pools, their life cycle was examined at one pool. Larvae of chironomids, mayflies (*Cloeon* dipterum), water bug (*Anisops ogasawarensis*) and diving beetles as well as larval *S. striolatum imitoides* coexisted among detritus on the bottom. Especially chironomid larvae, which are preferred by larval *S. striolatum imitoides*, were present at high density. Most eggs of *S. striolatum imitoides* laid in Autumn hatched by mid winter, then the larvae reached the final instar in late May. We estimated that one third of them became adult before mid June, when the water was drained for pool-cleaning. As a reason for the dominance of larval *S. striolatum imitoides*, the following three traits may have been responsible: (i) their life cycle coincides with the off-sea-

son for the pool, (ii) ♀♀ oviposit directly into the water, and (iii) larval *S. striolatum imitoides* prey on smaller larvae of other species of dragonflies because their eggs hatch earlier than other species." ["The importance of damselflies and dragonflies in biodiversity protection and environmental monitoring in the province of Ontario required an update to the currently available literature. To satisfy this need, an annotated list of the 168 damselfly and dragonfly taxa recorded in Ontario is presented. For each taxon, notes are provided on conservation status, flight period, habitat, distribution by county and district, and identification. In some cases, ecological and taxonomic information is provided. Temporal and geographic occurrence is discussed and county/district distribution maps are included. Keys and illustrations are included to assist in identification of species recently added to the Ontario fauna. Sources of information are outlined, and a list of references is included that covers Ontario and surrounding regions. Potential additions to the Odonata fauna of Ontario are discussed. Information necessary for participation in counts, surveys and research projects is also presented. This guide is designed to assist both the novice and experienced researcher. It includes information available up to 1999 and the publication of Ontario Odonata, vol. I in 2000, but it does not take into account information published in the latter source." 6859. Booth, A.J.; McKinlay, B.W. (2001): Spatial aspects of the reproductive and feeding biology of the striped robber, *Brycinus lateralis* (Pisces: Characidae), in the Okavango Delta, Botswana. African zoology 36(1): 31-40. (in English). [Okavango Delta, Botswana. Aspects of the reproductive and feeding biology of two allopatric populations of the striped robber, *Brycinus lateralis* were investigated. *B. lateralis* is an opportunistic micro-carnivore with immature fish feeding predominantly on *Daphnia* species and adults being largely insectivorous. The diet also includes adult and larval Odonata.] Address: Booth, A.J., Dept Ichthyology & Fishery Science, Rhodes University, P.O. Box 94, Grahamstown, 6140 South Africa. E-mail: t.booth@ru.ac.za

6860. Efitre, J.; Chapman, L.J.; Makanga, B. (2001): The inshore benthic macroinvertebrates of Lake Nabugabo, Uganda: seasonal and spatial patterns. African zoology 36(2): 205-216. (in English). ["Lake Nabugabo, Uganda, is a lake of particular interest because of the unusual nature of its benthic macroinvertebrate community. In this study we quantified the spatial and temporal distribution of benthic macroinvertebrates within the lake with a focus on habitat associations in inshore areas. We focused on four inshore habitats: *Nymphaea lotus* / *Nymphaea caerulea* (water lily), *Miscanthidium violaceum*, *Vossia cuspidata* (hippo grass) and forest edge. The most notable characteristic of the Nabugabo fauna was the absence of bivalves and crustaceans and the scarcity of gastropods that made up only 1.8%

of the numerical abundance of the benthos. The numerically dominant taxa were ephemeropterans (77.7%) and dipterans (11.1%). Annelids (5.4%), odonates (2.8%) and trichopterans (1.3%) comprised a much smaller component of the benthic assemblage. Total invertebrate abundance and the abundance of major taxa did not vary significantly across months, but habitat effects were evident. The water-lily habitat was very depauperate, which may reflect the low levels of dissolved oxygen near the sediments in this habitat. Lake Nabugabo is extremely poor in salts, mean conductivity in inshore sites ranging from 22.3 to 26.4 $\mu\text{S}/\text{cm}$ and 22.6 to 37.9 $\mu\text{S}/\text{cm}$ (K25) for surface and bottom waters, respectively. The low conductivity (low concentrations of ions) in Lake Nabugabo may limit colonization by molluscs and crustaceans that, with their calcareous shells or exoskeletons, may require water with a higher mineral content." 6863. Emiliyamma, K.G., Radhakrishnan, C. (2002): Additions to the Odonata (Insecta) of Thiruvananthapuram District, Kerala. *Zoos' Print Journal* 17: 914-917. (in English). ["Peters (1981) reported 26 species of Odonata from Thiruvananthapuram District of Kerala State, southern India. The present study is based on the Odonata collections made from this district, during the faunistic surveys conducted by Zoological Survey of India (Western Ghats Field Research Station, Calicut and Southern Regional Station, Chennai) in 1997, 1998 and 2001. As a result of these surveys, 27 species and subspecies of Odonata belonging to 17 genera and seven families could be collected and identified. Of these, 17 species and subspecies are new additions to the Odonata fauna of Thiruvananthapuram District. Accordingly, till date a total of 43 species and subspecies of Odonata are known from this district. A systematic list of all the 43 species recorded from the district and a systematic account of the species collected during the current surveys are provided. The specimens studied are deposited in the faunal depository of the Zoological Survey of India, Kozhikode." (Authors)] Address: Emiliyamma, K.G.

6864. Kopij, G. (2002): Food of the Lesser kestrel (*Falco naumanni*) in its winter quarters in South Africa. *Raptor Research* 36(2): 148-152. (in English). [In total, 2050

pellets were collected from Nov. 1997-Feb. 1998. The diet of *F. naumanni* during the non-breeding season was dominated by sun spiders. Orthopterans and beetles were also an important component, together forming 27.5% of the total number of prey items identified and 44.4% of the total wet biomass. Other arthropod groups, such as earwigs, termites, cockroaches, dragonflies (n = 2 specimens) and scolopendras constituted supplementary food. Only a few vertebrate items represented by small mammals were found.] Address: Kopij, G., Raczkka 13, 49-137, Korfantow, Poland.

6866. Rowe, C.; Hopkins, W.A.; Congdon, J.D. (2002): Ecotoxicological implications of aquatic disposal of coal combustion residues in the United States: a review. *Environmental Monitoring and Assessment* 80: 207-276. (in English). ["We provide an overview of research related to environmental effects of disposal of coal combustion residues (CCR) in sites in the United States. Our focus is on aspects of CCR that have the potential to negatively influence aquatic organisms and the health of aquatic ecosystems. We identify major issues of concern, as well as areas in need of further investigation. Intentional or accidental release of CCR into aquatic systems has generally been associated with deleterious environmental effects. A large number of metals and trace elements are present in CCR, some of which are rapidly accumulated to high concentrations by aquatic organisms. Moreover, a variety of biological responses have been observed in organisms following exposure to and accumulation of CCR-related contaminants. In some vertebrates and invertebrates, CCR exposure has led to numerous histopathological, behavioural, and physiological (reproductive, energetic, and endocrinological) effects. Fish kills and extirpation of some fish species have been associated with CCR release, as have indirect effects on survival and growth of aquatic animals mediated by changes in resource abundance or quality. Recovery of CCR-impacted sites can be extremely slow due to continued cycling of contaminants within the system, even in sites that only receive CCR effluents for short periods of time. The literature synthesis reveals important considerations for future investigations of CCR-impacted sites. Many studies have examined biological responses to CCR with respect to Se concentrations and accumulation because of teratogenic and reproductively toxic effects known to be associated with this element. However, the complex mixture of metals and trace elements characteristic of CCR suggests that biological assessments of many CCR-contaminated habitats should examine a variety of inorganic compounds in sediments, water, and tissues before causation can be linked to individual CCR components. Most evaluations of effects of CCR in aquatic environments have focused on lentic systems and the populations of animals occupying them. Much less is known about CCR effects in lotic systems, in which the contaminants may be transported downstream, diluted or concentrated in downstream areas, and accumulated

by more transient species. Although some research has examined accumulation and effects of contaminants on terrestrial and avian species that visit CCR-impacted aquatic sites, more extensive research is also needed in this area. Effects in terrestrial or semiaquatic species range from accumulation and maternal transfer of elements to complete recruitment failure, suggesting that CCR effects need to be examined both within and outside of the aquatic habitats into which CCR is released. Requiring special attention are waterfowl and amphibians that use CCR-contaminated sites during specific seasons or life stages and are highly dependent on aquatic habitat quality during those periods." 6870. Emiliyamma, K.G., Radhakrishnan, C. (2003): Fauna of protected areas - 4: Odonata (Insecta) of Indira Gandhi Wildlife Sanctuary and National Park, Tamil Nadu. *Zoos' Print Journal* 18: 1264-1266. (in English). [The Indira Gandhi Wildlife Sanctuary and National Park (10°13'08"-10°33'27"N & 76°49'02"-77°21'07"E), occupies an area of 958km² at an elevation of 340-2400m along the eastern slope of the Western Ghats in Coimbatore District, Tamil Nadu, India. Fraser (1931) reported 41 species and subspecies of Odonata from Anamalai and Mudis hills. Later, in his Fauna of British

India (1933, 1934 & 1936), Fraser added eight more species of Odonata occurring in the area. The present note deals with 22 species and subspecies of Odonata collected from these protected areas through our surveys. Of these, 10 species and one subspecies are new additions to the Odonata fauna of the area. Thus, altogether 60 species and subspecies are currently known to occur in the Park. A systematic list of all the species of Odonata known till date from this Sanctuary, and a systematic account of the 22 species and subspecies collected during our surveys are provided below. The materials studied are deposited in the faunal depository of the Zoological Survey of India, Southern Regional Station, Chennai." 6871. McHattie, S.D.J. (2003): Analysis of data on dispersal in southern damselflies (*Coenagrion mercuriale*). University of Liverpool BSc Zoology BIOL630: Honours Project: 41 pp. (in English). ["*Coenagrion mercuriale* is a rare species within the UK, of particular interest to conservationist groups. It is known that the damselfly is both a poor coloniser and the range over which it will travel is known to be very short. A good understanding of both how good a coloniser this species is and what distance it will travel to achieve this will help to induce more productive conservation of this endangered species; helping to recolonise nearby areas. The main objective of this study was to find correlations between size of area and movement of individuals at ten sites distributed around the Hampshire area in the South of England. Other correlations that were hoped to show relevance were that between population density and movement of individuals; correlations with rate of movement and comparisons between ♂♂ and ♀♀ with respect to distances travelled and rates of movement. It is also intended to bring light upon the issue of how far *C. mercuriale* will travel around its habitat to discover further habitats and breeding grounds. The results show that there are definitely correlations between population density and distances travelled (activity) but there are no significant differences between the studied sites with respect to rates of travel by *C. mercuriale*. It was also shown that there the sex of the individual has a significant effect on the activity of the insect but not on the rate of travel. Also, it was noted that individuals crossed the road between Upper and Lower Crockford with great hesitancy and on no occasion was an individual seen travelling further than just over one and a half kilometres. With this knowledge, and the prospect of further investigation, it is possible to ensure that the conservation of *C. mercuriale* can be maximised and habitats of suitable nature only attempted to be conserved if they are within suitable range of existing habitats." 6873. Staton, S.K.; Dextrase, A.; Metcalfe-Smith, J.L.; Di Mai, J.; Nelson, M.; Parish, J.; Kilgour, B.; (2003): Status and trends of Ontario's Sydenham river ecosystem in relation to aquatic species at risk. *Environmental Monitoring and Assessment* 88: 283-310. (in English). ["The Sydenham River in southwestern Ontario is located in the Mixedwood Plains Ecozone, which supports the greatest diversity of flora and fauna in Canada. The river historically supported a rich aquatic community that included 80 fishes and 34 species of freshwater mussels. Fourteen aquatic species native to the river (8 fishes, 5 mussels and 1 turtle) have been designated as endangered, threatened, or of special concern by the Committee on the Status of Species at Risk in Canada (COSEWIC). A multi-agency Recovery Team was formed in 1999 to ensure the continued survival of these and other rare species in the river. The Sydenham River Recovery Team is the first in Canada to adopt an ecosystem approach to recovery planning for aquatic species. Information on land use patterns, water quality trends, the physical condition of the river, and the distributions of aquatic species at risk was synthesized to gain an understanding of the overall health of the river and its major anthropogenic stresses. Seven of the species at risk have declined in distribution or abundance, and three may be extirpated. The main threat to fishes and mussels is heavy loadings of sediment, nutrients, and possibly pesticides to the river via tile drainage and overland runoff from agricultural lands. A strategy that incorporates four overall approaches (management, stewardship, research and monitoring, and awareness and outreach) was developed to recover and protect this globally significant freshwater ecosystem." (Authors) Eight species of Odonata considered to be rare in the Province of Ontario are occurring, but are not specified.] Address: Staton, Shawn, Great Lakes Laboratory for Fisheries and Aquatic Sciences, Department of Fisheries and Oceans, 867 Lakeshore Road, Burlington, ON, Canada. ["In total, 253 specimens of *Cobitis paludica* and 163 *Cobitis calderoni* were collected in the Lozoya River (Madrid, Spain) in April, May, July, September and December 1990. Both species showed high percentages of empty guts in all months. *C. paludica* fed mainly on detritus and invertebrates while *Cobitis calderoni* fed on invertebrates and unicellular algae. Preferred prey items were the larvae of Dipterans (Chironomidae, Simuliidae) and microcrustaceans, with Ephemeroptera (Caenis) in summer. *Cobitis calderoni* fed on the most abundant prey except in April and July, when it selected invertebrates. *C. paludica* selected invertebrates throughout all the months. Diet overlapping (Horn's Index) was complete except in September, when the abundance of invertebrates in both diets was similar. For the remaining months, food type (invertebrates, unicellular algae and detritus) abundance differed, minimizing the interspecific competition." 6884. Hayashi, F.; Dobata, S.; Futahashi, R. (2004): Larval morphology of the Japanese Mnais damselflies

(Odonata: Calopterygidae) distinguished by nuclear DNS (ITS 1) sequences. Tombo 47: 13-24. [A recent phylogenetic study of the Japanese Mnais damselflies (Odonata: Calopterygidae) based on DNA sequences of a nuclear ribosomal internal transcribed spacer 1 (ITS 1) and adult morphology suggested that this genus consists of two closely related species, M. strigata Selys, 1853 and M. costalis Selys, 1869 (Hayashi et al., 2004). In the present paper, we determined the ITS 1 sequence types and compared morphology of larvae. Apparent differences were found only in the shape of the lateral caudal gills, the end of which was greatly protruded in M. costalis (Figs. 1, 2), while only slightly pointed in M. strigata (Figs. 3, 4). In a population of M. strigata (from the Izu Peninsula in Shizuoka Prefecture to southern Yamanashi Prefecture) which has a unique ITS 1 sequence type, the shape of caudal gill ends was variable among individuals and often intermediate between the two species (Fig. 5). Therefore, this population of M. strigata may have a hybrid nature with M. costalis. In the larvae with regenerated gills, however, interspecific differences became unclear, and we must pay attention to identify them (Fig. 6). In the two species, the increase in gill length was greater than that in gill height, and so that larger larvae tended to have more elongated gill lamellae than smaller ones (Fig. 7). 6885. Hildrew, A.G.; Woodward, G.; Winterbottom, J.H.; Orton, S. (2004): Strong density dependence in a predatory insect: large-scale experiments in a stream. Jour. Animal Ecology 73: 448-458. [1. Empirical information about the intergenerational dynamics of stream insects is scarce, and most field experiments are conducted at small temporal and spatial scales that are inappropriate for assessing effects upon population dynamics. We performed a large-scale, intergenerational population manipulation of an abundant, stream-dwelling predator, the alderfly *Sialis fuliginosa*, by altering its recruitment over 3 consecutive years (it has a 2-year life cycle). 2. Experimental treatments were assigned to three contiguous 150-m stretches. Each year at least 92% of *S. fuliginosa* eggs, that are laid on the streamside vegetation, were removed from an upstream 'removal' stretch and transferred below an adjacent 'control' stretch to a downstream 'addition' stretch, where recruitment was thus effectively doubled. 3. Although manipulations were successful initially, the effects were transient. Strong density-dependent survival stabilized the population at a similar density in all three stretches within the first 4 months of life for the 1997 cohort and somewhat later for the 1998 cohort. Survey data suggested that intraguild predation (including cannibalism) and/or starvation, particularly early in the life cycle, might be regulating the *S. fuliginosa* population. 4. It is intriguing that this abundant predator, which is linked very richly within the complex Broadstone Stream food web, has a strongly stabilized population, even in the face of such a dramatic perturbation in recruitment." (Authors) The study includes many references to *Cordulegaster boltonii*.] Address: Hildrew, A.G., School of Biological Sciences, Queen Mary University of London, London E1 4NS, UK. 6891. Peacor, S.D.; Werner, E.E. (2004): How dependent are species pair interaction strengths on other species in the food web? *Ecology* 85(10): 2754-2763. (in English). ["In ecological theory species interaction strengths are typically described by constants or functions that depend on the densities of the two interacting species. However, if species' traits (phenotypes) are plastic, then modifications in these traits (induced by the presence of another species) could affect interaction strengths of the focal species with a number of other species in the system. The magnitudes of such higher-order effects on interaction strengths have not been reported and are not straightforward to measure. We present a methodology to quantify changes in consumer-resource interaction coefficients (a metric of in-

teraction strength) due to effects of predators on consumer (i.e., the prey of the predator) phenotype (e.g., nonlethal or trait-mediated effects). Application of this method to studies in diverse systems indicates that predators can strongly reduce consumer-resource interaction coefficients, often in the range of 20-80%. We use analytic and simulation models to show that effects on interaction coefficients of this magnitude can lead to trait-mediated effects that contribute more strongly than density-mediated effects to the net effects of predators on consumers and their resources, and even qualitatively change model predictions. Our results strengthen previous claims that trait-mediated effects strongly influence species interactions and suggest that recent calls to quantify interaction strengths must be broadened to include examination of the variation in interaction strengths due to their dependence on densities of other species (most notably predators) in food webs." (Authors) The study includes Odonata.] Address: Werner, E.E., Department of Biology, University of Michigan, Ann Arbor, MI, 48109 USA.

6893. Rothfels, C.J. (2004): Unicorn Clubtail (*Arigomphus villosipes*: Gomphidae): new records and summary of status in Ontario. *Ontario Odonata* 5: 5-11. (in English). [Canada; "Six new 2003 records of *A. villosipes* are presented, including new regional records for Halton and York. These new records, combined with new records from 2002, represent an approximate doubling of the known extant or historical records of this rare species in Ontario. These observations are of interest because *A. villosipes* has been considered extremely rare in Ontario and a recent evaluation suggested that it had declined. All known Ontario records are summarized, as are the identification issues and habitat preferences of this *Arigomphus*. Possible explanations for the influx of new records are discussed." (range extension as a result of climatic change) (Author)] Address: Rothfels, C.J.; crothfels@rbg.ca

6894. Silva-Santos, P.M.; Oliveira, S.V.; Cortes, R.M. V.; Albuquerque, A.C. (2004): Natural and anthropogenic variations in a channelized water course in Centre of Portugal. *Limnetica* 23(3-4): 257-270. (in English). ["The present study took place in the Mondego River, located in the Centre of Portugal. The lower sector of the river (Lower Mondego) is largely man-made due to regularization and rectification of the channel. The objective was to assess the impacts on the aquatic communities (fishes and benthic invertebrates). Fauna inventories were performed in June and September of 2000 and 2001, together with habitat characterization. Three sampling sites were selected in this segment and compared to a reference site located upstream. It is concluded that the presence of structures such as submerged weirs and riprap, promoted the diversity, due to the physical complexity, which they introduced into the system. The dramatic flood peaks that occurred in the winter of 2000/01 also caused substantial changes in the fluvial dynamics and in the habitats: the large amount of suspended

solids transported resulted in a riverbed of unstable fine materials, and in a subsequent biological impoverishment. However, both communities displayed a high resilience to these changes; the inter-annual differences being obscured by the seasonal ones on macroinvertebrate communities." (Authors) 12 odonate taxa are listed in the appendix.] Address: Silva-Santos, P.M., Lab. Ecologia Aplicada (LEA), Universidade de Trás-os-Montes e Alto Douro, Quinta de Prados, 5000-911, Vila Real, Portugal. Email: pedross@utad.pt

6895. Soininen, J.; Könönen, K. (2004): Comparative study of monitoring South-Finnish rivers and streams using macroinvertebrate and benthic diatom community structure. *Aquatic Ecology* 38: 63-75. (in English). ["In southern Finland, most of the rivers are turbid and suffer from eutrophication and leaching of suspended solids from diffuse sources. We first related benthic diatom and macroinvertebrate structure to environmental factors using direct ordination. Second, benthic diatoms and macroinvertebrates were simultaneously sampled in several South-Finnish rivers and streams to compare two monitoring methods. The study sites constituted of some large, moderately nutrient rich rivers and some smaller, less eutrophic streams situated on the south coast of Finland. Diatom species distribution was most affected by conductivity, total P and latitude. Species distribution of macroinvertebrates was mostly related to channel width, conductivity and pH. For diatoms, separation of community structure between sampling stations was clear, but corresponding macroinvertebrate communities were more similar to each other. Correlation between diatom and macroinvertebrate pollution indices was rather low and insignificant $r = 0.28$. As a whole, variation of macroinvertebrate index values CV 4.7% among replicate samples was slightly lower than for diatom index CV 6.0%. On the contrary, community similarity between the replicate samples was slightly lower among macroinvertebrates $r = 0.770$ due probably to their larger local scale spatial variation, sampling of more habitats and lower density compared to diatoms $r = 0.874$. In conclusion, multiple pressures affecting the river ecosystems at different spatial and temporal scales should lead to choosing more than one biological monitoring method with clearly identifiable responses." (Authors) *Calopteryx virgo* is included into the analysis.] Address: Soininen, J., Dept of Limnology & Environmental Protection, P.O. Box 65 (Biocenter 3, Viikki), FIN-00014 University of Helsinki, Finland. E-mail: janne.soininen@helsinki.fi

6896. Sutherland, D.A.; Oldham, M.J.; Jones, C.D.; Pratt, P.D. (2004): Odonata of Ontario's Hudson Bay Lowland. *Ontario Odonata* 6: 1-11. (in English). 6897. Urban, M.C. (2004): Disturbance heterogeneity determines freshwater metacommunity structure. *Ecology*, 85(11): 2971-2978. (in English). ["Metacommunity theories, which consider communities as interacting species assemblages connected by dispersal, differ in their assumptions about the importance of interspecific adaptations and environmental heterogeneity as controls of assemblage composition. I assess the relative importance of regional (dispersal) and local (abiotic and biotic environmental variation) processes in explaining

the structure of a freshwater pond metacommunity. Results did not support the hypothesis that dispersal was limited by interpatch distance. Instead, community diversity, composition, and trophic structure were best explained by local environmental variation associated with pond permanence. Many taxa were restricted either to temporary or semipermanent ponds, an outcome that suggests species trade off adaptations to disturbance with those to biotic interactions (species-sorting model) and that refutes the neutral model of interspecific equivalence. However, evidence for high dispersal rates, low-fitness habitats, and high temporal environmental variability indicated that interpatch dispersal also may influence local dynamics through mass effects. These results suggest that integrating the species-sorting and mass-effect niche assembly frameworks will provide a necessary step in the successful application of metacommunity theory.... Both odonates found in the study, *Sympetrum* and *Lestes*, only occurred in ponds containing high (>45%) macrophyte cover. Thus, habitat selection by mobile taxa may be an important means through which species track changes in pond permanence over time." (Author)] Address: Urban, M.C., School of Forestry and Environmental Studies, Yale University, 370 Prospect Street, New Haven, Connecticut 06520 USA. E-mail: urban@nceas.ucsb.edu

6900. Bree, D. (2005): Odonate range fluctuations as illustrated by occurrence records of three species from Prince Edward County, Ontario. *Ontario Odonata* 6: 16-20. (in English). [Canada; "The appearance and disappearance of *Ischnura hastata*, *Perithemis tenera*, and *Enallagma anna* in Prince Edward County between 1999 and 2004 is documented. Appropriate habitat for all three species occurs in Prince Edward but the County was beyond the known geographic range of all as of the year 2000. Their sporadic appearance there illustrates odonate occurrence patterns for species at the edge of their range. All three species exhibit very different dispersal characteristics. *I. hastata* routinely appears and disappears at localities, even within its core range. *P. tenera*, while common within its range, is sedentary and was not known to occur outside the Carolinian zone in Ontario prior to 2001. The *E. anna* has been experiencing a recent and rapid range expansion north-eastward. All three species have shown a similar occurrence pattern within Prince Edward County - sudden, unprecedented appearance in suitable habitat, sometimes in numbers suggesting a stable breeding population, then disappearance. It is speculated that winter temperatures may be the deciding factor in preventing permanent colonization of these species in Prince Ed-

ward." (Author)] Address: Bree, D., Box 123, Bloomfield, ON. K0K 1G0, Canada. Email: dbree@kos.net

[A baseline collection of Odonata for future monitoring was made around Queens University Biology Station, 35 N of Kingston, Ontario, Canada. At present 54 species are known from the region. They are documented in detail.] Address: Catling, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

6903. Catling, P.M. (2005): More on Zebra Mussels on exuviae. Ontario Odonata 6: 40. (in English). [A Zebra Mussel attached to an exuvium of *C. cynosura* was collected downstream from the Outlet River bridge in Sandbanks Provincial Park (43.89198 N, -77.21731 W), Canada on 29 Aug. 2003. The mussel is 8 mm long and suggests that the larvae may have spent a relatively long time in the final stage. The specimen is now in the national collection (CNC).] Address: Catling, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

6904. Catling, P.M. (2005): Observations of possible migration of Common Baskettail, *Epiptera cynosura* (Say), in Ontario and New York. Ontario Odonata 6: 12-13. (in English). [An unidirectional movement of approximately 500 *E. cynosura* was observed on 17-V-1998 on Walpole Island in Lambton County, Ontario, Canada. On June 5, 2004 an additional major northward movement of this species was recorded near Waddington, Louisville County, New York, USA. Some of the migrating specimens were hit by cars when crossing the highway.] Address: Catling, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

6905. Catling, P.M. (2005): Global warming a potential explanation for the extension of known range of *Hetaerina americana*. Ontario Odonata 6: 40-41. (in English). [Four criteria are outlined to assess range changes of Odonata with regard to climatic warming: (1) the possibility of the species having been overlooked should be small. (2) the species should not be strongly associated with new or man-made habitats. (3) the range expansion should not be part of a poorly understood and very broad scale invasion. (4) the geographic distribution of data and loss or alteration of habitat should minimally influence the patterns. Range alterations of *Hetaerina americana* and *Ischnura hastata* are briefly discussed.] Address: Catling, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

6906. Cocroft, R.B.; Rodriguez, R.L. (2005): The behavioral ecology of insect vibrational communication. *BioScience* 55(4): 323-334. (in English). ["Vibrational communication is widespread in insect social and ecological interactions. Of the insect species that communicate using sound, water surface ripples, or substrate

vibrations, we estimate that 92% use substrate vibrations alone or with other forms of mechanical signaling. Vibrational signals differ dramatically from airborne insect sounds, often having low frequencies, pure tones, and combinations of contrasting acoustic elements. Plants are the most widely used substrate for transmitting vibrational signals. Plant species can vary in their signal transmission properties, and thus host plant use may influence signal divergence. Vibrational communication occurs in a complex environment containing noise from wind and rain, the signals of multiple individuals and species, and vibration-sensitive predators and parasitoids. We anticipate that many new examples and functions of vibrational communication will be discovered, and that study of this modality will continue to provide important insights into insect social behaviour, ecology, and evolution." (Authors) Odonata are classified as insect not using vibrations for communication.] Address: Cocroft, R.B., Biological Sciences, University of Missouri-Columbia, Columbia, MO 65211, USA. 6911. Hutchinson, R.; Catling, P.M. (2005): The Canadian National Collection of Dragonflies. Ontario Odonata 6: 31-39. (in English). ["With the increasing focus on dragonflies as environmental indicators, the dragonfly section of the Canadian National Collection is assuming increasing importance. Started in 1886, the collection has grown rapidly and steadily since the 1940s as a

result of a well informed policy of general collecting by a large group of entomologists. The collection includes 14,060 mostly adult specimens on pins and 14,615 polypropylene envelopes with adults and 4,291 larval specimens preserved in alcohol for a grand total of at least 32,966 specimens. Although the collection is 95% Canadian, there is a good representation of material from other parts of the world and it is the best teaching collection in Canada. Within Canada, Ontario, the prairie provinces and Northwest Territories are particularly well represented. Principal collectors are B.E. Bowen (Ontario, Quebec), P.M. Catling (all Canada), D.F.J. Hilton (all Canada), R. Hutchinson (Quebec), J.E.H. Martin (all Canada), M.J. Oldham (Ontario) J.R. Vockerth (all Canada), E.M. Walker (all Canada) and J.B. Wallis (all Canada). Numerous publications are based on material in the collection, and some actively used databases have been largely derived from collection material. With very broad and extensive Canadian representation, and classification by several experts and some type and cited material, the collection is a major research tool." 6912. Kosterin, O.E.; Dubatolov V.V. (2005): A dragonfly (Odonata) collection from the Bol'shekhkhtsirskii State Nature Reserve (Khabarovskii Krai, Russia). *Animal World of the Far East* 5. Fauna of Russian Far East: collected research papers. Volume 5 - Blagoveshchensk State Pedagogical University, Blagoveshchensk: 9-14. (in Russian). [25 species of Odonata are reported for the Bol'shekhkhtsirskii State Natural Reserve and the Bolshoi Ussuriiskii Island (the environs of Khabarovsk). *Sympetrum infuscatum* (Selys, 1883) is for the first time recorded for Khabarovskii Krai Province. In June-September 2004, the second author undertook an expedition to Khabarovskii Krai, mostly in the Bol'shekhkhtsirskii State Nature Reserve, aimed to inventarise the butterfly fauna of this Reserve. Along with butterflies and moths, he collected also Odonata. It should be noted that he did not specially explore any water reserve, collecting took place in woody area and concerned foraging dispersed individuals, mostly ♀♀. Some individuals were attracted by light at night. However, just 66 specimens collected appeared to represent 25 species. This is not many, but any information on exact distribution of odonate species in the southern Far East of Russia is still to be accumulated to correctly outline species ranges, and especially the data on the fauna of Nature reserves are important in view of the goal of Nature protection. So the list of materials collected is published herewith. The specimens are kept in the collection of the Institute of Systematics and Ecology of Animals of the Siberian Division of the Russian Academy of Sciences, Novosibirsk (SZMN)." (Authors) The paper also includes a brief, critical discussion of the species status of the taxon *Cordulia amurensis*.] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. 6913. Piscart, C.; Moreteau, J.-C.; Beisel, J.-N. (2005): Biodiversity and structure of macroinvertebrate communities along a small permanent salinity gradient (Meurthe River, France). *Hydrobiologia* 551: 227-236. (in English) ["Changes in the macroinvertebrate community were investigated over 10 months at four sites along a

19 km salinity gradient (0.21–2.60 g l⁻¹) in a sixth-order stream, the Meurthe River, northeastern France. Abiotic characteristics other than salinity were similar between the sites. Macroinvertebrate taxonomic richness decreased by 30% downstream of the 1.4 g l⁻¹ sites while diversity, evenness or total abundance of taxa did not change along the gradient. In terms of functioning, a slight change in relative abundances of invertebrate feeding groups followed the salinity gradient. Eight invertebrate assemblages occurred within specific salinity distributions were identified. The exotics *Gammarus tigrinus*, *Dreissena polymorpha*, *Corbicula fluminalis* and *Corophium curvispinum*, were more abundant at the highest salinity site. These results suggest that rising salinity concentrations drastically affect the species composition, including favouring exotic species." (Authors)] Address: Beisel, J.-N., UFR SciFA, Laboratoire BFE, Université de Metz, Campus Bridoux, Av. du Général Delestraint, 57070, Metz, France. E-mail: beisel@sciences.univ-metz.fr

6914. Rennie, M.D.; Collins, N.C.; Purchase, C.F.; Tremblay, A. (2005): Predictive models of benthic invertebrate methylmercury in Ontario and Quebec lakes. *Can. J. Fish. Aquat. Sci.* 62: 2770-2783. (in English, with French summary). ["Multivariate analyses on benthic invertebrate methylmercury concentrations (MeHg) and water chemistry from 12 Quebec water bodies were used to guide the construction of simple, predictive models of benthic invertebrate [MeHg] in 23 lakes in Ontario and Quebec. Separate predictive models for collector–shredder and predatory benthic invertebrates were constructed using multiple regression and were assessed for their predictive utility by crossvalidation. Predatory benthic invertebrate [MeHg] was negatively related to pH and positively related to dissolved organic carbon (DOC) concentration (cross-validation $r^2 = 0.31$). Collector–shredder [MeHg] was positively related to [DOC] only (cross-validation $r^2 = 0.13$). Predictive utility of our models is similar to or surpasses that observed in previously published zooplankton MeHg models tested against independently collected data. Significant environmental variables and their contribution to the overall explanatory power of benthic invertebrate MeHg models are similar to those found in zooplankton models, suggesting that in both pelagic and benthic food webs, pH and DOC are important indicators of MeHg bioavailability. Although seasonal patterns in invertebrate [MeHg] were examined, none was detected. These models represent an effective means of identifying water bodies of interest for researchers and for reconstructing past benthic invertebrate [MeHg] patterns using archived water chemistry data." (Authors) "Anisoptera" are considered in this study.] Address: Rennie, M.D., Dept of Biology, University of Toronto at Mississauga, 3359 Mississauga Road N., Mississauga, ON L5L 1C6, Canada. 6919. Zivic, I.; Markovic, Z., Ilic, J. (2005): Composition, structure and seasonal dynamics of macrozoobenthos in the Temska and Visocica Rivers (Serbia). *Archives of Biological Sciences* 57(2): 107-118. (in English). ["We investigated macrozoobenthos communities in the Temska and Visocica Rivers at 10 localities during the summer and autumn of 2001. In 46 samplings of quantitative and 10 of qualitative analysis, 101 taxa from 17 groups of macrozoobenthos are identified. The most diverse group is the order Trichoptera (28 species from nine families). Less diverse with (only one species) are Nematomorpha, Hirudinea, Odonata, and Megaloptera. At all of the chosen localities, the most common species are *Elmis aenea* (70.00%), *Ancyclus fluviatilis*, and *Baetis* sp. (60.00%). All those localities on the Visocica and Temska Rivers are very similar. The index of similarity varies from 12.5% (between Vi0 and Te0) to 70.7% (between Te1 and Te2). In the Temska River the Shannon-Weaver diversity index varies from 1.80 (at Te3) to 2.45 (at Te0). In the Visocica River, the highest diversity of macrozoobenthos is at the Vi3 locality (2.59), the lowest at Vi0 (1.40). Less diverse macrozoobenthos communities are found at the Vi0 and Te3 localities. At the same time, these localities have the highest values of Simpson's index (0.35 and 0.34, respectively)." squamosissimus (Perciformes, Scianidae) in stretches under influence of the Capivara dam (Paranapanema and Tibagi rivers). *Iheringia Serie Zoologia* 96(1): 115-119. (in Portuguese, with English summary). ["*P. squamosissimus* was studied in five stretches in Paranapanema and Tibagi rivers under the influence of the Capivara reservoir. The samplings were made on a monthly basis during the 1992/1993 and 1994/1995 periods and seasonally during the 2001/2002 period. [...] A total of 993 specimens had their stomach analyzed. [...] The diet composition was compared among sampling periods and among stretches by the similarity analysis using the Bray-Curtis' coefficient. The results indicated that the consumption of food items was uniform in all periods and stretches analysed. The food items found were grouped in six categories: fishes, shrimp, Odonata, Ephemeroptera, other insect groups and "others" (plant material, detritus and rarely-found organisms). In all stretches and during all the studied periods, *P. squamosissimus* presented a carnivorous diet, and during the 2001/2002 period the item shrimp (*Macrobrachium amazonicum*) represented the largest portion of the diet. [...]"] (Authors)] Address: Bennemann, Sirlei T., Univ Estadual Londrina, Ctr Ciencias Biol, Dept Biol Anim. & Vegetal, Program Posgrad Ciencias Biol, BR-86051990 Londrina, PR, Brazil. 6921. Castillo, L.E.; Martinez, E.; Ruepert, C.; Savage, C.; Gilek, M.; Pinnock, M.; Solis, E. (2006): Water quality and macroinvertebrate community response following pesticide applications in a banana plantation, Limon, Costa Rica. *Science of the Total Environment* 367(1): 418-432. (in English). ["Pesticides used in banana production may enter watercourses and pose ecological risks for aquatic ecosystems. The occurrence and effects of pesticides in a stream draining a banana plantation was evaluated using chemical characterization, toxicity testing and macrobenthic community composition. All nematicides studied were detected in the surface waters of the banana plantation during application periods, with peak concentrations following applications. Toxicity tests were limited to the carbofuran application and no toxicity was observed with the acute tests used. However, since pesticide concentrations were generally below the lowest LC50 value for crustaceans but above calculated aquatic quality criteria, there remains a risk of chronic toxicity. Accurate ecological assessments of pesticide use in banana plantations are currently limited by the lack of local short-term chronic toxicity tests and tests using sensitive native species. Relatively constant levels of four pesticides (imazalil, thiabendazole, chlorpyrifos and propiconazole), which had toxic effects according to the 96h hydra and 21d daphnia chronic test, were recorded in the effluent of the packing plant throughout the study, indicating that the solid waste trap used in this facility was not effective in eliminating toxic chemicals. Certain taxa, such as *Heterelmis* sp. (Elmidæ), *Heteragrion* sp. (Megapodagrionidae, Odonata), *Caenis* sp. (Caenidae, Ephemeroptera), and *Smicridea* sp. (Hidropsychidae, Trichoptera), were more abundant at reference sites than in the banana farm waters, and may be good candidates for toxicity testing. Multivariate analyses of the macroinvertebrate communities clearly showed that the banana plantation sites were significantly different from the reference sites. Moreover, following the pesticide applications, all the banana plantation sites showed significant changes in community composition, with the same genera being affected at all sites and for all pesticides (terbufas, cadusafos and car-

bofuran). Consequently, the results presented here show that multivariate analysis of community composition was more sensitive in distinguishing pesticide effects than the toxicity tests and richness and composition measures used. We conclude that monitoring macroinvertebrate communities can be a powerful tool in the assessment of ecological effects of banana production." (Authors)] Address: Castillo, Luisa Eugenia, Univ. 6922. Catling, P.M.; Hutchinson, R.; Brunelle, P.M. (2006): Use of saltmarsh by dragonflies (Odonata) in the Baie des Chaleurs region of Quebec and New Brunswick in late summer and autumn. *Canadian Field-Naturalist* 120(4): 413-420. (in English). [nv; "During late summer and autumn, in the Baie des Chaleurs region of Quebec, 18 species of adult dragonflies were recorded during one or more visits of at least 2 hours each to 14 salt marshes. Three species, *Aeshna canadensis*, *Sympetrum danae* and *S. internum*, were present in more than half of the sites. The most abundant species was *S. internum* with over 100 seen at some locations. Adults of several species, including *Aeshna canadensis*, *A. umbrosa*, *Enallagma civile*, *E. hageni*, *Ischnura verticalis*, *Lestes disjunctus*, *Libellula quadrimaculata*, *Sympetrum danae*, *S. internum* and *S. obtusum*, occurred in relatively high frequencies in both Baie des Chaleurs salt marshes and in those elsewhere in Acadia. Within Baie des Chaleurs observations of emergence and/or presence of larvae, as well as regional abundance, were recorded for *Aeshna canadensis*, *A. umbrosa*, *Ischnura verticalis*, *Sympetrum costiferum*, *S. internum* and *S. vicinum*. Oviposition in salt marsh pools was recorded for *Aeshna canadensis*, *Enallagma civile*, *E. hageni*, *Ischnura verticalis*, *Lestes congener* and *Sympetrum danae*. The salt marsh dragonfly fauna of Baie des Chaleurs is significantly different from that of the rest of Acadia based on frequencies predicted from the latter region. To a large extent this difference is a result of significantly increased use of salt marsh habitat by adults of six species including *Lestes congener*, *Sympetrum danae*, *Aeshna canadensis*, *S. costiferum*, *Lestes disjunctus*, and *S. internum* (in order of decreasing significance) in Baie des Chaleurs in comparison with salt marshes elsewhere in Acadia. Local amelioration of salty conditions in certain salt marshes, superimposed on regional amelioration as a result of protection from storms and saltwater dilution in the Baie des Chaleurs estuary, may contribute to an environment where adaptation can occur or where already tolerant species can exist. Dragonflies use salt marsh habitat on the northeast coast of North America more extensively than is currently documented." 6923. Hevers, J. (2006): Die entomologischen Sammlungen des Staatlichen Naturhistorischen Museums in Braunschweig. *Braunschweiger Naturkundliche Schriften* 7(3): 697-757. (in German, with English summary). ["14 entomological collections of the State Museum of Natural History which can be attributed to specific collectors and 2 collections arranged in 1946-1949 are characterized by origin, amount, and composition: 10 collections concern Lepidoptera, 2 Coleoptera, 2 Diptera, 1 Hymenoptera, and 1 Odonata. This article also gives a short history of the entomological associations

of Braunschweig and presents 18 collectors with their biographies." (Author)] Address: Hevers, J., Staatliches Nat. Hist. Museum, Pockelsstr 10, D-38112 Braunschweig, Germany

6924. Hicks, B.J.; Bannon, H.J.; Wells, R D.S. (2006): Fish and macroinvertebrates in lowland drainage canals with and without grass carp. *Journal of Aquatic Plant Management* 44: 89-98. (in English). ["Diploid grass carp (*Ctenopharyngodon idella* L.) were introduced to a lowland Waikato drainage canal at an initial density of 40-80 kg ha⁻¹ (83-167 fish ha⁻¹) to control aquatic macrophytes and improve water flow. A near-by canal was left without grass carp to act as an untreated control. After 7 months, macrophytes occupied 17% of the water column in the treated canal compared to 78% in the untreated canal. Fish and macroinvertebrates in both canals were examined before and after the release of grass carp by sampling with replacement by fyke netting on seven occasions. Brown bull-head catfish (*Ameiurus nebulosus* (Lesueur)) and shortfinned eels (*Anguilla australis* Richardson) comprised most of the resident fish biomass in both canals; however, before grass carp stocking, eels were more abundant than catfish in the treated canal. There was no change in the abundance of resident fish after stocking, but young-of-the-year catfish had greater mortality and grew faster in the treated canal than in the untreated canal. Macroinvertebrates were primarily associated with aquatic macrophytes. Grass carp reduced aquatic macrophyte abundance in the treated canal by about 80%, which by inference reduced the abundance of associated macroinvertebrates, but there was no observed impact of grass carp stocking on the resident fish assemblage. We examined the relationship between head width and fish length, and from this determined that 70% of the grass carp could have escaped through the downstream retention screen. Despite this possibility, grass carp remained in the canal and effectively controlled aquatic macrophytes for 18 months." (Authors) Damselflies were included into the analysis, identifying them in one case as *Xanthocnemis zealandica*. Grass carp ingest macroinvertebrates probably as vicarious intake with the plants on which the macroinvertebrates live.] Address: Hicks, B.J. , Univ. Waikato, Sch. Sci. & Engn, Dept Biol. 6925. Hortwitz, R.J.; Flinders, C. (2006): Bioassessment Integration Study: Systems Ecology evaluation of US EPA Rapid Bioassessment Protocols in New Jersey (Macroinvertebrates, periphyton, fish, and habitat). Patrick Center Project #830, Project Final Report 06-06; submitted to Thomas Belton, Project Manager, New Jersey Department of Environmental Protection, Division of Science, Research and Technology, 401 East State Street, PO Box 409, Trenton, NJ 08608-1501, USA. March 6, 2006: 226 pp. (in English). ["The purpose of this project was to analyze existing fish, macroinvertebrate, and algal data to develop new methods for integrated stream bioassessment protocols. [...] 105 odonate species were seen at sampling stations (Table 3.7.1). *Calopteryx maculata* was the most common species present in 67 of the 68 samples. *Boyeria vinosa*, *Argia moesta*, *Ischnura verticalis*, and *Argia fumipennis* were present in more than 30 samples. All 61 sites had adult odonates present, although only 33 and 38 sites, respectively, had mating and ovipositing species.

Larvae were identified at 17 sites and exuvia at 25 sites. [...] *Cordulegaster obliqua*, *Ophiogomphus mainensis*, *Enallagma recurvatum*, *Stylurus scudderi*, *Libellula auripennis*, *Macromia alleghaniensis*, *E. pictum* were classified as Special Concern, while three species (*Gomphus apomyius*, *Ophiogomphus aspersus*, *Epitheca spinosa*) were classified as threatened. Most species with conservation concerns were collected from fewer than five sites, with only *M. alleghaniensis* and *E. pictum* (special concern) collected from eight sites each. Although the models were not significant ($p > 0.23$), macroinvertebrate metrics and land use variables accounted for 39.3% and 47.6% of the variation in Odonate adult and larvae richness, respectively. Odonate Adult Richness was positively associated with EPA Habitat Scores (Fig. 3.7.1) ($p=0.087$) and Odonate Larvae Richness was positively associated with the abundance of collector-gatherers ($p=0.098$) and scrapers ($p=0.073$) (Fig. 3.7.2). Both richness measures showed positive relationships with normalized macroinvertebrate family richness and Simpson's diversity metrics ($p=0.040-0.061$) (Figs. 3.7.3 and 3.7.4). Regression models predicting species richness of exuvia, oviposition, and mating accounted for 23.9%, 22.3%, and 19.1%. Like larvae richness, exuvia richness was positively associated with scraper abundance while both oviposition and mating richness metrics were positively related to Chiro: EPT metrics. With the exception of odonate adult richness, regression of macroinvertebrate PCs against odonate richness metrics were not significant and did not account for much variation in odonate richness. There was a significant positive relationship between odonate adult richness and MPCA3 ($p=0.003$) and MPCA4 ($p=0.049$) (Fig. 3.7.5) with the model accounting for 18.6% of variation among samples ($p=0.012$). Remaining odonate metric-MPCA regressions were not significant and accounted for less than 8% of variation." 6926. Joshi, P.C. (2006): Anthropogenic encroachments and population dynamics of insects in a moist deciduous forest in Uttaranchal, India. *Journal of Applied Bioscience* 32(1): 32-37. (in English). ["The species composition and community structure of insect fauna vis-a-vis various anthropogenic activities in selected habitats of a moist deciduous forest in Uttaranchal, India were studied for a period of two years. Four sites situated at an altitude ranging between 260 to 480 m from mean sea level with a range of anthropogenic activities, viz. a site with no ongoing disturbances, a naturally recovering site (deforested and replanted 25 years back), a moderately disturbed site (lightly grazed by cattle) and a severely disturbed site (artificially reforested and heavily grazed by live stock) were selected. The former three sites were mixed forests, dominated by *Shorea robusta* Gaertn. F and *Mallotus philippinensis* Muell.-Arg., and the latter site was a plantation of *Tectona grandis* Linn. F. All these sites supported a total of 150 species of insects belonging to 48 families and 9 orders. Order Lepidoptera was the most dominant order in terms of number of species and number of individuals recorded. *Eurema hecabe* Linnaeus was the most abundant species. The other abundant species included *Catopsila pomona* Fabricius (Lepidoptera), *Crocothemis servilia* (Drury) (Odonata), *Mylarbis* sp. (Heteroptera), *Catantops humilis humilii* Serv. and *Oxya ve-*

lox Fabricius (Orthoptera). *Udaspes folus* Cramer (Lepidoptera: Hesperidae) was the most rare species recorded from the naturally recovering site with no ongoing disturbances. The diversity, evenness, and richness of the sites tracked the intensity of the disturbances, the greatest value being associated with undisturbed site, followed by the naturally recovering site, the moderately disturbed site and, severely disturbed site. In all ecological measures, the effects of disturbances were much greater than the changes associated with seasonality. Thus it appears that insect communities are sensitive to anthropogenic disturbances and their community structure may be a viable diagnostic tool in assessing environmental conditions." 6931. Kraft, P.G.; Wilson, R.S.; Franklin, C.E.; Blows, M.W. (2006): Substantial changes in the genetic basis of tadpole morphology of *Rana lessonae* in the presence of predators. *Journal of Evolutionary Biology* 19(6): 1813-1818. (in English). ["Predator-induced morphological plasticity is a model system for investigating phenotypic plasticity in an ecological context. We investigated the genetic basis of the predator-induced plasticity in *Rana lessonae* by determining the pattern of genetic covariation of three morphological traits that were found to be induced in a predatory environment. Body size decreased and tail dimensions increased when reared in the presence of preying dragonfly larvae. Genetic variance in body size increased by almost an order of magnitude in the predator environment, and the first genetic principal component was found to be highly significantly different between the two environ-

ments. The across environment genetic correlation for body size was significantly below 1 indicating that different genes contributed to this trait in the two environments. Body size may therefore be able to respond to selection independently in the two environments to some extent." (Authors)] Address: Wilson, R.S., Univ. Queensland, Sch. Integrat. 6933. Muenz, T.K.; Golladay, S.W.; Vellidis, G.; Smith, L.L. (2006): Stream buffer effectiveness in an agriculturally influenced area, southwestern Georgia. Responses of water quality, macroinvertebrates, and amphibians. *J. Environ. Qual.* 35: 1924-1938. (in English). ["To determine useful metrics for assessing stream water quality in the Southeastern Coastal Plain, we examined differences among two buffered and three unbuffered streams in an agricultural landscape in southwestern Georgia. Potential indicators included amphibian diversity and abundance, aquatic macroinvertebrate populations, riparian vegetative structure, water quality, and stream physical parameters. Variability among sites and treatments (buffered vs. unbuffered) existed, with sites in the same treatment as most similar, and disturbances from a nearby eroding gully strongly affecting one unbuffered site. Of the invertebrate metrics examined, percentages of clingers, Ephemeroptera-Plecoptera-Trichoptera (EPT), Elmidae (Coleoptera), Crustacea (Decapoda and Amphipoda), and dipterans were found to be possible indicators of stream health for perennial streams within this region. Overall, buffered sites showed higher percentages of sensitive invertebrate groups and showed lower and more stable concentrations of nitrate N, suspended solids, and fecal coliforms (FCs). Percent canopy cover was similar among sites; however, riparian vegetative coverage and percent leaf litter were greatest at buffered sites. No differences in amphibian abundance, presence, and absence within the riparian area were apparent between sites; however, instream larval salamanders were more abundant at buffered streams. In this study, stream buffers appeared to decrease nutrient and sediment loads to adjacent streams, enhancing overall water quality. Selected benthic macroinvertebrate metrics and amphibian abundance also appeared sensitive to agricultural influences. Amphibians show potential as indicator candidates, however further information is needed on their responses and tolerances to disturbances from the microhabitat to landscape levels." (Author) A total of 23840 individual organisms were collected at the five sites including 4 odonate taxa.] Address: Muenz, Tara, J.W. 6938. Tosh, C.R.; Ruxton, G.D. (2006): Artificial neural network properties associated with wiring patterns in the visual projections of vertebrates and arthropods. *American Naturalist* 168(2): E38-E52. (in English). ["We model the functioning of different wiring schemes in visual projections using artificial neural networks and so speculate on selective factors underlying taxonomic variation in neural architecture. We model the high connective overlap of vertebrates (where networks have a dense mesh of connections) and the less overlapping, more modular architecture of arthropods. We also consider natural variation in these basic wiring schemes. Generally, arthropod networks are as efficient or more efficient in functioning compared to vertebrate networks.

They do not show the confusion effect (decreasing targeting accuracy with increasing input group size), and they train as well or better. Arthropod networks are, however, generally poorer at reconstructing novel inputs. The ability of vertebrate networks to effectively process novel stimuli could promote behavioural sophistication and drive the evolution of vertebrate wiring schemes. Vertebrate networks with less connective overlap have, surprisingly, similar or superior properties compared to those with high connective overlap. Thus, the partial connective overlap seen in real vertebrate visual projections may be an optimal, evolved solution. Arthropod networks with and without whole-cell neural connections within neural layers have similar properties. This indicates that neural connections mediated by offshoots of single cells (dendrites) may be fundamental to generating the confusion effect." (Authors) The paper includes some references to Odonata. (in English). ["The concentrations of heavy metals in different food web components, such as zooplankton, benthic invertebrates and fish, were examined in small humic lakes from southern Finland. Variation in metal concentrations in zooplankton was observed between different lakes and in benthic invertebrates between different animal groups. We found a significant relationship between lakewater pH and Cd concentration in isopods (*Asellus aquaticus*), while no relationship between the humic content of lakewater and Cd or Hg concentrations was observed. Annual variation in Cd, studied over a six-year period, was correlated with the amount of discharge, which indicated the importance of the annual loading of Cd from the catchment in determining accumulation in isopods. The metal concentrations in perch (*Perca fluviatilis*) were higher in a humic and acid lake than in a slightly humic lake and may partly be explained by the varying dietary regime of perch." (Authors) Cd, Cr, and Pb load in Odonata (Coenagrionidae, Libellulidae, Aeshnidae) is documented.] Address: Tulonen, Tiina, University of Helsinki, Lammi Biological Station, Pääjärvent. 320, 16900 Lammi, Finland. 6942. Urban, M.C.; Skelly, D.K.; Burchsted, D.; Price, W.; Lowry, S. (2006): Stream communities across a rur-

al-urban landscape gradient. *Diversity and Distributions* 12: 337-350. (in English). ["Rapid urbanization throughout the world is expected to cause extensive loss of biodiversity in the upcoming decades. Disturbances associated with urbanization frequently operate over multiple spatial scales such that local species extirpations have been attributed both to localized habitat degradation and to regional changes in land use. Urbanization also may shape stream communities by restricting species dispersal within and among stream reaches. In this patch-dynamics view, anthropogenic disturbances and isolation jointly reduce stream biodiversity in urbanizing landscapes. We evaluated predictions of stream invertebrate community composition and abundance based on variation in environmental conditions at five distinct spatial scales: stream habitats, reaches, riparian corridors and watersheds and their spatial location within the larger three-river basin. Despite strong associations between biodiversity loss and human density in this study, local stream habitat and stream reach conditions were poor predictors of community patterns. Instead, local community diversity and abundance were more accurately predicted by riparian vegetation and watershed landscape structure. Spatial coordinates associated with instream distances provided better predictions of stream communities than any of the environmental data sets. Together, results suggest that urbanization in the study region was associated with reduced stream invertebrate diversity through the alteration of landscape vegetation structure and patch connectivity. These findings suggest that maintaining and restoring watershed vegetation corridors in urban landscapes will aid efforts to conserve freshwater biodiversity." (Authors) Nine Odonata genera/taxa are listed in the appendix.] Address: Urban, M.C., School of Forestry and Environmental Studies, Yale University, 370 Prospect Street, New Haven, Connecticut 06520 USA. 6943. Werner, E.E.; Peacor, S.D. (2006): Lethal and nonlethal predator effects on an herbivore guild mediated by system productivity. *Ecology* 87(2): 347-361. (in English). ["Indirect effects propagated through intervening species in a food web have important effects on Community properties. Traditionally, these indirect effects have been conceptualized as mediated through density changes of the intervening species, but it is becoming increasingly apparent that those mediated through trait (phenotypic) responses also can be very important. Because density- and trait-mediated indirect effects have different properties, it is critical that we understand the mechanisms of transmission in order to predict how they will interact, and when or where they will be important. In this study, we examined the mechanisms and Consequences of the lethal (density-mediated) and, nonlethal (trait-mediated) effects of a larval odonate predator on a guild of four herbivore species (a larval anuran and three species of snails) and their resources. We also manipulated system productivity in order to explore the effects of environmental context on the transmission of these two types of indirect effects. We show that trait-mediated effects arising from the predator can be very strong relative to density-mediated effects on both the competing herbivores and the species composition and production of their resources. A number of these indirect effects are shown to be contingent on productivity of the system. We further present evidence that trait- and density-mediated indirect effects originating from a predator may be transmitted inde-

pendently through different routes in a food web, particularly when spatial responses of the transmitting prey are involved. Finally, effects on prey growth due to trait responses to the predator varied from negative to positive in predictable ways as a function of time and indirect effects oil the larger food web. These results indicate the important role that trait-mediated indirect effects can play in trophic cascades and keystone predator interactions, and we discuss how the mechanisms involved can be incorporated in theory." 6945. Wissinger, S.A.; McIntosh, A.R.; Greig, H.S. (2006): Impacts of introduced brown and rainbow trout on benthic invertebrate communities in shallow New Zealand lakes. *Freshwater Biology* 51(11): 2009-2028. (in English). ["1. Brown and rainbow trout have been introduced to many inland waters in New Zealand, but research on the impacts on native communities has focused mainly on streams. The purpose of this study was to compare the benthic communities of trout and troutless lakes. Based on previous studies in North America and Europe, we predicted that the benthic biomass, and especially the abundance of large invertebrates, would be lower in lakes with trout as compared to those without. We surveyed the invertebrate fauna of 43 shallow, high-elevation lakes (26 with and 17 without trout) in four geographic clusters on the central South Island and then conducted a detailed quantitative study of invertebrate biomass and community structure in 12 of these lakes. 2. Benthic community composition and diversity of lakes with and without trout were nearly identical and biomass was as high or higher in the lakes with as without trout. There was no evidence that trout have caused local extinctions of benthic invertebrates. Although the proportional abundance of large-bodied aquatic was slightly lower in lakes with than without trout, the abundance of several groups of large-bodied benthic taxa (dragonflies, caddisflies and water bugs) did not differ. 3. Our findings are in contrast to those in North American and Europe where trout introductions into previously troutless lakes have led to declines in the abundance of benthic invertebrates, especially large-bodied taxa. We propose that the modest effects of trout in New Zealand could be explained by (i) the high areal extent of submergent vegetation that acts as a benthic refuge, (ii) low intensity of trout predation on benthic communities and/or (iii) characteristics of the benthic invertebrates that make them relatively invulnerable to fish predation. 4. Regardless of the relative importance of these hypotheses, our results emphasise

that the same invertebrates occurred in all of the lakes, regardless of size, elevation and presence of trout, suggesting habitat generalists dominate the benthic fauna in shallow New Zealand lakes." (Authors)] Address: Wissinger, S.A., Allegheny Coll., Dept Biol., Meadville, PA 16335 USA. E-mail: swissing@allegheny.edu

6946. Azpilicueta Amorín, M.; Rey Rañó, C.; Docampo Barrueco, F.; Rey Muñiz, X.L.; Cordero River (2007): A preliminary study of biodiversity hotspots for Odonates in Galicia (NW Spain). *Odonatologica* 36(1): 1-12. (in English). ["The analysis of distribution data of Odonata in NW Spain indicates the presence of 49 species *Macromia splendens*, *Oxygastra curtisii*, *Gomphus graslini* and *Coenagrion mercuriale* are protected under the European Habitats Directive and Spanish Law. Localities of specimens collected between 1978 and 2004 were situated in UTM squares of 10x10 km to produce a map of species richness for the region. Additionally, all localities (UTM 1 x 1 km) where protected and rare species were found are introduced in a GIS system, on a map of the Natura 2000 network of the region. The results indicate that *O. curtisii* and *C. mercuriale* are common in NW Spain. As local rare taxa are identified *Brachytron pratense*, *Aeshna affinis* and *Erythromma viridulum*, because they were found in less than 10 squares, and are also relatively rare in the Iberian peninsula. As areas of special interest are selected those that include all known populations of *M. splendens*, *G. graslinii*, and *B. pratense*, all localities with at least 2 of the 4 protected species, and areas with more than 20 species. This gives a list of 24 hotspots, most of them (15) at least partially included in the Natura 2000 network. Unfortunately the analysis also reveals that the knowledge of this group is clearly fragmentary, with most records concentrated on the coastal region, and very few squares sampled more than 20 times, the minimum to obtain reliable data. Therefore a systematic sampling of the region is needed to properly identify areas with high species richness." 6948. Beatty, C.D.; van Gossum, H.; Sherratt, T.N. (2007): *Nesobasis* (Odonata: Zygoptera) species diversity and abundance: notes on an endemic damselfly genus of the island group of Fiji. *Odonatologica* 36(1): 13-26. (in English). ["Compared to other regions in the world, the islands scattered over the south-western Pacific Ocean remain largely unstudied with respect to damselfly biology. Only a few studies have been undertaken and these have been mainly of a taxonomic nature. Here, an overview is presented of the diversity, abundance, distribution and field diagnostic characteristics of species within the Fijian genus *Nesobasis*, one

of the most speciose odonate genera found in any oceanic island group in the world. 24 species (2 undescribed) were encountered during a 2-month visit in the dry season of 2005, collected from Viti Levu and Vanua Levu. This brings the total number of species currently known for the genus to 31 (of which only 21 are at present formally described). Information is provided on species diversity and abundances at the major collecting sites. For both islands the most speciose location harboured 8 species. Abundant species tended to be widespread, while less abundant species were usually restricted in occurrence to a few sites. Included are basic species descriptions and observations on reproductive activities." 6950. Bengen, E.; Ritzau, C.; Johanning, J. (2007): Es tanzt die schöne Libelle: Libellen zwischen Weser und Ems. Schriftenreihe des Landesmuseums für Natur und Mensch Oldenburg 54: 110 pp. (in German). [This book covers a regional dragonfly fauna of 41 species bordered by the rivers Ems and Weser, Niedersachsen, Germany. Each of the species is depicted with a colour photo and locality dates. Some rather traditional introductory information is given, but enriched by some special information on the regional dragonfly names and the origin of these names. Uniquely, each species is accompanied by a poem regarding dragonflies. The lyrics is contributed by Annette von Droste-Hülshof, Goethe, Rilke and many others. This is a quite nice coffee table book, including a few faunistic relevant species (e.g. on *Erythromma viridulum* and *Sympetrum fonscolombii*).] Address: Isensee Verlag, Haarenstr. 20, 26122 Oldenburg

6951. Bergou, A.J.; Xu S.; Wang Z.J. (2007): Passive wing pitch reversal in insect flight. *J. Fluid Mech.* 591: 321-337. (in English). ["Wing pitch reversal, the rapid change of angle of attack near stroke transition, represents a difference between hovering with flapping wings and with a continuously rotating blade (e.g. helicopter flight). Although insects have the musculature to control the wing pitch during flight, we show here that aerodynamic and wing inertia forces are sufficient to pitch the wing without the aid of the muscles. We study the passive nature of wing pitching in several observed wing kinematics, including the wing motion of a tethered dragonfly, *Libellula pulchella*, hovering fruitfly, hovering hawkmoth and simplified dragonfly hovering kinematics. To determine whether the pitching is passive, we calculate rotational power about the torsion axis owing to aerodynamic and wing inertial forces. This is done using both direct numerical simulations and quasi-steady fluid force models. We find that, in all the cases studied here, the net rotational power is negative, signifying that the fluid force assists rather than resists the wing pitching. To further understand the generality of these res-

ults, we use the quasi-steady force model to analyse the effect of the components of the fluid forces at pitch reversal, and predict the conditions under which the wing pitch reversal is passive. These results suggest the pitching motion of the wings can be passive in insect flight." 6952. Bogut, I.; Vidakovic, J.; Palijan, G.; Cerba, D. (2007): Benthic macroinvertebrates associated with four species of macrophytes. *Biologia, Bratislava* 62(5): 600-606. (in English). ["Benthic macroinvertebrates associated with four species of macrophytes (*Nymphoides peltata*, *Ceratophyllum demersum*, *Polygonum amphibium* and *Carex* sp.) were investigated during two growing seasons (2001 and 2002) in the slow-flowing Eonakut Channel in the Kopački rit Nature Park in Croatia. A total of 31 macroinvertebrate taxa were found. *C. demersum*, a submerged plant with dissected leaves, supported the highest macroinvertebrate abundance, almost seven times more than *N. peltata*, a floating plant with undisseminated leaves, which harboured the lowest abundance during the research period. Chironomidae larvae (50–83%) and Oligochaeta (14–46%) were the most abundant groups recorded on all macrophyte species. Water-level fluctuation, because of its influence on the appearance and growth of aquatic vegetation, and the trophic state of water within the macrophyte stands seemed to be the main factors which affected the taxonomic composition and abundance of macroinvertebrates." (Authors) With the exception of *Carex*, all vegetation types were inhabited by odonate larvae.] Address: Bogut, Irella, Department of Biology, University of J. J. 6954. Bried, J.T.; Ervin, G.N. (2007): Intraspecific models and spatiotemporal context of size–mass relationships in adult dragonflies. *J. N. Am. Benthol. Soc.* 26(4): 681-693. (in English). ["Length–mass equations are valued for their efficiency and reliability because many animals, including aquatic macroinvertebrates, show predictable correlations between mass and linear body dimensions. Our paper explores overlooked aspects of length–mass applications, including relationships for adult aquatic insects, intraspecific variation, and spatiotemporal context. We analyzed the length–mass relationship in 5 species of adult dragonfly (Anisoptera: Libellulidae: *Erythemis simplicicollis*, *Libellula incesta*, *Lydia*, *Pachydiplax longipennis*, *Perithemis tenera*) during 2 collection periods (early and late summer flight) at 3 study locations in northern Mississippi, USA. Despite narrow ranges in body and wing length, and given that dragonflies gain postemergence mass without associated changes in skeletal size, both body and wing

length showed potential for estimating individual dry mass ($R^2 = 0.5$ in most cases). We also found strong associations between dry and wet length and consistent variation in individual dry mass as a percentage of individual wet mass (65% water content) in these samples. Species-level mass estimates from independently derived species-level equations were far more accurate than estimates based on previously published equations for use at higher taxonomic levels (family, order). Patterns of individual mass per unit length generally differed among study locations and, especially, collection periods. Regression models with similar slopes (i.e., similar individual differences in mass per unit length) were susceptible to length-adjusted location or time effects (i.e., elevation differences in the best-fit lines). Our study underscores the importance of intraspecific variation, taxonomic resolution, and spatiotemporal context in length-based modelling of adult dragonfly mass." 6955. Buczyńska, E.; Buczyński, P.; Lechowski, I.; Stryjecki, R. (2007): Fish pond complexes as refugia of aquatic invertebrates (Odonata, Coleoptera, Heteroptera, Trichoptera, Hydrachnidia): a case study of the pond complex in Zalesie Kańskie (Central-East Poland). *Nature Conservation* 64: 39-55. (in English). ["In the years 2000 and 2001 selected groups of aquatic invertebrates were studied in the fishpond complex in Zalesie Kańskie (E of Lublin, central-eastern Poland), an area well-known for its nature values. The following taxa were recorded: 45 dragonfly species, 25 waterbug species, 99 beetle species, 35 caddisfly species and 55 water mite species. Based on the groups studied, the aquatic insect fauna occurring in the ponds and in other water bodies and habitats associated with them was characterised. The occurrence of legally protected species included in appendices of the Bern Convention and the Habitats Directive, as well as from Red Lists of Poland and the Lublin region, was analysed – 5, 4, 2, 8, 14 and 13 species were recorded respectively. Based on this data, it was concluded that the fishpond complex in Zalesie Kańskie can serve as a model of an area where fish-breeding does not destabilize the balance of ecosystems – on the contrary, it helps to maintain high natural values and biological diversity. Ways of exploiting this area in a nature-friendly manner were also indicated." (Authors)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

6956. Buktenica, M.W.; Girdner, S.F.; Larson, G.L.; McIntire, C.D. (2007): Variability of kokanee and rainbow trout food habits, distribution, and population dynamics, in an ultraoligotrophic lake with no manipulative management. *Hydrobiologia* 574: 235-264. (in English). [Oregon, USA; "Crater Lake is a unique environment to evaluate the ecology of introduced kokanee and rainbow trout because of its otherwise pristine state, low productivity, absence of manipulative management, and lack of lotic systems for fish spawning. Between 1986 and 2004, kokanee displayed a great deal of variation in population demographics with a pattern that reoccurred in about 10 years. We believe that the reoccurring pattern resulted from density dependent growth, and associated changes in reproduction and abund-

ance, driven by prey resource limitation that resulted from low lake productivity exacerbated by prey consumption when kokanee were abundant. Kokanee fed primarily on small-bodied prey from the mid-water column; whereas rainbow trout fed on large-bodied prey from the benthos and lake surface. Cladoceran zooplankton abundance may be regulated by kokanee. And kokanee growth and reproductive success may be influenced by the availability of *Daphnia pulicaria*, which was absent in zooplankton samples collected annually from 1990 to 1995, and after 1999. Distribution and diel migration of kokanee varied over the duration of the study and appeared to be most closely associated with prey availability, maximization of bioenergetic efficiency, and fish density. Rainbow trout were less abundant than were kokanee and exhibited less variation in population demographics, distribution, and food habits. There is some evidence that the population dynamics of rainbow trout were in-part related to the availability of kokanee as prey." (Authors) Odonata were confined to the stomachs of rainbow trout.] Address: Buktenica, M.W., U.S. National Park Service, Crater Lake National Park, PO Box 7, Crater Lake, OR 97604, USA. 6958. Campero, M.; Ollevier, F.; Stoks, R. (2007): Ecological relevance and sensitivity depending on the exposure time for two biomarkers. *Environmental Toxicology* 22(6): 572-581. (in English). ["Biomarkers are widely used to assess pesticide stress, but their ecological relevance and exposure time dependent sensitivity is still heavily debated. We studied both aspects in larvae of the damselfly *Coenagrion puella*, comparing the impact of low doses of atrazine, carbaryl, and endosulfan on two key biomarkers (acetylcholinesterase [AChE] activity and fluctuating asymmetry [FA]) and their relationship with life history traits (mortality, development time, growth rate, and body size). Larvae exposed to the pesticides had, in general, longer development times. Size, growth rate, and mortality were not affected by any of the pesticides. In the long-term exposure, AChE activity was diminished by atrazine treatments and stimulated by carbaryl treatments, and was not affected in the endosulfan treatments. FA decreased with increasing endosulfan concentrations and showed no reaction to atrazine or carbaryl. Overall, short-term exposure tended to overestimate the results of long-term exposure decreasing growth rates and enhancing inhibition of AChE activity in atrazine and carbaryl treatments. In line with its ecological relevance, relationship between biomarkers and life history traits showed that AChE inhibition was positively correlated with mortality, while FA was traded off with size. These results show that caution should be exerted when using these biomarkers to assess pesticide pollution in field situations." 6960. Chakona, A.; Marshall, B.; Brendonck, L. (2007): The effect of fish predation on benthic macroinvertebrates in a seasonal stream in north-western Zimbabwe. *African Journal of Aquatic Science* 32(3): 251-257. (in English). ["The cumulative impact of the entire fish assemblage on benthic macroinvertebrate assemblages was investigated over four months in a removal experiment in isolated pools that persist through the dry season, in an intermittent stream in north-western Zimbabwe. Macroinvertebrate taxonomic richness did not differ significantly between sampling dates, indicating that fish removal had no effect on the zoobenthos taxa richness but led instead to large increases in the densities of certain macroinvertebrates. There was a progressive increase in the body size of Odonata in fishless pools 34 and 55 days after treatment and, by 78 days post-treatment, the proportion of large-sized odonates was significantly higher in fishless than in control pools. Peak densities of predaceous invertebrates coincided with a sharp decline in macroinvertebrate densities in the fishless pools about three months after fish removal. The values for Strauss's food selection index were low (range -0.220 to 0.180) for all macroinvertebrates, indicating random feeding by fish. Results indicate that, although fish may be important predators, they are not keystone predators because the macroinvertebrate community structure in this temporary habitat was found to be influenced by the assemblages of both vertebrate and invertebrate predators, rather than by a single keystone predator." 6965. Dakou, E.; D'Heygere, T.; Dedecker, A.P.; Goethals, P.L.M.; Lazaridou-Dimitriadou, M.; De P (2007): Decision tree models for prediction of macroinvertebrate taxa in the river Axios (Northern Greece). *Aquatic Ecology* 41: 399-411. (in English). ["In this study, decision tree models were induced to predict the habitat suitability of six macroinvertebrate taxa: Asellidae, Baetidae, Caenidae, Gammaridae, Gomphidae and Heptageniidae. The modelling techniques were applied on a dataset of 102 samples collected in 31 sites along the river Axios in Northern Greece. The database consisted of eight physical-chemical and seven structural variables, as well as the abundances of 90 macroinvertebrate taxa. A seasonal variable was included allowing the description of potential temporal changes in the macroinvertebrate taxa. Rules relating the presence/absence of six benthic macroinvertebrate taxa with the 15 physical-chemical and structural river characteristics and the seasonal variable were induced using the J48 algorithm. In order to improve the performance and the interpretability of the induced models, three optimisation techniques were applied: tree-pruning, bagging and boosting. The predictive performance of the decision

tree models was assessed on the basis of the percentage of Correctly Classified Instances (CCI) and the Cohen's kappa statistic. The results of the present study demonstrated that although the models had a relatively high predictive performance, noise in the dataset and inappropriate input variables prevented to some extent, the models from making reliable predictions. Although tree-pruning did not improve significantly the reliability of the induced models, it reduced considerably the tree complexity and in this way increased the transparency of the trees. Consequently, the induced models allowed for a correct ecological interpretation. The effect of bagging and boosting on the other hand varied considerably between the different models, as well as within different repetitions of 10-fold cross-validation in an individual model. In some cases the predictive performance was improved, in others stable or even worsened. The effect of bagging and boosting seemed to be strongly dependent on the dataset on which the two techniques were applied. Tree-pruning thus proved to have a high potential when applied in models used for decision-making of river] Address: Goethals, P.L.M., Department of Applied Ecology and Environmental Biology, Laboratory of Environmental Toxicology and Aquatic Ecology, Ghent University, J. 6966. De Knijf, G.; Anselin, A.; Goffart, P.; Taily, M. (2007): Some aspects of Odonata distribution in Belgium. In: Levasseur, M. Dommangot G. & Jolivet, S. (eds.). Actes des Rencontres odonatologiques Ouest-Européennes 2005. Société française d'odonatologie (SFO), Bois-d'Arcy: 73-78. (in English). ["Some results of the Belgium atlas project are presented here. More than 65,000 records have been collected by 500 volunteers. Distribution data are presented for three periods in 10 x 10 km UTM squares : < 1950, 1950-1979 and >1980, and for the period 1990-2000 (the major part of the records) in 5 x 5 km squares. Due to special efforts in the '90's to obtain a high and detailed coverage of the whole country, 93.5% of all 10 x 10 km UTM squares have been investigated. During this recent period, also 63% of all 5 x 5 km squares have records. In general, Flanders, the northern part, is much better investigated than the southern part, Walonia. In total, 69 species were ever observed in Belgium, 66 of them present in the '90's. Only 2 species, *Nehalennia speciosa* and *Leucorrhinia caudalis* are now extinct. For ten species, records were missing during one of the periods. For each species, we mention the status, based on the number of occupied grid cells (5 x 5 km) since 1990. The highest species diversity can be found in the north-east of Belgium, the Campine region. Other regions with a high diversity are localised in the extreme south, the Lorraine. A map of the recent distribution is given five species. We hope that the information in this atlas will be helpful for conservation measures and as a starting point for more detailed research and monitoring." 6973. Ellenrieder, N. von (2007): Composition and structure of aquatic insect assemblages of Yungas mountain cloud forest streams in NW Argentina. Rev. Soc. Entomol. Argent. 66(3-4): 57-76. (in English, with Spanish review). ["Thirty three lotic environments in the Yungas mountain cloud forest of NW Argentina were sampled both in undisturbed forest areas and sites altered by human activities. Aquatic insects of 143 taxa in 55 families were collected. Cluster analysis suggested altitude as one of the main structuring variables of aquatic insect communities in these streams, and its importance was confirmed by non-metric multidimensional scaling (NMS); the environmental parameters measured that were best correlated with the ordination were altitude, water temperature, latitude and channel variables (width, percentage of large and small woody debris, of undercut banks, cobble and coarse gravel). Multi response permutation procedures (MRPP) showed streams in well preserved areas to significantly differ in their composition from streams in disturbed areas. Proportion of Elmidae and of Plecoptera individuals and number of Trichoptera taxa were the biological metrics best correlated with the local disturbance gradient, suggesting that an 'EIPT' index could be a useful component in the evaluation of the ecological status of these environments. Indicator species analyses identified some potential indicators of stream condition and disturbance factors affecting these streams." (Author) The analysis includes 23 odonate taxa.] Address: Ellenrieder, Natalia von, Museo de Ciencias Naturales, Universidad Nacional de Salta, Mendoza 2, Salta 4400, Argentina. 6974. Englund, R.A.; Wright, M.G.; Polhemus, D.A. (2007): Aquatic insect taxa as indicators of aquatic species richness, habitat disturbance, and invasive species impacts in Hawaiian streams. Bishop Museum Bulletin in Cultural and Environmental Studies 3: 207-232. (in English). ["In this study we provide a synthesis of numerous stream assessments in the Hawaiian Islands that began in the early 1990s and have continued to the present. Data from numerous sites within the five major high Hawaiian Islands with flowing streams (excluding Lāna'i, which lacks flowing waters) were used to assess native and introduced aquatic insect communities, the impacts of various invasive freshwater species and the threats from habitat disturbance. The primary objective of this study was to provide the first comprehensive analysis of aquatic insect populations in various urbanized and virtually pristine stream reaches on the five major Hawaiian Islands, and to assess if various suites of introduced aquatic species may be impacting aquatic insect populations. We were also interested in assessing the suitability of native aquatic insects as key indicator, flagship, or umbrella species regarding the overall health of Hawaiian aquatic ecosystems. If key indicator species can be found, then aquatic habitats with high

native biodiversity can be identified and management efforts can be made to ensure this high level of biodiversity persists. These indicator species could also be used for monitoring future rehabilitation programs on disturbed streams." (Authors) The study includes Odonata and focuses on the endemic genus *Megalagrion* demonstrating impacts of introduced Amphibia and fishes on Odonata.] Address: Englund, R.A., Hawaii Biological Survey, Bishop Museum, 1525 Bernice Street, Honolulu, Hawai'i 96817, USA, E-mail: englund@bishopmuseum.org

6977. Futahashi, R. (2007): Recent state on taxonomy of Japanese *Mnais* species. The Nature & Insects 42(9) (Special issue: Recent trends of Odonatology): 4-7. (in Japanese). [Translation by Naoya Ishizawa: "Introduction: Genus *Mnais* is one of the most difficult group for classification. So far hypotheses of one species to four species of the genus have been advocated (Table I), and no collective view was made among researchers. The reason of confusion is based on the morphology of external reproductive organs and wing veins, which contain wide variation and overlap within the genus. Reproductive isolation was expected to be clarified indirectly by DNA analysis. Author and colleagues conducted analyses of nuclear DNA and mitochondria DNA on 900 specimens from all over Japan, and we advocated that Japanese genus *Mnais* is composed of two species, and lastly classified into *Mnais costalis* Selys, 1869 and *Mnais pruinosa* Selys, 1853. The former was named as *Nihon-kawatombo* in Japanese and the latter

was named as *Asahina-kawatombo* after Dr. Asahina. Comparison between the new hypothesis and the former hypotheses Analysis of ITS region of nuclear DNA on Japanese *Mnais* species shows 4 types of base sequence, A, B, C, D. A type is distributed widely from Hokkaido to Kagoshima Prefecture, while, other three types were distributed allotopically to western Japan. The head of A type is relatively longer for its wing length than those of other types and also its pterostigma was more slender than others. Tips of anal gill of the larvae of A type are characteristically triangular. In the western Japan A type is distributed sympatrically with other types, however, at the same river A type is distributed to lower reach and other types are to upper reach. Thus, by the morphological differences and their habitat segregation A type was classified as the different species from other types, namely, A type was named *Nihon-kawatombo*, *M. costalis* and others, B, C, D were named *Asahina-kawatombo*, *M. pruinosa* (see Table I). Translators' notice: as to problems of comparison between the new hypothesis and the former hypotheses, the following literature may be useful. Hayashi, F., Dobata, S. & Futahashi, R. 2004. 6979. Grant, P.B.C.; Samways, M.J. (2007): Ectoparasitic mites infest common and widespread but not rare and red-listed dragonfly species. *Odonatologica* 36(2): 255-262. (in English) ["Freshwater ectoparasitic mites negatively alter host population dynamics by reducing survivorship, mating success, fitness and altering activity patterns. Hosts commonly include dragonflies. The Kogelberg Biosphere Reserve, South Africa, is a major hotspot for endemic dragonflies. All 38 dragonfly species in the reserve were sampled for ectoparasitic mites, but only 2 common, widespread species of Zygoptera, *Ischnura senegalensis* and *Ceriatagrion glabrum*, were infested with *Arrenurus* or *Leptus* mite species. None of the endemic or red-listed dragonflies were infested. Parasitism level was 3.5% for *C. glabrum* and 38% for *I. senegalensis*. Intensity of ectoparasites on individuals was high, with about eight ectoparasitic larva per individual. Larval mites preferentially associated with individual hosts already harbouring mites. High levels of species-specific parasitism likely reflects shared environmental requirements, preferential species selection, and lack of defensive behaviours to resist infestation. Characteristic scars from previous mite attachment observed on older individuals of *I. senegalensis* indicate that a much larger percentage of the population was actually parasitized, but detached as the individual aged. That the rare and red-listed species were apparently

immune from infestation is a positive note for their conservation." (Authors)] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

6980. Grehan, J.R. (2007): A brief look at Pacific biogeography: The trans-oceanic travels of *Microseris* (Angiosperms: Asteraceae). Ebach, M.C. & Tangney, R. (Eds.): *Biogeography in a Changing World*, CRC Press, Boca Raton. Systematics Association Special Volume Series: 83-94. (in English). ["The modern revolution in biogeography did not begin with plate tectonics. It began two decades earlier when Leon Croizat established geographic distributions as the empirical foundation of evolutionary biogeography. Comparative map analysis reveals patterns that are not accessible through other methods. The biogeography of *Microseris* (Angiosperms: Asteraceae) is used to illustrate the power of geographic analysis to provide unique insights into the biogeographic distributions and relationships of organisms. Explanations of dispersal as physical movement for *Microseris* are shown to be problematic by the congruent distributions and Pacific homology of this genus with groups of diverse means of dispersal such as daisies, dragonflies, millipedes, eyebrights, and seaweeds. The role of tectonics and the historical implications of *Microseris* biogeography for molecular clock theory are briefly discussed." (Author) The chapter contains several references to dispersal of Odonata. see: <http://www.sciencebuff.org/ftponly/microseris.pdf>]

6981. Herath, B.; Johnson, B.; Lunski, J.; Fuselier, L. (2007): Sex-specific antipredator response in *Anax junius*, a migratory dragonfly. Abstracts: North Central Branch of the Entomological Society of America: <http://esa.ent.iastate.edu/confreg/?gridaction=viewonepresentation&year=2007&presnum=044>. (in English). [Verbatim: Odonate populations often exhibit skewed adult population sex ratios that are likely tied to sex-specific life history strategies expressed by individuals when they are aquatic larvae. Differences in mortality between the sexes of the larvae can explain skewed adult population sex ratios. In dragonflies with female-biased sex ratios at emergence, ♂♂ likely assume a higher predation risk and hence, higher mortality. Further, predation risk is directly and positively related to activity levels. We investigated whether *Anax junius* larvae show sex-specific responses to predation risk in a series of laboratory experiments. We hypothesized that ♂♂ would assume greater predation risk compared to ♀♀ when faced with either a conspecific or a fish predator. Preliminary results indicate that the sexes respond similarly to a caged predator but that ♂♂ are more active than ♀♀ in the presence of a free-swimming predator. ♀♀ are more likely to strike at the predator and ♂♂ will feed more in the presence of a predator than will ♀♀. We are expanding this project to include response to chemical cues and additional species of odonates.] Address: Fuselier, Linda, Biosciences Department, 1104 7th Ave South, Minnesota State University, Moorhead, Moorhead, MN, 56563, USA

6982. Jeschke, J.M.; Tollrian, R. (2007): Prey swarming: which predators become confused and why?. *Animal Behaviour* 74: 387-393. (in English). ["When confronted with a swarm of their prey, many predators become confused and are less successful in their attacks. Despite the general notion that this confusion effect is a

major reason for prey swarm formation, it is largely unknown how widespread it is and which predator or prey traits facilitate or impede it. We carried out experiments with four predator-prey systems: *Aeshna cyanea* and *Chaoborus obscuripes* larvae, but not *Libellula depressa* and *Triturus alpestris* larvae, became confused when confronted with high *Daphnia* densities. When combining this result with literature data, we found that predators became confused in 16 of the 25 predator-prey systems studied to date. Tactile predators appear to be generally susceptible, whereas visual predators are susceptible mainly when their prey is highly agile. This difference probably results from the superiority of the visual sensory system. However, while our study is an important step towards the mechanistic understanding of predator confusion, it also reveals how poor this understanding currently is." 6984. Jocque, M.; Graham, T.; Brendonck, L. (2007): Local structuring factors of invertebrate communities in ephemeral freshwater rock pools and the influence of more permanent water bodies in the region. *Hydrobiologia* 592: 271-280. (in English). ["We used three isolated clusters of small ephemeral rock pools on a sandstone flat in Utah, USA to test the importance of local structuring processes on aquatic invertebrate communities. In the three clusters we characterized all ephemeral rock pools (total: 27) for their morphometry, and monitored their water quality, hydrology and community assemblage during a full hydrocycle. In each cluster we also sampled a set of more permanent interconnected freshwater systems positioned in a wash, draining the water from each cluster of rock pools. This design allowed additional testing for the potential role of more permanent water bodies in the region as source populations for the active dispersers and the effect on the community structure in the rock pools. Species richness and community composition in the rock pools correlated with level of permanence and the ammonia concentration. The length of the rock pool inundation cycle shaped community structure, most probably by inhibiting colonization by some taxa (e.g. tadpoles and insect larvae) through developmental constraints. The gradient in ammonia concentrations probably reflects differences in primary production. The more permanent water bodies in each wash differed both environmentally and in community composition from the connected set of rock pools. A limited set of active dispersers was observed in the rock pools. Our findings indicate that aquatic invertebrate communities in the ephemeral rock pools are mainly structured through habitat permanence, possibly linked with biotic interactions and primary production." (Authors) Larvae of "*Corduliidae*" and "*Coenagrionidae*"

were sampled at the more permanent pools.] Address: Jocque, Merlijn, Laboratory of Aquatic Ecology, K.U. Leuven, de Bériotstraat 32, 3000 Leuven, Belgium. E-mail: Merlijn.Jocque@bio.kuleuven.ac.be

6986. Jordan, S.; Barruet, E.; Olaf, M. (2007): Blue hawaiiense and beyond: Conservation genetics and comparative phylogeography of four Hawaiian Megalagrion damselfly species (Odonata: Coenagrionidae). *Bishop Museum Bulletin in Cultural and Environmental Studies* 3: 247-260. (in English). ["Hawaii's endemic *Megalagrion* damselflies are rivaled in their beauty and diversity only by the degree of threat posed to them by anthropogenic disturbance. In this preliminary study of phylogeography and conservation genetics, we have sequenced about 660 base pairs (bp) of the mitochondrial COII gene from 191 damselflies from four species, including 31 populations that span a gradient of endangerment. We applied phylogeographic analyses in order to understand their biogeographic history. Unlike *Megalagrion xanthomelas* and *M. pacificum*, *M. calliphya* and *M. hawaiiense* rarely share haplotypes between populations and between islands, even within the larger Maui Nui superisland, suggesting that these latter two species do not disperse as well across land or water. Their phylogenies also better reflect the geological history of the islands. We applied conservation genetic analyses in order to understand their genetic health. Under a conservation genetic paradigm, populations with low genetic diversity are generally considered to be at greater risk of decline and extinction than populations with high genetic diversity. Applying this principle to *Megalagrion* populations gave both expected and surprising results. Expected results included measurements of high diversity in most populations of *M. calliphya*, *M. hawaiiense*, and Hawai'i Island populations of *M. xanthomelas*. Low diversity was observed in populations known to be bottlenecked or relictual, including O'ahu and Maui *M. xanthomelas*, and *M. pacificum*. Surprising results included low genetic diversity in O'ahu Ko'olau and Hawai'i Onomea *M. hawaiiense*, Moloka'i *M. pacificum*, and West Maui *M. calliphya*. We propose that these latter three populations be monitored and managed to maximize their long-term genetic health." 6991. Lajeunesse, M.J. (2007): Ectoparasitism of damselflies by water mites in Central Florida. *Florida Entomologist* 90(4): 643-649. (in English). ["Little is known about the frequency of water mite ectoparasitism (Acari: Hydrachnida) within and among damselfly species of Central Florida. Here I present a field survey of the assemblage of damselflies and their water mite parasites at the Archbold Biological Station (Lake Placid, FL) during late Mar, 2006. During this period, 4 species of damselfly were abundant: *Ischnura hastata* (Say) and *Nehalennia gracilis* Morse captured only at pond sites; and *Argia fumipennis atra* Gloyd and *Ischnura ramburii* (Selys) captured at a lake site. Only pond damselflies had water mites, and 12.2% and 12.5% of *I. hastata* and *N. gracilis* were parasitized, respectively. These are 2 novel and unreported odonate-acari associations for this area. I also examined within-species differences in ectoparasitism by sex, body size, and wing-cell fluctuating asymmetry. However, these factors did not relate to the prevalence and intensity of parasitism in the field. My study indicates that brief surveys of odonates in Central Florida will likely generate novel, unreported associations with parasitic water mites—this information is important to Address the gap in natural history for southeastern distributions of North American water mites." 6993. Leitao, S.; Pinto, P.; Pereira, T.; Brito, M.F. (2007): Spatial and temporal variability of macroinvertebrate communities in two farmed Mediterranean rice fields. *Aquatic Ecology* 41: 373-386. (in English). ["The spatial and temporal variation of macroinvertebrate assemblages was studied in two Portuguese commercial rice agroecosystems under the effect of field management involving the application of pesticides and fertilizers. A faunal succession of organisms was observed on both fields. Grazers were the first to colonize the paddies after a dry period when pesticides were applied, followed by development into nymphs and by an increase in the abundance of the species after the application of fertilizers. At the end of the season when no pesticides or fertilizers were applied, the communities changed with the presence of adult predators as a result of an increase in prey. Insecticide application revealed specific taxa increase due to the lack of competition with the target organism. Macroinvertebrates tended to prefer infested field margins with aquatic, submerged vegetation, revealing a spatial distribution along the paddies. Two different sampling devices were used and proved necessary in documenting the macroinvertebrate communities (grab for benthic and hand-net for pelagic organisms)." (Authors) Records of *Crocothemis erythraea*, *Orthetrum brunneum*, *Sympetrum fonscolombii*, *Ischnura elegans*, *Libellulidae*, and *Coenagrionidae* are analysed.] Address: Leitao, S., Laboratório de Referência do Ambiente, Instituto do Ambiente, 2611-865 Amadora, Portugal. 6994. Lemelin, R.H. (2007): Finding beauty in the dragon: The role of dragonflies in recreation and tourism. *Journal of Ecotourism* 6(2): 139-145. (in English). ["In some Asian countries such as China and in Japan, Odonata (dragonflies, damselflies) have a long history of being involved in recreation and leisure activities. In contemporary Japan, dragonfly enthusiasts, much like birders elsewhere, pride themselves on recognizing many different types of Odonata. In fact, numerous symposia, festivals, and sanctuaries provide Japanese dragonfly enthusiasts with the opportunity to practice and perfect their skills (Primack et al., 2000). Dragonfly gatherings (e.g., counts, educational outings) in North America and Europe are also increasing in popularity. Facilitating the growth of these recreation activities, but more specifically the viewing of dragonflies, are the availability of books and field guides (Corbet, 1999; DuBois, 2005; Dunkle, 2000; Mead, 2003; Nikula et al., 2002), associations (e.g., Dragonfly Society of the Americas, Worldwide Dragonfly Association), and websites (e.g., Digital Dragonflies). This article examines discussion surrounding insect-human relationships while highlighting the contribution of one particular insect order – Odonata (Mitchell & Lasswell 2005; Moore 1997), and the role of this flagship species in socio-cultural norms (Samways 2005) in recreational and tourism activities." (Authors)] Address: Lemelin, R. Harvey, School of Outdoor Recreation, Parks and Tourism, Lakehead Univ., Ontario, Canada

- 6998.** Lorenzo Carballa, L.; Cordero Rivera, A. (2007): Are parthenogenetic and sexual *Ischnura hastata* damselflies equally fertile? Testing sexual conflict theories. *Ethology, Ecology & Evolution* 19(4): 291-298. (in English). ["Recent theories of sexual selection stress the importance of conflicts over reproduction in shaping the reproductive traits of ♂♂ and ♀♀. Except when the reproductive interests of both sexes coincide, which only occurs under strict monogamy, there is a conflict of interests between the sexes over the number of matings and reproductive decisions. It has been suggested that ♂♂ are selected to "harm" ♀♀ if this increases male reproductive success, even at the expenses of female fitness. One prediction of such an hypothesis is that sperm is selected to maximize the probability of fertilization, and this sometimes can cause a decrease in fertility due to polyspermy, genetic incompatibility, toxic seminal products that harm ♀♀, etc. We have tested this hypothesis by comparing the fertility rates of parthenogenetic and sexual *Ischnura hastata* populations. Our results show that sexual ♀♀ are less fertile than parthenogenetic ones, which is in agreement with the sexual conflict predictions tested in this study." - 7004.** McPeck, M.; Brown, J.M. (2007): Clade age and not diversification rate explains species richness among animal taxa. *The American Naturalist* 169(4): E97-E106. (in English). ["Animal taxa show remarkable variability in species richness across phylogenetic groups. Most explanations for this disparity postulate that taxa with more species have phenotypes or ecologies that cause higher diversification rates (i.e., higher speciation rates or lower extinction rates). Here we show that clade longevity, and not diversification rate, has primarily shaped patterns of species richness across major animal clades: more diverse taxa are older and thus have had more time to accumulate species. Diversification rates calculated from 163 species-level molecular phylogenies were highly consistent within and among three major animal phyla (Arthropoda, Chordata, Mollusca) and did not correlate with species richness. Clades with higher estimated diversification rates were younger, but species numbers increased with increasing clade age. A fossil-based data set also revealed a strong, positive relationship between total extant species richness and crown group age across the orders of insects and vertebrates. These findings do not negate the importance of ecology or phenotype in influencing diversification rates, but they do show that clade longevity is the dominant signal in major animal biodiversity patterns. Thus, some key innovations may have acted through fostering clade longevity and not by heightening diversification rate." (Authors) The data set includes Odonata.] Address: McPeck, M., Dept Biol. (2007): Allozyme and mitochondrial DNA variability within the New Zealand damselfly genera *Xanthocnemis*, *Austrolestes*, and *Ischnura* (Odonata). *New Zealand Journal of Zoology* 34: 371-380. (in English). ["We collected larval damselflies from 17 sites in the North, South and Chatham Islands, and tested the hypotheses that: (1) genetic markers (e.g., allozymes, mtDNA) would successfully discriminate taxa; and (2) the dispersal capabilities of adult damselflies would limit differentiation among locations. Four species from three genera were identified based on available taxonomic keys. Using 11 allozyme loci and the mitochondrial cytochrome c-oxidase subunit I (COI) gene, we confirmed that all taxa were clearly discernible. We found evidence for low to moderate differentiation among locations based on allozyme (mean $F_{ST} = 0.09$)

and sequence (COI) divergence (<0.034). No obvious patterns with respect to geographic location were detected, although slight differences were found between New Zealand's main islands (North Island, South Island) and the Chatham Islands for *A. colsonis* (sequence divergence 0.030–0.034). We also found limited intraspecific genetic variability based on allozyme data (Hexp < 0.06 in all cases). We conclude that levels of gene flow/dispersal on the main islands may have been sufficient to maintain the observed homogeneous population structure, and that genetic techniques, particularly the COI gene locus, will be a useful aid in future identifications." 7017. Polhemus, D.A. (2007): Biology Recapitulates Geology: the Distribution of Megalagrion Damselflies on the Ko'olau Volcano of O'ahu, Hawai'i. *Bishop Museum Bulletin in Cultural and Environmental Studies* 3: 233-246. (in English). ["Populations of endemic *Megalagrion* damselflies breeding in upland streams have exhibited a progressive decline in both range and num-

bers on O'ahu since the late 1970s, based on analysis of historical collection data and results of recent surveys. In particular, conservation status surveys conducted from 1991 onward determined that the 4 upland stream-breeding taxa on the island, 3 of which are endemic to O'ahu, have disappeared from many catchments they formerly inhabited, particularly in the Wai'anāe Mountains and on the leeward side of the Ko'olau Mountains. The remaining populations on the island are now disproportionately concentrated on windward slopes of the latter range, where they are clustered around exposures of the core dike complex of the Ko'olau volcano. This geological formation traps groundwater in dike-segregated compartments, thereby producing permanent surface flow in the upper reaches of many windward Ko'olau gulches, coupled with naturally interrupted midreaches immediately below that block the upstream migration of invasive species. The discovery of this correlation between geology and damselfly distributions has allowed predictive location of additional colonies by using geological maps, permitting future surveys to be more accurately targeted, and providing an objective basis for the delimitation of habitat critical to the survival of these species." (Author)] Address: Polhemus, D.A., Hawaii State Department of Land and Natural Resources, Division of Aquatic Resources, 1151 Punchbowl St., Honolulu, Hawai'i 96813, USA. 7018. Preston, D.J.; Englund, R.A.; Mcs Hane, M.K.K. (2007): Translocation and monitoring efforts to establish a second population of the rare *Megalagrion xanthomelas* (Sélvs-Longchamps) on O'ahu, Hawai'i (Zygoptera: Coenagrionidae). *Bishop Museum Bulletin in Cultural and Environmental Studies* 3: 261-276. (in English). ["The last remaining population of *M. xanthomelas* resides in a 100 meter reach of stream located on the grounds of Tripler Army Medical Center, O'ahu. Because actions may be taken that might jeopardize this only known O'ahu population, it has been considered imperative to establish a second population to prevent *M. xanthomelas* from going extinct on O'ahu. An attempt to establish this species at a stream in the Dillingham area of O'ahu was made in 1998, but unfortunately was unsuccessful. Because the Tripler population is so small and restricted in distribution, a second effort at translocation was attempted at a new location. We estimated the population size of *M. xanthomelas* at the Tripler site in 1997 and again in 2003 by mark-recapture and concluded that the Tripler population was stable and could withstand the removal and translocation of a small number of adults and larvae. A stream site located in Makiki Valley was selected for its lack of alien predators such as crayfish, prawns, and mosquito fish, and a number of adults and immatures were translocated to the Makiki site in August 2004. Monitoring of the Tripler and the Makiki sites is ongoing and an additional translocation of *M. xanthomelas* to Makiki is planned. Future conservation plans should also include the assistance of from the general public through avenues such as stocking of backyard ponds with *M. xanthomelas*." (Authors)] Address: Preston, D.J., Hawai'i Biological Survey, Bishop Museum, 1525 Bernice Street, Honolulu, Hawai'i 96817, USA. E-mail: davidp@bishopmuseum.org

7021. Robillard, A.L. (2007): Seasonal dynamics of a riparian food web in the Oregon coast range mountains. M.Sc Thesis, Fisheries Science, Oregon State University: 14 + 100 pp. (in English). ["Riparian areas are ecotones where aquatically- and terrestrially-derived insect biomass is exchanged between habitats, presenting consumers with new sources of energy, and resulting in a reciprocal subsidy. The relative contribution of energy exchange and the resulting impacts on vertebrate riparian consumers, such as fish or birds, remains poorly understood. We explored this reciprocal exchange within Honeygrove watershed--an alder dominated riparian system within the Oregon Coast Range. Diet samples were collected from birds and fish along with a suite of insect samples during the summer and fall of 2003 and spring 2004. We detected seasonal differences in the abundance and biomass of terrestrial and aquatic insects available to riparian consumers. Spring provided the most adult aquatic insect biomass, and biomass was similar in summer; the fall emergence was an order of magnitude less than the other seasons. Prey sources differed between salmonids. Salmonid diet varied in biomass consumption by season and prey type. Coho salmon (*Oncorhynchus kitsutch*) on average, consumed more benthic aquatic biomass than adult aquatic insect biomass regardless of season. Despite the availability of externally derived prey, this species depended more on stream-derived resources in summer and fall but not during spring. In all sampling seasons, co-occurring cutthroat trout (*Oncorhynchus clarkii*), consumed more terrestrial invertebrate biomass than aquatic biomass, on average. Only in summer, cutthroat trout ate more adult aquatic than benthic aquatic biomass. In fall, their consumption of adult and benthic insect biomass was equal. During spring, cutthroat trout consumption, on average, consisted of more benthic aquatic biomass than adult aquatic biomass. Bird diet samples obtained from commonly encountered species such as Swainson's thrush, Song Sparrow, and Pacificslope Flycatcher, showed more terrestrial derived than aquatic prey during the summer sampling season. These data provided evidence of a reciprocal subsidy occurring in the Honeygrove watershed. There is potentially a seasonal synchrony between the two habitats such that when prey availability is low in one habitat, it is subsid-

ized by the other's high productivity." (Author) Both, the diet of Pacific-slope Flycatcher and the two fish species contained few Odonata.] Address: not stated

7022. Rodríguez, A.; Rodríguez, B.; Rumeu, B.; Nogales, M. (2007): Seasonal diet of the Grey Heron *Ardea cinerea* on an oceanic island (Tenerife, Canary Islands): indirect interaction with wild seed plants. *Acta Ornithol.* 42: 77–87. (in English). ["In 199 pellets analyzed a total of 7460 prey items were counted, 96.2% of which were arthropods. Aeshnidae larvae made up 66.1 % of the total prey items and were the main invertebrate group. Vertebrates constituted 3.8%, with reptiles and mammals being the main prey of this type (1.8% each). Despite the small size of the invertebrates, this group reached > 60% in terms of biomass. All the main prey items varied significantly among seasons. Odonata was the most important group in all seasons, reaching its maximum value in summer. In the case of vertebrates, reptiles were captured mainly in spring, mammals in winter. With regard to indirect interaction with seeds, a total of 901 seeds associated with lizard remains were found in 77 pellets, indicating that they had previously been consumed by these reptiles. External visual damage of seeds was low and only 1.1% was destroyed. No seeds germinated after the four-month germination experiment and practically all of them were unviable. In conclusion, these results indicate that Grey Heron diet on islands varies in comparison with continental zones, including an important number of invertebrates and reptiles. Furthermore, this bird acts as an opportunistic secondary seed disperser, although its ecological effect does not seem to be very significant for the dynamics of the Canary Island ecosystems." 7024. Samways, M.J. (2007): Insect conservation: A synthetic management approach. *Annual Review of Entomology* 52: 465-487. (in English). ["Threats to insect diversity range from habitat loss and invasive alien organisms to environmental contamination and biological

control. Many of the threats are synergistic, with the joint impact of habitat loss and global climate change being highly adversely synergistic. Recent research on insect conservation has elucidated some basic principles for conservation management. There are six basic principles that are interrelated and together provide guidelines for synthetic conservation management of insects. They are maintain reserves (principle 1), maintain as much quality landscape heterogeneity as possible (principle 2), reduce contrast between remnant patches and neighbouring disturbed patches (principle 3), outside reserves, introduce land sparing (principle 4), simulate natural conditions and disturbance (principle 5), and connect similar patches of quality habitat (principle 6). These six principles constitute a coarse-filter, landscape approach. Permeating all six is the principle of maintaining healthy population levels, which require the combined support of the metapopulation trio of large patch (habitat) size, good patch quality, and reduced patch isolation. In addition to these six coarse-filter principles is an overlay of the fine-filter, species approach, in which particular species are given focused attention and management." (Author) The paper includes references to Odonata.] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

7025. Schiefenhövel, P. (2007): Libellen- und Köcherfliegengemeinschaften im Naturpark Soonwald-Nahe. Diplomarbeit, Lehrstuhl für Tierökologie und Tropenbiologie, Julius-Maximilians Universität Würzburg: 133 pp. (in German, with English summary). ["More and more natural habitats and landscapes are getting disturbed. Animals and plants that populated these habitats disappeared or could switch to secondary habitats. Such secondary biotopes can be found in the Soonwald which can be characterized by boggy environment. Species living in forest ponds in the Soonwald are diverse and some of them are seldom. I investigated the diversity and composition of Odonata and Trichoptera communities in 22 of these small water bodies. The impact of several environmental factors (pond volume, water temperature, isolation, vegetation of the water bodies and the shorelines, underground of the water bodies) on the two aquatic insect orders was examined. Habitat selection of five endangered dragonflies (*Leucorrhinia dubia*, *Aeshna juncea*, *Sympetrum danae*, *Lestes dryas*, *L. virens vestalis*) was investigated and I tried to find out what kind of composition of environmental factors were responsible to their distribution. Diversity and composition of dragonflies were strongly influenced by the environmental factors and shade next to six other factors (altitude, vegetation cover of emergent, submerged or reeded plants, abundance of peat-bogs and pond volume) was the most important factor. The dragonfly community was not influenced by factors characterizing the boggy environment of the ponds. However, the occurrence and the reproductive success of three endangered dragonflies was influenced by environmental factors (abundance of peat-bogs, trophic level, water temperature) which usually characterize bog ponds. The diversity and composition of caddisflies were influenced by individual analysed parameters namely by water temperature, sediment depth and pond volume. Reproductive success of caddisflies could not be analysed because emergence traps used in this study could not sample the entire pond area. Finally, advantages and disadvantages of this sampling method

are discussed. Furthermore, recommendations for habitat conservation and establishments of boggy ponds are given." (Author)] Address: not stated

7026. Sipkay, C.S.; Hufnagel, L.; Révbesz, A.; Petrányi, G. (2007): Seasonal dynamics of an aquatic macroinvertebrate assembly (Hydrobiological case study of Lake Balaton No. 2). Applied ecology and environmental research 5(2): 63-78. (in English). ["In 2002, 2003 and 2004, we took macroinvertebrate (including some Odonata taxa) samples on a total of 36 occasions at the Badacsony bay of Lake Balaton. Our sampling site was characterised by areas of open water (in 2003 and 2004 full of reed-grass) as well as by areas covered by common reed (*Phragmites australis*) and narrowleaf cattail (*Typha angustifolia*). Samples were taken both from water body and benthic ooze by use of a stiff hand net. We have gained our data from processing 208 individual samples. We took samples frequently from early spring until late autumn for a deeper understanding of the processes of seasonal dynamics. The main seasonal patterns and temporal changes of diversity were described. We constructed a weather-dependent simulation model of the processes of seasonal dynamics in the interest of a possible further utilization of our data in climate change research. We described the total number of individuals, biovolume and diversity of all macroinvertebrate species with a single index and used the temporal trends of this index for simulation modelling. Our discrete deterministic model includes only the impact of temperature, other interactions might only appear concealed. Running the model for different climate change scenarios it became possible to estimate conditions for the 2070-2100 period. The results, however, should be treated very prudently not only because our model is very simple but also because the scenarios are the results of different models." 7030. Susa, K.; Watanabe, M. (2007): Egg production in *Sympetrum infuscatum* (Selys) ♀♀ living in a forest-paddy field complex (Anisoptera: Libellulidae). Odonatologica 36(2): 159-170. (in English). ["Although the larval habitats of *S. infuscatum* are paddy fields, all adults leave the paddy fields for forest gaps after emergence, and remain there during their sexually immature stages. In late summer when they have matured, some visit the paddy fields in tandem flight for oviposition. However, many ♀♀ remain perching in the forest gaps, where no mating behaviour is observed. To evaluate the habitat selection of *S. infuscatum* ♀♀ in the forest gaps, fecundity was examined by means of dissection. In the morning, the ♀♀ re♀♀ in the forest gaps loaded fewer mature eggs (ca 100) than did ovipositing ♀♀ in the paddy fields (ca 300). ♀♀ remaining in the forest gaps throughout the day were not willing to visit the paddy fields for oviposition due to the low egg number loaded. This could be because these ♀♀ were developing their eggs, having loaded more sub-mature eggs (ca 60) than ovipositing ♀♀ in the paddy fields (ca 30). As a result, in the evening, ♀♀ that had developed nearly 500 eggs appeared. In an artificial oviposition experiment, the ♀♀ in the paddy fields released their eggs significantly faster (60 eggs/min) than did those in the forest gaps (16 eggs/min), and released almost all of their eggs, while the ♀♀ in the forest gaps retained a considerable number of eggs in their ovaries. Although ♀♀ load ovarioles irrespective of their age, the number of immature eggs per ovariole decreased with age. Consequently, a ♀♀ might have laid more than 2000 eggs in her life span. ♀♀ must visit the paddy fields cyclically several times in a single month and stay in the forest gaps during the other days." 7034. Tupinambas, T.H.; Callisto, M.; Santos, G.B. (2007): Benthic macroinvertebrate assemblages structure in two headwater streams, south-eastern Brazil. *Revista Brasileira de Zoologia* 24(4): 887-897. (in English, with Portuguese summary). ["From December 2003 to September 2004, benthic macroinvertebrates (BM), fishes, water and sediment were collected quarterly at six stations in two streams of the upper São Francisco River basin, south-eastern Brazil. We evaluated the ecological conditions, habitat diversity, water quality, composition and structure of BM communities, as well as the food habits of the local fish fauna. [...] We found 45 BM taxa, and Chironomidae (68%), Oligochaeta (10%) and Elmidae (8.5%) showed the highest abundances. From the stomach contents analysis of 13 fish species, 26 BM taxa were found, including four that were not collected in the sediment samples, being Chironomidae the dominant group (> 60%). Our results show that human activities such as forest clearing, agriculture and cattle rising have altered the habitat diversity in freshwater ecosystems in a process that affects the aquatic biota and thus the food availability to the fish fauna. The results also highlight the importance of the fish stomach contents analysis as a complementary tool in BM inventories." (Authors) Reference is made to "Odonata (Libellulidae, Coenagrionidae, Gomphidae)" without further details.] Address: Tupinambas, T. 7035. Ubukata, H.; Kurauchi, Y. (2007): Assessment of lake environment using dragonfly assemblage. A case study at Lake Takkobu, Kushiro Marsh, northern Japan. *Japanese Journal of Limnology* 68: 131-144. (in Japanese, with English summary). ["A periodical census of

mature dragonflies (Odonata) was conducted at 11 investigation sites along the shore of Lake Takkobu, Kushiro Marsh, Hokkaido in 2004, resulting in a record of 2,572 individuals of 18 species belonging to six families. Dragonfly abundance is analyzed in relation with the following five environmental factors: i.e., width of reed bed, water depth, coverage of aquatic macrophytes, ratios of gravels(=2mm) and silt(=0.075mm). The two-dimensional pattern in the dispositions of investigation sites observed on a detrended correspondence analysis (DCA) diagram of dragonflies broadly coincided with that of an actual pattern on the map, whereas this was not the case for that of a DCA diagram of the environmental factors. As the result of a canonical correspondence analysis (CCA) using both dragonfly and environmental data, the investigation sites were separated into four clusters: i.e., deep sites with rich aquatic macrophytes and wide reed beds; deep sites scarce in macrophytes; shallow sites with poor macrophytes and narrow reed beds; and shallower sites with an abundance of macrophytes. Based on the results of the CCA, most dragonfly species are selected as possible indicators of the environmental conditions of the lake: e.g., *Cercion calamorum* (Ris), *Enallagma circumlatum* Selys and six other species as those preferring sites rich in aquatic macrophytes, *E. circumlatum*, *Epitheca bimaculata sibirica* and five others as those favouring wider reed beds and deeper water; *Sympetrum striolatum imitoides* Bartenef, *Trigomphus melampus* (Sel.) and three others as those preferring sites scarce in macrophytes; *Orthetrum albistylum speciosum* (Uhler) preferring the shallowest water with the fewest macrophytes and reed beds; and *T. melampus* and *Sympetrum croceolum* (Sel.) favouring deeper water. Finally, some other factors that may influence the microdistribution of dragonflies in the lake are discussed." (Authors)] Address: Ubukata, H., Hokkaido Univ. 7036. Urban, M.C. (2007): Predator size and phenology shape prey survival in temporary ponds. *Oecologia* 154: 571-580. (in English). ["Theoretical efforts suggest that the relative sizes of predators and their prey can shape community dynamics, the structure of food webs, and the evolution of life histories. However, much of this work has assumed static predator and prey body sizes. The timing of recruitment and the growth patterns of both predator and prey have the potential to modify the strength of predator-prey interactions. In this study, I examined how predator size dynamics in 40 temporary ponds over a 3-year period affected the survival of spotted salamander (*Ambystoma maculatum*) larvae. Across communities, gape-limited predator richness, but not size, was correlated with habitat duration (pond permanence). Within communities, mean gape-limited predator size diminished as the growing season progressed. This size reduction occurred because prey individuals grew into a body size refuge and because the largest of the predators left ponds by mid-season. Elevated gape-limited predation risk across time and space was predicted by the occurrence of two large predatory salamanders: marbled salamander larvae (*Ambystoma opacum*) and red-spotted newt adults (*Notophthalmus viridescens*). The presence of the largest gape-limited predator, *A. opacum*, predicted *A. maculatum* larval survival in the Weld. The distribution of large predatory salamanders among ponds and across time is expected to lead to differing community dynamics and to gener-

ate divergent natural selection on early growth and body size in *A. maculatum*. In general, a dynamic perspective on predator size often will be necessary to understand the ecology and evolution of species interactions. This will be especially true in frequently disturbed or seasonal habitats where phenology and ontogeny interact to determine body size asymmetries. [...] The most abundant predator taxa were the caudates *Notoptthalmus viridescens* adults and *Ambystoma opacum* larvae, the anuran *Rana clamitans*, odonate larvae, including *Sympetrum*, *Aeshna*, *Pachydiplax*, and *Leucorhinia*, the coleopteran *Dytiscus*, the hemipterans *Lethocerus* and *Notonecta*, and the megalopteran *Chauliodes*." 7038. Van Gossum, H.; Beatty, C.D.; Charlat, S.; Waqa, H.; Markwell, T.; Skevington, J.H.; Tuiwawa, (2007): Male rarity and putative sex-role reversal in Fijian damselflies (Odonata). *Journal of Tropical Ecology* 23: 591-598. (in English). ["Behavioural sex-role reversal occurs when ♂♂ and ♀♀ exchange their standard roles in territorial defence or parental care. One circumstance under which sex-role reversal may occur is when ♂♂ are a limiting resource, so that ♀♀ have to compete for access to mates. Here we report on male rarity and male and female behaviour of species within the damselfly genus *Nesobasis*, endemic to Fiji. Earlier reports suggested that, in some members of this genus, ♂♂ were seldom observed and that ♀♀ of these species were consequentially territorial, a phenomenon described as 'sex-role reversal'. Quantitative estimation of the ratio of adult ♂♂ to ♀♀ at 15 localities in 13 *Nesobasis* species (1489 individuals) indicated that ♂♂ were extremely rare in some species, yet common in others. This interspecific variability in male rarity cannot be explained by elevation or habitat. Formal observations of three species with abundant ♂♂ revealed that ♂♂ of these species were highly territorial: they physically challenged intruders while remaining within a confined area. By contrast, in three species where ♂♂ were consistently rare or absent, ♀♀ were not territorial: instead, they moved widely and were primarily engaged in oviposition. While we do not know the underlying reason for the unusual rarity of ♂♂ at oviposition sites in some

species, it is clear that this rarity has not provided sufficient selection pressure to generate genuine sex-role reversal." (Authors)] Address: Gossum, H. van, Evolutionary Biology Group, University of Antwerp (RUCA), Groenenborgerlaan 171, B-2020 Antwerp, Belgium. E-mail: hvgossum@ruca.ua.ac.be

7039. von Ellenrieder, N.; Garrison, R.W. 7040. Watanabe, M.; Iwata, S. (2007): Evaluation of line transect method for estimating *Mortonagrion hirosei* *Asahina* abundance in a dense reed community (Zygoptera: Coenagrionidae). *Odonatologica* 36(3): 275-283. (in English). ["The results of the mark and recapture method for estimating the number of *M. hirosei* adults were compared to those of census counts using the line transect method carried out in the same habitat, a dense reed community established in brackish water. The mark and recapture method gave a daily estimate of about 1000 and 800 individuals of each sex at the peak population in early July of 2003 and 2004, respectively. These results did not agree with the estimate from the census counts, giving 600 S at that time in the same habitat. Some limitations of the line transect method were discussed for estimates of adults perching in the understory of the dense reed community. However, a relationship was observed with regard to daily population estimates of the line transect method and the mark and recapture method, indicating that the line transect method can be an effective tool for monitoring populations of the endangered damselflies inhabiting such a dense plant community." 7044. Wohlfahrt, B.; Mikolajewski, D.J.; Joop, G.; Vamosi, S.M. (2007): Ontogenetic changes in the association between antipredator responses and growth variables. *Ecological Entomology* 32(5): 567-574. (in English). ["1. An organism's growth parameters are expected to depend on environmental constraints, such as predation risk and food supply. However, antipredator responses, food intake, and thus growth of an animal may be mediated by behavioural traits, which are likely to differ among developmental stages. In this study, it was investigated how the relationship between growth and behavioural antipredator responses changes during ontogeny in the time-constrained dragonfly species *Libellula depressa*, and which factors influenced specific behavioural decisions at different points in ontogeny. 2. The results revealed that behavioural strategies differed between larval developmental stages, depending on associations between larval growth, food supply, and predation risk. Early in ontogeny, faster development was correlated with high larval activity and high food supply. This resulted in high activity levels under high food conditions irrespectively of predator presence, and under low food supply in predator absence only. In the intermediate stage of development, all larvae displayed a high activity level, which was correlated in general with fast development. However, growth later in ontogeny was not only influenced by the activity level, but also by predator presence and food supply, with larvae reared under high food supply and/or in presence of predators attaining a higher final mass. Thus, not only the way in which larval growth parameters and behaviour are related changed during development, but also whether the factors influenced larval growth and behaviour. Once the larvae reached the ultimate stage of development, in which they overwinter, behavioural patterns observed were consistent with model predictions. 3. It is advocated that behavioural plasticity of prey organisms in different developmental stages should be analysed in the context of associated growth variables." 7046. Abbott, J.K.; Bensch, S.; Gosden, T.P.; Svensson, E.I. (2008): Patterns of differentiation in a colour polymorphism and in neutral markers reveal rapid genetic changes in natural damselfly populations. *Molecular Ecology* 17(6): 1597-1604. (in English). ["The existence and mode of selection operating on heritable adaptive traits can be inferred by comparing population differentiation in neutral genetic variation between populations (often using F_{ST} values) with the corresponding estimates for adaptive traits. Such comparisons indicate if selection acts in a diversifying way between populations, in which case differentiation in selected traits is expected to exceed differentiation in neutral markers [F_{ST} (selected) > F_{ST} (neutral)], or if negative frequency-dependent selection maintains genetic polymorphisms and pulls populations towards a common stable equilibrium [F_{ST} (selected) < F_{ST} (neutral)]. Here, we compared F_{ST} values for putatively neutral data (obtained using amplified fragment length polymorphism) with estimates of differentiation in morph frequencies in the colour-polymorphic damselfly *Ischnura elegans*. We found that in the first year (2000), population differentiation in morph frequencies was significantly greater than differentiation in neutral loci, while in 2002 (only 2 years and 2 generations later), population differentiation in morph frequencies had decreased to a level significantly lower than differentiation in neutral loci. Genetic drift as an explanation for population differentiation in morph frequencies could thus be rejected in both years. These results indicate that the type and/or strength of selection on morph frequencies in this system can change substantially between years. We suggest that an approach to a common equilibrium morph frequency across all populations, driven by negative frequency-dependent selection, is the cause of these temporal changes. We conclude that inferences about selection obtained by comparing F_{ST} values from neutral and adaptive genetic variation are most useful when spatial and temporal data are available from several populations and time points and when such information is combined with other ecological sources of data." 7047. Abbott, J.K.; Svensson, E.I. (2008): Ontogeny of sexual dimorphism and phenotypic integration in heritable morphs. *Evol. Ecol.* 22: 103-121. (in English). ["In this study we investigated the developmental basis of adult phenotypes in a non-model organism, a polymorphic damselfly (*Ischnura elegans*) with three female colour morphs. This polymorphic species presents an ideal opportunity to study intraspecific variation in growth trajectories, morphological variation in size and shape during the course of ontogeny, and to relate these juvenile differences to the phenotypic differences of the discrete adult phenotypes; the two sexes and the three female morphs. We raised larvae of different families in individual enclosures in the laboratory, and traced morphological changes during the course of ontogeny. We used principal components analysis to examine the effects of Sex, Maternal morph, and Own morph on body size and body shape. We also investigated the larval fitness consequences of variation in size and shape by relating these factors to emergence success. ♀♀ grew faster than ♂♂ and were larger as adults, and there was sexual dimorphism in body shape

in both larval and adult stages. There were also significant effects of both maternal morph and own morph on growth rate and body shape in the larval stage. There were significant differences in body shape, but not body size, between the adult female morphs, indicating phenotypic integration between colour, melanin patterning, and body shape. Individuals that emerged successfully grew faster and had different body shape in the larval stage, indicating internal (non-ecological) selection on larval morphology. Overall, morphological differences between individuals at the larval stage carried over to the adult stage. Thus, selection in the larval stage can potentially result in correlated responses in adult phenotypes and vice versa." 7048. Adebote, D.A.; Oniye, S.J.; Muhammed, Y.A. (2008): Studies on mosquitoes breeding in rock pools on inselbergs around Zaria, northern Nigeria. *J. Vector. Borne Dis.* 45: 21-28. (in English). ["Background & objectives: Rainwater often collects in depressions on rocks to form pools that are ideal breeding sites of mosquito vectors of diseases. Knowledge on the existence of disease vectors in these remote and relatively inaccessible locations could improve epidemiologic understanding and control capabilities. This study identifies mosquito species, their relative abundance and physicochemical characteristics of breeding microhabitats in rock pools on four inselbergs in northern Nigeria. Methods: Soup ladle dipper was used to obtain representative samples of larval mosquitoes breeding in 141 rock pools on four inselbergs. Physicochemical parameters (depth, electrical conductivity, pH, surface area, temperature and total dissolved solids) of the pools were determined. Larvae were preserved in 70% alcohol and identified microscopically to species using taxonomic keys. Statistical correlation analysis and ANOVA were used to test the associations between physicochemical parameters and mosquito abundance, and for differences amongst inselbergs. Results: Of 2991 larvae, five species of mosquito distributed in three genera (*Anopheles*, *Aedes* and *Culex*) including *Ae. vittatus* (92.88%), *An. ardensis* (0.13%), *An. distinctus* (1.67%), *An. wilsoni* (0.13%) and *Cx. ingrami* (5.18%) bred in the rock pools. Up to five species occurred per pool in various conspecific and heterogeneric combinations. Except for *Ae. vittatus*, the physicochemical parameters of the pools correlate significantly with species abundance. Conclusion: *Ae. vittatus*, a potential vector of yellow fever in Nigeria breeds profusely in rock pools on inselbergs around Zaria. For comprehensive vector implication vector implication and control, rock pools should be amongst the habitats of focus in yellow fever epidemiology." (Authors) The discussion contains references to Odonata as predators of mosquitoes.] Address: Adebote, D.A, Department of Biological Sciences, Ahmadu Bello University, Zaria, Nigeria

7049. Baskinger, G.M.; Ware, J.L.; Kornell, D.D.; May, M.L.; Kjer, K.M. (2008): A phylogeny of *Celithemis* inferred from mitochondrial and nuclear DNA sequence data and morphology (Anisoptera: Libellulidae). *Odonatologica* 37(2): 101-109. (in English). ["The dragonfly genus *Celithemis* consists of 8 species, some of them common and brightly coloured, that are confined largely to eastern North America. Several species have been used in behavioural, ecological, and morphological stu-

dies, but their intrageneric phylogeny is unclear. In this paper is provided a phylogeny based on morphology and on data from mitochondrial and nuclear DNA sequences of multiple individuals of each species. The genus appears to be monophyletic, with one nested species pair (*C. amanda*+*C. martha*) receiving strong bootstrap support by both parsimony or maximum-likelihood criteria as well as high Bayesian posterior probability. A second group (*C. bertha*, *C. elisa*, *C. ornata* and *C. fasciata*) is well-supported in Bayesian analysis but only weakly by parsimony and maximum-likelihood bootstrap values. *C. verna* and *C. eponina* are probably basal to both these groups, but their relationship to each other is unclear. All individuals assigned to a species recognized on morphological grounds were recovered as monophyletic. The problematic taxa, *C. monomalaena* and *C. bertha leonora*, are shown definitively to be synonyms of *C. fasciata* and *C. bertha*, respectively." (Authors)] Address: May, M.L., Dept Entom., New Jersey Agricultural Experiment Station, Cook College, Rutgers Univ., New Brunswick, NJ 08901-8524, USA. E-mail: may@aesop.rutgers.edu

7050. Bedjanic, M. (2008): Notes on the synonymy, distribution and threat status of *Elatoneura oculata* (Kirby, 1894), an endemic damselfly from Sri Lanka (Zygoptera: Protoneuridae). *Odonatologica* 37(2): 145-150. (in English). ["Based on an examination of the material in the Natural History Museum in London, *Elatoneura bigemmata* Lieftinck, 1971 is a junior synonym of *E. oculata* (Kirby, 1894). A map of the currently known distribution of the species is provided. According to the IUCN criteria, due to its very small area of occupancy in SW Sri Lanka and pressure on its habitat, *E. oculata* is to be classified as globally endangered (EN)." 7051. Bernard, R.; Kosterin, O.E. (2008): Field notes of two hunters for *Nehalennia speciosa* in boggy Vasyugan Plain, West Siberia. *IDF-Report* 12: 1-34. (in English). ["One important result of our expedition is the picture of the summer aspect of the odonate fauna in these mostly primeval and remote boggy areas. In total, 34 odonate species were recorded, that is quite a few for an area of that size situated at such latitudes in Siberia and having a rather narrow spectrum of habitats predominated by large complexes of *Sphagnum* bogs and fens, and specific rivers bringing peaty waters. Our supposition that the boggy areas of the Vasyugan Plain in the West Siberian Lowland are a huge reservoir of *N. speciosa* was confirmed splendidly. It is worth noticing, however, that, although seemingly omnipresent in pools of *Sphagnum* bogs, it is not so abundant there. Possibly we visited this area near the end of the flight period of *N. speciosa* there, but nevertheless, the pattern of the species occurrence in the plain seems to be based on very numerous and dense but small local populations. Therefore, taking into account the total size of this giant boggy area, the population numbers in the Vasyugan Plain is certainly enormous. However, it is a rather recent picture, since the bogs are 5200 years old at most in some restricted areas, while the peatmoss prevailing stage of their development began just some 1500 years ago. Generally, the complex of peat-moss bog species is flourishing in the studied area. Along with *N. speciosa*, in all such habitats we recorded tyrphobiontic *Aeshna subarctica*, the records of which had hitherto

also been scarce in Siberia. The species is certainly very abundant in the Vasyugan Plain and is well separated spatially from two other co-occurring aeshnids in Sphagnum bogs – *A. juncea* and *A. crenata*. The picture we have drawn of the spatial, temporal and behavioural segregation between these aeshnids confirmed and developed earlier observations from Europe (Bernard 2002, unpublished data). One of the members of the mentioned complex of species, *C. johanssoni*, abundant in primary habitats – small bog water bodies – is completely missing in large oxbows and man-made large ponds. This absence seems to be related to higher nutrient levels and inappropriate or too poor vegetation. One mystery of peat-moss complexes remained undisclosed: this is the breeding places of the generally very abundant *S. arctica*. According to our observations the majority of so numerous individuals ceased their maturation period and disappeared, most probably to their breeding places. However, despite visiting various places in the peat-moss complexes, we failed to observe a single territorial male or ovipositing female. This resembles the situation described by Dijkstra & Koese (2001) from the Belarussian Polesse, where huge numbers of immature *arctica* were observed while at the same time there was no observation of true *arctica* reproduction or its original habitats. It seems that the original, stem habitats of this species may be situated in more central, largely flooded or more sinking parts of large Sphagnum complexes, may be also in large areas of mesotrophic fens overgrown with *Caricetum lasiocarpae*. The study area brought an interestingly high percentage of androchrome ♀♀ of *Calopteryx splendens* and dark-winged *Somatochlora* individuals, especially noteworthy in *S. flavomaculata*. Worth noticing was also the spatially separated occurrence of two subspecies (species?) of *Enallagma cyathigerum*: *cyathigerum* and *risi*. The records of *Gomphus vulgatissimus* and *Shaogomphus postocularis* extended the known range of these species 170–225 km and 185 km north, respectively. The former species, earlier known in Siberia from the only group of localities near Novosibirsk, turned out to be widely distributed and fairly abundant in the area of studies, and the latter was for the first time found west of the Ob'. From the zoogeographical point of view, records of *Leucorrhinia albifrons* and *L. pectoralis* were also very interesting, shifting their known northern range limits significantly to the north. As our studies showed, *Lestes virens*, *Coenagrion puella*, *C. pulchellum*, *Somatochlora flavomaculata* and *Sympetrum sanguineum* also reach or cross their hitherto known northern range limits in the studied area (cf. Belyshev 1973). To conclude, some absences should be stressed, both of the typical northern (boreal-alpine) species, such as *Aeshna caerulea* and *Somatochlora alpestris* (although theoretically they could be recorded, see Belyshev 1973) and some species which are common 200 km to the south, at Novosibirsk, such as *Aeshna mixta* or *Sympetrum pedemontanum* (Kosterin et al. 2001). We quite expected to meet *Aeshna serrata*, which is known even more northerly (Belyshev 1973), but there seemed to be no suitable habitats for it." 7054. Bybee, S.M.; Ogden, T.H.; Branham, M.A.; Whiting, M.F. (2008): Molecules, morphology and fossils: a comprehensive approach to odonate phylogeny and the evolution of the odonate wing. *Cladistics* 24: online first. (in English). ["We undertook a comprehensive morphological and molecular phylogenetic analysis of dragonfly phylogeny, examining both extant and fossil lineages in simultaneous analyses. The legitimacy of higher-level family groups and the phylogenetic relationship between families were tested. Thirteen families were supported as monophyletic (Aeshnidae, Calopterygidae, Chlorocyphidae, Euphaeidae, Gomphidae, Isostictidae, Lestidae, Libellulidae, Petaluridae, Platystictidae, Polythoridae, Pseudostigmatidae and Synthemitidae) and eight as non-monophyletic (Amphipterygidae, Coenagrionidae, Corduliidae, Megapodagrionidae, Protoneuridae and Synlestidae), although Perilestidae and Platycnemididae were recovered as monophyletic under Bayesian analyses. Nine families were represented by one species, thus monophyly was not tested (Epiophlebiidae, Austropetaliidae, Chlorogomphidae, Cordulegastriidae, Macromiidae, Chorismagrionidae, Diphlebiidae, Lestoideidae and Pseudolestidae). Epiprocta and Zygoptera were recovered as monophyletic. *Ditaxinera* is supported as the sister lineage to Odonata, Epiophlebiidae and the lestid-like damselflies are sister to the Epiprocta and Zygoptera, respectively. Austropetaliidae + Aeshnidae is the sister lineage to the remaining Anisoptera. *Tarsophlebia*'s placement as sister to Epiprocta or as sister to Epiprocta + Zygoptera was not resolved. Refinements are made to the current classification. Fossil taxa did not seem to provide signals crucial to recovering a robust phylogeny, but were critical to understanding the evolution of key morphological features associated with flight. Characters associated with wing structure were optimized revealing two wing character complexes: the pterostigma–nodal brace complex and the costal wing base & costal–ScP junction complex. In turn, these two complexes appear to be associated; the pterostigma–nodal brace complex allowing for further modification of the wing characters comprised within the costal wing base & costal–ScP junction complex leading the modern odonate wing." 7056. Carle, F.L.; Kjer, K.M.; May, M.L. (2008): Evolution of Odonata, with special reference to Coenagrionoidea (Zygoptera). *Arthropod Systematics & Phylogeny* 66(1): 37-44. (in English). ["A phylogeny including 26 families of Odonata is presented based on data from large and small subunit nuclear and mitochondrial ribosomal RNAs and part of the nuclear EF-1a. Data were analyzed using Bayesian methods. Extant Zygoptera and Anisoptera are monophyletic. The topology of Anisoptera is ((Austropetalidae, Aeshnidae) (Gomphidae (Petaluridae ((Cordulegastridae (Neopetalidae, Chlorogomphidae)) ((Synthemistidae, Gomphomacromiidae) (Macromiidae (Cordulidae s.s., Libellulidae)))))). Each of the major groups among anisopterans is well supported except the grouping of Neopetalia with Chloropetalia. Lestidae and Synlestidae form a group sister to other Zygoptera, and Coenagrionoidea are also monophyletic, with the caveat that Isostictidae, although well supported as a family, was unstable but not placed among other coenagrionoids. Calopterygoidea are paraphyletic and partly polytomous, except for the recovery of (Calopterygidae, Hetaeriniidae) and also (Chlorocyphidae (Epallagidae (Diphlebiinae, Lestoidinae))). Support for Epallagidae as the sister group of a clade (Diphlebiinae, Lestoideinae) is strong. Within Coenagrionoidea, several novel relationships appear to be well supported. First, the Old World disparoneurine protoneurids are nested within Platycnemididae and well separated from the protoneurine, *Neoneura*. The remaining coenagrionids are divided into two well-supported subdivisions. The first includes Pseudostigmatinae, stat. nov., Protoneurinae, a group of coenagrionids mostly characterized by having an angulate frons, and Argiinae (Argia). The second division includes typical Coenagrionidae." 7060. Catling, P.M.; Hughes, M. (2008): Variation in Canadian *Gomphus fraternus* (Odonata: Gomphidae) in relation to the recognition of subspecies *manitobanus*. *Canadian Entomologist* 140: 327-337. (in English, with French summary). ["Seven characters were evaluated in 146 specimens of *G. fraternus*, including both subspecies, *G. f. fraternus* (Say) and *G. f. manitobanus* Walker, to clarify their circumscription and geographic occurrence in Canada. Specimens corresponding to subspecies *manitobanus* were all from the Assiniboine and Red rivers and formed a discrete group in a principal components analysis, supporting their taxonomic recognition. Their distribution in Canada suggests a separation of subspecies near the boundary of the prairie ecozone in central southern Manitoba. In subspecies *fraternus* the extensor surfaces of the tibiae are largely black, with pale areas often lacking and rarely up to 50% of the segment length. Similarly the dorsal surface of abdominal segment 9 is largely black. If there is a pale area, it is <1 mm long. In subspecies *manitobanus* the extensor surfaces of the tibiae have pale markings on =50% of their lengths and the dorsal surface of abdominal segment 9 has a dorsal yellow spot =1.4 mm long. Widespread dragonflies in western North America are paler in drier climates and the increased pale colouration in the western subspecies *manitobanus* corresponds to this trend. Currently known only from Manitoba, subspecies *manitobanus* may occur in prairie habitats of the Midwestern United States, based on reports of pale individuals in that region." (Authors)] Address: Catling, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

7061. Chakona, A.; Phiri, C.; Magadza, C.H.D.; Brendonck, L. (2008): The influence of habitat structure and flow permanence on macroinvertebrate assemblages in temporary rivers in northwestern Zimbabwe. *Hydrobiologia* 607(1): 199-209. (in English). ["Temporary rivers within the Nyaodza-Gachegache subcatchment in northwestern Zimbabwe were investigated to examine the role of flow permanence and habitat structure on macroinvertebrate community composition. Macroinvertebrate communities of intermittent and ephemeral rivers displayed significant differences in the number of taxa, macroinvertebrate abundance, Shannon & Simpson diversity indices and in size class structure. Intermittent sites were characterised by higher numbers of taxa, diversity and Ephemeroptera and Trichoptera richness compared to ephemeral sites. The fauna of ephemeral sites was dominated by a single taxon (Afrobaetodes) (Eph., Baetidae) whilst larger sized taxa (e.g.

Elassoneuria (Eph., Oligoneuriidae), Dicroptilum (Eph., Baetidae), Aethaloptera (Trichoptera, Hydropsychidae), Pseudagrion (Odonata, Coenagrionidae) and Tholymis (Od., Libellulidae) were exclusively restricted to intermittent sites. Clear differences were observed between sand, gravel, cobble and vegetation habitats. Vegetation and cobbles supported distinct communities, with some taxa exclusively restricted either to vegetation (e.g. Pseudagrion, Leptocerina (Trich., Leptoceridae), Cloeon (Eph., Baetidae), Afronurus (Eph., Heptageniidae) and Povilla (Eph., Polymitarcidae) or cobble (e.g. Aethaloptera & Dicroptilum) habitats. In terms of ensuring optimum diversity within the subcatchment, we consider conservation of critical habitats (cobbles and vegetation) and maintenance of natural flows as the appropriate management actions." Address: Chakona, A., Univ. Lake Kariba Research Station, PO Box 48, Kariba, Zimbabwe. E-mail: achakona@yahoo.com

7062. Chelmick, D.C.; Pickess, B.P. (2008): Trithemis kirbyi Selys in southern Spain (Anisoptera: Libellulidae). Notulae odonologicae 7(1): 4-5. (in English). [The common African dragonfly, T. kirbyi, is recorded from southern Spain on 29 May 2007 near Manilva. As far as the authors can ascertain this is the first time this species has been observed in mainland Europe.] Address: Chelmick, D.C., High Beech Lane, Haywards Heath, West Sussex, RH16 1SQ, UK. 7063. Collier, K.J.; Lill, A. (2008): Spatial patterns in the composition of shallow-water macroinvertebrate communities of a large New Zealand river. New Zealand Journal of Marine and Freshwater Research 42: 129-141. (in English). ["Identifying the environmental factors influencing biotic patterns in large rivers will assist with extrapolating biological monitoring results to broader scale conclusions about river condition. In the present study, we collected macroinvertebrates and physico-chemical data at 47 shallow-water (<1-m deep) sites, including nine sites at major tributary junctions, during summer along the lower Waikato River, North Island, New Zealand. Macroinvertebrate communities were dominated by a few relatively abundant and widespread taxa. Upper site samples were characterised by high relative abundances of Diptera, but the significance of this group declined further downstream where Crustacea became more dominant. Overall, more taxa (36) were found at tributary junctions than at mainstem sites within four hydrogeomorphic zones (22-31 taxa per zone). Significant differences among faunal groups identified in a cluster analysis on relative abundance data were detected for the percentage of wood sampled, and for water conductivity which increased downstream at mainstem sites and was high at some junction sites. Non-metric multidimensional scaling of percentage abundance data revealed differences in community composition among zones, and among some mainstem and tributary junction sites. Geographic position (eastings and northings) was significantly correlated with taxa richness and community evenness (Pielou) at mainstem sites (excluding tributary junctions), reflecting an increase in sample diversity and less equitable taxonomic dominance with distance down river. Overall, these results point to an interplay between habitat patchiness and successional and hydrogeomorphic processes influencing macroinvertebrate community composition in the lower Waikato River. Such multiscale variations need to be accounted for in the design of invertebrate biomoni-

oring programmes if they are to represent the ecological condition of large river environments." (Authors) The list of taxa includes Austrolestes colenonensis, Xanthocnemis zealandica, and Anisoptera sp.. X. zealandica builds comparable high abundances in most of the sample localities especially the upper reaches of the river.] Address: Collier, K.J., Environment Waikato, P. O. 7064. Contreras-Garduno, J.; Cordoba-Aguilar, A.; Peralta-Vazquez, H.; Jimenez-Cortes, J.G.; Luna (2008): Differences in immune ability do not correlate with parasitic burden in two Zygoptera species (Calopterygidae, Coenagrionidae). Odonatologica 37(2): 111-118. (in English). ["Differences in phenoloxidase (PO) and hydrolytic enzymes (HE) activity, two key components in insect immune ability, were investigated in Hetaerina americana and Argia tezpi, to see if they are correlated with patterns of gregarine and mite infection. The prediction was that the species with the more robust immune responses would show a less intense parasitic burden. Fully mature adults of both sexes were used. No clear pattern was found: H. americana had higher PO activity while A. tezpi had higher HE activity but the latter species had a higher parasitic load for both parasites. Several possible explanations are discussed. However, it seems most likely that either the immune responses measured may be traded-off with other non-immune functions in which both species differ in investment or that both immune components may be traded-off with each other." 7067. De Block, M.; Slos, S.; Johansson, F.; Stoks, R. (2008): Integrating life history and physiology to understand latitudinal size variation in a damselfly. Ecography 31(1): 115-123. (in English). ["Our understanding of latitudinal life history patterns may benefit by jointly considering age and mass at maturity and growth rate. Additional insight may be gained by exploring potential constraints through pushing growth rates to their maximum and scoring physiological cost-related variables. Therefore, we reared animals of a univoltine Spanish

and Belgian population and of a semivoltine Swedish population of the damselfly *Enallagma cyathigerum* (spanning a latitude gradient of ca 2350 km) in a common environment from the eggs until adult emergence and exposed them to a transient starvation period to induce compensatory growth. Besides age and mass at maturity and growth rate we also scored investment in energy storage (i.e. triglycerides) and immune function (i.e. total activity of phenoloxidase). At emergence, body mass was greater in Spain and Sweden and lower in Belgium, suggesting a genetic component for the U-shaped latitudinal pattern that was found also in a previous study based on field-collected adults. The mass difference between univoltine populations can be explained by the shorter development time in the Belgian population, and this despite a higher growth rate, a pattern consistent with undercompensating countergradient variation. In line with the assumed shorter growth seasons, Belgian and Swedish animals showed higher routine growth rates and compensatory growth after transient starvation. Despite a strong link with metabolic rates (as measured by oxygen consumption) populations with higher routine growth rates had no lower fat content and had higher immune function (i.e. immune function decreased from Sweden to Spain), which was unexpected. Rapid compensatory growth did, however, result in a lowered immune function. This may contribute to the absence of perfect compensating countergradient variation in the Belgian population and the lowest routine growth rates in the Spanish population. Our results underscore the importance of integrating key life historical with physiological traits for understanding latitudinal population differentiation." 7068. De Block, M.; Campero, M.; Stoks, R. (2008): Developmental costs of rapid growth in a damselfly. *Ecological Entomology* 33(2): 313-318. (in English). ["1. Developmental costs of rapid growth in terms of increased fluctuating asymmetry are expected to contribute to the widespread occurrence of growth rates below the physiological maximum, but have rarely been demonstrated. Here, these costs are studied for the first time in an invertebrate, *Lestes viridis*, using a rearing experiment where early- and late-hatched larvae of both sexes were reared at decreasing or permanent water levels. 2. Late-hatched animals were more asymmetrical than early-hatched animals except for ♂♂ in the drying treatment. Also, ♀♀ were more asymmetrical than ♂♂ except in early-hatched animals in the drying treatment. 3. The data presented suggest that in ♀♀ but not in ♂♂ treatment groups with higher growth rates have more asymmetrical wings. However, at the individual level no relationship between growth rate and asymmetry was present. 4. Possible reasons why the suggested trade-off between growth and developmental instability was not present at the individual level, and at the group level only in ♀♀, are discussed." 7069. De Block, M.; McPeck, M.; Stoks, R. (2008): Stronger compensatory growth in a permanent-pond *Lestes* damselfly relative to temporary-pond *Lestes*. *Oikos* 117(2): 245-254. (in English). ["Compensatory growth where animals compensate for time stress or

transient nutritional or thermal stress by accelerating their growth rate is widespread. We know, however, relatively little about the evolution and ecological correlates of compensatory growth. For this we need studies on congeneric species with known phylogenetic relationships that also focus on the associated largely understudied costs. Here we tested for compensatory growth and associated costs in response to time stress (manipulated by photoperiod) and a transient period of starvation or cooling in larvae of the permanent-pond damselfly *Lestes eurinus*, and compare the results with former studies on temporary-pond *Lestes*. Larvae showed full compensation in body mass at emergence for all combinations of time stress and starvation or cooling. Unexpectedly, compensatory growth to starvation or cooling was not stronger under time stress. Instead, ♂♂ under time stress delayed emergence after these transient stressors. In line with a stronger compensatory growth response to time stress than to the other stressors, physiological costs in terms of a reduced investment in immune response (measured as phenoloxidase activity) and energy storage (measured as fat content) were detected only under time stress. Compared to temporary-pond *Lestes*, *L. eurinus* showed stronger compensatory growth to time stress. We hypothesize that the stronger compensatory (growth) response in permanent-pond *Lestes* co-evolved with their derived slower lifestyle when they invaded permanent ponds." 7070. De Marco, P.; Vital, M.V. (2008): Ecology of *Tigriagrion aurantinigrum* Calvert in response to variations in environmental conditions (Zygoptera: Coenagrionidae). *Odonatologica* 37(1): 1-11. (in English). ["The daily activity patterns, behaviour and population dynamics in Zygoptera are thought to be affected by the physical conditions of the environment. How and why the species reacts to those conditions is determined mainly by its bionomic characteristics. Here, an auto-ecological study is performed of *T. aurantinigrum*, in an attempt to clarify its responses to physical conditions. It is suggested that *T. aurantinigrum* could fit, with a few assumptions, in the "female-control" classification of odonate mating system. Some interactions were observed between individuals, but it is assumed that these play a role in sex recognition, rather than in territorial contests. The results indicate that this species is affected by the following physical conditions: the monthly rain fall, which has a positive effect on the abundance (with the possible exception of the heavy rain months); the water flow velocity, which seems to define a limit of its occurrence; and the daily variation in temperature, which seems to induce the species to restrict its activity to the hottest period of the day, as expected from a "thermal conformer". *T. aurantinigrum* appears to be affected by small scale variations of environmental variables, as observed by the differences of its abundance at the 3 different sites of this study. Under conditions of the current "forest-to-pasture" conversion that is common in the Brazilian Atlantic Forest region, the species is expected to increase its abundance and to broaden its geographical range, although water body alterations could limit this process." 7075. Dingemanse, N.J.; Kalkman, V.J. (2008): Changing temperature regimes have advanced the phenology of Odonata in the Netherlands. *Ecological Entomology* 33(3): 394-402. (in English). ["1. Responses of biota to climate change have been well documented for a restricted number of taxa. This study examined shifts in phenology of 37 species of the aquatic insect order Odonata in the Netherlands over the last decade. 2. The present study shows that adults of the Dutch dragonflies and damselflies have advanced their flight dates over recent years due to complex effects of changing temperature regimes on the timing of adult flight dates. 3. Flight dates did not respond to changes in autumn/winter temperatures, advanced with increases in spring temperatures of the focal and previous year, and delayed with increases in summer temperatures of the previous year. Climate change consequently advanced the flight dates of the Odonata because only spring temperatures have increased during the study period. 4. The findings imply that climate change can evoke strong phenological responses in aquatic insects. Moreover, shifts in phenology due to climate change are likely to vary both spatially or temporally, depending on the exact nature of climate change." 7078. Doi, H. (2008): Delayed phenological timing of dragonfly emergence in Japan over five decades. *Bio-logical letters* 4(4): 388-391. (in English). ["Recent increa-

ses in air temperature have affected species phenology, resulting in the earlier onset of spring life-cycle events. Trends in the first appearance of adult dragonflies across Japan were analysed using a dataset consisting of observations from 1953 to 2005. Dynamic factor analysis was used to evaluate underlying common trends in a set of 48 time series. The appearance of the first adult dragonfly has significantly shifted to later in the spring in the past five decades. Generalized linear mixing models suggested that this is probably the result of increased air temperatures. Increased summer and autumn temperatures may provide longer bivoltine periods and a faster growth rate; thus, the second generation, which previously hatched in summer, can emerge in the autumn causing the size of the population of dragonflies that emerge in spring to decrease. It is also possible that reduced dragonfly populations along with human development are responsible for a delay in the first observed dragonflies in the spring. However, human population density did not appear to strongly affect the appearance date. This study provides the first evidence of a delay in insect phenological events over recent decades." 7082. Fagundes, C.K.; Behr, E.R.; Kotzian, C.B. (2008): Diet of *Iheringichthys labrosus* (Siluriformes, Pimelodidae) in the Ibicuí River, Southern Brazil. *Iheringia, Sér. Zool., Porto Alegre*, 98(1): 60-65. (in English, with Portuguese summary). ["The diet of the benthic-feeding fish *Iheringichthys labrosus* (Lütken, 1874) was analyzed. Samples were taken bimonthly from December 1999 to January 2002, in three sites of the Ibicuí River, a tributary of Uruguay River basin (Rio Grande do Sul, Brazil). In each sampling point the specimens were collected in lentic and lotic environments. Gillnets and trammel nets were examined every 6 hours (6h, 12h, 18h and 24h). Diet description was based on the frequency of occurrence and the volume of each food item to obtain the Alimentary Index (IAi). The average stomach fullness was adopted to detect variations in the feeding activity according to the season, the circadian rhythm and the environment. Chironomids were the most important food item, followed by molluscs, and feeding activity was highest in summer, during daylight (6h and 12h), and in the lotic environment of the second sampling point." 7084. Fincke, O.M.; Hedström, I. (2008): Differences in forest use and colonization by Neotropical tree-hole damselflies (Odonata: Pseudostigmatidae): Implications for forest conversion. *Studies on Neotropical Fauna and Environment* 43(1): 35-45. (in English). ["Differential habitat use in primary and secondary forests was documented for two genera of giant damselflies (Pseudostigmatidae), important predators of tree-hole breeding mosquitoes in tropical forests. In a lowland moist forest of Panama, adults moved between old primary (>400 years old) and contiguous secondary forest (>60 years old) and reproduced seasonally in both types. However, the two *Mecistogaster* species were more common in secondary forest, whereas *Megaloprepus caerulatus* was most common in primary forest. These differences in landscape use were reflected in differential colonization of tree-hole analogs (plastic pots) in primary forest and highly altered secondary growth (<20 years old) in a lowland wet forest in Costa Rica where reproduction of both species was aseasonal. Larvae of *Mecistogaster linearis* were commonly found in pots at both habitat types, whereas *Megaloprepus*, the majority species, rarely colonized pots in altered sites. Our results suggest that *Megaloprepus* is particularly susceptible to forest conversion, and call for increased focus on the dispersal ability of all pseudostigmatids. In tropical moist and wet forests that harbour water-filled tree holes, the presence of the conspicuous *Megaloprepus* and similar species may serve as bio-indicators of a healthy predator guild, the loss of which may adversely

impact human health." (Authors)] Address: Finke, O.M., Dept Zool., Univ. Oklahoma, 730 Van Vleet Oval, Room 314, Norman, OK 73019, USA. E-mail: fincke@ou.edu

7087. Günther, A. (2008): Vergleichende Untersuchungen zum Reproduktionsverhalten südostasiatischer Chlorocyphidae und Calopterygidae (Odonata: Zygoptera). Dissertation an der TU Bergakademie Freiberg, Institut für Biowissenschaften: 228 pp. (in German, with English summary). [*Comparative study of the reproductive behaviour of Southeast-Asian Chlorocyphidae and Calopterygidae* (Odonata: Zygoptera): Many species of Jewels (Chlorocyphidae) and Demoiselles (Calopterygidae) exhibit highly complex and specialized reproductive behaviour, involving territoriality based on limitation of resources. ♂♂ display specialized, species-specific agonistic behaviour, and in most species mating is preceded by ritualized courtship of ♀♀ by ♂♂. In both cases visual communication involving ritualised display of ornamentation is of great importance. Inter- and intra-sexual signals are potentially part of mate recognition systems, which have evolved within communities of syntopic species. This thesis examines the possibilities of using knowledge of reproductive behaviour to differentiate taxa and to help reconstruct their phylogenetic relationships. The study was based on the analysis of behaviour in different parts of Southeast Asia and New Guinea, involving direct observation, partially supported by video footage. Sufficiently replicated and representative behavioural data for quantitative analysis was available for a total of 17 taxa of Jewels of the genera *Aristocypha*, *Disparocypha*, *Heliocypha*, *Libellago*

and *Rhinocypha* and for *Neurobasis kaupi*. For 14 of the 18 taxa no behavioural data had been hitherto published except by the present author. For a further 13 chlorocyphids and 4 *Neurobasis* species supplementary data was available. This account provides information on courtship behaviour and on territorial and oviposition behaviour, circadian activity and habitat requirements. Chlorocyphidae: All taxa studied showed a strong preference for lotic habitats. No reproduction in lakes and ponds or in tidal influenced streams was observed. A conspicuous feature of their habitat preference was the close association with forests, at least gallery forests fringing the streams. Most observations were from streams and rivers in closed forest habitats. The most common oviposition sites contained a wide range of plant substrates such as dead, rotting logs, small pieces of driftwood or petioles of fallen large leaves lying in the water. Mostly oviposition took place at the level of the water surface. An exception was exhibited by the three taxa of the *Libellago rufescens* complex. In these, eggs were laid in logs and robust pieces of driftwood with the female totally submerged. The ♀♀ of *Disparocypha biedermani* differed from all other Jewels by ovipositing in steep river banks, large logs lying over a stream well above the water and in the mossy bark of trees, some distance from the stream bed. *Heliocypha perforata limbata* and *Libellago semiopaca* provided examples of ♀♀ being able to assess an oviposition site based on the intensity of disturbance experienced during preceding days, with less disturbed sites preferred. ♂♂ of all species tried to defend small territories around oviposition sites and to monopolize this resource. Against rivals, a species-specific, ritualised threat behaviour could be observed. Agonistic behaviour was sometimes found to occupy most of the daily activity schedule. Physical contact was avoided strictly during aggressive interactions. Escalated displays included several ritualised flight patterns, including the motionless presentation of the terminally pigmented forewings (*Libellago*), a frontal presentation of the entire, largely iridescent wing surface by turning forward all wings simultaneously (*Aristocypha*, *Heliocypha*, *Rhinocypha*), the motionless presentation of the hindwings (*Aristocypha*, *Heliocypha*) and an alternating wing beat with intensified frequency (*Aristocypha*, *Disparocypha*, *Heliocypha*). In many cases, such as *Heliocypha perforata limbata*, the threat display obviously served to defend resources, and successful ♂♂ gained more mates. However this simple and obvious explanation, that the threat display of the male serves just to defend resources, was not sufficient to explain the results for three well-studied Sulawesi species of the *Rhinocypha tinctoria*-complex. In contrast to ♂♂ of *Heliocypha perforata limbata* the *Rhinocypha* ♂♂ did not increase their mating success by obtaining and defending a distinct territory. There was at least for two of the three species a negative correlation between the duration of threatening flights on a particular day and the numbers of successful matings for this day. The results support the hypothesis that threatening flights in long-time territorial species serve not only for the territory defence but rather to signal the presence of ♂♂ to arriving ♀♀. In most of the species mating behaviour was characterised by a preliminary courtship display by the male. A significant feature was the display of the legs in a species-specific way. In *Libellago stigmatizans* and *L. semiopaca* all 6 legs were included in the display, and were thrust forward exposing the white-pruinose inner faces of the tibiae. *L. semiopaca* displayed the morphologically unspecialized legs in a unique see-

mingly limp hanging posture. *Aristocypha fenestrata*, *Heliocypha biforata*, *H. fenestrata cornelii*, *H. perforata limbata* and the taxa of the *Rhinocypha tinctoria*-complex presented only the pruinosed middle and posterior legs in the courtship display. In all taxa the ♀♀ were encouraged to oviposit within ♂♂ territory by a postmating courtship display, and the female was, for a time, guarded. Remarkably, no alternative mating tactics without courtship were ever observed in any case in any of these species. The members of the *Libellago rufescens*-complex showed no courtship behaviour. In these taxa ♀♀, after mating, were led in tandem flight to the oviposition site. They avoided harassment by other ♂♂ by submerged oviposition. Similarly there was no courtship behaviour in *Disparocypha biedermanni*. ♂♂ of this taxon guarded small areas around especially attractive oviposition sites at the streams. The ♀♀ appeared at these rendezvous sites for mating but oviposition took place mostly outside these territories. In total four mating systems could be differentiated: "Long territoriality", "Short territoriality", "Male aggregations" and "Weak control". Based on all available information, i.e. the newly acquired and previously published results, the ritualised flight types and the mode of presentation of the legs by ♂♂ were found to be sufficiently stable in an evolutionary sense to reconstruct phylogenetic relationships. With these results a phylogenetic tree based on ethological data could be developed in Odonata for the first time. This is of special significance for the family Chlorocyphidae, as, despite extensive speciation, the different species show little structural morphological differentiation, especially in primary and secondary sexual organs, possibly as a result of species recognition systems strongly mediated by the display of visual ornaments. *Neurobasis kaupi* (Calopterygidae): The reproductive behaviour of *Neurobasis kaupi* was studied for the first time in Central and South Sulawesi. The species was recorded in a wide variety of clear and fast flowing creeks, streams and rivers, mostly in forested areas. The ♂♂ were territorial and defended potential oviposition sites, a limited resource. Territory residents demonstrated their presence by brief synchronized flashings of their iridescent blue hindwings as well as by regular inspection flights. Intruders were first driven off by short chasing flights. Longer lasting conflicts led to three different types of threatening flights, depending on the number of ♂♂ involved and the level of excitation. As in other Calopterygidae, ♂♂ of *N. kaupi* led receptive ♀♀ to potential oviposition sites. In courtship flight the male presented the iridescent upper sides of his stationary, depressed, quivering hindwings, with the hind margins broadly touching the water surface. Oviposition substrates were mostly submerged floating root mats or plants, optimally floating loosely at a depth of 5-15 cm below the water surface. The general patterns of behaviour of *N. kaupi* correspond to the known behaviour of other *Neurobasis* species. However, within this general framework there are clear differences between this species and others, especially *N. chinensis*. These involved distinct differences in pre and post courtship displays and in agnostic displays between ♂♂. The use of ethologic features in systematic-phylogenetic analysis seems promising for *Demoiselles* too. Due to the morphologically less differentiated ornamentation more intense observation seeking behavioural differences is needed, especially if differences in wing beat frequency and phase relationship of the wings in the display flights are to be analysed." 7088. Hacet, N.; Aktaç, N. (2008): Two new records of Odonata (Gomphidae) for Turkey, *Gomphus flavipes* (Charpentier, 1825) and *Ophiogomphus cecilia* (Geoffroy in Fourcroy, 1785), with distributional notes on *G. flavipes* and *G. ubadschii* Schmidt, 1953. *Entomological News* 119(1): 81-89. (in English). ["In this paper, we demonstrate the occurrence of *G. flavipes* in Turkey. The single European Turkish record of this taxon was until now confused with the closely related Asiatic species *G. ubadschii*, therefore it could be said that *G. flavipes* is new to Turkey. The distribution of the two species in Turkey is evaluated. Besides, *O. cecilia*, a species which was previously reported from Anatolia based on a misidentification, now for the first time is recorded for Turkey, in the Turkish Thrace." (Authors)] Address: Hacet, N., Trakya University, Faculty of Arts and Sciences, Department of Biology, Tr-22030 Edirne, Turkey. E-mail: nhacet@hotmail.com

7089. Hämäläinen, M. (2008): Philogangidae versus Diphlebiidae: nomenclatoric note on a family-group name (Zygoptera). *Not. Odonat.* 7(1): 12. (in English). [Verbatim: D.A.L. Davies & P. Tobin (1984, *The dragonflies of the world, a systematic list of the extant species of Odonata*, Vol. 1: Zygoptera, Anisozygoptera, Soc. Int. Odonatol., Utrecht) introduced the new family, Diphlebiidae, to house a single genus *Diphlebia* Selys, 1896. Presently in some publications, e.g. in G. Bebbly (1996, *Petalura Special-Volume 2*), G. Theischinger & J. Hawking (2006, *The complete field guide to dragonflies of Australia*, Collingwood) and in *World Odonata list* by Schorr et al., available on internet at <http://www.ups.edu/x6140.xml>, two genera *Diphlebia* and *Philoganga* Kirby, 1890 are included in the family called Diphlebiidae. R. Novelo-Gutierrez (1995, *Odonatologica* 24: 73-87) included also *Lestodea* Tillyard, 1913 in this family (but in a separate subfamily *Lestoideinae*). As already pointed out by J. Van Tol (1995, *Odonatologica* 24: 245-248) there exist available family-group names introduced on all three genera *Diphlebia*, *Philoganga* and *Lestoidea*, viz. (in chronological order) *Lestoidinae* [sic!] by Munz (1919, *Mem. am. ent. Soc.* 3: 1-78), *Philoganginae* (by C.H. Kennedy, 1920, *Ohio J. Sci.* 21: 19-29) and *Diphlebiidae* (Davies & Tobin, 1984, see above). Based on the principles of nomenclature, Van Tol concluded as follows "The correct family-group name for a group made of *Diphlebia*, *Philoganga* and *Lestoidea* is thus based on *Lestoidea*, introduced by Munz (1919): *Lestodeidae*. Novelo-Gutierrez also distinguishes two subfamilies, one including *Diphlebia* and *Philoganga*, the other *Lestoidea* only. Their correct names are *Philoganginae* and *Lestoideinae* respectively." Consequently, if the two genera *Diphlebia* and *Philoganga* alone are ranked as a family, its correct name is *Philogangidae* Kennedy, 1920. The present Code (International Commission on Zoological Nomenclature, 1999, *International Code of Zoological Nomenclature*, London) rules in Article 35.5. as follows: "Precedence for names in use at higher taxa. If after 1999 a name in use for a family-group taxon [...] is found to be older than a name in prevailing usage for a taxon at higher rank in the same family-group taxon [...] the older name is not to displace the younger name." However, this more liberal practice cannot be applied in this case, since the mutual priority of the family-group names based on these three genera was documented already in 1995 by van Tol (see

above.)] Address: Hämäläinen M., Dept Applied Zool., P.O. Box 27, FIN- 00014 University of Helsinki, Finland; E-mail: matti.hamalainen@helsinki.fi

7090. Hassall, C.; Thompson, D.J.; Harvey, I.F. (2008): Wings of *Coenagrion puella* vary in shape at the northern range margin (Odonata: Coenagrionidae). *International Journal of Odonatology* 11(1) 2008: 35-41. (in English). ["A previous study has shown that wing size in *C. puella* varied considerably along a latitudinal gradient in the UK. Using landmark data from wing images, patterns of shape variation were also determined along the same transect by geometric morphometric analysis of wing shape. Wing shape was uniform at all sites other than those closest to the range margin, which differed significantly. The potential mechanisms that might have generated such between-population variation are discussed." 7091. Heino, J. (2008): Patterns of functional biodiversity and function–environment relationships in lake littoral macroinvertebrates. *Limnol. Oceanogr.* 53(4): 1446-1455. (in English). ["I examined variability in the abundances of functional groups, functional diversity measures, and functional structure of littoral macroinvertebrate communities in relation to the environmental features of boreal lakes. The most important environmental variables shaping variation in the abundances of functional groups and functional structure were lake surface area, macrophyte cover, total phosphorous, and water hardness. The same environmental variables (i.e., lake surface area, macrophyte cover) accounted for variability in functional richness and functional diversity, while functional evenness was related to different environmental variables (i.e., hardness, colour). Lake surface area and macrophyte cover comprised the most important axes of habitat templates shaping the functional trait structure and biodiversity in boreal lakes: lake area mirrors habitat differences between smaller and larger lakes, and macrophyte cover portrays the effects of habitat structural complexity on functional biodiversity. Functional biodiversity measures were also strongly correlated to species-level measures, and the correlation between similarity in functional and taxonomic structure was strong. Functional and taxonomic measures of macroinvertebrate communities thus provide rather similar information about littoral communities and ecosystem functioning." (Authors) Odonata are mentioned at the genus level only.] Address: Heino, J., Finnish Environment Institute, Research Programme for Biodiversity, P.O. Box 413, FI-90014 University of Oulu, Oulu, Finland

7092. Hornung, J.P.; Foote, A.L. (2008): Comparing dietary preferences of Bufflehead ducklings in Western Canada through gut content and stable isotope analysis. *Aquatic Ecology* 42: 61-70. (in English). ["Aquatic invertebrates are essential for duckling growth and development. We present results on the trophic status and dietary analysis of Bufflehead (*Bucephala albeola*) ducklings from the boreal breeding grounds of western Canada. We estimated dietary preference by comparing invertebrates found in Bufflehead diets to those identified in standardized dip net samples at their wetland feeding sites. Stable isotope ratios of Bufflehead

and their prey were used as a second estimator of trophic position. Bufflehead ducklings preferentially foraged for larval Dytiscidae (predaceous diving beetles; 46% of total dietary biomass), Zygoptera larvae (damselflies; 14%) and non-Dytiscidae adult Coleoptera (5%; mainly Haliplidae). Results from stable isotope analyses supported these results; the separation between primary and secondary invertebrate consumers and ducklings was significant for all possible contrasts when considering nitrogen isotope ratios (Tukey HSD; $P < 0.001$). We iteratively explored all possible combinations of $\delta^{15}N$ and $\delta^{13}C$ data to generate a proportional range over which each food source may contribute to Bufflehead stable isotope signatures; these results suggested larval Zygoptera and larval Dytiscidae figure prominently in diets when accounting for isotope fractionation. The incorporation of prey availability into the metric of dietary preference, as opposed to the tabulation of ingested items alone, reduces the importance of invertebrate groups such as adult Dytiscidae as highlighted in previous studies." (Authors)] Address: Hornung, J.P., Dept of Renewable Resources, University of Alberta, 751 General Services Building, Edmonton, AB, Canada T6G 2H1. E-mail: jon.hornung@ualberta.ca

7093. Jiang, Y.-h.; Li, Z.-h.; Yu, W.-y. (2008): *Macromidia shiehae* sp. n., a new dragonfly from Jiangxi, China (Anisoptera, Corduliidae). *Odonatologica* 37(2): 157-160. (in English). ["The new species is described and illustrated. Holotype ♂: China, Jiangxi: Lushan Mt (Haihui), 31-V-2004; deposited in Nanjing Forestry Univ., Nanjing, China. It is related to *M. ellenae* Wilson and *M. hangzhouensis* Zhou & Wei, but it is differentiated from these by having the postclypeus with yellow on anterior margins, the median lobe of the prothorax with four fine, pale yellow streaks, thorax with 5 yellow stripes, and nodal index of fore- and hindwings lower than in any of the other 4 *Macromidia* species described from China." 7094. Jones, C.D. (2008): Skillet Club tail (*Gomphus ventricosus*) in Ontario. *Ontario Odonata* 7: 49. (in English). [Verbatim: In February 2007, I visited the insect collection at the University of Guelph to examine the two specimens of Skillet Clubtail (*Gomphus ventricosus*), the records of which are contained in the Ontario Odonata Database, housed and maintained at the Natural Heritage Information Centre (NHIC). One was collected at Ignace on July 7, 1978 and the other was collected at Forest on June 18, 1979. Given that this is such a rare species and that clubtails can be challenging to identify, I was interesting in examining the specimens. As it turned out, the specimen from Ignace is actually *G. exilis* (a ♂) and the one from Forest is actually *G. graslinellus* (a ♀). They are both pinned specimens and did not have any species labels on them but were simply in the unit tray labelled *G. ventricosus*. So, it would appear that the only known location we have for this species in Ontario is the historical (1924) record from "Ottawa", presumably from the Ottawa River.] Address: Jones, C.D., Box 182, Lakefield, Ontario, K0L 2H0, Canada. E-mail: colin.jones@mnr.gov.on.ca

7095. Joshi, P.C.; Kumar, K.; Arya, M. (2008): Assessment of insect diversity along an altitudinal gradient in Pinderi forests of Western Himalaya, India. *Journal of Asia-Pacific Entomology* 11(1): 5-11. (in English). ["In-

sect diversity, richness and abundance were evaluated at different altitudes in three forest habitats in the Western Himalayas. The habitats studied were all situated between 2100 and 3500 m and included a site with no disturbances, a site with a moderate level of disturbance and a site with a very high level of disturbance. The species composition and diversity of insects varied at all the three study sites, which demonstrates the effect of altitude and disturbances, as well as the effects of other ecological and climatic parameters on insect populations. The site at lowest altitude, which contained a moderate level of disturbance, supported the highest number of species (108), whereas the site at the highest altitude, which contained the maximum level of disturbance, supported the lowest number of species (77). When all of the sites were considered, 122 species of insects belonging to 43 families and 8 orders were recorded. Lepidoptera was the most dominant insect order recorded, with 46 species being observed. This was followed by Hymenoptera (20), Coleoptera (18), Orthoptera (12), Hemiptera (10), Odonata (9), Diptera (5) and Dermeptera (2). The most abundant species were *Vanessa cashmirensis* (Lepidoptera: Nymphalidae), *Pieris canidia indica* (Lepidoptera: Pieridae), *Apis laboriosa* (Hymenoptera: Apidae), *Anomala dimidiata* (Coleoptera: Scarabidae), *Chorthippus* sp. (Orthoptera: Acrididae), *Crocothemis servilia servilia* (Odonata: Libellulidae) and *Syrphus fulvifacies* (Diptera: Syrphidae). The site at the lowest altitude and the sites with the longest rainy seasons had the highest Shannon–Wiener Diversity." (Authors) The following odonate species are also listed: *Palpopleura sexmaculata*, *Sympetrum commixtum*, *Orthetrum sabina*, *O. glaucum*, *O. pruinatum neglectum*, *Anax immaculifrons*, *Cephalaescha orbifrons*, and *Macromia moorei*.] Address: Joshi, P.C., Dept Zool. & Environ. Sci., Gurukul Kangri Univ., Haridwar – 249404, India. E-mail Address: prakash127@yahoo.com

7096. Jovice. M.; Andjus, L.; Bedjanic, M.; Santovac, S. (2008): Review of the Odonata fauna of Montenegro. *Opusc. zool. flumin.* 224: 1-27. (in English). ["The 57 hitherto known species are listed along with the locality data and bibliographic references, where applicable. *Coenagrion pulchellum*, *Erythromma najas*, *Anaciaeschna isosceles*, *Anax parthenope*, *Brachytriton pratense*, *Cordulegaster heros*, and *Selysiotthemis nigra* were not previously recorded from Montenegro. The biogeographic composition of the fauna is analyzed. Observations on *Somatochlora metallica* from Mt Durmitor are briefly discussed, and a comprehensive bibliography on the odonate fauna of Montenegro is appended." (Authors)] Address: Jovic, M., Natural History Museum Belgrade, Njegoševa 51, P.O. Box 401, YU-11000 Belgrade, Serbia. E-mail: milos.jovic@nhmbeo.org.yu

7097. Kalkman, V.J. (2008): Two new dragonfly species from Yapen and Biak, Papua (Irian Jaya), Indonesia (Odonata). *Zoologische Mededelingen* 82(11): 81-89. (in English). ["During fieldwork on the island of Yapen (Indonesia, Papua (Irian Jaya)), conducted in July 2006, several undescribed species of Odonata were collected. Two of these are described based on material from Yapen and Biak (Papua (Irian Jaya), Indonesia): *Teinobasis sjupp* spec. nov. (type locality: Yapen Island) and *Macromia holthuisi* spec. nov. (type locality: Biak Island)." (Author)] Address: Kalkman, V.J., European Invertebrate Survey - Nederland, p/a Nationaal Natuurhistorisch Museum - naturalis, Postbus 9517,

7099. Kalkman, V.J.; Clausnitzer, V.; Dijkstra, K.D.; Orr, A.G.; Paulson, D.R.; van Tol, J. (2008): Global diversity of dragonflies (Odonata) in freshwater. *Developments in Hydrobiology* 198: 351-363. (in English). ["Larvae of almost all of the 5,680 species of the insect order Odonata (dragonflies and damselflies) are dependent on freshwater habitats. Both larvae and adults are predators. The order is relatively well studied, and the actual number of species may be close to 7,000. Many species have small distributional ranges, and are habitat specialists, including inhabitants of alpine mountain bogs, seepage areas in tropical rain forests, and waterfalls. They are often successfully used as indicators for environmental health and conservation management. The highest diversity is found in flowing waters in rain forests of the tropics, the Oriental and Neotropical regions being the most speciose. This paper discusses diversity, summarises the biogeography of dragonflies in the different biogeographical regions and gives the total number of species and genera per family per biogeographical region. Examples are given of areas of particular diversity, in terms of areas of endemism, presence of ancient lineages or remarkable recent radiations but no well-based review of areas with high endemism of dragonflies is available so far. The conservation status of dragonflies is briefly discussed. Species confined to small remnants of forest in the tropics are most under threat of extinction by human activities." (Authors)] Address: Kalkman, V.J., European Invertebrate Survey - Nederland, p/a Nationaal Natuurhistorisch Museum - naturalis, Postbus 9517, 2300 RA Leiden, The Netherlands. 7100. Khan, B.; Colbo, M.H. (2008): The impact of physical disturbance on stream communities: lessons from road culverts. *Hydrobiologia* 600: 229-235. (in English). ["This study examined the impact of physical disturbance from long-established road culverts on stream macroinvertebrate communities. Three streams within a 6 km section of highway on the Avalon Peninsula, Newfoundland, Canada, were sampled. Streams had the entire upstream watershed and at least 100 m downstream of the road with natural boreal forest/barren vegetation and all had, within the sampled reaches, similar physical streambed characteristics. The fauna on stones from riffles was sampled at two upstream and three downstream sites, i.e., from 50 m above to about 100 m below the road in each stream. A total of 33 taxa

were identified among the streams, with differences limited to a few rare taxa. The sample site communities did not significantly differ from each other with respect to the taxa present. Total macroinvertebrate abundance by site, for combined data of all streams, indicated the site at the exit of culvert plunge pool (site 3) had significantly elevated abundances. Analysis of individual taxa showed this was primarily due to very high numbers of *Simulium* species. The other most notable changes were a decrease in numbers of *Hydropsyche* species and *Elmidae* below the road. The abundances of the remaining taxa were more variable among all sites. The study indicated that longstanding point source physical disturbance primarily impacted taxa abundance rather than community present/absent data, which will recolonize the disturbed zone by downstream drift. The differences in abundance are probably the result of the cleaning of substrate by abrasion, movement of substrate and reduction of detritus during each spate." (Author) The study includes "Aeshna sp.".] Address: Colbo, M.H., Dept Biology, Memorial Univ. Newfoundland, St. John's, NL, Canada A1B 3X9. E-mail: mcolbo@mun.ca

7101. Kiyoshi, T. (2008): Differentiation of golden-ringed dragonfly *Anotogaster sieboldii* (Selys, 1854) (Cordulegastridae: Odonata) in the insular East Asia revealed by the mitochondrial gene genealogy with taxonomic implications. *Journal of Zoological Systematics and Evolutionary Research* 46(2): 105-109. (in English, with German summary). ["Molecular phylogeographical analyses of *A. sieboldii* were conducted to reveal the differentiation process of insular populations. The gene genealogy based on 845 bp of the mitochondrial genes (cytochrome oxidase subunit I and subunit II) indicated that *A. sieboldii* includes two deeply separated lineages. These two major lineages seem to have differentiated in Miocene before the formation of the insular East Asia. One lineage includes three inner clades that correspond to the populations of northern area (the Japanese main islands, Korean Peninsula, Yakushima), Amamioshima and Okinawajima. Populations of Central Ryukyu, including Amamioshima and Okinawajima, might have been divided from the northern populations in early Pleistocene. The other major lineage includes populations of the Yaeyama Group, Taiwan and East China. The former two populations were reconstructed as a reciprocal monophyletic group. Populations of Taiwan and Yaeyama Groups would have been separated from the continental ones in Pleistocene. These two highly divergent lineages should be recognized as distinct species. Furthermore, the mitochondrial lineages revealed six genetically distinct and geographically isolated assemblages: (1) northern populations, (2) Amamioshima, (3) Okinawajima, (4) Yaeyama Group, (5) Taiwan and (6) East China." (Author)] Address: Kiyoshi, T., Dept of Zoology, Graduate School of Science, Kyoto University, Kyoto, Japan. E-mail: kiyoshi@zoo.zool.kyoto-u.ac.jp

7102. Klass, K.-D. (2008): The female abdomen of ovipositor-bearing Odonata (Insecta: Pterygota). *Arthropod Systematics & Phylogeny* 66(1): 45-142. (in English). ["The exoskeleton and musculature of the middle and posterior abdomen in female *Calopteryx virgo* are described (segments IVff), including parts of the midabdominal nervous system. Based on a sample of 16 species of Odonata with a plesiomorphic morphology of the ovipositor (various Zygoptera, Epiophlebia, and Aeshnidae) the range of variation in the abdominal exoskel-

eton is documented, and a preliminary list and table of 79 characters are assembled. Abdominal muscles in Odonata are surveyed based on data from the literature. Topographic homologies between Odonata and other Insecta are discussed, with a focus on the female genitalic region and the terminal abdomen, and with consideration of previous ontogenetic studies. The results are used for including outgroup scorings into the character list for Odonata. Odonata conform with many Neoptera (e.g., Notoptera, pygidicranid Dermaptera) in the location of the female genital opening between or behind the gonapophyses VIII bases, contrasting with the VIIIth-segmental openings in other Neoptera (e.g., Dictyoptera, Ensifera, 'advanced' Dermaptera), Archaeognatha, and Zygentoma. The gonangulum in most Odonata consists, like in Archaeognatha and some Dermaptera, of two separate sclerites; this contrasts with the one-piece condition of the gonangulum in other Diptera and Epiophlebia. The interpretation of terminal appendages in Odonata as the true cerci is supported by musculature data, and it is shown that previous counter-arguments are invalid. While Epiophlebia is in many characters highly peculiar among Odonata, the abdominal characters provide no resolution for the relationships between Epiophlebia, Zygoptera, and Anisoptera. The monophyly of Zygoptera receives considerable support." (Author) Address: Klass, K.-D., State Natural History Collections Dresden, Museum of Zoology, Königsbrücker Landstraße 159, 01109 Dresden, Germany. E-mail: klaus.klass@snsd.smwk.sachsen.de]

7104. Kone, T.; Kouamélan, E.P.; Yao, S.S.; N'Douba, V.; Ollevier, F. (2008): First results of a study of the feeding habits of *Synodontis comoensis* (Siluriformes: Mochokidae) in a West African river (Comoé River, Comoé National Park, Côte d'Ivoire). *Aquatic Ecology* 42: 35-42. (in English). ["The feeding habits of *S. comoensis* have been studied for the first time. Specimens caught in the Comoé River (Comoé National Park, Côte d'Ivoire) had fed on different types of food including insects (Diptera, Ephemeroptera, Hymenoptera, and Isoptera), molluscs (gastropods and bivalves), oligochaetes, and macrophytes. The food items most frequently found in the stomach contents were chironomid larvae, oligochaetes, vegetable detritus, fruit, and gastropods. Correlation studies based on the index of preponderance of food items revealed noticeable variation in *S. comoensis* diet composition with fish size and season. Preferred food items of young fish were oligochaetes in the rainy season and vegetable detritus in the dry season. Food items preferred by larger fish were fruit and gastropods in the rainy season and chironomid larvae in the dry season." (Authors) *Phyllomacromia* sp. is the only taxon found in the diet of this fish.] Address: Koné, T., Laboratoire d'Hydrobiologie, UFR Biosciences, Uni-

versite' de Cocody, 22 BP 582 Abidjan, Ivory Coast. E-mail: Ktidiani@yahoo.fr

7105. Królak, E.; Korycińska, M. (2008): Taxonomic composition of macroinvertebrates in the Liwiec river and its tributaries (Central and Eastern Poland) on the basis of chosen physical and chemical parameters of water and season. *Polish Journal of Environmental Studies* 17(1): 39-50. (in English). ["The taxonomic composition of macroinvertebrates in the Liwiec River and its tributaries situated in central and eastern Poland was studied during three seasons (spring, summer and autumn). Simultaneously, physical and chemical parameters of water were measured. Water parameters were different in each study period. Macroinvertebrates samples collected in summer and autumn were much more diversified than the samples collected in spring. In the spring samples a greater EPT diversity was observed, while in the samples collected in autumn Odonata, Coleoptera and Heteroptera were more diversified. The values of the BMWP-PL index were slightly higher for the summer and autumn samples than for the spring ones. Correlation between the concentration of oxygen in water and the number of individuals of Plecoptera and Trichoptera larvae was noted. The negative correlation between the values of BOD5, the concentration of nitrate ions and conductivity, and the number of macroinvertebrate families was observed. A negative correlation also was noted between nitrate and phosphate ion concentrations and the number of individual insect larvae." (Authors)] Address: Królak, E., Dept of Ecology & Environmental Protection, University of Podlasie, Prusa 12, 08-110 Siedlce, Poland

7106. Krotzer, R.S.; Bried, J.T.; Krotzer, M.J. (2008): The Odonata Of Mississippi. *Bulletin of American Odonatology* 10(4): 65-91. (in English). ["An annotated faunal list of the Odonata occurring in Mississippi is presented, totalling 144 species (100 Anisoptera, 44 Zygoptera). Five species - *Enallagma davisii*, *Gomphus (Hylogomphus) geminatus*, *Epithea (Tetragoneuria) spinosa*, *Neurocordulia alabamensis*, and *Miathyria marcella*, are documented from the state for the first time. The presence in Mississippi of *Celithemis bertha* Williamson, previously reported from the state based on a misidentification, is confirmed. Four species from earlier Mississippi lists are removed, and nine potential additions to the state's fauna are discussed. A brief history of odonatological inventory in Mississippi is given, along with a discussion of the state's physiography and aquatic resources, relationships of its odonate fauna to that of its neighbouring states, and potential conservation measures that could benefit odonates and their habitats." 7107. Kukalova-Peck, J. (2008): Phylogeny of higher taxa in insecta: Finding synapomorphies in the extant fauna and separating them from homoplasies. *Evol. Biol.* 35: 4-51. (in English). ["Most currently applied systematic methods use post-groundplan character states to reconstruct phylogenies in modern higher Insecta/Arthropoda taxa. But, this approach is unable to separate synapomorphies from frequently occurring homoplasies. Conflicting, unresolved and unrealistic higher-level phylogenies result. The reasons are analyzed. A contrasting "groundplan" method, long used in Vertebrata and found to be superior in resolving higher-level

phylogenies, is described. This method, as used for insects, uses a highly diversified morphological organ system (such as limb/wing), identifies its homologues in all subphyla and classes, records the full history of its character transformation series in all lineages from the shared Paleozoic ancestor to modern times, pursues the full homologization of its character states in all modern orders, and verifies these data with evidence from other fields of biology. Only such an extremely broad dataset provides the complex information needed to identify and homologize the groundplan character states in modern orders and other higher taxa in the insect /arthropod fauna. After this is accomplished, the gate to recognizing higherlevel synapomorphies is open. Only groundplan-level character states include distinct synapomorphies, since homoplasies are either absent or easily detectable. Examples are given. The interpretations of higher phylogenies and evolutionary processes in Hexapoda, based on the unpredictable and often misleading post-groundplan character states found in extant, Tertiary and Mesozoic fauna, are critically compared with those based on the evolution of organ systems, by using the groundplan method." (Author) The paper includes many references to Odonata.] Address: Kukalova-Peck, Jarmila, Earth Sciences, Carleton University, Ottawa, ON, Canada K1S 5B6. E-mail: jarmilapeck@carleton.ca

7108. Lowe, C.D.; Harvey, I.F.; Thompson, D.J.; Watts, P.C. (2008): Strong genetic divergence indicates that congeneric damselflies *Coenagrion puella* and *C. pulchellum* (Odonata: Zygoptera: Coenagrionidae) do not hybridise. *Hydrobiologia* 605: 55-63. (in English). ["Coenagrionid damselflies are in general decline in the British Isles. Numerous factors have been implicated in the loss of these species including recent speculation that hybridisation between congeners may result in species decline. Here we use a panel of 12 microsatellite loci to examine levels of genetic divergence and the likely occurrence of hybridisation in five populations of *Coenagrion puella* and *C. pulchellum* using samples from four sites in south-east England. *C. puella* and *C. pulchellum* were highly genetically divergent, and there was no evidence of hybridisation between any of the populations examined, even where *C. puella* and *C. pulchellum* were sympatric. There was some suggestion that *C. pulchellum* was less genetically diverse than *C. puella*, though this may have been a result of ascertainment bias associated with cross-species application of microsatellite markers. We conclude that there is no evidence that hybridisation between *C. puella/pulchellum* could be responsible for the on-going demographic decline in *C. pulchellum*. Nevertheless, further genetic studies such as this one are likely to provide estimates of diversity, population structure and dispersal capacity that will be invaluable in future conservation management strategies for coenagrionid damselflies." 7109. Mahato, M.; Kennedy, J.H. (2008): Field experimental approach to detect urban impact on *Erpetogomphus designatus* Hagen in Selys larvae (Anisoptera: Gomphidae). *Odonatologica* 37(1): 13-28. (in English) "This study attempted to design and conduct an in situ field experiment using *E. designatus* larvae collected from the reference site and then exposed at 4 poten-

tially impacted urban sites; all in the sub-watersheds of the city of Denton, Texas, USA. Before placing them in the urban site enclosures, head width, total width, wing pad length and wet weight were measured. The surviving larvae were retrieved after 6 weeks and all parameters were measured again in order to assess the difference between the reference and urban sites. No survival was observed at 2 urbanized sites in both spring and summer, and at another urbanized site in spring. The differences in survival of the larvae may be influenced by the differences in hydrology and water quality, especially during the summer experimental period. In the spring, a statistically significantly higher growth rate ($p < 0.05$) occurred at one of the urban sites compared to the reference site. The difference in growth rate may have been influenced by less fluctuation and higher minimum water temperature at the urban site. Although the experiment was only partially successful, it did indicate that the local common odonate taxa found at the reference site could be used for field biomonitoring experiments to assess water quality of urban sites. If fully successful, this type of in situ field experiment may indicate actual impacts rather than attempting to apply conclusions based on either laboratory microcosm or mesocosm-based toxicity tests." (Authors)] Address: Mahato, M., URS Corporation, Dallas, TX 75234, USA. E-mail: Mmahato@gmail.com

7110. Mandal, S.K.; Ghosh, A.; Bhattacharjee, I.; Chandra, G. (2008): Biocontrol efficiency of odonate nymphs against larvae of the mosquito, *Culex quinquefasciatus* Say, 1823. *Acta Tropica* 106(2): 109-114. (in English). ["An estimation of the predatory efficiency of the nymphs of 5 coexisting odonate species *Aeshna flavifrons*, *Coenagrion kashmirum*, *Ischnura forcipata*, *Rhinocypha ignipennis* and *Sympetrum durum* using the fourth-instar larvae of *Culex quinquefasciatus* as prey, was made under laboratory and semi-field conditions. The daily feeding rate varied among the odonate species, at laboratory conditions. The mean number of IV instars *Cx. quinquefasciatus* larvae killed per day, ranged between 14 and 64 (64 mosquito larvae for *I. forcipata*, 57 for *A. flavifrons*, 45 for *R. ignipennis*, 25 for *S. durum* and 14 for *C. kashmirum*). The prey consumption was linearly related to the number of predators and prey available but inversely related with space. It was also noted that the feeding rates varied significantly between dark and light conditions, in all the odonate species. The presence of nymphs in semi-field conditions significantly lowered the mosquito larval density in dipper samples after 15 days from the introduction, followed by a significant increase of larval mosquito density after 15 days from the withdrawal of the nymphs. The results of the present observations are suggestive of the use of odonate nymphs in temporary pools or larger habitats where they can be a potential biological resource in regulating the larval population of the vector and pest mosquitoes." 7111. Markwell, K.A.; Fellows, C.S. (2008): Habitat and biodiversity of on-farm water storages: A case study in southeast Queensland, Australia. *Environmental Management* 41: 234-249. (in English). ["On-farm water storages (locally known as farm dams or farm ponds) are an important part of many agricultural landscapes, as they provide a reliable source of water for irrigation and stock. Although these waterbodies are artificially

constructed and morphologically simple, there is increasing interest in their potential role as habitat for native flora and fauna. In this article, we present results from a case study which examined the habitat characteristics (such as water physical and chemical parameters, benthic metabolism, and macrophyte cover) and the macrophyte and macroinvertebrate biodiversity of 8 farm ponds on 4 properties in the Stanley Catchment, Southeast Queensland, Australia. Each landowner was interviewed to allow a comparison of the management of the ponds with measured habitat and biodiversity characteristics, and to understand landowners' motivations in making farm pond management decisions. The physical and chemical water characteristics of the study ponds were comparable to the limited number of Australian farm ponds described in published literature. Littoral zones supported forty-five macroinvertebrate families, with most belonging to the orders Hemiptera, Coleoptera, Odonata, and Diptera. Invertebrate community composition was strongly influenced by littoral zone macrophyte structure, with significant differences between ponds with high macrophyte cover compared to those with bare littoral zones. The importance of littoral zone macrophytes was also suggested by a significant positive relationship between invertebrate taxonomic richness and macrophyte cover." 7112. Martens, A.; Ehmann, H.; Peitzner, G.; Peitzner, P.; Wildermuth, H. (2008): European Odonata as hosts of *Forcipomyia paludis* (Diptera: Ceratopogonidae). *International Journal of Odonatology* 11(1): 59-70. (in English). ["The biting midge *F. (Pterobosca) paludis* is the only ceratopogonid species known to parasitise Odonata imagines in Europe. In this study, based mainly on the analysis of about 200 photographically documented cases, data on host species, parasite load and undisturbed position on the odonate body were analysed. The list of hitherto known hosts is extended significantly to include 55 Odonata species. The records date from mid-May to the beginning of August. Most data originate from southern France, Switzerland, Germany, and Austria, with a few from Sweden and Croatia. Only ♀♀ of *F. paludis* were found on Odonata, attached to both sides of the wings with a preference for their basal half, and mostly facing the wing base. In Calopteryx species the midges were likewise present on the wing tips. In a few cases midges were also found on the odonate's thorax and abdomen." 7113. Matushkina, N.A. (2008): Skeletomuscular development of genital segments in the dragonfly *Anax imperator* (Odonata, Aeshnidae) during metamorphosis and its implications for the evolutionary morphology of the insect ovipositor. *Arthropod Structure & Development* 37(4): 321-332. (in English). ["The skeleton-muscular organisation of abdominal segments 7-9 in female *A. imperator* was examined in the stages of ultimate larva, teneral imago, and mature imago, with special emphasis on the transformation of the muscle arrangement. The absence of certain muscles in the genital segments compared to the 7th pre-genital segment was noted on all studied stages. Reductions of certain muscles in adults compared to those in larvae are re-

ported. Some of ovipositor's muscles appear already in larvae. Attachment sites of larval muscles are retained in freshly emerged ♀♀ concurrently with integument transformations. This situation allows for precise determination of the borders of newly differentiated genital sclerites and, therefore, of the possible origin of certain ovipositor elements in odonates. All changes in the segmental sets of studied abdominal muscles during metamorphosis are tabulated, and displacements of muscles are documented and illustrated. Schematic figures illustrating homologies between the parts of larval and imaginal abdominal sclerites are provided. The origins of the components of the endophytic ovipositor in Odonata as well as their implications for the evolutionary morphology of the insect ovipositor are discussed." 7114. Matushkina, N.A. (2008): The ovipositor of the relic dragonfly *Epiophlebia superstes*: a morphological re-examination (Odonata: Epiophlebiidae). *International Journal of Odonatology* 11(1): 71-80. (in English). ["The morphology of the endophytic ovipositor in *E. superstes* was studied with light and electron microscopy with special emphasis made on the musculature and micro-sculpture of the exoskeleton. Structural characters are described and illustrated. The musculature of the ovipositor has many similarities with zygopterans. The ovipositor and 10th abdominal segment bear groups of setae and campaniform sensilla, which probably contact the plant surface during egg laying. A group of campaniform sensilla on the base of the stylus may be responsible for the zigzag sequence of egg disposition in *E. superstes*. The phylogenetic significance of the microstructure of the ovipositor in *E. superstes* can be evaluated only after a systematic examination of representatives of other ovipositor-bearing Odonata." (2008): Food habits of feral cats (*Felis silvestris catus* L.) in insular semiarid environments (Fuerteventura, Canary Islands). *Wildlife Research* 35: 162-169. (in English). ["In this study, we present the first data on diet and impacts of feral cats on a semiarid island (Fuerteventura, Canary Islands). A total of 614 prey was identified in the 209 scats analysed. Introduced mammals, especially rabbits and mice, were the most consumed vertebrate prey and constituted more than 90% of biomass. Barbary ground squirrels, Algerian hedgehogs, and rats were preyed upon less even though they were abundant on the island. Invertebrates, mainly Orthoptera, Coleoptera, Hymenoptera and Odonata, were the second most important prey items (in terms of actual numbers) but they contributed only minimally with respect to biomass (<1.1%). The presence of terrestrial molluscs in the diet was interesting because they are a rare prey in an insular context. Birds and reptiles occurred at a low frequency. A total of 677 seeds was counted, mainly belonging to *Lycium intricatum* (Solanaceae) and two unidentified plant species. Levin's niche breadth was narrow due to the high consumption of mammals. Morisita's index showed a similar trophic overlap in diet with respect to the other xeric habitats of the Canary archipelago. Considering

that more than 90% of biomass corresponded to introduced mammals, we conclude that feral cats are not having a large direct impact on the native prey species." (Authors) The diet contains *Anax imperator* and indeterminate Odonata remains.] Address: Medina, F.M., Unidad de Medio Ambiente, Cabildo Insular de La Palma, Avenida Los Indianos 20, 2º, 38700 Santa Cruz de La Palma, Canary Islands, Spain. 7117. Mikolajewski, D.J.; Stoks, R.; Rolff, J.; Joop, G. (2008): Predators and cannibals modulate sex-specific plasticity in life-history and immune traits. *Functional Ecology* 22(1): 114-120. (in English). ["1. In organisms with complex life cycles, optimality models predict age and size at transition to translate larval condition into adult fitness. Recent studies, however, revealed that only a proportion of fitness is explained by age and size at transition. Moreover, sexes differ in the linkage of larval condition and adult fitness. 2. In this study, we tested the hypothesis that immune traits may be partly decoupled from age and size at habitat transition and therefore contribute to the sex-specific linkage of larval condition and adult fitness. 3. We reared larvae of the damselfly *Coenagrion puella* under the threat of predators and cannibals. We then examined sex-specific patterns in two life-history traits as well as two immune traits and tested for independency of the plastic responses among life-history and immune traits. 4. Results revealed immune traits to be partly decoupled from life-history traits. Moreover, the sexes differed in the plasticity of life-history as well as immune traits. Our results give strong evidence that sex-specific translation of larval condition into adult fitness may be linked to immune traits as well as age and size at transition." 7118. Molineri, C. (2008): Impact of rainbow trout on aquatic invertebrate communities in subtropical mountain streams of northwest Argentina. *Ecologia Austral* 18: 101-117. (in English). ["The present study was conducted to assess the effect of rainbow trout introduction on benthic invertebrate communities, stratified as epibenthos and infauna. Two main questions are explored: 1) do the trout-invaded streams show a different community structure than the streams with autochthonous fish?, and 2) does the presence of trout affect differentially the epibenthos and the infauna? Epibenthic and infaunal samples, drift samples and fish stomach content were sampled four times from three stations to assess the impact of rainbow trout (*Oncorhynchus my-*

kiss) on the invertebrate aquatic fauna. Only one species of native fish was recorded in the studied sites, the siluriform *Trichomycterus corduvense*. Both fish species were found always in allopatry. The trout-invaded site has a different community structure than the other streams with a much lower abundance of large and active epibenthic taxa (e.g., *Perlidae*, *Gripopterygidae*, *Hydropsychidae*, *Leptoceridae*, *Elmidae* adults) and an increase in the importance of infaunal organisms (*Chironomidae*, *Oligochaeta*). Diversity indices showed alternating and opposite high and low values along time in trout-free and invaded sites." 7124. Ohba, S.; Miyasaka, H.; Nakasuji, F. (2008): The role of amphibian prey in the diet and growth of giant water bug nymphs in Japanese rice fields. *Population Research* 50(1): 9-16-121-122. (in English). ["Predatory insects that depend upon particular prey animals are commonly regulated by the prey animal's abundance. Nymphs of the giant water bug *Kirkaldyia (=Lethocerus) deyrolli* (Heteroptera: Belostomatidae) are predators regarded as specialists in feeding on tadpoles. We studied the ontogenetic diet shift of aquatic nymphs by quantifying instar abundance and by analyzing captured prey and prey relative abundance during the period of rice irrigation in three localities. We also evaluated the contribution of major prey items (tadpoles, frogs, and Odonata nymphs) on specific growth rates of each nymphal stage in a rearing experiment. First to third-instar nymphs of *K. deyrolli* fed mainly on tadpoles, regardless of differences in prey availability. Nymphs of subsequent fourth and fifth instar stages shifted from tadpoles to other prey animals within each rice field. A rearing experiment demonstrated that giant water bug nymphs provided with tadpoles had greater specific growth rates at all nymphal stages, except for the final stage, than nymphs fed other prey (frogs and Odonata nymphs). The emergence of young *K. deyrolli* nymphs seemed to coincide with the period during which tadpoles became abundant in the rice fields. Consumption of tadpoles seems important to allow the nymph to complete its larval development in an unstable temporary habitat." 7127. Rach, J.; DeSalle, R.; Sarkar, I.N.; Schierwater, B.B.; Hadrys, H. (2008): Character-based DNA barcoding allows discrimination of genera, species and populations in Odonata. *Proc. R. Soc. (B)* 275: 237-247. (in English). ["DNA barcoding has become a promising means for identifying organisms of all life stages. Currently, phenetic approaches and tree-building methods have been used to define species boundaries and discover 'cryptic species'. However, a universal threshold of genetic distance values to distinguish taxonomic groups cannot be determined. As an alternative, DNA barcoding approaches can be 'character based', whereby species are identified through the presence or absence of discrete nucleotide substitutions (character states) within a DNA sequence. We demonstrate the potential of character-based DNA barcodes by analysing 833 odonate specimens from 103 localities belonging to 64 species. A total of 54 species and 22 genera could be discriminated reliably through unique combinations of character states within only one mitochondrial gene region (NADH dehydrogenase 1). Character-based DNA barcodes were further successfully established at a population level discriminating seven population-specific entities out of a total of 19 populations belonging to three species. Thus, for the first time, DNA barcodes have been found to identify entities below the species level that may constitute separate conservation units or even species units. Our findings suggest that character-based DNA barcoding can be a rapid and reliable means for (i) the assignment of unknown specimens to a taxonomic group, (ii) the exploration of diagnosability of conservation units, and (iii) complement-

ing taxonomic identification systems." (Authors)] Address: Hadrys, Heike, ITZ, Ecology & Evolution, TiHo Hannover, Bünteweg 17d, D-30559, Hannover, Germany. E-mail: heike.hadrys@ecolevol.de

7128. Ren, D.; Nel, A.; Prokop, J. (2008): New early griffenfly, *Sinomeganeura huangheensis* from the Late Carboniferous of northern China (Meganisoptera: Meganeuridae). *Insect Syst. Evol.* 38: 223-229 (in English) ["New griffenfly *Sinomeganeura huangheensis* gen. n., sp. n. (Meganeuridae) is described from Upper Carboniferous (Namurian) of the Tupo Formation in northern China (Ningxia Hui Autonomous Region). This taxon exhibits unique structure of the wing venation pattern. It is highly interesting in reference to the Namurian age known for the occurrence of two meganeurids until present (Namurotypus Brauckmann & Zessin, 1989 and Shenzhousia Zhang & Hong, 2006) as well as the palaeogeographical position of the locality far from all sites in Laurussia. We demonstrate that meganeurids with relatively small wings already co-existed with large species in the Namurian, as for the Stephanian and the Late Permian. Thus, *Sinomeganeura* demonstrates that the meganeurid diversity and wing venation disparity were comparable during the Namurian and the Stephanian, suggesting that this group already had a long history in the Early Carboniferous. Odonatoptera were probably the main, if not unique predators of the flying insects during the Late Paleozoic." - 7134.** Ruggiero, A.; Céréghino, R.; Figuerola, J.; Marty, P.; Angélibert, S. (2008): Farm ponds make a contribution to the biodiversity of aquatic insects in a French agricultural landscape. *Comptes Rendus Biologies* 331(4): 298-308. (in English, with French summary). ["Man made ecosystems provide a variety of resources that have strong economic values. We assessed the importance of 37 farm ponds for the biodiversity of Odonata in an agricultural landscape lacking natural wetlands in southwestern France. Farm ponds captured 40% of the regional species pool, including both common and rare species. The species assemblages were not correlated with pond use (e.g., cattle watering, duck farming, etc.) or to landscape variable. Species richness was correlated with pond area, suggesting that community diversity was primarily driven by autoecological processes. Farm ponds thus made a positive contribution to the maintenance of aquatic biodiversity. This added value for biodiversity should be considered when calculating the costs and benefits of constructing water bodies for human activities." - 7135.** Sato, M.; Kohmatsu, Y.; Yuma, M.; Tsubaki, Y. (2008): Population genetic differentiation in three sympatric damselfly species in a highly fragmented urban landscape (Zygoptera: Coenagrionidae). *Odonatologica* 37(2): 131-144. (in English). ["The Amplified Fragment Length Polymorphism technique was used to compare the levels of genetic diversity and differentiation among *Paracercion calamorum*, *Ischnura senegalensis* and *I. asiatica* and to compare the genetic structure of populations found in highly fragmented urban habitats to populations in relatively continuous rural habitats. For all 3 species, high genetic diversity was found in both areas. However, population genetic differentiation among urban populations was approximately twice that of rural populations, indicating that movements between habitat patches are more restricted in urban areas, probably due to human disturbances that may function as barriers. Interspecific differences regarding genetic diversity and differentiation are further discussed in terms of habitat specificity." - 7136.** Scanlon, A.T.; Petit, S. (2008): Biomass and biodiversity of nocturnal aerial insects in an Adelaide City park and implications for bats (Microchiroptera). *Urban Ecosyst.* 11: 91-106. (in English). ["Temporal variation of insect communities in urban environments is poorly known and mechanisms driving these changes are unclear, as are the implications for insectivorous predators. We examined the relationships between season and nocturnal aerial insect biomass and biodiversity, and between temperature and insect biomass in the Adelaide zoological gardens from December 2005 to September 2006. We also compared the effectiveness of two insect trap types and used a bat detector to assess bat activity in relation to insect biomass. During the study, 9,939 insects from 13 orders were collected at the Adelaide zoo with a Malaise trap and a light trap. Mass and diversity of insects were highest during warm months, as was bat activity, and bat activity was positively correlated with insect biomass. Winter-active insects consisted predominantly of Diptera and Lepidoptera, which may provide an important winter food resource for insectivorous bats. The Malaise trap attracted fewer insect orders and biomass than did the light trap, and insects congregated within 6 m of artificial lights, so bats that forage at lights may have an advantage in urban areas. A strong need for the inclusion of urban insects to biodiversity inventories exists in the context of bat conservation." (Authors) Odonata were also trapped, but biomass was as low to be further processed.] Address: Petit, Sophie, School of Natural and Built Environments, University of South Australia, Mawson Lakes, South Australia 5095, Australia. 7138. Schmidt, E.G. (2008): *Sympetrum depressiusculum* (Selys), a southern continental dragonfly depending on artificial habitats in atlantic northwestern Germany (State of Northrhine-Westphalia) (Anisoptera: Libellulidae). *Notulae odonatologicae* 7(1): 5-10. (in English). ["In the atlantic northwest of central Europe, *S. depress.* is confined to shallow artificial ponds with a particular aquatic vegetation, clear water, rich food supply (zooplankton, zoobenthos) for the larvae, and - due to drying up during winter - with reduced negative impact by fish. Essentially, water temperature has to rise above the average level typical for this region. Carp breeding ponds offer these conditions, favouring *S. depressiusculum* outside of its original area. The artificial carp breeding ponds provide invaluable chances for species conservation in this geographical region, furthering the state's official nature conservation management. Some lead water ponds near the Dutch-Belgian border (in the vicinity of Lommel) seem to provide similar habitat conditions. It is assumed, though still an open question, that *S. depressiusculum* is relying on the same ecological conditions in fish ponds in more continental areas of central Europe (e.g. the Lausitz district near the Oder; the Fränkisches Weihergebiet in the hilly zone of northern Bavaria). This paper should promote the verification of this assumption." (Author)] Address: Schmidt, E., Coesfelder Str. 230, D-48249 Dülmen, Germany

7139. Solimini, A.G.; Bazzanti, M.; Ruggiero, A.; Carchini, G. (2008): Developing a multimetric index of ecological integrity based on macroinvertebrates of mountain ponds in central Italy. *Hydrobiologia* 597: 109-123. (in English). ["The lack of biological systems for the assessment of ecological quality specific to mountain ponds prevents the effective management of these natural resources. In this article we develop an index based on macroinvertebrates sensitive to the gradient of nutrient enrichment. With this aim, we sampled 31 ponds along a gradient of trophic and with similar geomorphological characteristics and watershed use in protected areas of the central Apennines. A bioassessment protocol was adopted to collect and process benthic samples and key-associated physical, chemical, and biological variables during the summer growth season of 1998. We collected 61 genera of macroinvertebrates belonging to 31 families. We calculated 31 macroinvertebrate metrics based on selected and total taxa richness, richness of some key groups, abundance, functional groups and tolerance to organic pollution. The gradient of trophic was quantified with summer concentrations of chlorophyll *a*. We followed a stepwise procedure to evaluate the effectiveness of a given metric for use in the multimetric index. Those were the pollution tolerance metric ASPT, three metrics based on taxonomic richness (the richness of macroinvertebrate genera, the richness of chironomid taxa, and the percentage of total richness composed by Ephemeroptera, Odonata, and Trichoptera), two metrics based on FFG attributes (richness of collector gatherer taxa and richness of scraper taxa) and the habit based metric richness of burrowers. The 95th percentile of each metric distribution among all ponds was trisected for metric scoring. The final Pond Macroinvertebrate Integrity Index ranged from 7 to 35 and had a good correlation ($R^2 = 0.71$) with the original gradient of environmental degradation." (Authors) Odonata are treated on the genus level.] Address: Solimini, A.G., European Commission, Joint Research Centre, Institute for Environment and

Sustainability, TP 290, 21027 Ispra, Italy. E-mail: angelo.solimini@jrc.it

7140. Solomon, C.T.; Carpenter, S.R.; COLE, J.J.; Pace, M.L. (2008): Support of benthic invertebrates by detrital resources and current autochthonous primary production: results from a whole-lake ^{13}C addition. *Freshwater Biology* 53(1): 42-54. (in English). ["1. Secondary production of benthic invertebrates in lakes is supported by current autochthonous primary production, and by detritus derived from a combination of terrestrial inputs and old autochthonous production from prior seasons. We quantified the importance of these two resources for the dominant benthic insects in Crampton Lake, a 26 ha, clear-water system. 2. Daily additions of $NaH^{13}CO_3$ to the lake caused an increase in the stable carbon isotope ratios ($d^{13}C$) of the current primary production of phytoplankton and periphyton. We measured the response of four insect groups (taxon-depth combinations) to this manipulation, quantifying their current autochthony (% reliance on current autochthonous primary production) by fitting dynamic mixing models to time series of insect $d^{13}C$. 3. The $d^{13}C$ of all four groups increased in response to the manipulation, although the magnitude of response differed by taxon and by depth, indicating differences in current autochthony. Odonate larvae (Libellulidae and Corduliidae) collected at 1.5 m depth derived 75% of their C from current autochthonous primary production. Chironomid larvae collected at 1.5, 3.5 and 10 m depths derived, respectively, 43%, 39% and 17% of their C from current autochthonous primary production. 4. Both taxon-specific diet preferences and depth-specific differences in resource availability may contribute to differences in current autochthony. Our results demonstrate significant but incomplete support of insect production by current autochthony, and indicate that allochthonous inputs and old autochthonous detritus support a substantial fraction (25–83%) of insect production." 7141. Squires, Z.E.; Bailey, P.C.E.; Reina, R.D.; Wong, B.B.M. (2008): Environmental deterioration increases tadpole vulnerability to predation. *Biology letters* 4(4): 392-394. (in English). ["Human-induced environmental change is occurring at an unprecedented rate and scale. Many freshwater habitats, in particular, have been degraded as a result of increased salinity. Little is known about the effects of anthropogenic salinization on freshwater organisms, especially at sublethal concentrations, where subtle behavioural changes can have potentially drastic fitness consequences. Using a species of Australian frog (*Litoria ewingii*), we experimentally examined the effects of salinization on tadpole behaviour and their vulnerability to a predatory dragonfly nymph (*Hemianax papuensis*). We found that tadpoles exposed to an ecologically relevant concentration of salt (15% seawater, SW) were less active than those in our freshwater control (0.4% SW). Tadpoles in elevated salinity also experienced a higher risk of predation, even though the strike rate of the predator did not differ between salt and freshwater treatments. In a separate experiment testing the burst-speed performance of tadpoles, we found that tadpoles in saltwater were slower than those in freshwater. Thus, it would appear that salt compromised the anti-predator response of tadpoles and made them more susceptible to being captured.

Our results demonstrate that environmentally relevant concentrations of aquatic contaminants can, even at sublethal levels, severely undermine the fitness of exposed organisms." (Authors)] Address: Squires, Zoe E., School of Biological Sciences, Monash University, Victoria 3800, Australia

7142. Takahara, T.; Kohmatsu, Y.; Yamaoka, R. (2008): Predator-avoidance behavior in anuran tadpoles: a new bioassay for characterization of water-soluble cues. *Hydrobiologia* 607: 123-130. (in English). ["In freshwater systems, little is known about the characteristics of chemical cues derived from predators which induce defensive responses in prey species. To elucidate traits of predator chemical cues, we examined chemical cues originating from water incubated by the nymph of the dragonfly *Anax parthenope julius*, which induces low activity as predator-avoidance behaviour in tadpoles of two anuran species, the Japanese tree frog *Hyla japonica* and the wrinkled frog *Rana (Rugosa) rugosa*. *H. japonica* exhibited a reduction in tail movement time as low activity in response to both untreated incubation water and incubation water that had volatile substances removed by freeze-drying. The response threshold of *R. rugosa* to chemical cues was determined to be one dragonfly nymph in a water volume between 500 and 5,000 ml. We found that chemical cues inducing predator-avoidance behaviour in anuran tadpoles have water-soluble non-volatile characteristics. In this study, we devised both the bioassay to assess the effects of chemical cues and the method to enrich the cues by freeze-drying, which can serve as a tool in the process of identification of unknown chemical cues in freshwater predator-prey interaction." 7143. Takougang, I.; Barbazan, P.; Tchounwou, P.B.; Noumi, E. (2008): The value of the freshwater snail dip scoop sampling method in macroinvertebrates bioassessment of sugar mill wastewater pollution in Mbandjock, Cameroon. *International Journal of Environmental Research and Public Health* 5(1): 68-75. (in English). ["Macroinvertebrates identification and enumeration may be used as a simple and affordable alternative to chemical analysis in water pollution monitoring. However, the ecological responses of various taxa to pollution are poorly known in resources-limited tropical countries. While freshwater macroinvertebrates have been used in the assessment of water quality in Europe and the Americas, investigations in Africa have mainly focused on snail hosts of human parasites. There is a need for sampling methods that can be used to assess both snails and other macroinvertebrates. The present study was designed to evaluate the usefulness of the freshwater snail dip scoop method in the study of macroinvertebrates for the assessment of the SOSUCAM sugar mill effluents pollution. Standard snail dip scoop samples were collected upstream and downstream of the factory effluent inputs, on the Mokona and Mengoala rivers. The analysis of the macroinvertebrate communities revealed the absence of Ephemeroptera and Trichoptera, and the thriving of Syrphidae in the sections of the rivers under high effluent load. The Shannon & Weaver diversity index was lower in these areas. The dip scoop sampling protocol was found to be a useful method for macroinvertebrates collection. Hence, this

method is recommended as a simple, cost-effective and efficient tool for the bio-assessment of freshwater pollution in developing countries with limited research resources." (Authors) Odonata are treated on the family level.] Address: Takougang, I., Dept of Public Health, Faculty of Medicine & Biomedical Sciences, University of Yaounde I, P.O. Box 1364, Cameroon. 7145. Touchon, J.C.; Warkentin, K.M. (2008): Fish and dragonfly nymph predators induce opposite shifts in color and morphology of tadpoles. *Oikos* 117(4): 634-640. (in English). ["Many prey species, including amphibian larvae, can adaptively alter colouration and morphology to become more or less conspicuous to predators. Despite abundant research on predator-induced plasticity in tadpoles, the combination of colour and morphological responses to predators remains largely unexplored. We measured predator-induced morphological and colour plasticity in tadpoles. We reared tadpoles of the neotropical treefrog *Dendropsophus ebraccatus* with dragonfly nymph or fish predators, or in a predator-free control. After 10 days, we digitally photographed tadpoles and measured eight morphometric variables and five tail colour variables. Tadpoles reared with nymphs developed the largest and reddest tails, but incurred a developmental cost, being the smallest overall. Cues from fish induced an opposite tail phenotype in tadpoles, causing shallow achromatic tails. Control tadpoles developed intermediate tail phenotypes. This provides the first experimental evidence that tadpoles can shift both colour and morphology in opposite, predator-specific directions in response to a fish and an odonate predator. Despite mean differences, however, there was substantial variation in the degree of phenotype induction across treatments. Tail redness was correlated with tail spot size, but not perfectly, indicating that colour and morphology may be partially decoupled in *D. ebraccatus*. Balancing selection from multiple conflicting predators may result in genetic variation for developmental plasticity." (Authors)] Address: Touchon, J.C., Dept of Biology, Boston Univ., 5 Cummington St., Boston, MA 02215, USA. E-mail: jtouchon@bu.edu

7146. Trisnawati, I.; Nakamura, K. (2008): Abundance, diversity and distribution of above-ground arthropods collected by window traps from Satoyama in Kanazawa, Japan: an order level analysis. *Far Eastern Entomologist* 181: 1-23. (in English, with Russian summary). ["Satoyama, the traditional rural landscape of Japan, has been paid much attention because, beside its many important roles, it is a key to biodiversity conservation in Japan. The effects of habitat heterogeneity and restoration activities on the abundance and diversity of above-ground arthropod assemblages were studied using win-

dow traps in a "satoyama area" within Kanazawa University's Campus, Kanazawa, Japan in 2005 and 2006. Monthly samples were taken at upper and ground levels from nine sites, including forested areas and valley areas with paddies under restoration. A total of 93,134 individuals from 24 orders, including 18 Insecta orders, 3 Arachnida, 2 Crustacea and 1 Chilopoda, were collected during the study, and an order level analysis was carried out. At the upper level, Diptera was the dominant order (about 70%), followed by Homoptera and Coleoptera (5-10 %), and at ground level, Diptera (about 40%), Collembola (10%), and ants (8%) were dominant. DCA ordination revealed a clear separation of arthropod order compositions among different habitat types and between upper and ground levels, but the separation was less apparent between years. DCA ordination of 18 orders revealed the variation of spatial distribution of these orders in accordance with habit ("flying" or "non-flying") and habitat preference ("forests" or "cultivated valley" sites)." (Authors) The taxa list also includes Odonata, which are very rarely sampled.] Address: Nakamura, K., Division of Biodiversity, Institute of Nature & Environmental Technology, Kanazawa University, Kakuma, Kanazawa, 920-1192, Japan. E-mail: koji@kenroku.kanazawa-u.ac.jp

7147. Tsuchiya, K.; Hayashi, F. (2008): Surgical examination of male genital function of calopterygid damselflies (Odonata). *Behavioral Ecology and Sociobiology*: 1417-1425. (in English). ["Male genitalia show rapid and divergent evolution. It is rarely determined whether variation in male genital morphology influences male reproductive success. Male damselflies possess a unique aedeagus with a re-curved head and spiny lateral processes, and most ♀♀ have two sperm storage organs, a spherical bursa copulatrix and a tubular spermatheca. Previous studies have indicated that the re-curved head may remove bursal sperm, whereas the lateral processes remove spermathecal sperm. However, we need more direct evidence of these functions. We compared sperm number in female sperm storage organs by interrupting copulation to examine sperm removal by the male. In *Calopteryx cornelia*, ♂♂ removed almost all bursal sperm but only partially removed spermathecal sperm. In contrast, ♀♀ of *Mnais pruinosa* store sperm primarily in the bursa, and ♂♂ removed only bursal sperm. To examine the functions of male spiny lateral processes, we compared mating behaviour between control and experimental ♂♂ from which we removed (cut) the lateral processes. In *C. cornelia*, cutting of the lateral processes resulted in a decreased number of abdominal movements during copulation and no removal of spermathecal sperm. The amount of bursal sperm removed during copulation also decreased in experimental ♂♂ compared to the unmanipulated ♂♂. However, in *M. pruinosa*, the experimental removal of male lateral processes did not decrease the abdominal movements and little affected the removal of bursal sperm. Interspecific differences between *C. cornelia* and *M. pruinosa* may be caused by variation in the strategies of female sperm storage." (Authors)] Address: Tsuchiya, K., Department of Biology, Tokyo Metropolitan University, Minamiosawa 1-1, Hachioji Tokyo, 192-0397, Japan. E-mail: tsuchiya-kaori@ed.tmu.ac.jp

7148. Vadadi-Fülöp, C.S.; Hufnagel, L.; Sipkay, C.S.; Verasztó, C.S. (2008): Evaluation of climate change scenarios based on aquatic food web modelling. *Applied ecology and environmental research* 6(1): 1-28.

(in English). ["In the years 2004 and 2005 we collected samples of phytoplankton, zooplankton and macroinvertebrates in an artificial small pond in Budapest, Hungary. We set up a simulation model predicting the abundance of the cycloids, *Eudiaptomus zacharias* and *Ischnura pumilio* by considering only temperature as it affects the abundance of population of the previous day. Phytoplankton abundance was simulated by considering not only temperature, but the abundance of the three mentioned groups. This discrete-deterministic model could generate similar patterns like the observed one and testing it on historical data was successful. However, because the model was overpredicting the abundances of *Ischnura pumilio* and *Cyclopoida* at the end of the year, these results were not considered. Running the model with the data series of climate change scenarios, we had an opportunity to predict the individual numbers for the period around 2050. If the model is run with the data series of the two scenarios UKHI and UKLO, which predict drastic global warming, then we can observe a decrease in abundance and shift in the date of the maximum abundance occurring (excluding *Ischnura pumilio*, where the maximum abundance increases and it occurs later), whereas under unchanged climatic conditions (BASE scenario) the change in abundance is negligible. According to the scenarios GFDL 2535, GFDL 5564 and UKTR, a transition could be noticed." (Authors)] Address: Vadadi-Fülöp, C. S., Dept Syst. Zoology and Ecology, Eötvös Loránd University, H-1117 Budapest, Pázmány P. sétány 1/c, Hungary. E-mail: vadfulcsab@gmail.com

7149. Vargas, A.; Mittal, R.; Dong, H. (2008): A computational study of the aerodynamic performance of a dragonfly wing section in gliding flight. *Bioinspiration & Biomimetics* 3: 1-13. (in English). ["A comprehensive computational fluid-dynamics-based study of a pleated wing section based on the wing of *Aeshna cyanea* has been performed at ultra-low Reynolds numbers corresponding to the gliding flight of these dragonflies. In addition to the pleated wing, simulations have also been carried out for its smoothed counterpart (called the 'profiled' airfoil) and a flat plate in order to better understand the aerodynamic performance of the pleated wing. The simulations employ a sharp interface Cartesian-grid-based immersed boundary method, and a detailed critical assessment of the computed results was performed giving a high measure of confidence in the fidelity of the current simulations. The simulations demonstrate that the pleated airfoil produces comparable and at times higher lift than the profiled airfoil, with a drag comparable to that of its profiled counterpart. The higher lift and moderate drag associated with the pleated airfoil lead to an aerodynamic performance that is at least equivalent to and sometimes better than the profiled airfoil. The primary cause for the reduction in the overall drag of the pleated airfoil is the negative shear drag produced by the recirculation zones which form within the pleats. The current numerical simulations therefore clearly demonstrate that the pleated wing is an ingenious design of nature, which at times surpasses the aerodynamic performance of a more conventional smooth airfoil as well as that of a flat plate. For this reason, the pleated airfoil is an excellent candidate for a fixed wing micro-aerial vehicle design." 7150. Walther, D.A.; Whiles, M.R. (2008): Macroinvertebrate responses to constructed riffles in the Cache River, Illinois, USA. *Environmental Management* 41(4): 516-527. (in English). ["Stream restoration practices are becoming increasingly common, but biological assessments of these improvements are still limited. Rock weirs, a type of constructed riffle, were implemented in the upper Cache River in southern Illinois, USA, in 2001 and 2003–2004 to control channel incision and protect high quality riparian wetlands as part of an extensive watershed-level restoration. Construction of the rock weirs provided an opportunity to examine biological responses to a common in-stream restoration technique. We compared macroinvertebrate assemblages on previously constructed rock weirs and newly constructed weirs to those on snags and scoured clay streambed, the two dominant substrates in the unrestored reaches of the river. We quantitatively sampled macroinvertebrates on these substrates on seven occasions during 2003 and 2004. Ephemeroptera, Plecoptera, and Trichoptera (EPT) biomass and aquatic insect biomass were significantly higher on rock weirs than the streambed for most sample periods. Snags supported intermediate EPT and aquatic insect biomass compared to rock weirs and the streambed. Nonmetric multidimensional scaling (NMDS) ordinations for 2003 and 2004 revealed distinct assemblage groups for rock weirs, snags, and the streambed. Analysis of similarity supported visual interpretation of NMDS plots. All pair-wise substrate comparisons differed significantly, except recently constructed weirs versus older weirs. Results indicate positive responses by macroinvertebrate assemblages to in-stream restoration in the Cache River. Moreover, these responses were not evident with more common measures of total density, biomass, and diversity." (Authors)] Address: D. A. Walther (&) M. R. Whiles Dept of Zoology & Center for Ecology, Southern Illinois University Carbondale, Carbondale, IL 62901-6501, USA. E-mail: denise.walther@yahoo.com

7151. Wang, Y.; Wang, Y.; Lu, P.; Zhang, F.; Li, Y. (2008): Diet composition of post-metamorphic bullfrogs (*Rana catesbeiana*) in the Zhoushan archipelago, Zhejiang Province, China. *Frontiers of Biology in China* 3(2): 219-226. (in English). ["Bullfrogs (*Rana catesbeiana*) are listed as one of the 100 worst invasive alien species in the world. They are generalist predators and thus may affect native species through predation. In previous studies, the food contents of bullfrogs were mostly examined at a single site. In the present study, the diet composition of post-metamorphic bullfrogs on eight islands (Daishan, Liheng, Xiushan, Fodu, Taohua, Xiashi, Cezi, and Putuoshan) in the Zhoushan Archipelago, Zhejiang Province of China, were examined by using the stomach flushing method from June 30 to August 11 in 2005. A total of 391 individual frogs were measured, including 113 adults and 278 juveniles. The analysis of the stomach contents shows that, for adult bullfrogs, the most important prey (by diet volume) overall were Decapoda, Coleoptera, Odonata, Mesogastropoda, Raniformes, and Cypriniformes. For juvenile bullfrogs, these were Decapoda, Coleoptera, Cypriniformes, Odonata, Orthoptera, Hymenoptera, Lepidoptera larvae, Mesogastropoda, and Raniformes. Moreover, the prey size and diet volume increased with the body size of both adult and juvenile bullfrogs. The diet composition of primary preys of bullfrogs was significantly different among the islands. The results indicate that bullfrogs exert different predatory influences on native

fauna at different sites and that bullfrogs are generalist predators with extensive ecological impacts on native fauna." (Authors)] Address: Li, Y., Key Lab. of Animal Ecology and Conservation Biology, Institute of Zoology, Chinese Academy of Sciences, Beijing, 100080, China. Email: liym@ioz.ac.cn

7152. Ward, L.; Mills, P.J. (2008): Substrate selection in larval *Calopteryx splendens* (Harris) (Zygoptera: Calopterygidae). *Odonatologica* 37(1): 69-77. (in English). ["Under experimental conditions, the relationship between substrate composition, with and without the presence of an emergence support, and larval distribution was investigated. Results revealed that *C. splendens* larvae showed a clear preference for a pebble substrate as opposed to sand or silt, when all 3 substrates were equally available. However, the substrate type decreased in importance as the density of the emergence support increased. Results suggest that the morphological adaptations of *C. splendens* larvae, to cling to a substrate, can be utilised equally in a vegetated habitat and a habitat predominated by pebbles and cobbles. This has implications for the dispersal of *C. splendens* to areas containing, traditionally, less favoured habitat. Range expansion of *C. splendens* on its northern borders, where aquatic habitat characteristics can differ markedly from waterways in lowland southern England, is discussed." 7153. Watanabe, M.; Matsu'ura, S.; Fukaya, M. (2008): Changes in distribution and abundance of the endangered damselfly *Mortonagrion Hirosei* Asahina (Zygoptera: Coenagrionidae) in a reed community artificially established for its conservation. *Journal of Insect Conservation*: (in English). ["Population trends of the brackish water damselfly, *Mortonagrion Hirosei* were studied for 4 years in the reed community artificially established for conservation of this endangered species. Because of difficulty with mark-and-recapture experiments on this small damselfly with weak wings in the large dense reed community, census counts using the line transect method were performed to estimate the population parameters. The reed rhizomes were transplanted in January of 2003. A few adults immigrated to the community in the flying season of this year, but they were restricted near the original habitat. The number of adults throughout the flying season was estimated at 1,000. In 2004, the population included both the immigrants from the original habitat and the emergences from the established habitat, and the total population was estimated at 10,000, and the daily density in peak flight season was 20% that in the original habitat. An estimated 23,000 individuals were found all over the established habitat in 2005. In 2006, the estimated number of adults in the established habitat was 45,600, and the population density increased almost equal to that in the original habitat. Therefore we can conclude that the damselfly had settled in the established habitat.] Address: Watanabe, Mamoru, Graduate School of Life & Environmental Sciences, University of Tsukuba, Tsukuba, Ibaraki 305-8577, Japan. 7154. Wayland, M.; Headley, J.V.; Peru, K.M.; Crosley, R.; Brownlee, B.G. (2008): Levels of polycyclic aromatic hydrocarbons and dibenzothiophenes in wetland sediments and aquatic insects in the oil sands area of Northeastern Alberta, Canada. *Environ. monit. assess.*

136(1-3): 167-182. (in English). ["An immense volume of tailings and tailings water is accumulating in tailings ponds located on mine leases in the oil sands area of Alberta, Canada. Oil sands mining companies have proposed to use tailings- and tailings water-amended lakes and wetlands as part of their mine remediation plans. Polycyclic aromatic hydrocarbons (PAHs) are substances of concern in oil sands tailings and tailings water. In this study, we determined concentrations of PAHs in sediments, insect larvae and adult insects collected in or adjacent to three groups of wetlands: experimental wetlands to which tailings or tailings water had been purposely added, oil sands wetlands that were located on the mine leases but which had not been experimentally manipulated and reference wetlands located near the mine leases. Alkylated PAHs dominated the PAH profile in all types of samples in the three categories of wetlands. Median and maximum PAH concentrations, especially alkylated PAH concentrations, tended to be higher in sediments and insect larvae in experimental wetlands than in the other types of wetlands. Such was not the case for adult insects, which contained higher than expected levels of PAHs in the three types of ponds. Overlap in PAH concentrations in larvae among pond types suggests that any increase in PAH levels resulting from the addition of tailings and tailings water to wetlands would be modest. Biota-sediment accumulation factors were higher for alkylated PAHs than for their parent counterparts and were lower in experimental wetlands than in oil sands and reference wetlands. Research is needed to examine factors that affect the bioavailability of PAHs in oil sands tailings- or tailings water-amended wetlands." 7155. Westermann, K. (2008): Sex ratio in a population of *Lestes viridis*: spatial and temporal variability at emergence (Odonata: Lestidae). *International Journal of Odonatology* 11(1): 115-129. (in English). ["In a large population of *L. viridis* inhabiting a complex, extended system of channels in the floodplain of the Upper Rhine River near Weisweil (Baden-Württemberg, Germany) detailed samples of exuviae were collected from several subpopulations. For each sample the sex ratio was determined. For statistical reasons only samples with at least 700 exuviae were considered. These samples sometimes differed highly significant in the sex ratio at emergence. The sex ratio was sitespecific, but differed significantly for different subpopulations with variation in water temperature. Thus, damselfly larvae showed sex-dependent habitat preferences. The frequency of ♂♂ ranged from 49.4% to 57.5%. Statistically significant small-scale differences in sex ratio, which have not previously been described, could not be attributed to different preferences of the sexes with respect to larval habitat and emergence site. No coherent explanation for this phenomenon could be advanced. ♀♀ on average emerged earlier than ♂♂; in one of the samples the median emergence date differed by four days." 7156. Williams, P.; Whitfield, M.; Biggs, J. (2008): How can we make new ponds biodiverse? A case study monitored over 7 years. *Hydrobiologia* 597: 137-148. (in English). ["A new pond complex, designed to enhance

aquatic biodiversity, was monitored over a 7-year period. The Pinkhill Meadow site, located in grassland adjacent to the R. Thames, proved unusually rich in terms of its macrophyte, aquatic macroinvertebrate and wetland bird assemblages. In total, the 3.2 ha mosaic of ca. 40 permanent, semi-permanent and seasonal ponds and pools was colonized by approximately 20% of all UK wetland plant and macroinvertebrate species over the 7-year survey period. This included eight invertebrate species that are Nationally Scarce in the UK. The site supported three breeding species of wading bird and was used by an additional 54 species of waders, waterfowl and other wetland birds. The results from four monitoring ponds investigated in more detail showed that these ponds significantly supported more plant and macroinvertebrate species than both minimally impaired UK reference ponds, and other new ponds for which compatible data were available. Comparisons of the physico-chemical, hydrological and land-use characteristics of the Pinkhill pools with those of other new ponds showed that the site was unusual in having a high proportion of wetlands in the near surrounds. It also had significantly lower water conductivity than other ponds and a higher proportion of (non-woodland) semi-natural land in its surroundings. Given that ponds are known to contribute significantly to UK biodiversity at a landscape level, and that several thousand new ponds are created each year in the UK alone, the findings suggest that well designed and located pond complexes could be used to significantly enhance freshwater biodiversity within catchments." (Authors) The supplementary material to this paper contains a list of 13 odonate species observed at Pinkhill.] Address: Williams, P., Pond Conservation: The Water Habitats Trust, Oxford Brookes University, Gypsy Lane, Headington, Oxford OX3 0BP, UK. 7157. Yang, G.-h.; Mao, B.-y.; Xu, J.-s.; Yang, Z.-z. (2008): A preliminary report on the investigation of dragonflies from Cangshan Nature Reserve of Yunnan. *Journal of Dali University* 7(2): 9-11. (in Chinese, with English summary). [Checklist of Odonata from Cangshan National Nature Reserve of Yunnan, China. 1 species is said to be a new addition to the Chinese list, and 5 species were newly recorded in Yunnan. *Ischnura mildredae*, *I. senegalensis*, *Ceragrion fallax*, *Somatochlora dido*, *Epophthalmia elegans*, *Cephalaeschna magdalena*, *Anisogomphus maacki*, *Mesopodagrion tibetanum*, *Sympetrum darwinianum*, *S. fonscolombii*, *Pantala flavescens*, *Crocothemis servilia*, *Orthetrum japonicum* *internum*, and *O. sabina* are outlined in the discussion, and therefore should contain the new additions.] Address: Yang, G.-h., College of Life Science and Chemistry, Dali University, Dali, Yunnan, 671000, China

7158. Yu, X.; Yang, G.H.; Bu, W.-J. (2008): A study of the genus *Pyrrhosoma* from China with description of a new species (Odonata, Coenagrionidae). *Acta Zootaxonomica Sinica* 33(2): 358-362. (in Chinese, with English summary). ["The present paper sums up the research history of *Pyrrhosoma* Charpentier, with emphasis on diagnostic characters of the genus. Besides the red body colour, one important diagnostic character for *Pyrrhosoma* is the presence of distinct hook-like projection between male cerci and paraprocts, called the ventral branch by Kalkman (2006), which extended from the very base of cerci. As Asahina (1973) pointed out, Needham (1930) had confused *Pyrrhosoma tinctipenne* with *Calicnemia* sp. from China, however, his unique

figure about this species (Needham, 1930. p. 191 Fig. 12[5]) was right about *P. tinctipenne*. *Pyrhosoma latiloba* sp. nov. (Holotype ♂, Zhongdian, Yunnan, China, 4 Aug. 2005, YANG Guo-Hui leg., Paratype 1 ♀, ditto.) Type specimens will be deposited in the Institute of Entomology, College of Life Sciences, Nankai University, Tianjin, China. The new species is similar to *P. tinctipenne* from China. The differences between these two species were listed in a table. The new species can be distinguished from two European species by colour pattern and the shape of ligula." (Authors)] Address: Yu, X., Inst. Entomology, College of Life Sciences, Nankai University, Tianjin 300071, China

7159. Zampella, R.A.; Bunnell, J.F.; Procopio, N.A.; Bryson, D.E. (2008): Macroinvertebrate assemblages in blackwater streams draining forest land active and abandoned cranberry bogs. *Wetlands* 28(2): 390-400. (in English). ["Cranberry agriculture is a major land use in parts of the New Jersey Pinelands, USA. We compared the composition of genus-level macroinvertebrate assemblages collected from three habitats (muck, vegetated muck, and woody debris) in 12 New Jersey Pinelands blackwater streams draining forest, abandoned-cranberry bogs, and active-cranberry bogs and evaluated whether variations in macroinvertebrate assemblages were related to differences in land uses within the associated drainage basins. All 12 streams were relatively slow moving and acidic, with low conductance values and dissolved oxygen concentrations. Muck was the dominant substrate at most stream sites. Many of the taxa that we encountered are adapted to lentic habitats, slow-moving lotic habitats, or low-oxygen environments. Macroinvertebrate composition differed significantly between the active-cranberry streams and the other two stream types and was associated with a complex environmental gradient represented by variations in dissolved oxygen, temperature, specific conductance, stream width, and woody debris. Overall, the effect of stream type appeared to overshadow that of the three different habitats. Although we cannot conclude that subtle between-site differences in dissolved oxygen were responsible for variations in community composition, many of the genera associated with the forest and abandoned-bog/active-cranberry ends of the community gradient are reported to have contrasting tolerances to low-oxygen levels. The relationship between reduced canopy cover and both lower woody-debris cover and higher stream temperatures, which can influence dissolved-oxygen levels, was most likely related to forest-canopy removal associated with historic and active-cranberry agriculture." (Authors) The study includes records of *Ischnura* sp.] Address: Zampella, R.A., Pinelands Commission, P.O. Box 7, New Lisbon, New Jersey, USA 08064. E-mail: zampella@njpinelands.state.nj.us

7166. Samways, M.J.; Stewart, D.A.B. (1997): An aquatic ecotone and its significance in conservation. *Biodiversity and Conservation* 6: 1429-1444. (in English) ["Aquatic invertebrates were sampled throughout an area of transition between a well-established reservoir and a perennial stream in the KwaZulu-Natal Midlands of South Africa. The visibly obvious separation of stream and reservoir was not reflected by the invertebrates. Communities overlapped in species, ranging from fast-flowing stream and moderate-flowing stream, through a transitional ecotone, which ran along the exposed reservoir edge and stream edges, to sheltered edges of reservoir and stream then to open reservoir. These features reflected the degree of water movement (whether from waves or ripples) and type of substratum, rather than visibly lotic or lentic conditions. The main aquatic ecotone between the open reservoir and the main stream was therefore not at the mouth of the stream but along the edges of both systems. The centre of the reservoir and centre of the stream, although physically connected, were quite different in their invertebrates and were separate 'patches' with a sharp boundary. They were faunistically connected through the communities of the edge ecotone. The ecotone acted like a semi-permeable membrane to the drifting stream fauna with movement back again apparently mostly in the air, suggesting a 'patchy metapopulation' model. Both the river continuum and boundary concepts were

applicable to this multi-system. The ecotone did not show any edge effect and accords more with the 'variegation' than 'fragmentation' model. The great difference in patterns of pelagic, littoral and terrestrial communities has important implications for zoning of water bodies for different conservation and recreation activities." (Authors) Odonata are listed or treated at several occasions.] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. 7167. Turner, A.M.; McCarty, J.P. (1997): Resource availability, breeding site selection, and reproductive success of red-winged blackbirds. *Oecologia* 113(1): 140-146. (in English) [oas 23;"Red-winged blackbirds are polygynous and show strong breeding site preferences, but it is unclear which environmental factors regulate their reproductive success and are ultimately responsible for shaping their patterns of habitat selection and their mating system. We evaluated the effect of variation in insect emergence rates on the reproductive success of male and female redwings nesting on replicate ponds. The number of male and female redwings that settled on a pond varied two- to three-fold among ponds, but was not related to insect emergence rates. Insect emergence rates had a positive effect on the number of nestlings successfully fledged by females, the number of nestlings fledged from male territories, and on the mass of nestlings at fledging. *Typha* stem density also varied widely among ponds, and was positively related to male and female settling density and mass of nestlings at fledging, but not to the number of nestlings fledged by females or males. We conclude that alternative breeding sites differ in their ability to support redwing reproduction, and that the availability of emerging odonates is an important environmental factor influencing the reproductive success of both male and female red-winged blackbirds." 7169. Carvalho, A.L.; Nessimian, J.L. (1998): Odonata do Estado do Rio de Janeiro, Brasil: habitats e hábitos das larvas. Ecol. Insetos Aquát. Rio de Janeiro, 5 (Série Oecologia Brasiliensis): 3-38. (in Portuguese, with English summary) ["Odonata from Rio de Janeiro State, Brazil: habitats and habits of the larvae - Rio de Janeiro State is located in southeastern Brazil, occupying only 0,52% (44,268 Km²) of the total area of the country. Species of 77 genera and 12 families are currently known to occur in this State: Calopterygidae (2 gen.); Dictyrididae (1 gen.); Lestidae (1 gen.); Megapodagrionidae (2 gen.); Perilestidae (1 gen.); Coenagrionidae (14 gen.); Protoneuridae (5 gen.); Pseudosligmatidae (1 gen.); Aeshnidae (10 gen.); Gomphidae (11 gen.); Corduliidae (2 gen.); Libellulidae (27 gen.). Information about habitat preferences and habits of larvae of 133 species of 62 genera were considered in this study, being 19 of them registered for the first time. It was observed that species of 27 genera are lotic dwellers and those of 27 others associated with lentic habitats. Species of 8 genera occur both in lentic and lotic waters. There is no information about larvae of 15 genera yet. In relation to the habits of the larvae it was observed that the majority of Zygoptera from lentic habitats behave as climbers (e.g. *Acanthagrion* spp., *Idioneura ancilla*, *Ischnura* spp., *Leptagrion* spp., *Telebasis* spp.), as the major part of Aeshnidae too (e.g. *Aeshna* spp., *Coryphaeschna* spp., *Gynacantha* spp., *Neuraeschna costalis*, *Remartinia lutetpennis*). Representatives of these two groups become clingers in lotic habitats (e.g. *Argia* spp., *Hetaerina* spp., *Heteragrion* spp., *Limnetron* spp., *Oxyagrion* spp., *Staurophlebia reticulata*). Some Zygoptera has been classified secondarily as swimmers (e.g. *Lestes* spp., *Perilestes fragilis*). Almost all of the species of Gomphidae behave as burrowers. From the other side, the Libellulidae and Corduliidae have been considered as sprawlers in almost their totality." (in English) ["As a preliminary stage in characterizing the biodiversity patterns of pristine stream habitats in Russian Karelia, the macroinvertebrate fauna and bryophyte flora were studied in three river systems of the Tolvajärvi area. The pristine watercourses of this area are among the few representative watercourses to be used as reference sites for the studies dealing with the impact of forestry on lotic biodiversity. The benthic fauna and flora of the area were found to include many species considered as endangered, rare or with a northern distribution in Finland. In Canonical Correspondence Analysis, the most important environmental variables affecting the distribution and abundance of the benthic fauna were the abundance of aquatic mosses, the amount of organic matter and woody debris, the size of the drainage area and the concentrations of nutrients and iron in the water. Filter feeding trichopteran and algae feeding chironomid larvae dominated the stable lake outlet habitats with abundant moss vegetation, while small streams with higher nutrient and iron concentrations and large amount of organic matter were dominated by shredding stonefly species of the genera *Nemoura*, *Nemurella* and *Leuctra*." (Authors) The following Odonata taxa are listed: *Calopteryx virgo*, Coenagrionidae indet., *Aeshna grandis*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia*, *Cordulegaster boltonii*, Corduliidae indet., *Somatochlora metallica*, *Leucorrhinia* sp. indet. and *L. albifrons*] Address: Vuori, K.-M., North Karelia Regional Environment Centre, P.O. 7179. Werren, J.H.; Windsor, D.M. (2000): *Wolbachia* infection frequencies in insects: evidence of a global equilibrium? Proc. R. Soc. Lond. B 267: 1277-1285. (in English) ["*Wolbachia* are a group of cytoplasmically inherited bacteria that cause reproduction alterations in arthropods, including parthenogenesis, reproductive incompatibility, feminization of genetic males and male killing. Previous general surveys of insects in Panama and Britain found *Wolbachia* to be common, occurring in 16-22% of species. Here, using similar polymerase chain reaction methods, we report that 19.3% of a sample of temperate North American insects are infected with *Wolbachia*, a frequency strikingly similar to frequencies found in two other studies in widely separated locales. The results may indicate a widespread equilibrium of *Wolbachia* infection frequencies in insects whose maintenance remains to be explained. Alternatively, *Wolbachia* may be increasing in global insect communities. Within each of the three geographic regions surveyed, Hymenoptera are more frequently infected with A group *Wolbachia* and Lepidoptera more frequently infected with B group *Wolbachia*.] Address: Werren, J.H., Department of Biology, University of Rochester, Rochester, NY 14627, USA

(in English) ["We provide quantitative information on the diet of nestling Bitterns, examine the factors influencing diet composition and determine whether adult females are choosing particular species and size of prey. Sixty regurgitate samples from 44 broods were examined during visits to Bittern nests made at nine sites in England from 1996 to 2001. Compositional analysis was used to assess influence of age, season and year effects on diet. The fish component of the diet was compared with species found to be generally available within each site from electro fishing data. Eel *Anguilla anguilla* and Rudd *Scardinius erythrophthalmus* made up the greatest proportion of biomass of the diet and this proportion did not significantly change with the age of the chicks. [...]" (Authors) Libellulidae contributed only rarely to the diet of the chicks.] Address: Royal Society for the Protection of Birds, The Lodge, Sandy, Bedfordshire, SG19 2DL; E-mail: Gillian.Gilbert@rspb.org.uk

7191. Mukhtar, M.; Herrel, N.; Amerasinghe, F.P.; Ensink, J.; van der Hoek, W.; Konradsen, F. (2003): Role of wastewater irrigation in mosquito breeding in south Punjab, Pakistan. *Southeast Asian jour. trop. med. public health* 34(1): 72-80. (in English) ["Mosquito breeding within the wastewater irrigation system around the town of Haroonabad in the southern Punjab, Pakistan, was studied from July to September 2000 as part of a wider study of the costs and benefits of wastewater use in agriculture. The objective of this study was to assess the vector-borne human disease risks associated with mosquito species utilizing wastewater for breeding. Mosquito larvae were collected on a fortnightly basis from components of the wastewater disposal system and irrigated sites. In total, 133 samples were collected, about equally divided between agricultural sites and the wastewater disposal system. [...] The prevalence of established vectors of human diseases such as *An. stephensi* (malaria), *Cx. tritaeniorhynchus* (West Nile fever, Japanese encephalitis) and *Cx. quinquefasciatus* (Bancroftian filariasis, West Nile fever) in the wastewater system indicated that such habitats could contribute to vector-borne disease risks for human communities that are dependent upon wastewater use for their livelihoods. Wastewater disposal and irrigation systems provide a perennial source of water for vector mosquitoes in semiarid countries like Pakistan. Vector mosquitoes exploit these sites if alternative breeding sites with better biological, physical, and chemical conditions are not abundant." (Authors) The paper also contains a few notes on Odonata specified on the genus level.] Address: Mukhtar, M., International Water Management Institute (IWMI), 12 Km Multan Road, Chowk Thokar Niaz Baig, Lahore 53700, Pakistan. 7193. Prokop, J. (2003): Remarks on palaeoenvironmental changes based on reviewed Tertiary insect associations from the Krušné hory piedmont basins and the Ěeské stědohoří Mts in northwestern Bohemia (Czech Republic). *Acta zoologica cracoviensia*, 46 (suppl. - Fossil Insects): 329-344. (in English) ["Cenozoic insect fauna of northwestern Bohemia is preserved in fluviolacustrine deposits of the Krušné hory piedmont basins and the Ceské stredohorí Mts. The fossil insect assemblages are correlated with palaeobotanical results. The local palaeoenvironmental conditions such as the distance from the shoreline or water depth are interpreted. A reflection of changes in distribution of fossil entomofaunas is compared with relevant world localities of different palaeoenvironments. The sparse fossil insect taphocoenoses fill a gap in record of significant diverse non-marine invertebrate communities and serve for reconstruction of terrestrial palaeoecosystems. The selected fossil sites demonstrate insect taphocoenoses formed under conditions of the palaeoenvironment of a diatomaceous lake with subtropical forests (Kuěln), lowlands of riparian and mesophytic forests (Kundratice - Seifhennersdorf), warm-temperate swamp to riparian forests (Bilina mine) and lake sedimentation near mixed mesophytic forests (Mokřina). The aim is to compare fossil entomofaunas from several periods within Tertiary in northwestern Bohemia and search for analogous palaeoenvironmental conditions in other areas. The results are correlated with the previously proposed palaeobotanical models." (Author) Many references to Odonata are made.] Address: Prokop, J. 7195. Wada, S. (2003): Scientific Report of Nakaikemi Marsh, Tsuruga, Fukui Prefecture. Chapter 8 Insect Fauna of Nakaikemi Marsh and its neighboring areas. (4) The Odonata fauna in Nakaikemi and its current status. Research Report from the National Institute for Environmental Studies, Japan 176: 291-307. (in Japanese) ["In this report, *Sympetrum pedemontanum elatum* (Selys, 1872) is added to the Odonata fauna of Nakaikemi, and the total number of the Odonata species recorded there reached 70 (belonging to 10 families), which attains approximately 35% of the Japanese Odonata fauna (total 197 species). The biodiversity of Odonata in Nakaikemi reflects the diversity of the aquatic environments there, but the abandonment of paddy cultivation and the construction of the road in the wetland in recent years have caused some drastic changes in the aquatic environment, such as the succession of the

wetland, water pollution, the disappearance of several species of aquatic plants, and a marked increase in the number of the American crawfish in almost every canal and wetland in Nakaikemi. These changes have caused fatal damage to the habitats of many Odonata species. The number of larvae of the inhabitants of the canals and wetlands has remarkably decreased, and two vulnerable species, *Aeschnophlebia longistigma* Selys, 1883 and *Aeschnophlebia anisoptera* Selys, 1883, which are typical wetland inhabitants, have not been recorded in Nakaikemi for more than five years." (2004): Biodiversity associated with an irrigated rice agro-ecosystem in Sri Lanka. *Biodiversity and Conservation* 13: 1715-1753. (in English) ["Irrigated rice fields are temporary wetland agro-ecosystems, managed with a variable degree of intensity. A survey was carried out in Sri Lanka to document the overall biodiversity associated with this unique agro-ecosystem, using a combination of sampling techniques to document different groups of fauna and flora. The total number of biota recorded and identified from the rice field ecosystem during the entire study period consisted of 494 species of invertebrates belonging to 10 phyla and 103 species of vertebrates, while the flora included 89 species of macrophytes, 39 genera of microphytes and 3 species of macrofungi. Of the total species documented, 15 species of invertebrates and one weed species are new records to Sri Lanka. Arthropods were the dominant group of invertebrates (405 species), of which 55 species were rice pest insects, and 200 species were natural enemies of pest insects. The fauna and flora recorded from the rice field were observed to follow a uniform pattern of seasonal colonization and succession during successive rice cultivation cycles. The biodiversity of the irrigated rice agro-ecosystem interests both agroecologists and conservation biologists. Therefore, the integrated efforts of these two groups can result in the formulation of strategies based on biodiversity as an organizing principle in the sustainable management of the rice field agro-ecosystem." (Author) 19 Odonata taxa are listed.] Address: Bambaradeniya, C.N.B., IUCN - The World Conservation Union, Sri Lanka Country Office, No. 53, Horton Place, Colombo 07, Sri Lanka. 7198. Dijkstra, K.-D. (2004): Dragonflies (Odonata) of Mulanje Mountain, Malawi. *Nyala* 22: 3-8. (in English) ["Sixty-five species of Odonata are recorded from Mulanje and its slopes. Only eight species dominate on the high plateau. Among them are two relict species of conservation concern: The endemic *Oreocnemis phoenix* (monotypic genus) and the restricted-range species *Chlorolestes elegans*. The absence of mountain marsh specialists on the plateau is note-worthy. Mulanje's valleys, of which Likabula and Ruo are best known, have a rich dragonfly fauna. The Eastern Arc relict *Nepogom-*

phoides stuhlmanni is common here." (Author)] Address: Dijkstra, K.D., Curator of invertebrates, National Zoological Collection of Suriname, University of Suriname, P.O. Box 9212, Paramaribo, Suriname. E-mail: Dijkstra@naturalis.nnm.nl

7199. Giribet, G.; Edgecombe, G.D.; Carpenter, J.M.; d'Haese, C.A.; Wheeler, W.C. (2004): Is Ellipura monophyletic? A combined analysis of basal hexapod relationships with emphasis on the origin of insects. *Organisms, Diversity & Evolution* 4: 319-340. (in English) ["Hexapoda includes 33 commonly recognized orders, most of them insects. Ongoing controversy concerns the grouping of Protura and Collembola as a taxon Ellipura, the monophyly of Diplura, a single or multiple origins of entognathy, and the monophyly or paraphyly of the silverfish (Lepidotrichidae and Zygentoma s.s.) with respect to other dicondylous insects. Here we analyze relationships among basal hexapod orders via a cladistic analysis of sequence data for five molecular markers and 189 morphological characters in a simultaneous analysis framework using myriapod and crustacean outgroups. Using a sensitivity analysis approach and testing for stability, the most congruent parameters resolve Tricholepidion as sister group to the remaining Dicondylia, whereas most suboptimal parameter sets group Tricholepidion with Zygentoma. Stable hypotheses include the monophyly of Diplura, and a sister group relationship between Diplura and Protura, contradicting the Ellipura hypothesis. Hexapod monophyly is contradicted by an alliance between Collembola, Crustacea and Ectognatha (i.e., exclusive of Diplura and Protura) in molecular and combined analyses." (Authors) Many references are made to Odonata; Anax junius and Libellula pulchella are represented in the analyses.] Address: Giribet, G., Dept of Organismic & Evolutionary Biology, Museum of Comparative Zoology, Harvard University, 16 Divinity Avenue, Cambridge, MA 02138, USA. 7201. McCoy, M.W.; Savitzky, A.H. (2004): Feeding ecology of larval *Ambystoma mabeei* (Urodela: Ambystomatidae). *Southeastern Naturalist* 3(3): 409-416. (in English) ["*A. mabeei* is listed as threatened in Virginia due to its rarity and susceptibility to urbanization and poor forestry practices. The purposes of this study were to determine the composition of the diet of larval *A. mabeei* and to compare larval diet in different geographic regions to gain insights into the ecology of Virginia populations. Ninety-eight percent (N = 75) of all *A. mabeei* larvae dissected contained food items. Virginia samples harbored higher loads of gastric parasites (Nematodes) than individuals from other locations. Furthermore, prey species found in the stomachs of Virginia specimens were different than those of conspecifics from more southern locations. Higher loads of gastric parasites in Virginia animals may be related to their diet, which in turn is related to the forest cover over natural ponds.

Habitat disturbance and parasite prevalence may have major implications both for larval survival and for the long-term persistence of *A. mabeei* populations in this portion of their range." (Author) Odonata contributed to the diet of salamanders as follows: North Carolina: 12.2% and Virginia: 11.1%.] Address: McCoy, M., Dept of Zoology, University of Florida, PO Box 118525, Gainesville, FL 32611-8525, USA. 7202. Murphy, G.W. (2004): Uptake of mercury and relationship to food habits of selected fish species in the Shenandoah river basin, Virginia. Thesis, Master of Science, Fisheries and Wildlife Sciences, Faculty of the Virginia Polytechnic Institute and State University: 221 pp. (in English) [Mercury poses significant challenges to human health and fisheries management. Historical industrial practices in Waynesboro, Virginia left portions of the Shenandoah River basin contaminated with mercury and stringent health advisories for fish consumption. I investigated processes affecting the bioaccumulation of mercury in *Catostomus commersoni*, *Ictalurus punctatus*, *Lepomis auritus*, and *Micropterus dolomieu* by studying food habits, total mercury and methylmercury in common prey items, and bioaccumulation dynamics of methylmercury in the mercury contaminated South River and South Fork of the Shenandoah River and uncontaminated North River. Additionally, I evaluated sexual and seasonal variations of total mercury in *M. dolomieu* in the South Fork of the Shenandoah River. Algae, aquatic insects, crayfish, detritus, and fish accounted for 75-97% of the diet. Total mercury in aquatic invertebrates and forage fish in contaminated rivers ranged from 66.7-398.3 and 198.0-594.9 ng/g wet weight, while total mercury in aquatic invertebrates and forage fish in the reference river were 4.4 and 29.3 ng/g. Model simulations indicated that dietary pathways accounted for 87% of methylmercury uptake by fish in contaminated rivers, but only 57% in the reference river. Total mercury in *M. dolomieu* was 19-20% higher in females than males and 14-21% higher during spring than summer and fall. Results of this study indicate that bioenergetics based bioaccumulation models are valuable tools for evaluating field data, identifying processes critical to contaminant accumulation, and comparing outcomes of alternative management options associated with pollution control, ecosystem management, and/or restoration activities for management guidance prior to costly expenditures." (Author) Odonata are treated on the order level. Predacious aquatic invertebrates (e.g., Odonata) normally exhibited higher concentrations of total mercury than herbivorous and detritivorous invertebrates.] Address: not stated

7206. Poulton, B.C. (2004): Chapter 4. Aquatic invertebrates of Lisbon Bottom Wetlands. Ecological dynamics of wetlands at Lisbon Bottom, Big Muddy National Fish and Wildlife refuge, Missouri: 83-113. (in English) ["Aquatic macroinvertebrates were sampled both qualitatively and quantitatively from March-July 1999 to characterize the community composition and density in different types of wetlands at Lisbon Bottom based on water source, permanence, available vegetation structure, and timing of flood pulses. Twelve wetlands were sampled 1-2 times per month to document species richness (timed sweep-net sample), and eight wetlands were sampled at least once every two weeks for measuring macroinvertebrate density (0.24-m dia. stovepipe). From this study and previous macroinvertebrate research including adjacent riverine habitats (Lisbon Chute, mainstem Missouri River, etc.). a total of 260 species are known to exist in the Lisbon area, over half of which are unique to the flood-plain wetland complex. Richness of Odonata, Coleoptera, Hemiptera, and Ephemeroptera was high in vegetated areas of most wetlands: however, richness of Diptera was lower than that reported in other studies and the Trichoptera were nearly absent. Temporary wetlands held water throughout the winter months due to the fall 1998 flood, and the invertebrate community was dominated by overwintering species and groups of pioneer taxa that were available for dispersal to other basins after flooding occurred in mid-April. Species richness was lowest in deep scours, and highest in seasonal wetlands. Both species richness and density (#/m²) were highest when margin vegetation was inundated, which corresponds with a period of 2-3 weeks after the flood pulse. Richness and density were also highest in seasonal wetlands: scours had lowest species richness throughout the early part of the study, but increased by late spring and summer periods. In all but the deep scours, the ratio of predator / herbivore-detritivores gradually declined during the study period, and the ratio of benthic / pelagic invertebrates peaked during the post-flood period. Both of these indicators appear to correspond with changes in the availability of organic matter due to flooding. Recommendations and goals for managing flood-plain wetlands for maximization of wildlife value will also maximize the availability and productivity of macroinvertebrate food sources for other wildlife species, while increasing biodiversity.] Address: <http://infolink.cr.usgs.gov/Science/Lisbon/4Invertebrates.pdf>

7207. Puyshkin, V.B., Yevstafiev, A.I., Gromenko, V.M. & Ruybka, T.S. (>2004?): *Insecta* [sic!], Odonata. Biodiversity of the Crimean Peninsula: 131-135. (in Russian) [Based on 11 of the papers that deal with odonate fauna of the Crimean Peninsula a list is compiled showing the distribution and abundance of the 49 recorded species across 12 steppe and 9 mountain landscape units. The species are then explicitly listed again under

three distribution headings: i) species restricted to a certain distribution zone, ii) species typical for one zone but also found in the other, iii) species with azonal distribution and again under four abundance groups (massive, common, rare, very rare). It is concluded that the dragonfly fauna of the Crimean Peninsula is heterogeneous, that several species should be included in the Red Data Book and that further investigations are necessary. Abstracter's note: Caution might be necessary in adopting even these very general conclusions as the large number of misspellings and taxonomic mistakes and the incomplete literature treatment suggests this survey is not exhaustive.] Address: not stated

7208. Reash, R.J. (2004): Dissolved and total copper in a coal ash effluent and receiving stream: Assessment of in situ biological effects. *Environmental Monitoring and Assessment* 96(1-3): 203-220. (in English) ["An in situ chemical and biological study was conducted in the lower Muskingum River (southeast Ohio, U.S.A.) to evaluate potential effects of copper (Cu) discharged from a coal ash effluent. Effluent total Cu, dissolved Cu, TSS and pH measurements were performed monthly during January-December 1995. Benthic macroinvertebrates were sampled at five river locations using artificial substrate samplers, and in situ Cu analyses were conducted. Effluent Cu (total) ranged from 8 to 142 µg L⁻¹ (mean = 58 µg L⁻¹), but dissolved Cu never exceeded 78 µg L⁻¹ (mean = 20 µg L⁻¹). The mean ratio of dissolved Cu to total Cu in these samples was 32%. Total Cu concentrations at the biological sampling sites adjacent to the effluent discharge were higher than levels at ambient sites, but dissolved Cu levels were similar among all sites. The macroinvertebrate community proximal to the coal ash effluent had the highest number of taxa and total number of individuals; a high number of mayfly and caddis fly taxa; and the highest Invertebrate Community Index score. The high water velocity of the discharge (which likely contained particulate organic matter) apparently created a favorable microhabitat that, combined with Cu-complexing constituents in the discharge, superceded potential adverse effects of high Cu levels. This study emphasizes the importance of instream biological data when obtained in conjunction with chemical analyses." (Author) Macroinvertebrate taxa collected in Hester-Dendy samplers at five locations on the Muskingum River, August-September 1995 include *Boyeria vinosa*, *Argia tibialis*, *Coenagrion* sp., *Neurocordulia molesta*, *Celithemis* sp., and *Macromia taeniolata*] Address: Reash, R.J., American Electric Power, Water and Ecological Resource Services, Columbus, Ohio, U.S.A. 7209. Relyea, R.R.; Auld, J.R. (2004): Having the guts to compete: how intestinal plasticity explains costs of inducible defences. *Ecology Letters* 7: 869-875. (in English) ["Predators commonly induce phenotypic changes that make prey better at surviving predation at the cost of reduced growth. While we have a good understanding of how trait changes affect predation risk, we lack a mechanistic understanding of why predator induced phenotypes differ in growth. Using two mesocosm experiments, we combined phenotypic plasticity theory with predictions from optimal digestion theory to demonstrate that intra- and interspecific competition induced relatively long guts while predators induced relatively short guts. The longer guts induced by competition appear to be an adaptive response that allows more efficient digestion and more rapid growth whereas the

shorter guts induced by predators appear to result from a tradeoff of building larger tails in predator environments at the cost of smaller bodies. By combining these two bodies of theory, we now have a much better understanding of the mechanisms that cause the phenotypic trade-offs that select for inducible defences." (Authors) The predator used was a late instar *Anax junius* naiad.] Address: Relyea, R.A., Dept Biol. Sciences, University of Pittsburg, Pittsburgh, Pennsylvania 15260, USA. 7211. Smith, A.T. (2004): Natural and sexual selection in three species of odonates. Thesis, MSc., Department of Biology, University of Victoria: IX, 114 pp. (in English) ["Evolution is driven mainly by natural and sexual selection, which can be confounded by sex, mating system and environmental influences. Odonates have three important selective episodes during the adult life stage: survival to sexual maturity; survival after sexual maturity and mating success. Using mark-recapture and logistic regression, I examined natural selection in adult males and females of two species of non-territorial damselflies, *Lestes congener* and *L. disjunctus* and one species of territorial dragonfly, *Sympetrum pallipes* in two successive years at Galiano Island, B.C. Females gained more mass over the maturation period than males, but the difference was smaller in territorial *S. pallipes*. Sexual size dimorphism was therefore greater at maturity than emergence but less so in *S. pallipes*. Female survival was lower than male survival over the maturation period and survival over the maturation period was lower than survival after maturity in some groups. Before maturity, small male *L. congener* survived better and male *S. pallipes* with small wing loading values survived less well. No measurable difference was found between female and male survival after maturity in any species and wing loading was a better predictor of survival than body size. I also tested for sexual selection on males of all three species. As predicted, selection on body size was not detectable in both *Lestes* species. In male *S. pallipes*, small males had a mating advantage early in the season but large males had an advantage late in the season. This was attributed to density or weather effects. Large male *S. pallipes* had greater territorial success, but were not more likely to achieve mating success. There were large differences in body size between years in all groups, but the direction of change did not correspond with the direction of selection. The importance of measuring selection over more than one generation and improved observational methods are discussed further.] Address: not stated

7212. Suttle, K.B.; Power, M.E.; Levine, J.M.; McNeely, C. (2004): How fine sediment in riverbeds impairs growth and survival of juvenile salmonids. *Ecological Applications* 14(4): 969-974. (in English) ["Although excessi-

ve loading of fine sediments into rivers is well known to degrade salmonid spawning habitat, its effects on rearing juveniles have been unclear. We experimentally manipulated fine bed sediment in a northern California river and examined responses of juvenile salmonids and the food webs (treated on the family level and including Odonata) supporting them. Increasing concentrations of deposited fine sediment decreased growth and survival of juvenile steelhead trout. These declines were associated with a shift in invertebrates toward burrowing taxa unavailable as prey and with increased steelhead activity and injury at higher levels of fine sediment. The linear relationship between deposited fine sediment and juvenile steelhead growth suggests that there is no threshold below which exacerbation of fine-sediment delivery and storage in gravel bedded rivers will be harmless, but also that any reduction could produce immediate benefits for salmonid restoration." 7218. Acuna, V.; Munoz, I.; Giorgi, A.; Omella, M.; Sabater, F.; Sabater, S. (2005): Drought and postdrought recovery cycles in an intermittent Mediterranean stream: structural and functional aspects. *J. N. Am. Benthol. Soc.* 24(4): 919-933. (in English) ["The effects of the intensity of seasonal droughts on stream ecosystems were studied in the Fuirosos, an intermittent forested Mediterranean stream. Macroinvertebrate community structure and stream ecosystem metabolism were measured during seasonal summer droughts in 2001, 2002, and 2003. Ecosystem metabolism was profoundly affected by stream intermittency. Organic matter that accumulated during the dry period enhanced ecosystem respiration during the postdrought recovery. Highest biotic diversity was found at low water levels as the stream dried and contracted. Macroinvertebrate community response to drying was stepped and apparently defined by thresholds of transition from drying to cessation of flow and from the dry phase to restoration of flow. Environmental conditions changed markedly with cessation of flow, causing large changes in community structure during 2001 and 2003 (dry years). Drying caused an increase in macroinvertebrate density that peaked in isolated pools soon after flow ceased, but then decreased rapidly because of the physicochemical changes associated with fragmentation of the watercourse. The macroinvertebrate community at the end of the summer dry phase (when flow resumed) differed from the community that had been present before drying began. Differences in community structure during the summer dry period were not as marked in 2002 (a wet year) as in 2001/2003. The influence of drought on the macroinvertebrate community differed across substrata. Drying led to significant changes in density on cobbles and leaves, but not on sand. Few taxa resisted drying, and resilience to drying was the dominant response to disturbance in the Fuirosos." (Authors) The list of macroinvertebrate taxa from the Fuirosos includes *Calopteryx* sp. and *Onychogomphus* sp.] Address: Acuna, V., Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA. 7232. Revenga, C.; Campbell, I.; Abell, R.; de Villiers, P.; Bryer, M. (2005): Prospects for monitoring freshwater ecosystems towards the 2010 targets. *Phil. Trans. R. Soc. B* 360: 397-413. (in English) ["Human activities have severely affected the condition of freshwater ecosystems worldwide. Physical alteration, habitat loss, water withdrawal, pollution, overexploitation and the introduction of nonnative species all contribute to the decline in freshwater species. Today, freshwater species are, in general, at higher risk of extinction than those in forests, grasslands and coastal ecosystems. For North America alone, the projected extinction rate for freshwater fauna is five times greater than that for terrestrial fauna—a rate comparable to the species loss in tropical rainforest. Because many of these extinctions go unseen, the level of assessment and knowledge of the status and trends of freshwater species are still very poor, with species going extinct before they are even taxonomically classified. Increasing human population growth and achieving the sustainable development targets set forth in 2002 will place even higher demands

on the already stressed freshwater ecosystems, unless an integrated approach to managing water for people and ecosystems is implemented by a broad constituency. To inform and implement policies that support an integrated approach to water management, as well as to measure progress in halting the rapid decline in freshwater species, basin-level indicators describing the condition and threats to freshwater ecosystems and species are required. This paper discusses the extent and quality of data available on the number and size of populations of freshwater species, as well as the change in the extent and condition of natural freshwater habitats. The paper presents indicators that can be applied at multiple scales, highlighting the usefulness of using remote sensing and geographical information systems technologies to fill some of the existing information gaps. Finally, the paper includes an analysis of major data gaps and information needs with respect to freshwater species to measure progress towards the 2010 biodiversity targets." 7237. Verberk, W.; van Kleef, H.; Dijkman, M.; van Hoek, P.; Spierenburg, P.; Esselink, H. (2005): Seasonal changes on two different spatial scales: response of aquatic invertebrates to water body and microhabitat. *Insect Science* 12: 263-280. (in English) ["Knowledge about the spatial and temporal scales of both habitat use and the functional significance of different adaptations is essential for an understanding of the population dynamics of invertebrate assemblages. This fundamental knowledge is not only interesting from an academic point of view, but is sorely lacking and needed in the field of restoration ecology. Many species are threatened due to degradation. Knowing what environmental conditions are needed during the life cycle of these species is important in the design of restoration measures which aim to lift existing bottlenecks for threatened species. To assess the relative importance of water type and microhabitat in structuring the invertebrate assemblage during different seasons, invertebrates were sampled in three water bodies differing in trophic level and acidity. Different parts within a water body (microhabitats) were sampled separately and each water body was sampled in all four seasons. Results show that water body is an important factor structuring the invertebrate assemblage early in the season, whereas microhabitat became more important later in the season. Structural complexity of microhabitats was related to the type of locomotion employed by invertebrates. Seasonal differences could be related to population dynamics (reproduction, mortality). Moreover, fluctuations in resource availability were expected to differ between the water bodies, with highest fluctuations in the eutrophic water body and with fluctuations becoming less predictable later in the season. This was confirmed by the data: species synchronization to pulses in food availability was strongest in the eutrophic water body. Moreover, synchronization was strongest in summer, while in autumn waters were invaded by dispersive species. Based on these results a synthesis is presented on the functioning of the different waters during the different seasons." (Authors) 16 Odonata taxa are treated.] Address: Verberk, W., Bargerveen Foundation, c/o Dept of Environmental Studies, Faculty of Science, Mathematics and Computing Science, Radboud University of Nijmegen, PO Box 9010, 6500 GL Nijmegen, The Netherlands. 7238. Batista, J.D. (2006): Longitudinal distribution of adult Odonata in Cerrado streams: an ecophysiological hypothesis. Dissertação apresentada à Universidade Federal de Viçosa, como parte das exigências do Programa de Pós-Graduação em Entomologia, para obtenção do título de Magister Scientiae. Viçosa. Minas Gerais. Brasil: VIII, 41 pp. (in Portuguese, with English summary) ["The longitudinal distribution of adult Odonata was examined in streams of different channel width in the Pindaíba River Basin, in the municipalities of Barra do Garças and Nova Xavantina. The general purpose was to evaluate the existence of environmental gradients that affect the longitudinal distribution of Odonata. and to establish testable predictions to this predator group regarding the River Continuum Concept. Two hypotheses were tested: (1) increasing channel width longitudinally along the basin causes an increase of light input, and. assuming restraints and distinct abilities,

there would be a decrease of Zygoptera and increase of Anisoptera species richness. (2) Dragonflies are affected by the gradient generated through river continuum mechanisms, increasing species richness in medium-sized streams. I sampled 19 sites in rivers and streams from 1 to 6 orders, and in each site I sample once in the dry and once in the rainy seasons. Quantitative survey was conducted through scan method in fixed areas, counting visually on Odonata adults along 100 meters of the waterbody, divided into 20 stretches of 5 meters each. Channel width and depth measures were taken at the beginning, middle, and end of each 20-meter region. A total of 549 individuals were collected, distributed in one family, 13 genera and 17 species of Anisoptera, and six families, 15 genera and 30 species of Zygoptera. The abundance and proportion of Zygoptera species decrease while Anisoptera increase with channel width and mean depth of rivers and streams. The channel width was considered the best predictor of Odonata species distribution. The distribution of Odonata species richness, did not corroborate the hypotheses of higher species richness in the middle courses of streams. The results obtained in this study confirm the thermoregulation hypothesis as a determining factor in the distribution of Odonata species in the system." (Author) For details see: <http://www.tede.ufv.br/tesesimplificado/tdearquivos/11/TDE-2006-11-08T092832Z-69/Publico/texto%20completo.pdf>

7239. Braune, E. (2006): Spatially explicit models for interacting populations in a changing landscape: A case study on Namibian dragonflies (Odonata). Dissertation, Fakultät für Physik und Geowissenschaften, Technische Universität Carolo-Wilhelmina zu Braunschweig: 134 pp., Anhang. (in English) ["I have developed a model system, which allows the modelling of the responses of the three major ecological groups of dragonflies in arid Namibia under current and future climatic conditions. The habitat models that were introduced in Chapter 2 served to distinguish the three groups regarding their ecological preferences. Especially the use of the habitat web was valuable for the evaluation of the relative habitat preferences. Additionally it allowed estimating the different preferences of the species regarding the landscape layers, which were included in the landscape model (Chapter 4.2). The population dynamic model, which refined the extended Leslie matrix approach for age and size structured populations via the introduction of inter- and intraspecific interactions, showed the importance of the colonisation sequence of the dragonflies at the habitat. The model indicated that local extinctions due to size differences of larval stages are possible between the two species types "migrant" and "resident". The chosen mathematical approach did reproduce the pattern of multivoltinism, which is typical for tropical centred dragonflies, very well (Chapter 3). The construction of the landscape and especially its inherent dynamic was another crucial aspect of this work. The use of satellite images for the derivation of the ecological relevant landscape parameters combined with indispensable expert knowledge about the processes and characteristics of the landscape sectors facilitated to change the model's scale (Chapter 4.2.2). The larger scale led to new insights for the explanation of occurring spatial distribution patterns of the dragonflies. The dynamic change of the landscape showed that in more arid regions the residential species with longer duration of their larval stages were impeded by the smaller number of habitats and a higher level of habitat variability in

terms of continuity (Chapter 4.2.3). The combination of landscape dynamics with the dispersal abilities of the modelled species made the impact of landscape fragmentation in the more arid regions apparent (Chapter 4.3.3). Theoretical scenarios were used to get first results of the model's performance in an explicit spatial context. These scenarios showed the general importance of habitat structures preferred by the residents as a refuge and source habitat, but also as an obstacle for dispersal and consequently the colonisation of habitats in larger distance. The migrant, defined as a habitat generalist, was able to establish at least small subpopulations in the most distant habitats (Chapter 4.3.4). The results of the scenarios based on the real landscape sections in the Swakop River catchment were compared with the survey data from the wetland below the S. von Bach dam. This validation showed that the results of the spatially explicit model reproduced the patterns observed in reality very well (Chapter 4.3.5.2). The coexistence of two residential species in a community seems to be difficult to realise as the results have shown competitive exclusion of the weaker disperser (Chapter 4.3.5.1). Therefore species with equal life-history parameters are supposed to use other mechanisms to coexist in the same habitat. One possible factor, which may promote coexistence despite of the same life-cycle or competitive advantage of one species, may be resource partitioning in the freshwater habitat. Furthermore, the habitat preferences, which were confirmed by the HSM, were also reflected by the spatial patterns produced by the model. Regarding aspects of conservation biology, the model clearly indicated the importance of permanent and well vegetated habitats for the residential species with certain habitat preferences. In the model, these habitats were represented by the outlets of the dams but also permanent springs may provide the required properties and should therefore be regarded as valuable for conservation. The application of climate change scenarios based on IPCC forecasts showed that the mean metapopulation densities in the investigated landscape sections will potentially decrease. Fragmentation of the landscape regarding the presence of freshwater habitats will increase and affect especially the species with poorer dispersal abilities. However, the survival of this species was possible despite of the aggravation of the habitats. Nevertheless, the theoretical scenarios have shown that extreme fragmentation may lead to isolation of a species, which enhances the risk of a complete extinction of a metapopulation (Chapter 4.3.5.3). More empirical data concerning the construction of the landscape and its dynamic are just as desirable as more information on the parameters which drive the local population dynamics. Both would lead to an improved model whose accuracy would increase regarding the predictions of changes in the water balance. Another factor promoting the model's accuracy would be the linkage between the cellular automata to model the far distance dispersal. This would certainly improve the results especially for the migrant species. A refinement of the scale of the cellular automaton on the locality level would also add accuracy. To minimise the proximate extension of calculation time this should only be done in regions with high water densities, where a multitude of single but linked freshwaters exist. The model approach, which was presented in this work, allows making predictions of the spatial patterns of dragonfly communities in the arid regions of Namibia. A change in the lifehistory parameters of the species may allow modelling of other species or communities,

respectively. Furthermore, the implementation of other ecologically relevant properties of the landscape is possible if the information for the construction of the landscape layer exists. Hence, other dragonfly communities can be modelled with little effort. The presented model system can be used as a tool for the assessment of biodiversity of Odonata and may help to identify and emphasise valuable regions for freshwater conservation management." 7241. Budha, P.B. (2006): *Dragonfly biodiversity: Important management tool for providing safe drinking. Biodiversität und Naturlandschaft im Himalaya - Biodiversity and Natural Heritage of the Himalaya II.* - ISBN 10: 3-00-019541-6: (in English) ["Nepal is located in the center of the Himalayas that makes it a transitional zone between the palaerctic and Indo-Malayan biogeographical regions creating a unique and rich biodiversity. In view of species diversity, Nepal occupies the 25th global position however proper estimation of the most diverse insects has yet to be done at national level. Dragonfly biodiversity of Nepal includes about 171 reported dragonfly species from different altitudinal range from 130m to the highest elevation 6300m, however, intensive studies in several unexplored locations of the country can produce many new records to science. Three species of dragonflies; *Epiophlebia laidlawi*, *Caliphaea confusa* and *Philoganga montana*, which are included in priority species of Oriental biodiversity, and IUCN/SCC-Dragonfly Action Plan are found in Nepal but their conservation strategies are not yet developed. A relict dragonfly *E. laidlawi* is rare and listed as a 'threatened' species in the Red Data List of IUCN. Furthermore, distribution of this indicator species for healthy environment and rivers of the Himalayas, is restricted to Shivapuri National Park, the nearest national park from capital city, the Kathmandu. Shivapuri is the most important watershed area in Nepal, which supplies more than 40 percent drinking water to people of the capital but it is always in pressure due to increasing activities for recreation, hiking and trekking by many foreigners and people of Kathmandu. Pollutants may rise from a wide range of deliberate waste disposal loaded with sediments, nutrients and toxins that are flushed in from the altered watersheds. *in situ* conservation of *E. laidlawi* including other dragonflies is an important tool for watershed management and its monitoring but also implies for safe drinking water supply initiatives to Kathmanduities." 7242. Choong, C.Y. (2006): *Dive.Dive.Dive. Oviposition behaviour of Euphaea impar.* Malaysian Naturalist 59 (1): 46-48. (in English) [Verbatim: [...] The female lifted herself, and hovered over the stream at a height of 15-20cm. Suddenly, she dived at high speed into the stream against the current at an angle of 45-70 de-

grees. She failed to break the water surface, however, as the running water was too fast. She then retreated to her original perch, [...] but after five minutes, she tried diving again into the same spot. This time she successfully penetrated the water. [...] In the water, she clung to the slime-covered rocks and plant roots at the bottom of the stream, which was 5-10cm deep. Slowly, she crawled forwards and backwards, ovipositing eggs. All the time her head was against the water current so that her body and wings were anti-parallel to the water flow. After she had finished depositing her eggs, she suddenly released her legs, allowing the current to push her out of the water. She then vanished into the forest. The entire underwater process took 30 minutes. Corbet (1983) described submerged oviposition as a slow backing down into the water. Therefore, my observation of flight-dive oviposition has not yet been recorded in odonates [John Truemen, pers. comm.]. Most members of the family Euphaeidae breed in running water (Silsby 2001), so it is not surprising to note that *E. impar* chooses to oviposit in fast-running forest streams. The flight-dive oviposition behaviour with the absence of any male might explain Silsby's (2001) comment that copulation and oviposition has rarely been witnessed in Euphaeidae. - 7247.** Juen, L. (2006): Distribution of Odonata species and beta diversity pattern among streams of Central Amazonia. *Dissertação apresentada à Universidade Federal de Viçosa, como parte das exigências do Programa de Pós-Graduação em Entomologia, para obtenção do título de Magister Scientiae*. Viçosa. Minas Gerais. Brasil: VIII, 64 pp. (in Portuguese, with English summary) ["The Amazon region has the largest drainage basin of the world, which is constituted by a diversity of waterbodies, and almost all of them are resulting from the junction of small streams ("igarapes") that drain the forest. The igarapes present acid, nutrient-poor waters, and their food chains are dependent on allochthonous materials provided by the forest that fall into the igarape, as pollen, flowers, fruits, leaves, branches, insects and spiders. In spite of that, the Terra-Firme system in the Amazon is recognized as the ecosystem of higher species diversity on the planet. This work aimed to describe the distribution and the beta diversity pattern of the species comprising the Odonata communities present in the Adolfo Ducke Forest Reserve river basins. It also objectives to provide information about determining factors of the fauna similarity among sites, in order to select viable units for Odonata conservation. Samples were carried out in 24 igarapes (eleven of 15', eight of 2U and five of 31 order) distributed in four river basins, and in each basin it was conducted samples in six igarapes. The samples constituted on visual counting of adult individuals of Odonata present in 100 meters along each waterbody, divided into 20 stretches of 5 meters. The sampling time constituted of one hour duration on average. The total fauna of Odonata founded in the Ducke Reserve was of 17 species observed and 23 (= 4,77) estimated. The cluster analysis of the abiotic data demonstrated high similarity among the igarapes. The micro-drainage basins were compared in relation to species richness and they were similar statistically, and the same result was also obtained for beta diversity. The low value of beta diversity index demonstrated high fauna similarity among the igarapes. The relationship of beta diversity between the environmental data and the distance among the igarapes was highly non-significant. The low values of beta diversity index may be attributed to the high similarity of the environmental data, which presented small variation in the abiotic data, and also to the distance scale of this study, which may be small enough to not represent a barrier to Odonata dispersion. Another factor that may have contributed to these values is the occurrence of a long period of environmental stability in the Amazon that allowed the species distribution in the environment, even those with low dispersion capacity. The basic environmental variables (channel width and depth) were related to species richness increase. These results are important to species conservation, and indicate the necessity of including intermediate-size streams, with higher variation in depth and channel width, to be used as one selection criteria in the choice of environmental protection areas.] Address: not stated

- 7250.** Koops, R.-J.; Schut, D.; Groenendijk, D. (2006): Ecological differences between *Leucorrhinia dubia* and *L. rubicunda* in The Netherlands. *Brachytron* 8(2): 3-11. (in Dutch, with English summary) ["The population trend of *L. dubia* is negative, whereas the abundance rate of *L. rubicunda* showed a slight increase during the same period. However, in general both species share the same type of habitat and therefore it was questioned what the reason might be for this difference in abundance rates. The aim of this study was to assess the ecological differences between these two dragonfly species. In total 24 mostly acidic soft water shallow lakes were sampled on *Leucorrhinia* larvae. Two or more transects were placed in different parts of the pools. From each transect different measurements were taken, like pH, conductivity, water depth, detritus layer and vegetation composition. The results suggest that *L. dubia* has a smaller pH-range in comparison to *L. rubicunda*. Both *Leucorrhinia* species prefer heathland above forest in the direct surrounding of a shallow lake. The

vegetation surveys show that both dragonfly species are strongly correlated with the presence of peat moss (*Sphagnum* sp.). The results also indicate that *L. rubicunda* has a wider ecological niche than *L. dubia*. The habitats of both species are acid or slightly acidic, oligo- to mesotrophic moorland pools with *Sphagnum* vegetation; however, *L. rubicunda* range includes a lower pH. Therefore it may be more resistant to acidification." (Authors)] Address: Groenendijk, D., De Vlinderstichting, Postbus 506, NL 6700 AM Wageningen, The Netherlands. 7251. Mattei, D.; Cataudella, S.; Mancini, L.; Tancioni, L.; Migliore, L. (2006): Tiber river quality in the stretch of a sewage treatment plant: Effects of river water or disinfectants to *Daphnia* and structure of benthic macroinvertebrates community. *Water Air Soil Pollut.* 177: 441-455. (in English) [oas 23; The evaluation of Tiber River quality, in a stretch including a sewage treatment plant, has been carried out by the contemporary evaluation of water effect on *Daphnia* and benthic macroinvertebrates community structure. To achieve a good status of a river water by the end of 2015, as provided in the Water Framework Directive (WFD) 2000/60/EC, is necessary to know the quality starting point. To this end, several endpoints are expected by the WFD, including *Daphnia* toxicity test and macroinvertebrate community analysis. River water sampling was conducted in the four seasons, from upstream to downstream a sewage treatment plant. I endpoint. At the outfall of the sewage treatment plant, river water showed very high acute toxicity to *Daphnia* only in summer; some toxic effect can be found also upstream in spring. Results at the outfall were consistent with the hypothesis that disinfectants, mainly used in summer to treat discharging waters, are responsible of river water acute toxicity: *Daphnia* tests with each disinfectant (NaClO, PAA, ClO₂) showed high toxicity. River waters were also utilized in *Daphnia* reproduction tests. Samples at the outfall (excluding the summer one, undoubtedly toxic) caused slight reduction in survival and fecundity. Disinfectants were also checked in reproduction tests. Still at NOEC_{24h}, they caused a significant toxicity on both death rate and reproduction. II endpoint. Macroinvertebrate benthic community composition (including *Ischnura*, *Pyrrosoma*, *Platycnemis*, and *Orthetrum*) was evaluated upstream and downstream the sewage treatment plant, on these data Extended Biotic Index (EBI), was determined to get a score as quality class. A reduction of water quality score was found downstream the plant, one season delayed (autumn) respect the acute test on *Daphnia*. Effect of disinfectant discharge, river dilution capability on a short spatial scale and use of different endpoints are discussed in term of river stretch quality.] Address: Migliore, Luciana, Dipartimento di Biologia, Università "Tor Vergata", Via della Ricerca Scientifica I-00133 Roma, Italy. E-mail: luciana.migliore@uniroma2.it

7252. Moore, N.W. (2006): Use of the herbicide Glyphosate to control Common Reed (*Phragmites australis*) and its effects on dragonfly populations. *J. Br. Dragonfly Society* 21(2): 37-42. (in English) ["Conclusions: Spraying the encroaching reed bed on my pond in August 2003 succeeded in killing off all the reeds. One pair of Reed Warblers lost their habitat and disappeared. Otherwise there was no evidence of harm to Moorhens, Grass Snakes, Smooth Newts and dragonflies; on the contrary, the increase of suitable habitat allowed

the populations of adult insects to increase. It is just possible that some Smooth Newts and some larvae of *Pyrrosoma nymphula*, which were sprayed in the first year of their development, were adversely affected. In the instance of my pond, spraying was clearly beneficial. To what extent is my experience generally applicable? The toxicity of a herbicide can be affected by concentration levels and formulations; the effects in the field can be affected by weather and the date of spraying. Nevertheless when the choice is between losing most if not all of the dragonflies and relatively small risks attendant on any herbicide application, the risk is obviously worth taking. The experience of others in similar circumstances would be valuable." (Author)] Address: Moore N.W., The Farmhouse, 117 Boxworth End, Swavesey, Cambridge CB4 5RA, United Kingdom

7253. Nedbalová, L.; Vrba, J.; Fott, J.; Kohout, L.; Kopáček, J. (2006): Biological recovery of the Bohemian Forest lakes from acidification. *Biologia*, Bratislava, 61/Suppl. 20, Section Zoology: S453-S465. (in English) [Czech Republic; Bavaria, Germany. "A limnological survey of eight small, atmospherically acidified, forested glacial lakes in the Bohemian Forest (Šumava, Böhmerwald) was performed in September 2003. Water chemistry of the tributaries and surface layer of each lake was determined, as well as species composition and biomass of the plankton along the water column, and littoral macrozoobenthos to assess the present status of the lakes. The progress in chemical reversal and biological recovery from acid stress was evaluated by comparing the current status of the lakes with results of a survey four years ago (1999) and former acidification data since the early 1990s. Both the current chemical lake status and the pelagic food web structure reflected the acidity of the tributaries and their aluminium (Al) and phosphorus (P) concentrations. One mesotrophic (Plešné jezero) and three oligotrophic lakes (Ěrné jezero, Ěrtovo jezero, and Rachelsee) are still chronically acidified, while four other oligotrophic lakes (Kleiner Arbersee, Prášílské jezero, Grosser Arbersee, and Laka) have recovered their carbonate buffering system. Total plankton biomass was very low and largely dominated by filamentous bacteria in the acidified oligotrophic lakes, while the mesotrophic lake had a higher biomass and was dominated by phytoplankton, which apparently profited from the higher P input. In contrast, both phytoplankton and crustacean zooplankton accounted for the majority of plankton biomass in the recovering lakes. This study has shown further progress in the reversal of lake water chemistry as well as further evidence of biological recovery compared to the 1999 survey. While no changes occurred in species composition of phytoplankton, a new ciliate species was found in one lake. In several lakes, this survey documented a return of zooplankton (e.g., Cladocera: *Ceriodaphnia quadrangula* and Rotifera: three *Keratella* species) and macrozoobenthos species (e.g., Ephemeroptera and Plecoptera). The beginning of biological recovery has been delayed for ~20 years after chemical reversal of the lakes." (Authors) The list of taxa includes eight Odonata species.] Address: Nedbalová, Linda, Biology Centre AS CR, Institute of Hydrobiology, Na Sádkách 7, CZ-37005 Ěeské Budjovice, Czech Republic

7255. Ramberg, L.; Hancock, P.; Lindholm, M.; Meyer, T.; Ringrose, S.; Sliva, J.; van As, J.; VanderPost, C. (2006): Species diversity of the Okavango Delta, Botswana. *Aquatic Sciences* 68: 310-337. (in English) ["Pinhey recorded a total of 92 species in the Delta. 25 years later Kipping found one species new for the area and one new for science. On the other hand he could only find 70 out of the 92 species found by Pinhey, although his sampling intensity compares well with that of Pinhey both in time and space. Nine of the "missing" species are Zygoptera and seven of them had been recorded from three or more localities in the Delta. Out of the 13 Anisoptera that could not be found again, five had been found in three or more localities. For the species found in only 1–2 localities the problems of sampling rare species arise. However, when there are indications that species which were fairly wide spread up to the mid-seventies are now absent, there are reasons to look for other explanations. There has been a gradual decline in flooding of the Delta since the mid-seventies which could have resulted in a loss of suitable aquatic habitats for the larvae or in a loss of suitable flying prey for hunting adults. Another factor is the aerial spraying against tsetse flies in the Delta which took place during the eighties and then again 2001–02. During the first period fairly potent insecticides such as dieldrin were used but over smaller areas in each year. In the recent spraying, however, the entire Delta south of the Panhandle was sprayed; the northern part in 2001 and the southern part in 2002; totaling to about 17,000 km². Deltamethrin was used which has some good properties such as its short half-life in nature and its specificity for invertebrates. Adult Odonata experienced high mortality during the spraying of deltamethrin and the same results were recorded for larvae of the families living on the sediment surface or on vegetation." (Author).] Address: Ramberg, L., Harry Oppenheimer Okavango Research Centre, University of Botswana, P. Bag 285, Maun, Botswana. E-mail: ramberg@mopipi.ub.bw

(2006): Closely related *Wolbachia* strains within the pumpkin arthropod community and the potential for horizontal transmission via the plant. *Microbial Ecology* 51: 294-301. (in English) ["Phylogenetic studies have implicated frequent horizontal transmission of *Wolbachia* among arthropod host lineages. However, the ecological routes for such lateral transfer are poorly known. We surveyed the species of two arthropod communities, one on pumpkin and the other on loofah plants, for *Wolbachia*, constructed *wsp* gene phylogenies of those *Wolbachia* strains found to infect community members, and established ecological links among infected members. Four taxonomically diverse insects in the pumpkin arthropod community contained very closely related *Wolbachia* *wsp* sequences (G1.5% divergence by Kimura-2-parameter distances). These insects, namely, the whitefly *Bemisia tabaci*, the planthopper *Nisia nervosa*, the flea beetle *Phyllotreta* sp., and the fleahopper *Halticus minutus*, were all collected from pumpkin leaves. They were ecologically linked through feeding on the same leaf substrate. Unlike other infected leaf insects, the whitefly population appeared to have a permanent breeding relationship with pumpkin plants, and high and stable, but not fixed, monthly *Wolbachia* infection rates. Our findings suggest potential roles for the plant in *Wolbachia* transmission and for whiteflies in being an infection source for other pumpkin leaf-feeding insects." (Authors) The tests included *Ischnura* sp.] Address: Milne, J.R., Department of Biology, Faculty of Science, Mahidol University, Rama VI Road, Bangkok 10400, Thailand. E-mail: frjm@mahidol.ac.th

7260. Strayer, D.L. (2006): Challenges for freshwater invertebrate conservation. *J. N. Am. Benthol. Soc.* 25(2): 271-287. (in English) ["Freshwater invertebrate conservation faces 5 important challenges. First, 10,000 species of freshwater invertebrates around the world may already be extinct or imperiled. Second, human pressures on freshwater resources are intense and will increase in the coming decades, putting yet more species at risk. Third, scientific knowledge about freshwater invertebrates, although substantial and useful for many groups, is far less than for the vertebrates for which much of contemporary conservation biology was designed. Even the best-known freshwater invertebrates that have achieved legal protection are perhaps 1% as well studied as the typical vertebrate. Fourth, becau-

se freshwater ecosystems are downhill from and embedded in their watersheds, freshwater conservation usually has to manage entire watersheds rather than small local sites where imperiled species occur. Fifth, society spends only modest amounts of money for freshwater invertebrate conservation. The median expenditure in Fiscal Year 2003 for freshwater invertebrate species on the US Endangered Species List was only US\$24,000, and only a small minority of imperiled species is listed and receives even this modest attention. Considering these serious challenges, I believe that we need to think deliberately about the best approaches for conserving freshwater invertebrate biodiversity. The best solution may be to move away from a species-based approach that is largely derived from a terrestrial model towards broader, regional approaches that try to satisfy legitimate human needs for fresh water while preserving as much biodiversity as possible." 7265. Brockhaus, T. (2007): Bildet der Jenissei eine pleistozän entstandene Faunengrenze? Eine Diskussion am Beispiel der paläarktischen Libellenfauna (Odonata). *Entomol. rom.* 12(1): 41-59. (in German, with English summary) ["The current distribution of many palaeartic dragonflies can be explained by a hypothetic peri-glacial fauna that existed through the entire ice age. This amends the established hypotheses claiming the sole re-immigration from refugia in post-glacial times. The peri-glacial dragonfly fauna may be the cold-tolerant part of a pre-glacial pliocene fauna. With the new hypothesis the following types of distribution of palaeartic dragonflies can be explained: • species with a trans-palaeartic east to west distribution, e. g. *Lestes sponsa*, *Sympetrum danae* • species with a trans-palaeartic east to west distribution, centring in the boreal zone, e. g. *Aeshna crenata*, *Somatochlora sahlbergi* • western and eastern palaeartic distributions of subspecies and closely related species, e. g. *Leucorrhinia rubicunda* and *L. intermedia* • cold-tolerant species with a disjunctive distribution, e. g. *Coenagrion hylas*, *Somatochlora alpestris* More types of distribution are presented, such as western and eastern palaeartic ranges and ranges which are the results of refugia (*Coenagrion mercuriale*, *Somatochlora meridionale*, *Ischnura aralensis*). During the peak of the Saale glacial period when even western Siberia was covered by an icesheet parts of the peri-glacial fauna were probably subdivided into eastern and western populations. This may have happened near the Jenissei river or further east around the Jenissei, Western and Eastern Sajon mountain ranges. The genetic differentiation of these populations led to their current status as subspecies or species. The ranges of some cold-tolerant species disintegrated after the ice-age leading to boreo-montane and other disjunctions." flavescens (Odonata, Anisoptera, Libellulidae) e perda do investimento reprodutivo em áreas antropizadas. Boletim do Museu de Biologia Prof. Mello Leitao (Nova Série) 21: 7-18. (in Portuguese, with English summary) ["Behaviour of *P. flavescens* and waste of reproductive investment in urban areas - *P. flavescens* is an exophytic, territorial and migratory dragonfly. Due to its migratory behaviour, this species is commonly recorded in dry areas. However, the presence of *P. flavescens* in parking areas and the occurrence of ovipositions over reflective automobile hood surfaces are not well understood. This work presents data on the behaviour of *P. flavescens* in different areas with and without vehicles to evaluate the reproductive investment of this species in parking areas. There was correlation between the frequency of *P. flavescens* captures and the number of parked vehicles. We also recorded preference for thermoregulation activities over light-colored cars (higher light reflection indexes). Focal observation indicates that common behaviours at parking areas were similar to those registered at flooded areas and very distinct from those observed over pasture, where we registered only foraging behaviour. Eggs collected over car hood were fecundated and viable, indicating some waste of reproductive investments. Results suggest that parking areas could favour the occurrence of *P. flavescens* at urban areas. However the loss in reproductive efforts could be selecting against the animals showing this behaviour." 7275. Gunzburger, M.S. (2007): Evaluation of seven aquatic sampling methods for amphibians and other aquatic fauna. *Applied herpetology* 4: 47-63. (in English) ["To design effective and efficient research and monitoring programs researchers must have a thorough understanding of the capabilities and limitations of their sampling methods. Few direct comparative studies exist for aquatic sampling methods for amphibians. The objective of this study was to simultaneously employ seven aquatic sampling methods in 10 wetlands to compare amphibian species richness and number of individuals detected with each method. Four sampling methods allowed counts of individuals (metal dipnet, D-frame dipnet, box trap, crayfish trap), whereas the other three methods allowed detection of species (visual encounter, aural, and froglogger). Amphibian species richness was greatest with froglogger, box trap, and aural samples. For anuran species, the sampling methods by

which each life stage was detected was related to relative length of larval and breeding periods and tadpole size. Detection probability of amphibians varied across sampling methods. Box trap sampling resulted in the most precise amphibian count, but the precision of all four count-based methods was low (coefficient of variation > 145 for all methods). The efficacy of the four count sampling methods at sampling fish and aquatic invertebrates was also analyzed because these predatory taxa are known to be important predictors of amphibian habitat distribution. Species richness and counts were similar for fish with the four methods, whereas invertebrate species richness and counts were greatest in box traps." Odonata accounted most significantly to this result. "An effective wetland amphibian monitoring program in the southeastern United States should include multiple sampling methods to obtain the most accurate assessment of species community composition at each site. The combined use of frogloggers, crayfish traps, and dipnets may be the most efficient and effective amphibian monitoring protocol." 7276. Guo, T. (2007): Design and prototype of a hovering ornithopter based on dragonfly flight. Bachelor of Science, Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge: 31 pp. (in English) ["Hovering is normally achieved using a horizontal wing path to create lift; bees, wasps and helicopters use this technique. Dragonflies hover using a unique method, by flapping along an inclined stroke plane. This seems to create a higher efficiency than is possible for normal hovering. The aim of this project is to build a mechanical model to mimic the aerodynamic properties and hovering motion of dragonflies. Through the design and evaluation of this model, we can evaluate the mechanical feasibility of reproducing the wing path using single motor control and establish whether the difference in stroke plane is advantageous for the dragonfly. By adjusting the initial angle of attack of the ornithopter's wings, we can artificially recreate varying stroke planes. A comparison of the resultant lift generated from different stroke planes showed that greater lift forces were generated with non-zero stroke planes as demonstrated in normal hovering." (Author)] Address: Guo, Theresa, Massachusetts Institute of Technology, Department of Mechanical Engineering, 77 Massachusetts Avenue, Room 3-173, Cambridge, Massachusetts 02139, USA

7280. Kalkman, V.J. (2007): *Archboldargia scissorhandsi* spec. nov. from Papua, Indonesia ((Zygoptera: Coenagrionidae). *Odonatologica* 36(2): 201-206. (in English) ["The new species is described, based on a single male. Holotype male: Indonesia: Papua (formerly Irian Jaya), Pass Valley, Ibem R., 13/20-V-1999; deposited in ZMAN, Amsterdam. A key to the *Archboldargia* males is given and some notes on the distribution of the genus are provided." (Author)] Address: Kalkman, V.J., European Invertebrate Survey - Nederland, p/a Nationaal Natuurhistorisch Museum - naturalis, Postbus 9517, 2300 RA Leiden, The Netherlands. E-mail: kalkman@naturalis.nl

7281. Kalnins, M. (2007): Protected aquatic insects of Latvia – *Leucorrhinia pectoralis* (CHARPENTIER, 1825) (Odonata: Libellulidae). *Latvijas entomologs* 44: 26-32. (in English) ["Published data, collections, data collected during the project „Analysis of the Specially Protected Nature Territories in Latvia and Establishing of EMERALD/Natura 2000 Network“ and material collected by Latvian entomologists have all been used in the analysis of the distribution of this species. The distribution of *L. pectoralis* was mapped using a basic grid of 5x5 km squares in the Baltic grid system. In total, *L. pectoralis* is recorded from 98 squares in Latvia. The most known localities are concentrated in central and northern Latvia. The majority of localities of *L. pectoralis* in Latvia have been recorded in the natural eutrophic lakes with Magnopotamion- or Hydrocharition-type vegetation (21 records) and oxbow lakes (44 records). Other *L. pectoralis* habitats are hard oligo-mesotrophic lakes with benthic vegetation of *Chara* spp. (3 localities), natural dystrophic lakes and ponds in active raised bogs or transition mires (15 localities), dystrophic water bodies also (11 localities). Only in a few cases species have been observed in ponds (2 localities) and oligotrophic to

mesotrophic standing waters with *Littorelletea uniflorae* and/or *Isoëto-Nanojuncetea* vegetation (3 localities)." (Author)] Address: Kalnins, M., Nature Protection Board, Eksporta iela 5, LV-1010 Riga, Latvia. E-mail: martins.kalnins@dap.gov.lv

7282. Ketelaar, R.; Bouwman, J.H.; Felix, R.P.W.H. (2007): Notes on the habitat of *Sympecma paedisca* in Buryatia, Southeast Siberia, Russia. *Brachytron* 11(1): 91-96. (in Dutch, with English summary) ["In June 2007 the authors visited the federal subject Buryatia of the Russian Federation. On four localities populations of *S. paedisca* were found. In this article a short description and photographs are published. Two localities are more or less comparable to the habitat in The Netherlands, with dense helophyte vegetations of *Phragmites australis*. The two other habitats are different from the European reference: a small sweet water brook floating in a saline lake in the steppe region and helophyte vegetation in the summerbed of a broad river." (Authors)] Address: Ketelaar, P., p/a De Vlinderstichting, Postbus 506, NL-6700 AM Wageningen, The Netherlands. E-mail: ketelaar@vlinderstichting.nl

7283. Ketelaar, R.; Manger, R.; Ruiter, E.J.; Uilhoorn, H.M.G.; de Boer, E.P. (2007): Analysis of the distribution of *Sympecma paedisca* in the Netherlands. *Brachytron* 11(1): 5-20. (in Dutch, with English summary) ["[...] Prior 1970, *S. paedisca* was a rather common damselfly in the northern part of the Netherlands. A negative trend started, leading to the virtually disappearance around 1980. A long period followed with only a few records, and no known populations. In 1997 however, the species was rediscovered in De Weerribben, one of the largest mesotrophic peat moors in the Netherlands. Since then a remarkable recovery followed with a strong increase in number in De Weerribben and also reproduction at a second site, the Kuinderplas. At the end of summer numbers of *S. paedisca* are also increasing on heaths and dry forest edges in the provinces of Drenthe, Friesland and Overijssel, sometimes over eighty kilometres away from the reproduction sites. In spring no sign of reproduction has been seen here so far. It is documented in this article that this remarkable pattern already existed before 1970, when *S. paedisca* was still a rather common species. Reproduction occurs in more or less mesotrophic to eutrophic waters with abundant vegetation. After emergence, a large part of the population departs to drier areas. It is hypothesized in this article that these individuals do not return to their sites of origin, but wander around searching for possible reproduction sites. The fact that no new reproduction sites at these sandy soils have been found (neither have been in the past), suggest that these areas are not suitable and that all these individuals do starve without having reproduced." (Authors)] Address: Ruiter, E., Cornelis Houtmanstraat 10, 8023 EA Zwolle, The Netherlands. E-mail: e.j.ruiter@plajiet.nl

7284. Ketelaar, R.; Ruiter, E.J.; Uilhoorn, H.M.G.; Manger, R.; de Boer, E.P. (2007): Habitat choice of *Sympecma paedisca* in the Netherlands. *Brachytron* 11(1): 21-33. (in Dutch, with English summary) ["In the Netherlands, reproduction of *S. paedisca* occurs in marshes with mesotrophic to eutrophic water. The presence of vegetation succession stadia with abundant *Typha angustifolia*, *T. latifolia* and *Phragmites australis* is essential. Eggs are predominantly deposited in floating dead leaves, stems and roots of these plants. Reproduction

sites are mostly sheltered against wind and cold and warm up easily in early spring when oviposition takes place. *S. paedisca* is very scarce at localities that are too open and on sites with encroachment of trees that became too shady. The most important reproduction site in the Netherlands is the peat reserve De Weerribben in the province of Overijssel. After emergence, a part of the population stays within the nature reserve and hibernates in moist forests in tussocks of *Molinia caerulea*. Another part migrates to drier heath lands, sometimes at tens of kilometres distance where they hibernate in either *Molinia caerulea* or *Calluna vulgaris*. After hibernation, the first active individuals of *S. paedisca* were seen on February 27th. Along the edges of the woods and on sheltered sites small insects are caught and eaten, providing energy for the reproduction period from March-May." (Authors) The paper also includes habitat analysis from Baden-Württemberg and Bavaria, Germany, and Poland.] Address: Ruiter, E., Cornelis Houtmanstraat 10, 8023 EA Zwolle, The Netherlands. E-mail: e.j.ruiter@plajiet.nl

7285. Kosterin, O.E. (2007): Strekozy (Insecta, Odonata) Akademgorodka [Dragonflies (Insecta, Odonata) of Akademgorodok]. In: Priroda Akademgorodka: 50 let spustya [The Nature of Akademgorodok: 50 years passed], . I. F. Zhimulev (ed.), SO RAN Publishing House, Novosibirsk: 74-91. 7286. Liu, T. (2007): Design of a flapping mechanism for reproducing the motions at the base of a dragonfly wing. Bachelor of Science, Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge: 50 pp. (in English) ["Insect flight is being studied to aid in the development of micro-air vehicles that use the flapping wing model in an attempt to achieve the high levels of maneuverability that insects have. The flight of the dragonfly has been chosen to be modeled because of its exceptional flight capabilities. This thesis addresses the flapping mechanism designed for the root of each wing. The prototype of the mechanism, built at a scale of four times the size of a dragonfly having a wingspan of 150 mm, is able to create motions in the wing of flapping and feathering, and can vary the stroke plane. The coning angle can be set between tests. The design process began with considering two methods of actuation, a four-bar transmission mechanism used in the Micromechanical Flying Insect developed in the UC Berkeley Biomimetic Millisystem Lab, and by pivoting the wing support directly with cables or rigid links. The second design was chosen to be developed further. A functional prototype was built from acrylic and parts made using stereo lithography." (Author)] Address: Liu, Teresa, Massachusetts Institute of Technology, Department of Mechanical Engineering, 77 Massachusetts Avenue, Room 3-173, Cambridge. Massachusetts 02139. USA

7287. López-Casas, S.; Jiménez-Segura, L.F. (2007): Reproduction and feeding of *Nicuro Pimelodus blochii* (Valenciennes, 1840) (Pisces: Pimelodidae) in Vachimnero floodplain lake, Magdalena river basis, Colombia. *Actual Biol.* 29(87): 193-201. (in Spanish, with English summary) [In *Pimelodus blochii* stomachs contents of

aquatic and terrestrial animal fragments of at least 16 taxa (including Odonata) were found suggesting that this species has a wide trophic niche and an opportunistic omnivorous feeding behaviour.] Address: López-Casas, Silvia, Laboratorio de Ictiología. Instituto de Biología. Universidad de Antioquia. Medellín (Antioquia), Colombia. E-mail: silvilopezcasas@yahoo.com

7289. Mancic, C.O. (2007): Inventory of the dragonfly collection from Iron Gate Museum, Drobeta Turnu-Severin. *Drobeta, Seria St.Naturii XVII*: 172-183. (in English) [The material deposited in the Iron Gate Museum, Drobeta Turnu-Severin consists of 815 specimens of 43 species. *Coenagrion ornatum* is very important from the Natura 2000 viewpoint and *Lestes macrostigma* is a scarce species in Romania *Chalcolestes parvidens*, *Pyrrhosoma nymphula*, and *Stylurus flavipes* are also note worthy.]

7290. Manger, R. (2007): Exterior characteristics of *Sympecma paedisca* in the Netherlands. *Brachytron* 11(1): 63-74. (in Dutch, with English summary) ["In this article a description of the exterior aspects of a hibernating population of *S. paedisca* in the Netherlands is provided. The average body length of the hibernating winter damsel was 37.0 mm. The population studied showed some variation in colour and markings at the thorax. Ten percent of the population showed reduced markings and another thirteen percent showed still bright background colour in the hibernation period from October to April. During the three to four months of hibernation no colour changes appeared. In the reproductive period the individuals became more dull and darker coloured." (Author) The paper also includes remarks and pictures of *Sympecma gobica* from Kazakhstan, and from *S. fusca*.] Address: Manger, R., Stoepveldsingel 55, 9403 SM Assen. The Netherlands. E-mail: rmanger@planet.nl

7291. Manger, R.; Dingemanse, N.J. (2007): Survival and biotope selection of *Sympecma paedisca* in a winter habitat in the Netherlands. *Brachytron* 11(1): 52-62. (in Dutch, with English summary) ["This article provides a description of the habitat, behaviour and survival of adults of *S. paedisca* during wintertime. The study was conducted between 2003 and 2006 in the province of Drenthe, the Netherlands. The habitat consisted of heather (*Calluna vulgaris*, *Erica tetralix*) and purple moorgrass (*Molinia caerulea*), surrounded by pine forest (*Pinus*). Capture-recapture techniques were used to study behaviour and survival during wintertime. Hibernating adults were highly philopatric and only moved over small distances within the study area. Recaptures of adults marked elsewhere showed that wintering individuals reached the wintering habitat using stopover-sites. Monthly survival rates (December through March) were high (winter 2004/2005: 75%; 2005/2006: 100%).

Nevertheless, 58% of the hibernating adults did not survive the winter of 2004/2005. The area was used only for hibernation; reproductive behaviour was never observed and reproduction sites were not found. Based on the descriptions of habitat, behaviour and survival during winter, it is suggested that variation in winter survival plays an important role in the population dynamics of this species." (Author)] Address: Manger, R., Stoepveldsingel 55, 9403 SM Assen. The Netherlands. E-mail: rmanger@planet.nl

7292. Manger, R. (2007): Both *Sympecma paedisca* and *Sympecma fusca* in the same breeding habitat. *Brachytron* 11(1): 83-86. (in Dutch, with English summary) ["In 2007 for the first time reproduction of *S. paedisca* was observed outside the well known reproduction sites in the Netherlands. The distance from this peat hole to the peat bogs in De Weerribben is about 17 kilometers. It was also the first time both *S. paedisca* and *S. fusca* were observed together within the reproduction period for at least five weeks. The observations include both reproduction activity of Siberian winter damsel and Common Winter Damsel. The reproduction site is located along a stream and includes several mesotrophic ponds." (Author)] Address: Manger, R., Stoepveldsingel 55, 9403 SM Assen. The Netherlands. E-mail: rmanger@planet.nl

7293. Markovic, G.S.; Simic, V.M.; Ostoji, A.M.; Simic, S.B. (2007): Seasonal variation in nutrition of chub (*Leuciscus cephalus* L., Cyprinidae, Osteichthyes) in one reservoir of west Serbia. *Proc. Nat. Sci, Matica Srpska Novi Sad* 112: 107-113. (in English) ["*L. cephalus* is abundantly present fish species in the Balkan freshwaters, which indicates a good adaptation to the environmental conditions existing in the most of reservoirs. The fish species is abundant in the Meduvršje reservoir situated on the Zapadna Morava river (West Serbia, the Danube basin) as the only predator found here. In the period from 1996 to 2002, the intestinal content of 88 individuals of different age was analyzed. The zoophytophage character of diet was found to be largely shared with plant components all the year round. The differences in the trophic spectrum over the various seasons existed between the individuals of different age with high individual variations being found, too." (Authors) Odonata are the most frequent prey of *L. cephalus*. Larvae of *Lestes* sp. *Aeshna* sp. *Anax imperator*, *Gomphus vulgatissimus*, and *Brachytron pratense* are mentioned.] Address: Simic, V., Faculty of Sciences Kragujevac, University of Kragujevac, R. Domanovića 16, 34000 Kragujevac, Serbia. E-mail: goranmsv@tfc.kg.ac.yu

7294. McGeoch, M.A. (2007): Insects and bioindication: Theory and progress. *The Royal Entomological Society 2007. Insect Conservation Biology* (eds A.J.A. Stewart, T.R. New and O.T. Lewis): 144-174. (in English) ["The search for broad, repeatable patterns and the development of theory should be the major goal of biological disciplines, where theory is defined as 'empirically based mechanistic explanation of pattern in nature' (Price, 1991; Price et al., 1995). The state of bioindication is now at the point where the framework for developing a theory of bioindication has been well established. The process of theoretical development in bioindication may be considered to include: (i) delineation of objectives and the empirical collection of facts supporting the identity of species responsive, or related, to the EP of inte-

rest; (ii) the generation of hypotheses regarding these responses or relationships; (iii) independent testing of these hypotheses and acceptance or rejection of putative bioindicators; and finally (iv) further development of selected bioindicators to facilitate their use and maximize their suitability for conservation management and policy. The current primary weakness in this framework, at least for insect bioindicators, is the dearth of studies that have established robust bioindicators, and the narrow set of bioindication scenarios and geographic regions addressed by those that have. Insects have contributed substantially to the development of new methods for bioindication, and patterns are beginning to emerge of those insect taxa best suited to bioindication with different objectives, in different environments and geographical regions. However, in spite of an enormous groundswell flagging the importance of bioindication and the potential of insect bioindicators, only a handful of rigorous, fully developed insect bioindication systems have been realized. Perhaps there is a dichotomy between the desired role of indicators and realistic constraints on that role. Alternatively, perhaps the incentive and demand for insect bioindicators have not been sufficiently great. Optimistically, the field has perhaps merely required time to mature, develop methods and establish sufficient direction, and the next decade will see a proliferation of robust insect bioindication systems, as well as their widespread adoption in policy and management." (Author) Odonata contributed app. 5% to the frequency of bioindication publications involving different taxa.] Address: McGeoch, Melodie, Centre for Invasion Biology, Department of Conservation Ecology & Entomology, University of Stellenbosch, Private Bag X1, Matieland 7602, South Africa.

7295. Mertens, J.; Beladjal, L.; Janssens, F.; Matthys, P. (2007): Pitfall trapping in flooding habitats: a new technique reveals *Archisotoma pulchella* (Collembola: Isotomidae) as new to the Belgian fauna. *Belg. J. Zool.* 137(2): 177-181. (in English) ["Flooding habitats are unique ecosystems with complex land-water interactions. Research on their terrestrial component is seriously hindered by the lack of an adequate and efficient technique for pitfall trapping. This paper focuses on three consecutive items: (1) the description of a new type of trap, developed for use in temporarily submersed areas; (2) evaluation of its potential usefulness by a literature search of pitfall trapping in diverse environments (1998-2003); (3) its application in the trapping of arthropods inhabiting a salt marsh. The literature search demonstrates a bias towards forests, neglecting flooding biotopes. Beetles and spiders are by far the prominent taxa studied that way. Apart from some Diptera, *Archisotoma pulchella*, a new species of Collembolan for the Belgian fauna, is the only arthropod species trapped by the described sampling technique on the mud flats of the intertidal zone of the Ijzer estuary (Belgium), albeit in very high numbers. Additional sampling provided records from the Schelde estuary, and allows reconstructing some characteristics of its population dynamics." (Authors) Literature search of pitfall trapping resulted in records of trapped Odonata; these are not specified.] Address: Mertens, J., Terrestrial Ecology Unit, Ghent University, Ledeganckstraat 35, B-9000 Ghent, Belgium. E-mail: Johan.Mertens@UGent.be

7296. Muranyi, D. (2007): Contribution to the Odonata fauna of Albania. *Folia entomologica hungarica* 68: 41-53. (in English) ["New records of 34 species collected in

Albania during nine collecting trips between 2002 and 2006 are given. Distributional or taxonomical notes are given for 14 species. *Somatochlora meridionalis* and *Sympetrum depressiusculum* are new to the fauna of Albania. The first record of *Somatochlora flavomaculata* for Albania is given based on material from the Natural History Museum, London. The number of known species of Albanian Odonata accounts to 55." (Author)] Address: Muranyi, D., Department of Zoology, Hungarian Natural History Museum, H-1088 Budapest, Baross u. 13, Hungary. E-mail: muranyi@zool.nhmus.hu

7297. Muzon, J.; Pessacq, P.; Ramos, L. (2007): Odonata type specimens preserved in the Museo de la Plata, Argentina. *Odonatologica* 36(2): 301-306. (in English) ["Type collection preserved at Museo de La Plata includes 105 specimens of Odonata (6 holotypes, 1 neotype, 6 allotypes and 96 paratypes), representing 13 names belonging to Coenagrionidae (5), Lestidae (1), Megapodagrionidae (1), Aeshnidae (4), Gomphidae (1) and Libellulidae (1). Preservation status and label details of primary types are stated." (Authors)] Address: Muzón, J., Inst. Limnol. "Dr. R.A. Ringuelet", C.C. 712, AR-1900 La Plata, Argentina. 7301. Orr, B.; Hämäläinen, M. (2007): The Metalwing Demoiselles (*Neurobasis* and *Matronoides*) of the Eastern Tropics. *Natural History Publications*. ISBN-13: 9789838121231: 115 pp-["The metalwing demoiselles of the eastern tropics include 14 species in two genera

of calopterygid damselflies, distributed from Pakistan and Sri Lanka in the west, to southern China and New Guinea in the east. With their brilliant iridescent hindwings, the males of *Neurobasis* are among the most conspicuous and well-known inhabitants of clear forest streams throughout the region. The renowned odonatologist M.A. Lieftinck was so impressed by their beauty he called them the 'Birds of Paradise' among Odonata. A lifetime goal of Lieftinck, and before him Friedrich Ris, was to produce a full taxonomic revision of the group. Sadly, both died before their aims could be realised. This book provides this revision. Patterns of speciation are discussed in their zoogeographical context and in the light of recent molecular studies of the higher classification of the Calopterygidae. The book also includes a detailed historical account of the study of metalwings, beginning with the description of '*Libellula chinensis*' by Carl von Linné, the father of taxonomy, from a decorative coloured drawing in a book on rare birds, published in 1750. In the past few decades, a good deal of work has focussed on the biology of these insects, including analyses of their complex mating behaviour and of the physical basis for their brilliant colours. This book summarises all published information on all aspects of metalwing biology, and includes also many original observations on their ecology and behaviour, based on the authors' personal experiences." (Publisher)]

7302. Papazian, M.; Dumont, H.J.; Mary-Sasal, N.J. (2007): The Odonata of the Pacific ocean islands of Wallis and Futuna, with special reference to speciation in *Ischnura aurora* (Brauer). *Odonatologica* 36(1): 53-62. (in English) ["A collection of adult specimens made during a hydrobiological mission (5-23 X 2004) to the French Pacific Island Territories of Wallis and Futuna is studied. It constitutes the first odonate inventory from this archipelago, and is composed of 10 species (8 Anisoptera, 2 Zygoptera), all of which were known from the Pacific before. Pacific island material of *Ischnura a. aurora* (Brauer, 1865) is compared with specimens from the western part of the range of this species. These represent a good subspecies *I. a. rubilio* Selys, 1876. Furthermore, 2 new synonyms of *I. aurora* are proposed."] Address: Papazian, M., Le Constellation Bat A, 72 Avenue des Caillols, F-13012 Marseille, France

7307. Ruiter, E.J.; Manger, R. (2007): Hibernation in the Netherlands, not quite easy for *Sympecma paedisca*. *Brachytron* 11(1): 42-49. (in Dutch, with English summary) ["Until 2002 it was unknown where *S. paedisca* hibernated in the Netherlands. With research first winter sightings were established which enabled the researchers to monitor the hibernating damselflies during wintertime. *S. paedisca* hibernates in the drier areas near the reproduction sites, but also on similar areas far from De Weerribben. They hibernate till 60 cm above ground level in free hanging position often on *Calluna vulgaris* and *Molinia caerulea*, but also on *Rubus fruticosus* and young trees like *Betula* and *Quercus robur*. Cryptical hibernation as known from abroad, could not be established." (Authors)] Address: Ruiter, E., Cornelis Houtmanstraat 10, 8023 EA Zwolle, The Netherlands. E-mail: e.j.ruiter@plajiet.nl

7308. Ruiter, E.J.; Uilhoorn, H.M.G.; Manger, R.; Keteleer, R.; de Boer, E.P. (2007): Recapture of *Sympecma paedisca* over great distance. *Brachytron* 11(1): 34-41. (in Dutch, with English summary) ["From 2002 till 2004 hundreds *S. paedisca* were marked on behalf of a capture-mark-recapture experiment. Short range recapture showed that several individuals stayed on the same area for weeks. Three individuals were recaptured on places far away from the reproduction site, a unique result. Thanks to these recaptures we can establish that the *S. paedisca* damselfly migrates on purpose to places where they hibernate. The reason for this migration is

not known yet. Probably they search for new reproduction sites. Part of the population hibernates within the boundaries of the reproduction site (De Weerribben), but a significant number migrates to heath lands in the provinces of Friesland, Drenthe and Overijssel where they hibernate. After wintertime they disappear; where they go to still remains uncertain." (Authors)] Address: Ruiter, E., Cornelis Houtmanstraat 10, 8023 EA Zwolle, The Netherlands. E-mail: e.j.ruiter@plajiet.nl

7309. Sato, M.; Riddiford, N. (2007): A preliminary study of the Odonata of S'Albufera Natural Park, Mallorca: status, conservation priorities and bio-indicator potential. *Journal of Insect Conservation* 12(5): 539-548. (in English) ["This study obtained baseline information for adult Odonata and assessed their conservation priorities and suitability as biological indicators in S'Albufera Natural Park in Mallorca, Spain. At this site, human activities in and around the wetland have raised concerns about their impact on the ecosystem. Investigations on adult diversity produced records of 14 species (four Zygoptera and 10 Anisoptera) and included the first record of *Erythromma viridulum* for the park. Detrended Correspondence Analysis (DCA) ordination categorised study sites according to their geographical locations in the park and showed clustering of the sites around particular species based on these locations. This pattern might reflect the differences in brackishness in water supplied by different water sources. Canonical Correspondence Analysis (CCA) indicated that some environmental factors were related to particular species. Water flow, vegetation, and depth and size of a water body could discriminate stenotopic species from eurytopic species. Only a few species appeared to be tolerant to the sites with high salinity and low oxygen concentration. The ordination results can be useful for establishing conservation priorities with information of species diversity, abundance, distribution and flight period. Although, with the current limited basic information, the use of Odonata species as biological indicators seems to be difficult, some clear relationships between environmental factors and particular species indicate the great potential of using adult Odonata as biological indicators in the park." 7310. Sharma, G.; Joshi, P.C. (2007): Diversity of Odonata (Insecta) from Dholbaha Dam (Dist. Hoshiarpur) in Punjab Shivalik, India. *Journal of Asia Pacific Entomology* 10(2): 177-180. (in English) ["Study on the species diversity of the order Odonata was carried out during 2002 - 2004 at Dholbaha dam, which has a moist deciduous forest surrounding it in district Hoshiarpur, Punjab, India. A total of 30 species belonging to 7 families of order Odonata were recorded during the study period. The family Libellulidae, represented by 18 species was the most dominant followed by Coenagrionidae (6 species), Aeshnidae (2 species) and Calopterygidae, Chlorocyphidae, Euphaeidae and Gomphidae each having 1 species. In terms of total number of individuals, family Libellulidae constituted maximum with 64.36% followed by Coenagrionidae (28.50%), Chlorocyphidae (1.83%), Gomphidae (1.62%), Euphaeidae (1.56%), Calopterygidae (1.38%) and Aeshnidae (0.75%). *Pantala flavescens* (Fabricius), a migratory species was the most dominant in number of individuals constituting 17.12% of the total. The least dominant species included *Anax immaculifrons* Rambur (0.38%) and *Anax*

parthenope parthenope (Selys) (0.36%). Shannon-Wiener index of species diversity of Odonata was 2.988 and 3.029 during 2002-2003 and 2003-2004, respectively. Seven new species have also been reported from the Dholbaha dam during this study period thus increasing the total species number of odonates so far recorded from this area from 29 to 36." (Authors)] Address: Sharma, G., Division of Entomology, Indian Agricultural Research Institute, Pusa campus, New Delhi-110012, India. E-mail: gauravpandit2@rediffmail.com

7311. Svensson, E.I.; Karlsson, K.; Friberg, M.; Eroukhanoff, F. (2007): Gender differences in species recognition and the evolution of asymmetric sexual isolation. *Current Biology* 17: 1943-1947. (in English) ["Closely related sympatric species are expected to evolve strong species discrimination because of the reinforcement of mate preferences. Fitness costs of heterospecific matings are thought to be higher in females than in males, and females are therefore expected to show stronger species discrimination than males. Here, we investigated gender and species differences in sexual isolation in a sympatric species pair of *Calopteryx* damselflies. The genus *Calopteryx* is one of the classic examples of reproductive character displacement in evolutionary biology, with exaggerated interspecific differences in the amount of dark wing coloration when species become sympatric. Experimental manipulation of the extent of dark wing coloration revealed that sexual isolation results from both female and male mate discrimination and that wing melanization functions as a species recognition character. Female choice of conspecific males is entirely based on wing coloration, whereas males in one species also use other species recognition cues in addition to wing color. Stronger species discrimination ability in males is presumably an evolutionary response to an elevated male predation risk caused by conspicuous wing coloration. Gender differences in species discrimination and fitness costs of male courtship can thus shed new light on the evolution of asymmetric sexual isolation and the reinforcement of mate preferences." 7312. Tol, J. van; Gassmann, D. (2007): Zoogeography of freshwater invertebrates of southeast Asia, with special reference to Odonata. In: Renema, Willem (Ed.): *Biogeography, Time and Place - Distributions, Barriers and Islands. Topics in Geobiology, Vol. 29.* Dordrecht (Springer): 45-91. (in English) [oas 23, Present patterns in the distribution of the regional freshwater invertebrates are the result of complex historical and ecological processes. Many orders of aquatic insects are known in the fossil record from as early as the Early Permian, while the earliest fossils of Odonata date from the Middle Carboniferous. Thus, the breakup of Gondwana, that started in the Late Jurassic, is relevant to our understanding of the present distributional patterns. The geological history of Southeast Asia is extremely complex. The separation of India / Seychelles and Madagascar from Africa at 130 Ma, the subsequent breakup of India / Seychelles and Madagascar at 88 Ma, and the collision of India with Asia at 65-56 (or 43) Ma, significantly changed the western part of the area discussed. The southeastern part of the area changed under the influence of the northward rafting Australian plate from 85 Ma. The southwest directed subduction of the Pacific plate formed several arc-systems at the western margin

of that plate. A very important reorganisation of plate boundaries occurred at 25 Ma, when the New Guinea passive margin collided with an island arc including the eastern Philippine, Halmahera and South Caroline arc-systems, and when the northwestern corner of the Australian plate collided with Southeast Asia in the Sulawesi region. Information on the subaerial history of the respective terranes is still fragmentary. Diversity and distribution of most groups of freshwater invertebrates of Southeast Asia are still underexplored, while phylogenetic reconstructions including taxa of South America or Africa are virtually absent. Various examples from the literature are discussed. A phylogenetic reconstruction and a historical-biogeographic scenario of the Platycnemididae, which special reference to the Calicnemiinae, is presented as one of the first examples of such an analysis of a widespread group. The Calicnemiinae of Southeast Asia are derived from African Platycnemididae. The sister-group of the Southeast Asian taxa is *Leptocnemis cyanops* Selys, a species confined to the Seychelles. The Malesian Calicnemiinae are derived from ancestors on the mainland of Asia, and may have dispersed along the Izu-Bonin arc at the subduction zone of the Pacific plate along the Philippine plate at 40-50 Ma, but alternatively, the Late Cretaceous 'Inner Melanesian Arc' (Mindanao to New Zealand) sensu Polhemus (1995) may have been the route of dispersal. A clade of the genera *Lieftinckia* and *Risocnemis*, confined to the Solomon islands and the Philippines, respectively, represents a more recent westward dispersal of the Calicnemiinae, using the Caroline and Philippine Arcs during the Oligocene. Various other small-scale phylogenetic reconstructions and biogeographical analyses are discussed in Odonata and other freshwater invertebrates. Phylogenetic studies of aquatic and semi-aquatic Heteroptera significantly contribute to our understanding of the areas of endemism and their relationships in Southeast Asia. The areas of endemism in New Guinea are generally congruent with geological entities recognized, e.g. the northern New Guinea terranes, as well as the central New Guinea terranes which are associated with an 'Inner Melanesian Arc'. Special attention is paid to the fauna of Sulawesi. Areas of endemism in Odonata and Heteroptera are generally congruent. Area cladistic reconstructions based on distribution patterns and phylogenetic reconstructions of e.g., *Protosticta* Selys (Odonata, Platystictidae) and genera and species of Chlorocyphidae (Odonata), show a pattern of (Northern arm(Southwest arm(Central ++ Southeast arm))), which is a reflection of the geological history of the island. The biogeographical patterns recognized in freshwater invertebrates of Malesia do not principally differ from those found in strictly terrestrial taxa. The distribution of land and water is responsible for the composition of the biotas during the Cenozoicum. It is not clear whether rafting of biotas on the various island arcs, or congruent patterns in dispersal, are to be considered the underlying principle. The extreme habitat requirements and poor dispersal power of many freshwater organisms, make a dispersal scenario unlikely. However, recent studies show that such habitat specialization may develop rapidly." 7316. Yasuoka, J.; Levins, R. (2007): Ecology of vector mosquitoes in Sri Lanka – Suggestions for future mosquito control in rice ecosystems. Southeast Asian J. trop. med. public health 38(4): 646-657. (in English) ["Mosquito-borne diseases are a major public health threat in Asia. To explore effective mosquito control strategies in rice ecosystems from the ecological point of view, we carried out ecological analyses of vector mosquitoes in Sri Lanka. During the 18-month study period, 14 *Anopheles*, 11 *Culex*, 5 *Aedes*, 2 *Mansonia*, and 1 *Armigeres* species were collected, most of which are disease vectors for malaria, filariasis, Japanese encephalitis, or dengue in Sri Lanka and elsewhere in Asia. The density and occurrence of *Anopheles* and *Culex* species were the highest in seepage pools and paddy fields, where the majority of niche overlaps between larval mosquito and aquatic insect species were observed. All 7 aquatic insect species - identified in case of Odonata as Aeshnidae, Gomphidae, Libellulidae -, which are larval mosquito predators, overlapped their niche with both *Anopheles* and *Culex* larvae. This suggests that conserving these aquatic insect species could be effective in controlling mosquito vectors in the study site. Correlations between several climatic factors and mosquito density were also analyzed, and weather conditions, including higher temperature, lower relative humidity, and higher wind velocity, were found to affect mosquito oviposition, propagation, and survival. These findings deepen our understanding of mosquito ecology and will strengthen future mosquito control strategies in rice ecosystems in Asia." 7319. Zhou, C.F. (2007): The bracing and fusing pattern of longitudinal veins at base in living mayflies (Insecta: Ephemeroptera). Acta Entomologica Sinica 50(1): 51-55. (in English, with Chinese summary) ["The bracing and merging pattern of basal longitudinal veins plays an important role in phylogeny reconstruction within Pterygota. Unfortunately, the basal venation pattern of living mayflies has changed from the ancestral state in most species' but in very rare cases' the origins of some longitudinal vein bases are preserved and visible. The wing base of *Siphuriscus chinensis* has an independent subcostal brace partial stem of the media' visible stem of the cubitus' and indications of the origins of MA and Rs. This kind of wing base plus those of *Ephemera rufomaculata* and *Chromarcys magnifica* show the venation groundplan of modern Ephemeroptera (stem of M parallel to or fused with R basally' MA and Rs fused together for certain distance then separate Cu independent at base). This pattern seems close to that of Neoptera while different from Odonata. In the latter, the M fused with Cu basally. The hypothesized function of subcostal brace in mayflies is to strengthen the connection between distantly separated longitudinal veins because of sclerite plate at radius vein base. This hypothesis also can be used to explain complicated and unique venation of Odonata." 7321. Anholt, B.R. (2008): Chapter 13. Fitness landscapes, mortality schedules, and mating systems. In: Dragonflies: Model Organisms for Ecological and Evolutionary Research, ed. A. Córdoba-Aguilar. Oxford University Press: 167-175. (in English) ["Acquiring the resources for reproduction comes at the risk of death. After emergence, females of most odonate species gain

more mass than males and concomitantly suffer higher mortality rates. Differences in adult mortality rates affect the operational sex ratio. The expected number of future matings for males affects whether males should defend territories or contact guard mates. Where females gain much more mass than males and suffer higher mortality as a result, a male with a mate has a very low expectation of additional matings and should contact guard a mate to maximize reproductive success. When the operational sex ratio is less male-biased, a male with a mate may have additional opportunities to mate and can maximize his reproductive success by territorial behaviour." 7322. Arimoro, F.O.; Iwegbue, C.M.A.; Enemudo, B.O. (2008): Effects of cassava effluent on benthic macroinvertebrate assemblages in a tropical stream in southern Nigeria. *Acta Zoologica Lituanica* 18(2): 147-156. (in English, with Latvian summary) ["Extraction of starch from cassava roots (*Manihot esculenta*, woody shrub of the Euphorbiaceae) requires large amounts of water. After separation of starch and fiber, residual water contains small amounts of starch, proteins and hydrocyanic acid. When this water is released directly into streams and rivers, residual starch can cause rapid growth of bacteria, resulting in oxygen depletion and detrimental effects on aquatic life. Cassava generally contains cyanogens and glycosides that are easily hydrolyzed into hydrogen cyanide. Toxicological effects of cyanide on organisms have been documented by various authors. [...] The study of the effect of cassava effluents on macroinvertebrates along downstream reaches of the Orodo River, the Niger Delta was carried out monthly from January to June 2006. Three study stations were selected along the river course (upstream of the cassava impacted site, the cassava-impacted site, and downstream of the cassava impacted site). The study showed that cassava effluents caused a decrease in dissolved oxygen and pH and an increase in biochemical demand (BOD) and nitrates. Significant differences in these parameters were established among the stations sampled. A post hoc test indicated that station II (the cassava impacted site) was the cause of the observed differences. A total of 55 benthic macroinvertebrate taxa with a mean of 6,116 individuals were collected from the three stations along the river. The analysis showed that the overall density of fauna differed significantly among the stations. Cassava effluents permitted the dominance of oligochaetes and dipterans at station II and this resulted in a decline and total elimination of other benthic macroinvertebrates, which are intolerant of the effects of effluents. These preliminary data suggest that the response of benthic macroinvertebrates is important in the study of impacted aquatic systems and that macroinvertebrates have a great capacity to recover from the cassava effluent impact in terms of taxonomic diversity." (Authors) Odonata were represented by members of four families, and were found in comparable low abundance at stations I and III.] Address: Arimoro, F.O., Dept of Zoology, Delta State University, P. M. B. 1, Abraka, Nigeria. E-mail: fransarimoro@yahoo.com

7323. Baker, R.A.; Mill, P.J.; Zawal, A. (2008): Ectoparasitic water mite larvae of the genus *Arrenurus* on the damselfly *Coenagrion puella* (Linnaeus) (Zygoptera: Coenagrionidae). *Odonatologica* 37(3): 193-202. (in English) ["Parasitic larval mites of the genus *Arrenurus*

have been found on *C. puella*. *A. bicuspidator*, *A. cuspidator* and *A. maculator* make up over 80% of the total mites identified. The other species found were *A. bruzei*, *A. claviger* and members of the *A. affinis* complex. Mites are found mainly between the second and third pairs of legs and behind the third pair. *A. bicuspidator* and *A. cuspidator* share these sites with numbers spread roughly equally on both sites. *A. maculator* is found almost exclusively behind the third pair of legs and on the first abdominal segment of the host. Smaller numbers are found on the abdominal segments where *A. claviger* is the dominant species. The larval mites show a preference for female hosts. Size differences between the *Arrenurus* spp. are considered." (Authors)] Address: Zawal, A., Dept Invertebrate Zoology and Limnology, University of Szczecin, Waska 13, PO-71-415 Szczecin, Poland. 7327. Bernard, R.; Buczyński, P. (2008): Conservation status and habitat selection of *Nehalennia speciosa* (Charpentier, 1840) in Poland. *Odonatrix* 4(2): 43-60. (in Polish, with English summary) [The paper updates the current knowledge on the distribution and habitat of *N. speciosa* in Poland. 65 localities of *N. speciosa* have been discovered in Poland so far, including 31 ones presented in the first synthesis (Bernard 1998). Some corrections and completions to several of these 'old' localities are added. The increase in number of known localities is mostly the result of intensified odonatalogical exploration during the last ten years. However, a colonization of new sites is also possible on a small scale as Brzeziczno Lake (colonized after 1997) shows.] Address: Bernard, R., Dept of General Zoology, Adam Mickiewicz University, Umultowska 89, PL-61-702 Poznan, Poland; E-mail: rbernard@main.amu.edu.pl

7328. Bernotiene, R.; Bartninkaite, I.; Višinskiene, G. (2008): Diffusion of *Bacillus thuringiensis* bacteria and their effect on aquatic invertebrates in the Nemunas River after using VectoBac 12AS preparation. *Ekologija* 54(2): 93-97. (in English) ["Blackfly control with the microbiological preparation VectoBac 12AS was started in Lithuania in 1999. This preparation is based on bacterium *Bacillus thuringiensis* var. *israelensis*. The VectoBac 12AS is applied at a single point from a bank prominence from the year 2000. Investigations were carried out in April-June of 2006 and 2007. The bacteria were found in the Nemunas River 164 km downstream the point of application of the larvicide 3 days after the application. This showed that VectoBac 12AS reached this segment of the river in 3 days. The density of *B. thuringiensis* bacteria decreased downstream from the point of application of the preparation. The highest density of bacteria was found in blackfly larvae, lower densities were found in the ground and on water plants. The effect of VectoBac 12AS on nontarget invertebrates was estimated in study sites from the point of application up to Druskininkai. Using the method of application from one point, this distance of the river was affected by the highest doses of preparation, and its effect on nontarget organisms could be seen in this part of the river. The usage of the preparation had no effect on nontarget invertebrates in the Nemunas River. Significant differences in Chironomid density were detected only in one study site, 6 km downstream the point of application of the larvicide. At a distance of 14 km from the point of application and downstream the river, no differences in the density of Chironomid larvae were detected." (Authors) Three Odonata taxa were identified but are not specified.] Address: Bernotiene, Rasa, Institute of Eco-

logy of Vilnius University, Akademijos 2, LT-08412 Vilnius, Lithuania. E-mail: rasab@ekoai.lt

7331. Boudot, J.-P. (2008): *Selysiothemis nigra* (Vander Linden, 1825), nouveau pour le Maroc, et autres observations sur les Odonates du Maghreb nord-occidental (Odonata: Anisoptera: Libellulidae). *Martinia* 24(1): 3-29. (in French, with English summary) ["During a 2007 summer odonatalogical trip in Morocco, carried out with the intention to gain additional information on some threatened and endemic species in the NW Maghreb, allowed us to record and document *Selysiothemis nigra* (Vander Linden, 1825) for the first time in this country. The latter was present in a significant number at a temporary lake on the border of the Sahara. The occurrence of such a very mobile species on a temporary water body is typical for species well adapted to desert environments, for which a rapid and opportunistic colonization of recent ephemeral water bodies is crucial to reproduce. Dense populations of *Pyrrhosoma nymphula* (Sulzer, 1776), an European species confined in Africa to scarce Moroccan highlands and regarded as a last glacial relict, were found in small habitats within the NE end of the Middle Atlas, about 100 km apart from the previously known localities. Additionally, *Ischnura fontaineae* Morton, 1905 was discovered on a permanent salty river in a subdesertic environment, at the margin of the Sahara, 350 km SW from the previously known locality. This is the single place where this species is known in the western half of Morocco. *Cordulegaster princeps* Morton, 1915, a Moroccan endemic confined to the Middle and High Atlas ranges, remains well established on middle and high elevation rivers and brooks, up to 2600 m a.s.l., and was found to reproduce even in small spring areas with poor seepage water. Some middle and low elevation populations have been found to turn extinct, however, due to excessive water use and stream drying up in agricultural and urban areas. *Calopteryx exul* Selys, 1853, a Maghrebian endemic extending from Morocco to Tunisia in the Atlas ranges, was found only in one locality. Its conservation status is worrying, in Morocco as well as in any other Maghrebian country. Altogether, 34 species were brought on record, among which *Onychogomphus costae* Selys, 1885 is more widely distributed than currently believed. The IUCN category is indicated for every threatened

species." (Author)] Address: Boudot, J.-P., Centre de Pédologie Biologique, 17, rue Notre-Dame de Pauvres, B.P. 5, F-54501 Vandoeuvre-lès-Nancy, France. e-mail: boudot@cpb.cnrs-nancy.fr

7332. Bouwman, J.; Ketelaar, R. (2008): New records of *Coenagrion armatum* in Schleswig-Holstein (Odonata: Coenagrionidae). *Libellula* 27(3/4): 185-190. (in English, with German summary) ["In early May 2008 a short survey was carried out to search for *C. armatum* in Schleswig-Holstein, Germany. On 06-V-2008, we found the species at two localities: Möwensee near Süderlügum, and Jardelunder Moor on the German-Danish border. Some details are provided on composition and structure of the vegetation. It is stated that *C. armatum* has always been present in Schleswig-Holstein but has largely been overlooked in the past years." (Authors)] Address: Bouwman, J., Dutch Butterfly Conservation, P.O. Box 506, NL-6700 AM Wageningen, The Netherlands. E-mail: jaap.Bouwman@vlinderstichting.nl

7333. Bouwman, J.H.; Kalkman, V.J.; Abbingh, G.; de Boer, E.P.; Geraeds, R.P.G.; Groenendijk, D.; Ketelaar, R.; Manger, R. Termaat, T. (2008): An update of the distribution of dragonflies in The Netherlands. *Brachytron* 11(2): 103-198. (in Dutch, with English summary) ["Dutch dragonflies are winners, the number of observers and the number of records keep increasing and in addition many of the species are also showing an increase. The latter is largely due to the improved water quality and the climate change which is favoring many southern species. As a result the distribution patterns shown in the book 'The Dutch Dragonflies' (NVL, 2002) are already out-dated. The 10 year anniversary of the Dutch Society for Dragonfly research (NVL), the 25 year anniversary of the Dutch Butterfly Conservation and the 33 1/3 anniversary of the European Invertebrate Survey Netherlands was used as an nice excuse to make a new overview of the Dutch dragonfly fauna. This review deals with 67 species. Four species known only from records prior to 1990 are not discussed (*Coenagrion mercuriale*, *Nehalennia speciosa*, *Epithea bimaculata* and *Oxygastra curtisii*). The distribution of the species is presented for two periods: 1990-1997 and 1998-2007. The first period is the same as in the book 'The Dutch Dragonflies' (NVL, 2002). About three times the number of records was available for the second period (308.000) compared to the first (101.000). The increase shown by many species can partly be explained by the increase in records. However many species now occur in areas where they were absent in the first period although these areas were well investigated during that period. This shows that the increase of these species is genuine and not merely a artifact of the increased research activity. Besides maps also a histogram of the flight-period for the period 1998-2007 is given. The histogram is based on unique records (a species, on one day in a square kilometer). The recorded numbers have therefore no influence on the histogram. The text of each species discusses the distribution, habitat and flight-period but the latter two only when new information became available since the publication of the former atlas (NVL, 2002). The Dutch Butterfly Conservation and Dutch Statistics Netherland (CBS) are organizing the Dutch Dragonfly Monitoring Scheme since 1998. In this project dragonflies are counted largely by volunteers using a standardized method. This has made it possible to calculate trends for 33 of the 67 species. For these species also a trend graphic is presented."

7343. Céréghino, R.; Ruggiero, A.; Marty, P.; Angélibert, S. (2008): Biodiversity and distribution patterns of freshwater invertebrates in farm ponds of a south-western French agricultural landscape. *Hydrobiologia* 597: 43-51. (in English) ["We assessed the importance for biodiversity of man-made farm ponds in an agricultural landscape in SW France lacking natural wetlands. The ponds were originally created to provide a variety of societal services (irrigation, visual amenity, water for cattle, etc.). We also assessed the environmental factors influencing invertebrate assemblages in these ponds. Only 18 invertebrate taxa out of 114 taxa occurring in the study area were common to ponds and rivers indicating that the contribution of farm ponds to freshwater biodiversity was potentially high. A Self-Organizing Map (SOM, neural network) was used to classify 36 farm ponds in terms of the 52 invertebrate families and genera they supported, and to specify the influence of environmental variables related to land-use and to pond characteristics on the assemblage patterns. The SOM trained with taxa occurrences showed five clusters of ponds, most taxa occurring only in 1-2 clusters of ponds. Abandoned ponds tended to support higher numbers of taxa, probably because they were allowed to undergo a natural succession. Nevertheless, abandoned ponds were also amongst the largest, so that it remained difficult to separate the effects of pond size and abandonment, although both factors were likely to interact to favour higher taxon richness. The invertebrate communities in the ponds appeared to be influenced mainly by widely acting environmental factors (e.g. area, regionalization of assemblages) with little evidence that pond use (e.g. cattle watering, amenity) generally influenced assemblage composition. Our results support the idea that agricultural landscapes containing man-made ponds make a significant contribution to freshwater biodiversity indicating that protection of farm ponds from threats such as in-filling and pollution can make a positive contribution to the maintenance of aquatic biodiversity. This added value for biodiversity should be considered when calculating the economic costs and benefits of constructing water bodies for hu-

man activities." (Authors) Odonata are treated but without details.] Address: Céréghino, R., EcoLab, UMR 5245, Université Paul Sabatier, 118 route de Narbonne, 31062 Toulouse cedex 9, France. E-mail: cereghin@cict.fr

7344. Chakona, A.; Phiri, C.; Magadza, C.H.D.; Brendonck, L. (2008): The influence of habitat structure and flow permanence on macroinvertebrate assemblages in temporary rivers in northwestern Zimbabwe. *Hydrobiologia* 607(1): 199-209. (in English) ["Temporary rivers within the Nyaodza-Gachegache subcatchment in northwestern Zimbabwe were investigated to examine the role of flow permanence and habitat structure on macroinvertebrate community composition. Macroinvertebrate communities of intermittent and ephemeral rivers displayed significant differences in the number of taxa, macroinvertebrate abundance, Shannon and Simpson diversity indices and in size class structure. Intermittent sites were characterised by higher numbers of taxa, diversity and Ephemeroptera and Trichoptera richness compared to ephemeral sites. The fauna of ephemeral sites was dominated by a single taxon (*Afrobaetodes*) (Eph., Baetidae) whilst larger sized taxa (e.g. *Elassoneuria* (Eph., Oligoneuriidae), *Dicentropilum* (Eph., Baetidae), Aethaloptera (Tri., Hydropsychidae), *Pseudagrion* (Odonata, Coenagrionidae) and *Tholymis* (Odonata, Libellulidae) were exclusively restricted to intermittent sites. Clear differences were observed between sand, gravel, cobble and vegetation habitats. Vegetation and cobbles supported distinct communities, with some taxa exclusively restricted either to vegetation (e.g. *Pseudagrion*, *Leptocerina* (Tri., Leptoceridae), *Cloeon* (Eph., Baetidae), *Afronurus* (Eph., Heptageniidae) and *Povilla* (Eph., Polymitarciidae) or cobble (e.g. Aethaloptera and *Dicentropilum*) habitats. In terms of ensuring optimum diversity within the subcatchment, we consider conservation of critical habitats (cobbles and vegetation) and maintenance of natural flows as the appropriate management actions." 7346. Cocksedge, B.; Parr, A. (2008): Atypical Black Scarce Chaser *Libellula fulva* in Hampshire. *Atropos* 35: 63. (in English) [Verbatim: On the afternoon of 11 June 2008 Brian Cocksedge visited Blashford Lakes Nature Reserve, near Ringwood in Hampshire, UK. The weather was warm with little wind. Along the small track between the car park and the Wildlife Trust centre an unusual black dragonfly was seen. Normally the only all-black species in the UK is the (male) Black Darter *Sympetrum danae*, but this dragonfly was clearly not that species. The general body shape and heavy black mark at the base of the hindwing, coupled with a dark streak near the base of the forewing, indicated that the dra-

gonfly was instead a Scarce Chaser *Libellula fulva*. This species is occasionally reported from Blashford Lakes, and old females are known to become rather dull and dark in colouration. Typically in such females there is, however, still some indication of the row of triangles along the mid-line of the abdomen that is normally a distinctive identification feature. The Blashford dragonfly was, however, very dark all over, with a featureless abdomen. Close examination of photos taken revealed that despite the brown eyes, darkened wing-tips and other aspects of the general appearance, the individual was a male. The end of the abdomen was thus more tapered than in females, and the anal appendages were not the expected short, widely-spaced, female cerci but instead stouter, more centrally-placed male claspers. The dragonfly thus seems to be a male Scarce Chaser which had developed beyond its initial immature colouration, but which somehow lacked the normal blue abdominal pruinescence and blue tint to the eyes seen in mature males. Some rubbing off of the waxy pruinescence, so revealing a black background colour to the abdomen, frequently occurs in males after mating—apparently caused by the grip of the female—but the total lack of blue (even on the eyes) in the present individual seems exceptional. Advanced abrasion of the pruinescence as a factor of age seems unlikely given the relatively early date. Perhaps something like a mutation, or possibly weather conditions, interfered with the normal development of the blue pruinescence. (Authors)] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK. E-mail: Adrian.parr@bbsrc.ac.uk

7347. Conniff, K.L.; van der Poorten, N.E. (2008): First description of female *Elatoneura caesia* (Selys, 1860) and amended description of male *E. caesia* and male and female *E. centralis* (Selys, 1860) from Sri Lanka, with notes on behaviour, habitat, and distribution and field identification characters. *Odonatologica* 37(4): 361-366. (in English) ["The female of *E. caesia* is described and figured for the first time. In earlier publications, *E. caesia* and *E. centralis* were confused with each other (cf. F.C. FRASER, 1933, The fauna of British India including Ceylon and Burma: Odonata, vol. 1, pp. 238-241, Taylor & Francis, London). Amended descriptions of the male of *E. caesia* and of both sexes of *E. centralis* are provided. Key phenotypic differences between the 2 species are illustrated, and additional notes are given on behaviour, habitat and distribution." (Authors)] Address: Conniff, K.L., 11WMI, RO. 7348. Contreras-Garduño, J.; Buzattob, B.A.; Serrano-Menesesa, M.A.; Nájera-Cordero, K.; Córdoba-Aguilera, A. (2008): The size of the red wing spot of the American rubyspot as a heightened condition-dependent ornament. *Behavioral Ecology* 19: 724-732. (in English) ["We investigated an ornamental trait known to reflect male fighting ability and tested whether it shows heightened condition dependence compared with nonornamental traits in the American rubyspot (*Hetaerina americana*). Adult males bear red wing spots, the size of which is sexually selected: large-spotted and fatter males are more successful in territorial competition and obtain more matings than are nonterritorial males. First, to see whether spot area may signal fighting ability at a particular age (to discriminate animals that are unlikely to compete), we investigated the age at which males engaged more in fighting and compared their fat reser-

ves and muscle mass at 3 ages (young, middle aged, and old) and territorial status. Middle-aged males showed the highest fat and muscle values, engaged more in fighting, and were predominantly territorial. Second, we looked for traits not shaped by sexual selection: we compared red chroma and brightness of spot and thorax, spot area, muscle mass, and fat reserves in winner and loser males after a territorial contest. The only difference was that winners had larger spot areas and higher fat reserves. Finally, an immune challenge-based experiment was performed during the development of spot area and its color properties (chroma and brightness). Compared with a control (unchallenged) group, the results revealed that area decreased, brightness increased, and there was no change in red chroma, muscle mass, and fat reserves in challenged animals. Thus, spot area is a stress-sensitive, energy-reflecting trait that is likely to be used for communication during territorial competition in these damselflies" (Authors)] Address: Cordoba-Aguilar, A., Centro de Investigaciones Biologicas, Universidad Autonoma del Estado de Hidalgo, Apdo. 7349. Corbet, P.S.; May, M.L. (2008): Fliers and perchers among Odonata: dichotomy or multidimensional continuum? A provisional reappraisal. *International Journal of Odonatology* 11(2): 155-171. (in English) ["We revisit the hypothesis, first advanced in 1962, that, with regard to their means of thermoregulation and overt behaviour, two types of Odonata can be recognised: fliers, when active (during reproductive activity, primarily, or foraging) remain on the wing, whereas perchers, when similarly engaged, spend most of the time on a perch from which they make short flights. First, in light of the available data, we restrict the hypothesis to apply primarily to activity at the rendezvous. Next, we review evidence, including direct measurements of body temperature coupled with activity budgets, to test the proposition that the hypothetical classification constitutes a dichotomy rather than a continuum. We conclude: (1) that there is merit in retaining the dichotomous classification into fliers and perchers, together with the thermoregulatory capabilities assigned to each category; (2) that the distinction between fliers and perchers is sufficiently discrete to be a useful predictor of the suite of thermoregulatory strategies and energy demands characteristic of representatives of each category; and (3) that, within each category a continuum exists such that the capacity to heat the body by irradiation (i.e. ectothermally) or by metabolic heat production (endothermy) increases with body size. Some departures from expectation based on the percher/flier dichotomy reflect the increased flight activity that occurs at the rendezvous under conditions of heightened conspecific or interspecific interference. Other apparent anomalies are identified as topics for potentially fruitful research." 7352. Corbi, J.J.; Jancso, M.A.; Trivinho-Strixino, S.; dos Santos, A. (2008): Environmental evaluation of metals in sediments and dragonflies due to Sugar Cane cultivation in Neotropical streams. *Water, Air, & Soil Pollution* 195: 325-333. (in English) ["The use of fertilizers, containing different metals ions such as lead(II), chromium(III), cadmium(II), copper(II) and zinc(II), in the soil, for sugar cane cultivation, may cause impacts on the hydric resources of the adjacent areas. The scope of this study was to evaluate the impacts of sugar cane cultivation based on metal concentrations in sediments and dragonflies (Odonata). The bioavailability of such metals was determined in ten Neotropical streams. Six streams were located on areas with sugar cane cultivation, without riparian vegetation (classified as impacted area) and four streams were located on forested areas (reference sites). The results showed that there are high concentrations of metals in the sediments and dragonflies in streams located on impacted areas. The contamination by metals of aquatic insects of terrestrial adult life cycle, as Odonata organisms, represents a dangerous link for the transference of metals to upper trophic levels, as fishes, reptiles, birds and mammals." 7355. Cordoba-Aguilar, A.; Cordero-Rivera, A. (2008): Chapter 15. Cryptic female choice and sexual conflict. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 189-203. (in English) ["Females may choose their male mates. However, both sexes may engage in a kind of dispute not to be coerced into mating (for females) and to be chosen (for males). These two hypotheses (called female choice and sexual conflict, respectively) are currently in vogue in studies of sexual reproduction. This chapter highlights some instances where both can be tested in odonates. These instances are: during copula invitation by males, for the duration of copulation, and during the male post-copulatory displays preceding and during oviposition. There are four other aspects that may be investigated to see the prevalence of each hypothesis: the differences of genitalic diversity across populations, the genitalic complexity at the multiple species level, the female benefits when mating with 'attractive' males, and the costs to evade superfluous matings." 7356. Córdoba-Aguilar, A. (Ed.) (2008): *Dragonflies and Damselflies - Model Organisms for Ecological and Evolutionary Research*. ISBN-13: 978-0-19-923069-3: 256 pp. (in English) ["Dragonflies and Damselflies documents the latest advances in odonate biology and relates these to a broader ecological and evolutionary research agenda. Despite being one of the smallest insect orders, dragonflies offer a number of advantages for both laboratory and field studies. In fact, they have been crucial to the advancement of our understanding of insect ecology and evolution. This book provides a critical summary of the major advances in these fields. Contributions from many of the leading researchers in dragonfly biology offer new perspectives and paradigms as well as additional, unpublished, data. The editor has carefully assembled a mix of theoretical and applied chapters (including those addressing conservation and monitoring) and achieves a balance of emerging and established research topics, providing suggestions for future study in each case.

7357. This accessible text is not about dragonflies per se but an essential source of knowledge that describes how different sets of evolutionary and ecological principles/ideas have been tested on a particular taxon. It will therefore be suitable for graduate students and researchers in entomology, evolutionary biology, population and behavioural ecology, and conservation biology. It will of course be of particular interest and use to those working on insects and an indispensable reference text for odonate biologists." 7358. Correia, A.M.; Anastacio, P.M. (2008): Shifts in aquatic macroinvertebrate biodiversity associated with the presence and size of an alien crayfish. *Ecological Research* 23: 729-734. (in English) ["To investigate the effects of *Procambarus clarkii* on macroinvertebrate diversity, we conducted a mesocosm experiment simulating small pools in rice field pads after the rice season. We hypothesized that crayfish predation would negatively impact macroinvertebrate diversity, and the magnitude of this impact should vary with the size of *P. clarkii*. We conducted a short-term mesocosm experiment to determine macroinvertebrate diversity in the presence of three size classes and in the absence of crayfish, as well as the diet composition of crayfish from the three size classes. At the end of the experiments, the diet of crayfish was composed of the most available taxa (Culicidae, Chironomus, Tanytarsini and Orthocladinae). These results also show evidence that, in confined areas, crayfish are important predators of major rice pests such as rice Chironominae larvae. Macroinvertebrate diversity was negatively affected by crayfish presence, but the effect was inversely proportional to crayfish size. The highest diversity index was obtained in the absence of *P. clarkii*, and juvenile crayfish significantly reduced macroinvertebrate diversity. Thus, the impact of *P. clarkii* on aquatic macroinvertebrates is size dependent and may be relevant in small pools formed in rice field pads from early autumn to late winter. Overall, our findings suggest that the negative effects of *P. clarkii* on macroinvertebrate diversity may be particularly strong in local natural assemblages confined to puddles of water or small ponds in wetland areas." 7361. Cremona, F.; Planas, D.; Lucotte, M. (2008): Assessing the importance of macroinvertebrate trophic dead ends in the lower transfer of methylmercury in littoral food webs. *Can. J. Fish. Aquat. Sci.* 65(9): 2043-2052. (in English, with French summary) ["Total mercury and methylmercury concentrations ([THg], [MeHg]) were measured in littoral macroinvertebrates from Lake St. Pierre, Quebec, Canada. Functional groups (detritivore, grazer, edible predator, inedible predator) explained the greatest fraction of [MeHg] variation compared with time (year, month), and space (station and shore). Greatest [THg] and [MeHg] were found in inedible predators mostly from families of heteropterans and coleopterans. Detritivores and grazers exhibited the lowest Hg concentrations, while edible predators were intermediate. Inedible predators also had the highest percentage of MeHg ([MeHg]/[THg]), with some taxa close to 100%. Such high percentages are seldom observed in freshwater organisms other than piscivorous fish. MeHg burden (concentrations × biomass) in inedible predators accounted for 10% of the MeHg pool for the whole invertebrate community. These large quantities of MeHg are sequestered in aquatic "trophic dead ends" and could partly explain the low [MeHg] measured in fish, compared with [MeHg] of macroinvertebrates from Lake St. Pierre and other freshwater ecosystems with large littoral zones. We recommend taking into account the inedible organisms in Hg cycling models to avoid a possible overestimation of the MeHg pool available to fish." (Authors) The paper contains some references to Odonata.]

7362. Crumrine, P.W.; Switzer, P.V.; Crowley, P.H. (2008): Chapter 3. Structure and dynamics of odonate communities: accessing habitat, responding to risk, and enabling reproduction. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 21-39. (in English) ["This chapter highlights the key abiotic and community-level interactions that influence odonate community structure. Three important life-history based issues central to odonate communities are developed: habitat access, response to risk during the larval stage, and emergence and reproduction. Each issue is addressed by considering relevant ecological theory and identifying and reviewing empirical studies with odonates that address hypotheses raised by theoretical studies. Although numerous short-term studies at relatively small spatial scales have been conducted with odonate larvae, very little is known about the relative impacts of competition, cannibalism, predation, intraguild predation and size structure on odonate population dynamics, and community structure in natural systems. Long-term studies at multiple life history stages and levels of organization are required to generate a more complete understanding of odonate communities, and ecological communities in general." 7364. Davies, G.B.P. (2008): Book review. 'Dragonflies and damselflies of South Africa.' Michael J. Samways Sofia/Moscow: Pensoft Publ., 2008. 297 pp. Softcover. ISBN 978-954-642-330-6. Price: 39 Euro. Pensoft Online Bookshop: <http://www.pensoft.net/>. *African Invertebrates* 49(2): [Verbatim: As attractive, generally large, diurnal, predatory insects, the Odonata have long attracted research interest from entomologists. In our region, a firm foundation for odonatology was laid by Elliot Pinhey, Boris Balinsky and others. This research mantle has been carried forward by Michael Samways and his students, who have devoted the last two decades to their study, firstly in KwaZulu-Natal, and more recently in the Western Cape. 'Dragonflies and damselflies of South Africa' (hereafter 'DDSA') is the culmination of much of Samways's investigation into our dragonfly fauna, and it is unequivocally a significant milestone for South African (and African) odonatology. As the Odonata are aquatic insects, it is instructive to remember that South Africa is largely an arid country, with vast areas of western South Africa falling below the 600 mm isohyet. Consequently, our dragonfly fauna is small (ca 158 species) relative to tropical Africa, but it does have the advantage of mixing dazzling tropical forms like *Anax tristis* with endemic, localized temperate taxa like the *Ecchlorestes* species. 'DDSA' is a most attractive volume and, although running to nearly 300 pages, the book is nevertheless compact and lightweight. I am not sure whether the author and the publishers intended this as a field-guide or a more formal handbook. The Preface (p. 5) does mention the words field guide, but I get the impression from its large mass of text and data that 'DDSA' is, in fact, a hybrid between the two. This 'schizophrenic' nature is perhaps the book's weakest aspect. As I will discuss below, there are some features that detract from the book's effectiveness as a classic field-guide, while others mar its handbook status. The book begins with concise chapters on dragonfly biology and ecology. These notes highlight many interesting facets of South African dragonfly biology, e.g. that certain taxa (such as *Sympetrum fonscolombii*) are migratory, or that Western Cape Odonata divide into two phenological categories, 'spring species' and 'autumn species'. Regrettably, Samways is unable to expand on such interesting topics, and, perhaps even worse, none of the statements in these opening chapters is referenced, making it difficult to trace the primary source of a particular conclusion or result. There are also tips on conservation (a field that Samways has been especially active in), photographing, collecting and even rearing dragonfly larvae and building a 'dragonfly pond' for one's garden. I was interested to learn that pinning specimens with spread wings has fallen out of favour with odonatologists, who now prefer to accession material by placing specimens in plastic envelopes. There are two keys in the book: one to major groupings and a longer key to species. The latter is liberally illustrated with drawings of genitalia, wings, etc. I have not had an opportunity to test the keys, but they appear comprehensive and well-written. The species accounts include notes on identification, a description of the entire insect (face, eyes, prothorax, synthorax etc.), distribution (with map, but provincial boundaries are not indicated), habitat, behaviour and comparison with similar species. Usefully, there are also two bar graphs for each account, one showing phenology (flight period) and the other a 'dragonfly biotic index', which shows sensitivity to pollution, habitat disturbance etc. Most accounts have two colour photographs, generally of male and female, although

occasionally only one sex is illustrated. All 416 photographs of dragonflies and damselflies are of a high standard, but some appear to have been reproduced too darkly. Samways deserves much credit for successfully photographing all the South African Odonata taxa. Given the often wary nature of dragonflies, this is a most praiseworthy achievement. Sketches of genitalia and wing photos also appear, these duplicating the images from the species key. It is evident, therefore, that a large amount of information is incorporated into each species account. This is welcome on one level for comprehensiveness, but for field-guide purposes it is a daunting torrent of data to wade through. This abundance of text and data gives Samways's book a rather cramped and 'busy' feel; a definite negative feature. Possibly as a result of the cramped nature of the individual species accounts, on pp. 204-213 a section entitled 'Additional photographs' appears. It is wonderful to have these additional photos, but something of an oddity to have them divorced from the respective accounts. Why not just insert the relevant photos after each account as an extra page for the particular species? Inevitably, Samways's book invites comparison with the two-volume field guides privately published by Warwick and Michèle Tarboton (Tarboton & Tarboton 2002, 2005). Those two excellent books broke new ground in being the first field guides to South African Odonata. 'DDSA' has an obvious edge in that the dragonflies and damselflies are all in one volume. 'DDSA' is brim-full of information, as mentioned, and scores points over the Tarboton guides, which were marked by their concision. Samways's colour photos of live or freshly killed individuals also means that the true colours of the insects comes across clearly in his book. The Tarbotons in some cases had to use old museum specimens. A striking example of this is *Lestiniogomphus angustus*: Samways's photograph (p. 125) shows this stunning dragonfly with its vibrant yellow and black coloration and reddish abdominal apex to great advantage, whereas the same insect in Tarboton is a dried-out, dull, brown husk. On the other hand, the text-heavy feel of 'DDSA' contrasts negatively with the neat, uncluttered layout of the Tarboton guides, which also gave maximum space to the dragonflies themselves rather than to the text. 'DDSA' is finished off with a check-list providing Latin and vernacular names of Odonata and references to relevant pages. The check-list is followed by a glossary of mostly morphological terms, an extensive bibliography that lists 118 publications on taxonomy, ecology and conservation of Afrotropical dragonflies and damselflies, and by a five-page general index. Like butterflies, all South African Odonata now have English common names, but problematically many differ between Samways and the Tarbotons. There is no correct answer to what is a subjective decision on which name to use, but the differences between the books may cause frustration amongst users. To sum up, 'Dragonflies and Damselflies of South Africa' is an admirable volume which is a credit to author and publisher. 'DDSA' is highly recommended to established entomologists and novices, as well as to ecologists, conservation specialists, naturalists, etc. South African scientific community is immeasurably strengthened by having this book available, and the order now begins to rival the butterflies for sumptuous and accessible coverage. 7365. De Block, M.; Stoks, R. (2008): Short-term larval food stress and associated compensatory growth reduce adult immune function in a damselfly. *Ecological Entomology* 33(6): 796-801. (in English) [" 1. In animals with a complex life cycle, larval stressors may carry over to the adult stage. Carry-over effects not mediated through age and size at metamorphosis have rarely been studied. The present study focuses on the poorly documented immune costs of short-term food stress both in the larval stage and after metamorphosis in the adult stage. 2. The present study quantified immune function [number of haemocytes, activity of prophenoloxidase (proPO) and phenoloxidase (PO)] in an experiment where larvae of the damselfly *Lestes viridis* were exposed to a transient starvation period. 3. Directly after starvation, immune variables were reduced in starved larvae. Levels of proPO and PO remained low after starvation, even after metamorphosis. In contrast, haemocyte numbers were fully compensated by the end of the larval stage, yet were lower in previously starved animals after metamorphosis. This can be explained as a cost of the observed compensatory growth after starvation. Focusing only on potential costs of larval stressors within the larval stage may therefore be misleading. 4. The here-identified immunological cost in the adult stage of larval short-term food stress and associated compensatory growth strongly indicates that physiological costs may explain hidden carry-over effects bridging metamorphosis. This adds to the increasing awareness that the larval and adult stages in animals with a complex life cycle should be jointly studied, as trade-offs may span metamorphosis." 7366. De Block, M.; McPeck, M.A.; Stoks, R. (2008): Life-history evolution when *Lestes* damselflies invaded vernal ponds. *Evolution* 62: 485-493. (in English) ["We know little about the macroevolution of life-history traits along environmental gradients, especially with regard to the directionality compared to the ancestral states and the associated costs to other functions. Here we examine how age and size at maturity evolved when *Lestes* damselflies shifted from their ancestral temporary pond habitat (i.e., ponds that may dry once every decade or so) to extremely ephemeral vernal ponds (ponds that routinely dry completely each year). Larvae of three species were reared from eggs until emergence under different levels of photoperiod and transient starvation stress. Compared to the two temporary-pond *Lestes*, the phylogenetically derived vernal-pond *Lestes dryas* developed more rapidly across photoperiod treatments until the final instar, and only expressed plasticity in development time in the final instar under photoperiod levels that simulated a later hatching date. The documented change in development rate can be considered adaptive and underlies the success of the derived species in vernal ponds. Results suggest associated costs of faster development are lower mass at maturity and lower immune function after transient starvation stress. These costs may not only have impeded further evolution of the routine development rate to what is physiologically maximal, but also maintained some degree of plasticity to time constraints when the habitat shift occurred." 7369. Dorn, N.J. (2008): Colonization and reproduction of large macroinvertebrates are enhanced by drought-related fish reductions. *Hydrobiologia* 605: 209-218. (in English) ["Aquatic predators and habitat permanence can jointly affect benthic invertebrate biomass and community composition. In 2006 I sampled fish and invertebrates in ten ponds embedded in a seasonal wetland before and after a natural drought. Drought reduced fish biomass and density leaving some ponds in a fishless condition when rains returned in July. In July, large aquatic insects and crayfish colonized and reproduced in the ponds, but did not colonize all of the ponds equally. Using measurements of fish abundance and other environmental parameters of the ponds, I conducted linear regression analyses to explore potential drivers of variable invertebrate biomass in July. Fish biomass had a negative effect on invertebrate biomass and it explained more of the variation in total invertebrate biomass and total non-shrimp biomass than fish abundance (number of fish caught). Dissolved oxygen and pond depth were both correlated with fish biomass, but were poorer predictors of invertebrate biomass. Ponds with few or no fish had 209 greater total biomass and 2009 more non-shrimp biomass than ponds with high fish biomass. Shrimp dominated the invertebrate composition, and were only found in the two deepest ponds with the highest fish biomass; predatory insects and crayfish dominated the other eight ponds. When taxa were analyzed separately, fish biomass explained a large portion of the variation for predatory insects (Coleoptera, Hemiptera, and Odonata) and crayfish (*Procambarus allenii*), but dissolved oxygen was the best predictor of larval stratiomyid (order Diptera) biomass. These results are generally consistent with studies demonstrating negative effects of fish on large predatory invertebrates, but also suggest that more severe local droughts can seasonally enhance insect and crayfish populations by generating fishless or nearly fishless conditions." 7372. Dyatlova, E.S.; Kalkman, V.J. (2008): The Odonata of southwestern Ukraine, with emphasis on the species of the EU Habitats Directive. *Libellula* 27(3/4): 275-290. (in English, with German summary) ["From 2006 to 2008 a database with records of Odonata from southwestern Ukraine - the provinces of Odessa, Mykolaiv and Kherson - was built. This database holds records from literature, collections and fieldwork and contains over 1500 records. Distribution maps of all species have been made available on the Internet. In total 48 of the 74 Ukrainian species were recorded from this area. The area has a relatively low diversity of aquatic habitats and a large percentage of freshwater habitats consist of large lakes or large rivers characterised by high flood events in winter and spring. These habitats generally have a low diversity of Odonata, although densities can be very high. Species in the Habitats Directive occurring in the area are *Coenagrion ornatum*, *Gomphus flavipes* and *Sympecma paedisca*. Based on their occurrence and the presence of species of the Ukrainian Red List and species rare in southwestern Ukraine, six 'Important Dragonfly Areas' were selected: Reservoirs in a lower part of Khadzhibejski Liman, the basins of Southern Bug and Ingul rivers, the Lower Dniestr with tributaries and lakes and Dniestrovski Liman, the Kinburn Peninsula, the Dniepr delta, and the Lower Danube with the pre-Danube region. Large areas of southwestern Ukraine are poorly studied, and more field-work will undoubtedly result in the recognition of more areas with a high importance for Odonata." (Authors)] Address: Dyatlova, Elena, Odessa National I. I. Mechnikov University, Biological Faculty, Department of Zoology, Shampanski pereulok, 2, UA-Odessa, 65058, Ukraine. 7375. Ellenrieder, N. von; Garrison, R.W. (2008): *Drepanoneura* gen. nov. for *Epipleoneura letitia* and *Protoneura peruviana*, with descriptions of eight new *Protoneuridae* from South America (Odonata: Protoneuridae). *Zootaxa* 1842: 1-34. (in English, with Spanish summary) ["A new genus, *Drepanoneura* (type species *Drepanoneura loutoni* sp. nov.), is described to include *Epipleoneura letitia* Donnelly, *Protoneura peruviana* Fraser, and six new congeneric species from South America: *D. donnellyi*, *D. flinti*, *D. janirae*, *D. loutoni*, *D. muzoni*, and *D. tennesse*. *Drepanoneura* is similar to *Epipleoneura* and *Epipotoneura* in venational characters, but differs from them in morphology of male cercus, genital ligula, female pronotum, and epiproct. A new species of *Epipleoneura* from Venezuela, *E. demarmelsi*, and a new species of *Epipotoneura* from Brazil, *E. machadoi*, are described, and diagnostic illustrations for the poorly known *Epipotoneura nehalennia* Williamson are also presented. A generic characterization, diagnoses, and keys for species of *Drepanoneura* are provided, as well as diagnostic illustrations and distribution maps for all involved species." (Authors)] Address: Ellenrieder, Natalia von, Mus. Ciencias Naturales, Univ. Nacional de Salta, Mendoza 2, Salta 4400, Argentina. E-mail: natalia.ellenrieder@gmail.com

7376. Ellenrieder, N. von; Garrison, R.W. (2008): *Oreiallagma* gen. nov. with a redefinition of *Cyanallagma* Kennedy 1920 and *Mesamphiagrion* Kennedy 1920, and the description of *M. dunklei* sp. nov. and *M. ecuatoriale* sp. nov. from Ecuador (Odonata: Coenagrionidae).

Zootaxa 1805: 1-51. (in English, with Spanish summary) ["In this paper we re-evaluate *Cyanallagma* Kennedy 1920, which currently includes 15 species, and we address another five species that share diagnostic characters with some of them but are currently placed within *Leptagrion* Selys 1876, *Mesamphiagrion* Kennedy 1920, and *Telagrion* Selys 1876. A new genus, *Oreiallagma*, is described to include 5 species originally placed in *Acanthagrion* Selys 1876, *Cyanallagma*, and *Telagrion*. These species are *O. thelakterion* (De Marmels 1997) (type species), *O. acutum* (Ris 1918), *O. oreas* (Ris 1918), *O. prothoracicum* (Kimmins 1945), and *O. quadricolor* (Ris 1918). The last stadium larva of *O. quadricolor* is described. The remaining species currently included in *Cyanallagma* are allocated to two separate genera: *Cyanallagma sensu stricto* and *Mesamphiagrion*. *Cyanallagma sensu stricto* comprises southern South American species including the type species, *Cyanallagma interruptum* (Selys 1876). *Mesamphiagrion* Kennedy 1920 includes a cluster of species from northwestern South America that are considered congeneric with the type species *Mesamphiagrion occultum* (Ris 1918). Two new species from Ecuador, *M. dunklei* and *M. ecuatoriale*, are described and *Argia hebdomatica* Navás 1934 is found to be a junior synonym of *M. ovigerum* (Calvert 1909). Synonymic lists, diagnoses, illustrations, keys, and distribution maps for the three genera are provided." 7377. Faraone, F.P.; Lillo, F.; Giacalone, G.; Lo Valvo, M. (2008): The large invasive population of *Xenopus laevis* in Sicily, Italy. *Amphibia-Reptilia* 29: 405-412. (in English) ["The worldwide spread of invasive species is considered to be one of the main causes of global amphibian declines and the loss of bio diversity in general. The African Clawed Frog, *Xenopus laevis*, shows a strong ability to establish populations and invade various geographic regions. In 2004 *X. laevis* was found in Sicily for the first time. The Sicilian population is probably the largest in Europe with a range of about 225 km² in an area characterized by numerous agricultural ponds. This high density of ponds has potentially facilitated the dispersal of *X. laevis*. The frogs can move far from rivers or watercourses by utilizing the ponds as suitable "islands". The analysis of their diet shows that the aquatic larvae of nektonic insects comprise the major portion in terms of mass while small planktonic crustaceans are the most numerous component. There is a significant difference between the diet of adults and juveniles." (Authors) Odonata contribute significantly to the diet of *X. laevis*.] Address: Lo Valvo, M., Dipartimento di Biologia Animale "G. Reverberi", Università degli Studi di Palermo, Via Archirafi 18, I-90123 Palermo, Italy. E-mail: mlovalvo@unipa.it

7378. Ferland-Raymond, B.; Murray, D.L. (2008): Predator diet and prey adaptive responses: Can tadpoles distinguish between predators feeding on congeneric vs. conspecific prey? *Can. J. Zool.* 86(12): 1329-1336. (in English, with French summary) ["Predator diet can play an important role in facilitating detection of predation risk among prospective prey, and such detection should have adaptive significance in reducing mortality in environments where not all predators confer similar risk. In the laboratory, we tested behavioural and morphological responses of tadpoles from two congeneric

frog species (bullfrog (*Rana catesbeiana* Shaw, 1802) and mink frog (*Rana septentrionalis* Baird, 1854)) to cues from an odonate predator (genus *Aeshna* Fabricius, 1775). In a separate experiment we found that both frog species had similar baseline vulnerability to *Aeshna* predation, implying that species' responses to predators feeding on conspecific vs. congeneric prey also would be similar. Both species reduced their activity in the presence of predators feeding on tadpoles of either species vs. those fed invertebrates (*Libellulidae*) or not subjected to predators (controls). Bullfrog tadpoles grew bigger than controls when exposed to predators fed mink frog tadpoles only, whereas mink frogs failed to show a comparable response. Neither species exhibited changes in shape that were attributable to predator diet. Our results suggest that closely related frog species do not distinguish between predators feeding on conspecific vs. congeneric prey, implying that selection favours generalized antipredator responses when prey species are subject to similar predation risk." 7379. Fleck, G.; Brenk, M.; Misof, B. (2008): Larval and molecular characters help to solve phylogenetic puzzles in the highly diverse dragonfly family *Libellulidae* (Insecta: Odonata: Anisoptera): The *Tetrathemistinae* are a polyphyletic group. *Organisms Diversity and Evolution* 8(1): 1-16. (in English) ["The systematics of the dragonfly family *Libellulidae* remains an unsolved puzzle. The classification into subfamilies relies primarily on wing venational characters, as is the case for most systematic hypotheses on dragonflies. In this study, we show that the discovery of unknown libellulid larvae can change tremendously our views on phylogenetic relationships. The larvae of the genera *Micromacromia* Karsch, 1889 and *Allorhizucha* Karsch, 1889 are described and illustrated. They are briefly compared with the larva of *Neodythemis* Karsch, 1889. The larvae of *A. klingi* Karsch, 1889 and *N. africana* Fraser, 1954 are extremely similar. The larva of *M. camerunica* Karsch, 1889 displays well developed dorsal hooks on abdominal segments 4-8, which distinguishes it from other closely allied genera. *Micromacromia*, *Allorhizucha* and *Neodythemis* are traditionally placed within the *Tetrathemistinae*, but their larvae strongly resemble those in the subfamily *Libellulinae*. Larval morphological studies and a molecular analysis based on mitochondrial SSU, LSU and tRNA valine imply that *Micromacromia*, *Allorhizucha* and *Neodythemis* have to be placed in the subfamily *Libellulinae*. Consequently, the subfamily *Tetrathemistinae* becomes a polyphyletic group. Our analysis suggests that imaginal characters, and in particular wing venation, are much more often prone to homoplasious evolution than previously anticipated. Taxonomic or systematic works predominantly based on wing venation might be in need of substantial revision, at least within this dragonfly family, presumably even in the whole suborder Anisoptera, based on independent character sets like larval and molecular data." 7380. Fleck, G.; Ullrich, B.; Brenk, M.; Wallnisch, C.; Orland, M.; Bleidissel, S.; Misof, B. (2008): A phylogeny of anisopterous dragonflies (Insecta, Odonata) using mtRNA genes and mixed nucleotide/doublet models. *Journal of Zoological Systematics and Evolutionary Re-*

search 46(4): 310-322. (in English) ["The application of mixed nucleotide/doublet substitution models has recently received attention in RNA-based phylogenetics. Within a Bayesian approach, it was shown that mixed models outperformed analyses relying on simple nucleotide models. We analysed a mt RNA data set of dragonflies representing all major lineages of Anisoptera plus outgroups, using a mixed model in a Bayesian and parsimony (MP) approach. We used a published mt 16S rRNA secondary consensus structure model and inferred consensus models for the mt 12S rRNA and tRNA valine. Secondary structure information was used to set data partitions for paired and unpaired sites on which doublet or nucleotide models were applied, respectively. Several different doublet models are currently available of which we chose the most appropriate one by a Bayes factor test. The MP reconstructions relied on recoded data for paired sites in order to account for character covariance and an application of the ratchet strategy to find most parsimonious trees. Bayesian and parsimony reconstructions are partly differently resolved, indicating sensitivity of the reconstructions to model specification. Our analyses depict a tree in which the damselfly family *Lestidae* is sister group to a monophyletic clade *Epiophlebia* + Anisoptera, contradicting recent morphological and molecular work. In Bayesian analyses, we found a deep split between *Libelluloidea* and a clade 'Aeshnoidea' within Anisoptera largely congruent with Tillyard's early ideas of anisopteran evolution, which had been based on evidently plesiomorphic character states. However, parsimony analysis did not support a clade 'Aeshnoidea', but instead, placed *Gomphidae* as sister taxon to *Libelluloidea*. Monophyly of *Libelluloidea* is only modestly supported, and many interfamily relationships within *Libelluloidea* do not receive substantial support in Bayesian and parsimony analyses. We checked whether high Bayesian node support was inflated owing to either: (i) wrong secondary consensus structures; (ii) under-sampling of the MCMC process, thereby missing other local maxima; or (iii) unrealistic prior assumptions on topologies or branch lengths. We found that different consensus structure models exert strong influence on the reconstruction, which demonstrates the importance of taxon-specific realistic secondary structure models in RNA phylogenetics." 7382. Flenner, I.; Sahlen, G. (2008): Dragonfly community re-organisation in boreal forest lakes: rapid species turnover driven by climate change?. *Insect Conservation and Diversity* 1: 169-179. (in English) ["1. Climate change affects many ecosystems on earth. If not dying out or migrating, the species affected have to survive the altered conditions, including changes in community structure. It is, however, usually difficult to distinguish changes caused by a changing climate from other factors. 2. Forestry is considered to be the major disturbance factor in Swedish forests. Here, we use forest lake data sets from 1996 and 2006 which include species abundance data for dragonfly larvae, water plant structure, forest age and forestry measures during a period of 25 years: from 1980 to 2005. Hence, we were able to discriminate between forestry effects and changes in species composition driven by recent climate change. 3. We explored effects on regional species composition, species abundance and ecosystem functions, such as changes in niche use, utilising dragonflies (Odonata) as model organisms. 4. Our results show that dragonflies react rapidly to climate change, showing strong responses over such a short time span as 10 years. We observed changes in both species composition and abundance; former rare species have become more frequent and now occur in lakes of a wider quality range, while former widespread species have become more selective in their choice of waters. The new communities harbour about the same number of species as before, but seen from a regional perspective, diversity is reduced. 5. We predict that the altered species composition and abundance might raise new demands in conservation planning as well as altering the ecological functions of the aquatic systems." (Authors)] Address: Flenner, Ida, Ecology and Environmental Sciences, Halmstad University, PO Box 823, SE-30118 Halmstad, Sweden. E-mail: ida.flenner@hh.se

7383. Forbes, M.R.; Robb, T. (2008): Chapter 14: Testing hypotheses about parasite-mediated selection using odonate hosts. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research* edited by Alex Córdoba-Aguilar. Oxford University Press.: 175-189. (in English) ["Parasites are thought to select for host traits, such as elaborate ornaments and intricate immune systems. Dragonflies have proven useful hosts for studying parasite-mediated selection. This chapter summarizes whether parasites exert fitness costs on their dragonfly hosts and affect signals and the mating success of males. It also reviews determinants of resistance against ectoparasitic mites, which is present in many dragonfly species and introduces recent work suggesting that host gender and age influence immunological responses to bacterial and artificial challenges. The chapter highlights that the likelihood of demonstrating parasite-mediated selection might depend on whether or not the species being considered is a generalist parasite. New ideas on elucidating how dragonfly prey species should deal with threats from multiple enemies, such as predators and parasites, are considered." 7385. Gaino, E., Piersantia, S.; Rebor, M. (2008): Egg envelope synthesis and chorion modification after oviposition in the dragonfly *Libellula depressa* (Odonata, Libellulidae). *Tissue and Cell* 40(5): 317-324. (in English) ["*Libellula depressa* (Odonata, Libellulidae) is an exophytic dragonfly ovipositing eggs in clutches on the surface of floating plants and algae. The present work investigates, at ultrastructural level, the gradual differentiation of the egg envelopes and the chorionic changes after egg deposition in water. The ovary of the mature female of *L. depressa* is composed of numerous strings of panoistic ovarioles, where the eggshell formation takes place gradually throughout the activity of the follicle cells. The present data show that the egg envelopes are constituted of a very thick electron-dense vitelline envelope, a thin endochorion and an extremely thick exochorion composed of a fibrillar matrix resting on a thin electron-dense layer. After deposition in water, *L. depressa* eggs, initially white and almost transparent, gradually become brown spots in a semitransparent jelly coat, rich of incorporated debris. The jelly coat enveloping the eggs of *L. depressa* derives exclusively from the exochorion, constituted of a fibrillar matrix, which swells at contact with water. The jelly-like coat performs an adhesive function and presumably a protective role during egg segmentation and ensuing larval hatching." (in English, with Portuguese summary) ["In the lakes of the Middle Rio Doce, Minas Gerais (MG), two groups of larval Libellulidae are distinguished by preferences of habitat use: one uses mainly aquatic macrophytes and the other uses the bottom substrate. The goal of this work was to verify if there is a morphological distinction between the two groups of species. Thirteen body measures were taken from the larvae and analyzed. No difference was found between the two groups of species regarding the body size, but shape differences were observed for two morphological variables. The species that use mainly macrophytes tend to have larger relative measures of the labium and smaller measures of the abdomen width. Advantages in resource obtainment and in vulnerability to predation are probably the explanations for the morphological divergence among these larval groups." (Authors) The paper considers the following taxa: *Erythrodiplax* sp., *Idiataphe amazonica*, *Miathyria simplex*, *Micrathyria* sp. 1 and M. sp. 2, *Tauriphila australis*, *Traemea binotata*, *Erythemis peruviana*, *Brachymesia furcata*, *Diastatops obscura*, *Orthemis discolor*, *Perithemis mooma*, and *Dythemis multipunctata*.] Address: Giacomini, H.C., Departamento de Ecologia, Campus de Rio

7397. Gossum, H. van; Sherratt, T.N.; Cordero-Rivera, A. (2008): Chapter 17. The evolution of sex-limited colour polymorphism. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 219-231. (in English) ["Species that exhibit genetic colour polymorphism are ideal for studying the micro-evolutionary forces that maintain genetic variation in nature. One very intriguing polymorphism is the coexistence of several discrete morphs within only one sex, with one morph often resembling the opposite sex in colour and sometimes behaviour. In males, this resemblance often allows access to receptive females, while in females the polymorphism appears related to avoiding excessive male sexual harassment. One might wonder why natural selection does not simply give rise to a single best male and female type for each species. The phenomenon of sex-limited polymorphisms provides an important opportunity to test contemporary ideas relating to sexual selection and sexual conflict, and the diversity of polymorphisms that have arisen in odonates clearly offers one of the best natural systems for among species and population comparative research." (in English, with Czech summary) [27 species of the regional 65 dragonfly species are red listed.] Address: Harabiš, F., Department of Ecology and environment, Faculty of Environmental sciences, Czech university of life sciences Prague, Kamýcká 129, CZ-165 21 Prague 6, Czech Republic.

7402. Hardersen, S. (2008): Dragonfly (Odonata) communities at three lotic sites with different hydrological characteristics. *Italian Journal of Zoology* 75(3): 271-283. (in English) ["At the nature reserve "Bosco della Fontana" (Lombardy, Italy) the communities of larval and adult dragonflies were studied at three sites in small streams. The larval communities were investigated by collecting exuviae. Site 1, a stream section which falls dry in March–April due to human intervention, had a community of larval dragonflies where species typical of running water were almost absent. Here *Ischnura elegans* was the dominant species, accounting for more than 64% of the total number of exuviae. Additionally, other species typical for stagnant water were present. However, reproductively active adults of rheophilous species were dominant when flowing water was abundant at this site in summer. In contrast, at the two other sites, where flowing water is present throughout the entire year, rheophilous species were dominant in the larval community and in the adult communities. It is concluded that streams with a highly modified hydrology may represent "ecological traps" for specialized species and that dragonfly surveys solely based on the observation of adults can be misleading." (Author)] Address: Hardersen, S., Centro Nazionale per lo Studio e

la Conservazione della Biodiversità Forestale, Corpo Forestale dello Stato, Strada Mantova, 29, I-46045 Marmirolo (MN), Italy. E-mail: s.hardersen@libero.it

7403. Hassall, C.; Thompson, D.J.; Harvey, I.F. (2008): Latitudinal variation in morphology in two sympatric damselfly species with contrasting range dynamics (Odonata: Coenagrionidae). *Eur. J. Entomol.* 105: 939-944. (in English) ["Geographic range expansion is one of the best documented macroecological consequences of climate change. A concomitant change in morphology has been demonstrated in some species. The relationship between latitudinal variation in morphology (e.g. Bergmann's rule) and the morphological consequences of microevolutionary pressures at expanding range margins have received little attention in the literature. Here we compare morphology of males of two Palearctic damselfly species, *Coenagrion puella* and *Pyrrosoma nymphula*. *C. puella* has recently expanded its range from the north of England into Scotland. *P. nymphula* does not exhibit a range margin in the United Kingdom and has established populations in northern Scotland. We demonstrate evidence for spatially correlated variation in body size across the sampling sites between the two species but a deviation in patterns of dispersal-related morphology. *P. nymphula* exhibited very weak relationships between dispersal-related morphology (wing loading and thorax : abdomen mass ratio) and latitude. However, the more southerly distributed *C. puella* exhibited strong relationships between mass investment in dispersal-related morphology and latitude. These trends appear to indicate compensatory growth patterns in cooler environments like those demonstrated for other species. The limits of this compensation for conditions that are close to the limits of a species' tolerance may contribute to the determination of the range margin. Greater variation in morphology towards the range margin has been observed in previous studies in Odonata. As such, the location of the sampling sites relative to the range margin of each species (closer in *C. puella* than *P. nymphula*) is highlighted as a potential contributing factor to the variation observed.] Address: Hassall, C., Biosciences Building, Crown Str., University of Liverpool, L69 7ZB Liverpool, UK. 7404. Hassall, C.; Thompson, D.J. (2008): The effects of environmental warming on Odonata: a review. *Int. Journal of Odonatology* 11(2): 131-153. (in English) ["Climate change brings with it unprecedented rates of increase in environmental temperature, which will have major consequences for the earth's flora and fauna. The Odonata represent a taxon that has many strong links to this abiotic factor due to its tropical evolutionary history and adaptations to temperate climates. Temperature is known to affect odonate physiology such as developmental rate, phenology and seasonal regulation as well as immune function and the production of pigment for thermoregulation. A range of behaviours are likely to be affected which will, in turn, influence other parts of the aquatic ecosystem, primarily through trophic interactions. Temperature may influence changes in geographical distributions, through a shifting of species' fundamental niches, changes in the distribution of suitable habitat and variation in the dispersal ability of species. Finally, such a rapid change in the environment results in a strong selective pressure towards adaptation to cope and the inevitable loss of some populations and, potentially, species. Where data are lacking

for odonates, studies on other invertebrate groups will be considered. Finally, directions for research are suggested, particularly laboratory studies that investigate underlying causes of climate-driven macroecological patterns." (Authors)] Address: Thompson, D. 7411. Hope, P. (2008): The Vagrant Emperor *Anax ephippiger* (Burmeister, 1839): proof of breeding in Turkey. *J. Br. Dragonfly Society* 24(1): 32-36. (in English) [Mugla province, 50m from the Mediterranean Sea at Cahs (near Fethiye), Turkey; 17-XI-2004, *A. ephippiger* settled at the base of a stem of *Typha angustifolia*. The following year exuviae collected from the location were identified to be *A. ephippiger*. This is the first proof of breeding for this species in Turkey.] Address: Hope, P., English Bridge Court, Wyle Cop, Shrewsbury, Shropshire SY1 1XH, UK

7412. Hope, P. (2008): Balkan Emerald *Somatochlora meridionalis* (Neilson, 1935) — A remarkable extension of the distribution range in Turkey. *J. Br. Dragonfly Society* 24(1): 14-18. (in English) ["Whilst working on a United Nations (Development Project) biodiversity study at Gokova in southwest Turkey in 2003 (Hope, 2004), I caught a metallic green dragonfly at a stream in the Cetibeli Forest. Although initially assumed to be a Brilliant Emerald *Somatochlora metallica*, the specimen was sent to Dr R. R. Askew for positive identification. He informed me that it was in fact a Balkan Emerald *Somatochlora meridionalis* and, according to him, not recorded in Asian Turkey. Later correspondence with odonatologists from the Natural History Museum (European Invertebrate Survey, Nederland) in Leiden, The Netherlands, confirmed that it was scarce to fairly common in Thrace (European Turkey) and had been recorded in the adjacent Asian Turkey just over the Bosphorus. My discovery put it some 900km to the south of any previous records, a remarkable extension of its distribution range." (Author)] Address: Hope, P., 2 English Bridge Court, Wyle Cop, Shrewsbury, Shropshire SY1 1XH, UK

7413. Hunger, H.; Schiel, F.-J. (2008): Erstnachweis von *Gomphus flavipes* am deutsch-schweizerischen Hochrhein (Odonata: Gomphidae). *Libellula* 27(3/4): 221-228. (in German, with English summary) ["At 29-VI, 23-VII, 27-VIII and 09-VIII-2008, four exuviae of *Stylurus flavipes* were found on the High Rhine east of Basle, three on the German bank and one on the Swiss bank. This is the first confirmed record of *S. flavipes* in Switzerland, although a previous occurrence of the species in the Canton of Vaud is regarded as likely. The fin-

dings are described and briefly discussed." (Authors)] Address: Hunger, H., Institut für Naturschutz und Landschaftsanalyse (INULA), August-Ganther-Straße 16, D-79117 Freiburg, Germany. E-mail: holger.hunger@inula.de

7414. Ishizawa, N. (2008): Factors in the selection of oviposition mode in *Sympetrum infuscatum* (Selys) (Anisoptera: Libellulidae). *Odonatologica* 37(4): 317-328. (in English) ["The study was conducted at rice paddies in the cool temperate area of central Japan. The oviposition time period was limited to between ca 10:00 a.m. and 14:00 p.m. with a peak around noon. At an ambient temperature (T_a) below 30°C most pairs oviposited in tandem (TO) but at a T_a above 30°C in mid-summer most pairs separated shortly after the start of TO. The females continued to oviposit while being escorted by their partners. The regression coefficient of male body temperature (T_b) in ovipositing pairs was characteristically greater than that of the female, and it is suggested that the male is more dependent on T_a than is the female. Although the duration of oviposition was a little longer in pairs that separated after the start of oviposition, this difference was not significant. The reason why *S. infuscatum* starts oviposition in such a hot season of summer seems to be due to the morphological feature of its slender abdomen, which decreases abdominal light absorption at low T_a in the autumn." (Author)] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozavva City, Saitama Pref., Japan. E-mail: isizawa7@rivo.mediatti.net

7415. Jacobsen, D.; Marin, R. (2008): Bolivian Altiplano streams with low richness of macroinvertebrates and large diel fluctuations in temperature and dissolved oxygen. *Aquatic Ecology* 42: 643-656. (in English) ["We sampled benthic macroinvertebrates and recorded oxygen and temperature regime during 2-day periods in 12 stream sites at an altitude of 3,800–4,000 m a.s.l. on the Bolivian Altiplano, during low flow conditions at the end of the dry season. Eight of the sites were relatively unpolluted, while the remaining four sites were affected by domestic/industrial sewage. Compared to other Andean streams, the fauna was poor with a total of 28 and a mean of 11 taxa (mostly families) in the unpolluted sites. The entire EPT group was represented by just five families. Of these, only Baetidae and Hydroptilidae were common. At all sites, the dominant taxa were found among just four taxa (Elmidae, Chironomidae, Oligocheata and Hyallellidae). Mean water temperature was 12.9 C°, while mean diel amplitude was 13.4 C° and the maximum range 17.4 C°. Ten richness and biotic indices were used to analyse for effects of temperature and oxygen on the fauna. Most measures of fauna richness were negatively correlated with mean and max temperature (even excluding the four polluted sites), while biotic indices were mostly uncorrelated with temperature. Thus, the large fluctuations in temperature seemed to exclude taxa, thereby reducing overall diversity of Altiplano streams. Oxygen saturation also varied considerably, with a mean diel range of 48% and a maximum range of 93%. Richness measures were uncorrelated with oxygen %, while all biotic indices were positively correlated with either mean or min oxygen %. Most measures of faunal composition showed a marked shift at levels of 10–30% min oxygen saturation. Earlier studies of high Andean streams in Ecuador have shown a major shift in faunal composition at 50–60% oxygen saturation. The fauna in the Altiplano streams may be

adapted to the large fluctuations in oxygen saturation, and therefore more robust towards low oxygen saturations. The implications for biotic assessment of Altiplano streams are discussed." (Authors) A few Aeshnidae were collected.] Address: Jacobsen, D., Freshwater Biological Laboratory, Institute of Biology, University of Copenhagen, Helsingørsgade 51, Hillerød 3400, Denmark. 7416. Jara, F.G. (2008): Tadpole–odonate larvae interactions: influence of body size and diel rhythm. *Aquatic Ecology* 42(3): 503-509. (in English) ["Several studies have shown that prey and predator body size may affect the outcome of predator–prey interactions. However, few studies have taken in account the changes on predator–prey interactions over 24 h. In a tropical freshwater system I evaluated how predator and prey size, and their diel rhythm in activity influenced the interaction between *Physalaemus pustulosus* tadpoles and dragonfly larvae. Tadpoles of different size classes were exposed to two size classes of the dragonfly larvae *Rhionaeschna spec.* Feeding trials were conducted during day and night. Tadpole activity showed a diel rhythm and affected size-selective predation of the smallest dragonfly larvae, but not of the larger ones. Predator and prey size had a significant effect on the prey survivorship and prey size had a significant effect on the preference of the predator. The interaction between both factors was significant, indicating that they did not operate independently. I conclude that the predator–prey interactions between odonate larvae and anuran tadpoles were mainly affected by the size of the prey and the predator, and less by the diel activity pattern of the prey." 7418. Johansson, F.; Mikolajewski, D.J. (2008): Chapter 10. Evolution of morphological defences. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 127-139. (in English) ["Understanding the ecology and evolution of morphological defences in animals and plants may help us to understand and protect biodiversity. Several species of dragonfly larvae express lateral and dorsal abdominal spines. In some species these spines seem to be fixed, and in others they are induced by the presence of predatory fish. Larger spines are adaptations to reduce predation risk by fish, but incur a cost because large spines are associated with a higher predation risk by invertebrate predators. The difference in vulnerability to different predators has the potential to affect temporal and spatial variation in the morphology of dragonfly larvae, and may ultimately re-

sult in speciation. Future focus on the joint evolution of correlated defensive traits such as morphology and behaviour and their plasticity might be fruitful for a better understanding of the development of animal diversity." 7420. Jovic, M.; Santovac, S.; Andjz, L. (2008): *Leucorrhinia caudalis* (Charpentier, 1840) - a new or an ex dragonfly species in Serbian fauna? *Bulletin of the Natural History Museum Belgrade* 1: 161-171. (in English, with Serbian summary) ["The discovery of 11 specimens (4males, 7females) of *L. caudalis* in the entomological collection of the National Museum in Zrenjanin is presented. This material from the early 1970's represents the first reliable data about the occurrence of this species in Serbian territory and should, therefore, be considered a new species of Serbian fauna. Contemporary literature data about this endangered species in the region are discussed. Attempts to find a present population in the locality cited on the specimen's labels remained unsuccessful. Both the original list of the species collected together with the specimens *L. caudalis* and the list of those collected in the same locality thirty-five years later are given and commented upon. Remarks about habitat destruction and the possibilities of survival of this species in N Serbia are also presented." (Authors)] Address: Jovic, M., Natural History Museum Belgrade, Njegoševa 51, P.O. Box 401, YU-11000 Belgrade, Serbia. E-mail: milos.jovic@nhmbeo.org.yu

7421. Jung, S.W.; Hguyen, V.V.; Nguyen, Q.H.; Bae, Y.J. (2008): Aquatic insect faunas and communities of a mountain stream in Sapa Highland, northern Vietnam. *Limnology* 9(3): 219-229. (in English) ["Aquatic insect communities were investigated from the Muonghoa Stream in the Sapa Highland (highest peak 3,143 m), a subtropical mountain stream in northern Vietnam. Field investigations for quantitative (Surber net 50 cm 9 50 cm, mesh size 0.2 mm, riffle and pool/run) and qualitative (hand net, mesh size 1 mm) sampling were conducted at nine sites along the watercourse between 27 November and 2 December 2005. As a result, a total of 216 species (the majority of them undescribed) belonging to 139 genera, 61 families, and nine orders were recognized: 53 Ephemeroptera species (24.5%), nine Odonata species (4.2%), 15 Plecoptera species (6.9%), seven Hemiptera species (3.2%), 35 Coleoptera species (16.2%), one Megaloptera species (0.5%), 29 Diptera species (13.4%), 66 Trichoptera species (30.6%), and one Lepidoptera species (0.5%). Trichoptera, Ephemeroptera, and Coleoptera represented the major aquatic insect groups with regard to taxonomic and individual richness, whereas Hemiptera and Odonata were relatively less diverse and abundant than in studies of

other tropical Southeast Asian streams. The dominance, richness, and diversity indices (H0) fell within the following ranges [mean \pm standard deviation (SD)]: 0.18–0.76 (0.42 \pm 0.19), 4.13–9.19 (7.06 \pm 1.45), and 1.61–3.22 (2.67 \pm 0.55), respectively. Riffle habitats generally yielded numbers of aquatic insect species and individuals approximately twice that sampled in pool/run habitats. Shredders were relatively larger in proportion within the headwater reach, whereas scrapers and collector-gatherers were more abundant in the middle and lower stream reaches. This functional feeding group composition is characteristic of temperate streams in East Asia. The results of detrended correspondence analysis and Bray–Curtis cluster analysis indicated that aquatic insect compositions at the sampling sites were very reflective of the reach characteristics, which evidence gradual changes with altitude and stream order along the stream watercourse. This is the first comprehensive investigation of aquatic insects in highland Southeast Asian regions." (Authors) Odonata are treated on the genus level.] Address: Y. J. Bae (&) Lab of Animal Systematics and Ecology, Division of Life Sciences and Biotechnology, Korea University, 1 Anam-dong, Seongbuk-gu, Seoul 136-701, South Korea e-mail: yjbae@korea.ac.kr

7422. Kadoya, T.; Suda, S.; Nishihiro, J.; Washitani, I. (2008): Procedure for predicting the trajectory of species recovery based on the nested species pool information: Dragonflies in a wetland restoration site as a case study. *Restoration Ecology* 16(3): 397-406. (in English) ["Restoration of seminatural habitats in the rural agricultural landscape has become an urgent matter in environmental conservation. We propose here a procedure for predicting the trajectory of species recovery and for specifying the priority of habitat types for restoration of a rural agricultural landscape. We then apply it as a case study to the recovery of dragonfly species in the Azame restoration project that began in 2003 in northern Kyushu, Japan. We examined the nestedness of the regional distribution of dragonflies using a national database on wildlife distribution and listed the recorded species in order of their prevalence in the region. We also conducted a census of adult dragonflies currently found at the restoration site to assess species richness. By comparing these data, we identified species potentially capable of inhabiting the restoration site and, based on their habitat requirements, suggest what type of habitat (e.g., bogs and marshes, ponds, and bodies of slow-moving water) should be restored preferentially. We observed significant nestedness in the presence–absence matrix for dragonfly species and thus predict that species recovery at the restoration site will follow the regional order of prevalence of the species. The required habitat types did not differ significantly between the currently observed species and the potential species, which indicates that all these habitat types should be restored in the project." (Authors)] Address: Kadoya, T., Department of Ecosystem Studies, Graduate School of Agricultural and Life Sciences, The University of Tokyo, 1-1-1 Yayoi, Bunkyo-ku, Tokyo 113-8657, Japan. 7425. Kalnins, M. (2008): Protected aquatic insects of Latvia – *Leucorrhinia albifrons* (BURMEISTER, 1839) and *L. caudalis* (CHARPENTIER, 1840) (Odonata: Libellulidae). *Latvijas Entomologs* 45: 5-13. (in English) ["Published data, collections, data collected during the project „Analysis of the Specially Protected Nature Territories in Latvia and Establishing of EMERALD/Natura 2000 Network” and material collected by Latvian entomologists have all been used in the analysis of the distribution of this species. The distribution of *L. albifrons* and *L. caudalis* were mapped using a basic grid of 5x5 km squares in the Baltic grid system. In total, *L. albifrons* is recorded from 96 squares and *L. caudalis* - from 80 squares in Latvia. The most known localities are concentrated in central and northern Latvia. The majority of localities of *L. albifrons* in Latvia has been recorded in natural eutrophic the Lakes with Magnopotamion or Hydrocharition – type vegetation and in natural dystrophic the Lakes and ponds, in active raised bogs or transition mires. Other *L. albifrons* habitats are polytrophic the Lakes and polytrophic oxbow the Lakes with Magnopotamion or Hydrocharition type vegetation, hard oligo-mesotrophic the Lakes with benthic vegetation of *Chara* spp. The majority of localities of *L. caudalis* in Latvia has been recorded in natural eutrophic the Lakes with Magnopotamion or Hydrocharition – type vegetation, polytrophic the Lakes and polytrophic oxbow the Lakes with Magnopotamion or Hydrocharition type vegetation. Other *L. albifrons* habitats are hard oligo-mesotrophic the Lakes with benthic vegetation of *Chara*

7426. Keil, P.; Simova, I.; Hawkins, B.A. (2008): Water-energy and the geographical species richness pattern of European and North African dragonflies (Odonata). *Insect Conservation and Diversity* 1(3): 142-150. (in English) ["1. Environmental correlates of broad-scale patterns of Odonata species richness were studied in Europe and part of northern Africa using 220 × 220-km gridded data. Relationships with 11 environmental variables were tested using multiple regression. 2. Two models were constructed: (i) for the entire data set covering both Europe and northern Africa, and (ii) only for Europe. 3. Across both regions, actual evapotranspiration had the strongest relationship with richness, followed by weaker associations of potential evapotranspiration (a concave polynomial) and summer vegetation index (a positive linear relationship). Within Europe the strongest predictor was a concave polynomial of potential evapotranspiration, followed by vascular plant species richness (a positive relationship) and annual precipitation (a concave polynomial). 4. A test of metabolic theory identified strong non-linearity in the temperature-richness relationship, and geographically weighted regression indicated consistency with the theory in a very limited part of Europe. 5. The results are most consistent with the hypothesis that broad-scale species richness patterns are primarily determined by water-energy balance, similar to many fully terrestrial insect groups." 7428. Koenig, W.D. (2008): Chapter 12. Lifetime reproductive success and sexual selection theory. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 153-167. (in English) ["This chapter summarizes studies of lifetime reproductive success (LRS) conducted on odonates. Such studies have focused on many characters, but have typically concluded that survivorship — the main component of natural selection, is more important than mating efficiency — a primary component of sexual selection, in determining LRS. They have also frequently found that environmental fac-

tors are important and that selection and the opportunity for selection vary considerably depending on density, sex ratio, and community composition. LRS studies have been most successful when focused on specific traits and when complemented by experimental manipulations. Progress in understanding the current actions of natural and sexual selection is thus most likely to involve long-term LRS work combined with experimental or comparative approaches. Particularly desirable are studies that incorporate the larval stage in fitness calculations, perform parentage analyses to determine realized fitness, and consider the role of non-breeding behaviours such as foraging efficiency." 7443. Ma, J.; Liang, B.; Zhang, S.; Metzner, W. (2008): Dietary composition and echolocation call design of three sympatric insectivorous bat species from China. *Ecol. Res.* 23: 113-119. (in English) ["By examining an extensive data set covering a period of 2 years, the present study identifies the dietary composition of three sympatric insectivorous bat species in rural areas of Beijing municipality. Each species clearly has different preferences for particular food items. Greater horseshoe bats, *Rhinolophus ferrumequinum*, preferred to catch nocturnal, actively flying insects, mostly moths (Lepidoptera), and to a lesser percentage flies (Diptera), beetles (Coleoptera), and flying ants and termites (Hymenoptera). Other nocturnal insects which do not exhibit any perceptible wing movements, such as true bugs (Homoptera), or strictly diurnal insects that hardly ever fly in the dark, such as grasshoppers (Orthoptera) and dragon- and damselflies (Odonata), were never found in droppings of horseshoe bats. Large mouse-eared bats, *Myotis chinensis*, preferentially glean relatively large terrestrial prey of the order Coleoptera (mostly carabid beetles) and Orthoptera, whereas greater tube-nosed bats, *Murina leucogaster*, consume predominantly smaller, diurnal Coleoptera (mostly soldier beetles, *Cantharidae*, and ladybugs, *Coccinellidae*). Our findings also indicate previously not described, significant spectro-temporal differences in the echolocation signals of *M. chinensis* and *M. leucogaster*. The results suggest that in our study area the dramatic differences in the dietary composition of these three bat species are mainly based upon differences in their foraging behaviors, including differences in their echolocation signal structure. The dietary data provide important background information for conservation efforts, such as habitat protection." 7444. Macagno, A.L.M.; Boano, G.; Palestini, C.; Stasi, M.; Rolando, A. (2008): Movement and demographics of *Libellula fulva* (Odonata, Libellulidae). *Environ. Entomol.* 37(5): 1145-1153. (in English) ["Many capture-recapture studies on adult dragonflies have found male-biased sex ratios. However, few have estimated survivorship of males and females separately from data on frequency of recaptures in the field. Even when daily survival and capture probabilities are estimated separately, controversies can arise on whether sex biases in local survival are to be attributed to mortality or permanent emigration from the study site. The knowledge of male and female movements, assessed on an appropriate scale (i.e., within and outside the breeding site), can help address this issue. In this paper, we performed a 4-yr capture-recapture study of two *L. fulva* populations in northwest Italy. Cormack-Jolly-Seber models

were used to get unbiased estimates of demographic parameters (daily survival and capture probabilities, sex ratio, mean life span, and population size). Movement parameters were measured directly by georeferencing encounters. Moderate differences in survival, with males surviving better than females, were found in one population and not in the other, suggesting that these differences are not an inherent characteristic of the species. In the population with lower female survival, females were not more vagile than males, thus indicating their lower survival was caused by actual mortality rather than to emigration. In the population with no survival differences between males and females, marked males outnumbered females, but estimated sex ratios were 1:1 or female biased. Therefore, raw field data were misleading because they led to underestimates of the more elusive sex and overestimates of the more detectable one (males). Survival and movement differences detected in the two populations are discussed in the framework of local environmental and demographic factors." 7446. Marden, J.H. (2008): Chapter 19: Dragonfly flight performance: a model system for biomechanics, physiological genetics, and animal competitive behavior. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 249-261. (in English) ["Adult dragonflies are heavily dependent on their flight muscles and flight ability for nearly all of their adult activities. This chapter reviews research that presents dragonflies as model organisms for examining mechanisms that underlie variation in flight performance within and between species, molecular mechanisms by which muscle performance is adjusted within individuals, and how these physiological traits affect territorial and mating success. Results of these studies in dragonflies have provided fundamental new knowledge that informs the theoretical bases of a number of fields: biomechanics of animal locomotion, physiological genetics, and game theory approaches to animal contests. New insights that cross the boundaries of these disparate fields demonstrate the payoff for performing integrative research." 7449. May, M.L.; Matthews, J.H. (2008): Chapter 6. Migration in Odonata: a case study of *Anax junius*. In: Alex Córdoba-Aguilar (Editor): *Dragonflies and damselflies: Model organisms for ecological and evolutionary research*. Oxford Scholarship Online Monographs: 63-79. (in English) ["Migration by Odonata may illuminate patterns and evolution of insect migration in general. As aquatic/aerial carnivores dragonflies differ from most migratory insects, and because they are large and diurnal, observational techniques are available that are impossible in most other insects. Geographic analysis of genetic structure and stable and radiogenic isotope composition and use of newly developed radio-tracking techniques has been applied to migration in the North American dragonfly, *Anax junius*. Southbound migrants move up to 2,800 km. Developmental phenology suggests early ('resident') and late ('migrant') cohorts at most sites, but these groups appear genetically identical, and the species is essentially panmictic in eastern North America. Apparently environmental cues and physiological responses to photoperiod and temperature engender migratory behaviour. Successful radio-tracking of individual *A. junius* has revealed alternating periods of migration and energy replenishment, and responses to wind and temperature similar to avian migration." (Authors)] Address: May, M.L., Dept Entom., New Jersey Agricultural Experiment Station, Cook College, Rutgers Univ., New Brunswick, NJ 08901-8524, USA. E-mail: may@aesop.rutgers.edu

7450. McCauley, S.J.; Davis, C.J.; Relyea, R.A.; Yurewicz, K.L.; Skelly, D.K.; Werner, E.E. (2008): Metacommunity patterns in larval odonates. *Oecologia* 158: 329-342. (in English) ["The growth of metacommunity ecology as a subdiscipline has increased interest in how processes at different spatial scales structure communities. However, there is still a significant knowledge gap with respect to relating the action of niche- and dispersal-assembly mechanisms to observed species distributions across gradients. Surveys of the larval dragonfly community (Odonata: Anisoptera) in 57 lakes and ponds in southeast Michigan were used to evaluate hypotheses about the processes regulating community structure in this system. We considered the roles of both niche- and

dispersal-assembly processes in determining patterns of species richness and composition across a habitat gradient involving changes in the extent of habitat permeance, canopy cover, area, and top predator type. We compared observed richness patterns and species distributions in this system to patterns predicted by four general community models: species sorting related to adaptive trade-offs, a developmental constraints hypothesis, dispersal assembly, and a neutral community assemblage. Our results supported neither the developmental constraints nor the neutral-assemblage models. Observed patterns of richness and species distributions were consistent with patterns expected when adaptive tradeoffs and dispersal-assembly mechanisms affect community structure. Adaptive trade-offs appeared to be important in limiting the distributions of species which segregate across the habitat gradient. However, dispersal was important in shaping the distributions of species that utilize habitats with a broad range of hydroperiods and alternative top predator types. Our results also suggest that the relative importance of these mechanisms may change across this habitat gradient and that a metacommunity perspective which incorporates both niche- and dispersal-assembly processes is necessary to understand how communities are organized." 7453. McPeck, M.A. (2008): Chapter 5. Ecological factors limiting the distributions and abundances of Odonata. In: Alex Cordoba-Aguilar (Editor): *Dragonflies and damselflies: Model organisms for ecological and evolutionary research*. Oxford Scholarship Online Monographs: 51-63. (in English) ["This chapter reviews the ecological processes that define and limit the distributions and abundances of many odonate species across eco-

logical environments. Distributions of species among standing bodies of water seem to be limited mainly by the distributions of their predators in the larval stage (e.g., larger dragonflies and fish). Although species also show restricted distributions among flowing water habitats, much less is known about the ecological processes that constrain their distributions. Many different types of species interactions (e.g., resource abundances, competitors, predators, parasites) contribute to the limitation of local abundances. Directions for potential future research are suggested." (Publisher)] Address: McPeck, M., Dept Biol. Sci., Dartmouth College, Hanover, New Hampshire 03755, USA. E-mail: mark.mcpeek@dartmouth.edu

7454. McPeck, M.A.; Shen, L.; Torrey, J.Z.; Farid, H. (2008): The tempo and mode of 3-dimensional morphological evolution in male reproductive structures. *American Naturalist* 171(5): E158-E178. (in English) ["Various evolutionary forces may shape the evolution of traits that influence the mating decisions of males and females. Phenotypic traits that males and females use to judge the species identity of potential mates should evolve in a punctuated fashion, changing significantly at the time of speciation but changing little between speciation events. In contrast, traits experiencing sexual selection or sexually antagonistic interactions are generally expected to change continuously over time, because of the directional selection pressures imposed on one sex by the actions of the other. To test these hypotheses, we used spherical harmonic representations of the shapes of male mating structures in reconstructions of the evolutionary tempo of these structures across the history of the *Enallagma* damselfly clade. Our analyses show that the evolution of these structures is completely consistent with a punctuated model of evolutionary change, and a constant evolutionary rate throughout the clade's history. In addition, no interpopulation variation in shape was detected across the range of one species. These results indicate that male mating structures in this genus are used primarily for identifying the species of potential mates and experience little or no selection from intraspecific sexual selection or sexual antagonism. The implications of these results for speciation are discussed." (Authors)] Address: McPeck, M., Dept Biol. Sci., Dartmouth College, Hanover, New Hampshire 03755, USA. 7455. McPeck, M.A. (2008): The ecological dynamics of clade diversification and community assembly. *American Naturalist* 172: E270-E284. (in English) ["Clades diversify in an ecological context, but most macroevolutionary models do not directly encapsulate ecological mechanisms that influence speciation and extinction. A data set of 245 chordate, arthropod, mollusk, and magnoliophyte phylogenies had a majority of clades that showed rapid lineage accumulation early with a slowing more recently, whereas a small but significant minority showed accelerated lineage accumulation in their recent histories. Previous analyses have demonstrated that macroevolutionary birth-death models can replicate the pattern of slowing lineage accumulation only by a strong decrease in speciation rate with increasing species richness and extinction rate held extremely low or absent. In contrast, the metacommunity model presented here could generate the full range of patterns seen in the real phylogenies by simply manipulating the degree of ecological differentiation of new species at the

time of speciation. Specifically, the metacommunity model predicts that clades showing decelerating lineage accumulation rates are those that have diversified by ecological modes of speciation, whereas clades showing accelerating lineage accumulation rates are those that have diversified primarily by modes of speciation that generate little or no ecological diversification. A number of testable predictions that integrate data from molecular systematics, community ecology, and biogeography are also discussed." 7459. Moore, N.W. (2008): The Norfolk Hawker *Aeshna isosceles* and Water Soldier *Stratiotes albidus*: a study of their relationship at Castle Marsh, Suffolk and elsewhere in the Broads 1991-2004. *J. Br. Dragonfly Society* 24(2) : 71-87. (in English) ["The relationship between *S. aloides* and *A. isosceles* was studied at the Suffolk Wildlife Trust Nature Reserve at Castle Marsh, 1991 to 2004. During that period *S. aloides* was affected by saline pollution of the northern part of the reserve and by changes in management. It decreased slightly and then increased considerably. The numbers of territorial male *A. isosceles* remained fairly similar throughout the period. *A. isosceles* was mainly, but not only, found on dykes with thick monocultures of *S. aloides*. The presence of territorial males on dykes with little or no *S. aloides* was possibly due to their being driven out of the better habitats by more successful individuals. The situation at Castle Marsh was found to be typical of most of the Broadland area. However, *A. isosceles* occurred in the upper Waveney valley and on the Hundred River where

the water courses had no *S. aloides* but which did have thick growths of other aquatic plants, notably Common Bladderwort *Utricularia vulgaris* and Frogbit *Hydrocharis morsus-ranae*. *A. isosceles* occurred at densities broadly similar to those in 5. *aloides* dykes, its preferred habitat. Interspecific aggression between *A. isosceles* and the males of six other species was studied. It mainly occurred with *A. grandis* and with *L. quadrimaculata*; although it occurred frequently it had no discernible effect on the distribution of the species concerned. Both *S. aloides* and *A. isosceles* are under the threat of extinction from rising sea levels caused by climate change. The natural recolonisation of the Fens, where both species are now extinct, is shown to be unlikely. Therefore an experimental study at Wicken Fen NNR — the most suitable fenland site - has been initiated. *S. aloides* has been reintroduced. If the reintroduction is successful, and if it is necessary, *A. isosceles* will also be reintroduced." 7460. Müller, O. (2008): Larval habitats and life history of the Crete Island endemic *Boyeria cretensis* (Odonata: Aeshnidae). *International Journal of Odonatology* 11(2): 195-207. (in English) ["*Boyeria cretensis* belongs to the most threatened European dragonfly species. It is restricted to some isolated permanent streams on the island of Crete. The streams have a pronounced gallery vegetation and are situated in a narrow belt of altitude between 50 and 400 m. We understand very little about the biology of this species so information is required to develop effective conservation measures. The life cycle and spatial distribution of the larvae were studied at a small perennial stream in the central part of Crete during three consecutive years. The larvae showed a preference for calcareous sinter mineral substrate associated with organic material such as roots, leaves and wood. This microhabitat selection is supposed to be mainly an antidrift strategy, since *B. cretensis* lives in habitats with a dynamic hydrology during the rainy period in winter. On the other hand, it may also be a strategy to avoid predation from fish and crabs. The last seven larval stadia were determined by wing sheath length and head width. Based on data of head width frequency distributions, a univoltine or semivoltine life cycle is discussed." (Author)] Address: Müller, O., Birkenweg 6d, D-13206 Libbenichen, Germany. 7465. Nel, A.; Huang, D.-y.; Lin, Q.-b. (2008): A new genus of isophlebioid damselfly-like dragonflies with "calopterygid"-like wing shape from the Middle Jurassic of China (Odonata: Isophlebioidea: Campteropterygidae). *Eur. J. Entomol.* 105(4): 783-787. (in English) ["*Zygotarawia reni*, a new campteropterygid genus and species is described from the Middle Jurassic of China. This fossil has a wing shape unique for this clade, i.e. a fore- and hind wing of the same width and very shortly petiolated, and hind wing cubito-anal area nearly as narrow as that of the forewing. This wing shape is convergently similar to that of recent Zygoptera: Calopterygidae, as well as to several other Cenozoic zygopteran clades, suggesting similar styles of flight and habits, i.e. predation on small insects and flight along trees of river banks.] Address: Nel, A., CNRS UMR 5202, CP 50, Entomologie, Muséum National d'Histoire Naturelle, 45 Rue Buffon, F-75005, Paris, France; e-mails: anel@mnhn.fr;

7466. Niven, J.E.; Graham, C.M.; Burrows, M. (2008): Diversity and evolution of the insect ventral nerve cord. *Annual Review of Entomology* 53: 253-271. (in English) ["Is the remarkable diversity in the behaviour of insects reflected in the organization of their nervous systems? The ventral nerve cords (VNCs) have been described from over 300 insect species covering all the major orders. Interpreting these data in the context of phylogenetic relationships reveals remarkable diversity. The presumed ancestral VNC structure is rarely observed; instead the VNCs of most insects show extensive modification and substantial convergence. Modifications include shifts in neuromere positions, their fusion to form composite ganglia, and, potentially, their separation to revert to individual ganglia. These changes appear to be facilitated by the developmental and functional modularity of the VNC, a neuromere for each body segment. The differences in VNC structure emphasize trade-offs between behavioural requirements and the costs incurred while maintaining the nervous system and signaling between its various parts. The diversity in structure also shows that nervous systems may undergo dramatic morphological changes during evolution." (Authors) The analysis includes *Petalura gigantea*, *Lesites tenuatus*, and *Anax junius*.] Address: Niven, J.E., Department of Zoology, University of Cambridge, Cambridge CB2 3EJ, UK. 7471. Oertli, B. (2008): Chapter 7. The use of dragonflies in the assessment and monitoring of aquatic habitats. In: Alex Cordoba-Aguilar (Editor): *Dragonflies and damselflies: Model organisms for ecological and evolutionary research*. Oxford Scholarship Online Monographs: 79-97. (in English) ["Odonata constitute a valuable tool for various types of bioassessment and biomonitoring of aquatic habitats, such as the measure of biodiversity, the appraisal of waterbody health or integrity (including water quality and ecosystem function), the monitoring of management or restoration practices, and the detection and prediction of biological impacts of climate warming. Furthermore, they have already provided excellent data sets for hypothesis testing in ecology or evolution. An efficient sampling method for Odonata should account for the three live stages, i.e., larvae, exuviae, and adults. However, as this approach may be too expensive, most existing methods only focus on one stage. In applied issues, the adult stage is surveyed at a low cost, and is therefore useful for rapid assessments; it can serve for preliminary screening, for example when identifying local hotspots of diversity or, on the contrary, to mark degraded sites." (Publisher)] Address: Oertli, B., Dept of Nature Management, Univ. of Applied Sciences of Western Switzerland - EIL, 1254 Jussy, Geneva, Switzerland. E-mail: beat.oertli@hesge.ch

7472. Oertli, B.; Indermuehle, N.; Angélibert, S.; Hinden, H.; Stoll, A. (2008): Macroinvertebrate assemblages in 25 high alpine ponds of the Swiss National Park (Cirque of Macun) and relation to environmental variables. *Hydrobiologia* 597: 29-41. (in English) ["High-altitude freshwater ecosystems and their biocoenosis are ideal sentinel systems to detect global change. In particular, pond communities are likely to be highly responsive to climate warming. For this reason, the Swiss National Park has included ponds as part of a long-term monitoring programme of the high-alpine Macun cirque. This cirque covers 3.6 km², has a mean altitude of 2,660 m a.s.l., and includes a hydrographic system composed of a stream network and more than 35 temporary and permanent ponds. The first two steps in the

programme were to (i) make an inventory of the macroinvertebrates of the waterbodies in the Macun cirque, and (ii) relate the assemblages to local or regional environmental variables. Sampling was conducted in 25 ponds between 2002 and 2004. The number of taxa characterising the region (Macun cirque) was low, represented by 47 lentic taxa. None of them was endemic to the Alps, although several species were cold stenothermal. Average pond richness was low (11.3 taxa). Assemblages were dominated by Chironomidae (Diptera), and Coleoptera and Oligochaeta were also relatively well represented. Other groups, which are frequent in lowland ponds, had particularly poor species richness (Trichoptera, Heteroptera) or were absent (Gastropoda, Odonata, Ephemeroptera). Macroinvertebrate assemblages (composition, richness) were only weakly influenced by local environmental variables. The main structuring processes were those operating at regional level and, namely, the connectivity between ponds, i.e. the presence of a physical connection (tributary) and/or small geographical distance between ponds. The results suggest that during the long-term monitoring of the Macun ponds (started in 2005), two kinds of change will affect macroinvertebrate assemblages. The first change is related to the natural dynamics, with high local-scale turnover, involving the metapopulations characterising the Macun cirque. The second change is related to global warming, leading to higher local and regional richness through an increase in the number of colonisation events resulting from the upward shift of geographical ranges of species. At the same time the cold stenothermal species from Macun will be subject to extinction." (Authors)] Address: Oertli, B., Dept of Nature Management, University of Applied Sciences of Western Switzerland - EIL, 1254 Jussy, Geneva, Switzerland. E-mail: beat.oertli@hesge.ch

7473. Okajima, R. (2008): The controlling factors limiting maximum body size of insects. *Lethaia* 41(4): 423-430. (in English) ["The purpose of this study is to consider the controlling factors limiting maximum body size of insects. For this analysis, we set up and quantitatively verify the following working hypothesis: insect body sizes can be explained only by the historical changes in the oxygen supply. The present study focuses on the body size of the Protodonata and Odonata. The amount of oxygen needed and that of oxygen entering the insect body was calculated using allometric equations. The theoretical maximum sizes at each geologic time were estimated from palaeo-atmospheric oxygen partial pressure and compared with the maximum size of known fossilized insects. The historical change in fossilized insect sizes was much larger than that in theoretical sizes. Additionally, from the Jurassic, despite an increase in the partial pressure of oxygen, which would theoretically increase maximum size, the maximum size of fossilized insects became smaller. These findings are inconsistent with the expectations of the working hypothesis. Oxygen supply is likely to partially limit the maximum size of insects with additional factors." (Author)] Address: Okajima, Ryoko, Department of Ecology and Evolutionary Biology, Graduate School of Life Sciences, Tohoku University, Aoba-yama, Sendai 980-8578, Japan. E-mail: okajima@mail.tains.tohoku.ac.jp

7474. Ott, J. (2008): Die Kleine Pechlibelle – *Ischnura pumilio* (Charpentier, 1925) (Odonata: Coenagrionidae) in der Pfalz: ein Profiteur von Regenrückhaltebecken, Naturschutzgewässern und der Klimaänderung. Main-

zer naturwiss. Archiv 46: 233-261. (in German, with English summary) [*I. pumilio* "was not very common in Rhineland-Palatinate (Germany) during the last decades; in particular it was rare in the central part of the biosphere reserve "Palatinate Forest". Outside the Palatinate Forest *I. pumilio* was found more often, e.g. in the Rhine Valley (e.g. Rhinehesse, Bienwald), or along the Haardtrand at lower altitudes. Here it is mainly present in young and shallow waters, mostly in ponds created for nature conservation measurements (protection of amphibians). Another habitat it typically inhabits are water retention ponds near roads. Both types are maintained (road authorities, nature conservation organisations) and kept in early successional stages. In 2007 the species was found in several waters in the Palatinate Forest for the first time, also with indigenous populations. The species was profiting of lower water tables – a consequence of climatic changes in the area. To arrive at these waters the species must have crossed at least several kilometres of dense forest which is a remarkable fact. The possible ways of the colonisation are discussed in relation to its larval development and voltinism. The larvae of this species, being obviously a generalist, can live in a wide range of abiotic conditions: some of these waters had a pH of only 3.3 and the conductivity varied between 13 and 9109 µS/cm. Larvae were found to survive a period of about 3 weeks in a dried out pond. Finally, aspects of nature conservation and the classification of *I. pumilio* in Red Lists are discussed." 7477. Parr, A. (2008): Dragonfly news for spring and early summer 2008. *Atropos* 35: 54-55. (in English) [Verbatim: The first half of 2008 saw many insect groups well down in numbers, no doubt reflecting in part the poor summer the year before. While dragonflies were perhaps less affected than many groups, the early 2008 season still turned out to be relatively uneventful, though fortunately with a few highlights. A period of warm weather in the first half of May, associated with a lengthy spell of easterlies, probably came too early in the season to be highly productive. As the weather turned later in the month, some spectacular counts of *Libellula quadrimaculata* at Dungeness in Kent (where there were morning roosts of 650 on 17 May and 700 on 22 May) were thought to result from mass emergences. The very end of May through to 1 July saw a scattering of reports of *Sympetrum fonscolombii* from

south coast sites (Cornwall, Devon, Hampshire, Sussex and Kent), as well as singletons at the traditional sites of Spurn, East Yorkshire, and Middleton, Lancashire. There was also one record from Co. Wexford, Ireland. These various sightings probably relate largely, though perhaps not entirely, to local breeding since many individuals were immatures, and an exuvia was found at Rye Harbour in Sussex on 30 June. Given the very low numbers seen at most sites the fate of many of these breeding colonies remains unclear, though it is possible that some additional individuals went unrecorded given the largely indifferent weather. In addition to Red-veined Darter there was also one record of *S. flaveolum* during the spring—from Carvey Wick, Essex, on 25 June. Probably the major highlight of May /June was the continuing good fortunes of *Libellula fulva*. Numbers at many established sites, including some areas only recently colonised, were high. Large numbers were, for example, seen at sites along the Great Ouse between St Ives, Cambridgeshire, and Roxton, Bedfordshire, on 18 May, with 'hundreds' together near Brampton, Cambridgeshire. After an apparent absence of a decade or more, good numbers were also seen in the Sandwich Bay area of Kent. More dramatically still there were several reports from entirely new areas, including the Isle of Wight, the Somerset Levels, and even sites in the Attingham area of Shropshire. These latter sightings represent the most north-westerly in Britain. It is hoped to provide a more detailed analysis of the on-going range expansion of Scarce Chaser in a future issue. July was rather quiet, despite a hot spell and generally southeasterly winds during the last third of the month. A total of three records of *Anax parthenope* seemed unexpectedly low given recent trends, but one (a male on 24 July) was at least from the probable breeding site of Maxey Gravel Pits, Cambridgeshire, where oviposition was seen in 2007. The other records came from Sandwich, Kent (12 July), and near Havenstreet, Isle of Wight (28 July). No reports have as yet been received from likely breeding sites besides Maxey but the implications of this are still unclear, not least because there is some potential flexibility in the length of the lifecycle in Britain. The month ended with small numbers of Red-veined Darter at Keyhaven, Hampshire, on 30 July." (Author)] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK. 7478. Parr, A.J. (2008): Migrant and dispersive dragonflies in Britain during 2007. *J. Br. Dragonfly Society* 24(2) : 62-70. (in English) ["The 2007 dragonfly season was one of contrast. April 2007 was the warmest April on record, but although resident species started flying unusually early, little of note was reported on the migrant front. Mid-summer was often wet to very wet, with temperatures somewhat lower than in many recent summers. Some short spells of hot settled weather were however observed, and these were often associated with migratory influxes and/or enhanced internal dispersal. Although there was no repetition of the dramatic migrations of 2006, the year was thus far from uneventful. *Sympetrum fonscolombii* once again occurred in good numbers, and *Anax parthenope* also maintained a strong presence. Several unusual 'one-off' sightings were similarly made — notably a Norfolk Hawker *Aeshna isosceles* reported from Hampshire and a female *Lestes viridis* reported from Suffolk. This latter record is only the third report of the species from Britain in the last hundred years." (Author)] Address: Parr, A.J., 10

7483. Pott, C.; Labandeira, C.C.; Krings, M.; Kerp, H. (2008): Fossil insect eggs and ovipositional damage on bennettitalean leaf cuticles from the Carnian (Upper Triassic) of Austria. Jour. Paleontol. 82(4): 778-789. (in English) ["Two types of evidence for insect ovipositional activity (i.e., actual egg chorions and ovipositional damage) occur on Nilssoniopteris (bennettitalean foliage) leaf cuticles from the Carnian of Austria and provide a rare direct insight into insect egg morphology and oviposition in the Late Triassic. The egg chorions have exclusively been found on *N. haidingeri* leaves, where they are attached to the outer surface of the abaxial cuticle; one specimen suggests that the eggs were arranged in circles. It is impossible at present to determine the affinities of the eggs; possible producers may be beetles, dragonflies, sawflies, or other allied basal Hymenoptera. Ovipositional damage occurs on *N. angustiarum* leaves in the form of lenticular egg impressions surrounded by a narrow, elevated margin. The impressions are visible on the ad- and abaxial cuticle, and coincide when both cuticles are superimposed, which indicates that the eggs producing these impressions were injected into the interior of the leaf. Producers of eggs that may have caused these damages are perhaps dragonflies or damselflies. The restricted occurrence of the two types of ovipositional activity suggests that some kind of host specificity existed, perhaps related to specific preferences in larval diet." 7485. Principe, R.E. (2008): Taxonomic and size structures of aquatic macroinvertebrate assemblages in different habitats of tropical streams, Costa Rica. Zoological Studies 47(5): 525-534. (in English) ["Taxonomic

and size structures of macroinvertebrate assemblages associated with different habitats of tropical streams of Costa Rica were analyzed. Surber samples were taken in riffle and run habitats in 2 streams. Invertebrates were identified and measured, and the biomass was estimated. The taxonomic richness and total abundance were higher in riffle habitats. Correspondence analysis showed a clear separation between riffle and run samples. The IndVal method identified the characteristic assemblages in each habitat type. Tricladida, Hydrachnidia, Leptophlebiidae, Hydropsychidae, Simulium sp., Corynoneurini, Orthoclaudiinae, and Empididae showed significant indicator values for riffle habitats; whereas Bivalvia, Tanyptodinae, and Chironomini were the characteristic taxa from runs. The length-frequency distribution of riffles differed from that in runs in both streams as measured by Kolmogorov-Smirnov tests. The largest organisms were found in run habitats, with macroinvertebrates belonging to the 1st size class being the most abundant in riffles. Although larger organisms were found in runs, differences in total biomass between habitats were not observed due to the high number of small invertebrates collected in riffles. The size spectrum for the entire benthic community showed that the total biomass was relatively equitably distributed among the size classes, although a peak was suggested for medium size classes. When the size spectrum was separately analyzed in each habitat, a peak was also suggested in riffles. Differences in the physical attributes of riffles and runs were clearly reflected in the taxonomic composition of the size spectra. Patterns observed in taxonomic and size structures may indicate different ecological functioning at the habitat level in the tropical streams studied." 7486. Pritchard, G. (2008): The life history of a temperate zone dragonfly living at the edge of its range with comments on the colonization of high latitudes by Neotropical genera of Zygoptera (Odonata). *International Journal of Odonatology* 11(2): 209-223. (in English) ["Of the many Zygopteran genera that occur in the Neotropics, only five (Hetaerina, Archilestes, Lestes, Argia, and Ischnura) are represented north of 40°N in North America, and only three of these (Hetaerina, Archilestes, and Argia) probably had a tropical origin. In the two genera of Lestidae (Archilestes and Lestes) the life history of temperate-zone populations is usually regulated by an egg diapause, whereas in the two genera of Coenagrionidae (Argia and Ischnura) larval diapause synchronizes life histories with seasonal temperature changes. This paper presents data on the life history of a northern population of a species in the first genus, Hetaerina americana living in a geothermally influenced stream near to the northern edge of the species' range in western North America. Larval growth is affected by temperature and differs between warmer and cooler years, but generally larvae appear to grow very rapidly during summer and even grow over winter. Two peaks of larval recruitment each year and a decrease in final stadium size over the summer may be evidence for bivoltinism, and the absence of final stadium larvae in October, November, and December indicates a short-day regulatory diapause in F-1 larvae. A long-day diapause which prevents autumnal metamorphosis of larvae appears not to be present. It is not known whether the tactics that allow New World species of Zygoptera to survi-

ve at mid- to high-temperate latitudes are also present in their tropical congeneric relatives, but it does appear that diapause expression has been associated with speciation in the temperate zone." 7487. Radwell, A.J.; Brown, A.V. (2008): Benthic meiofauna assemblage structure of headwater streams: density and distribution of taxa relative to substrate size. *Aquatic Ecology* 42: 405-414. (in English) ["Permanent meiofauna taxa and portions of the population of other invertebrates that are temporarily in the meiofauna size class are often precluded from stream studies and assessments. This study was designed to determine the identity, density, and distribution of major meiofauna taxa relative to substrate size in a set of similar headwater streams. Using a coring technique, meiofauna (80 mm–1 mm) and substrate samples were collected from 11 Ozark headwater streams in the Boston Mountain ecoregion of Arkansas, USA. Mean meiofauna density among streams was 1739 ± 436 organisms per l. Permanent meiofauna taxa (Copepoda, Cladocera, Ostracoda, Rotifera, Nematoda, Hydrachnida, and Tardigrada) comprised 22.5% of the organisms collected with a mean density of 394 ± 233 organisms per l; temporary meiofauna taxa (Oligochaeta, Turbellaria, Hydroidea, Chironomidae, Ephemeroptera, and other insects - including Odonata) comprised the remainder with a density of 1346 ± 308 organisms per l. [...] The potential value of inclusion of meiofauna in stream environmental assessments is discussed." 7488. Raihani, G.; Serrano-Meneses, M.A.; Córdoba-Aguilar, A. (2008): Male mating tactics in the American rubyspot damselfly: territoriality, nonterritoriality and switching behaviour. *Animal Behaviour* 75(6): 1851-1860. (in English) ["Odonates exhibit a wide range of territorial and nonterritorial mating tactics and are ideal for investigating alternative reproductive behaviours. We studied male mating tactics in the American rubyspot damselfly, Hetaerina americana, a species that exhibits red wing spots that have been suggested to have evolved as a consequence of male–male contests. In this species mating success is enhanced by the ability of males to defend territories along streams and rivers, which depends on the amount of thoracic fat reserves available. Previous studies on this species have distinguished between territorial and nonterritorial males, in which the former obtain significantly more matings than the latter. In our study, however, we found a third reproductive tactic: switching. Switcher males exhibit both territorial and nonterritorial tactics and a mating success similar to that of territorial and nonterritorial males, although this result may be confounded by the small sample size used for this analysis. We suggest that the different mating tactics may be condition determined: territorial males contained the highest fat reserves, nonterritorial males had the least fat content and switchers had intermediate fat loads. We also show that there were no age differences between males using these tactics. Our results suggest that territorial behaviour is extremely plastic in this species. Finally, we discuss the implications of our study and directions for future work on territorial and nonterritorial reproductive tactics in odona-

tes." (Authors)] Address: Córdoba-Aguilar, A., Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo, Apdo. P. 69-1, Plaza Juárez, Pachuca, Hidalgo 42001, Mexico E-mail: acordoba@uaeh.reduaeh.mx

7489. Rebora, M.; Piersantia, S.; Gaino, E. (2008): The antennal sensilla of the adult of *Libellula depressa* (Odonata: Libellulidae). *Arthropod Structure & Development* 37(6): 504-510. (in English) ["An ultrastructural investigation (SEM, TEM) on the antennal flagellum of the adult of the dragonfly *Libellula depressa* (Odonata: Libellulidae) revealed sensilla located in pits on the lateral-ventral side of the antenna. These sensilla are represented by sensilla coeloconica and by deeply sunken sensilla. The sensilla coeloconica are innervated by three unbranched dendrites, which enter the peg and show a dendrite sheath ending at the base of the peg. The peg has no socket and its cuticle is irregular with wide pore-like structures at the base of which actual pores are visible. The structure of these coeloconic sensilla is in agreement with that reported for single-walled insect chemoreceptors. The deeply sunken sensilla are represented by two kinds of sensilla styloconica, named type-1 and type-2, located at the bottom of deep cavities appearing as simple openings on the antennal surface. These sensilla are no-pore sensilla with inflexible socket and unbranched dendrites and, notwithstanding their structural differences, share common features typical of thermo/hygroreceptors. The presence of chemoreceptors in adult dragonflies sheds light on evolutionary trends in insect perception; the previously unknown occurrence of thermo/hygroreceptors in dragonflies is very important in view of the reported ability of Odonata to thermoregulate heliothermally." 7493. Remsburg, A.J.; Olson, A.C.; Samways, M.J. (2008): Shade alone reduces adult dragonfly (Odonata: Libellulidae) abundance. *Journal of Insect Behavior* 21(6): 460-468. (in English) ["We demonstrate that physical habitat conditions influence adult dragonfly (Odonata: Anisoptera) riparian site selection. In naturally treeless riparian areas of South Africa, invasive trees create shade and reduce native vegetation. We hypothesized that most breeding odonates select riparian areas (1) without shade, and (2) with high density and variety of understory perch structures. In two experiments at reservoir shorelines, we varied shade and perch structures. Dragonfly abundances (predominantly *Trithemis* species) were lower at sites with high (75%) or moderate (55%) shade cover than at sites with no shade, and lower at bare sand sites than sites containing stick perches. Perch density and variety (variety of heights and diameters) did not affect dragonfly abundance. These results indicate that shade alone directly reduces dragonfly habitat selection, isolating one aspect of habitat change that can alter insect behaviours." 7494. Ren, D., Nel, A. & Prokop, J. (2008): New early griffenfly, *Sinomeganeura huangheensis* from the Late Carboniferous of northern China (Meganisoptera: Meganeuridae). *Insect Systematics & Evolution* 39: 223-229. (in English) ["New griffenfly *Sinomeganeura huangheensis* gen. n., sp. n. (Meganeuridae) is described from Upper Carboniferous (Namurian) of the Tupo Formation in northern China (Ningxia Hui Autonomous Region). This taxon exhibits unique structure of the wing venation pattern. It is highly interesting in reference to the Namurian age known for the occurrence of two meganeurids until present (*Namurotypus Brauckmann & Zessin, 1989* and *Shenzhousia Zhang & Hong, 2006*) as well as the palaeogeographical position of the locality far from all sites in Laurussia. We demonstrate that meganeurids with relatively small wings already co-existed with large species in the Namurian, as for the Stephanian and the Late Permian. Thus, *Sinomeganeura* demonstrates that the meganeurid diversity and wing venation disparity were comparable during the Na-

murian and the Stephanian, suggesting that this group already had a long history in the Early Carboniferous. Odonoptera were probably the main, if not unique predators of the flying insects during the Late Paleozoic." 7497. Rudolf, V.H.W.; Armstrong, J. (2008): Emergent impacts of cannibalism and size refuges in prey on intraguild predation systems. *Oecologia* 157 : 675-686. (in English) ["Many organisms undergo ontogenetic niche shifts due to considerable changes in size during their development. These ontogenetic shifts can alter the trophic position of individuals, the type and strength of ecological interactions across species, and allow for cannibalism within species. In this study we ask if and how the interaction of a size refuge and cannibalism in the prey alters the dynamics of intraguild predation (IGP) systems. By manipulating the composition of large cannibalistic (*Aeshna umbrosa*) and predatory (*Anax junius*) dragonfly larvae in mesocosms we show that the interaction of cannibals and predators was non-linear and increased the survival of prey. The structure of the final resource community shared by prey and predator differed between small and large dragonfly treatments but not within size classes across species. In general, the small prey stage showed similar shifts in microhabitat use and refuge use when exposed to either conspecific cannibals or predators, while large cannibals showed no clear anti-predator response. However, further behavioral experiments revealed that specific behavioral components, such as distances between individuals or number of movements, differed when individuals

were exposed to either cannibals or predators. This indicates that individuals discriminated between conspecific or heterospecific predators. Furthermore, in similar experiments large cannibals and predators showed different behaviors when exposed to conspecifics rather than to each other. These changes in behavior are consistent with the observed increase in prey survival. In general, the results indicate that cannibalism and ontogenetic niche shifts can result in behavior-mediated indirect interactions that reduce the impact of the predator on the mortality of its prey and alter the interactions of IGP systems. However, they also indicate that size is not the sole determinant and that we also need to account for the species identity when predicting the dynamics of communities." (Authors)] Address: Rudolf, V., Mountain Lake Biological Station, Pembroke, VA, USA. E-mail: volker.rudolf@rice.edu

7498. Rudolf, V.H.W. (2008): The impact of cannibalism in the prey on predator-prey system. *Ecology* 89: 3116-3127. (in English) ["Cannibalism is ubiquitous in natural communities and has the potential to alter the functional relationship of predator-prey interactions. Although cannibalistic species are frequently subject to predation, the consequences of cannibalism in the prey for predator-prey interactions are poorly understood. Using a dragonfly larvae system, I provide the first experimental evidence that cannibalism in the prey creates behaviour- and density-mediated indirect effects that result in nonlinear predator-prey interactions. As a consequence, cannibalism in the prey altered the functional relationship of the predator and its prey and reduced the impact of the predator on prey mortality by 47%. By parameterizing a mechanistic predation model, I show that the nonlethal interaction between cannibals and predators reduced cannibalism rates, which explained almost two times more of the observed mortality reduction than the consumption of cannibals. However, only a model that accounted for both behavioural interactions and the consumption of cannibals could predict 100% of the observed mortality. Using the mechanistic model, I discuss the long-term effects of cannibalism on community dynamics and how they can differ from effects of simple density-dependent mortality. In general, these results demonstrate the importance of accounting for the trophic structure in cannibalistic populations and the resulting nonlinear interactions to predict predator-prey dynamics." (Author)] Address: Rudolf, V., Dept of Ecology and Evolutionary Biology, Rice University, Houston, Texas 77005 USA. E-mail: volker.rudolf@rice.edu

7499. Rust, J.; Petrulevicius, J.F.; Nel, A. (2008): The first damselflies from the lowermost eocene of Denmark, with a description of a new subfamily (Odonata, Zygoptera, Dysagrionidae). *Palaeontology* 51(3): 709-713. (in English) ["*Eodysagrion mikkelsenii* gen. et sp. nov., type species of the new subfamily Eodysagrioninae, and the dysagrionine *Primorilestes madseni* sp. nov., the first thaumatoneurid damselflies from the lowermost Eocene of Denmark, are described. They confirm the presence of this American family in the Palaeogene of Western Europe." (Authors)] Address: Rust, J., Inst. of Palaeontology, University of Bonn, Nussallee 8, 53115 Bonn, Germany. 7500. Sahlén, G.; Haase, S.; Suhling, F. (2008): Morphology of dragonfly larvae along a habitat gradient: interactions with feeding behaviour and growth (Odonata: Libellulidae). *International Journal of Odonatology* 11

(2): 225-240. (in English) ["It has been shown that life history, behavioural as well as morphological traits vary with the habitats occupied by odonate larvae. Here we ask the following questions: (1) Are the morphological traits, which are associated with perception and foraging, related to the larval habitat? (2) Do these traits influence foraging success and growth rate? We analysed the morphology of species pairs belonging to the genera *Crocothemis*, *Orthetrum* and *Trithemis*; one species in each pair occurring in perennial spring-fed streams, the other able to develop in temporary waters. A PCA reveals four principal components of morphological characters which may be expressed as PC1: prey handling, PC2: visual perception, and PC3 and PC4: density of long and short setae on the feet. The variances of PC1, PC2 and PC3 were affected by phylogeny. PC1, PC2 and PC4 differed between habitats. Species of perennial springs had larger values for visual perception. These waters are clear and larger eyes should be beneficial. But, a high PC2 value was associated with low growth rate and did not affect foraging success. We therefore conclude that investment in better sight made by perennial water species may reflect the need of avoiding predators. Development in temporary waters mainly requires rapid growth and species may not be capable to invest also in visual perception. PC1 was negatively correlated with foraging behaviour and PC3 was positively so. This indicates the importance of prey capture mode to foraging success, which may, however, not translate into a higher growth rate." (Authors)] Address: Sahlén, G., Syst. Zoology, Evolutionary Biology Centre, Uppsala University, Norbyvägen 18D, S-752 36 Uppsala, Sweden. E-mail: goran.sahlen@set.hh.se

7502. Samways, M.J.; Grant, P.B.C. (2008): Elephant impact on dragonflies. *Journal of Insect Conservation* 12(5): 493-498. (in English) ["African elephants and other indigenous megaherbivores have a major impact on local vegetation structure, including aquatic communities, as their big feet and large mass pound the fringes of water bodies. This disturbance is likely to have a profound influence on the structure and composition of insect assemblages in these habitats. We investigated which dragonfly (Odonata) species were tolerant of trampling by elephants and other game. Assemblage composition differed according to extremely high, very high or high disturbance levels. Dragonfly abundance was greatest where impact was high, and decreasing when disturbance became very high or extremely high. Several odonate species are well-adapted to fairly high levels of disturbance, although too much is impoverishing. Medium and low impact sites were geographically separated, and this, combined with much lower disturbance levels, had a considerable influence on promoting regional dragonfly diversity. Several regional specialist species only occurred in the geographically separated, low-impact sites. The full complement of dragonflies is present only when there is a combination of va-

rious disturbance levels combined with spatial variation. Elephant impact is similar to that of humans, with too much of either or both, leading to a species-poor, habitat-generalist dragonfly assemblage." 7503. Samways, M.J. (2008): Chapter 8. Dragonflies as focal organisms in contemporary conservation biology. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 97-109. (in English) ["Freshwater ecosystems worldwide are highly threatened. As a consequence, many dragonfly species are also threatened. The threats to them are many and varied, including invasive alien plants and habitat loss. Global climate change is also beginning to affect them, with some species changing their geographical ranges. Worldwide assessments are being made of dragonfly conservation status. They are one of the highest profile invertebrates in conservation awareness, planning, and action. One reason for this is that they are highly valued, being iconic, aesthetic, and sensitive bioindicators of landscape change. They are both important subjects in their own right as well as important role players in overall biodiversity conservation." (Publisher)] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

7504. Schiel, F.-J.; Rademacher, M. (2008): Artenvielfalt und Sukzession in einer Kiesgrube südlich Karlsruhe. *Ergebnisse des Biotopmonitoring zum Naturschutzgebiet „Kiesgrube am Hardtwald Durmersheim“*. *Naturschutz und Landschaftsplanung* 40(3): 87-94. (in German, with English summary) [The study presents the results of a six year monitoring programme, carried out between 1993/94 and 2005 in a gravel pit in the Upper Rhine Valley south of Karlsruhe (Germany, Federal State of Baden-Württemberg). The gravel pit shows a very high biodiversity of plants and animals, also including 34 dragonfly species. A few species of shallow, temporary water bodies are listed. "From 2000 onwards extensive management measures have been carried out to preserve the characteristic habitats and the species diversity of the gravel pit, focussing on the conservation of the pioneer habitats 'dune vegetation' and 'open temporary water zones' and on the control of neophytes." 7505. Schultz, T.D.; Anderson, C.N.; Symes, L.B. (2008): The conspicuousness of colour cues in male pond damselflies depends on ambient light and visual system. *Animal Behaviour* 76(4): 1357-1364. (in English) ["The colours of male coenagrionid damselflies have been interpreted by some as intraspecific signals that reduce intrasexual harassment by advertising the unprofitability of pursuing conspecific males as potential mates. As visual cues, male colours should be conspicuous to other males under the specific light environments where males search for females. We tested this prediction by using spectroradiometry and two models of damselfly colour vision to determine the chromatic and achromatic contrast of males from six species of *Enallagma* damselflies with pond backgrounds under

the ambient light conditions when each species was most active. The males of five species were active at the time when their colour was most conspicuous against aquatic vegetation. Three blue species were most active and attained their highest levels of contrast during midday, while species that became active in late afternoon or evening reflected longer wavelengths and increased in brightness contrast under low sun angles. A sixth species, *Enallagma pictum*, departed from this pattern. We propose that colour may serve as a signal of both sexual and species identity among males." 7507. Serrano-Meneses, M.A.; Córdoba-Aguilar, A.; Székely, T. (2008): Chapter 18. Sexual size dimorphism: patterns and processes. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 231-249. (in English) ["Odonates provide excellent model organisms for testing functional explanations of sexual size dimorphism (SSD) because of their wide variety of habitats, morphology, development, feeding behaviour, and mating strategies. This chapter discusses three major functional hypotheses of SSD and uses data on 133 odonate species to describe their patterns of SSD. It shows that SSD centres around monomorphism in dragonflies, whereas SSD is mostly male-biased in damselflies. Interestingly, phylogenetic comparative analyses suggest that damselflies — but not dragonflies — exhibit allometry consistent with Rensch's rule. Sexual selection acts mainly on males, whereas fecundity selection appears to influence female body size. Further tests, however, are essential, in particular of fecundity selection and the differential niche-utilization." 7508. Serrano-Meneses, M.A.; Sanchez-Rojas, G.; Córdoba-Aguilar, A. (2008): Sexual selection as the possible underlying force in calopterygid wing pigmentation: comparative evidence with *Hetaerina* and *Calopteryx* (Zygoptera: Calopterygidae). *Odonatologica* 37(3): 221-233. (in English) ["Five hypotheses for the evolution of conspicuous male wing pigmentation have been proposed: sexual selection, differential niche utilization, predator warning, social badge and ecological character displacement. Here, the sexual selection and ecological character displacement hypotheses are compared. First, the coefficients of variation (CVs) of pigmentation were compared against the CVs of a selec-

ted set of other animals' traits that are known to be maintained by either natural or sexual selection. *Hetaerina americana*, *H. vulnerata*, *Calopteryx aequitabilis*, *C. haemorrhoidalis* and *C. xanthostoma* were used in order to compare CVs. Second, it was predicted that pigmentation should not differ in species whose populations are in sympatry (compared to allopatry) if sexual selection is driving the evolution of pigmentation (compared, for example, to an ecological character displacement hypothesis in which pigmentation between spp. should differ). Here, the pigmentation of sympatric and allopatric populations of *H. americana* and *H. vulnerata* were compared. The study produced 2 main results. First, the CVs of pigmentation were not different from the CVs of sexually selected traits in other animals; nevertheless, they were different from those of naturally selected traits. Second, the pigmentation of the 2 species in sympatry did not differ significantly. The same was true for allopatric populations. Taken together, these results suggest that sexual selection is the main mechanism of maintenance of pigmentation in these animals. Other alternative hypotheses for the evolution of pigmentation (differences in habitat use in both sexes, warning to predators by males and ecological character displacement) are discussed in the light of these results." (Authors)] Address: Serrano-Meneses, M.A., Dept Biology and Biochemistry, University of Bath, Claverton Down, Bath BA2 7AY, UK. E-mail: mserrano@miranda.ecologia.unam.mx

7509. Sharma, A.; Sharma, R.C.; Anthwal, A. (2008): Surveying of aquatic insect diversity of Chandrabhaga river, Garhwal Himalayas. *Environmentalist* 28(4): 395-404. (in English) ["Aquatic insect diversity in the Chandrabhaga, an important headwater stream of Garhwal Himalayas, was surveyed for a period of twelve months (October 1999 to September 2000). All the important physico-chemical environmental variables (temperature, water velocity, hydromedian depth, transparency, turbidity, total dissolved solids, pH, alkalinity, dissolved oxygen, free CO₂, nitrates, phosphates, sodium and potassium) of the aquatic ecosystem were measured monthly for one year. Aquatic insects were sampled from three sites (S1, S2 & S3) of the headwater stream Chandrabhaga. Aquatic insects of Chandrabhaga were represented by the members of the orders of Ephemeroptera, Trichoptera, Coleoptera, Diptera, Plecoptera and Odonata. The maximum density of aquatic insects was recorded in the month of March (4,165 ind. m⁻²) and minimum in the month of August (680 ind. m⁻²). The annual contribution of Trichoptera (38%) and Ephemeroptera (32%) was observed to be maximum, while Odonata contributed minimum (2%) to the total aquatic insect density. The present study on the relationship between physico-chemical environmental variables and the density of aquatic insects revealed that the velocity of water, hydromedian depth, turbidity and dissolved oxygen in addition to composition and texture of the bottom substrates have significant impact on benthic aquatic insects' density and their diversity. The ecological relevance of the measured hydrological attributes was investigated by composing their degree of correlation with insects density and diversity. The diversity index (Shannon-Weiner) of aquatic insects dwelling in the Chandrabhaga river ranged from 2.54 to 3.86. Some of the natural and anthropogenic environmental factors contributing towards the degradation of the watershed of the Chandrabhaga have been identified, and ameliorative measures for the conservation of the aquatic in-

sect diversity have been suggested." (Authors)] Address: Sharma, A., Dept of Environmental Sciences, H.N.B Garhwal University, P.O. Box 67, Srinagar, Garhwal, 246174, Uttarakhand, India. Email: drrameshcs-harma@yahoo.com

7510. Shcherbakov, D.E. (2008): On Permian and Triassic insect faunas in relation to biogeography and the Permian–Triassic crisis. *Paleontological Journal* 42(1): 15-31. (in English) [„The taxonomic diversity dynamics of pterygote insects in the Permian and Triassic at the family/age level are considered. Different metrics of taxonomic diversity are compared. Biogeographic and taphonomic aspects of changes in the composition of insect faunas in the Permian and about the P–T transition are discussed. Some changes in the Permian insect faunas are of a biogeographic nature and do not indicate global changes in diversity. Insects with aquatic immatures (including Odonata) were rather common in the Permian and Early Triassic, but these immatures are well represented in only few localities." 7511. Simaika, J.P.; Samways, M.J. (2008): Chapter 9. Valuing dragonflies as service providers. In: Alex Cordoba-Aguilar (Editor): *Dragonflies and damselflies: Model organisms for ecological and evolutionary research*. Oxford Scholarship Online Monographs: 109-125. (in English) [„Valuing the services provided by ecosystems and their components is emerging as a new, practical tool for conservation of biodiversity. One such framework for quantifying those components of biodiversity and their attributes, which are important for the diversity of ecosystem services, is the Service Providing Unit (SPU). This framework provides a conceptual link between ecosystem services and the role of populations of different species in providing these services. Dragonflies provide several ecosystem services to humanity at the population level. Their role as SPUs encompasses most of the 28 ecosystem services, directly or indirectly, as recognized by the Millennium Ecosystem Assessment, in the categories of provisioning, cultural, supporting, and regulating services. Service provision by dragonflies can be quantified, for example, in pest control and riparian restoration. As the SPU concept, as a value metric, has considerable currency with dragonflies, there is merit in investigating its application to other invertebrate taxa and ecosystems." ISSN 1995-0829, *Inland Water Biology*, 2008, Vol. 1, No. 1, pp. 84–92. © Pleiades Publishing, Ltd., 2008. Original Russian Text © I.A. Skalskaya, A.I. Bakanov, B.A. Flerov, 2008, published in *Biologiya Vnutrennikh Vod*, No. 1, 2008, pp. 89–98: (in English) [„The special traits of zooperiphyton and zoobenthos structures in a small river were studied. Under conditions of maximal proximity of niches, these groups of invertebrates retain taxonomic and ecological heterogeneity. Differences in zooperiphyton and zoobenthos taxonomic structures are most pronounced in terms of presence of dipterans, oligochetes, and molluscs. In the periphyton, the dominant groups are chironomid (orthocladines, chi-

ronomines, and tanitarsines) larvae, oligochetes of Naididae and molluscs of Limnaeidae. In the benthos chironomid (chironomines and tanirodines), oligochetes of Tubificidae, and molluscs of Pisidiidae are dominant. On average, the bottom invertebrates are considerably larger than fouling organisms. At similar abundance values, the biomass of benthos is by an order of magnitude higher compared to zooperiphyton. Ranging of average biomasses of zooperiphyton and zoobenthos revealed that the leader common for both communities is the large and mobile predatory leech, *Erpobdella octoculata*. The anthropogenic impact and zoogenic (beavers) impact upon the river biota are comparable to each other." 7516. Starmore, A. (2008): Submerged oviposition behaviour in the Large Red Damselfly *Pyrrhosoma nymphula* (Sulzer) on the Isle of Lewis. *J. Br. Dragonfly Society* 24(2) : 45-50. (in English) [P. nymphula "was observed and photographed in oviposition at two locations

on the Isle of Lewis in the summer of 2007. The usual method was for the male, with the female in tandem, to land on a stem of the Bogbean *Menyanthes trifoliata* and then, with both grasping the stem, the female to start laying eggs in the stem, progressing downwards until her abdomen was about half submerged, while always holding her wings clear of the surface. On one occasion a female grasped a leaf with the abdomen three quarters submerged and the wing tips immersed. On 1 July the female of a pair became completely submerged. In all cases the male remained in the sentinel position while contact guarding the female." (Author)] Address: Starmore, Alice, Hedmark, 42 Gress, Isle of Lewis HS2 ONB, UK

7517. Stevens, L.E.; Bailowitz, R.A. (2008): Odonata of Ash Meadows National Wildlife Refuge, Southern Nevada, USA. *Journal of the Arizona-Nevada Academy of Science* 40(2): 128-135. (in English) ["The Odonata of Ash Meadows National Wildlife Refuge (AMNWR) in southern Nevada were studied bimonthly in 2004 and 2005, revealing 32 species, a moderately high level of diversity for this relatively small, semi-isolated southern Nevada valley. *Enallagma civile* was the most regularly encountered species, followed by *Rhionaeschna multicolor*, *Argia sedula*, and *Pachydiplax longipennis*. Fourteen species were detected at three or fewer sites. The assemblage was co-dominated by taxa with ranges centered in North America and western North America, and 25% of the fauna were Mexican-neotropical. We report *Macrodiplax balteata* as new to Nevada's Odonata list, and six other new Nye County records. Odonata larval density/m² and overall species richness (but not Shannon-Weiner diversity) were highest in the largest AMNWR wetlands, regardless of whether they were natural or anthropogenic, and were greater in two restored springs. Several of the most regularly detected larval Anisoptera (i.e., *Erpetogomphus compositus* and *Erythemis collocata*) were benthic ooze dwellers that have a flattened body morphology, which may allow them to avoid predation by non-native *Procambarus clarki* crayfish. Geomorphic restoration of springs may increase Odonata production, while augmentation of habitat area may increase species richness." 7518. Stoks, R.; Johansson, F.; De Block, M. (2008): Chapter 4. Life-history plasticity under time stress in damselfly larvae. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 39-51. (in English) ["Animals often face time stress because they have to reach a certain stage before a certain time horizon (e.g., the onset of winter or pond drying). Damselflies react to time stress with a shortening of their development time, and often show compensatory growth to avoid a smaller size at metamorphosis. Behaviour (increased foraging) and digestive physiology (increased growth efficiency) underlie this life history plasticity. Both ecological and physiological costs of this accelerated life history have been shown: time-stressed larvae are less responsive to predators and hence suffer higher mortality by predation, and show larger mass loss during starvation and reduced investment in immune function and in energy storage. These costs may explain why time-stressed larvae suffer a reduced lifetime mating success in the adult stage." (Publisher)] Address: Stoks, R., Laboratorium voor Aquatische Ecolo-

Oxford University Press: 203-219. (in English) ["This chapter discusses causes and consequences of territorial behaviour in odonates. In territorial species, males may use two mating tactics or strategies that may be environmentally or genetically determined: territoriality and non-territoriality. The tactic a male exhibits in each particular case is determined by the cost-benefit ratio of territorial and non-territorial behaviours. The main benefit of territoriality is increased access to females, and the costs may accumulate due to e.g., predation, injuries, and/or energy loss due to territorial contests. Moreover, density of both males and females as well as sex-ratio at breeding sites both contribute to the costs and benefits of each tactic. Interspecific aggression by heterospecific males may also influence the profitability of these tactics." 7522. Takahara, T.; Kohmatsu, Y.; Yamaoka, R. (2008): Predator-avoidance behavior in anuran tadpoles: a new bioassay for characterization of water-soluble cues. *Hydrobiologia* 607(1): 123-130. (in English) ["In freshwater systems, little is known about the characteristics of chemical cues derived from predators which induce defensive responses in prey species. To elucidate traits of predator chemical cues, we examined chemical cues originating from water incubated by the nymph of the dragonfly *Anax parthenope julius*, which induces low activity as predator-avoidance behaviour in tadpoles of two anuran species, the Japanese tree frog *Hyla japonica* and the winkled frog *Rana (Rugosa) rugosa*. *H. japonica* exhibited a reduction in tail movement time as low activity in response to both untreated incubation water and incubation water that had volatile substances removed by freeze-drying. The response threshold of *R. rugosa* to chemical cues was determined to be one dragonfly nymph in a water volume between 500 and 5,000 ml. We found that chemical cues inducing predator-avoidance behaviour in anuran tadpoles have water-soluble non-volatile characteristics. In this

study, we devised both the bioassay to assess the effects of chemical cues and the method to enrich the cues by freeze-drying, which can serve as a tool in the process of identification of unknown chemical cues in freshwater predator-prey interaction." 7527. Torreias, S.R. da S.; Neiss, U.G.; Hamada, N.; Ferreira-Keppler, R.L.; Lencioni, F.A.A. (2008): Description of the larva of *Bromeliagrion rehni* (Odonata: Coenagrionidae) with bionomic notes concerning its phytotelmic habitat in central Amazonas, Brazil. *Rev.*

Bras. Zool. 25(3): 479-486. (in English, with Portuguese summary) ["The last-stage larva of *Bromeliagrion rehni* Garrison in De Marmels & Garrison, 2005 is described and illustrated and bionomics and habitat information on this species are provided. The study was conducted in the Reserva Florestal Adolpho Ducke, located near Manaus, state of Amazonas, Brazil. Twelve samplings were done between April, 2003 and April, 2005: six in the rainy season and six in the dry season. In each sampling month, 12 bromeliads (*Guzmania brasiliensis* Ule, 1907, Bromeliaceae) were collected, six of which were terrestrial and six epiphytic, yielding 144 samples. A total of 75 specimens of *B. rehni* were collected. The relationship between larval *B. rehni* abundance and the measured environmental parameters (volume (ml), pH, season and stratum) was significant (ANCOVA, $F = 5.296$, d.f. = 130, $p < 0.001$). Larvae were most abundant in the rainy season ($p < 0.01$) and water volume was positively related to the abundance of *B. rehni*. Larvae of *B. rehni* can be distinguished from those of *B. fernandezianum* (the only species in the genus with described larvae) by the number of setae in the prementum and by the color of the apical region of the femur. The association of this species with phytotelmata of *G. brasiliensis* is reported here for the first time."] (Authors)] Address: Torreias, Sharlene R. da S., Divisão de Curso de Entomologia, Coordenação de Pesquisas em Entomologia, Instituto Nacional de Pesquisas da Amazônia. Caixa Postal 478, 69011-970 Manaus, Amazonas, Brasil. E-mail: robertatorreias@hotmail.com

7528. Trockur, B.; Didion, A. (2008): In: Rote Liste gefährdeter Pflanzen und Tiere des Saarlandes: XV Rote Liste und Faunenliste der Libellen (Odonata) des Saarlandes (3. Fassung). Ministerium für Umwelt und DE-LATTINIA (Hrsg.); Atlantenreihe Band 4: 485-498. (in German, with French and English summaries) ["In correlation with new methodic proposals regarding the compilation of red lists in Germany and the actualization of the data bank for the extension of the species- and biotope-protection-programme for the Saarland, the knowledge on the dragonfly fauna of the Saarland at the end of 2004 was analyzed and, based on this knowledge, the actual draft of the red list was outlined. The improved knowledge of the last years leads to a decrease of so-called "D-species" (data deficient) in the present red list. Although several species could be released from the red list, leading to an absolute red list-number of only 17 species, the conditions have not really improved. Thus the increase of extremely rare species (category R) from earlier one to now five species has to be noticed and nine percent of the species are ranked into the new category V (near threatened). In comparison to 1997, species released from the red list and of which the red list category was improved respectively, are noted in a blue list. For the species actually remaining in the red list, their threat-reasons are discussed."] (Authors)] Address: Trockur, B., Brückenstr. 25, 66636 Tholey-Hasborn, Germany. E-mail: Bernd-Trockur@gmx.de

7529. Tynkkynen, K.; Grapputo, A.; Kotiaho, J.S.; Rantala, M.J.; Väänänen, S.; Suhonen, J. (2008): Hybridization in *Calopteryx damselflies*: the role of males. *Animal behaviour* 75: 1431-1439. (in English) ["Females are often considered responsible for hybridization between two species because usually they are the choosier sex and their cooperation is needed for successful copulation. However, males can also be responsible for hybridi-

zation, for example in species in which males are able to force copulation. We studied the pattern of hybridization in two congeneric damselfly species, *Calopteryx splendens* and *Calopteryx virgo*, and provide evidence that F1 hybrids between the two damselfly species occur in the wild. According to mitochondrial DNA analysis, hybridization is reciprocal: five of seven hybrids were sired by *C. splendens* and two by *C. virgo* males. We conducted an experiment that revealed that males of both species have surprisingly poor premating reproductive isolation in that they accept heterospecific females, but *C. splendens* males were less discriminating against con- and heterospecific females than were *C. virgo* males. Moreover, our data on the number of hybrids sired by either species in the wild are congruent with the results of the discrimination experiment, supporting the conclusion that males may be responsible for the hybridization. Our results suggest that the males' role in hybridization studies should no longer be neglected." 7530. Tynkkynen, K.; Kotiaho, J.S.; Svensson, E. (2008): Chapter 11. Interspecific interactions and premating reproductive isolation. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 139-153. (in English) ["Two species can interact in several ways: there may occur interspecific competition or aggression, the two species may hybridize or they may interact indirectly through different predator-prey interactions. One consequence of these interactions is the evolution of premating reproductive isolation between the two species. For example, there may be divergent selection on male secondary sexual characters, which results in enhancement of premating reproductive isolation of two closely related species. This chapter focuses on two questions: firstly, how do interspecific hybridization, aggression and predation, affect premating reproductive isolation? Secondly, is reproductive isolation a direct target of selection or does it evolve as a correlated response to selection on other traits? This chapter uses *Calopteryx* damselflies as model organisms in this discussion, which have been under intensive study concerning these topics." 7532. Usherwood, J.R.; Lehmann, F.-O. (2008): Phasing of dragonfly wings can improve aerodynamic efficiency by removing swirl. *J. R. Soc. Interface* 5: 1303-1307. (in English) ["Dragonflies are dramatic, successful aerial predators, notable for their flight agility and endurance. Further, they are highly capable of low-speed, hovering and even backwards flight. While insects have repeatedly modified or reduced one pair of wings, or

mechanically coupled their fore and hind wings, dragonflies and damselflies have maintained their distinctive, independently controllable, four-winged form for over 300 Myr. Despite efforts at understanding the implications of flapping flight with two pairs of wings, previous studies have generally painted a rather disappointing picture: interaction between fore and hind wings reduces the lift compared with two pairs of wings operating in isolation. Here, we demonstrate with a mechanical model dragonfly that, despite presenting no advantage in terms of lift, flying with two pairs of wings can be highly effective at improving aerodynamic efficiency. This is achieved by recovering energy from the wake wasted as swirl in a manner analogous to coaxial contra-rotating helicopter rotors. With the appropriate fore-hind wing phasing, aerodynamic power requirements can be reduced up to 22 per cent compared with a single pair of wings, indicating one advantage of four-winged flying that may apply to both dragonflies and, in the future, biomimetic micro air vehicles." 7533. Van Gossum, H.; Robb, T.; Forbes, M.R.; Rasmussen, L. (2008): Female-limited polymorphism in a widespread damselfly: morph frequencies, male density, and phenotypic similarity of andromorphs to males. *Can. J. Zool.* 86(10): 1131-1138. (in English, with French summary) ["In several animal species, one male type coexists with two to several female types, a polymorphism often explained in the context of sexual selection. Where it occurs, one female morph typically resembles the conspecific male phenotype, but the degree of resemblance varies across species. Here, we question whether the degree of phenotypic similarity between male-like females and males varies within species. Phenotypic resemblance is hypothesized to depend on the potential for frequency- and density-dependent selection on male and (or) female phenotypes. We studied six populations of *Nehalennia irene* that differed widely in estimates of morph frequency and male density. Male-like females resemble males more than another female type resembles males, across populations, when comparisons are based on abdominal patterns. Abdomen phenotype does matter in male-female interactions of damselflies. Furthermore, male-like females were more similar to males at low and high density sites compared with sites with intermediate densities, contrary to the hypothesis that the potential for male harassment influences the degree of phenotypic similarity. Additionally, male-like females of most populations converged on the abdominal phenotype of males of one population rather than on that of syntopic males; a problem that has not received any attention." 7534. van Gossum, H.; Beatty, C.D.; Tokota'a, M.; Sherratt, T.N. (2008): The Fijian Nesobasis: a further examination of species diversity and abundance (*Zygoptera: Coenagrionidae*). *Odonatologica* 37(3): 235-245. (in English) ["Recently, an overview of the diversity, abundance, distribution and morphological characteristics of species of the genus *Nesobasis*, endemic to Fiji, was presented for species occurring on the 2 largest islands of the archipelago: Viti Levu and Vanua Levu. Here, this

knowledge is extended by providing more extensive diversity and abundance data for the island of Vanua Levu, as well as for 4 smaller islands in Fiji: Taveuni, Koro, Ovalau and Kadavu. Previous research indicated that the *Nesobasis* species inhabiting Viti Levu and Vanua Levu are unique, with these islands having no species in common. The new data confirm this proposal and also show that smaller islands in proximity to these 2 larger islands usually contain a subset of the large island's *Nesobasis* fauna. The island of Koro, however, is unusual in that, while its *Nesobasis* species are predominantly those found on Vanua Levu, it also harbours *N. rufostigma*, a species occurring on Viti Levu. Further, *N. recava* is endemic to Kadavu and is not found on Viti Levu, the nearest large island. Species richness is higher on large than small islands while mean species abundances were consistently higher on large islands compared to small islands. The pattern of distribution and speciation in this genus is quite complex, and is the subject of ongoing research." 7535. van Kleef, H.; van der Velde, G.; Leuven, R.S.E.W.; Esselink, H. (2008): Pumpkinseed sunfish (*Lepomis gibbosus*) invasions facilitated by introductions and nature management strongly reduce macroinvertebrate abundance in isolated water bodies. *Biol. Invasions* 10: 1481-1490. (in English) ["*L. gibbosus*, originates from Eastern North America and was introduced to the Netherlands in 1902 as an aquarium and garden pond fish. At present the pumpkinseed is widely spread throughout the Netherlands and occurs in a variety of aquatic habitats. It is especially abundant in moorland pools, fishing ponds and urban waters. Strong population development of the pumpkinseed appears to be facilitated by nature management practices in existing ponds (the removal of accumulated organic matter and macrophytes) and by creating new ponds. These measures enhance suitable breeding habitats that are free of competitors and predators. Isolated waters harbouring pumpkinseed were more often situated close to human habitation and infrastructure than could be expected based on the distribution of randomly selected isolated waters, identifying introductions as an important dispersal mechanism. In order to minimize the chances of introductions, planning of nature management practices should be done at distances over 250 m from human habitation and 100 m from infrastructure. Macroinvertebrate (including Odonata) abundance in pools populated by pumpkinseed was eighty three percent lower than in pools without pumpkinseed, probably due to opportunistic feeding and high pumpkinseed abundances. Currently there is little experience with pumpkinseed control. However, options to be explored include: decreasing depth of colonized waters by filling them with soil allowing them to occasionally dry up, introducing native competitors and predators and the use of biodegradable piscicides. In addition, limitation of the sale of pumpkinseed is required as well as public education on the consequences of introducing exotic species." (2008): Divergence dates of libelluloid dragonflies (Odonata: Anisoptera) estimated from rRNA using paired-site substitution models. *Molecular Phylogenetics and Evolution* 47: 426-432. (in English) ["Conclusions: The results of our analyses here, coupled with the general desirability of utilizing evolutionary models that are biologically realistic, suggest that it is very important to take stem pairing into account during analyses of rRNA data sets. The impact of using paired-sites substitution models on divergence time estimates is not easily predictable, particularly when explicit models of among-lineage rate heterogeneity are used in conjunction with partitioned analyses of complex data. Paired-sites models apparently do not lead to uniformly lower dating estimates, although it is necessary to investigate a wider range of data sets before further inferences can be made. Accordingly, it is prudent to assess the effects of model selection on resulting date estimates, as well as on the consequent ecological and biogeographic interpretations." - 7541.** Waterkeyn, A.; Grillas, P.; Vanschoenwinkel, B.; Brendonck, L. (2008): Invertebrate community patterns in Mediterranean temporary wetlands along hydroperiod and salinity gradients. *Freshwater Biology* 53: 1808-1822. (in English) ["1. Temporary aquatic habitats often are inhabited by a unique fauna and flora and contribute significantly to regional diversity. Temporary wetlands around the world are disappearing rapidly. The individual and interacting impacts of factors influencing community structure and dynamics in temporary wetlands are not always well known. 2. Camargue wetlands are mainly characterized by variable salinity and hydroperiod. The individual and combined impacts of these local factors, together with regional variables, on invertebrate communities remain unknown. We therefore characterized and sampled invertebrates in 30 temporary wetlands along salinity and hydroperiod gradients in the Camargue (Southern France) 3, 5 and 7 months after inundation. 3. Over the three sampling occasions, a total of 17 cladoceran species and 49 macroinvertebrate taxa were identified. Hydroperiod and salinity were the most important variables explaining variation in taxonomic composition and can be considered key factors shaping the invertebrate communities in Camargue wetlands. The impact on taxon richness was significantly positive for hydroperiod but significantly negative for salinity. Regional factors had no significant effect on the structure of the studied invertebrate communities, suggesting that dispersal was not limiting and that species sorting was the most important structuring process. 4. The results of this study suggest that the combined and interacting effects of salinization and hydrological modification of Mediterranean temporary wetlands (due to water management, climate change, etc.) can result in reduced diversity in large numbers of Mediterranean wetlands and induce a considerable decline in regional diversity of aquatic invertebrates." (in English) ["A population of the dragonfly *Orthetrum coerulescens* (Fabricius) was observed at four wetland zones at Holt Lowes, Norfolk between 26 May and 1 8 September 2003. Territories occurred in discrete areas throughout the wetland zones of the site. The territories of 40 marked males were described and measured. Males averaged 59.6 ± 14.4 flights per hour and the mean number of matings was 1.1 ± 1.1 per hour with the males which held larger territories achieving more matings. It is suggested that this may be due to the arrangement and density of territories rather than size per se. The mean territory size was $5.75 \pm 10.16\text{m}^2$ with, on average, almost 50 per cent of the territory over water. The mean height of the vegetation within each territory was 356mm (range 50 - 600mm). Males spent on average 5.9 ± 2.0 min h⁻¹ in flight, or about 10 per cent of their time. Habitat quality is discussed in relation to competition and territory fidelity. A case is argued for the site north of the Northern Mire being the area of highest habitat quality; it was occupied first, it was tiarest to the approaching females and there was some evidence that competition was highest in this zone. It was also where the males showed the greatest territory fidelity. The relationship between territory holders and wandering males is discussed." (2008): Sediment quality assessment of road runoff detention systems in Sweden and the potential contribution of tire wear. *Water Air Soil Pollut.* 194: 301-314. (in English) ["Sediments from 18 different road runoff detention systems, located on the Swedish West Coast, were assessed for their ecological hazard potential. Thirteen of the sites were detention ponds, three were manholes within the

same sedimentation construction, and two were detention basins handling wash water from road tunnels. Sediments from all sites were analysed for a range of physico-chemical parameters and contaminants, and screened for acute toxicity using *Hyalella azteca* (sediment), *Daphnia magna* (elutriate), and *Ceriodaphnia dubia* (elutriate) as the test organisms, and for chronic toxicity using *C. dubia* as the test organism. The benthic fauna (including "Odonata") of the thirteen detention ponds was also studied. Sediment quality guidelines probable effect levels were exceeded for one or several contaminants at half of the sites, and one third revealed toxicity in some of the bioassays. Most of the detention ponds were dominated by tolerant taxa indicating low biological quality. Relationships between contaminant concentrations, toxicity in bioassays, and benthic fauna were, however, found to be weak. Extractable organic Zn, which was used as a tire wear marker, correlated with Zn, Cu, presumably from brake linings, and W, a common component of tire studs. The highest concentration, which was found in the manholes (14 mg kg⁻¹ ds), corresponds to a tire wear concentration of 11 g kg⁻¹ ds. The results of the present study have shown that traffic related contaminants accumulate in the studied runoff treatment systems, and, therefore, the maintenance of them is crucial in order to prevent contamination of surrounding waters.] Address: Wik, Anna, Department of Plant- and Environmental Sciences, University of Gothenburg, Box 461, 405 30 Gothenburg, Sweden. 7546. Wildermuth, H. (2008): Habitat requirements of *Orthetrum coerulescens* and management of a secondary habitat in a highly man-modified landscape (Odonata: Libellulidae). *International Journal of Odonatology* 11(2): 261-276. (in English) ["Due to the destruction of its primary habitats, the West Palaearctic libellulid *Orthetrum coerulescens* has suffered much decline in central Europe. However, at the regional scale it has survived in a variety of secondary habitat, such as draining ditches. In order to find adequate measures for its conservation and promotion, habitat use and habitat recognition of *O. coerulescens* were investigated by description and experimentation at fenland ditches in a small nature reserve in the Swiss Plateau. This breeding habitat, which harbours a viable population, had been restored and maintained for 25 years. The most densely populated sites comprised small ditches between 40-70 cm wide, with rather sparse vegetation of narrow-leaved plants and that had parts of the water surface uncovered; the peaty, mud ground was partly overgrown with submerged pads of stonewort (*Chara* spp.). Water was mainly supplied by seepage springs with a mixture of local slow flow that were hardly recognizable and shallow sites, which were used for oviposition. In hot summer spells the water temperature could exceed 30°C. Some freezing occurred in winter, but the mud was permanently ice-free. The development of the breeding population, which comprised more than 200 individuals in 2006, was followed over two subsequent years. My data indicate that conservation and promotion of *O. coerulescens* populations in small ditches can be achieved by relatively simple habitat maintenance, such as a rotational strategy of clearing ditches, using of small weirs to prevent or protract desiccation and annual cutting of the surrounding litter meadows." 7547. Wildermuth, H. (2008): Konstanz und Dynamik der Libellenfauna in der Drumlinlandschaft Zürcher Oberland. Rückblick auf 35 Jahre Monitoring. *Vierteljahrsschrift der Naturforschenden Gesellschaft in Zürich* 153(3/4): 57-66. (in German, with English summary) ["In the «Drumlin Landscape Zurich Oberland» (47°19'N, 08°48'E), a nature reserve consisting of fragmented and disturbed bogs, fens and woodland with a variety of small water bodies, 51 dragonfly (Odonata) species had been recorded during ca. 1000 monitoring days from 1973 to 2007. Regular reproduction was found in 27 species, all the others reproduced sporadically or occurred as vagrants. *Nehalennia speciosa* became extinct, and three species have colonized the reserve permanently since 2005. Quantitative exuviae collections of the Anisoptera on six focus peat ponds during 24 years revealed strong spatial differences and temporal fluctuations of the annual population size of all species. These dynamics were considered in the mode of peat pond management that was especially aimed at *Leucorhinia pectoralis*. In the course of the monitoring period fruitful interactions between research and water management arose, resulting in successful conservation and promotion of the local dragonfly fauna. The indigenous populations can only be preserved and promoted by creating new water bodies and by sophisticated management of the extant waters. The results of this long-term study underline the importance of the moorland reserve as a biodiversity hotspot in a highly man-modified landscape." 7548. Willkommen, J. (2008): The morphology of the pterothorax of Ephemeroptera, Odonata and Plecoptera (Insecta) and the homology of wing base sclerites and flight muscles. *Stuttgarter Beiträge zur Naturkunde A, Neue Serie* 1: 203-300. (in English, with German summary) ["The ability to fly was the decisive factor for the evolutionary success of the most diverse group of insects, the Pterygota. Nevertheless, the ground plan of the functionally important wing base has not been sufficiently clarified. The aim of this study is to homologise the wing base sclerites of Ephemeroptera, usually regarded as sister group of the remaining Pterygota, with that of other basal pterygote lineages and to reconstruct the ground plan of the wing base of Pterygota. The pterothoracic musculature of representatives of the three basal lineages of Pterygota (Ephemeroptera, Odonata and Neoptera) is also described and discussed. Contrary to previous hypotheses, it is shown that most elements of the neopteran wing base are also present in Ephemeroptera and Odonata. The wing base in the ground plan of Pterygota is presumably composed of three axillary sclerites. The proximal median plate is probably also present in the ground plan of Pterygota. The first axillary is provided with two muscles. The third axillary is equipped with a short muscle that originates from the epimeron. This muscle is interpreted as another ground plan character of Pterygota. In Plecoptera a second muscle inserts at the third axillary sclerite. It originates from the episternum and is most likely an autapomorphic character of Neoptera. The results imply that the wing base of the Plecoptera is close to the pterygote ground plan. It is assumed that the wing base of Ephemeroptera and Odonata is secondarily stiffened. The so-called basalare and its associated muscles in Ephemeroptera and Odonata are probably not homologous to the basalare and respective muscles in Neoptera.

The enlarged subalare and associated muscles, the large dorsal longitudinal muscle, the small metathorax and shortened hind wings in Ephemeroptera suggest that mayflies have a derived flight apparatus in many respects. The Odonata on the other hand show different specialisations, namely a synthorax, large direct flight musculature, and a fusion of second and third axillary with the proximal median plate. Though the wing base in both taxa is secondarily stiffened, the specialisations of Ephemeroptera and Odonata may have evolved independently from each other." 7549. Wilson, A.L.; Watts, R.J.; Stevens, M.M. (2008): Effects of different management regimes on aquatic macroinvertebrate diversity in Australian rice fields. *Ecological Research* 23(3): 565-572. (in English) ["The maintenance of invertebrate diversity within agricultural environments can enhance a number of agronomically important processes, such as nutrient cycling and biological pest control. However, few Australian studies have been undertaken which specifically address the effects of commercial management regimes on rice field biodiversity. In this study, we compared aquatic macroinvertebrate communities within Australian rice fields cultivated under three commercial management regimes: conventional-aerial (agrochemicals applied, aerially sown), conventional-drill (agrochemicals applied, directly drill-sown) and organic-drill (agrochemical-free, directly drill-sown). These comparisons were undertaken using a combination of community assessment approaches, including morphospecies richness, abundance, diversity and community composition. In general, greater biodiversity existed within macroinvertebrate communities that developed under organic management regimes than under conventional regimes (i.e., higher morphospecies richness and Shannon diversity). Although there were significant differences in several parameters across management regimes early in the rice-growing season, as the growing season progressed the invertebrate communities that developed in the different management regimes became more similar. Only community composition analyses showed significant differences late in the growing season, with functional differences across aquatic faunal assemblages suggested by increased predator abundance in communities sampled from the organic management regime. In order to improve biodiversity within these aquatic environments, management techniques need to be examined individually and the most disruptive processes identified. Alternative management procedures can then be developed that minimise biodiversity loss whilst still delivering required agronomic outcomes." (Authors) List of morphospecies includes Odonata.] Address: Wilson, A.L., Inst. 7552. Wootton, R.J.; Newman, D.J.S. (2008): Chapter 20. Evolution, diversification, and mechanics of dragonfly wings. In: *Dragonflies: Model Organisms for Ecological and Evolutionary Research*, ed. A. Córdoba-Aguilar. Oxford University Press: 261-290. (in English) ["This chapter shows how the patterns of evolution and diversification of odonatoids, and by implication those of other flight-active taxa can be illuminated by studying their flight mechanics. The relationships between flight capabilities and wing and body design are discussed; and the functional significance of familiar wing characters and character states are investigated and compared in a range of extant and extinct odonates, using simple physical models. Convergence in wing shape and in some other characters is shown to be widespread, reflecting similarities in flight behaviour and performance in different taxa throughout the long history of the Superorder. Anagenesis — evolutionary 'improvement' — is also widely recognizable. Three important areas for future research are identified: detailed comparative investigations of flight performance; comparative morphometric analysis of functionally interpretable wing and body characters; and detailed Finite Element modelling of selected wing characters, rather than superficial analyses of complete wings." 7559. Brodin, T. (2009): Behavioral syndrome over the boundaries of life—carryovers from larvae to adult damselfly. *Behavioral Ecology* 20(1): 30-37. (in English) ["Activity is an important behavioral trait that mediates a trade-off between obtaining food for growth and avoiding predation. Active individuals usually experience a higher encounter rate with food items and suffer higher predation pressure than less active individuals. I investigated how activity of the damselfly *Lestes* congener is affected by larval state and predator presence and if larval behavioral type (BT) can be used to predict larval boldness, foraging success, and adult BT. Activity level of individual larvae was studied without predator at 2 different physiological states (hungry and fed) and in 2 predator treatments: familiar predator cues and unfamiliar predator cues. Larvae did not adjust their activity

depending on state or when subjected to unfamiliar predator cues, but a general reduction in activity was seen in the familiar predator treatment. Hence, active individuals remained active compared with their conspecifics, independent of state or predator treatment. Active individuals were also bolder and more efficient foragers than their less active conspecifics. Furthermore, both adult activity and boldness were correlated with larval BT. The results illustrate that BT of a larvae is carried over many different situations keeping active larvae active even in maladaptive situations, demonstrating how a behavioral syndrome may constrain behavioral plasticity. Furthermore, results showed that behavioral syndromes can carry over from larvae through metamorphosis and dictate the BT of the adult." (Author)] Address: Brodin, T., Dept Ecol. and Environ. 7561. Chang, X.; Zhai, B.; Wang, B.; Sun, C. (2009): Effects of the mixture of avermectin and imidacloprid on mortality and developmental stability of *Copera annulata* (Odonata: Zygoptera) larvae. *Biological Journal of the Linnean Society* 96(1): 44-50. (in English) ["The present study explored the effects of mixture of avermectin and imidacloprid on the level of fluctuating asymmetry (FA) and mortality of *Copera annulata* larvae. The results showed that the mortality of larval damselflies treated with different concentrations of insecticide did not differ significantly. However, we found that the levels of FA of two traits were significantly different with different treatments but the others did not show any differences. Explicitly, FA of two traits increased with increasing pesticide concentration. There was a significantly negative relationship between first femur length and the absolute difference between its right and left sides. There was no relationship with respect to the absolute difference between the right and left sides of all traits and their body size. FA was not associated with mortality. Our results emphasized that insecticide had potential effects on bilaterally symmetrical traits of damselfly larvae, although they were no longer treated with insecticide during the last rearing." 7562. Fraker, M.E. (2009): The effect of prior experience on a prey's current perceived risk. *Oecologia* 158(4): 765-774. (in English) ["The prior experience of prey may influence how they assess the level of predation risk associated with an information source. Here, I present the results from a set of experiments that demonstrate how the prior experience of green frog (*Rana clamitans*) tadpoles can influence their risk assessment during exposure to the chemical cue of predatory larval dragonflies (*Anax* spp.) consuming conspecific tadpoles. At the short-term scale, green frog tadpoles perceived a higher level of risk when consecutive cue exposures overlapped, but only when the total chemical cue concentration was weak. Weaker chemical cue concen-

trations may be less reliable than stronger cue concentrations, and overlapping cue exposures may increase the degree of certainty that tadpoles have in their perceived risk. When consecutive cue exposures did not overlap, tadpoles assessed the risk associated with each cue exposure independently. Predator-conditioned tadpoles responded longer during exposure to the *Anax* chemical cue than nonconditioned tadpoles, which suggests that a tadpole's long-term experience eventually does influence its risk assessment. In general, the results suggest that a prey's prior experience may influence its current perceived risk by influencing either the degree of certainty in or the level of its perceived risk. Understanding how the prior experience of prey influences their current risk assessment requires that the rate of decay of the value of prior experience should be identified at two timescales as an indicator of the current level of predation risk." 7564. Hassall, C.; Thompson, D.J.; Harvey, I.F. (2009): The impact of climate-induced distributional changes on the validity of biological water quality metrics. *Environmental Monitoring and Assessment*: (in English) ["We present data on the distributional changes within an order of macroinvertebrates used in biological water quality monitoring. The British Odonata (dragonflies and damselflies) have been shown to be expanding their range northwards and this could potentially affect the use of water quality metrics. The results show that the families of Odonata that are used in monitoring are shifting their ranges poleward and that species richness is increasing through time at most UK latitudes. These past distributional shifts have had negligible effects on water quality indicators. However, variation in Odonata species richness (particularly in species-poor regions) has a significant effect on water quality metrics. We conclude with a brief review of current and predicted responses of aquatic macroinvertebrates to environmental warming and maintain that caution is warranted in the use of such dynamic biological indicators."
