11060. Barnes, D.K. (2004): Use of benthic macroinvertebrates to assess impacts of agricultural land use in nontidal coastal plain streams. MSc. Thesis, Department of Environmental Sciences, University of Virginia: X + 151 pp. (in English) ["During recent history, anthropogenic activities in coastal watersheds have played a major role in increasing nutrient transport to rivers and offshore waters, often with detrimental consequences. Research on nutrient enrichment has focused primarily on lakes, rivers, and estuaries, while enrichment in coastal plain streams has been greatly understudied. Benthic macroinvertebrates are often extremely sensitive to enrichment, and as a result, are commonly used in biomonitoring of nutrient pollution. This study examined the impacts of agricultural land use in coastal streams on Virginia's Eastern Shore, through assessment of macroinvertebrate community structure and monitoring of a variety of chemical and physical parameters. Nine catchments ranging in agricultural land use from 28 to 91 % of watershed area were sampled seasonally from June 2003 to March 2004. Water and sediments were analyzed for nutrients, chlorophyll, organic matter, and dissolved oxygen. To assess macroinvertebrate community structure, sediment cores were collected, sieved through 0.5 mm mesh, and organisms retained on the sieves were identified to genus where possible. Twenty-one metrics of community structure were calculated, including measures of taxonomic richness, taxonomic composition, tolerance, feeding roles, and delta¹⁵N signatures. Though nitrate fluxes were higher in watersheds with higher % agriculture, elevated loadings were not related to changes in autotrophic biomass, decomposition, or macroinvertebrate commu-

nities that were predicted to occur with increasing nutrient enrichment. Therefore, the sampling reaches are likely on the low end of the nutrient enrichment spectrum, perhaps because of depleted nutrient concentrations potentially resulting from low surface runoff and/or retention by riparian vegetation. However, the streams are probably towards the high end of the scale with respect to allochthonous organic enrichment. Increased inputs of riparian detritus were linked to elevated decomposition, increased abundance of macroinvertebrates, and a shift in community structure toward dominance by tolerant taxa, all patterns which were hypothesized to occur in response to nutrient enrichment. Overall, nutrient pollution from cropland agriculture in coastal watersheds with flat topography and forested riparian zones was insufficient to produce undesirable changes in nontidal streams. In these systems, local factors were more important than watershed land use in dictating macroinvertebrate community structure." (Author) Taxa - including Odonata - are treated at the genus level.] Address: not stated

11061. Eda, S. (2004): Annual meeting of the Japanese Society for Odonatology in 2004. *Tombo* 47: 58. (in Japanese, with English caption.) [The Annual meeting of the Japanese Society for Odonatology was held at Prefectural Museum of Nature and Human Activities in Sanda city, Hyogo Prefecture, on November 20 and 21, 2004 and 86 members attend.] Address: Eda, S., 3-4-25 Sawamura, Matsumoto, Nagano 390-0877, Japan. E-mail: SND 02767@nifty.com

11062. Futahashi, R. (2004): Record of the migrant species, *Sympetrum fonscolombii*, in Kôto-ku, Tokyo. *Tombo* 47: 46. (in Japanese, with English summary) [A male of *S. fonscolombii* was captured in Koto-ku, Tokyo, on 23-X-2004. This is the second record of the species from Kanto district, Japan.] Address: Futahashi, R., Fujiwara Lab., Univ. Tokyo, Biosci. Bldg 501, Kashiwa, Chiba, 377-8562, Japan

11063. Futahashi, R.; Hayashi, F. (2004): Distribution patterns of two damselfly species, *Mnais costalis* and *M. strigata*, in the Boso peninsula, Chiba prefecture. *Tombo* 47: 41-46. (in Japanese, with English summary) ["A total of 106 *Mnais* damselflies collected from the Boso Peninsula, Chiba Prefecture, central Japan, were classified into *M. strigata* Selys, 1853 (48 males, 9 females), *M. costalis* Selys, 1869 (40 males, 8 females), and their hybrid F1 (1 female) based on DNA sequences of a nuclear ribosomal internal transcribed spacer 1 (ITS 1). The peculiar forma *edai* Asahina, 1976 known from this peninsula was identified as one wing-colour form of *M. strigata*. The two species were distributed parapatrically with a narrow contact zone; i. e., *M. strigata* was restricted to the southern mountainous area of the Boso Peninsula, while *M. costalis* was distributed in the northern area of the Kanto plain. The two species were quite similar in their external morphology, excluding some different relationships between head width and forewing length and between pterostigma length and widths." (Authors)] Address: Futahashi, R., Fujiwara Lab., Univ. Tokyo, Biosci. Bldg 501, Kashiwa, Chiba, 377-8562, Japan

11064. Futahashi, R.; Hayashi, F. (2004): DNA analysis of hybrids between *Sympetrum e. eroticum* and *S. bacha matutinum*. *Tombo* 47: 31-36. (in English, with Japanese summary) ["The parent species of interspecific hybrids can be determined using nuclear and mito-

chondrial DNA analyses, as the latter is inherited maternally. In this study, we examined DNA from three field-caught individuals that appeared morphologically to be hybrids between two *Sympetrum* dragonflies, *S. eroticum eroticum* (Selys, 1883) and *S. baccha matutinum* Ris, 1911. All three hybrids had mixed nuclear DNA sequences (ribosomal RNA internal transcribed spacers 1 and 2 regions) of *S.e.e.* and *S.b.m.*, but had mitochondrial DNA sequences (large subunit ribosomal RNA gene) of *S.b.m.* only. This suggests that these hybrids were derived from interspecific mating between male *S.e.e.* and female *S.b.m.* Interspecific mating tandems have been reported in the field, and all but one involved male *S.e.e.* X female *S.b.m.* Therefore, male *S.e.e.* are apt to catch females of another species, and the direction of gene flow with hybridization between the two species is non-reciprocal." (Authors)] Address: Futahashi, R., Fujiwara Lab., Univ. Tokyo, Biosci. Bldg 501, Kashiwa, Chiba, 377-8562, Japan

11065. Hämäläinen, M.; van Tol, J. (2004): Note on the nomenclature of the Japanese *Mnais* species. Tombo 47: 12. (in English) [Verbatim: Hayashi & al. (2004) revised the taxonomy of the Japanese *Mnais* taxa. Two good species, *M. costalis* Selys, 1869 and *M. strigata* Selys, 1853 were recognized and *M. nawai* Yamamoto, 1956 was downgraded to synonymy with *M. costalis*. The authors claimed that *Mnais strigata* is the correct name of the taxon traditionally called *M. pruinosa* Selys, 1853 and presented the latter as a synonym. The act was justified as follows: "... *M. strigata* appeared before *M. pruinosa* in Selys' (1853) paper; so by page precedence *strigata* is the valid name. However, this act was not in agreement with the International Code of Zoological Nomenclature (ICZN, 1999). The descriptions of *Mnais strigata* and *M. pruinosa* were printed on p. 20 and 20-21, respectively, in Selys Longchamps (1853). When these taxa are ranked as synonyms, the correct name must be selected according to the rules of Article 24 (Precedence between simultaneously published names, spellings or acts). Article 24. 2.1 determines that the precedence is fixed by the action of the first author citing in a published work those names or acts and selecting from them; this author is termed the "First Reviser". In this case Selys Longchamps (1873) was the "First Reviser", since on p. 473 (p. 9 in reprint) he explicitly considered *costalis* and *strigata* as varieties of *Mnais pruinosa*, thus giving precedence to the name *pruinosa*. Consequently: *Mnais pruinosa* Selys, 1853; Synonym: *Mnais strigata* Hagen in Selys, 1853.] Address: Hämäläinen M., Dept Applied Zool., P.O. Box 27, FIN-00014 University of Helsinki, Finland; E-mail: mati.hamalainen@helsinki.fi

11073. Yodo, T; Iguchi, K. (2004): Feeding habits of the alien species, Smallmouth Bass in the Nogu River, Central Japan. *Suisanzoshoku* 52(4): 395-400. (in Japanese, with English summary) ["Stomach contents of 82 larvae and juveniles and 30 young and adults of smallmouth bass *Micropterus dolomieu* collected in the Nogu River, Nagano Prefecture were examined. The Nogu River is a moderate to rapidly flowing stream and the current velocities of sampling stations were 16.5 to 73.4 cm/s (mean, 57.3). Smallmouth bass larvae and juveniles mainly fed on aquatic insects which were represented by chironomid larvae or baetid nymphs. Although, aquatic insects such as baetid and heptageniid nymphs were also important prey of young and adult smallmouth bass, they fed on various prey including fishes with a well developed swimming ability such as ayu *Plecoglossus altivelis altivelis* or masu salmon *Oncorhynchus masou masou*. With growth their main prey items shifted from stationary to slow moving benthic

and finally to free swimming species. We conclude that smallmouth bass damage to the stream-dwelling fishes as competitors for prey resources in addition to the direct predator." (Authors) Diet is listed at the family level including Gomphidae, Libellulidae, and Corduliidae.] Address: Yodo, T., Dept of Life Sciences, Faculty of Biore-sources, Mie Univ., 1515 Kamihama, Tsu, Mie 514-8507, Japan

11076. Paulson D.R. (2005): Dragonflies in the canopy. *WHAT'S UP? The Newsletter of The International Canopy Network* 12(1): 7-8. (in English) [Verbatim: In the past few years, I have made dry-season visits to undisturbed rainforest sites in southern Venezuela and southern Peru, and it got me thinking about dragonflies and their use of three-dimensional space in forests. We know very little about this. When we see them in forested areas, it's either at or near ground level or - if in clearings or light gaps - perhaps in flight well above us, cruising around after flying insects. These recent visits are the first ones during which I have actively searched for dragonflies in the tropical rainforest canopy. Unfortunately, I could do so only from ground level, as neither of these sites had canopy access, so I was limited to what I could see by scanning with binoculars. I know that many odonates perch on tips of leaves and twigs, so I spent time scanning such potential perches, and if conditions were right, I could sometimes see they were occupied. It's well known that productivity is higher where there is sunlight, and of course there is much more sunlight at the upper levels of the canopy than down on the forest floor, where the aquatic breeding habitats for most dragonflies are located. Thus dragonflies feeding in rain forests should tend to move upward into the canopy, all other things being equal. In Venezuela, where the forest was fairly open, we saw numerous anisopterans perched high in the trees, usually on twigs. They varied in size but were obviously libellulids, including at least *Erythrodiplax*, *Micrathyria*, and *Orythemis*. The most easily identifiable were the little black-

winged beauties of the genus *Zenithoptera*, which perch with wings drooped and form tiny black parasols at the tips of upward pointing twigs and vines. The pale line through midwing distinguishes them easily from *Diastatops*, a related genus with all black or black and red wings, which I saw once in a similar situation. In Peru, we saw *Zenithoptera* again in the same sorts of places, as well as *Micrathyria*, *Misagria*, and *Orthemis* well up in the trees. However, *Erythrodiplax* in that forest usually perched low. At least some of these dragonflies were surely spending the dry season as immatures, delaying reproductive activity until the rains began, but others were probably reproductively active. While watching odonates at a sun-drenched grass bed in a small forest swamp completely surrounded by trees, I saw several *Zenithoptera fasciata* drop vertically out of the canopy like a falling leaf, land in the sun on the grass with wings closed, then droop them suddenly to catch the sun with their brilliant blue upper surfaces. Each of these individuals stayed for only a minute or two, then suddenly ascended back into the canopy, disappearing as mysteriously as they appeared. I assume they were visiting the mating rendezvous site, although surprisingly briefly. I spent time along a small sandy stream in the Peruvian forest, and at one place the stream was wide enough to present a vertical wall of foliage on either side, well insolated at midday. I scanned this foliage wall with binoculars and found damselflies mostly of the genera *Argia* and *Hetaerina* spread all across it, perched on leaf tips. I saw none above about 10 meters in height, but it surely became more difficult to see them at higher levels if they were up there. Among them was a female *Heteragrion* and a female of the rare *Heliocharis amazona*. As I watched, one after another launched itself out into the open at intervals after flying insect prey. Open air, sunshine, and abundant perch sites combined to make this an ideal spot for a damselfly picnic. These odonates all forage by sallying forth to capture flying insects, as far as I know, and their perches, right out in the open, are just as appropriately situated for them as they are for flycatchers, jacamars, and other sallying birds of the same habitat. One morning it was exceptionally windy, with tall canopy trees swaying and creaking, and this was the final bit of evidence that convinced me the canopy was full of odonates. There were more individuals and more species in evidence along the trail than I saw at any other time, and I could explain their presence only by the hypothesis that the winds had forced them down to lower levels. With limited evidence, I believe that rain forests are full of dragonflies at all levels, especially during the dry season when they're not breeding. They may be there as well during the wet season. I know people who have observed dragonfly behavior in and above rainforest canopies from canopy walkways and towers, but I haven't been so fortunate. This remains a dream that I hope to fulfill sometime, somewhere.] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dpaulson@ups.edu

11080. Indermühle, N.; Oertli, B. (2006): Restoration of riverine ponds along the Rhone River (Teppes de Verbois, Canton of Geneva, Switzerland): what is the gain for Odonata? *Archives des Sciences A* 59(2-3): 243-250. (in English, with French summary) ["The Teppes de Verbois Site is a recent example of riverine pond restoration in the canton of Geneva (Switzerland). Between 1999 and 2001, four permanent and several small temporary ponds (total surface of the waterbodies: about 7 ha) have been dug on the site of an ancient gravel pit. During 2004, the four permanent ponds were sampled for Odonata once a month from May to September. Adult Odonata were identified and their abundance estimated. A total of 25 species was identified, representing more than half of the species occurring in the canton of Geneva. Two species among them are Swiss Red List species: *Orthetrum albistylum* (EN) and *Gomphus pulchellus* (VU). They are considered as target species for the management of the restored Teppes de Verbois site. The creation of these off-channel habitats appears to have very positive impacts on Odonata. On the level of the canton, the species richness of the Teppes de Verbois has reached (and partly even out-matched) the richness of the other nature reserves, after only four years of colonisation. On a regional scale, the new ponds improve the network of alluvial habitats, allowing each Odonata metapopulation to become more abundant and to find more breeding sites. On a national and international level, the high abundance of *Gomphus pulchellus* is of particular interest, as this dragonfly is the only European endemic species occurring in the canton of Geneva." (Authors)] Address: Oertli, B., Dept of Nature Management, University of Applied Sciences of Western Switzerland, EIL HES de Lullier-Geneva, 150 route de Présinge, CH-1254 Jussy, Switzerland. (in English) ["Insect fauna in adjacent areas of Demilitarized Zone (DMZ) in Korea was surveyed seasonally in 2001 - 2003. The survey area was divided into 3 regions (eastern mountain, middle inland, and western coastal regions) in accord-

ance with administrative districts and topography. Sampling methods such as sweeping, sieving, beating, brushing and suction were used depending on the environmental and military conditions. Total 361 genera and 437 species of 116 families belonging to 14 orders were identified. Among these, 46 species were new to insect fauna of DMZ areas. Species richness was the highest in the eastern mountain region. Numbers of habitat-common and -specific species were 96 (22%) and 195 (47.2%), respectively. The insect species community similarity was highest (0.64) between eastern mountain region and western coastal region. Insect orders showing high species richness were Coleoptera (38.9%), Lepidoptera (19.2%), Orthoptera (9.4%), and Hemiptera (9.2%). These results will be useful information for study of history on the change of insect fauna and future conservation in DMZ areas." (Authors) The paper lists 10 Odonata species from the Eastern mountain and Middle inland regions.] Address: Kim, Seung-Tae, Dept of Forest Environment, Korea Forest Research Institute, Seoul 130-712, Korea. 11082. Lailvaux, S.P.; Irschick, D.J. (2006): A functional perspective on sexual selection: insights and future prospects. *Animal Behaviour* 72: 263-272. (in English) ["A large number of sexual selection studies have focused on examining the morphological and behavioural factors involved in male combat and female choice, such as whether large males achieve higher reproductive success compared with smaller males. However, until recently, the mechanistic reasons why such cues are linked to male dominance or female choice have been elusive. An emerging body of work shows that physiological and whole-organism performance capacities are important in individual reproductive success. Males with high performance or other physiological capacities (e.g. endurance, biting) often enjoy an advantage over males with poorer performance capacities during male-male contests. In contrast, few studies have examined links between performance and female choice. Here, we highlight recent key literature integrating sexual selection, performance and physiology. We also point to areas where a more rigorous investigation of underlying physiological processes may yield insights into sexual selection. In particular, we note that current progress in several important areas may be hampered by an inadequate physiological understanding of condition. We suggest a conceptual approach that may shed light on the physiological factors underlying condition, and we point out several other potentially important avenues for future research." (Authors) The review includes studies on *Calopteryx maculata* and *C. virgo*.] Address: Lailvaux, S.P., Functional Morphology Laboratory, Department of Biology, University of Antwerp, Universiteitsplein 1, Wilrijk B-2610, Belgium. 11085. Dyuzhaeva, I.V. (2007): Concerning the role of the Samara State University Botanical Garden in urban insects preservation. *Samara Luka: Bull.* 16(1-2): 174-181. (in Russian, with English summary) ["During 30-years researches within the botanical garden territory, 773 species of insects from 15 groups, 123 families and 553 genera have been revealed. After 1990 here about 50 species of insects have ceased to meet or became extremely rare." (Author) Taxa - including Odonata - are treated at the family level.] Address: not stated

11086. Faucheux, M.; Meurgey, F. (2007): Première description des sensilles sur l'antenne larvaire d'un Anisoptère; *Aeshna cyanea* (Odonata: Anisoptera; Aeshnidae). Comparaison avec les antennes des Zygoptères. *Bull. Soc. Sci. Nat. Ouest Fr.* 29(4): 192-202. ["The sensilla on the larval antennae of *A. cyanea* have been described by means of scanning electron microscopy and compared with those of Zygoptera, the larval antenna comprises a scape, a pedicel and a 5-segmented flagellum. No sensillum has been observed on the scape. The pedicel bears two sensillum types: typical aporous sensilla chaetica and spatula-shaped aporous sensilla chaetica. A few aporous sensilla filiformia are distributed on the whole length of the flagellomeres. Other sensilla filiformia are lined up to a circle at the apex of these flagellomeres. An aporous curved sensilla chaeticum occurs at the apex of the 4th flagellomere. Two sensilla campaniformia are located on the 5th flagellomere. Judging from their morphological characteristics and their position on the antennae, the typical sensilla chaetica of the pedicel are proprioceptors, those of the flagellum are tactile; the spatula-shaped sensilla chaetica are proprioceptors; the sensilla filiformia are vibroreceptors; the curved sensillum chaeticum is a proprioceptor making possible the positioning of the flagellomeres, and the apical sensilla campaniformia probably provide an osmoreceptive function. No chemoreceptor has been observed. The larval antennal sensory equipment of the anisopteran *Aeshna cyanea* resembles that of the larvae of Zygoptera." (Authors)] Address: Faucheux, M.J., Laboratoire d'Endocrinologie des Insectes Sociaux, Université de Nantes, 2 rue de la Houssinière, B.P. 92208, F-44322 Nantes Cedex 03, France. 11087. Gabriels, W. (2007): Multimetric assessment of freshwater macroinvertebrate communities in Flanders, Belgium. PhD thesis. Faculty of Bioscience Engineering, Ghent University, Belgium. ISBN-number: 978-90-5989-203-3: 207 pp + appendices. (in English) [Since the Belgian Biotic Index (BBI) does not meet all the requirements of the European Water Framework Directive (WFD; EU, 2000), a new index, the Multimetric Macroinvertebrate Index Flanders (MMIF) for assessing rivers and lakes is proposed. This index is developed using the database of macroinvertebrate samples provided by the Flemish Environment Agency. The MMIF is calculated based on macroinvertebrate community data obtained using the same sampling and identification procedure as the BBI. The index calculation is a type-specific multimetric system based on five equally weighted metrics, which are taxa richness, number of Ephemeroptera, Plecoptera and/or Trichoptera taxa, number of other sensitive taxa (including Odonata at the family level), the Shannon-Wiener diversity index, and the mean tolerance score. The final index value is expressed as an EQR ranging from zero for bad status to one for high status. The MMIF combines the robustness of the BBI and the long-term experience in Flanders with the flexibility of multimetric indices, while at the same time taking into account the technical requirements of the WFD. For details see: <https://archive.ugent.be/retrieve/4808/Gabriels2007PhD-thesis.pdf>] Address: not stated

11088. Henriques-de-Oliveira, C.; Baptista, D.F.; Nessimian, J.L. (2007): Sewage input effects on the macroinvertebrate community associated to *Typha domingensis* Pers in a coastal lagoon in southeastern Brazil. *Braz. J. Biol.* 67(1): 73-80. (in English, with Portuguese summary) ["This study was carried out at Imboassica Lagoon, located in an urban zone in the municipality of Macaé, Rio de Janeiro state, Brazil. This lagoon has been subject to anthropogenic impacts due to the increasing city population, such as the input of sewage. Areas of variable degree of anthropogenic influence in the lagoon were compared regarding the structure of the macroinvertebrate community associated to *Typha domingensis* leaves. For sampling, we used 35 x 20 cm net plastic bags, with 6.8 mm mesh containing *T. domingensis* leaves for colonization. Two different sampling stations were selected: station A, under direct input of sewage; and station B with lesser sewage influence. The bags were removed after 20, 40 and 75 days of colonization. For each sample the Shannon-Wiener Diversity, Pielou Evenness, Jaccard Similarity Indices, Correspondence Analysis and taxonomic richness were calculated. A total of 31,874 individuals were sampled, belonging to 34 taxa. The main taxonomical groups were: Oligochaeta (41%), Chironomidae (40%), Ancyliidae (4.6%), Polymitarcyidae (4%) and Thiaridae (3%). At station A, the taxonomic richness, the Evenness and Diversity values were lower than in station B. On the other hand, the total density was three times higher in station A than in B. It was already possible to discriminate the community structure of each sampling station in the first sampling. Trichoptera and Ephemeroptera were the main exclusive groups of station B and are considered good water quality indicators due to their high sensibility to contamination. The major contribution to discriminate between the macroinvertebrate communities of the two sample stations came from Chironomidae, Oligochaeta and Ephemeroptera." (Authors) Taxa including Odonata are treated at the family or genus level. Odonata, mainly Coenagrionidae, represented

only 0.5% of all specimens collected.] Address: Henriques-de-Oliveira, C., Laboratório de Entomologia, Departamento de Zoologia, Instituto de Biologia, Universidade Federal do Rio de Janeiro, CP 68044, CEP 21944-970, Cidade Universitária, Rio de Janeiro, RJ, Brazil. E-mail: crikes@acd.ufrj.br

11091. Meurgey, F. (2007): A contribution to the knowledge of the Odonata of Dominica (British West Indies) November 11 - December 07 2006. *NHMN (Nantes Museum of Natural History) Contribution to odonatology* 4: 22 pp. (in English) ["The dragonfly fauna of the Lesser Antilles actually counts 135 species - 59 without Trinidad, which is definitely South American - there are 37 species in Guadeloupe (Meurgey, 2006b) and 24 in Martinique (Meurgey, 2005). It seems that the paucity of species in Dominica is due to 1) the lack of standing water habitats (95% of Odonata reproduce in standing water), and 2) the lack of studies, with only two surveys. The number of species from Martinique, which is quite equal to those from Dominica, is due to a high level of disturbances, pollutions and urbanization. We think that the fauna of Dominica could be reach 30-35 species. The origin of the dragonfly fauna of the Lesser Antillean Islands is still poorly known. Dominica is situated near the middle of the Lesser Antilles and its dragonfly fauna is mainly composed with South American species. These species have strongest relative abundances and, in general, are the most frequently observed. There is no endemic species on Dominica. Two species, however, have a worldwide distribution restricted to some Lesser Antilles islands (Guadeloupe, Dominica and Martinique): *Argia concinna* and *Protoneura ailsa*. Antillean species: Four species restricted to the West Indies occurs in Dominica. *Enallagma coecum* is mentioned from Cuba to Ste Lucia, but seems to be replaced in the Greater Antilles by *Enallagma cardenium*. *Orthemis macrostigma*, at that time, occurs only in the Lesser Antilles and seems to be replaced by others undescribed species in the Greater Antilles. *Tramea insularis* is mentioned in the Greater Antilles from Cuba to Puerto-Rico, and in the Lesser Antilles, only on Guadeloupe and Dominica. Finally, *Brechmorhoga grenadensis* is restricted to some Lesser Antillean islands (Guadeloupe,

Dominica, Martinique, Grenada). South American and Central American species: On the 25 species occurring in Dominica, 17 have a South American or Central American centred distribution. Some of these species occurs both in Central and South America: *Ischnura hastata*, *Ischnura ramburii*, *Lestes forficula*, *Lestes tenuatus*, *Telebasis corallina*, *Anax concolor*, *Rhionaeschna psilus*, *Triacanthagyna trifida*, *Brachymesia furcata*, *Brachymesia herbida*, *Erythemis vesiculosa*, *Erythrodiplax umbrata*, *Dythemis sterilis*, *Miathyria marcella*, *Micrathyria aequalis*, *Micrathyria didyma*, *Tramea abdominalis*. Wide ranging species: This group comprises *Anax ephippiger* and *Pantala flavescens*, which is a cosmopolitan species, present in all continents, excepted Europe. Considered as a pioneer in newly or disturbed habitats, with a short larval development, *Pantala flavescens* is scarce on Dominica and fairly common in neighbouring islands. More astounding is the lack of *Anax junius* on Dominica. This North American species occurs both in the Antilles and South America, as well as Russia, east Asia and Polynesia. Common in Guadeloupe and Martinique, where this species regularly breed, it was never mentioned from Dominica." (Author)] Address: Meurgey, F., Muséum d'Histoire naturelle de Nantes, 12, rue Voltaire, F-44000 Nantes, France. E-mail: Francois.Meurgey@mairie-nantes.fr

11092. Thompson, D.J.; Watts, P.C.; Saccheri, I.J. (2007): 12. Conservation genetics for insects. Stewart, A.J.A., T.R. New & O.T. Lewis (eds): *Insect Conservation Biology: Proceedings of the Royal Entomological Society's 23rd Symposium: The 22nd Symposium of the Royal Entomological Society: 280-300.* (in English) ["The importance of inbreeding and genetic drift for population persistence is likely to vary considerably among insect species, depending on their genetic load (of deleterious mutations) and the need to adapt to environmental change over differing spatial and temporal scales. It would therefore be valuable to collect more data on inbreeding depression in insects and also to characterize the ecological context of selective environments, which determine the relative magnitude of hard versus soft selection and the demographic consequences of selection. While purely ecological management is aimed at maintaining a given census population size, genetic management is focused on the maintenance of effective population size. As we have discussed, these two measures of population size may differ by an order of magnitude or more, but in most insects both remain something of a mystery. This said, we summarize the features that predispose many insects to such genetic effects ... The second major genetic issue is the number of founders or immigrants that should be introduced. Inbreeding depression can be largely avoided with effective population sizes greater than 50 (1% inbreeding per generation), which may be equivalent to 100 or 1000 individuals. Maintaining genetic diversity, particularly the contribution of rare alleles, would require an effective population size closer to 1000 (Nunney and Campbell, 1993). ... We can illustrate (at least the first of these issues in practical terms by returning to the endangered damselfly *Coenagrion mercuriale*. ... Newly restored habitat close to existing sites can expect natural recolonization in ecological time (or could be augmented from existing strong populations in the Itchen Valley or Beaulieu Heath, New Forest). Those populations in which genetic erosion has taken place, for example Nant Isaf in Anglesey and the Devon sites of Aylesbeare Common and Colaton Ra-

leigh Common, should clearly be augmented from the UK stronghold sites. The issue is straightforward for the Devon sites where the habitat and phenology is similar to key sites within New Forest, so the source for the material to be reintroduced can be identified clearly. The issue is less clear-cut for the Nant Isaf site, which is one of only two fen sites for *C. mercuriale* in the UK. The other fen site, in Oxfordshire, is also genetically depauperate, whereas the UK stronghold sites are not fens. We can be less confident that augmentation would be successful, though there would appear to be no options other than waiting for the Nant Isaf population to become extinct." 11097. Ellenrieder, N. von; Lozano, F. (2008): Blues for the red Oxyagrion: a redefinition of the genera *Acanthagrion* and *Oxyagrion* (Odonata: Coenagrionidae). *International Journal of Odonatology* 11(1): 95-113. (in English, with Spanish summary) ["Examination of diagnostic features for all known species of *Acanthagrion* and *Oxyagrion* shows color pattern alone not to be a reliable diagnostic character. Both genera are redefined based on morphological characters, and some colour pattern characters which further aid in their diagnoses. A preliminary phylogenetic analysis indicates both genera are monophyletic. They are distinguished from other genera of Neotropical coenagrionids by their decumbent cerci with a dorso-basal tubercle in males correlated with the presence of paired mesepisternal fossae in females. *Acanthagrion* and *Oxyagrion* can be unequivocally distinguished from each other by the minimum width of abdomen, shape of distal portion of genital ligula and position of lateral lobes of genital ligula relative to flexure in males, development of mesepisternal carinae and of dark mid-dorsal and humeral stripes in females, and ratio of caudal lamellae to abdominal length in ultimate larval instars. According to our redefinition we transfer *A. ablutum* (a 'blue' species), *A. hermosae* and *A. imeyiense* to *Oxyagrion*, and *O. egleri* to *Acanthagrion*. The generic placement of '*A. taxaense*' and '*O. pseudocardinale*' is deemed doubtful." 11098. Geraeds, R.P.G. (2008): Two larvae of the Golden-ringed dragonfly found in the Swalm brook. *Natuurhistorisch Maandblad* 97(5): 122-124. (in Dutch, with English summary) ["During a survey of the Swalm brook by the fish study group of the Natuurhistorisch Genootschap on 29 September 2007, a larva of the Golden-ringed dragonfly (*Cordulegaster boltonii*) was caught, near the German border. Since this species is very rare in the Netherlands, the site was visited again on 5 October 2007, and a second larva was found at this location. Until recently, the populations of *C. boltonii* in the Meinweg and Haeseraalbroek nature reserves were the only known populations in the Netherlands, but the species

has frequently been spotted at other locations since the end of the previous century. Also, two new breeding sites have been found in the province of Limburg, viz. the Aalsbeek/Molenbeek and Venbeek brooks. Since the Dutch part of the Swalm brook does not appear to be an ideal breeding water for *C. boltonii*, it is not likely that this brook actually hosts a population. The larvae probably reached the Dutch part of the Swalm by larval drift from the upstream German part or from one of its tributaries. It is thus possible that *C. boltonii* may some day colonise smaller streams like the Eppenbeek and Teutebeek brooks in the Swalm valley." (Author)] Address: Geraeds, R.P.G., Bergstraat 70, NL-6131 AW Sittard, The Netherlands

11099. Hothem, R.L. (2008): Mercury contamination in Foothill Yellow-legged Frogs (*Rana boylei*) and invertebrates from Harley Gulch, California, 2007. Administrative Report. Prepared for: The Bureau of Land Management, U.S. Department of the Interior, U.S. Geological Survey, Western Ecological Research Center: 24 pp. (in English) [USA "Fish and wildlife may bioaccumulate mercury (Hg) to concentrations that adversely affect their reproduction, growth, and survival. In May 2007, we collected aquatic invertebrates and *Rana boylei* from sites within the Harley Gulch watershed for comparison with those collected from Harley Gulch in earlier years and from reference sites. Aquatic invertebrates were analyzed for both total Hg and MeHg. Methylmercury concentrations in water striders and larval dragonflies collected in 2007 were higher from below the confluence of the west and east forks of Harley Gulch (lower Harley Gulch) than from the East Fork. Dragonflies ("*Aeshnidae*, *Libellulidae*") from the West Fork wetland pond were also higher than the East Fork. All samples had higher MeHg concentrations than references collected from the Bear River at the Highway 20 Bridge in 1999-2002. The 2007 samples, collected at Harley Gulch in the spring (May) had lower concentrations of Hg than the samples collected in the fall (October) of 2002. All frogs were analyzed for total Hg at a contract laboratory; selected frogs were also analyzed for methylmercury (MeHg). Mercury concentrations in frogs from lower Harley Gulch in 2007 were similar to frogs collected in 1997 and 1998 from lower Harley Gulch and from upstream in the Turkey Run and Abbot Mine drains. Mercury concentrations in foothill yellow-legged frogs collected from lower Harley Gulch were significantly higher than both frogs collected from the east branch of Harley Gulch in 2007 and those from three reference sites sampled in 1997. In 31% of the frogs collected from lower Harley Gulch in 2007, the concentration of total Hg exceeded the FDA criterion (1.0 ig/g) for regulation of commercial fish, and all frogs exceeded the EPA criterion (0.3 ig/g) for issuance of human health advisories for fish consumption. The Hg concentrations in frogs collected from lower Harley Gulch and the mine drains in 1997-1998 and from lower Harley Gulch in 2007 all exceeded the MeHg criterion for the protection of piscivorous wildlife (0.077 ig/g). Mercury bioaccumulation in frogs and invertebrates corroborated previous findings that identified the presence of significant sources of Hg within the Harley Gulch subwatershed." (Author)] Address: Hothem, R.L., Dixon Field Station, U.S. Geological Survey, Western Ecological Research Center, 6924 Tremont Road, Dixon, CA 95620, USA

She invites people to walk through these reserves and get acquainted with the species diversity "from bogs to dunes, from forests to heathland". Background information, as pictures to identify the species and trails where to explore the species, will help to spend some pleasurable times. Be inspired by the crisp text and beautiful pictures, pull on your hiking shoes and explore the Dutch wealth of butterflies and dragonflies!]

11104. Timms, B.V. (2008): The ecology of episodic saline lakes of inland eastern Australia, as exemplified by a ten year study of the Rockwell-Wombah Lakes of the Paroo. Proceedings of the Linnean Society of New South Wales 129: 1-16. (in English) ["Studies on salt lakes are mostly snapshots of their unique characteristics and relationships. Longer term studies provide different perspectives on variability in hydrology, salinity and biological communities. Such a study on five lakes near the Paroo River in the northwestern Murray-

Darling Basin showed most hold water episodically for about 80% of the time, but each fluctuate over a characteristic salinity range : unnamed lake 0.6 - 19 gL⁻¹, Wombah 1.2-30 gL⁻¹, North Blue 0.3 - 31 gL⁻¹, Mid Blue 0.7 - 103 gL⁻¹, and Bulla 1.8 - 262 gL⁻¹. Generally, instantaneous biodiversity is low and not necessarily correlated with salinity, but unlike southern seasonal salt lakes, species accumulation lists are long, approaching 80 species of invertebrates, 50 bird species and a few fish species per lake. Diversity is promoted by salinity fluctuation and habitat heterogeneity. Most species reach peak abundance in any season as long as conditions are within their physiological salinity tolerances. Invertebrate fauna is of inland affinities, but with some localized substractions and additions explained by hydrology and/or salinity; waterbird numbers are influenced by events elsewhere in Australia as well as by local conditions. Like most naturally salinised lakes, production can be high, especially at low to moderate salinities and algal blooms occur naturally from time to time." (Author) Littoral invertebrates in the five lakes include the following Odonata species: *Austrolestes annulosus*, *Ischnura heterosticta*, *Xanthagrion erythroneurum*, *Diplacodes bipunctata*, *Hemicordulia tau*, *Hemianax papuensis*, and *Tramea loewii*.] Address: Timms, B., School of Environmental and Life Sciences, University of Newcastle, Callaghan, NSW, 2308, Australia. 11111. Perinkova, P.; Fischer, O.A. (2009): Dragonflies (Insecta: Odonata) of Trebic Region and its surroundings. *Acta rerum naturalium* 7: 103-120. (in Czech, with English summary) ["In total 38 dragonfly species were found in 134 localities of the Trebic Region and its surroundings (Czech Republic, Southwest Moravia, 49°27' - 48°58'N 15°36' -16°18'E) in 2001-2004 and 2006-2007. An atypical intra-species tandem of two males of *Leucorrhinia pectoralis* was observed. Nine dragonfly imagoes of four species were obtained by short-term breeding of the last instar larvae in a laboratory. The number of species was influenced by elevation, the numbers of the species were 38 and 19 at elevations of 241 - 449 m and 600 - 650 m a.s.l., respectively. The occurrence of dragonfly species in localities was confirmed by findings of 87 dragonfly exuvia and 318 imagoes collected. The most important localities with 17, 16, and 15 dragonfly species found were Oslavicka and Rapotice, Budisov near Trebic, and Hrutov, respectively.

The area under study is therefore valuable and interesting from a faunistic point of view." (Authors) The following species are of regional interest: *Lestes barbarus*, *L. virens*, *L. dryas*, *Erythromma viridulum*, *Coenagrion hastulatum*, *Aeshna isoceles*, *Anax parthenope*, *Orthetrum albistylum*, *Crocothemis erythraea*, *Sympetrum danae*, *L. pectoralis* and *Onychogomphus forcipatus*.] Address: Perinkova, P., Muzeum Vysociny Trebic, Prirodovedne prac., Zámek c 1, CZ-674 01 Trebic, Czech Republic. E-mail: p.perinkova@zamek-trebic.cz

11112. Reece, B.A. (2009): Diversity, distribution, and development of the Odonata of the southern high plains of Texas. Ph.D. thesis, Graduate Faculty of Texas Tech University: IX + 117 pp. (in English) ["The diversity, distribution, and developmental patterns of odonates were examined in the playa system of the Southern High Plains of Texas, USA from 2003-2008. Comparisons were made in these factors between playas surrounded by the two dominant forms of land use (cropland, grassland). Controlled field and lab experiments were performed to examine the causal relationship between environmental variables and growth, development, and survival of larvae of a focal species. Land-use type did have an influence on certain variables, but not consistently or on all variables. Over one hundred new county records were discovered, indicating how little is known about this system. In addition, the dragonfly holdings at the Museum of Texas Tech University were sorted, identified, and compiled, revealing numerous other new county records." (Author)] Address: Reece, B.A., Dept of Biological Sciences, Texas Tech University, Lubbock, TX 79409-3131, USA. E-mail: b.reece@ttu.edu

11113. Rödder, D.; Dambach, J. (2009): Modelling future trends of relict species. In: Habel, J.C. & T. Assmann (eds.): *Relict Species: Phylogeography and conservation biology*. Springer, Berlin: 373-383. (in English) ["Distribution patterns of species vary over space and time. This becomes most evident considering the differences between the current and Last Glacial Maximum (LGM, 21,000 BP) distribution patterns of species in the Northern hemisphere. Most warm-adapted species experienced reduction and fragmentation of ranges because of intrusion by uninhabitable continental ice sheets causing distributional shifts and fragmentation of primary habitats. On the other hand, cold-adapted species were able to expand their ranges. Today, ranges of those species are restricted to current refugia as can be observed in glacial relict species. Understanding refugial distributions of species has been a core task in historical bio-geography. Before the 1990s, refugia were preliminarily identified based on disjunctions of species distributions, distribution patterns of sister species, and the fossil records. More recently, phylogeographic approaches based on intraspecific molecular analyses and spatial modelling approaches based on ecological properties of species have been developed." (Authors) *Aeshna caerulea* and *Bombina variegata* are used as model organisms. Today's distribution of *A. caerulea* was taken from Kuhn & Burbach (1998) and Sternberg & Buchwald (2000) and its potential distribution computed with Maxent 3.2.1 derived from current climatic conditions. Higher Maxent values suggest higher climatic suitability. Figure 2b,c show potential distributions of *A. caerulea* assuming two different paleoclimatic scenarios depicting climatic conditions as expected for 21,000 BP (b) CCSM; 2C: MIROC; for details see Rödder et al. 2008, Chap. 22. Areas of currently known dis-

tribution of *A. caerulea* are highly congruent with the proposed potential distribution of the CEM even in small and disjunctive ranges. Projections of the CEM onto palaeoclimatic scenarios suggest potential migration pathways during the LGM connecting most current refugia." Address: Rödder, D., Dept of Biogeography, Univ. of Trier, D-54286 Trier, Germany. E-mail: roedder@uni-trier.de

11114. Suhling, F.; Samways, M.J.; Simaika, J.P.; Kipping, J. (2009): Chapter 5. The status and distribution of dragonflies (Odonata). In: Darwall, W.R.T., Smith, K.G., Tweddle, D. & Skelton, P. (eds): The status and distribution of freshwater biodiversity in southern Africa. Gland, Switzerland: IUCN and Grahamstown, South Africa: SAIAB. ISBN: 978-2-8317-1126-3: viii + 120 pp. (in English) ["The southern African region covered here contains 22 of the freshwater ecoregions defined by Thieme et al. (2005). These 22 ecoregions are categorized under six major habitat types, which are the basis for this report. The biological distinctiveness and current conservation status of each ecoregion, summarized from Appendix D of Thieme et al. (2005), is listed in Table 1.1 in Chapter 1 of this report. We comment here on the status of these ecoregions relative to the occurrence of endemic, rare and threatened dragonfly species." (Authors)] Address: Suhling F., Inst. of useful images in a reasonable amount of time." Address: Ware, Jessica, Division of Invertebrate Zoology, American Museum of Natural History, 79th and Central Park West, New York, NY, 10024, USA. E-mail: jware@amnh.org

11118. Zhang, Z.-s.; Wang Q.-c.; Lü, X.-g.; Zheng, D.-m.; Sun, X.-j.; Zhang, X.-y.; Zhang, S.-q. (2009): Heavy metal contents in insects collected from the Huludao City suffering pollution by zinc smelting and Chlor-Alkali production. *Environmental Science* 30(7): 2077-2081. (in Chinese, with English summary) [Verbatim: 14 insect species (including "dragonfly larvae"), which were classified to three groups: the herbivorous, the polyphagous and the carnivorous, and earthworms were collected from the grasslands in Huludao City, Liaoning Province, China. [...] Mercury, cadmium and lead contents were 0.168, 9.19 and 12.58 mg·kg⁻¹ in the herbivorous insects, 0.375, 24.43 and 17.71 mg·kg⁻¹ in the polyphagous insects, 0.928, 29.78 and 18.39 mg·kg⁻¹ in the carnivorous insects. It showed that heavy metal pollution in biota in Huludao City was heavy. Bioaccumulation abilities to heavy metals significantly differed with insect species. Snails and dragonflies could accumulate more mercury than the other insects, and spiders could accumulate the most cadmium and lead in all species. These three metals investigated in insects were all sorted as the herbivorous < the polyphagous < the carnivorous. Cadmium and lead contents between the polyphagous and the carnivorous varied slightly. Correlation analysis showed that cadmium and lead contents were significantly related, but mercury and cadmium or mercury and lead were not. It indicated that cadmium and lead in insects were from the same pollution sources while mercury was more complex.] Address: Zhang, Z.-s., Key Laboratory of Wetland Ecology and Environment, Northeast Institute of Geography and Agricultural Ecology, Chinese Academy of Sciences, Changchun 130012, China

11122. Beintema, A.J.; van der Winden, J.; Baarspul, T.; de Krijger, J.P.; van Oers K.; Keller, M. (2010): Black Terns *Chlidonias niger* and their dietary problems in Dutch wetlands. *Ardea* 98: 365-372. (in English) ["Black Terns have shown a decrease of well over 90% as a breeding bird in The Netherlands during the twentieth century. Two hypotheses have been put forward for this decline: the disappearance of the floating plant Water Soldier *Stratiotes aloides*, which used to be the favourite nesting substrate of the terns, and a decrease of available insect food for the chicks, notably dragonflies. Both effects are attributed to eutrophication of surface waters. Reproductive bottlenecks vary greatly among areas and habitats. In river landscapes, no signs of food shortage could be found, and loss of nesting substrate has been successfully compensated for by offering artificial nest rafts. Extremely low fledging success in moors and in lowland grasslands is caused by food problems. In this case, artificial rafts are less successful. With decreased insect availability, fish and earthworms have become more important in the chicks' diet, but these are less reliable as a food source. Fledging success greatly depends on the amount of fish in the diet. Also, a minimum amount of fish is always needed to cover the calcium need of the chicks. In north-eastern Poland, there were no problems with either nesting places or food for the chicks." (Authors) Frequency of Odonata as diet depends on the habitat. The study also analysed Calcium content in Odonata. ("Aeshna spec., *Libellula quadrimaculata*, *Sympetrum cyathigerum* [sic], *Lestes sponsa* and *Lestes spec.*")] Address: Beintema, A.J., Alterra, P.O. Box 47, 6700 AA Wageningen, The Netherlands. 11127. Das, S.K.; Sahu, H.K.; Rout, S.D. (2010): Odonates of Baripada Division of Similipal Biosphere Reserve. Tigerpaper - Regional Quarterly Bulletin on Wildlife and National Parks Management 24(2): 13-16. (in English) ["This study records the distribution of 31 species of odonates in the Baripada Division of SBR [...] *Pantala flavescens* and *Orthetrum sabina* were more abundant during the monsoon season. [...] *Ischnura aurora* was more abundant than others inside the study area. [...] The prey of the adults consists mostly of the harmful insects of crops, orchards and forests, and thus has a regulatory impact on agroforestry. Their aquatic larvae constitute a natural biological control over mosquito larvae and thus help to control several epidemic diseases like malaria, dengue, filarial, etc. (Mittra, 2002). But several developmental activities such as the construction of buildings, roads, and stone crushers in the peripheral areas have a direct impact on the population of the odonates as their habitats and food are being destroyed by such activities. In temperate regions, the greatest threat to many Odonata species is the intensification of modern agriculture (Moore,

1991a). It may lead to the local extinction of sensitive species. Public awareness is required to conserve these odonates and their habitats. An extensive odonatological survey needs to be carried out to explore the rich diversity of these elegant insects." (Authors) Address: Das, S.K., Department of Wildlife and Conservation Biology, North Orissa University, Sri Ramchandra Bihar, Takatpur, Baripada, Orissa-757003, India. E-mail: sunit.das219@gmail.com

11128. Davenport, J.M.; Chalcraft, D.R. (2010): COS 116-3: Contrasting effects of different types of habitat complexity on predator-prey interactions. The 95th ESA Annual Meeting (August 1 -- 6, 2010): (in English) [Verbatim: Background/Question/Methods: Habitat complexity is often viewed as an important factor that can reduce the impact of predators on prey by providing refugia for prey. Sit-and-wait predators, however, may perform better in complex environments that provide more perches or hiding places for the predator. Although natural environments are composed of many structural elements (types of habitat complexity) few researchers have examined how multiple types of habitat complexity affect predator-prey interactions. We conducted an experiment in artificial ponds to examine how different types of habitat complexity (amount of benthic leaf litter versus amount of emergent vegetation) influence the effect of a sit-and-wait top predator (larval dragonflies; *Anax* spp.) on fitness components of an intermediate predator (larval salamanders; *Ambystoma opacum*). We expected that 1) increasing amounts of emergent vegetation will enhance the effect of *Anax* on *A. opacum* fitness components by increasing perch sites for *Anax* to hunt from, 2) increasing amounts of litter will reduce the effect of *Anax* on *A. opacum* fitness components by providing benthic refugia for *A. opacum*, and 3) the effect of emergent vegetation on the foraging success of *Anax* will be greatest in ponds with less leaf litter due to the fact that there is less refuge space. Results/Conclusions: We observed a trend in ponds with no *Anax* for *A. opacum* to have higher survivorship when there was a low amount of leaf litter present in the pond. *Anax* reduced *A. opacum* survivorship but the extent of reduction depended on the amount and type of habitat complexity present. Specifically, increasing amounts of emergent vegetation in ponds with low amounts of litter enhanced the negative effect of *Anax* on *A. opacum* survival. Increasing amounts of emergent vegetation in ponds with a high abundance of leaf litter, however, caused non-linear changes in the effect of *Anax* on *A. opacum*. Although a high abundance of emergent vegetation in ponds with a high abundance of litter enhanced the effect of *Anax* on *A. opacum* survival, a low abundance of emergent vegetation in ponds with a high abundance of litter reduced the effect of *Anax* on *A. opacum* survival. Our study found that the amount of habitat complexity may have unexpected effects on intermediate predator performance in the absence of top predators. Our results also demonstrate that different types of habitat complexity can alter predator-prey interactions in different ways – some forms of complexity benefit the predator while other forms benefit prey.] Address: Davenport, J.M., East Carolina University, USA

11129. Díaz, F.; Schmitt, F. (2010): Primer registro de Garza chiflón (*Syrigma sibilatrix*) en Chile. Boletín Chileno de Ornitología 16(1): 48-50. (in Spanish, with English summary) [The first record of the Whistling Heron is

11131. Downie, J.R.; Hancock, E.G.; Muir, A.P. (2010): The diet of the paradoxical frog *Pseudis paradoxa* in Trinidad, West Indies. The Herpetological Journal 20(2): 111-114. ["The diet of adult and late metamorphic *P. paradoxa* in Trinidad was assessed from stomach contents. *P. paradoxa* consumed a wide taxonomic and size range of invertebrates, mostly insects, but also arachnids, crustaceans (crabs) and annelids. There was little evidence for ontogenetic changes in prey taken, but larger females had taken larger prey than smaller individuals. Although most prey items could have been captured above the water surface, some must have been taken below the surface. The significance of these findings is discussed in the light of *Pseudis*'s unique life history and evolution (individuals are essentially full size at metamorphosis; adults are fully but secondarily aquatic) and in comparison with previous reports." (Authors) Imaginal Odonata accounted to 8.7%, and larval to 1.4% of all prey items. Compared with the mass of the additional prey, Odonata seem to have a significant contribution to nutrition of *P. paradoxa*.] Address: Muir, Anna, Institute of Biodiversity, Animal Health and Comparative Medicine, Room 411, Graham Kerr Building, University of Glasgow, G12 8QQ, UK

11136. Gauquie, B. (2010): Habitats de l'Orthétrum brun (*Orthetrum brunneum*) et de l'Orthétrum bleuissant (*Orthetrum coerulescens*) sur le territoire du Parc naturel des Plaines de l'Escaut et dans le bassin carrier tournois. Les Naturalistes belges 91(3-4): 37-53. (in French, with English summary) ["During this last five years, I undertook a specific search on two rare *Orthetrum* species in Belgium (*O. coerulescens* and *O. brunneum*), both recently discovered in Western Hainaut province. The exploration area is Tournai and the territory of the Natural Park of the Plains of the Schelde, which extends east to west from Bernissart to Antoing. *O. brunneum* was found on five sites and *O. coerulescens* on three sites. Following data analysis, it seems that in the region *O. coerulescens* is more a stenotopic species, selecting only limestone quarries and *O. brunneum* is an eurytopic species, occupying more varied environments, nevertheless at least four abiotic parameters characterize in common the breeding sites of the two species: a sunny environment, a shallow water, with good physicochemical conditions and constantly renewing seepage, or flow resurgence. If these ecological requirements are met, it appears that, among other factors (biotic or abiotic), the vegetation structure is of crucial importance for the reproduction of either species. At sites with still water, *O. brunneum* proves to be a pioneer species essentially, eventually disappearing when the vegetation becomes too high. For *O. coerulescens*, eutrophication is really a non-favourable factor, but the vegetal cover did not appear to be influential."] (Author)] Address: Gauquie, B., Chargé de mission Ressources et milieux naturels, Parc naturel des Plaines de l'Escaut, rue des Sapins 31, 7603 Bon-Secours, Belgium. 11138. Gonzalez, S.C.; Touchon, J.C.; Vonesh, J.R. (2010): PS 19-152: The interactions between competition, predation, and phenotypic plasticity on the survival and growth of two Neotropical hyliid tadpoles. The 95th ESA Annual Meeting (August 1 -- 6, 2010): (in English) [Verbatim: Background/Question/Methods: Recent literature reviews reveal that competition typically has stronger effects on growth than the presence of predators, while predation has larger effects on survival. Further, past studies show that predators typically lessen the negative effect of competition on growth and also make interspecific competition beneficial for the survival of focal species. We examine the independent and combined effects of competition and predation for survival and growth of the tadpoles of two co-occurring Neotropical hyliid frogs (*Agalychnis callidryas* and *Dendropsophus ebraccatus*). Our experiment crossed tadpole species composition (single and mixed at single total density) with the presence or absence of a free-roaming predator (*Anax* sp. dragonfly larva) using a 3x2 factorial design. Six replicates were conducted in 300 L mesocosms at the Smithsonian Tropical Research Center, Gamboa, Panama. Results/Conclusions: Dragonfly larvae were effective predators of both species, but had larger effects on *A. callidryas* survival. *A. callidryas* grew faster in the presence of *D. ebraccatus*, suggesting it is a more effective competitor. *A. callidryas* reduced *D. ebraccatus* growth in the absence of dragonflies; however, this effect disappeared when predators were present. Though our results are largely consistent with similar previous studies, one interesting difference did emerge. Not only did predation have larger effects on survival than competition, but predator presence resulted in a much larger reduction in tadpole growth than competition – even though predation increased per capita resource levels. This can be attributed to either changes in feeding behaviour or metabolic costs of alteration of phenotypically plastic traits. Thus, in our study, predator effects dominated survival and growth and highlight the importance of top-down effects, as well as costs associated with phenotypic plasticity, in shaping interactions between these species.] Address: not stated

11139. Gonzalez-Bellido, P.T.; Olberg, R.; Leonardo, A. (2010): Attack of the dragonfly: receptive fields and anatomy of the target selective descending neurons. Abstracts of the 9th International Congress of Neuroethology, Salamanca (Spain) 2-7 August 2010. P 396: 650. (in English) ["Dragonflies detect prey against a clear sky and then follow an interception trajectory to capture their target. These flights typically last 350ms from take-off to interception, and the accuracy afforded by the dragonfly retina is paramount for success. Despite this, little is known about the spatial and temporal response properties of the neurons underlying this behaviour. We have begun to record intracellularly in libellulid dragonflies (*L. lydia* and *L. luctuosa*) from a class of neurons that respond solely to small moving targets (Ol-

berg, 1986). Using a custom-built 360Hz DMD projector, we have begun to make 0.25° resolution measurements of target-selective descending neuron (TSDN) spatiotemporal receptive fields, in an effort to develop quantitative circuit models of these cells. After mapping a TSDN receptive field, the cell is filled with a tracer dye (Lucifer yellow and/or neurobiotin) to confirm its identity, its three-dimensional structure, and its pre- and post-synaptic targets. Standard histological techniques do not adequately preserve the fragile structure of the dragonfly nerve cord. In libellulids, the diameter of TSDN axons ranges from 16-25µm, while the cervical connective is only 230µm wide - over 1/3 the volume of the cord is comprised of the cytosol within these axons. Consequently, it is necessary to embed the cord in resin to prevent rupture during semi-thin sectioning. The dehydration required for resin causes major deformation and shrinkage of the cervical connective in protocols in which osmium is omitted to preserve fluorophore signals. Whole-mounted cords are sufficiently transparent for 2-photon imaging, but the brain and ganglia are too thick to be optically sectioned in this manner. We will discuss the development of a tissue clearing protocol suitable for large insects, that preserves the anatomy of the ventral cord, keeps background fluorescence low, fluorophore signal high and antigenicity intact." 11140. Groner, M.L.; Buck, J.C.; Blaustein, A.R.; Rolins-Smith, L.A.; Reinert, L.K.; Relyea, R.A. (2010): COS 39-8: Scared sick? Effects of sublethal exposure to predators and pesticides on life history traits and disease susceptibility in wood frogs. The 95th ESA Annual Meeting (August 1 -- 6, 2010): (in English) [Verbatim: Background/Question/Methods: Recent reviews hypothesize that pathogen-associated amphibian declines may be exacerbated by immunosuppression triggered by exposure to contaminants and/or stress hormones released in response to environmental changes. Currently, there are few empirical data in support of these hypotheses. We exposed wood frog tadpoles (*Rana sylvatica*) to sublethal concentrations of malathion (0, 10, 100 ppb), and cues from caged dragonfly predators (*Anax junius*). We measured effects of these treatments on life history traits (growth, development and survival) and the susceptibility of wood frog metamorphs to the fungal pathogen *Batrachochytrium dendrobatidis* (B.d.). Results/Conclusions: Both treatments had mild negative effects on wood frog development, but not growth. Survival was also slightly lower in the highest pesticide treatment when predators were present, but not when predators were absent, supporting past evidence that these stressors can have synergistic negative effects on survival. Surprisingly, mortality rates in frogs exposed to B.d. were lower in individuals stressed by predator cues, while malathion did not effect survival. Overall these data fail to show that contaminants and predator stress cause higher rates of mortality associated with B.d., although they do show that environmental context can alter life history traits and disease susceptibility. Further tests are needed to show whether such stressors alter immune system function and if these results are robust for other pathogens.] Address: Relyea, R.A., Dept Biol. Sciences, University of Pittsburgh, Pittsburgh, Pennsylvania 15260, USA. E-mail: rarelyea@pitt.edu

(in English) ["Results from field experiments using a fluorescence lidar system to monitor movements of insects are reported. Measurements over a river surface were made at distances between 100 and 300 m, detecting, in particular, damselflies entering the 355 nm pulsed laser beam. The lidar system recorded the depolarized elastic backscattering and two broad bands of laser-induced fluorescence, with the separation wavelength at 500 nm. Captured species, dusted with characteristic fluorescent dye powders, could be followed spatially and temporally after release. Implications for ecological research are discussed." (Authors) The paper includes a reference to Odonata] Address: Guan, Zuguang, Department of Biology, Lund University, SE-223 62 Lund, Sweden. E-mail: zuguang.guan@fysik.lth.se

11143. Haislip, N.A.; Hoverman, J.T.; Miller, D.L.; Gray, M.J. (2010): COS 53-6: Predators and infectious diseases: Does the threat of predation increase susceptibility to Ranavirus in larval anurans. The 95th ESA Annual Meeting (August 1 -- 6, 2010): (in English) [Verbatim: Background/Question/Methods: The emergence of infectious diseases has sparked concern throughout the scientific community because they threaten global biodiversity, and consequently can impact the structure and function of ecological communities. Ecological stressors may be important components contributing to the emergence of infectious diseases. While organisms are surrounded by a diversity of ecological stressors, predation risk is one of the common stressors in nature. In response to predators, prey can adaptively alter their behaviour, morphology, and life history traits. Although enhancing survival, the stress of predators can suppress immune function, which may increase susceptibility to pathogens. Thus, predator-rich communities may be hotspots for disease emergence. For over three decades, amphibian populations have been declining across the globe. While there are many hypothesized causes of these declines, the emergence of infectious diseases is receiving increased attention. More specifically, ranaviruses have been reported as the etiologic agent in amphibian die-offs on five continents, in four Canadian provinces, and in over thirty U.S. states, infecting dozens of species. Other than the association with amphibian die-off events, little is known about the ecology of the amphibian-ranavirus system. Our goal was to determine if the risk of predation increases the susceptibility of tadpoles from four amphibian species (*Hyla chrysoscelis*, *Lithobates clamitans*, *Lithobates sylvaticus*, and *Pseudacris feriarum*) to ranaviral infection and disease. Our experimental design was a factorial combination of two virus treatments and three predator treatments. The virus treatments consisted of a no-virus control and a virus exposure of 103 plaque-

forming units mL⁻¹. The predator treatments were a no-predator control and predator cues from either larval dragonflies (*Anax* sp.) or adult water bugs (*Belostoma flumineum*). Each of the six treatments was replicated five times for a total of thirty experimental units. Results/Conclusions: We found that tadpoles of the four species reduced activity by 22-48% following continuous exposure to invertebrate predator cues. In addition, virus exposure resulted in reduced activity for *Hyla chrysoscelis* and *Lithobates clamitans*, and significantly reduced survival by 17-100% across all species. Exposure to predator cues did not affect survival or infection rates, and did not interact with the virus treatments. Together, our results suggest that the expression of adaptive inducible defenses in anuran larvae does not increase ranaviral disease risk. However, additional studies are needed that test other natural (e.g., competition) and anthropogenic (e.g., pesticide) stressors to understand disease risk within natural communities.] Address: not stated

11144. Hermans, J.T. (2010): De Libellenfauna van Zuid-Limburg. *Natuurhistorisch Maandblad* 99(9): 189-200. (in Dutch, with English summary) ["The article presents an overview of our present knowledge about the dragonflies of the southern part of the province of Limburg. 55 species of dragonflies were observed between 1990 and 2007. Dragonflies of oligotrophic waters (moorland pools or bogs) such as *Ceriagrion tenellum*, *Leucorrhinia rubicunda*, *Aeshna juncea* or *Somatochlora arctica* are restricted to the area around the villages of Brunssum and Schinveld. Species such as *Ischnura elegans*, *Coenagrion puella*, *Aeshna cyanea* and *Libellula depressa*, which show no preference for a particular type of water, are widespread and abundant in Southern Limburg. Species which prefer running waters are found in the valleys of the river Meuse and the larger brooks, such as Geul and Gulp. Some dragonfly habitats, such as pools and limestone quarries, are discussed separately. Several pools in the Mergelland (the southwestern part of Southern Limburg) have disappeared and many are in a deplorable state due to lack of maintenance. The most common species breeding in such pools are *A. cyanea*, *I. elegans* and *L. depressa*. Limestone quarries are of great importance for dragonflies. The sheltered situation and the continuing limestone extraction provide a special and warm habitat. Most of the dragonfly species recorded there, like *Ischnura pumilio*, *Orthetrum brunneum* and *O. coerulescens* need the dynamic environment found in these quarries." 11145. Holland, M.P.; Marino, J.A. (2010): PS 15-120: Predator cues and parasitism: Effects of two stressors on anuran larvae. The 95th ESA Annual Meeting (August 1 -- 6, 2010): (in English) [Verbatim: Background/Question/Methods: Parasite infection and predatory stress often simultaneously impact wildlife populations, with potentially complex effects on the traits and fitness of the affected animals. For instance, nonconsumptive predator effects may decrease the ability of a potential prey individual to tolerate intense macroparasite infections. In this study, we examined the responses of green frog (*Rana clamitans*) larvae to echinostome (Digenea: Echinostomatidae) parasite infection and predator chemical cue. In two aquaria experiments, we measured activity levels, growth, and mor-

ality of larvae after exposure to echinostome cercariae, larval *Anax* (Odonata) predator cue, or the combination of cercariae and predator cue. Due to the costs associated with each stressor, we predicted that the combination treatment would result in synergistic effects on behaviour, growth, and mortality. Results/Conclusions: As expected, individuals exposed to predator cue showed decreased activity levels and growth in comparison to controls. Exposure to predator cue did not affect mortality. Infected individuals showed decreased activity level and higher mortality, but growth was not affected. Contrary to our predictions, we did not observe an interaction between these stressors with respect to either traits or mortality. These results suggest that, at least at a small scale, we can treat these stressors as additive. However, further studies that incorporate additional interactions between these natural enemies may demonstrate other important synergisms.] Address: Holland, Manja P., University of Michigan, USA

11148. Meutter, F. van de (2010): Colonisation and habitat preference of *Crocothemis erythraea* in De Maten (Genk, Belgium). *Brachytron* 13(1/2): 32-40. (in Dutch, with English summary) ["This study describes the arrival and colonization of a pond complex situated in North-eastern Belgium by *C. erythraea*. The presence of *C. erythraea* was monitored by both samplings for larvae and observations of adults. The prevalence of adults and especially larvae increased exponentially during the course of this study, indicating that a large metapopulation could be established within only a few years. The presence of *C. erythraea* larvae was positively related to low cover of floating-leaved vegetation and a high raver of submersed filamentous algae and other vegetation. The presence of adults was positively related to water temperature, possibly reflecting a preference for ponds with a high insolation. We found a weak match between ponds where patrolling males were

seen and the presence of larvae, possibly indicating that different pond types are selected, although we may have missed larvae occurring at low densities. The colonization of the study area is part of an ongoing northern range shift of this species and exemplifies how quickly a locality may be colonized, and next could serve as a source of dispersal that engage in new colonization events." (in Dutch, with English summary) ["In 2007 the Dutch Society for Dragonfly Studies (NVL) celebrated its 10th anniversary. For ten years the NVL closely cooperated with Dutch Butterfly Conservation (De Vlinderstichting) and European Invertebrate Survey (EIS-NL). This cooperation turned out to be successful and resulted in some remarkable projects. For example: the realization of the atlas on Dutch dragonflies in 2002. This publication appeared as volume 4 in the series *Fauna of The Netherlands*. Another notable event was the Dutch/German symposium at Kranenburg (Germany) in 2004. Cooperation across borders is one of the main goals of the NVL, because after all dragonflies do not acknowledge borders and conservation is a matter of international importance. At this moment the NVL is involved by the realization of an Atlas on European Dragonflies (Kalkman, in prep.). On a national scale the NVL is working on more ecological knowledge of specific species. In 2002-2007 the ecology of *Sympecma paeidisca* was studied, resulting in a special edition of *Brachytron* which presented the results (*Brachytron* 11 (1). 2007). This publication appeared courtesy of Dutch Butterfly Conservation and EIS-NL. Hopefully, the successful cooperation between the three organizations will be preceded for at least another ten years." 11157. Silver, C.A. (2010): Macroinvertebrate communities of temporary prairie pothole wetlands. M.Sc. thesis, Dept Biol. Sci., University of Calgary: XI + 143 pp. (in English) ["Macroinvertebrate communities were sampled in rotationally grazed, temporary wetlands in the prairie pothole region. Seven wetlands were grazed when temporary wetlands contained water (early grazed), and six wetlands were grazed when temporary wetlands were dry (late grazed). Late grazed wetlands contained more abundant and diverse macroinvertebrate communities than early grazed wetlands. Phylogenetic comparison of macroinvertebrates from temporary wetlands with those from permanent wetlands suggested the temporary community was influenced by environmental filtering, while the permanent community was influenced by biotic interactions, indicating fewer groups were able to survive the short wet period of temporary wetlands, compared to permanent wetlands. Both taxonomic and functional traits perspectives demonstrated that rotational grazing created two distinct habitats, by allowing late grazed wetlands to escape grazing pressure during the wet season. Given contrasting patterns observed between permanent and temporary wetlands, macroinvertebrate diversity at the landscape level is best served by maintaining wetlands of varying permanence." (Author) Taxa including Odonata are treated at the genus level.] Address: Silver, Carly Ann, Dept of Biological Sciences, University of Calgary, T2N 1N4, Calgary, Alberta, Canada. 11158. Smith, G.R.; Boyd, A.; Dayer, C.B.; Ogle, M.E.; Terlecky, A.J.; Dibble, C.J. (2010): Effects of sibship and the presence of multiple predators on the behavior of Green Frog (*Rana clamitans*) tadpoles. *Ethology* 116 (3): 217-223. (in English) ["In nature, prey are exposed

to multiple predators simultaneously. We examined the effects of the cues of two potential predators, mosquitofish and odonate larvae, individually and in combination on the behaviour of *R. clamitans* tadpoles. In addition to examining the behavioural response of green frog tadpoles to multiple predators, we examined variation in behaviour among tadpoles from different egg masses (i.e. different sibships). Sibships differed in activity level and there was a significant predator cue by sibship interaction. Two sibships were relatively more active in the control and odonate predator cue treatments but showed reduced activity in treatments containing mosquitofish cues, whereas the remaining sibships showed consistently low levels of activity in all predator cue treatments, including the control. The use of the vegetated side of the aquarium did not differ between tadpoles exposed to the different predator cues. Sibship had no effect on tadpoles' use of the vegetated side of the aquarium, and there was no interaction between sibship and predator cue. Our results suggest that green frogs did not respond to simultaneous exposure to multiple predator cues any differently than they did to exposure to individual predator cues. More importantly, our results suggest variation, possibly genetically based, in behavioural responses of tadpoles to predators, and thus selection on these behaviours is possible. Of particular interest is that there was variation in behavioural responses to a non-native predator (*Gambusia affinis*), suggesting an evolutionary response to an invasive predator is possible." (Authors)] Address: Smith, G.R., Dept Biol., Denison Univ., Granville, OH 43023, USA. E-mail: smithg@denison.edu

11159. Sudo, S (2010): Micro swimming robots based on small aquatic creatures. In: Amitava Mukherjee (ed.), *Biomimetics Learning from Nature*, ISBN 978-953-307-025-4, 534 pages, Publisher: InTech 2010: (in English) ["Conclusion: The swimming behaviour of small aquatic creatures was analyzed using the high speed video camera system. Based on the swimming analysis of the aquatic creatures, the micro swimming mechanism and micro diving robot propelled by alternating magnetic field were produced. The swimming characteristics of the micro mechanism and micro diving robot were developed. The swimming mechanism and diving robot swam successfully in the water. Frequency characteristics of the swimming mechanism and diving beetle robot were examined. The diving robot showed the higher swimming velocities at $f_0=4-12\text{Hz}$. These experiments show the possibility of achievement of the micro robot driving by the wireless energy supply system. The results obtained are summarized as follows: (1) In the power stroke of the diving beetle swimming, hind legs are extended and driven backward to generate forward thrust. While in recovery stroke, hind legs are returned slowly to their initial position. (2) In forward swimming of the dragonfly nymph, only the fore pair and the middle pair of legs are active as a thrust generator. The orbits of fore- and middle-legs show almost the same, and draw the circle partially of the orbit. (3) The micro swimming mechanism composed of the NdFeB permanent magnet and film fin are driven by the alternating magnetic field. The swimming velocity of the micro mechanism depends on the frequency of alternating magnetic field at the constant voltage. (4) Flow visualization around the micro mechanism was created by the motion of powder and slow shutter speed photographic technique. The forward and backward surface flows and vortex flows around the micro mechanism were

generated by the robot driving. (5) Visualization photographs of flow field around the tethered opossum shrimp show the generation of tow vortices in right and left sides of the body. (6) The diving robot can dive into the water by sweeping the frequency of magnetic field. The diving robot can swim backward by the change of magnetic field frequency." 11160. Tończyk, G. (2010): Dragonflies and damselflies (Odonata) of the Tatra Mountains - history and present-day. In: Mirek Z. (ed) Nauka a zarządzanie obszarem Tatr i ich otoczeniem. Tom II: Człowiek i środowiska. Tatrzański Park Narodowy, Polskie Towarzystwo Przyjaciół Nauk o Ziemi - Oddział Krakowski, Zakopane: 101-105. (in Polish, with English summary) ["Studies upon Odonata in the Tatra Mts. have long, nearly 150 year old tradition. So far almost 20 scientific papers concerning this group have been published. The studies were conducted since the mid 19th century, with particular intensity in 1920s. The list of species reported in the publications counts from 25 to 39 species. Such a big count difference results from unprecise delimitation of the Tatra and Podtatrze areas as well as from including in the list occasional visitors from neighbouring regions. Unfortunately, lack of contemporary studies makes impossible to define the present state of odonatofauna in the Tatra Mts. Only 14 species are represented in the data collected after 1990. Also, it is hard to precise the number of species breeding and developing in this area - most probably it is 26 species. In most valuable species, one can include locally occurring *Somatochlora alpestris*, and *S. arctica*, the latter recently not confirmed from the area. Both species are included in the Polish Red List of Threatened Odonata Species, respectively in categories NT and EN. In the Polish section of the Tatra Mts., Toporowe tarns and Smreczyński tarn can be recognised as centres of their breeding and diversity." 11161. Veling, K. (2010): Dragonfly working groups: more than the sum of its parts. *Brachytron* 13(1/2): 55-64. (in Dutch, with English summary) ["At least 38 dragonfly working groups exist in The Netherlands, ranging from working groups studying dragonflies only, to working groups studying other insect groups as well. Group excursions, inventories of nature areas, identification courses and publication of regional distribution atlases are among the many activities organised by working groups. Studying dragonflies together is very stimulating and has several advantages. By working together, mapping the dragonflies of a whole region becomes possible in an effective way. The amount of work can be divided and members can replace each other during vacations. During the process, less experienced dragonfly enthusiasts learn quickly from more experienced recorders. Furthermore, working groups have a more formal position, e.g. when giving advices to nature managers. But the main reason for many people to join a dragonfly working group might well be that watching dragonflies together is just much more fun!" 11165. Zhang, X.-j.; et al. (not stated) (2010): Study on molecular phylogeny to the species of Anisoptera (Insecta: Odonata) based on CO II complete genes. *Journal of Anhui Agri. Sci.* 38(5): 2264-2267. (in Chinese, with English summary) [Verbatim: "Objective: The research aimed to study the molecular phylogeny to the species of Anisoptera (Insecta: Odonata) based on CO II complete genes. Method: Non-special primers were designed on the CO II genes of Odonata. CO II complete genes of 6 genera, including 8 species of 5 families in Anisoptera, had been sequenced and analyzed. The phylogenetic trees were reconstructed using ClustalX1. 8, ContigExpress, MEGA2. 1, PHYL IP3. 6a and MrBayesV3. 0 softwares, and maximum parsimony and maximum likelihood methods, respectively. Results: The results show that A + T contents of CO II genes of Libellulidae are lower (68.6%) in Insecta, which proves Odonata is an original group. Every sequence includes 2 Cys, which differs from the other groups of Insecta. Do not agree with the view of raising Macrominae into Macromidae. Agree with the views of putting both Aeshnidae and Cordulegastridae into Aeshnidae, and raising Gomphidae into a superfamily. Order of the evolution relationship of 5 families is: Gomphidae -> Cordulegastridae -> Aeshnidae -> Corduliidae -> Libellulidae. Conclusion: The study can provide the relative basis for

molecular phylogeny study of Odonata." The study includes the following taxa: *Orthetrum albistylum*, *O. sabina*, *Sympetrum eroticum*, *S. kunckeli*, *Epophthalmia elegans*, *Anax parthenope julius*, *Anotogaster kuchenbeiseri*, *Davidius bicornutus*, and *Pseudagrion civicum*.] Address: Zhang, X.-j., Dept of Laboratory Medicine, Bengbu Medical College, Bengbu, Anhui 233000, China

11167. Adandedjan, D.; Laleye, P.; Ouattara, A.; Gourene, G. (2011): Distribution of benthic insect fauna in a West African Lagoon: The Porto-Novo Lagoon in Benin. *Asian Journal of Biological Sciences* 4(2): 116-127. (in English) ["The distribution of aquatic insect fauna of Porto-Novo lagoon was studied through seasonally sampling from July 2007 to June 2008. A total of 52 taxa belonging to 7 orders and 29 families were recorded. The richest taxonomic diversity was observed for Heteroptera, Ephemeroptera and Odonates. Certain species such as *Diplonychus* sp. (Belostomidae), *Chironomus* sp., *Chironomus formosipennis* and *Polypedium fuscipenne* (Chironomidae) and *Libellulidae* (*Libellula* sp.) were the most constant taxa observed during the sampling period. The distribution pattern observed thanks to the Kohonen map (SOM) is characterized by a rich assemblage and varied from upstream to downstream. The highest specific diversity (69.29%) was got during the low rainy season (October) and the lowest (29.8%), during the high dry season (February). This pattern resulted from the species reproductive process of most insects orders, in relation with a decrease of the rate of the salinity and an increased water temperature. But then, the low rate of species richness recorded during the dry season will be explained by the lacking of efficient recruiting and a strong predation during this period. Besides, hydrological factors and human activities could be also the important factors of controlling the distribution of this fauna. The invasion of the lagoon by the floating vegetation can be advanced as a factor of forage of the temporal variations of the organisms." (Authors) The identification of Odonata is suspicious, because the taxa list includes European representatives.] Address: Adandedjan, D., Laboratoire d'Hydrobiologie et d'Aquaculture, FSA-UAC, Faculté des Sciences Agronomiques- Université d'Abomey-Calavi, 01 BP 526 Cotonou Bénin

11168. Ahmadi, R.; Mohebbi, F.; Hagigi, P.; Esmaily, L.; Salmanzadeh, R. (2011): Macro-invertebrates in the wetlands of the Zarrineh estuary at the south of Urmia Lake (Iran). *Int. J. Environ. Res.* 5(4): 1047-1052. (in English) ["This research summarizes the data on benthic macro invertebrates collected from 25 points in the Urmia Lake wetlands during November 2008 to February 2009. The purpose of the study was to assess the effects of elevated salinity and nutrient (nitrogen and phosphorus) levels on macro invertebrate abundance and composition. A total of 32 taxa were collected, and the common taxa, including Chironomidae (midges), Corixidae (wa-

ter boatmen), Erythemis (damselflies) [sic], Ephemerella (mayflies), Hyalella (amphipods), and snails. Samples at ponds with salinities greater than 10 ppt showed a shift in community composition to salt-tolerant taxa and a reduction in total diversity. The corixid *Trichocorixa verticalis*, the brine shrimp *Artemia partenogenetica*, and the dipteran *Ephydra* are salt-tolerant species that only occur at high salinity levels. Ponds relatively high in nutrients had fewer total taxa, reduced abundance and diversity of aquatic beetles, lower diversity index values, and a greater dominance by chironomids than ponds low in nutrients. It is suggested to allocate about 10 × 10⁶ cubic meters freshwater of the represented rivers to these wetlands to improve their trophic condition and transfer their hypereutrophic waters into the Urmia Lake for more production of the macro invertebrates both in the wetlands and on the lake." (Authors) Identification is said to be realised by Watson, J.A.L. & Arrell, A.F. (1991). *Odonata* (Dragonflies and Damselflies). Ch. 17 in CSIRO (ed) *The Insects of Australia*. A textbook for students and research workers. Carlton, Melbourne University press, pp. 294-310. Even in this case it is an enigma to identify and find *Erythemis* - an American species - in Iran.] Address: Ahmadi, R., Iranian Artemia Research Center, P.O. Box: 57157-1367 Urmia, Iran. 11170. Andrew, R.J.; Verma, P.; Rathodi, M.K. (2011): Post ovipositional changes in the egg chorionic ultrastructure of the dragonfly *Pantala flavescens* (Fabricius) (Insecta: Odonata: Anisoptera). *Biological Forum* 3(2): 22-24. (in English) ["The ultrastructure of the egg chorion of *P. flavescens* is described using the light and scanning electron microscope. The egg of *Pantala flavescens* is oval and the chorion is distinctly divided into an outer exochorion and an inner endochorion. The egg measures about $720 \pm 20 \times 530 \pm 10 \mu\text{m}$ in unwetted condition. The endochorion is light yellow, but turns

brown within a few hours in water. The exochorion which envelopes the endochorion as a thin covering which expands into a transparent thick, sticky, jelly-like structure when it comes in contact with water and therefore, the egg in wet condition bloats and measures $870 \pm 20 \times 550 \pm 20 \mu\text{m}$. The apically placed micropylar apparatus is nipple shaped, formed of a small sperm storage chamber (atrium) and a median projecting micropylar stalk. The stalk is of 'concave cone' type and possesses a pair of subterminal orifices. A circular groove demarcates the exochorion and the micropylar apparatus." 11172. Arnaiz, O.L.; Wilson, A.L.; Watts, R.J.; Stevens, M.M. (2011): Influence of riparian condition on aquatic macroinvertebrate communities in an agricultural catchment in south-eastern Australia. *Ecol. Res.* 26: 123-131. (in English) ["Riparian vegetation is known to affect aquatic macroinvertebrate communities through contributions of organic matter and shading. Despite the widespread degradation of riparian vegetation in Australia, there are relatively few studies examining the effect of changes in riparian vegetation on in-stream macroinvertebrate assemblages on individual catchments. In particular, information is lacking on the responses of macroinvertebrate communities in catchments dominated by agriculture, where farms that are managed at the paddock scale result in riparian vegetation condition varying over relatively short distances. In this study, macroinvertebrate assemblages were assessed from 12 reaches along a 25-km section of a small agricultural stream in southeastern Australia. Riparian condition was assessed using in-stream coarse woody debris (CWD) levels and the rapid appraisal of riparian condition (RARC) index, a numerical system for categorising the health of riparian areas that incorporates sub-indices reflecting habitat continuity, vegetation cover, plant debris levels, native vegetation dominance, and other indicative features. There was a significant positive correlation between RARC scores and macroinvertebrate taxon richness ($p < 0.01$), and also between

CWD scores and macroinvertebrate taxon richness ($p < 0.05$). In contrast, there was no significant correlation observed between riparian condition and the other macroinvertebrate indices (abundance, Shannon diversity, SIGNAL and SIGNAL2). Macroinvertebrate communities were significantly different in stream reaches from different riparian condition categories (ANOSIM; $p < 0.05$). Our results indicate that efforts to rehabilitate riparian vegetation may have a positive effect on in-stream biota even when implemented at a relatively small scale by individual landholders. ... Corduliidae (Odonata) were unique to 'very poor' riparian condition reaches." 11178. Baumart, J.; Dalosto, M.; Santos, S. (2011): Effects of carbofuran and metsulfuron-methyl on the benthic macroinvertebrate community in flooded ricefields. *Acta Limnologica Brasiliensia* 23(2): 138-144. (in English, with Portuguese summary) ["This study evaluated the effect of the insecticide carbofuran and the herbicide metsulfuron-methyl on the abundance and diversity of benthic macroinvertebrates in a paddy ricefield. To achieve this goal, two pesticide treatments [the insecticide carbofuran (IC) and the herbicide metsulfuron-methyl (HM)] and a control (Co) treatment with no added pesticide were established in an experimental area of the Plant Science Department of the Federal University of Santa Maria. Soil samples were collected in triplicate from each treatment 30 days before and 1, 10, and 51 days after the pesticide application, for macrofauna identification. Among the 21 taxa identified, Trichoceridae was present only in Co, Hydroptilidae was recorded only in IC, and Corixidae in HM. In Co, the most abundant group was Annelida, while in IC and HM Diptera (Chironomidae) was dominant. Significant differences were observed between Co and IC, in the density of Odontoceridae (Control>IC) and Hydrophilidae (Control<IC), and between Co and HM in the density of Odontoceridae (Control>HM) and Hirudinea (Control<HM). In spite of the possible negative effects of the pesticides on the benthic community, the assemblages recovered rapidly." (Authors) Odonata are treated at the family level; to the abstracters it remains unclear in what extent they are afflicted by the insecticides.] Ad-

11181. Bernard, R.; Heiser, M.; Hochkirch, A.; Schmitt, T. (2011): Genetic homogeneity of the Sedgling *Nehalennia speciosa* (Odonata: Coenagrionidae) indicates a single Würm glacial refugium and trans-Palaeartic postglacial expansion. *Journal of Zoological Systematics and Evolutionary Research* 49(4): 292-297. (in English) ["The phylogeographic structures of taiga species often support the hypothesis of East Palaeartic refugia for these taxa, but the phylogeographic structures of northern temperate and southern boreal bog species are still poorly understood. Therefore, we analysed the genetic diversity and differentiation of a stenotopic damselfly, *N. speciosa*, across its trans-Palaeartic range by means of sequencing two mitochondrial gene fragments, 16S rRNA-ND1 and cytochrome c oxidase II. Only four single nucleotide polymorphisms were detected over the 1130 sequenced nucleotides. This low genetic diversity and differentiation and thus the lack of phylogeographic structure imply postglacial expansion from a single Würm Ice Age refugium, most likely located in the Far East of Asia, i.e. Manchurian refugium. From here, the species could have colonized large parts of the Palaeartics, including Europe, during the postglacial." (Authors) Individuals from 12 localities all over the natural range of *N. speciosa* were collected. Five of these localities are in Europe: one in Bavaria (Germany), three in Poland and one in Lithuania. The remaining seven localities are in Asia, two of them in the West Siberian Lowland, one in the Amur Province, one in the Russian Far East and three in Japan.] Address: Bernard, R., Dept of General Zoology, Adam Mickiewicz University, Umultowska 89, PL-61-702 Poznań, Poland; E-mail: bernard@amu.edu.pl

11184. Boets, P.; Lock, K.; Goethals, P.L.M. (2011): Using long-term monitoring to investigate the changes in species composition in the harbour of Ghent (Belgium). *Hydrobiologia* 663: 155-166. (in English) ["The macroinvertebrate community of the harbour of Ghent was studied by analysing 135 samples taken at different sampling locations from 1990 until 2008. The results showed that the current Crustacea and Mollusca communities are mainly represented, in terms of abundances, by alien species. In total, seven alien and four indigenous crustacean species were found. Mollusc diversity was higher, with a total of 14 species, four of which were alien. Macroinvertebrate diversity was very low at the beginning of the 1990s, but increased due to the improvement of the chemical water quality achieved by sanitation and stricter environmental laws. This is reflected by the dissolved oxygen concentration, which increased from an average of 2 mg/l to an average of 9 mg/l, allowing more sensitive species to establish. Since 1993, the number of alien taxa has augmented, whereas the number of native taxa has remained stable. The improvement of the chemical water quality and the simultaneous increase in total number of species were also reflected in an increase of the Multimetric Macroinvertebrate Index Flanders, which is used to assess the ecological water quality in Flanders. Due to intensive international boat traffic and the low species diversity, the harbour of Ghent is highly vulnerable for invasions. Stronger regulations and a better understanding about the contribution of shipping, shortcuts via artificial water ways, habitat degradation and environmental pollution are required to reduce the further spread of alien species." (Authors) *Coenagrion puella*, *Ischnura elegans*] Address: Boets, P., Laboratory of Environmental Toxicology and Aquatic Ecology, Ghent University, J. Plateaustraat 22, 9000 Ghent, Belgium. Evol. Biol.* 25(1): 196-209. (in English) ["North American *Enallagma* damselflies radiated during the Pleistocene, and species differ mainly by reproductive structures. Although morphologically very different, *Enallagma hageni* and *Enallagma ebrium* are genetically very similar. Partitioning of genetic variation (AFLP), isolation by distance and clustering analyses indicate that these morphospecies are locally differentiated genetically. Spatial analyses show that they are rarely sympatric at local sites, and their

distributions form a mosaic of patches where one is clearly dominant over hundreds of square kilometers. However, these morphospecies are also not genetically more similar when they are sympatric, indicating that hybridization is probably not occurring. Given that these morphospecies are ecologically equivalent, strong assortative mating, reproductive interference and fast post-glacial recolonisation may explain the origin and maintenance of these distributional patches across eastern North America. By limiting opportunities for gene flow, reproductive interference may play an unsuspected role in accelerating genetic differentiation in the early phases of nonecological speciation." (Authors)] Address: Turgeon, Julie, Dépt de biologie, Univ. Laval, 1045 avenue de la Médecine (Vachon 3048), Quebec City, QC G1V 0A6, Canada. E-mail: julie.turgeon@bio.ulaval.ca

(2011): Gewässertypspezifische Bewertung von Restrukturierungsmaßnahmen an einem Tieflandbach durch libellenkundliche Untersuchungen (Insecta: Odonata). *Beiträge zur Entomofaunistik* 12: 25-40. (in German, with English summary) ["Dragonfly surveys as a tool for assessing the restoration of a small lowland brook. The ecological status of a restored stretch of a small river in the lowland areas of eastern Austria was assessed by a dragonfly survey. Restoration measures were carried out in a retention area by river widening and the construction of back waters. The assessment which is oriented towards the Water Framework Directive (WFD) is based on the comparison between the status quo and a river-type-specific reference condition; key elements are the species composition and the Odonata Habitat Index (OHI).

A total of 21 species were recorded at two sites situated in the restored area, 16 species of them were classified as autochthonous. The species list and OHI values reflect the broad range of relevant dragonfly habitats. The ecological status of this river stretch was ranked as class II ("good ecological status") in the 5-tiered WFD classification scheme. Species numbers recorded at two canalised and straightened stretches of the river system (6 species / 5 autochthonous species) and OHI values show a significant deviation from the river-type-specific reference condition." 11191. Crabtree, A.G. (2011): Modelling a small pond odonate population: Exploring the complex life history dynamics of *Pachydiplax longipennis* (Odonata: Libellulidae). M.Sc. thesis. Northern Illinois University: 150 pp. (in English) ["Members of the insect order Odonata are excellent examples of organisms that demonstrate complex life histories. Both the larval and adult stages must be studied to understand the dynamics of such species. A population of *P. longipennis* was studied at a small fishless pond in north central Illinois in 2008 and 2009. Additionally, a dynamic population model of the species was developed using the graphical modelling software, STELLA, to further understand the life history dynamics of *P. longipennis*. The larval dragonfly community in the pond was composed of nine species, all of which were also present as adults. The adult dragonfly community contained an additional four species, for a total of 13. Although, the maximum larval density of *P. longipennis*, which occurred in the middle of the summer, was ~15 m² in 2008 and 2009, mean density was higher in 2009. Based on this maximum density, it was estimated the maximum larval population size for the pond was ~170,000. Head capsule width and total length of larvae were used to identify 14 larval instar classes for the species. Changes in head capsule width between adjacent instar classes generally conformed to Dyar's Ratio, with the exception of the changes between the first and last two instars. Skipping of instar classes was common among larvae reared in the lab. Mean maximum *P. longipennis* adult abundance occur-

red in July in both 2008 and 2009. It was higher in 2008 than that observed in 2009, ~12 per 10 m sector versus 8 per 10 m sector. The estimated adult population size in 2009 based on mark-recapture data using Craig's estimation method was 2,000. Average clutch size, determined from six captured, mated females, was 1,238±431 eggs per clutch. Average clutch survivorship was 27.51%±16.38. A density-ceiling model generated a stable population of *P. longipennis* larvae and adults that cycled in 54 week intervals. Short term (2 years) results predicted an early instar larval population of ~175,000 individuals, a late instar larval population of ~40,000, and an adult population of ~4,000. Long term (20 years) results predict early instar larval population of ~300,000 individuals, a late instar larval population of ~75,000, and an adult population of ~6,000. Long term estimates were comparable to those predicted by larval and adult sampling. Sensitivity analysis of varying mortality rates found that changing early instar larval mortality rate had a significant impact on observed abundances in all modelled life stages, while changes in breeding adult mortality had little effect. Simulations of ten different survivorship scenarios of larval and adult mortality resulted in three specific categories of response in terms of larval and adult abundances: one or both reached carrying capacity, both went extinct, or either or both stabilized at an intermediate abundance. Scenario results also suggested a greater importance of larval stage mortality rates, similar to the results of the sensitivity analysis. A density-dependent model generated unrealistic results in both short term and long term simulations." (Author)] Address: not stated.

11195. Delclos, P.; Rudlof, V.H.W. (2011): Effects of size structure and habitat complexity on predator-prey interactions. *Ecological Entomology* 36(6): 744-750. (in English) ["(1) A predator's ability to suppress its prey depends on the level of interference among predators. While interference typically decreases with increasing habitat complexity, it often increases with increasing size differences among individuals. However, little is known about how variation in intrinsic factors such as population size structure alters predator-prey interactions and how this intrinsic variation interacts with extrinsic variation. (2) By experimentally varying the level of vegetation cover and the size structure of the predatory *Ischnura posita*, we examined the individual and interactive effects of variation in habitat complexity and predator size structure on prey mortality. (3) Copepod prey survival linearly increased as the *I. posita* size ratio decreased and differed by up to 31% among different predator size structures. Size classes had an additive effect on prey survival, most likely because intraspecific aggression appeared size-independent and size classes differed in microhabitat preference: large *I. posita* spent 14% more time foraging on the floor than small larvae and spent more time in the vegetation with increasing habitat complexity. Despite this difference in microhabitat use among size classes, habitat structure did not influence predation rates or interference among size classes. (4) In general, results suggest that seasonal and spatial variation in the size structure of populations could drive some of the discrepancies in predator-mediated prey suppression observed in nature, and this variation could exceed the effects of variation in habitat structure." 11198. Epstein, D.M. (2011): 15N tracer and modelling analyses of nutrient transport through lakes in a subalpine watershed. M.Sc. thesis, Ecology, Utah State University, USA. All Graduate Theses and Dissertations. Paper 932. <http://digitalcommons.usu.edu/etd/932>: 107 pp. (in English) ["Lakes have historically been overlooked as important nutrient processors within their watersheds. In general ecologists have focused on streams as zones of uptake and transformation, while viewing lakes as simple nutrient traps. However, recent research has highlighted the large influence that lakes may have on water chemistry within their watersheds. Within the field of limnology, researchers have traditionally focused on the pelagic zone for in-lake production. Further research in shallow lakes has highlighted the role benthic production within the littoral zone plays in the lake ecosystem. The greater influence of lakes is highlighted when comparing watersheds containing lakes with watersheds composed of solely stream channels. To assess the influence that lakes have on water chemistry and nutrient transport, both field and modelling analyses were performed for Bull Trout Lake, Idaho. In 2008 a large field sampling effort was conducted along with a 15N tracer experiment to characterize the limnology of Bull Trout Lake (Idaho) and nitrogen uptake and transport through the lake. Following the termination of the field season a multi-lake ecosystem model was developed with the use of a one-dimensional lake water quality model. Results from both experiments demonstrated the role of Bull Trout Lake as a nutrient processor and source within its watershed and further suggested the added influence additional lakes might have on water chemistry. The outcomes of the tracer study indicated that pelagic primary producers have the first opportunity to assimilate nitrogen delivered by the inflow stream; however, nutrients incorporated into plants within the littoral zone are held on to longer. Further the tracer experiment demonstrated the small role that large organisms have in ecosystem nutrient dynamics. The multi-lake model demonstrated the effect of BTL as a nutrient source within the watershed and indicated that although multiple lakes in sequence may have additive effects, most of this influence is expressed in the first two lakes of a series. Our research provides examples of valuable tools in limnological research. While whole-lake tracer studies have rarely been performed, they are extremely effective in understanding ecosystems. Additionally, even though lake models may be simplifications of natural systems, they can provide an efficient means of understanding lake functioning and testing hypotheses." (Author) The thesis includes data on Odonata, but without any taxonomic details.] Address: Epstein, D.M., Utah State University

11199. Ferreira Rezende, C.; Mazzoni, R.; Pellegrini Caramaschi, E.; Rodrigues, D.; Moraes, M. (2011): Prey

selection by two benthic fish species in a Mato Grosso stream, Rio de Janeiro, Brazil. *Rev. Biol. Trop.* 59(4): 1697-1706. ["Key to understand predator choice is the relationship between predator and prey abundance. There are few studies related to prey selection and availability. Such an approach is still current, because the ability to predict aspects of the diet in response to changes in prey availability is one of the major problems of trophic ecology. The general objective of this study was to evaluate prey selection by two species (*Characidium cf. vidali* and *Pimelodella lateristriga*) of the Mato Grosso stream, in Saquarema, Rio de Janeiro, Brazil. Benthos and fishes were collected in June, July and September of 2006 and January and February of 2007. Fish were collected with electric fishing techniques and benthos with a surber net. ... The most abundant families in both benthos and diet of both fish species were the same, indicating that these species consume mainly most abundant prey in the environment. We concluded that prey selection occurs even for preys that had small abundance in the environment. However, it is the availability of the macroinvertebrate resources that determines the major composition of items in diet of fish, demonstrating that the abundance is the factor that most influences the choice of prey." (Authors) Relative density (%) of Odonata during the five sampling months (150 samples) accounted to 0.32%. Odonata contributed 0.47% and 1.25% to the diet items in *Characidium cf. vidali vidali* and *Pimelodella lateristriga* respectively.] Address: Ferreira Rezende, Carla, Laboratório de Ecologia de Peixes, Instituto de Biologia, Departamento de Ecologia, Universidade Federal do Rio de Janeiro, Av. Mal. Trompowski, s/n CCS Bloco Alha do Fundão, 21941-590, Rio de Janeiro, RJ, Brazil. E-mail: carlarezende

11200. Fincke, O.A.; Tylczak, L.A. (2011): Effects of zebra mussel attachment on the foraging behaviour of a larval dragonfly, *Macromia illinoiensis*. *Ecological Entomology* 36(6): 760-767. (in English) ["(1) Larvae of *M. illinoiensis* are often colonised by the zebra mussel, *Dreissena polymorpha* Pallas, a recent invader to North America. To determine how mussel attachment affects an individual's foraging behaviour, we quantified capture of *Hexagenia limbata* Hexes mayfly prey and the distance moved by newly-molted final instars before and after an individual's colonisation with zebra mussels. (2) In night trials, larvae sprawled above the sand, and caught more mayflies than individuals in daytime trials, but the estimated distance travelled did not differ. When resting under a layer of sand with only its eyes exposed during the day, an individual could capture a mayfly prey using a sit-and-wait ambush strategy. When sprawled above the sand, some larvae caught prey that rested on their legs. (3) When mussel-free, individuals captured more prey than they did when carrying zebra mussels, although mussel attachment per se did not affect the estimated distance that a larva moved. (4) During day trials, but not night ones, the increasing mussel load of colonised individuals decreased prey capture and the distance moved in an apparent step-wise function. Although the number of mussels carried did not differ, night foragers carried a heavier load. Independent of time of the day, the distance an individual travelled when mussel-free was predictive of the number of prey it caught when colonised, suggesting that the greater general activity of some individuals helped mitigate negative effects that mussel attachment had on prey capture. (5) Our results add to a growing number of nega-

tive effects of zebra mussel colonisation on sprawling and hiding dragonfly larvae. Although the impact of these costs on dragonfly populations remains to be determined, a decrease in this guild of predators whose life cycle spans aquatic and terrestrial habitats might have cascading effects across ecosystems." (Authors)] Address: Fincke, O.M., Dept Zool., Univ. Oklahoma, 730 Van Vleet Oval, Room 314, Norman, OK 73019, USA. E-mail: fincke@ou.edu

11201. Fleck, G. (2011): Phylogenetic affinities of Petaluridae and basal Anisoptera families (Insecta: Odonata). *Stuttgarter Beiträge zur Naturkunde A, Neue Serie* 4: 83-104. (in English, with German English) ["The petalurid genus *Phenes* has a larval proventriculus with only four dental folds. This genus is considered as the sister group of remaining Petaluridae and placed in the *Pheninae* subfam. nov. Two possible phylogenies of the Petaluridae are proposed and diagnoses of Tachopteryginae, Tanypteryginae, and Petalurinae are amended. The Petalurinae are split into Petalurini tribe nov. and Uropetalini tribe nov. The Petaluridae, Austropetalidae and Aeshnidae are gathered in the new clade Siphonoprocta taxon nov. with Petaluridae sister taxa of (Aeshnidae + Austropetalidae). The relative positions of the main basal clades Gomphida, Siphonoprocta and Cavilabiata are not solved. Within Cavilabiata the Cordulegastroidea and Neopetalidae are considered sister taxa and are gathered in the Cordulegastroidea comb. nov., and the Chlorogomphidae are considered to represent the sister group of all remaining Cavilabiata or to represent the sister group of the Cordulegastroidea." 11202. Flynn, K.E.; Moon, D.C. (2011): Effects of habitat complexity, prey type, and abundance on intraguild predation between larval odonates. *Hydrobiologia* 675 (1): 97-104. (in English) ["Intraguild predation is an important interaction in which predators feed on a shared prey as well as on each other. It occurs frequently between larval odonates in freshwater lentic communities, and understanding the factors influencing this interaction remains an important objective. An experiment carried out in mesocosms and utilizing a factorial design investigated the strength of intraguild interactions between *Sympetrum vicinum*, and *Enallagma civile*, under two levels each of habitat complexity (high or low), prey abundance (high or low) and prey type (amphipods or blackworms). Effects of treatments on size, mortality and emergence of larval odonates were evaluated. Shared prey abundance had little impact on intraguild interactions, affecting only the mass of the intraguild prey *E. civile*. Habitat complexity affected the size of *E. civile*, as length and wet mass were significantly greater in low complexity mesocosms. Prey type seemed to be the most important factor in the experiment, influencing all response variables measured. When shared prey consisted of larger, more active blackworms, intraguild predation decreased, and *E. civile* experienced lower mortality, achieved greater length and mass, and had greater emergence success. Results of this study suggest that prey type and habitat complexity can be more important than prey abundance in mediating intraguild predation." (Authors)] Address: Moon, D.C., Dept Biol. Univ. of North Florida, Jacksonville, FL, USA. E-mail: dmoon@unf.edu

11203. Fritz, L.L.; Heinrichs, E.A.; Machado, V.; Andreis, T.F.; Pandolfo, M.; de Salles, S.M.; de Oliveira, J.V.; Fiuza, L.M. (2011): Diversity and abundance of arthropods in subtropical rice growing areas in the Brazilian south. *Biodiversity and conservation* 20(10): 2211-2224. (in English) ["This paper describes a survey of arthropods in rice-growing areas of Rio Grande do Sul, Brazil, undertaken to identify the main groups of insect pests and their natural enemies present in three producing regions during the stages of crop development. The study was conducted during the crop years 2007/2008 and 2008/2009 in the municipalities of Cachoeira do Sul, Eldorado do Sul and Capivari do Sul. A total of 44,231 arthropods were collected: 26,821 in 2007/2008 and 17,410 in 2008/2009. Spatial and temporal patterns were analyzed utilizing the 28 principal families and applying the Morisita–Horn coefficient and the Detrended Correspondence Analysis (DCA). Both results demonstrated variances of abundance and richness from 1 year to the next in the evaluated areas. The results indicate that the arthropod communities in southern Brazilian rice crop agro-ecosystems are formed of a few families with high abundance and a large number of other smaller families. Among the phytophagous arthropods found, Pentatomidae, Orthoptera and planthoppers were predominant while the natural enemies were mainly predatory mites, spiders, Hymenoptera and Odonata. This study demonstrates that irrigated rice fields located in subtropical areas of the Brazilian South sustain a great variety of arthropods which facilitate studies on bio-diversity conservation and the development of sustainable management of the pests." 11204. Gliwa, B. (2011): On the names of dragonflies and damselflies. New and rare for Lithuania insect species 23: 115-119. (in Lithuanian, with English summary) ["The paper criticizes the common view in Lithuania to call the scientific names of taxa "Latin" and introducing an additional layer of "Lithuanian scientific names". It is outlined that the scientific names aren't Latin but following the ICZN rules only. They can be seen as a part of the sociolect used by Lithuanian zoologists, which is a subset of the Lithuanian language. There is no need for additional Lithuanian taxa names in science. However, vernacular names can be useful in a wider discussion. Wherever possible, traditional names should be used. Adaption of the scientific names or translation are recommended ways of forming. Creation of new ad hoc names should be limited to a minimum. There is no need to normalize vernacular names." (Author)] Address: Gliwa, B., Lithuanian Entomological Society, Akademijos 2, 08412 Vilnius, Lithuania. E-mail: gliwa@sargeliai.org

11205. Gonzalez, S.C.; Touchon, J.C.; Vonesh, J.R. (2011): Interactions between competition and predation shape early growth and survival of two Neotropical hyliid tadpoles. *Biotropica* 43(5): 633-639. (in English, with Spanish abstract) ["Experimental studies in temperate regions have revealed that competition and predation interact to shape aquatic communities. Predators typically reduce the effect of competition on growth and competitors provide alternative prey subjects, which may also alter predation. Here, we examine the independent and combined effects of competition and predation on the survival and growth of hatchling tadpoles of two widespread co-occurring Neotropical hyliid frogs

(*Agalychnis callidryas* and *Dendropsophus ebraccatus*). Using 400 L mesocosms, we used a 2 × 3 factorial substitutive design, which crossed tadpole species composition with the presence or absence of a free-roaming predator (*Anax amazili* larva). Dragonflies were effective predators of both species, but had larger effects on *A. callidryas* survival. Both species had similar growth rates when alone, whereas *A. callidryas* grew 30% faster than *D. ebraccatus* when they co-occurred, suggesting interspecific rather than intraspecific competition had relatively stronger effects on *D. ebraccatus* growth, while the opposite was true for *A. callidryas*. Predator presence dramatically reduced growth rates of both species and erased this asymmetry. Results suggest that the effects of predator induction (i.e., nonconsumptive effects) on growth were larger than both consumptive and competitive effects. Our study demonstrates that predators have strong effects on both survival and growth of prey, highlighting the potential importance of predators in shaping prey populations and tropical aquatic food web interactions." 11206. Greeney, H.F.; Dyrz, A. (2011): Breeding biology of Pale-edged Flycatcher (*Myiarchus cephalotes*) in northeastern Ecuador. *Ornitología Colombiana* 11: 49-57. (in English, with Spanish summary) ["We made observations on the reproductive habits of *M. cephalotes* nesting in nest boxes and under the eaves of human dwellings in northeastern Ecuador. We found a total of six nests, likely built by the same two pairs. Nest construction lasted around 23 days at one nest and was performed only by the female. Most clutches are initiated during the drier months, but there may be some breeding year-round. Clutch size ranged from two to three eggs. Only females incubated and spent the night on the nest. Patterns of attendance during incubation were fairly regular and eggs were covered for 62% of daylight hours. Incubation period was 18 days at two nests. At two nests eggs hatched synchronously and at a third two eggs hatched 24 h prior to the final egg. The nestling period was 18 days. Based on observations of one banded pair in 2008 and 2009, females provide the majority of nestling care (61%). Nestlings were provisioned with a large percentage of adult Lepidoptera and cicadas, with females bringing predominantly Lepidoptera and males favouring cicadas. After leaving the nest, young birds remained with their parents for at least 10 weeks and were still provisioned by them for at least the first nine weeks." (Authors) Odonata accounted to 2.1% of the nestlings diet.] Address: Greeney, H.F., Yanayacu Biological Station & Center for Creative Studies c/o Foch 721 y Amazonas, Quito, Ecuador. 11210. Gualdoni, C.M.; Duarte, C.A.; Medeot, E.A. (2011): Estado ecológico de dos arroyos serranos del sur de Córdoba, Argentina. *Ecología Austral* 21: 149-162. (in Spanish, with English summary) ["Ecological status of two mountain streams of the south of Córdoba, Argentina: The development of methodology that allows us to assess the environmental deterioration of fluvial systems from the biotic components has been of high attention in the last time. With the aim to evaluate the ecological state of two mountains streams in sections that cross communes of tourist interest, indexes of water and riparian forest quality were combined. In each stream, two stations were selected, one downstream and the other upstream of the recreation areas. Environmental data were registered and benthos samples were collected in the main geomorphological units, during high and low water periods. Metric indexes and Índice Biótico Carcarañá (IBC) based on benthic macroinvertebrates were calculated, and the marginal forest quality was determined by the Riparian Quality Index (QBR). The results were integrated by a modification of index ECOSTRIMED to evaluate the ecological status of the fluvial system. In both streams, the physico-chemical variables showed normal values and the metric indexes determined that the water quality vary between "moderately deteriorated" and "little deteriorated", whereas the IBC revealed a "unpolluted environment" in all sampling situations. Application of QBR showed that the riparian forest with important alterations and extreme degradation were located close to urban areas, while in the other reaches the alteration degree was translated in judgments of acceptable and good quality. When combining the results of the metric indexes with those of the QBR, in both streams were obtained quality judgments that indicated "good" and "intermediate" ecological status in the stretches located upstream of urban areas and "intermediate" in the stretches downstream of recreation areas. The results of this study contribute to corroborate that, from a biological perspective; the application of a set of metric is the most efficient and economic methodology, to evaluate the quality of the water since they integrate infor-

mation derived from diverse aspects of the benthonic community. Although in the studied streams the water didn't have very good biological quality, in urban reaches, the degradation or elimination of the marginal vegetation was the main determinant of the altered ecological quality." (Authors) Taxa - including Odonata - are treated at the order level.] Address: Gualdoni, Cristina, Dto. de Ciencias Naturales, Facultad de Ciencias Exactas, Físico-Químicas y Naturales, Universidad Nacional de Río Cuarto. Río Cuarto, Córdoba, Argentina. E-mail: cgualdoni@exa.unrc.edu.ar

11211. Gutierrez, Jr., P.M.; Torres, M.A.J.; Demayo, C.G. (2011): Thin-plate spline (TPS) and correlation based on distances (CORIANDIS) analyses as tools for the analysis of morphological differences in dragonfly wings. 2011 2nd International Conference on Environmental Science and Technology, IPCBEE vol. 6, IACSIT Press, Singapore: V2-375-V2-379. (in English) ["This study was aimed to analyzed the morphological disparity in the wing shape and venation of five different dragonfly species namely: *Pantala flavescens*, *Aethriamanta brevipennis*, *Libellula incestra*, *Libellula croceipennis*, and *Gomphus externus* using Thin-Plate Spline (TPS) coupled with CORIANDIS analysis. These were done for triangle, anal loop and outline shape of the left and right forewings and hindwings of the dragonfly samples. Results showed that the locations of the species in the "compromise" space reflect a high similarity between species 2 and 3 (*A. brevipennis* and *L. incestra* respectively) however, species 1, 4 and 5 (*P. flavescens*, *L. croceipennis* and *G. externus*, respectively) show disparity with each other. Furthermore, there is congruence of anal loops (left forewings and right forewings) characters in species 1 (*P. flavescens*) and the triangle left forewing and anal loop right forewing in species 4 (*L. croceipennis*). Stacked bar graphs also shows that species 1 (*P. flavescens*) departs considerably from other species, although this seems to be largely a function of disparity of character 1 (triangle right forewing) alone. Species 3 and 4 (*L. incestra* and *L. croceipennis* respectively) show close similarity of outline left hind wing (dark red). The high similarity of the character is maybe due to the fact that these two different species belong to the same genus. Species 2 and 3 (*A. brevipennis* and *L. croceipennis*) also indicate close similarity of outline left hind wing and anal loop right hind wing characters (dark red and yellow-green respectively). Species 5 (*G. externus*) indicates high level disparity of outline left hind wing (dark red) character from other dragonfly species. Results of this study suggests that Thin-Plate Spline (TPS) and CORIANDIS analysis can be used as a tool for morphological disparity in dragonfly wings using various characters like triangle, anal loop and outline." (Authors) Comment of Reagan Villanueva: "Well, you are right about the ID. They listed 2 species totally impossible in the country and two near impossible. I think the right ID is *Rhodothemis rufa* for *Libellula croceipennis*, *Aethriamanta brevipennis* is *Orthemum prunosum clelia* (young male), *Libellula incestra* as *Potamarcha congener*; *Gomphus externus* as *Ictinogomphus tenax* female. The good thing, the *Pantala* is correctly identified."] Address: Gutierrez, Jr., P.M., Misamis Occidental National High School, Gov. Anselmo Bernad St., Poblacion 1, Oroquieta City, Philippines. K.; Dévai, G. (2011): Morphometric and molecular studies on the populations of the damselflies *Chalcolestes viridis* and *C. parvidens* (Odonata, Lestidae). *International Journal of Odonatology* 14(4): 329-339. (in English) ["Morphometric and genetic differences were analysed for two closely related damselflies, *Chalcolestes viridis* and *C. parvidens*. A total of 305 male individuals were collected from six European countries (Austria, Croatia, Germany, Greece, Hungary and Portugal). Measurements from a total of 28 populations of *C. viridis* and *C. parvidens* and several intermediate forms were collected to determine if they can be definitely distinguished using simple morphometric characters. DNA sequences from two independent loci (nuclear ribosomal ITS region and mitochondrial cytochrome oxidase I gene) were analysed to test whether these taxa represent separate monophyletic groups as well as to compare the genetic distance with those found between well-accepted European *Lestes* species. Discriminant analysis revealed that *C. viridis* and *C. parvidens* are differentiated in morphometric space. Individuals with intermediate anal appendage traits overlapped with both *C. viridis* and *C. parvidens* which raised the possibility that they are merely subspecies of a single species. However, genetic analysis of both investigated DNA regions showed that the two *Chalcolestes* taxa did not share haplotypes, indicating their status as true species. Furthermore, they formed a monophyletic group separated from the investigated *Lestes* species, supporting the recognition of the genus *Chalcolestes*. The two *Chalcolestes* species are very closely related compared with European *Lestes* species, suggesting that their divergence occurred relatively recently." 11214. Hamasaki, K.; Yamanaka, T.; Tanaka, K.; Nakatani, Y.; Iwasaki, N.; Sprague, D.S. (2011): Environmental characteristics accounting for odonate assemblages in rural reservoir ponds in Japan. *JARQ* 45(2): 187-196. (in English) ["To clarify the effect of environmental factors on odonate assemblages in rural reservoir ponds, we surveyed the odonate adults in 70 study ponds in Ibaraki Prefecture, Japan, during three sampling periods in 2005. Cluster analysis, indicator species analysis (INSPAN), and non-metric multidimensional scaling (NMDS) were used in combination to determine the relationship between odonate assemblages and environmental variables, i.e., biotic, physicochemical, and regional variables (the types of land use surrounding the ponds). A total of 41 odonate species were recorded in the study ponds, and 24 of them, excluding rare species, were used for each analysis. The study ponds were classified into six groups, and significant indicator species were selected from four of these

groups. Examination of the correlation between each environmental variable and NMDS axes 1 and 2 revealed the profound effects of the presence of forest, paddy field, or open area around the ponds on the indicator species composition of each group. It was also revealed that the aquatic vegetation and forests around the ponds provide desirable conditions for the odonates and, in contrast, concrete revetment has a detrimental effect. These results suggest that the recent decrease of forests around ponds and the reconstruction with concrete revetment will have a negative effect on the odonate assemblages in ponds." 11217. Hassall, C.; Hollinshead, J.; Hull, A. (2011): Environmental correlates of plant and invertebrate species richness in ponds. *Biodiversity and Conservation* 20: 3189-3222. (in English) ["Ponds (lentic water bodies <2

ha) constitute a considerable biodiversity resource. Understanding the environmental factors that underlie this diversity is important in protecting and managing the habitat. We surveyed 425 ponds for biological and physical characteristics with 78 of those also surveyed for chemical characteristics. A total of 277 invertebrate species and 265 plant species were found. Species richness varied between 2 and 99 (mean 27.2 ± 0.6 SE) for invertebrates and 1 and 58 (mean 20.8 ± 0.4 SE) for plants. Generalised additive models were used to investigate variables that correlate with the species richness of plants and invertebrates, with additional models to investigate insect, Coleoptera, Odonata, Hemiptera, Trichoptera and Mollusca species richness. Models performed reasonably well for invertebrates in general ($R^2 = 30.3\%$) but varied between lower-order invertebrate taxa (12.7–34.7%). Ponds with lower levels of shading and no history of drying contained higher numbers of species of plants and all invertebrate groups. Aquatic plant coverage positively correlated with species richness in all invertebrate groups apart from Trichoptera and the presence of fish was associated with high invertebrate species richness in all groups apart from Coleoptera. The addition of chemistry variables suggested non-linear relationships between oxygen demand and phosphate concentration and higher-order richness. We demonstrate that the composition of biological communities varies along with their species richness and that less diverse ponds are more variable compared to more diverse ponds. Variables positively correlated with richness of one taxon may be negatively correlated with that of another, making comprehensive management recommendations difficult. Promoting a high landscape-level pond biodiversity will involve the management of a high diversity of pond types within that landscape." 11218. Haught, S.; von Hippel, F.A. (2011): Invasive pike establishment in Cook Inlet Basin lakes, Alaska: diet, native fish abundance and lake environment. *Biol. Invasions*. 13: 2103-2114. (in English) ["Northern pike (*Esox lucius*) were introduced to the northern Susitna Basin of south-central Alaska in the 1950's, and have since spread throughout the upper Cook Inlet Basin. Extirpations of several native fish populations have been documented in this area. It is hypothesized here that invasive pike remodel the ecology of lakes by removing vulnerable prey types and that these changes are reflected in the diet of invasive pike. Trends in pike diet suggest that pike switch to less desirable but more abundant macroinvertebrate prey as preferred fish prey are eliminated. The impacts of pike introduction were studied in detail for one species of resident fish, the threespine stickleback (*Gasterosteus aculeatus*). Stickleback abundance decreases as pike invasion progresses. Conductivity is a significant environmental predictor of stickleback abundance, with higher conductivity apparently mitigating population reduction. Higher conductivity water may lessen the physiological costs of developing more robust armor, which reduces vulnerability to predation. Maximum lake depth also appears to predict stickleback abundance, though this trend was only marginally significant. Deeper lakes may provide an open-water refuge from pike predation by allowing stickleback to exist outside of the pike inhabited littoral zone. These findings indicate the importance of diverse habitat types and certain chemical and physical charac-

teristics to the outcome of invasion by fish predators." (Authors) Where stickle backs were absent, more Odonata larvae were preyed by pikes.] Address: Haught, S., Department of Biological Sciences, University of Alaska Anchorage, 3211 Providence Dr., Anchorage, AK 99508-4614, USA. 11223. Jeziorski, P.; Holuša, O. (2011): *Gomphus pulchellus* Sélys, 1840 does not belong to the dragonfly (Odonata) fauna of the Czech Republic. *Cas. Slez. Muz. Opava (A)* 60: 217-222. (in English, with extensive Czech summary) [*Gomphus pulchellus* is eliminated from the Czech list of Odonata. "This decision is based on the revision of the material deposited in all major Czech and Slovak museums, on the revision of several other dragonfly collections, as well as on an extensive faunistic research carried out by the authors during the last twenty years. In addition, the published data were critically evaluated. In summary, no documented specimens in museums or private collections was found, and there are no recent records from the Czech Republic. Hence deletion of *G. pulchellus* from the species list of the Czech Republic is suggested. Reasons for the absence in the Czech Republic are discussed." (Authors)] Address: Jeziorski, P., Na Bělidle 1, CZ-735 64 Havířov-Suchá, Czech Republic. E-mail: jezirko@post.cz

11224. Jones, G. (2011): Challenges facing conservation of rare damselfly and stonefly in Cairngorms. *Scottish Invertebrate News* 2(2): 10. (in English) ["*Coenagrion hastulatum* is listed as endangered on the Odonata Red Data List for Great Britain 2008 and most of its known UK breeding sites are in the Cairngorms National Park. As one of our most endangered damselflies it also appears on the Scottish Biodiversity List. In 1996 the Northern damselfly was confirmed as breeding at 21 of 26 historic sites. Of these, only 10 were found to be producing more than 100 adults. A high proportion of these were on the RSPB's Abernethy Reserve. Two additional sites for the species have recently been identified, one of which has historic records of Northern damselfly up until 1914. However, it is a both are currently threatened as they are within the footprint of proposed developments: a large new town. An Camas Mor, on Rothiemurchus Estate (the other side of the River Spey from Aviemore) and a supermarket car park for a new Tesco store in Aviemore. Understanding the factors that limit the dispersal of the Northern damselfly could guide conservation efforts for the shrinking semi-natural habitat around Aviemore. If breeding lochans are saved, attention will need to be given to the management of nearby scrubby-ground that is used for foraging and during maturation of recently emerged adults." (Author)] Address: not stated

11226. Kalniņš, M. (2011): The distribution of southern dragonfly (Odonata) species in Latvia and adjacent territories. *Environmental and Experimental Biology* 9: 43-52. (in English) ["The aim of the present study was to summarize published and unpublished information on changes of the dragonfly fauna in Latvia and adjacent territories during the last 20 years and to provide a prognosis of future changes. All published and unpublished data were summarized for the selected species. Unsystematic inspection of the potential habitats was carried out in the field, mostly in southern and central parts of the country. The identification of specimens in collections was checked. In total 19 species were identified whose borders of distribution areas or separate localities are relatively close to the territory of Latvia or which are known as species that rapidly disperse in the northern direction. Seven of these species are mentioned in the literature as probable for Latvia. Five of the species that are included in the lists were recorded for the first time in Latvia during the last 20 years." (Author) The following species are discussed in detail: *Lestes barbarus*, *Chalcolestes viridis*, *Sympetma fusca*, *Coenagrion ornatum*, *Erythromma viridulum*, *Aeshna affinis*, *A. serrata*, *A. crenata*, *Anax parthenope*, *A. ephippiger*, *Orthetrum coerulescens*, *O. albistylum*, *O. brunneum*, *Sympetrum depressiusculum*, *S. fonscolombii*, *S. meridionale*, *S. eroticum*, *S. pedemontanum*, and *Crocothemis erythraea*.] Address: Kalniņš, M., Nature Conservation Agency, Siguldas novads, Baznīcas iela 7, LV-2150, Sigulda, Latvia. 11227. Karlsson, T. (2011): The Sedgling *Nehalennia speciosa* in Sweden (Odonata: Coenagrionidae). *Entomologisk Tidskrift* 132(3): 129-140. (in Swedish, with English summary) ["*N. speciosa* is redlisted as endangered in Sweden. This paper presents the current knowledge of the species in Sweden. Records of the species, its distribution and status are presented, and the habitat at the current localities for the species are described. *Nehalennia speciosa* was considered extinct in Sweden, but during the period 2006-2011 six new localities have been found. The species is generally thought being highly stenotopic. It is confined to water with low trophy, pH and conductivity, and with a specific vegetation consisting of submerged vegetation (*Sphagnum* mosses and *Utricularia*) and formations of narrow-leaved plants (mostly selected *Carex lasiocarpa* and *C. limosa*). The habitat in Sweden seems, however, to differ some. The current localities for the species are nutrient poor wetlands with a vegetation like the one described above (*C. lasiocarpa* predominates), but they are all mires rich in minerals with fairly high pH (7.0-8.0) and conductivity (11.7-15.5). Changes in vegetation structure (mainly domination of *Phragmites australis*) are the main threat to the species, and management by mowing is needed." (Author)] Address: Karlsson, T., Västanågatan 27B, 582 35 Linköping, Sweden. E-mail: tommy.karlsson@bredband.net

11228. Kharitonov, A.Yu.; Popova, O.N. (2011): Migrations of dragonflies (Odonata) in the south of the West Siberian plain. *Entomological Review* 91(4): 411-419. (in English) ["The paper presents a summary of mass dragonfly migrations observed previously in Russia, in particular in West Siberia. From 1969 to 2009, the authors studied the dynamics of dragonfly population,

their spatial distribution and movements in the West Siberian forest-steppe. The main studies were conducted in the Lake Chany basin (the Biological Station of the Institute of Animal Systematics and Ecology, Siberian Division, Russian Academy of Sciences). The spatial redistribution of dragonflies is regarded as a balance of homing and wandering behaviour. Homing results in a relative stability of local dragonfly populations and assemblages, while wandering leads to dispersal of dragonflies from their emergence sites and colonization of new habitats; the latter is especially important due to the ephemeral nature of many shallow reservoirs where the nymphs develop. The formation of more or less constant migration routes is a peculiar variant of wandering activities. A special type of dragonfly migrations is mass exodus from native habitats, triggered by excessive population growth and leading to elimination of all or most individuals. Such migrations not only optimize the size of dragonfly populations but also facilitate removal of nutrients and organic matter from eutrophic water bodies. An original generalized classification of dragonfly migrations is proposed." 11229. Kische-Machumu, M.A.; Witte, F.; Wanink, J.H.; Katunzi, E.F.B. (2011): The diet of Nile perch, *Lates niloticus* (L.) after resurgence of haplochromine cichlids in the Mwanza Gulf of Lake Victoria. *Hydrobiologia* 682: 111-119. (in English) ["Haplochromine cichlids used to be the main prey of the introduced Nile perch, *Lates niloticus*, in Lake Victoria. After depletion of the haplochromine stocks at the end of the 1980s, Nile perch shifted to the shrimp *Caridina nilotica* and to a lesser degree to its own young and the cyprinid *Rastrineobola argentea*. In the present study, we investigated the Nile perch diet in the northern Mwanza Gulf after resurgence of some of the haplochromine species and compared it with data collected in the same area in 1988/1989. It became clear that haplochromines are again the major prey of Nile perch. The dietary shift from invertebrate feeding (shrimps) to feeding on fish (haplochromine cichlids) occurs at a smaller size than it did when Nile perch were taking primarily dagaa and juvenile Nile perch as their fish prey. The apparent preference for haplochromines as prey has reduced the degree of cannibalism considerably, which may have a positive impact on Nile perch recruitment." (Authors) The quantity of Odonata didn't change between the two periods compared.] Address: Kische-Machumu, M.A., Tanzania Fisheries Research Institute, P.O. Box 78850, Dar es Salaam, Tanzania. 11230. Klemmer, A.J. (2011): The influence of stream-derived detritus subsidies on lake benthic community composition and trophic interactions. M.Sc. thesis, Fac. Grad. Studies (Forestry), University of British Columbia, Vancouver: XII + 77 pp. (in English) ["Cross-ecosystem subsidies are important for the structure and functioning of communities within many ecosystems. Increases in subsidies have been modelled to increase trophic cascade strength within recipient systems, because of the donor-controlled addition of a resource. Streams receive high inputs of detrital subsidies and what is not processed within the system is transported downstream. Therefore, streams that flow into lakes have the potential to provide large amounts of detritus to lakes compared to the transfer of detritus from forested lake

edges. I hypothesized that streams would increase detritus standing stocks around stream mouths in lakes, that streams would affect the benthic invertebrate community composition, and that those effects would change with distance from the lake shore. To test this I conducted a survey of detritus standing stocks and benthic invertebrate communities at six stream/lake interface and six forest/lake interface sites within two lakes. I found that streams and distance into lakes affected detritus standing stocks, but the effect was only seen when individual pairings of stream and forest sites were examined. I also found that headwater streams significantly altered invertebrate community composition in the lake littoral zone, even up to a distance of 27 meters into the lakes, with some taxa only found at stream/lake interfaces. These results suggest that streams alter the amount of basal resources through subsidies and contribute to whole lake biodiversity. My second hypothesis was that increased detritus in lakes would increase trophic cascade strength. To test this hypothesis, I conducted an in-lake cage experiment in which I manipulated detritus standing stocks (5 densities) and presence of a top-predator (trout). I found that increasing subsidies altered strength of trophic cascades. But unexpectedly, low detritus treatments experienced the strongest positive effect on algal biomass. At intermediate detritus levels there was a switch in the indirect effects of predators, and at the highest detritus densities predators had a negative indirect effect on algal biomass. These results provide evidence that along a gradient of detritus subsidies, trophic cascade strength experiences threshold responses in where predators may have strong, but opposite indirect effects on primary production." (Author) Taxa including Odonata are treated at the genus level.] Address: not stated

11231. Kloskowski, J. (2011): Differential effects of age-structured common carp (*Cyprinus carpio*) stocks on pond invertebrate communities: implications for recreational and wildlife use of farm ponds. *Aquacult. Int.* 19: 1151-1164. (in English) ["Sustainable development of common carp *Cyprinus carpio* pond fisheries in Europe postulates their multifunctional use, integrating exploitation of aquaculture resources with recreational services and maintenance of high levels of local biodiversity. Age classes of farmed carp are grown separately and pond ecosystems may be differently affected by different ontogenetic stages of fish. To examine these relationships, a study was conducted on spring and summer diet of carp, invertebrate abundance and community structure, and water quality characteristics in ponds stocked with three carp age classes in SE Poland. With the exception of young-of-the-year fish in spring, benthic dipterans prevailed in the diets of all carp age classes and their consumption increased from spring to summer. Zooplankton featured in the diet of carp only in spring. Medium- and large-sized cladocerans predominated among microcrustaceans found in the guts of one- and two-year-old carp. Consequently, in summer, total biomass of medium- and large-sized cladoceran grazers was substantially lower in ponds stocked with older-age fish than in ponds used for production of 1-summer-old fingerlings. The relatively sparse submerged vegetation cover and low water transparency in ponds with older fish stocks compared to ponds with young-of-the-year carp indicate a transition to a turbid water state mediated by a trophic cascade mechanism in the presence of older-age fish. ... Densities of macroinvertebrates were significantly affected by the age of carp in the ponds.

With the exception of Diptera there were differences in the densities of all individual macroinvertebrate groups between pond categories. In all macroinvertebrate taxa, densities decreased with carp age, but the differences between pond categories were significant only in Ephemeroptera and Odonata between 0+ and older carp cohorts." 11233. Koch, K.; Fuchs, N.; Sahlén, G. (2011): Morphology of follicle cells of Libellulidae (Odonata). *International Journal of Odonatology* 14(3): 257-267. (in English) ["In libellulids, mature oocyte size varies within and between individual ovaries. The regulating mechanism is not yet understood. Variations in the contents of the follicle cells, and thereby their ability to secrete material into the oocyte, might explain some of the observed differences in oocyte size. We therefore investigated the follicle cell surface, the interstitial space width between follicle cells and between follicle cells and oocytes, the number of nuclei, and the cell compartment proportions using scanning and transmission electron microscopy. In all investigated species, the follicle cells were covered by a basal lamina. We found cytoplasmic microvilli and septate junctions. As we could not find any pores or other structures on the cell surface, endocytosis seems to be the only mechanism transporting material into the follicle cells. Larger follicle cells had larger interstitial gaps between follicle cells and oocytes, larger nuclei and a larger mitochondrial area. Larger interstitial spaces between follicle cells and oocytes may afford more room that can be filled with material from the follicle cell layer. More mitochondria could provide more energy/ATP needed for the transport of the material. The quantity of free ribosomes and the mean number of nuclei seemed to be even more important to the productivity of the follicle cell. All these variations in cell contents cause productivity differences among follicle cells and may explain some of the size differences between oocytes within individual ovaries in libellulids." 11237. Kweka, E.J.; Zhou, G.; Gilbreath, T.M.; Afrane, Y.; Nyindo, M.; Githeko, A.K.; Yan, G. (2011): Predation efficiency of *Anopheles gambiae* larvae by aquatic predators in western Kenya highlands. *Parasites & Vectors* 2011, 4:128: 7 pp. (in English) ["Background: The current status of insecticide resistance in mosquitoes and the effects of insecticides on nontarget insect species have raised the need for alternative control methods for malaria vectors. Predation has been suggested as one of the important regulation mechanisms for malaria vectors in long-lasting aquatic habitats, but the predation efficiency of the potential predators is largely unknown in the highlands of western Kenya. In the current study, we examined the predation efficiency of five predators on *Anopheles gambiae* s.s larvae in 24 hour and semi-field evaluations. Methods: Predators were collected from natural habitats and starved for 12 hours prior to starting experiments. Preliminary experiments were conducted to ascertain the larval stage most predated by each predator species. When each larval instar was subjected to predation, third instar larvae were predated at the highest rate. Third instar larvae of *An. gambiae* were introduced into artificial habitats with and without refugia at various larval densities. The numbers of surviving larvae were counted after 24 hours in 24. In semi-field experiments, the larvae were counted daily until they were all either consumed or had developed to the pupal stage. Polymerase chain reaction was used to confirm the presence of *An. gambiae* DNA in predator

guts. Results: Experiments found that habitat type ($P < 0.0001$) and predator species ($P < 0.0001$) had a significant impact on the predation rate in the 24 hour evaluations. In semi-field experiments, predator species ($P < 0.0001$) and habitat type ($P < 0.0001$) were significant factors in both the daily survival and the overall developmental time of larvae. Pupation rates took significantly longer in habitats with refugia. *An. gambiae* DNA was found in at least three out of ten midguts for all predator species. *Gambusia affinis* was the most efficient, being three times more efficient than tadpoles. Conclusion: These experiments provide insight into the efficiency of specific natural predators against mosquito larvae. These naturally occurring predators may be useful in biocontrol strategies for aquatic stage *An. gambiae* mosquitoes. Further investigations should be done in complex natural habitats for these predators." (Authors) The dragonfly larvae's efficacy in reducing the survival rates of third instar larvae of *An. gambiae* s.s was assessed in semi-field experimental settings. Their efficiency was estimated as high as 59.6%.] Address: Kweka, E.J., Centre for Global Health Research, Kenya Medical Research Institute, P. O. Box 1578, Kisumu 40100, Kenya. 11239. Landis, D.A.; Fiedler, A.K.; Hamm, C.A.; Cuthrell, D.L.; Schools, E.H.; Pearsall, D.R.; Herbert, M.E.; Doran, P.J. (2011): Insect conservation in Michigan prairie fen: addressing the challenge of global change. *Journal of Insect Conservation* 16(1): 131-142. (in English) ["Prairie fen is a globally rare, groundwater dependent peatland community restricted to discrete portions of the glaciated north central USA. Prairie fen harbours a diverse flora composed of sedge wetland and tallgrass prairie species ... Here we investigate how global change drivers, including land use change, climate change, and invasive species, may interact to threaten this important community. Specifically, we examine how characteristics of prairie fen habitats—e.g., formation and distribution—interact with the biology of rare fen insects to suggest appropriate short to long term conservation strategies. Our results suggest that

prairie fen associated insects are rare for a variety of reasons, including host plant specialization, habitat specialization, and shifting landscape context that limits opportunities for dispersal. We recommend that current conservation efforts focus on stabilization and restoration of existing prairie fens, coupled with directed surveys to monitor population change in insects of concern, and restoration of the landscape matrix to facilitate metapopulation dynamics. In the future, due to the severely fragmented nature of Michigan landscapes, captive rearing and assisted migration may be necessary to conserve some prairie fen insect species. Overall, the effective conservation of fen associated insects will require a shared vision by multiple actors and a willingness to pursue that vision over a long time frame." (Authors) Tab. 1 list insects of conservation concern in prairie fen and associated aquatic communities in Michigan, USA, including *Cordulegaster erronea* and *Williamsonia fletcheri*.] Address: Landis, D.A., Department of Entomology, 204 Center for Integrated Plant Systems, Michigan State University, East Lansing, MI 48824-1311, USA. 11240. Lawrence, J.E.; Deitch, M.J.; Resh, V.H. (2011): Effects of vineyard coverage and extent on benthic macroinvertebrates in streams of Northern California. *Annales de Limnologie - International Journal of Limnology* 47(4): 347-354. (in English) ["Vineyards are a dominant feature of many landscapes in Mediterranean-climate regions. We examined the effects of streamflow declines, associated with vineyard water-withdrawals for frost protection, on benthic-macroinvertebrate communities at three sites along three small streams in the Mediterranean-climate region of Northern California. One site was heavily affected by water withdrawals for frost protection, the other two were not. In addition, we examined relationships between vineyard coverage and benthic-macroinvertebrate community response using data from 59 sampling events at 39 sites along 35 small streams in Napa County, California. We tested three a priori hypotheses in terms of the response of biological traits of benthic macroinvertebrates to high vineyard coverage: (1) proportion of individuals with semi-voltine (i.e., one generation every 2 years) life cycles would be lower compared to those with uni- and multi-voltine cycles, (2) proportion of individuals able to undergo diapause would be higher, and (3) proportion of individuals with the ability to burrow into the substrate would be higher. In the three-site study, we found that vineyard water-withdrawals for frost protection coincided with consistently lower values in both the benthic-macroinvertebrate index of biotic integrity (B-IBI) developed for Northern California streams and the ratio of Ephemeroptera–Plecoptera–Trichoptera to Odonata–Coleoptera–Hemiptera individuals (EPT/OCH), a metric developed for European Mediterranean streams. In the broader-scale study, we observed that vineyard-coverage levels above about 20% coincided with lower values of the B-IBI. The semi-voltine life-cycle trait was lower above this level, whereas the diapause and burrowing traits were not affected." 11243. Lorenzo-Carballa, M.O.; Hadrys, H.; Cordero-Rivera, A.; Andres, J.A. (2011): Population genetic structure of sexual and parthenogenetic damselflies inferred from mitochondrial and nuclear markers. *Heredity* 108: 386-395. (in English) ["It has been postulated that obligate asexual lineages may persist in the long term if they escape from negative interactions with either sexual lineages or biological enemies; and thus, parthenogenetic populations will be more likely to occur in places that are difficult for sexuals to colonize, or those in which biological interactions are rare, such as islands or island-like habitats. *Ischnura hastata* is the only known example of natural parthenogenesis within the insect order Odonata, and it represents also a typical example of geographic parthenogenesis, as sexual populations are widely distributed in North America, whereas parthenogenetic populations of this species have only been found at the Azores archipelago. In order to gain insight in the origin and distribution of parthenogenetic *I. hastata* lineages, we have used microsatellites, mitochondrial and nuclear DNA sequence data, to examine the population genetic structure of this species over a wide geographic area. Our results suggest that sexual populations of *I. hastata* in North America conform to a large subdivided population that has gone through a recent spatial expansion. A recent single long distance dispersal event, followed by a demographic expansion, is the most parsimonious hypothesis explaining the origin of the parthenogenetic population of this species in the Azores islands." 11245. Marinov, M. (2011): Dragonflies (Insecta: Odonata) from the Western Rhodopes (Bulgaria and Greece). In: Beron P. (ed) *Biodiversity of Bulgaria. 4. Biodiversity of Western Rhodopes (Bulgaria and Greece) II*. Pensoft & Nat. Mus. Natur. Hist. Sofia: 145-161. (in English) ["A total of 52 Odonata species are reported here for the Western Rhodopes with six new species for the region: *Lestes barbarus*, *L. macrostigma*, *Erythromma najas*, *Cordulegaster bidentata*, *Sympetrum vulgatum*, *S. flaveolum*. At least 58 species could be expected within the Western Rhodopes area. The same number was given as probable for the eastern part of the mountain by MARINOV 2004." (Publisher) *Note of the editor*: This paper is a poor reprint of the original publication Marinov, M., 2007. Odonata of The Western Rhodopes, with special reference to the wetlands North of the town of Smolyan, South Bulgaria. *Notulae Odonatologicae* 6(9): 97-108. It suffers several major faults, which are entirely due to the lack of communication between the editors of the volume and the author of the paper. The later saw it already integrated amongst other articles and printed out without being able to make any final comments and suggestions for improvement. People interested in the region are advised to search for the original paper and not consider this low quality reprint in their research.]]

11246. Maroneze, D.M.; Tupinambas, T.H.; Alves, C.B.M.; Vieira, F.; Pompeu, P.S.; Callisto, M. (2011): Fish as ecological tools to complement biodiversity inventories of benthic macroinvertebrates. *Hydrobiologia* 673: 29-40. (in English) ["Sampling benthic macroinvertebrates in large rivers has several limitations, arising not only from the selectivity of traditional sampling gears but also from difficulty in capturing organisms that inhabit the deeper zones and high current velocities. Considering the importance of benthic macroinvertebrates as a food resource for fishes, the sampling restrictions in sediment collection done by dredges, and the importance of surveying benthos biodiversity, the objective of this study was to evaluate the stomach contents of five commonly occurring insectivorous fish species as a means of complementing a benthic macroinvertebrate inventory. Three sampling campaigns (fish and benthic macroinvertebrate) were conducted in a reach of the Araguari River (Minas Gerais, Brazil), approximately 9 km long and 90 m wide. *Astyanax altiparanae* Garutti & Britski 2000, *Leporinus friderici* (Bloch 1794), *Leporinus amblyrhynchus* Garavello & Britski 1987, *Iheringichthys labrosus* (Lütken 1874) and *Pimelodus maculatus* Lacepede de 1803 were the fish species collected and studied. To determine benthic macroinvertebrate taxonomic richness, a total of 54 Van Veen sediment samples were obtained. We compared lists of the benthic taxa found in fish stomachs with those from the sediment samples. The differences in the taxonomic composition of the benthic macroinvertebrate communities between the sediment samples and each fish species stomachs contents were assessed through NMDS and ANOSIM analyses, using a Sorensen similarity index with the presence/absence of taxa data. Independ-

ent of sampling period, additional benthic macroinvertebrate families or classes were provided by identifying fish stomach contents. We found a total of 30 taxa in this study (including "Coenagrionidae, Gomphidae, Libellulidae"), including 5 unique taxa (or 17% of the total) in the sediment samples, 9 unique taxa (30%) in the stomach samples, and 16 taxa (53%) common to both. The NMDS and ANOSIM analyses showed a significant separation between Van Veen sediment samples and two fish species stomach contents— *L. amblyrhynchus* and *P. maculatus*. These results indicate that fish can be used as additional samplers and are an efficient method to complement the benthic taxonomic inventory obtained through traditional sediment sampling techniques in large areas, as river segments and catchments." 11247. Martins, F.A.; del Claro, K. (2011): Natural history in dragonfly (Odonata) interactions of Cerrado vegetation. *Capa* 5(2): 20 pp. (in Portuguese, with English summary) ["The description of dragonfly species natural history involves the study of important features on Odonata community, as interspecific and intraspecific interactions and climatic parameters. This study aimed to investigate the most important features those can contribute to the inclusion of *Ischnura ramburii* in interaction ecology studies on Cerrado. The study was conducted at a permanent pond, in a nature reserve at Clube de Caça e Pesca Ipororó de Uberlândia. Behaviour observations were done and species biology data were quantified. Predation behaviour usually occurs on the pond, in areas with prey abundance. Individuals use their legs to catch their prey. The breeding happens in the air. The oviposition is endofitic and during it, female and male remain on tandem position. Female eventually remains submerged during the egg lay. On agonistic interactions between intraspecific and interspecific males were observed the behavioural patterns: i) tolerance; ii) perch; iii) caution display and; iv) attack. Besides this, faceoff, behaviour in which two damselflies stand face to face for some seconds, was observed in this species. It was verified higher abundance on the hottest months of the year (spring and summer). It wasn't found a direct correlation between the environment middle temperature and abundance of individuals, along the seasons ($r_s = 0,800$; $p > 0,05$), but is verified a trend to correlation." (Authors)] Address: Martins, F.A., Laboratório de Ecologia Comportamental e Interações, Instituto de Biologia, Universidade Federal de Uberlândia, Rua Ceará, s/nº Bloco 2D - Campus Umuarama, 38400-902, Uberlândia, MG - Brasil - Caixa Postal: 593. 11249. Matushkina, N.A. (2011): Morphology of exophytic ovipositors in dragonflies (Odonata: Gomphidae, Corduliidae, Libellulidae), with particular reference to ovipositor muscles and sensilla. *International Journal of Odonatology* 14(3): 223-248. (in English) ["A comparative study of female external genitalia was carried out in representatives of three dragonfly families that lay eggs exophytically, with special emphasis placed on skeletal musculature and sensilla. Female external genitalia are characteristically represented by the vulvar lamina and rudiments on the 9th sternum. In a gomphid, *Gomphus vulgatissimus*, and a cordulid, *Cordulia aenea*, the vulvar laminae bear numerous styloconic sensilla and sparse campaniform sensilla. In addition, the rudiments of *C. aenea* are richly furnished with basiconic sensilla, each with an apical pore. In corduliids and libellulids the ovipositor musculature is formed by two antagonistic muscles, contractions of which cause up- and downward movements of the middle part of the 9th sternum, where rudiments are usually located. Characteristically, gomphid females lack both the ovipositor-related muscles and rudiments. Based on the present results, the rudiments may be reasonably homologized with the gonapophyses of the 9th segment of the plesiomorphic well-developed ovipositor. The proposed functional interpretations of the ovipositor derivatives in Odonata with exophytic oviposition are discussed in light of their egg laying behaviour." (Author) The analysis includes the following taxa: *Gomphus vulgatissimus*, *Onychogomphus forcipatus*, *Lindenia tetraphylla*, *Cordulia aenea*, *Epithea bimaculata*, *Somatochlora metallica*, *Orithetrum cancellatum*, *Sympetrum vulgatum*, and *S. sanguineum*.] Address: Matushkina, Natalia, Department of Zoology, Biological Faculty, Kyiv National University, vul. Thesis, College of Arts and Sciences, Georgia State University: X + 66 pp. (in English) ["To determine the relationship between the abundance and den-

sity of benthic invertebrates, and the critical shear stress of individual grain sizes, a reach along Smith Creek, was divided into ten 2m x 2m quadrants. Within each quadrant, five randomly selected clasts for each grain size ranging from 2.26 to 25.6 cm were cleaned for benthic invertebrates. Wolman pebble counts for each quadrant were also conducted and used to determine the critical Shields stress per grain size fraction from the model given by Wiberg and Smith (1987) that explicitly accounts for particle hiding/sheltering effects in mixed-bed rivers. Particle entrainment values were then compared with estimated bankfull Shields stress values to determine sediment transport potential during bankfull flow. Invertebrate abundance was strongly positively correlated with critical Shields stress up to the 18.0 cm grain size, indicating a preference for certain grain sizes; while density was positively correlated with all grain sizes present." (Author) Among 9114 collected specimens only one Odonata was represented.] Address: Mayoral, Helen, College of Arts and Sciences, Georgia State University, USA. E-mail: hmayoral1@student.gsu.edu

11257. Molina, C.I.; Gibon, F.-M.; Oberdorff, T.; Dominguez, E.; Pinto, J.; Marin, R.; Roulet, M. (2011): Macroinvertebrate food web structure in a floodplain lake of the Bolivian Amazon. *Hydrobiologia* 663: 135-153. (in English) ["Two stable isotopes $\delta^{13}C$ and $\delta^{15}N$ were used to identify the energy sources and trophic relationships of the main freshwater macroinvertebrates in a floodplain lake of the Beni River (Bolivian Amazonia). Four energy sources (seston, bottom sediment, periphyton, and aquatic macrophytes) and macroinvertebrate communities were collected during three periods of the river hydrological cycle. Macroinvertebrates showed greater temporal variation in isotope values than their food sources. Six trophic chains were identified: four were based on seston, periphyton, C3 macrophytes, and bottom sediments, and the last two chains on a combination of two carbon sources. One mixed seston and periphyton sources during the wet season while the other mixed periphyton and macrophytes sources during the wet and dry seasons. Periphyton was the most

important energy source supporting the highest number of trophic levels and consumers. The macrophytic contribution was only significant during the dry season. Bottom sediments constituted a marginal energy source. As each season is associated with different physical and chemical conditions, processes organizing macroinvertebrate food web structure in the Beni floodplain seem strongly linked to hydrological seasonality." (Authors) The authors analyzed 243 macroinvertebrate samples representing 38 taxa. The dominant taxa were *Belostoma* sp., (Hemiptera), *Dythemis* sp., *Limnetron* sp. (Odonata), *Hydrophilus* spp. (Coleoptera), *Palaeonetes ivonicus* (Crustacea, Decapoda) and *Pomacea scalaris* (Mollusca, Gasteropoda). Ten out of the 38 taxa are Odonata (treated at the genus level).] Address: Molina, C.I., Instituto de Ecología, Unidad de Limnología, UMSA, Casilla Postal #10077, La Paz, Bolivia. 11259. Muehlbauer, J.D.; Doyle, M.W.; Bernhardt, E.S. (2011): Macroinvertebrate community responses to a dewatering disturbance gradient in a restored stream. *Hydrology and Earth System Sciences* 15: 1771-1783. (in English) [North Carolina, USA; "Dewatering disturbances are common in aquatic systems and represent a relatively untapped field of disturbance ecology, yet studying dewatering events along gradients in non-dichotomous (i.e. wet/dry) terms is often difficult. Because many stream restorations can essentially be perceived as planned hydrologic manipulations, such systems can make ideal test-cases for understanding processes of hydrological disturbance. In this study we used an experimental drawdown in a 440 ha stream/ wetland restoration site to assess aquatic macroinvertebrate community responses to dewatering and subsequent rewetting. The geomorphic nature of the site and the design of the restoration allowed dewatering to occur predictably along a gradient and decoupled the hydrologic response from any geomorphic (i.e. habitat heterogeneity) effects. In the absence of such heterogeneous habitat refugia, reach-scale wetted perimeter and depth conditions exerted a strong control on community structure. The community exhibited an incremental response to dewatering severity over the course of this disturbance, which was made manifest not as a change in community means but as an increase in community variability, or dispersion, at each site. The dewatering also affected inter-species abundance and distributional patterns, as dewatering and rewetting promoted alternate species groups with divergent habitat tolerances. Finally, our results indicate that rapid rewetting – analogous to a hurricane breaking a summer drought – may represent a recovery process rather than an additional dis-

turbance and that such processes, even in newly restored systems, may be rapid." 11265. Pan, B.-Z.; Wang, H.-J.; Liang, K.-M.; Wang, H.-Z. (2011): Macrozoobenthos in Yangtze floodplain lakes: patterns of density, biomass, and production in relation to river connectivity. *Journal of the North American Benthological Society* 30(2): 589-602. (in English) ["A systematic investigation of macrozoobenthos was conducted in Yangtze floodplain waters to reveal patterns of density, biomass, and production in relation to river connectivity. In the Yangtze connected lakes, 78 taxa belonging to 33 families and 62 genera were identified. Macrozoobenthos density was 327 individuals/m², biomass was 1.40 g dry mass/m², and production was 3.23 g dry mass m² y⁻¹. The assemblages were characterized by high diversity, high production, and high bivalve-filterer abundance. The key factor determining the macrozoobenthic assemblages was river connectivity. As river connectivity increased, 3 types of response patterns were observed: 1) density, biomass, and production of collector-filterers (mainly *Bivalvia*), shredders (e.g., *Stictochironomus*), and predators (e.g., *Dytiscidae*) showed unimodal changes, i.e., first increased and then decreased; 2) density, biomass, and production of collector-gatherers (mainly *Tubificidae* and *Chironomidae*) decreased continuously; and 3) density of scrapers (mainly *Gastropoda*) decreased, whereas their biomass and production changed unimodally. At an intermediate level of river connectivity, biomass and production of total macrozoobenthos reached maxima, whereas density decreased with increasing river connectivity.

Previous research showed that a diversity of zoobenthos also peaks at moderate connectivity with rivers. Therefore, to maintain high productivity as well as high biodiversity in the Yangtze floodplain, protecting the remnants of riverconnected lakes and linking disconnected lakes freely with the mainstream are crucial." (Authors) The list of taxa includes for Dongting Lake '*Dromogomphus* sp.', a nearctic species not occurring in China.] Address: Wang, H.-Z., State Key Laboratory of Freshwater Ecology and Biotechnology, Institute of Hydrobiology, Chinese Academy of Sciences, Wuhan, Hubei 430072, China. 11266. Parr, A.J. (2011): Migrant and dispersive dragonflies in Britain during 2010. *J. Br. Dragonfly Society* 21(2): 69-79. (in English) ["The year 2010 was a relatively low-key one for many of our commoner migrant species but some highly noteworthy events took place with rarer species. Literally dozens of *Aeshna affinis* were seen in southeast England during late July-August, principally around the Thames Estuary. With oviposition being noted, it is even possible that local breeding populations may become established. Southeast England also saw several records of *Lestes barbarus* during the year, as well as the discovery of new sites for *Lestes viridis* away from the recently-established Suffolk population. Perhaps the highlight of the year was the re-discovery of *Coenagrion scitulum*, after an absence from the UK of nearly 60 years. Arrivals of this species must however have taken place prior to 2010, since, in addition to adults, small numbers of exuviae were also discovered, indicating that successful breeding had already taken place. Clearly Britain's dragonfly fauna is currently going through a period of considerable flux." (Author)] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK. 11269. Petruck, A.; Stöffler, U. (2011): On the history of chloride concentrations in the River Lippe (Germany) and the impact on the macroinvertebrates. *Limnologica*

- Ecology and Management of Inland Waters 41(2): 143-150. (in English) ["The River Lippe is situated at the northern part of the Rhenish-westphalian coal mining area, Germany and has a long history of being affected by mining water discharge. There has, however, been a massive decrease in the discharge of mining water over the past few decades. While early in the last century concentrations of up to 3500 mg l⁻¹ of chloride were observed, the mean concentration is now below 400 mg l⁻¹. At the same time the water quality has improved greatly so factors other than chloride concentration may be influencing the macroinvertebrate community. Macroinvertebrate data collected from three sites along the River Lippe was analyzed for a change in the occurrence of salt tolerant species in an area where mining water discharge ended in 2000. It was found that also during the period of discharges the macroinvertebrate community was dominated by freshwater species and therefore the impact of mining water discharges in the upper River Lippe is considered to be minor. It was also found that for some species (*Nais elinguis*, *Bithynia tentaculata* and *Gammarus tigrinus*) their proposed salinity preference did not correlate with their occurrence in the field. This may be an area that requires further research. ... The predominant taxa of the collected individuals were Crustacea (18.24%), Gastropoda (15.59%), Ephemeroptera (10.61%) Odonata (10.40%), Diptera (9.75%), Trichoptera (9.63%), Lamellibranchata (6.73%) and Coleoptera (5.02%) ..."] (Authors)] Address: Petruck, A., Emschergerossenschaft/Lippeverband Essen, Kronprinzenstr. 24, 45128 Essen, Germany. 11273. Poiron, C.; Meurgey, F. (2011): The Odonata of St Lucia (Lesser Antilles) - Survey Report March 9-30 2011. *L'Herminier Natural History Society - Contribution to odonatology # 2*: 21 pp. (in English) ["The dragonfly fauna of the Lesser Antilles actually numbers 48 valid species (Meurgey & Poiron, in prep). There are 38 species in Guadeloupe (Meurgey, 2006b), 30 in Martinique (Meurgey, 2005) which both are the richest islands. Species richness decrease to the south with only 7 species in St. Vincent (Meurgey, 2010) and 19 in Grenada (Meurgey, 2009). Saint Lucia appear as a medium rich island, and the paucity of species could be due to 1) the lack of standing water habitats (95% of Odonata reproduce in standing water), and 2) the lack of studies, with only two surveys known to us. Among surveyed stations, 62% belongs to lotic habitats and 30% to lentic habitats. The remaining pertain to specific habitats: trail, grassland, ditch... The number of species in Martinique, which is quite equal to those of St Lucia, is due to a high level of disturbances, pollutions and urbanization. We think that the fauna of St Lucia could reach 30-35 species. Hurricane Tomas passed by the Island in November 2010. He especially opened many forested areas. We observed that several streams and rivers are now open, without canopy and colonized by vagrant species such as *Pantala flavescens*, *Orthemis macrostigma* or *Tramea abdominalis*. We also saw trees down across rivers creating microhabitats and promoting the development of some species such as *Protoneura ailsa*. This information must be verify with further surveys before and after the passage of an hurricane. It is difficult to have an idea of what species could be present in these habitats before Tomas. As for other islands, the odonate fauna of St Lucia is dominated by wide ranging species. Two of them, *Ischnura ramburii* and *O. macrostigma* are the commonest species in a great variety of habitat. The most interesting thing is that these two common species are followed by Lesser Antillean endemics (*P. ailsa* and *Dythemis sterilis*), which have been recorded from 20 (26%) and 27 (36%) localities respectively." (Authors)] Address: Meurgey, F., Muséum d'Histoire naturelle de Nantes, 12, rue Voltaire, F-44000 Nantes, France. E-mail: Francois.Meurgey@mairie-nantes.fr

11274. Popoola, K.O.K.; Otalekor, A. (2011): Analysis of aquatic insects' communities of Awba Reservoir and its physico-chemical properties. *Research Journal of Environmental and Earth Sciences* 3(4): 422-428. (in English) ["This study was conducted to assess the Awba reservoir insects' communities and the health status through the determination of insects' abundance, composition, distribution and water qualities parameters. Water samples and insects were collected bi-weekly from August through December, 2009. Insects were

sampled using standard entomological methods, while water samples was analyzed using standard Winkler's titrimetric and APHA methods to determine the chemical properties. Water analyses and insects' identifications were conducted in the laboratory in Dept of Zoology, University of Ibadan, Oyo State. The results show that only DO and phosphate-phosphorus had significant difference ($p < 0.05$). A total of 1,154 insects were recorded, Chironomidae and Culicidae were most abundant. The chemical properties and the distinct taxa found in the water suggest that the water body is polluted and may be dangerous to the health of people around the reservoir." (Authors) The paper contains information on heavy metal (zinc, copper, lead, cadmium) impact on Odonata identified at the genus level.] Address: Popoola, K., Department of Zoology, University of Ibadan, Oyo State, Nigeria

11278. Sánchez-Guillén, R.A.; Hansson, B.; Wellenreuther, M.; Svensson, E.I.; Cordero-Rivera, A. (2011): The influence of stochastic and selective forces in the population divergence of female colour polymorphism in damselflies of the genus *Ischnura*. *Heredity* 107(6): 513-522. (in English) ["Disentangling the relative importance and potential interactions of selection and genetic drift in driving phenotypic divergence of species is a classical research topic in population genetics and evolutionary biology. Here, we evaluate the role of stochastic and selective forces on population divergence of a colour polymorphism in seven damselfly species of the genus *Ischnura*, with a particular focus on *I. elegans* and *I. graellsii*. Colour-morph frequencies in Spanish *I. elegans* populations varied greatly, even at a local scale, whereas more similar frequencies were found among populations in eastern Europe. In contrast, *I. graellsii* and the other five *Ischnura* species showed little variation in colour-morph frequencies between populations. FST-outlier analyses revealed that the colour locus deviated strongly from neutral expectations in Spanish populations of *I. elegans*, contrasting the pattern found in eastern European populations, and in *I. graellsii*, where no such discrepancy between morph divergence and neutral divergence could be detected. This suggests that divergent selection has been operating on the colour locus in Spanish populations of *I. elegans*, whereas processes such as genetic drift, possibly in combination with other forms of selection (such as negative frequency-dependent selection), appear to have been present in other regions, such as eastern Europe. Overall, the results indicate that both selective and stochastic processes operate on these colour polymorphisms, and suggest that the relative importance of factors varies between geographical regions." 11279. Schmera, D.; Baur, B. (2011): Testing a typology system of running waters for conservation planning in Hungary. *Hydrobiologia* 665(1): 183-194. (in English) ["Landscape and site classifications are increasingly being used in conservation planning and biodiversity management. We examined the utility of a simple typology system for predicting the conservation value of running-water sites in Hungary using aquatic invertebrates. Aquatic invertebrates (444 species) were collected by kick and sweep sampling technique, in a few cases also with a net, at 317 running-water sites covering the entire area of Hungary. On the basis of three criteria (naturalness, altitude and size of catchment area) we obtained a typology scheme distinguishing five running-water types: artificial lowland stream, natural highland river, natural highland stream, natural lowland river and natural lowland stream. We expressed the conservation value of each site using the numbers of native species, unique native species, red-list species, protected species and alien species. Furthermore, the conservation value of each river type was expressed by a measure of beta diversity. Our results show that any interpretation

of the effect of a single criterion might be misleading. Consequently, the use of the whole typology system is recommended. The study revealed that all stream types are valuable to a certain extent because they maintain distinct biological communities. We found that the conservation value of artificial watercourses is comparable to that of natural running-water sites. We identified that natural lowland rivers and artificial lowland streams are the ones mostly exposed to species invasions. These findings are essential in maintaining and protecting conservation values of any freshwater ecosystem, and may contribute to management decisions on running waters in Hungary." (Authors) Odonata are included into this study; but no species details are given.] Address: Schmera, D., Section of Conservation Biology, Department of Environmental Sciences, University of Basel, St. Johanns-Vorstadt 10, 4056 Basel, Switzerland. 11280. Seibert, J.R.; Phelps, Q.E.; Tripp, S.A.; Garvey J.E. (2011): Seasonal diet composition of adult Shovel-nose Sturgeon in the Middle Mississippi River. *The American Midland Naturalist* 165(2): 355-363. (in English) ['Coenagrionidae' and 'Gomphidae' contributed 1,39% to the mass of diet from 123 specimens of shovel-nose sturgeon (*Scaphirhynchus platyrhynchus*) in the Middle Mississippi River (MMR) between Cairo, IL and St. Louis, MO (RKM 0–320), USA. "Dominant prey items throughout all seasons (winter, spring, summer and fall) were Chironomidae, Hydropsychidae, Ephemeridae and Corophiidae respectively. Corophiidae is an exotic amphipod that has not previously been documented in the MMR. The total abundance of diet items was high during winter through spring and low during summer through fall. Ephemeridae dominated in winter. Hydropsychidae was the most important prey item during spring through summer. Corophiidae dominated diets in the fall. Temperature and perhaps low river discharge appeared to affect prey consumed, with high temperatures and low discharge during summer through fall causing low energy intake, lowered condition and likely poor growth." 11281. Shama, L.S.; Campero-Paz, M.; Wegner, K.M.; De Block, M.; Stoks, R. (2011): Latitudinal and voltinism compensation shape thermal reaction norms for growth rate. *Molecular Ecology* 20(14): 2929-2941. (in English) ["Latitudinal variation in thermal reaction norms of key fitness traits may inform about the response of populations to climate warming, yet their adaptive nature and evolutionary potential are poorly known. We assessed the contribution of quantitative genetic, neutral genetic and environmental effects to thermal reaction norms of growth rate for populations of *Ischnura elegans*. Among populations, reaction norms differed primarily in elevation, suggesting that time constraints associated with shorter growth seasons in univoltine, high-latitude as well as multivoltine, low-latitude populations selected for faster growth rates. Phenotypic divergence among populations is consistent with selection rather than drift as QST was greater than FST in all cases. QST estimates increased with experimental temperature and were influenced by genotype by environment interactions. Substantial additive genetic variation for growth rate in all populations suggests that evolution of trait means in different environments is not constrained. Heritability of

growth rates was higher at high temperature, driven by increased genetic rather than environmental variance. While environment-specific nonadditive effects also may contribute to heritability differences among temperatures, maternal effects did not play a significant role (where these could be accounted for). Genotype by environment interactions strongly influenced the adaptive potential of populations, and our results suggest the potential for microevolution of thermal reaction norms in each of the studied populations. In summary, the observed latitudinal pattern in growth rates is adaptive and results from a combination of latitudinal and voltinism compensation. Combined with the evolutionary potential of thermal reaction norms, this may affect populations' ability to respond to future climate warming." (Authors)] Address: Shama, Lisa, Lab. (2011): Differential accumulation of mercury and other trace metals in the food web components of a reservoir impacted by a chlor-alkali plant (Flix, Ebro River, Spain): Implications for biomonitoring. *Environmental Pollution* 159(6): 1481-1489. (in English) ["Comparative studies of biomonitors of trace metal contamination are relatively scarce. We took advantage of a point source pollution in a reservoir (Flix, Spain) to compare trace metal (Hg, Pb, Cd, Se, As, Zn, Cu, Cr) bioaccumulation patterns among 16 food web components. Our results indicate that most organisms are suitable for Hg biomonitoring, whereas other metals are better monitored by only some of them. Biofilms and zebra mussel were the organisms with larger and more diverse biomonitoring capacity. However, we show that using groups of biomonitors increase the scope and strengths of the conclusions and specific goals can be better addressed. We conclude providing an overview of the strengths and weaknesses of the main organisms considered for biomonitoring trace metals in rivers and reservoirs." (Authors) Fig. 5. presents data on mercury and other trace metal concentrations in Coenagrionidae (*Erythromma* sp., *Ischnura* sp.) from the Flix reservoir.] Address: Soto, D., Centre for Advanced Studies of Blanes (CEAB-CSIC), Accés a la Cala St. Francesc 14, 17300 Blanes, Spain

11284. Tajiri, R.; Misaki, K.; Yonemura, S.; Hayashi, S. (2011): Joint morphology in the insect leg: evolutionary history inferred from Notch loss-of-function phenotypes in *Drosophila*. *Development* 138: 4621-4626. (in Eng-

lish) ["Joints permit efficient locomotion, especially among animals with a rigid skeleton. Joint morphologies vary in the body of individual animals, and the shapes of homologous joints often differ across species. The diverse locomotive behaviours of animals are based, in part, on the developmental and evolutionary history of joint morphogenesis. We showed previously that strictly coordinated cell-differentiation and cell-movement events within the epidermis sculpt the interlocking ball-and-socket joints in the adult *Drosophila* tarsus (distal leg). Here, we show that the tarsal joints of various insect species can be classified into three types: ball-and-socket, side-by-side and uniform. The last two probably result from joint formation without the cell differentiation step, the cell-movement step, or both. Similar morphological variations were observed in *Drosophila* legs when Notch function was temporarily blocked during joint formation, implying that the independent acquisition of cell differentiation and cell movement underlay the elaboration of tarsal joint morphologies during insect evolution. These results provide a framework for understanding how the seemingly complex morphology of the interlocking joint could have developed during evolution by the addition of simple developmental modules: cell differentiation and cell movement. ... The proximal tarsal joint of the bristletail (*Archeognatha*), the tarsal joints of the firebrat (*Apterygota*) and those of *Orthetrum albistylum*, *Epiophlebia superstes*, *Ischnura senegalensis* (Paleoptera) consisted of two pieces of hard cuticle that lined the cavity and were positioned side by side, without one enwrapping the other." 11287. Thompson, D.J.; Hassall, C.; Lowe, C.D.; Watts, P.C. (2011): Field estimates of reproductive success in a model insect: behavioural surrogates are poor predictors of fitness. *Ecology Letters* 14(9): 905-913. (in English) ["Understanding, and therefore measuring, factors that determine fitness is a central problem in evolutionary biology. We studied a natural population of *Coenagrion puella* over two entire breeding seasons, with over a thousand individuals uniquely marked and genotyped, and all mating events at the rendezvous site recorded. Using a parentage analysis, fitness of individuals in the first generation was quantified as the numbers of offspring that survived to maturity. Although mating behaviour can be predicted by environmental and demographic variables, the numbers of mature offspring produced (fitness) cannot, and crucially, are poorly correlated with behavioural observations of mating. While fitness of both sexes was positively related to mating behaviour and to female's ectoparasite burden, these behavioural observations explained little more variance in offspring production than environmental and demographic variables. Thus, we demonstrate that behavioural measures of reproductive success are not necessarily reliable estimates of fitness in natural populations." 11289. Torres-Cambas, Y.; Cordero-Rivera, A. (2011): Limited spermathecal sperm removal ability in the damselfly *Hypolestes trinitatis* (Gundlach) (Odonata: Megapodagrionidae). *International Journal of Odonatology* 14(4): 321-328. (in English) ["It has been hypothesized that sperm removal ability in male Odonata has promoted sexual conflict over the sperm stored in the reproductive tract of the female. Although there is evidence supporting this hypothesis, most studies have been conducted in a small number of species from spe-

cific families. We explored sperm removal ability in the Antillean Megapodagrionidae, *H. trinitatis* through examination of specialized structures on the genital ligula ("penis") and through measurement of sperm volumes stored in the sperm storage organs (bursa copulatrix and spermathecae) at different stages of the copula. Males removed sperm from the bursa, but not from the spermathecae. The penis has four finger-like terminal processes covered by spines which could contribute to sperm removal. Given the width of the penile processes, males could introduce them into the spermathecae to remove sperm; however this does not seem to occur. A possible explanation for the sperm removal pattern of *H. trinitatis* could be that the penile processes are prevented to reach the sperm stored due to their position in relation to the spermathecae during the copulation." 11290. Torres-Cambas, Y.; Fonseca-Rodríguez, R. (2011): Sex ratio, survival, and recapture rate in a Cuban population of the damselfly *Hypolestes trinitatis* (Odonata: Megapodagrionidae). *Acta ethologica* 14: 69-76. (in English) ["Male-biased sex ratios in adult odonate populations have been the subject of vigorous discussion between the students of this order of insects. The debate has centered on whether the observed male bias in many populations is real, perhaps due to unequal survival rates, or whether it is an artifact caused by differences in recapture probabilities. A mark-recapture study to assess the relative contribution of survivorship and recapture rates on male-biased sex ratio was performed in a Cuban population of the damselfly *Hypolestes trinitatis*. Maximum likelihood theory and Akaike information criterion were used for parameter estimation and model selection, respectively. Females in the sample were outnumbered two to one by males. Estimated recapture and survival rates were 0.188 (females) and 0.638 (males), and 0.933 (females) and 0.944 (males), respectively. Recapture rates only partially explained the bias since the population sex ratio estimated after correcting for differences in this parameter was male biased (1.5). The observed higher survival probabilities in males could have generated the male-biased population sex ratio. Therefore, we concluded that the observed male-biased population sex ratio in *H. trinitatis* is real." (Authors)] Address: Y. 11291. Trewick, S.A.; Wallis, G.P.; Morgan-Richards, M. (2011): The invertebrate life of New Zealand: A phylogeographic approach. *Insects* 2(3): 297-325. (in English) ["Phylogeography contributes to our knowledge of regional biotas by integrating spatial and genetic information. In New Zealand, comprising two main islands and hundreds of smaller ones, phylogeography has transformed the way we view our biology and allowed comparison with other parts of the world. Here we review studies on New Zealand terrestrial and freshwater invertebrates. We find little evidence of congruence among studies of different taxa; instead there are signatures of partitioning in many different regions and expansion in different directions. A number of studies have revealed unusually high genetic distances within putative species, and in those where other data confirm this

taxonomy, the revealed phylogeographic structure contrasts with northern hemisphere continental systems. Some taxa show a signature indicative of Pliocene tectonic events encompassing land extension and mountain building, whereas others are consistent with range expansion following the last glacial maximum (LGM) of the Pleistocene. There is some indication that montane taxa are more partitioned than lowland ones, but this observation is obscured by a broad range of patterns within the sample of lowland/forest taxa. We note that several geophysical processes make similar phylogeographic predictions for the same landscape, rendering confirmation of the drivers of partitioning difficult. Future multi-gene analyses where applied to testable alternative hypotheses may help resolve further the rich evolutionary history of New Zealand's invertebrates." (Authors) The paper briefly refers on Nolan, L.; Hogg, I.D.; Sutherland, D.L.; Stevens, M.I.; Schnabel, K.E. allozyme and mitochondrial DNA variability within the New Zealand damselfly genera *Xanthocnemis*, *Austrolestes*, and *Ischnura* (Odonata). *New Zeal. J. Zool.* 2007, 34, 371-380.] Address: Trewick, S.A., Phoenix Lab, Ecology Group, Inst. Natural Resources, Massey Univ., Private Bag 11-222, Palmerston North 4442, New Zealand

11292. von Ellenrieder, N. (2011): Odonata (dragonflies and damselflies) of the Kwamalasamutu region, Surinam. O'Shea, B.J., L.E. Alonso, & T.H. Larsen, (eds.). 2011. A Rapid Biological Assessment of the Kwamalasamutu region, Southwestern Suriname. *RAP Bulletin of Biological Assessment* 63. Conservation International, Arlington, VA: 56-78. (in English) ["94 Odonata species, representing one-third of the species known from Suriname, were registered at forest rivers, streams, and swamps; in particular 57 species were found at the Kutari River Site (Camp 1), 52 at the Sipaliwini River Site (Camp 2), and 65 at the Werehpai Site (Camp 3). 14 species represent new records for Suriname, of which four, belonging to the genus *Argia*, are new to science, and five represent first records of a species at a new locality since their original descriptions, increasing considerably their known extent of occurrence. The results indicate a healthy watershed and well preserved forest at all three sites; if forest cover and stream morphology are maintained in the area, the present odonate assemblages are expected to persist." 11293. Walia, G.K.; Kaur, H.; Kaur, J. (2011): Karyotypic variations in the chromosome complement of *Pantala flavescens* (Fabricius) of the family Libellulidae (Anisoptera: Odonata). *Cytologia* 76(3): 301-307. (in English) ["Male germ cell complement of *P. flavescens* has been investigated. Specimens were collected from the surrounding area of the Harike wetlands in the Punjab state of India. The species possesses $2n$ male=23m as the diploid chromosome number, which is less than the type number, $2n$ male=25m, of the family. In the chromosome complement, one autosomal bivalent is extraordinarily large due to the fusion of 2 autosomes and is responsible for the reduction in chromosome number. Precocious segregation of the m bivalent has also been noticed in some meiotic cells. This type of variations in the chromosome number and behaviour of m chromosomes indicate that the species is under the process of karyotypic evolution." 11294. Watt, T. (2011): New pond gets approval of Emerald damselflies. *Scottish Invertebrate News* 2(2): 7. (in English) [Verbatim: The North East Ranger Service has been watching damselflies starting to colonise the new pond at Castle Fraser in Aberdeenshire, just five months after it was dug on a snowy day in March. Pairs of *Lestes sponsa* have been seen flying together around the pond and then settling on emergent vegetation to lay their eggs. The neighbouring flight pond at Castle Fraser is home to 10 species of dragonflies and damselflies including *Coenagrion hastulatum*, which is a red data book species found in the British Isles only in a few locations in Scotland. They also have the most northern record in Britain of the azure damselfly, which is more common further south. The new pond was created to provide a safety net in case anything happened to the existing populations of these and the other damselflies, and also to allow their populations to hopefully increase.] Address: not stated

11295. Watts, P.C.; Thompson, D.J. (2011): Developmental plasticity as a cohesive evolutionary process between sympatric alternate-year insect cohorts. *Heredity* 108(3): 236-241. (in English) ["Many species, particularly insects, pass through a series of distinct phases during their life history, with the developmental timing directed towards appropriate resources. Any factor that creates variation in developmental timing may partition a population into discrete populations—or 'cohorts'. Where there is continued failure to recruit outside the natal cohort then alternate cohorts will have their own internal dynamics, eventually leading to independent demographic and evolutionary trajectories. By contrast, continued variation in development rates within a cohort—cohort splitting—may homogenise otherwise independent demographic units. Using a panel of 14 microsatellite loci, we quantify the genetic signature of apparent demographic isolation between coexisting, but alternate, semivoltine cohorts of *Coenagrion mercuriale* at locations that span its distribution in the UK. We find consistently low levels of genetic divergence between sympatric cohorts of *C. mercuriale*, indicative of developmental plasticity during the larval stage (unregulated development) whereby some individuals complete their development outside the predominant 2-year (semivoltine) period. Thus, individuals that alter their developmental rate successfully recruit to a different cohort. Despite maintaining contrasting population sizes, gene flow between alternate cohorts broadly is sufficient to place them on a similar evolutionary trajectory and also buffers against loss of genetic diversity. Such flexible larval development permits a response to local conditions and may facilitate response to environmental change."] Address: Watts, P.C., School of Biological Sciences, The Biosciences Building, Crown Street, University of Liverpool, Liverpool, L69 7ZB, UK. 11296. Weech, S.A.; Scheuhammer, A.M.; Wayland, M. E. (2011): Selenium accumulation and reproduction in birds breeding downstream of a uranium mill in northern Saskatchewan, Canada. *Ecotoxicology* 21(1): 280-288. (in English) ["Selenium (Se) concentrations in aquatic invertebrates and bird eggs collected along the treated effluent receiving environment of the Key Lake uranium mill in northern Saskatchewan were significantly greater than from nearby reference areas, and in some cases (e.g., eggs of common loons — *Gavia immer*) were higher than commonly used thresholds for adverse re-

productive effects in birds (i.e., 5 µg/g dry weight in diet; 12–15 µg/g dry weight in eggs). Mean Se concentrations in tree swallow (*Tachycineta bicolor*) eggs reached a maximum of 13.3 µg/g dry weight at the point of treated effluent discharge and exhibited a gradient of decreasing Se concentrations with increasing distance from the effluent discharge, probably reflecting both effluent dilution and local site fidelity by nesting swallows. In some cases, high intra-clutch variability in Se concentrations in mallard (*Anas platyrhynchos*) and tree swallow eggs was observed in high-Se sites, suggesting that a single egg randomly sampled from a nest in an area of higher Se exposure may not be representative of Se concentrations in other eggs from the same nest. Overall, tree swallow reproductive success was similar in both exposed and reference areas... Odonata larvae, Trichoptera larvae and Hirudinea tended to have the highest Se concentrations, whereas near-surface insects such as Corixidae, Gerridae) and Gyrinidae had lower Se concentrations. In general, Se concentrations in invertebrates tended to be highest at Wolf and Unknown lakes, which are closest to the treated effluent discharge."] (Authors)] Address: Weech, S., Minnow Environmental Inc, 101-1025 Hillside Avenue, Victoria, BC V8T 2A2, Canada. 11297. Weidel, B.; Carpenter, S.R.; Kitchell, J.F.; Vander Zanden, M.J. (2011): Rates and components of carbon turnover in fish muscle: insights from bioenergetics models and a whole-lake ¹³C addition. *Can. J. Fish. Aquat. Sci.* 68: 387-399. (in English, with French summary) ["Stable isotopes are widely employed to describe energy flow in aquatic communities, though interpretation of results can be confounded by the fact that organisms integrate over vastly different time scales. We used results from a 56-day whole-lake ¹³C addition and a bioenergetic modelling approach to estimate dorsal muscle carbon turnover rates in a natural setting for three sizes of bluegill (*Lepomis macrochirus*), largemouth bass (*Micropterus salmoides*), and yellow perch (*Perca flavescens*). Generally, dynamic ¹³C models with a metabolic tissue replacement term were better supported than models predicting isotopic change from growth alone, except when relative growth rates were highest (age 0 bluegill). Across species and size classes, the percentage of carbon change due to tissue replacement was variable (2%–80%) and independent of fish size. The half-life of ¹³C in age 0 fishes was similar and ranged from 8 to 18 days. In contrast, adult tissue half-lives were much longer (116–173 days). Based on these and previously published estimates, fish mass (g) was a strong predictor of fish carbon turnover rates, \ln : $\log(I) = -3.65 - 0.20 \log(\text{mass})$, $r^2 = 0.71$."] (Authors) Benthic diet classifications included Odonata. Odonata larvae contributed significantly to the diet of the studied fish species.] Address: Weidel, B., Center for Limnology, University of Wisconsin, Madison, Wisconsin 53706, USA. 11301. Westermann, K. (2011): Zweigipfelige Emergenzperiode der Kleinen Zangenlibelle (*Onychogomphus forcipatus*) im Fluss-System Elz-Leopoldskanal-Restrhein. *Naturschutz südl. Oberrhein* 6: 157-166. (in German, with English summary) [Baden-Württemberg, Germany; "In 2006, 2008, 2009, and 2010 a total of 14900 exuviae of *O. forcipatus* were collected at six sampling sections along the Elz-Leopoldskanal-Restrhein river system. The sampling sections were up to 25 km away from each other. The emergence period was between 40 and 76 days along the different sections. It began as early as 21st of May. The last imagines emerged on 12th of August. The emergence period always consisted of two main peak phases of mostly two to three weeks followed by a longer phase of lower emergence. Weather and water discharge had no effect on the seasonal pattern of emergence. It is possible that individuals from different larval stadia emerged during the different emergence phases. There may have been different conditions for development during the different phases. On isolated days the emergence rates were significantly decreased due to flooding, persistent strong winds or continuous rain. At one section the emergence rates increased significantly on three days following flooding during the previous nights. The floodings possibly caused drifting of larvae that were ready to emerge." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

11304. Wilson, R.J.; Maclean, I.M.D. (2011): Recent evidence for the climate change threat to Lepidoptera and other insects. *J. Insect Conserv.* 15: 259-268. (in English) ["Climate change is now estimated by some biologists to be the main threat to biodiversity, but doubts persist regarding which species are most at risk, and how best to adapt conservation management. Insects are expected to be highly responsive to climate change, because they have short life cycles which are strongly influenced by temperature. Insects also constitute the most diverse taxonomic group, carrying out biotic interactions of importance for ecological functioning and ecosystem services, so their responses to climate change are likely to be of considerable wider ecological significance. However, a review of recent published evidence of observed and modelled effects of climate change in ten high-ranking journals shows that comparatively few such studies have focused on insects. The majority of these studies are on Lepidoptera, because of the existence of detailed contemporary and historical datasets. These biases in published information may influence conclusions regarding the threat of climate change to insect biodiversity. Assessment of the vulnerability of insect species protected by the Bern Convention on the Conservation of European Wildlife and Natural Habitats (including Odonata) also emphasises that most information is available for the Lepidoptera. In the absence of the necessary data to carry out detailed assessments of the likely effects of climate change on most threatened insects, we consider how autecological studies may help to illuminate the potential vulnerability of species, and draw preliminary conclusions about the priorities for insect conservation and research in a changing climate." 11312. Bonada, N.; Doledec, S.; Statzner, B. (2012): Spatial autocorrelation patterns of stream invertebrates: exogenous and endogenous factors. *Journal of Biogeography* 39: 56-68. (in English) ["Aim To investigate spatial autocorrelation of taxonomic stream invertebrate groups (richness and composition) at a large geographical scale and to analyse the importance of exogenous and endogenous factors. Location The Mediterranean Basin. Methods For exogenous factors, we used large-scale factors related to climate, geology and river zonation; for endogenous factors, we used the dispersal mode of each taxonomic group. After describing and analysing spatial patterns of genus richness and genus composition of stream invertebrate groups in the Mediterranean Basin, we computed Moran's I before and after accounting for the exogenous factors and related it to the endogenous factors. Results In relation to genus richness, most of the taxonomic groups did not show significant spatial autocorrelation, suggesting that no main large-scale exogenous or endogenous factors were important and that local-scale factors were probably controlling taxonomic richness. In contrast, for ge-

nus composition, all taxonomic groups except Odonata had significant spatial autocorrelation before accounting for the environment. After accounting for the environment, most taxonomic groups still had a significant spatial autocorrelation, but it decreased with their increasing dispersal ability (from Crustacea to Coleoptera). Thus, spatial taxonomic composition of groups with the strongest dispersal potential is mainly related to exogenous factors, whereas that of groups with weaker dispersal potential is related to a combination of exogenous and endogenous factors. Main conclusions Our results illustrate the importance of dispersal as an endogenous factor causing spatial autocorrelation and suggest that ignoring endogenous factors can lead to misunderstandings when explaining large-scale community patterns." Non-irradiated xiphidiocercariae are released by the planorbis snail *Indoplanorbis exustus* (Deshayes). Metacercariae occur in the haemocoel of dragonfly nymphs (Libellulidae) and become infective to the frog *H. tigerinus* within 15 days. The pre-patent period is 45 days. Growth and development of both metacercariae and adults are described in detail. Comments on the systematic position

of *Ganeo Klein*, 1905 are included." (Authors) Address: Brinesh, R., Dept of Zoology, University of Calicut, Kerala 673 635, India. E-mail: brineshr@gmail.com

11316. Butler, G.L.; Wooden, I.J. (2012): Dietary habits of a large, long-lived endangered Australian percichthyid, the eastern freshwater cod *Maccullochella ikei*. *Endang. Species Res.* 16: 199-209. (in English) ["The diet of *M. ikei* Rowland, 1985 was studied over 2 consecutive years in the Mann and Nymboida River system, Australia, to determine summer and winter feeding habits. Food items were extracted using non-destructive gastric lavage. In total, 268 *M. ikei* were gut-flushed over the 2 yr of the study; 191 contained at least 1 food item. A large variety and broad size range of items were recovered, from small aquatic insects to relatively large terrestrial animals. We found significant differences between the food items consumed by *M. ikei* in summer and winter. Seasonal differences related to the increased occurrence of crustaceans, small fish and terrestrial animals in the diet of *M. ikei* during winter, and more aquatic insects and molluscs in summer. Food items differed significantly among size classes, with larger *M. ikei* consuming fewer crustaceans and more large fish and terrestrial animals. Our study revealed that *M. ikei* displays high plasticity in seasonal dietary habits, changes diet and foraging tactics as it grows, and appears to not always consume what would be considered optimal forage...." (Authors) Aquatic insects were nearly exclusively represented by Odonata (*Hemicordulia intermedia*, *H. tau*, *Hemigomphus* sp., *Hemianax papuensis*, Zygoptera) and estimated to app. 10% of the total food weight.] Address: Butler, G.L., Department of Primary Industries NSW, Grafton Fisheries Centre, PMB 2, Grafton, New South Wales 2460, Australia. E-mail: gavin.butler@industry.nsw.gov.au

11317. Chand, S. (2012): *Journal of Experimental Zoology, India* 15(1): 213-218 (in English) [A continuous forty hours of treatment of last instar naiad of *T. auroa* under LC₅₀ concentration, 5.12×10⁻⁷ and 7.60×10⁻⁸ ppm of chlorpyrifos and quinalphos respectively has proved toxic and induced histopathological derangements in various tissues of midgut. The mesenteron has observed to be prone to both the pesticides. The chlorpyrifos separated the epithelial folds and widen the inter fold space up to the basement membrane. The quinalphos penetrated inside the epithelial folds and damaged cellular mass. Both the pesticides induced the movement of cytoplasmic contents at various degrees towards the apical end of the epithelial folds. This movement presumed to be the genesis of intense vacuolation at the basal ends of all the epithelial cells. The continuous pressure of the internal cellular contents and weekend cell boundaries have caused the violent exclusion of cell contents. The nuclear membrane at many places damaged by chlorpyrifos and severely affected by quinalphos." (Author) Address: Chand, S., Dept Zol., R.P.G. College, Jamuhai, Jaunpur - 222 001, India

11318. Chand, S. (2012): Impact of pyrethroid and organophosphorus pesticides on the level of various amino acids in the gut tissues of naiad of *Trithemis aurora* (Burm.) dragonfly (Libellulidae: Odonata). *Journal of Experimental Zoology, India* 15(1): 291-298 (in English) [The occurrence and level of various amino acids in different regions of gut tissues of last instar naiad of *T. aurora* were analysed through the one dimensional paper chromatography. In various regions of gut there observed the levels of different amino acids. Among twenty

four amino acids several amino acids were observed missing in various gut tissues. Several amino acids were observed in moderate concentration and several amino acids in high concentration. Some of the amino acids were in feeble concentration. Impact of pyrethroid and organophosphorus pesticides was observed on the level of various essential and non essential amino acids in gut regions. The 2.691×10^{-5} , 2.5×10^{-3} , 5.12×10^{-7} , 7.6×10^{-8} ppm of LC₅₀ concentrations of cypermethrin, deltamethrin, chlorpyrifos and quinalphos applied respectively for 40 hrs. to observe the impact of these pesticides on the distribution and level of various amino acids. It was found that there was a great change in the distribution and level of various amino acids in various regions of gut under pesticidal stress." (Author) Address: Chand, S., Dept of Zoology, R.P.G. College, Jammu, Jaunpur - 222 001, India

11319. Clausnitzer, V.; Dijkstra, K.D.B.; Koch, R.; Boudot, J.-P.; Darwall, W.R.T.; Kipping, J.; Samraoui, B.; Samways, M.J.; Simaika, J.P.; Suhling, F. (2012): Focus on African freshwaters: hotspots of dragonfly diversity and conservation concern. *Frontiers in Ecology and the Environment* 10(3): 129-134. (in English) ["This is the first continent-wide overview of insect diversity and status sufficiently fine-scaled to be used in conservation planning. We analyze patterns of richness and the conservation status of African Odonata to determine threats to species and freshwater habitats, location of diversity hotspots, necessary conservation actions, and research gaps. Major centers of dragonfly diversity in Africa are tropical forest areas that include highlands. Most threatened species – as classified by the International Union for Conservation of Nature global Red List – are concentrated in highlands from Kenya to South Africa (together with the Cape Floristic Region), western Africa (including mountains on the Cameroon–Nigeria border), and Ethiopia. Currently available knowledge can be applied throughout Africa's freshwater systems to help minimize or mitigate the impact of future development actions, allowing dragonflies to act as "guardians of the watershed". The private sector can be advised to safeguard sensitive habitats and species when selecting sites for development. Key sites and species for monitoring can be identified by checking the distribution of threatened species at www.iucnredlist.org." 11320. Combes, S.A.; Rundle, D.E.; Iwasaki, J.M.; Crall, J.D. (2012): Linking biomechanics and ecology through predator–prey interactions: flight performance of dragonflies and their prey. *The Journal of Experimental Biology* 215: 903-913. (in English) ["Aerial predation is a highly complex, three-dimensional flight behavior that affects the individual fitness and population dynamics of both predator and prey. Most studies of predation adopt either an ecological approach in which capture or survival rates are quantified, or a biomechanical approach in which the physical interaction is studied in detail. In the present study, we show that combining these two approaches provides insight into the interaction between hunting dragonflies (*Libellula cyanea*) and their prey (*Drosophila melanogaster*) that neither type of study can provide on its own. We performed >2500 predation trials on nine dragonflies housed in an outdoor artificial habitat to identify sources of variability in capture success, and analyzed simultaneous predator–prey flight kinematics from 50 high-

speed videos. The ecological approach revealed that capture success is affected by light intensity in some individuals but that prey density explains most of the variability in success rate. The biomechanical approach revealed that fruit flies rarely respond to approaching dragonflies with evasive maneuvers, and are rarely successful when they do. However, flies perform random turns during flight, whose characteristics differ between individuals, and these routine, erratic turns are responsible for more failed predation attempts than evasive maneuvers. By combining the two approaches, we were able to determine that the flies pursued by dragonflies when prey density is low fly more erratically, and that dragonflies are less successful at capturing them. This highlights the importance of considering the behaviour of both participants, as well as their biomechanics and ecology, in developing a more integrative understanding of organismal interactions." 11321. Curry, C.J.; Zhou, X.; Baird, D.J. (2012): Congruence of biodiversity measures among larval dragonflies and caddisflies from three Canadian rivers. *Freshwater Biology* 57(3): 628-639. (in English) ["(1) Scientists tasked with collecting taxon richness and assemblage variation data for conservation purposes have identified biomonitoring studies as potential sources of information. This approach assumes that biodiversity patterns revealed by biomonitoring reflect those of the wider community, an assumption not thoroughly tested in riverine ecosystems. (2) We compared patterns of taxon richness and assemblage variation in an important biomonitoring group (Trichoptera) with a group with high conservation significance (Odonata) at 34 sites across three fifth-order catchments. We also explored the effect of abundance on observed patterns by rarefying the larval Trichoptera data set. (3) Our results indicate that Trichoptera do not fully reflect site-scale taxon richness or assemblage variation in Odonata. The magnitude of odonate assemblage variation was much greater than that of Trichoptera for one of the catchments. Odonata and Trichoptera richness was moderately correlated in two catchments, while assemblage variation was strongly correlated in another pair of catchments. However, comparisons based on rarefied data eliminated differences in the magnitude of assemblage variation and strengthened correlations in richness and assemblage variation, suggesting the lack of congruence in these measures might be due to differences in abundance among groups. Further, incomplete taxonomy may mask additional assemblage variation, particularly in Trichoptera. (4) Conservation planning in riverine ecosystems based on proxies derived from biomonitoring data should proceed cautiously until we understand how well the resulting information reflects biodiversity patterns in under-sampled taxa and habitats. Future studies of biodiversity congruence should consider both richness and assemblage variation as each provides valuable information for conservation-related decisions. The taxonomic resolution and relative abundance of comparison groups can potentially impact the strength, direction and statistical significance of patterns. Researchers should employ species-level taxonomy and account for differences in abundance among groups through rarefaction where at all possible and DNA-based taxonomy methods can support this." tute and Department of Biology, University of New Brunswick, PO Box 4400 Fredericton, New Brunswick, Canada E3B 5A3. E-mail: colin.curry@unb.ca

11322. Dallas, H.F.; Rivers-Moore, N.A. (2012): Critical thermal maxima of aquatic macroinvertebrates: towards identifying bioindicators of thermal alteration. *Hydrobiologia* 679: 61-76. (in English) ["Water temperature is an important abiotic driver of aquatic ecosystems. It influences many aspects of an organism's existence including its growth, feeding and metabolic rates; emergence; fecundity; behaviour and ultimately survival. All organisms have an optimum temperature range within which they survive and are able to thrive. Determining upper thermal limits provides insight into the relative sensitivity of organisms to elevated temperatures. Thermally sensitive taxa may be useful as bioindicators of thermal alteration and used in the generation of target thermal thresholds for aquatic systems. This study determined the upper thermal limit (CT_{max}) of a range of aquatic macroinvertebrates from rivers in the south-western Cape, South Africa, using the dynamic Critical Thermal Method. The study focused on the taxonomic level of family as an initial screening tool for ranking thermal sensitivity. Of the 27 families examined, four were both thermally sensitive and highly suitable as test organisms, including Paramelitidae, Notonemouridae, Telo-ganodidae and Philopotamidae. Five families were moderately sensitive and highly suitable, including Palae-monidae, Heptageniidae, Leptophlebiidae, Corydalidae and Aeshnidae. Preliminary experiments to determine potential sources of variation in CT_{max} revealed that thermal sensitivity was relatively uniform within families, but that acclimation temperature influenced CT_{max}. Further investigation of the influence of thermal history, acclimation temperature and rate of temperature change on CT_{max} is necessary. Target water temperatures for river management will be derived using CT_{max} data, in addition to longer duration experimental data, which will be linked to in situ temperature data." 11323. de Sousa, V.T.T.; Barreto, T.F.; Rossa-Feres, D. (2012): Predation risk and jumping behavior in *Pseudopaludicola aff. falcipes* tadpoles. *Behavioral Ecology* 22(5): 940-946. (in English) ["Tadpoles of *Pseudopaludicola aff. falcipes* are capable of jumping out of small temporary puddles where they occur. In this system, odonate naiads are the main predators. Considering the hypothesis that jumping behaviour represents an anti-predator tactic, we addressed the following predictions: 1) tadpoles will jump more frequently from puddles with predators than from puddles without predators; 2) tadpole mortality will increase if tadpoles are prevented from jumping; 3) it would be more common to find tadpoles in puddles where predators are absent; and 4) predator and prey coexistence would be more probable in large puddles than in small ones. To test predictions 1) and 2), we conducted 2 laboratory experiments. In Experiment 1, we evaluated the jump frequency of tadpoles in 3 treatments (tadpoles in the presence or absence of a predator, or using an inanimate object as predator presence control). In Experiment 2, we compared tadpole survival in 2 conditions: Tadpoles were allowed or not to jump. To test predictions 3) and 4), we conducted a field study to determine how predators and

prey are distributed throughout the habitat. Experiments demonstrated that jumping behaviour occurred more frequently when a predator was present and that tadpoles prevented from jumping were more susceptible to predation. The field study indicated that tadpoles and odonate naiads were distributed in a negatively associated, but puddle-size dependent pattern. Our results are congruent with the predictions, therefore, confirming the jumping behaviour as an effective antipredator tactic." (2012): Laser bionic strengthening local grid of mould surface. *Journal Applied Mechanics and Materials* 101-102: 893-896. (in English) ["For the short life of enterprise hot work die directly caused to problems in the waste of resources and the rising cost of production. Based on studying the biological prototype of crack-resistance of dragonfly wings and finding surface thermal fatigue crack is one of the main factors affecting life of the hot work mould, it is put forward thoughts about the local laser bionic strengthening the grid mould surface. Different from the traditional mould surface integral laser transformation hardening (LTH) technology, by using laser melting simulating dragonfly wings to block localized crack in the partial surface of mold, bionic strengthened die life is improved within 1~1.5 times. Experiment results on die steel shows that it is provided a new method to improve the service life of die casting mold and promoting this technology will bring significant economic benefits for the mold industry." 11325. Didham, R.K.; Blakely, T.J.; Ewers, R.M.; Hitchings, T.R.; Ward, J.B.; Winterbourn, M.J. (2012): Horizontal and vertical structuring in the dispersal of adult aquatic insects in a fragmented landscape. *Fundamental and Applied Limnology / Archiv für Hydrobiologie* 180(1): 27-40 (in English) ["Determining the relative importance of longitudinal dispersal of adult aquatic insects along stream corridors versus their lateral dispersal through upland terrestrial habitats is crucial to understanding the impact of land-use change on ecological and evolutionary processes within streams. However, there is a curious mismatch between trap capture studies, which find low lateral movement rates away from streams, and many population genetic studies, which show low levels of genetic divergence among streams, implying high rates of lateral movement. Here, we take advantage of a serendipitous observation of high relative capture frequencies of adult aquatic insects in the forest canopy, to question whether the flight-height preferences of adults might resolve this apparent 'interbasin dispersal paradox'. In a large-scale study of the effects of habitat fragmentation on invertebrate community structure, 347 passive flight interception traps were deployed at ground level (10,211 trap-days sampling effort) and canopy level (7,595 trap-days) to determine not only the horizontal component of land-use impacts on adult aquatic insects, but also the vertical component of adult movement through the forest canopy in a heavily-fragmented landscape. Two-thirds of adult aquatic insects (Ephemeroptera, Pleco-

ptera, Trichoptera, Megaloptera and Odonata [Austrolestes colenonis]) were captured in the forest canopy, rather than at ground level. Multivariate ordination analysis showed that vertical trapping height and surrounding terrestrial land use had the greatest effects on species composition of dispersing adults, whereas distance to the nearest stream had no significant effect. Of the species that were abundant enough to test statistically, the majority of caddisfly and mayfly species were captured significantly more frequently in the canopy than expected by chance alone, whereas stoneflies were more frequently captured at ground level. These results provide a unique insight into the possible reason why long-distance dispersal of aquatic adults has so rarely been observed. The prosaic explanation may simply be that adults of many species disperse through the forest canopy, and well above ground level." (2012): Preliminary sampling of arthropod fauna of transgenic cassava in confined field trial. *African Journal of Biotechnology* 11(21): 4802-4809. (in English) ["Water (Basin and pitfall) and sweepnet traps were used to ascertain the population dynamics of the arthropod fauna of transgenic cassava in a confined field trial (CFT) at National Root Crops Research Institute (NRCRI), Umudike, Nigeria. The trial took place from August to November, in 2009 and February to July, in 2010 to identify the major arthropods associated with the crop and to monitor

changes in their populations for effective management. Trapped arthropods were sorted and identified by means of a hand lens and a taxonomic key and their relative abundance determined. Most of the order (seven out of the eight recorded) were trapped in the basin and sweepnet traps. Twenty families and numerous mostly unidentified genera and species were collected during the sampling period. Isoptera were the most abundant group, most of which were trapped while foraging and prospecting for nectar, mate, oviposition site, or were accidentally caught. This was followed by Coleoptera and Orthoptera. The least abundant order was Spirostreptida. Basin traps capture the highest number of arthropods of diverse families, followed by pitfall then sweepnet. A lower arthropod weekly mean abundance was recorded in 2009 (129.55) than in 2010 (132.08)." (Authors) *Anax* sp. accounted in 2009 to a relative abundance in catches of app. 7%, and in 2010 of app. 1%.] Address: Ehisianya, C.N., National Root Crops Research Institute, Umudike, Abia State, Nigeria. Res.* 110(1): 245-250. (in English) ["We studied parasitism by gut protozoans (Apicomplexa: Eugregarinidae) in *N. irene*. We tested whether there was any seasonal pattern, as has been found for other parasites of damselflies and which has implications for selection on emergence and breeding. Using aggregate data from 12 date-by-site comparisons involving five sites, we found that both prevalence and intensity of gregarine parasitism were seasonally unimodal. Parasitism first increased and then declined seasonally after peaking midseason. This damselfly species has shown seasonal increases in density followed by declines at several sites including a site sampled in this study. Therefore, similar seasonal changes in a directly transmitted parasite were expected and are now confirmed. Other factors that might account for seasonal changes in parasitism by gregarines are either unlikely or can be discounted including sampling of older damselflies mid-season but not late in the season, or sex biases in parasitism and overrepresentation of the more parasitized sex mid-season." 11334. Giugliano, L.; Hardersen, S.; Santini, G. (2012): Odonata communities in retrodunal ponds: a comparison of sampling methods. *International Journal of Odonatology* 15(1): 13-23. (in English) ["Dragonflies are commonly used as indicators of environmental quality

and different methods have been employed to monitor odonate assemblages, such as surveys of all adults, evaluations based on breeding adults, sampling of larvae and collection of exuviae. Results obtained with different sampling methods may not be interchangeable, as the different life stages (e.g. larvae, adults) differ in mobility (aquatic, aerial) and as they are subjected to different ecological constraints. Therefore generalization about habitat quality based on only one survey method might be questionable. Additionally, detectability of species might vary when different methods are used. In this study, nine retrodunal ponds in the Migliarino, San Rossore, Massaciuccoli Regional Park (Tuscany, Italy) were repeatedly and contemporaneously sampled during May–September 2008 with the following methods: all adults, breeding adults, larvae and exuviae. In total, 22 species were detected and the results showed that the four methods were not interchangeable. First, some species were only found using certain methods. Second, univariate measures of diversity obtained with the four sampling methods were considerably different. Alpha diversity was maximal when computed on all adults and minimal with exuviae; breeding adults and larval collection had intermediate values. Beta diversity showed an inverse trend, with the lowest value for "all adults" surveys and higher values for all the others. Finally, congruence among the assemblages revealed by the four methods was generally low. The results show that the four survey techniques are not interchangeable and that monitoring of Odonata has to be based on a carefully chosen method, which should reflect the aim of the study." 11336. Greenwood, M.J.; Harding, J.S.; Niyogi, D.K.; McIntosh, A.R. (2012): Improving the effectiveness of riparian management for aquatic invertebrates in a degraded agricultural landscape: stream size and land-use legacies. *Journal of Applied Ecology* 49: 213-222. [New Zealand; "(1) Riparian management has been embraced by water and land managers globally to offset the deleterious effects of intensive agricultural land use on aquatic ecosystems. However, the documented responses of stream communities to riparian management have been variable, particularly in highly degraded systems. (2) We used boosted regression trees and structural equation models to assess the effects of riparian condition and stream size on the invertebrate communities of 64 agricultural waterways on the Canterbury Plains, New Zealand. We hypothesized that small streams would be more degraded than larger wa-

terways but would show a greater increase in the abundance of pollution-sensitive aquatic invertebrates in response to riparian management. We also predicted that land-use legacies of poor in-stream habitat would reduce the effectiveness of current riparian management. The two strongest determinants of community structure were primarily in-stream habitat, where sedimentation and low water velocity had negative impacts on stream communities, and stream size, with smaller waterways generally more impacted than large waterways. Not surprisingly, with >150 years of agriculture and patchy riparian management on the plains, current management has not greatly improved in-stream habitat and thus had little effect on the abundance of sensitive aquatic insect (EPT) taxa. (3) Managed streams did, however, have more pollution-sensitive communities in general. This was largely mediated by decreased stream temperature, narrower/deeper channels and greater organic matter resources in streams with riparian planting and restricted stock access. Thus, if water velocity and sedimentation issues can be mitigated, then riparian management should become more effective. (4) Synthesis and applications. Within the context of a degraded agricultural landscape, we identified factors limiting the effectiveness of riparian management for stream invertebrate communities. Riparian management should primarily target and protect small streams and those without degraded in-stream habitat. Intensive management, such as in-stream habitat or channel morphology modification, may be needed to address historical factors (e.g. low velocity and sedimentation), which otherwise may continue to limit community recovery." 11337. Hager, B.J.; Kalantari, N.J.; Van Scholte, A. (2012): The distribution of *Cordulegaster* (Odonata: Cordulegasteridae) nymphs in seeps and springs of Nelson Swamp (Madison County, NY). *Northeastern Naturalist* 19(sp6): 67-76 (in English) ["Given the presence of foraging and reproducing adult *Cordulegaster* (spiketail) dragonflies in Nelson Swamp (Madison County, NY), we examined nymph distribution and abundance in the seeps and springs found within the swamp. From 9 September–4 November 2010, we surveyed 8 sites along Chittenango Creek in order to determine: (1) the species present and their distribution / occurrence among sites, (2) factors influencing species presence and abundances, and (3) patterns in size and age distribution among and within sites. For sites, we delineated habitat zones (inlet, middle, outlet), determined the benthic substrate, and measured shoreline perimeters. For nymphs, we measured head width, body length, and wing pad length and identified some to species. The majority of spiketails we identified were *C. diastatops*; *C. maculata* was also present. Most nymphs occurred in inlets with muck and cobble bottoms and in water depths less than 10 cm. Spiketail densities ranged from 0.13–8.13 individuals/m of shoreline. Smaller individuals occurred in cobble substrate, while muck substrates had individuals of larger size and greater abundance. We demarcated at least 2 age cohorts of nymphs based on their body measurements in relation to growth patterns observed in other spiketail species." gram, Cazenovia College, 22 Sullivan Street, Cazenovia, NY 13035. USA. E-mail: bhager@cazenovia.edu.

11338. Harabis, F.; Dolný, A. (2012): Underground mining can contribute to freshwater biodiversity conservation: Allogenic succession forms suitable habitats for dragonflies. *Biological Conservation* 145: 109-117 (in English). ["Human-induced changes negatively affect all components of freshwater ecosystems and comprise the major cause of global loss of diversity and the biotic homogenization of freshwater faunas. The high diversity of dragonflies in heavily industrialized areas is therefore paradoxical, to say the least. We compared diversity of dragonflies in three main freshwater habitat types (natural and human-made) occurring in Upper Silesia (Central Europe). We used multivariate methods and diversity indices for a general analysis, comprising both species richness and the species composition of assemblages. We recorded 50 species in mine subsidence pools from the total of 54 sampled species. These included a high proportion of habitat specialists (typically threatened species). We emphasize that secondary habitats (e.g. spontaneously originated mine subsidence pools) should not a priori be regarded as ecological traps, because these often are the available habitats with highest quality. These habitats significantly outweigh ponds in species richness and proportion of habitat specialists. The conservation potential of specific secondary habitats lies in the fact that these habitats can substitute for very rare natural wetlands often restricted to higher elevations. We assume that high diversity in this type of secondary habitats is not random, but rather that it depends on environmental heterogeneity caused by a specific allogenic succession process occurring as a direct consequence of mining. Highlights: *Dragonflies as bioindicators in lentic habitats of strongly man-modified landscape. *Several specific secondary habitats substitute for natural habitats. *High species richness and habitat specialists in mine wetlands are not random. *This phenomenon is closely associated with a specific allogenic succession. *The secondary habitats should not a priori be regarded as ecological traps." 11339. Harabis, F.; Dolný, A. (2012): Human altered ecosystems: suitable habitats as well as ecological traps for dragonflies (Odonata): the matter of scale. *Journal of Insect Conservation* 16(1): 121-130. (in English) ["Habitat loss and degradation can be considered as major threats to freshwater invertebrates. These often irreversible processes lead to reduction of habitat patch quality and cause local extinctions of dragonflies, notably of habitat specialists. However, the biodiversity of specific secondary habitats is very high. Here, we present findings from a 10-year study that intensively monitored odonate fauna in the Upper Silesian industrial coal region having many secondary habitats characterized by very frequent disturbances due to soil instability. We evaluated qualitative changes in the dragonfly assemblages on 10 patches using a modified dragonfly biotic index. Data analysis was supplemented by a model examining population dynamics of the threatened dragonfly *Leucorrhinia pectoralis*, using the capture-mark-recapture method, as an effective indicator of habitat quality. We show that dynamics of environmental conditions in secondary habitats are reflected in popula-

tion dynamics of dragonfly populations and assemblages. As frequency of *L. pectoralis* population extinctions within the patch is considerable and independent of size and spatial isolation of single habitats, these can be regarded as ecological traps. Nevertheless, the metapopulation dynamics may be a key adaptation of dragonflies to frequent freshwater habitat disturbances. We suggest that local extinctions are effectively balanced with (re-)colonization of newly emerging freshwater habitats. These findings have implications for potential conservation management of specific human-made habitats, because secondary habitats with a great diversity of succession stages arising directly as a consequence of environmental instability may be considered as partial alternatives to natural habitats in cultural landscapes." 11340. Hassall, C.; Thompson, D.J. (2012): Study design and mark-recapture estimates of dispersal: a case study with the endangered damselfly *Coenagrion mercuriale*. *Journal of Insect Conservation* 16: 111-120. (in English) ["Accurate data on dispersal ability are vital to the understanding of how species are affected by fragmented landscapes. However, three factors may limit the ability of field studies to detect a representative sample of dispersal events: (1) the number of individuals monitored, (2) the area over which the study is conducted and (3) the time over which the study is conducted. Using sub-sampling of mark-release-recapture data from a study on *C. mercuriale*, we show that maximum dispersal distance is strongly related to the number of recaptured individuals in the mark-release-recapture study and the length of time over which the study is conducted. Median dispersal distance is only related significantly to the length of the study. Spatial extent is not associated with either dispersal measure in our analysis. Previously consideration has been given to the spatial scale of dispersal experiments but we demonstrated conclusively that temporal scale and the number of marked individuals also have the potential to affect the measurement of dispersal. Based on quadratic relationships between the maximum dispersal distance, recapture number and length of study, we conclude that a previous study was of sufficient scale to characterise the dispersal kernel of *C. mercuriale*. Our method of analysis could be used to ensure that the results of mark-release-recapture studies are independent of levels of spatial and temporal investment. Improved confidence in dispersal estimates will enable better management decisions to be made for endangered species." 11341. Horst, J. (2012): Synergistic effects of stress and pesticides on the growth and development of *Hyla versicolor* (Eastern gray tree frog). Bachelor of Arts, Biology. The College of Wooster: (in English) ["Amphibian populations have been significantly declining worldwide over the past twenty years, and the possible causes of such declines are currently under research. This study was undertaken to determine the synergistic effects of stress and pesticides on *H. versicolor*. Experimentation took place in twenty 150 gal cattle tanks. Treatments in-

cluded a blank control, a pesticide control, predator stress with pesticide, and drought stress with pesticide. All pesticide treatments included Roundup® at ecologically relevant concentrations of 3 ppm. Predator stressed treatment groups were exposed to *Anax* sp. (dragonfly larvae) predator cues, and drought stressed treatment groups were manipulated by removing water every four days. Survivorship, weight at metamorphosis, and days to metamorphosis data were analyzed. Survivorship (K-W test; chi square = 15.727, $p = 0.001$) and days to metamorphosis (ANOVA; $F = 21.508$, $df = 3$, $p = 0.00$) were significantly negatively affected when tadpoles were exposed to multiple stressors. Survivorship of the predator/pesticide treatment was significantly lower than that of drought/pesticide treatment groups. Days to metamorphosis were also significantly fewer when exposed to Roundup® alone. Mass at metamorphosis was not significantly affected (ANOVA; $F = 1.555$, $df = 3$, $p = 0.239$). The synergism of Roundup® and stressors that tadpoles commonly encounter significantly affected *H. versicolor* larvae survivorship and growth." (Author)] Address: not stated

11345. Ishizawa, N. (2012): Oviposition behaviour of *Sympetrum frequens* (Selys) (Odonata: Libellulidae). *International Journal of Odonatology* 15(1): 1-12. (in English) ["Oviposition behaviour by *S. frequens*, a species

endemic to Japan, has been observed throughout its entire breeding season, which extended for about one month after the harvest of rice. Approximately 50% of oviposition events occurred during the first week of the reproduction period. Sunny oviposition sites were preferentially selected by ovipositing pairs. The starting time of oviposition was highly correlated with the ambient temperature (T_a), the days elapsed since the beginning of the oviposition period, and the weather of the day. The mean duration of oviposition (DO) was 325.0 ± 194.7 s in tandem oviposition (TO) and 152.5 ± 101.8 s in oviposition of the female alone (single oviposition; SO), and DO was poorly correlated with T_a . Dip rate (DR) was constant throughout the oviposition bout; however, wing-stroke frequency (WSF) of the tandem male declined from the start of oviposition to its end. The WSF of males in TO was 39.4 ± 2.8 Hz, significantly higher than that of tandem females (34.5 ± 3.0 Hz, $p < 0.0001$), but that of females in SO was as high as that of tandem males (39.7 ± 3.7 Hz). WSF was negatively correlated with T_a . In TO the male expends more energy than the female and it controls flight direction, so for the female TO is energetically less costly than SO. Furthermore, flying-oviposition into mud is more effective than non-contact flying-oviposition as the number of eggs per dip in the former exceeds one and more eggs are deposited per time unit than in the latter." Biodiversity Science 20(1): 24-31. (in Chinese, with English summary) ["In order to study the effect of repeated release of *N. cucumeris* on the species composition and diversity of arthropod community in citrus ecosystems, we established bio-control orchards, natural orchards and chemical control orchards in the Mawei and Jin'an experimental field of Fuzhou, China. Our results indicated that the species richness of bio-control orchards was higher than that of natural or chemical control orchards at both sites. Diversity and evenness indices were higher in bio-control orchards than those of other orchards in the Mawei site, and those of chemical control orchards were the lowest. Among the variously managed orchards in Jin'an, evenness and diversity indices were highest in the natural orchards and lowest in chemical orchards. Our study suggests that citrus ecosystem arthropod diversity can be enhanced by releasing *N. cucumeris* to fight against the citrus pest mites while reducing the spraying of pesticide." age during larval development on adult body size, body mass, physiology and developmental time in a tropical damselfly. Journal of Insect Physiology 58(3): 318-326. (in English) ["Few studies have looked jointly at the effects of larval stressors on life history and physiology across metamorphosis, especially in tropical insects. Here we investigated how the variation of food availability during the larval stage of the tropical and territorial *Hetaerina americana* affects adult body size and body mass, and two physiological indicators of condition – phenoloxidase activity (an indicator of immune ability) and protein concentration. We also investigated whether larval developmental time is prolonged when food is scarce, an expected situation for tropical species whose larval time is less constrained, compared to temperate species. Second instar larvae were collected from their natural environments and reared in one of two diet regimes: (i) "rich" provided with five *Artemia salina* prey every day, and (ii) "poor" provided with two *A. salina* prey every day. In order to compare how distinct our treatments were from natural conditions, a second set of last-instar larvae were also collected and allowed to emerge. Only body size and phenoloxidase increased in the rich regime, possibly to prioritize investment on sexually selected traits (which increase mating opportunities), and immune ability, given pathogen pressure. The sexes did not differ in body size in relation to food regimes but they did differ in body mass and protein concentration; this can be explained on the basis of the energetically demanding territorial activities by males (for the case of body mass), and female allocation to egg production (for the case of protein). Finally, animals delayed larval development when food was scarce, which is coherent for tropical environments. These findings provide key insights in the role of food availability in a tropical species." the Satsunan Islands, which are part of the Ryukyu Archipelago, and lie south of the Osumi Peninsula about 60 km from Kyu-shu (30°48'N 130°25'E), Japan. The islands are of volcanic origin and have a total area of approximately 1,030 km². The climate is subtropical. Records of *Agriocnemis femina*, *Ischnura asiatica*, *Orthetrum glaucum*, *Pantala flavescens*, *Trithemis aurora* are documented.] Address: Kanai, K., Kagoshima Prefectural Museum, 1-1 Shiroyama-cho, Kagoshima City, 892-0853, Japan

11351. Kim, M.; Yoo, J.-c. (2012): Diet of yellow bitterns (*Ixobrychus sinensis*) during the breeding season in South Korea. *Journal of Ecology and Field Biology* 35(1): 9-14. (in English) ["Yellow bitterns are a small wetland bird common to Asian countries including South Korea, Japan, and China. The aim of this study is to describe diet of yellow bitterns during the breeding season in artificial wetland of northeastern South Korea between May to August 1999-2001. For the purposes of this paper, we observe the frequency of nest visiting by parents during the chick rearing period. A total of 98 boluses regurgitated by 52 chicks aged 1 day to 11 days after hatching form the sample and are shown to contain 323 food items. A bolus contained mean 3.8 items and weighs 0.2 g to 7.7 g. The most regularly occurring food items recorded are fish (63%) and insects (33%). In terms of fish, top mouth minnows (*Pseudorasbora parva*) and crucian carps (*Carassius auratus*) are frequently observed. In terms of insects, there are mosquitoes (Diptera), instars of dragonfly (Libellulidae), damselflies (Coenagrionidae) and water bugs (*Diplonychus japonicus*). Yellow bitterns were also shown to feed on bullfrogs (*Rana catesbeiana*), shrimp (Palaemonidae), and spiders (Araneae). The size of fish in a bolus ranged from 15.56 mm to 93.73 mm (mean, 37.08 mm). The amount of food can be observed to increase with the age of chicks ($r = 0.279$, $P = 0.025$, $N = 64$) but parents did not provide larger fish as chicks grew. Parent birds visited nests more frequently when they have a larger brood ($F_{1,21} = 14.529$, $P = 0.001$). Our results suggest that fish is the most important prey during the breeding season and that age of chicks is related to amount of diet in yellow bitterns." (Authors)] Address: not available

11352. Koizumi, N.; Quinn, T.W.; Jinguji, H.; Nishida, K.; Watabe, K.; Takemura, T.; Mori, A. (2012): Development and characterization of 23 polymorphic microsatellite markers for *Sympetrum frequens*. *Conservation Genetics Resources* 4(1): 67-70. (in English) ["23 polymorphic microsatellite markers for *Sympetrum frequens* were developed and characterized. The number of distinct alleles per locus in 32 individuals ranged from 2 to 23. The observed heterozygosity ranged from 0.031 to 0.938, while the expected heterozygosity varied from 0.031 to 0.922. No loci deviated significantly from Hardy-Weinberg equilibrium, no linkage disequilibrium was observed between pairs of loci and no loci showed evidence of null alleles. These microsatellite markers are expected to contribute to future investigations of genetic variation and structure in *S. frequens* populations." 11356. Lawrence, J.E.; Deitch, M.J.; Resh, V.H. (2012): Effects of vineyard coverage and extent on benthic macroinvertebrates in streams of Northern California. *Annales de Limnologie* 47(4): 347-354. (in English) ["Vineyards are a dominant feature of many landscapes in Mediterranean-climate regions. We examined the effects of streamflow declines, associated with vineyard water-withdrawals for frost protection, on benthic-macroinvertebrate communities at three sites along three small streams in the Mediterranean-climate region of Northern California. One site was heavily affected by water withdrawals for frost protection, the other two were not. In addition, we examined relationships between vineyard coverage and benthic-macroinvertebrate community response using data from 59 sampling events at 39 sites along 35 small streams in Napa County, California. We tested three a priori hypotheses in terms of the response of biological traits of benthic macroinvertebrates to high vineyard coverage: (1) proportion of individuals with semi-voltine (i.e., one generation every 2 years) life cycles would be lower compared to those with uni- and multi-voltine cycles, (2) proportion of individuals able to undergo diapause would be higher, and (3) proportion of individuals with the ability to burrow into the substrate would be higher. In the three-site study, we found that vineyard water-withdrawals for frost protection coincided with consistently lower values in both the benthic-macroinvertebrate index of biotic in-

tegrity (B-IBI) developed for Northern California streams and the ratio of Ephemeroptera–Plecoptera–Trichoptera to Odonata–Coleoptera–Hemiptera individuals (EPT / OCH), a metric developed for European Mediterranean streams. In the broader-scale study, we observed that vineyard-coverage levels above about 20% coincided with lower values of the B-IBI. The semi-voltine life-cycle trait was lower above this level, whereas the diapause and burrowing traits were not affected." (Authors)] Address: Lawrence, J., Dept Environ. 11360. McClure, C.J.W.; Rolek, B.W.; McDonald, K.; Hill, G.E. (2012): Climate change and the decline of a once common bird. *Ecology and Evolution* 2(2): 370-

378. (in English) ["Climate change is predicted to negatively impact wildlife through a variety of mechanisms including retraction of range. We used data from the North American Breeding Bird Survey and regional and global climate indices to examine the effects of climate change on the breeding distribution of the Rusty Blackbird (*Euphagus carolinus*), a formerly common species that is rapidly declining. We found that the range of the Rusty Blackbird retracted northward by 143 km since the 1960s and that the probability of local extinction was highest at the southern range margin. Furthermore, we found that the mean breeding latitude of the Rusty Blackbird was significant and positively correlated with the Pacific Decadal Oscillation with a lag of six years. Because the annual distribution of the Rusty Blackbird is affected by annual weather patterns produced by the Pacific Decadal Oscillation, our results support the hypothesis that directional climate change over the past 40 years is contributing to the decline of the Rusty Blackbird. Our study is the first to implicate climate change, acting through range retraction, in a major decline of a formerly common bird species." (Authors) The breeding success and site selection of Rusty Blackbirds is closely tied to shallow water and macroinvertebrate prey, particularly odonates (Matsuoka et al. 2010). Therefore, the decline of the species is discussed in the framework of altering diet availability, mainly Odonata.] Address: McClure, C.J.W., Dept of Biological Sciences, 331 Funchess Hall, Auburn University, Alabama 36849, USA. 11361. McGuffin, M.; Baker, R.L. (2012): Larval *Ischnura verticalis* (Odonata: Coenagrionidae) respond to visual cues of predator presence. *Journal of Insect Behavior* 25(2): 143-154. (in English) ["Larvae of some species of damselflies respond to chemical cues of fish predators but, while larvae of many species are thought to detect prey through vision, there is little evidence that larvae respond to visual cues of predator presence. This laboratory study indicated larval *Ischnura verticalis* behaviours are affected by visual cues and, to a much lesser extent, chemical cues of fish; there was no significant interaction between the effects of visual and chemical cues. Responses to chemical cues of fish did not depend on whether fish were fed *I. verticalis* larvae versus commercial fish food. Larvae were more active in the spring than the fall when they were likely in diapause. Results suggest larvae can use vision to detect large, active predators but can also detect predators through olfaction when visual cues are unreliable." 11364. Nel, A.; Bechly, G.; Prokop, J.; Béthoux, O.; Fleck, G. (2012): Systematics and evolution of Paleozoic and Mesozoic damselfly-like Odonoptera of the 'Protozygopteran' grade. *Journal of Paleontology* 86: 81-104. (in English) ["The Paleozoic to Mesozoic grade 'Protozygoptera' is revised. It appears to be composed of two main lineages, namely the superfamily Permagrionoidea, and the Archizygoptera. The latter taxon forms a monophyletic group together with Panodonata (= crown-Odonata plus their closest stem-relatives). Therefore, the 'Protozygoptera' as previously understood is paraphyletic. Diagnostic characters of the 'Protozygoptera', Permagrionoidea, and Archizygoptera are re-evaluated. The *Permolestidae* is considered as a junior synonym of the *Permagrionidae*. The following new taxa are described: *Permolestes sheimogorai* new species, *Permolestes soyanaensis* new species, *Epilestes angustapterix* new species, *Solikamptilon pectinatus* new species (all in *Permagrionidae*); *Lodeviidae* new family (for *Lodevia*); *Luseiidae* new family (including *Luseia breviata* new genus and species); *Kennedyia azari* new species, *Kennedyia pritykinae* new species, *Kennedyia ivensis* new species, *Progoneura grimaldii* new species (all in *Kennedyidae*); *Engellestes chekardensis* new genus and species (in *Bakteniidae*); and *Azaronera permiana* new genus and species (in *Voltzialestidae*). The *Kaltanoneuridae* and *Oboraneuridae* are revised. The evolution of protozygopteran Odonoptera during the transition from the Permian to the Triassic is discussed. The larger taxa of the permagrionoid lineage apparently did not cross through the Permian–Triassic boundary, unlike the more gracile Archizygoptera. This last group shows a remarkable longevity from the late Carboniferous to the Early Cretaceous. It also presents a great

taxonomic and morphological stability, with genera ranging from the Permian to the Triassic, and a wing venation pattern nearly unchanged from the late Carboniferous to the Late Triassic. The mass extinction at the end of the Permian period seemingly had a minor effect on these tiny and delicate insects." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. 11368. Ohba, S.-y.; Inatani, Y. (2012): Feeding preferences of the endangered diving beetle *Cybister tripunctatus orientalis* Gschwendtner (Coleoptera: Dytiscidae). *Psyche*, Article ID 139714, doi:10.1155/2012/139714: 3 pp. (in English) ["The numbers of *C. tripunctatus orientalis* (Cto) diving beetles are declining in most regions of Japan, and it is included in the Red Data List of species in 34 of 47 prefectures of Japan. However, basic ecological information about Cto, such as its feeding habits, remains unknown. In order to elucidate the feeding habits of Cto larvae, feeding preference experiments were carried out in 2nd and 3rd instar larvae. The number of Odonata nymphs consumed was significantly higher than the number of tadpoles consumed, indicating that Cto larvae prefer Odonata nymphs to tadpoles. In addition, all the first instar larvae of Cto developed into second instars when they were supplied

with motionless Odonata nymphs, but their survival rate was lower when they were supplied with motionless tadpoles. These results suggest that Cto larvae prefer insects to vertebrates." 11369. Outomuro, D.; Bokma, F.; Johansson, F. (2012): Hind wing shape evolves faster than front wing shape in Calopteryx damselflies. *Evolutionary Biology* 39(1): 116-125. (in English) ["Wing shape has been shown in a variety of species to be influenced by natural and sexual selection. In damselflies, front- and hind wings can beat independently, and functional differentiation may occur. Males of Calopteryx damselflies show species-specific nuptial flights that differ in colour signalling with the hind wings. Therefore, hind wing shape and colour may evolve in concert to improve colour display, independent of the front wings. We predicted that male hind wing shape evolves faster than front wing shape, due to sexual selection. Females do not engage in sexual displays, so we predicted that females do not show differences in divergence between front- and hind wing shape. We analysed the non-allometric component of wing shape of five European Calopteryx taxa using geometric morphometrics. We found a higher evolutionary divergence of hind wing shape in both sexes. Indeed, we found no significant differences in rate of evolution between the sexes, despite clear sex-specific differences in wing shape. We suggest that evolution of hind wing shape in males is accelerated by sexual selection on pre-copulatory displays and that this acceleration is reflected in females due to genetic correlations that somehow link the rates of wing shape evolution in the two sexes, but not the wing shapes themselves." 11372. Ratti, J.; Vachtsevanos, G. (2012): Inventing a biologically inspired, energy efficient micro aerial vehicle. *Journal of Intelligent & Robotic Systems* 65(1-4):

437-455. (in English) ["In recent years, research efforts have focused on the design, development and deployment of unmanned systems for a variety of applications ranging from intelligence and surveillance to border patrol, rescue operations, etc. Micro Aerial Vehicles are viewed as potential targets that can provide agility and accurate small area coverage while being cost-effective and can be easily launched by a single operator. The small size of MAVs allows such flight operations within confined space but the control effectors must provide sufficient maneuverability, while maintaining stability, with only limited sensing capability onboard the platform. To meet these challenges, researchers have long been attracted by the amazing attributes of biological systems, such as those exhibited by birds and insects. Birds can fly in dense flocks, executing rapid maneuvers with g-loads far in excess of modern fighter aircrafts, and yet never collide with each other, despite the absence of air traffic controllers. This paper introduces a novel framework for the design and control of a Micro Air Vehicle. The vehicle's conceptual design is based on biologically-inspired principles and emulates a dragonfly (Odonata-Anisoptera). A sophisticated multi-layered Hybrid & Linear/Non-Linear controller to achieve extended flight times and improved agility compared to other Rotary and Flapping Wing MAV designs. The paper addresses the design and control features of the proposed QV design and gives an overview on the developmental efforts towards the prototyping of the flyer. The potential applications for such a high endurance vehicle are numerous, including air-deployable mass surveillance in cluster and swarm formations. The disposable nature of the vehicle would help in battle-field deployment as well, where such a MAV would be made available to soldiers for proximity sensing and threat level assessment. Other applications would include search and rescue operations and civilian law-enforcement." 11373. Relyea, R.A. (2012): New effects of Roundup on amphibians: Predators reduce herbicide mortality; herbicides induce antipredator morphology. *Ecological Applications* 22: 634-647. (in English) ["The use of pesticides is important for growing crops and protecting human health by reducing the prevalence of targeted pest species. However, less attention is given to the potential unintended effects on nontarget species, including taxonomic groups that are of current conservation concern. One issue raised in recent years is the potential for pesticides to become more lethal in the presence of predatory cues, a phenomenon observed thus far only in the laboratory. A second issue is whether pesticides can induce unintended trait changes in nontarget species, particularly trait changes that might mimic adaptive responses to natural environmental stressors. Using outdoor mesocosms, I created simple wetland communities containing leaf litter, algae, zooplankton, and three species of tadpoles (wood frogs [*Rana sylvatica* or *Lithobates sylvaticus*], leopard frogs [*R. pipiens* or *L. pipiens*], and American toads [*Bufo americanus* or *Anaxyrus americanus*]). I exposed the communities to a factorial combination of environmentally relevant herbicide concentrations (0, 1, 2, or 3 mg acid equivalents [a.e.]/L of Roundup Original MAX) crossed with three predator-cue treatments (no predators, adult

newts [*Notophthalmus viridescens*], or larval dragonflies [*Anax junius*]). Without predator cues, mortality rates from Roundup were consistent with past studies. Combined with cues from the most risky predator (i.e., dragonflies), Roundup became less lethal (in direct contrast to past laboratory studies). This reduction in mortality was likely caused by the herbicide stratifying in the water column and predator cues scaring the tadpoles down to the benthos where herbicide concentrations were lower. Even more striking was the discovery that Roundup induced morphological changes in the tadpoles. In wood frog and leopard frog tadpoles, Roundup induced relatively deeper tails in the same direction and of the same magnitude as the adaptive changes induced by dragonfly cues. To my knowledge, this is the first study to show that a pesticide can induce morphological changes in a vertebrate. Moreover, the data suggest that the herbicide might be activating the tadpoles' developmental pathways used for antipredator responses. Collectively, these discoveries suggest that the world's most widely applied herbicide may have much further-reaching effects on nontarget species than previously considered." 11374. Ren, H.-H.; Wang, X.-S.; Chen, Y.-L.; Li, X.-D. (2012): Biomechanical behaviors of dragonfly wing: relationship between configuration and deformation. *Chinese Physics B* 21(3) (034501): 10 pp. (in English) ["In this paper, the natural structures of a dragonfly wing (*Pantala flavescens*), including the corrugation of the chordwise cross-section, the sandwich microstructure veins, and the junctions between the vein and the membrane, have been investigated with experimental observations, and the morphological parameters of these structural features are measured. The experimental result indicates that the corrugated angle among the longitudinal veins ranges from 80° to 150°, and the sandwiched microstructure vein mainly consists of chitin and protein layers. Meanwhile, different finite element models, which include models I and I* for the planar forewings, models II and II* for the corrugated forewings, and a submodel with solid veins and membranes, are created to investigate the effects of these structural features on the natural frequency/modal, the dynamical behaviours of the flapping flight, and the deformation mechanism of the forewings. The numerical results indicate that the corrugated forewing has a more reasonable natural frequency/modal, and the first order up-down flapping frequency of the corrugated wing is closer to the experimental result (about 27.00 Hz), which is significantly larger than that of the planar forewing (10.94 Hz). For the dynamical responses, the corrugated forewing has a larger torsional angle than the planar forewing, but a lower flapping angle. In addition, the sandwich microstructure veins can induce larger amplitudes of torsion deformation, because of the decreasing stiffness of the whole forewing. For the submodel of the forewing, the average stress of the chitin layer is much larger than that of the protein layer in the longitudinal veins. These simulative methods assist us to explain the flapping flight mechanism of the dragonfly and to design a micro aerial vehicle by automatically adjusting the corrugated behaviour of the wing." 11378. Sánchez-Guillén, R.A.; Wellenreuther, M.; Cordero-Rivera, A. (2012): Strong asymmetry in the relative strengths of prezygotic and postzygotic barriers between two damselfly sister species. *Evolution* 66(3): 690-707. (in English) ["One of the longest debates in biology has been over the relative importance of different isolating barriers in speciation. However, for most species, there are few data evaluating their relative contributions and we can only speculate on the general roles of pre- and postzygotic isolation. Here we quantify the absolute and cumulative contribution of 19 potential reproductive barriers between two sympatric damselfly sister species, *Ischnura elegans* and *I. graellsii*, including both premating (habitat, temporal, sexual and mechanical isolation) and postmating barriers (prezygotic: sperm insemination success and removal rate, oviposition success, fertility, fecundity; postzygotic: hybrid viability, hybrid sterility and hybrid breakdown). In sympatry, total reproductive isolation between *I. elegans* females and *I. graellsii* males was 95.2%, owing mostly to a premating mechanical incompatibility (93.4%), while other barriers were of little importance. Isolation between *I. graellsii* females and *I. elegans* males was also nearly complete (95.8%), which was caused by the cumulative action of multiple prezygotic ($n = 4$, 75.4%) and postzygotic postmating barriers ($n = 5$, 7.4%). Our results suggest that premating barriers are key factors in preventing gene flow between species, and that the relative strengths of premating barriers is highly asym-

metrical between the reciprocal crosses." (Authors)] Address: Sánchez-Guillén, Rosa, Depto de Ecología e Biología Animal, E.U.E.T. Forestal, Universidade de Vigo, Pontevedra, Spain. E-mail: rguillen@uvigo.es

11379. Sánchez-Herrera, M.; Ware, J.L. (2012): Biogeography of dragonflies and damselflies: Highly mobile predators. In: Stevens, L. (Ed.): *Global Advances in Biogeography*. InTech: 291-306. (in English) ["Conclusion: The biogeography of Odonata is a rich area of study that needs further attention. As one of the basal-most taxa in Insecta (Grimaldi and Engel, 2005), our understanding of the origin of flying insects will be greatly improved by additional study, particularly through research that includes thorough analyses of stem and crown group taxa. Future work should explore the biogeography of lesser-studied zygopteran groups from South America, and expand understanding of species rich groups like the Libelluloidea and Gomphidae. Odonata have been heralded as model indicators for climate change, due in part to their great dispersal capabilities, and earlier emergence has been documented in our warming climate (e.g., Hassell et al., 2007). Range expansion of tropical taxa is predicted into higher latitudes. Although some Odonata ranges fluctuate with environmental changes, northward range expansions have been reported over the last 40 years among several European taxa (e.g., Hickling et al., 2005). The future biogeographical distribution of Odonata undoubtedly will be influenced directly and indirectly by anthropogenically altered climate." (Authors)] The paper reviews the following subjects: "2. What are dragonflies and damselflies? Real hunters; 2.1 Ecology and behaviour; 2.2 Species diversity and biogeography; 2.3 Dispersal in Odonata, flight behaviour and migration; 3. Anisoptera phylogeny; 3.1 Biogeography of the dragonfly superfamily Libelluloidea and Australian endemism; 4. Biogeography of Zygoptera." 11380. Shinohara, S.; Obata, A.; Seki, M.; Ichihara, K.; Ishida, E.H. (2012): Study of airfoils for the unique micro wind turbine blade. Design for innovative value towards a sustainable society: 691-696. (in English) ["An airfoil of insect's wing is completely different from the conventional streamlining airfoil, and it has very thin corrugated cross section. As you can see from the flight of insects, their wings are used in the low speed region, functioning in a speed region different to the ones in which streamlining airfoil is used. Studies on the aerodynamic characteristics of the corrugated wing in the low speed region are very limited, with many aspects still remaining unknown. In order to clarify aerodynamic characteristics of corrugated airfoil in the low speed region, we have developed our own system composed of micro three-component balance and swirl-type experimental water channel, and investigated the aerodynamic characteristics of the corrugated airfoil and curved plate having smooth cross section in the low speed regions ($Re=7,000$ and $11,000$). This investigation revealed that, in the low speed regions the aerodynamic characteristics of the corrugated airfoil was equivalent to or superior than those of the curved plate, and it was also found that the aerodynamic characteristics of the

curved plate were very susceptible to the changes in Reynolds number whereas those of the corrugated wing were insusceptible to the changes. In the past, a small wind turbine has not been paid much attention as a source of alternative energy because of its low availability in low wind speed region and of its difficulty in handling it. All of these issues inherent in the small wind turbine will be solved by adopting the corrugated wing in the wind turbine. All of these findings from our investigation are reported in this paper." (Authors)] The paper includes references to Odonata wing morphology.] Address: Seki, M., Department of Aerospace Engineering, and Micro Flying Robot Laboratory, Nippon Bunri University, 1727 Ichigi, Oita 870-3979, Japan

11381. Smith, A.J.; Cook, T.J. (2012): Revision of the genus *Prismatospora* and description of *Prismatospora cloptoni* n. sp. (Apicomplexa: Actinocephalidae: Acanthosporinae) from naiads of the Green Darner, *Anax junius* (Odonata: Anisoptera: Aeshnidae), in east Texas, U.S.A. *Comparative Parasitology* 79(1): 9-14. (in English) ["*Prismatospora cloptoni* n. sp. (Apicomplexa: Eugregarinida: Actinocephalidae: Acanthosporinae) is described from naiads of *A. junius* collected from the pond at the Sam Houston State University Center for Biological Field Studies, Walker County, Texas, USA. This is the second species described in the genus, and it confirms the generic hypothesis of *Prismatospora*. The generic diagnosis is revised to reflect common characters of its constituent species." 11382. Sun, J.; Bhushan, B. (2012): The structure and mechanical properties of dragonfly wings and their role on flyability. *Comptes Rendus Mécanique* 340(1): 3-17. (in English) ["Dragonfly wings possess great stability and high load-bearing capacity during flapping flight, glide, and hover. Scientists have been intrigued by them and have carried out research for biomimetic applications. Relative to the large number of works on its flight aerodynamics, few researchers have focused on the insect wing structure and its mechanical properties. The wings of dragonflies are mainly composed of veins and membranes, a typical nanocomposite material. The veins and membranes have a complex design within the wing that give rise to whole-wing characteristics which result in dragonflies being supremely versatile, maneuverable fliers. The wing structure, especially corrugation, on dragonflies is believed to enhance aerodynamic performance. The mechanical properties of dragonfly wings need to be understood in order to perform simulated models. This paper focuses on the effects of structure, mechanical properties, and morphology of dragonfly wings on their flyability, followed by the implications in fabrication and modelling." 11383. Takahara, T.; Kohmatsu, Y.; Maruyama, A.; Yamaoka, R. (2012): Predator-specific inducible morphological changes in two Japanese anuran tadpoles. *Herpetology Notes* 5: 43-47. (in English) ["We evaluated inducible morphological changes in tadpoles of two anuran species, the Japanese tree frog (*Hyla japonica*) and the wrinkled frog *Glandirana* (*Rana*) *rugosa*, against two predator types, which were represented by

a predatory fish (*Carassius auratus*) and the nymph of a dragonfly (*Anax parthenope julius*). In the presence of fish cues, *H. japonica* developed shallower tail fins, whereas *G. rugosa* did not exhibit such morphological change. Both tadpole species developed deeper tail fins in the presence of dragonfly nymph cues. The predator specific responses for the species' tadpoles are likely to optimize avoidance of lethal attacks by predators. The interspecific differences in inducible morphological defence traits might be related to the balance with the effects of other defensive traits and explained by the frequency and time of their encounters with predators." 11385. Termaat, T.; Kalkman, V.J. (2012): Odonata Red List Report 2011 using Dutch and IUCN criteria. *Brachytron* 14(2): 75-187. (in Dutch, with English summary) ["In this report a proposal is published for a revised Red List for Dragonflies. When the Dutch Ministry of Economic Affairs, Agriculture and Innovation publishes this list in the government gazette, the Red List of 1997 will be replaced. In addition, this report presents a regional Red List following the internationally used criteria of IUCN, so that the situation in The Netherlands can be compared with that in other countries. All 65 species regularly reproducing in The Netherlands were assessed in order to decide whether they should be red-listed according to the criteria of the Dutch government. Red List species are species that became extinct after 1900 and species that are threatened. The threatened species are subdivided in four categories. ... The 2011 Red List includes the following numbers of species per category: 5 Extinct in The Netherlands, 4 Critically endangered, 6 Endangered, 6 Vulnerable, and 2 Susceptible. Thus, the Red List comprises 23 species (35% of the assessed species). The other 42 species are Not threatened at present. In order to make a clean comparison between the new Red List and the 1997 Red List, the latter has been reconstructed using the current improved method and partly with additional data. The reconstructed 1997 Red List comprises 27 species (44% of the assessed species). These are categorised

as follows: 8 species Extinct in the Netherlands, 4 Critically endangered, 8 Endangered, 6 Vulnerable en 1 Susceptible. The other 34 species were Not threatened at present. A comparison between both Red Lists shows a fairly positive picture. The 2011 Red List includes three species less than the 1997 list, despite the fact that four species appear on the Red List for the first time (two of which after becoming recently established). Three species previously extinct in The Netherlands have reappeared. And most species of running waters and fens show a positive trend. Species of softwater lakes are increasing too, but alarming exceptions exist. According to the IUCN criteria, which chiefly assess the situation over the past ten years, 19 species feature on the Red List. These are categorized as follows: 3 Regionally Extinct, 2 Critically Endangered, 4 Endangered, 3 Vulnerable, and 7 Near Threatened. By IUCN criteria, the other 46 species are assessed as not threatened and belong to Least Concern. The most important causes of decline of dragonflies are habitat destruction due to intensified use of land and environmental problems such as acidification, eutrophication, and desiccation. These threats were strongest in the period 1950-1980. Most habitat-specialised species had their strongest decline during those years. From the 1990s onward many species have reversed their negative trend, due to improvement of the environment and nature restoration measures. The higher number of warm summers has also had a positive influence on some species. Potential negative effects of climate change on northern and northeastern dragonfly species are still insufficiently known. To enable Red List updating, the data collected by volunteers within the framework of distribution research and the Dutch Dragonfly Monitoring Scheme are indispensable." (Authors)] Address: Termaat, T., Rijnsteeg 8-10a, 6708 PP Wageningen, The Netherlands. E-mail: tim.termaat@vlinderstichting.nl

11386. Theischinger, G.; Jacobs, S. (2012): Surprise re-discovery of *Acanthaeschna victoria*, a key taxon in dragonfly evolution (Odonata, Aeshnoidea, Telephlebitidae). *Agrion* 16(1): 3-9. (in English) ["During monitoring by the Office of Environment and Heritage in south-eastern New South Wales a rather large number of larvae of the rare and elusive dragonfly species *A. victoria*, a key taxon in dragonfly evolution, were found at three new localities. The southernmost of these at Nadgee extends the range of the species south by more than 200 km to 5 km from the NSW/Victoria border and suggests that the species will eventually be found in Victoria. Rearing of the larvae in Sydney confirmed the hitherto only supposed identity of the larvae, and provided for the first time information on the morphology of the female larva and on the coloration of the subadult imagines. The rearing also provided new information on food of the larvae, life history and phenology. Some of the reared subadults were released in their natural habitat, and specimens were preserved for future DNA analysis for phylogenetic studies. A thought is given to the possible future usage – when more data are available – of *A. victoria* as an indicator species for ecological condition and climate change." (Authors)] Address: Theischinger, G., Water Science, Office of Environment & Heritage, Dept of Premier & Cabinet, PO Box 29, Lidcombe NSW 1825, Australia. E-mail: Gunther.Theischinger@environment.nsw.gov.au

11387. Umar, D.M.; Marinov, M.G.; Schorr, M.; Chapman, H.M. (2012): Odonata attracted by light - a new topic for myth-busters. *International Dragonfly Fund* -

Report 43: 1-52. (in English) ["Six Odonata species were collected during night light trapping on the Mambilla Plateau, Taraba State Nigeria. Being predominantly diurnal insects, Odonata captured in light traps have always been considered as an anomaly. The new data initiated an extensive interrogation of all records on Odonata collected near artificial light sources. A total of 415 records (402 published and 13 new) are presented here with a summary of previous discussions and new discussion points. The general conclusion is that Odonata are mainly confused by, rather than attracted to the light. New avenues for further research in this field are suggested based on previous important studies undertaken on Odonata morphology and physiology." (Authors)] Address: Marinov, M., 7/160 Rossall Str., Merivale 8014, Christchurch, New Zealand. E-mail: milen.marinov@canterbury.ac.nz

11388. Verdonschot, R.C.M.; Peeters, E.T.H. (2012): Preference of larvae of *Enallagma cyathigerum* (Odonata: Coenagrionidae) for habitats of varying structural complexity. *Eur. J. Entomol.* 109(2): 229-234. (in English) ["In macrophyte-rich lentic ecosystems, higher numbers of damselfly larvae occur in areas where there is structurally complex vegetation than in those where the plant architecture is relatively simple. Biotic interactions rather than morphological constraints are considered to underlie this pattern. We investigated whether the preference of the larvae of *E. cyathigerum* for a particular habitat was retained in absence of prey, predators and / or conspecifics. A series of laboratory choice experiments was conducted in which combinations of sediment and artificial plants differing in structural complexity were offered simultaneously to the larvae. Larvae preferred patches with structurally complex vegetation over patches with simply structured vegetation or lacking vegetation. Patches with simply structured vegetation were preferred over those with bare sediment, but the number of larvae showing a clear choice, which is regarded as an indication of the strength of the preference for a particular habitat, was relatively low compared to the number of individuals responding when complex vegetation was present. Based on the results presented, we conclude that the preference of *E. cyathigerum* larvae for structurally complex vegetation is independent of the presence of predators, prey or competitors. This suggests that this behaviour of the larvae is either learned or an innate response." (Authors)] Address: Verdonschot, R. Dept of Freshwater Ecology, Centre for Ecosystem Studies, Alterra, Wageningen UR, P.O. Box 47, 6700 AA, Wageningen, The Netherlands. E-mail: ralf.verdonschot@wur.nl

11389. Willigalla, C.; Fartmann, T. (2012): Patterns in the diversity of dragonflies (Odonata) in cities across Central Europe. *Eur. J. Entomol.* 109: 235-245. (in English) ["Urbanisation is an important cause of species extinctions. Although urban water systems are also highly modified, studies on aquatic or semi-aquatic organisms are rare. The aim of this study is to identify the factors that determine species richness of Odonata in 22 Central European cities and along an urban-rural gradient within six of them. With 64 indigenous species in total and an average of 33 species per city, the species richness of Odonata in Central European cities is comparatively high. A generalised linear model indicates that species richness is positively related to city area. Additional predictors are climatic variables (temperature amplitude, sunshine duration and July temperature) and the year last studied. Since most cities are usually lo-

cated in areas with naturally high habitat heterogeneity, we assume that cities should be naturally rich in dragonflies. The role of city area as a surrogate for habitat and structural richness most likely explains why it is strongly associated with Odonata species richness. The relationship between species richness and the climatic variables probably reflects that Odonata species richness in Central Europe is limited by warm and sunny conditions more than by availability of water. The temporal effect (the year last studied) on species richness is likely to be a consequence of the recent increase in Mediterranean species associated with global warming. Urbanisation clearly has an adverse effect on the species diversity of Odonata. Species richness increases along a gradient from the centre of a city to the rural area and is significantly highest in rural areas. This pattern probably reflects a gradient of increasing habitat quality from the centre of cities to rural areas. Moreover, the number of water bodies is generally very low in the city centres. Based on our results, we make recommendations for increasing the abundance and number of species of dragonflies in cities." (Authors)] Address: Fartmann, T., Dept Community Ecol., Inst. Landscape Ecology, Univ. of Münster, Robert-Koch-Str. 28, 48149 Münster, Germany. E-mail: fartmann@uni-muenster.de

11390. Wohlfahrt, B.; Vamosi, S.M. (2012): Predation and habitat isolation influence the community composition-area relationship in dytiscid beetles (Coleoptera: Dytiscidae). *Community Ecology* 13(1): 1-10 (in English) ["A major goal in ecology remains the understanding of patterns in diversity and distributions of species in natural communities. The species-area relationship is an important tool for investigating differences among communities, and may be also influenced by habitat isolation and dominant predator presence. In this two-year study, we evaluated the influences of habitat area, isolation and predation on community composition of dytiscids in two geographical regions dominated by different top predators (large predaceous dragonfly larvae or fish). Contrary to expectations, surface area, isolation and predator presence/absence alone did not significantly influence dytiscid species richness and total abundance, but in association with other environmental variables, such as submerged macrophyte growth forms. Components of habitat heterogeneity likely outweighed effects of area and predation regime on prey species diversity. However, differences in the set of abundant species were best explained by habitat surface area. Thus, in contrast to species diversity, gradients in community composition were not outweighed by components of heterogeneity. In this study, predator presence was not correlated with habitat isolation. Instead, our results revealed that the effect of predator presence/absence on prey community composition and the resulting set of coexisting species may depend on habitat isolation. Within regions, the effect of large predaceous dragonfly larvae on species composition may depend on pond surface area, whereas the presence of fish influenced species composition alone and in association with area. We advocate that regional differences in environmental gradients be considered when community composition is evaluated." 11391. Wong, D.C.C.; Pearson, R.D.; Elvin, C.M.; Merritt, D.J. (2012): Expression of the rubber-like protein,

resilin, in developing and functional insect cuticle determined using a *Drosophila* anti-rec 1 resilin antibody. *Developmental Dynamics* 241(2): 333-339. (in English) ["Background: The natural elastomeric protein, insect resilin, is the most efficient elastic material known, used to store energy for jumping and flight in a variety of insects. Here, an antibody to recombinant *Drosophila melanogaster* pro-resilin is used to examine resilin expression in *Drosophila* and a wider range of insects. Results: Immunostaining of *Drosophila* embryos reveals anti-resilin reactivity in epidermal patches that exhibit a dynamic spatial and temporal expression through late embryogenesis. Resilin is also detected in stretch receptors in the embryo. In developing adult *Drosophila*, resilin pads are described at the base of wings and at the base of flexible sensory hairs in pupae. Resilin is also detected in embryos of the tephritid fruitfly, *Bactrocera tryoni*, and two well-known concentrations of insect resilin: the flight muscle tendon of the dragonfly and the pleural arch of the flea. Conclusions: The anti-Rec1 antibody developed using *Drosophila* pro-resilin as antigen is cross-reactive and is useful for detection of resilin in diverse insects. For the first time, resilin expression has been detected during embryogenesis, revealing segmental patches of resilin in the developing epidermis of *Drosophila*." 11394. Yu, G.a.; Huang, H.Q.; Wang, Z.; Brierley, G.; Zhang, K. (2012): Rehabilitation of a debris-flow prone mountain stream in southwestern China – Strategies, effects and implications. *Journal of Hydrology* 414–415: 231-243. (in English) ["Rehabilitation of Shengou Creek, a small, steep mountain stream in southwestern China that is prone to debris flows, started more than 30 years ago through an integrated program of engineering applications (check dams and guiding dikes), biological measures (reforestation), and social measures (reducing human disturbance). Small and medium-sized check

dams and guiding dikes were constructed on key upper and middle sections of the creek to stabilize hillslopes and channel bed. Meanwhile, *Leucaena leucocephala*, a drought-tolerant, fast-growing, and highly adaptive plant species, was introduced to promote vegetation recovery in the watershed. The collective community structure of tree, shrub, and herb assemblages in the artificial *L. leucocephala* forest, which developed after 7 years, enhanced soil structure and drastically reduced soil erosion on hillslopes. Cultivation of steep land was strictly controlled in the basin, and some inhabitants were encouraged to move from upstream areas to downstream towns to reduce disturbance. These integrated measures reduced sediment supply from both hillslopes and upstream channels, preventing sediment-related hazards. The development of natural streambed resistance structures (mainly step-pool systems) and luxuriant riparian vegetation aided channel stability, diversity of stream habitat, and ecological maintenance in the creek. These findings are compared with Jiangjia and Xiaobaini Ravines, two adjacent non-rehabilitated debris-flow streams which have climate and geomorphologic conditions similar to Shengou Creek. Habitat diversity indices, taxa richness, biodiversity, and bio-community indices are much higher in Shengou Creek relative to Jiangjia and Xiaobaini Ravines, attesting to the effectiveness of rehabilitation measures" (Authors) The density of benthic macroinvertebrates (ind/m²) including Gomphidae, Aeshnidae, Cordulegasteridae and Euphaeidae is presented in table 5.] Address: Huang, H.Q., Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, 11A Datun Road, Chaoyang District, Beijing 100101, China. 11395. Zhu, B.L.; Wu, H.P.; Xiao, T.H. (2012): Study of aerodynamic interactions of dual flapping airfoils in tandem configurations. *Applied Mechanics and Materials* 160: 301-306. (in English) ["The unsteady viscous flow fields of dual flapping airfoils in tandem configurations are simulated by a Navier-Stokes Solver based on dynamic deformable hybrid meshes. Aerodynamic interactions of three motion models are studied including flapping fore airfoil with fixed aft airfoil, two airfoils flapping in phase and out-of-phase. The results indicate that the aft airfoil in the wake of the flapping fore airfoil has great influence on the aerodynamic performance. When the fore airfoil flaps with a fixed aft airfoil, the thrust generation and thrust propulsive efficiency were enhanced by 65% and 44% respectively, compared to that of single flapping airfoil. When the two airfoils stroke in phase, the thrust generation is twice over that of single flapping airfoil. However the out-of-phase stroking has relatively much lower thrust...In fact, the flapping wing MAV's cruising speed is about several meter per second. The aerodynamic force of dual flapping airfoils was studied based on like dragonfly wing [7-8], now it is still difficult that apply to MAV due to complexity of flapping configuration." (Authors)] Address: Zhu, B., Nanchang Hangkong University, Nanchang 330063. China. E-mail: Jzhubaoli@126.com

(in English) ["A study of the fauna and flora of a rice-field ecosystem was carried out during a single cultivation cycle, in a terraced paddy field (0.5ha) located at Ampitiya, Kandy during May-October 1992. The occurrence of animals and plants was studied in relation to the different ecological phases of the paddy field, growth stage of the paddy plant, and agronomic practices. A total of 77 species of invertebrates, 45 species of vertebrates and 34 species of weeds was recorded from the study site. 95% of the invertebrate fauna consisted of arthropods, represented by 53 families in four classes. About half of the vertebrates recorded were birds consisting of 22 species in 14 families. Monocot weeds belonging to the families Commelinaceae, Cyperaceae and Poaceae dominated the field at different stages of the cultivation cycle. The aquatic phase encompassing the vegetative and reproductive stages of the rice plant supported the greatest number of invertebrate fauna (68 species). The application of insecticides resulted in a considerable decrease in the numbers of invertebrate fauna." 11397. Nel, A.; Bechly, G.; Jarzembowski, E.; Martinez-Delclòs, X. (1998): A revision of the fossil petalurid dragonflies (Insecta: Odonata: Anisoptera: Petalurida). *Paleontologia Lombarda Nuova serie X*: 1-68. (in English, with French and Italian summaries) ["A new family, genus and species of Petalurida, *Cretapetalura brasiliensis* gen. nov. et sp. nov. (Cretapetaluridae fam. nov.) is described from the Lower Cretaceous Santana Formation of the Araripe Basin of Brazil, and a new subfamily, genus and species of Petalurida, *Pseudocymatophlebia henningi* gen. nov. et sp. nov. (Pseudocymatophlebiinae subfam. nov. in Aktassiidae) is described from the Lower Cretaceous Weald Clay of England. A new species *Aktassia pritykinae* sp. nov. is described from the Lower Cretaceous of Mongolia. The description of new material enables us to revise the phylogenetic position of the

genera *Protolindenia* Deichmüller 1886, *Aeschnogomphus* Handlirsch 1906, *Mesuropetala* Handlirsch 1906, and *Cymatophlebia* Deichmüller 1886 from the Upper Jurassic of Germany, and to designate neotypes for *Protolindenia wittei* and *Mesuropetala koehleri*. *Aeschnogomphus* and *Aktassia* Pritykina 1968 are considered to be sister-genera within the Petalurida - Aktassiidae (subfamily Aktassiinae stat. nov.). *Aeschnogomphus buchi* (Hagen 1848) is recognized as valid name for *Aeschnogomphus charpentieri* (Hagen 1848). *Mesuropetala*, formerly considered to be a petalurid, is regarded as a basal Aeshnoptera; and *Protolindenia*, formerly considered to be a gomphid, is transferred to the Petalurida, as most basal member of the stem-group of Petaluridae. The phylogenetic positions of *Mesuropetala auliensis* Pritykina 1968, *Mesuropetala costalis* Pritykina 1968, *Protolindenia aktassica* Pritykina 1968 (in *Kazakhophlebiella* gen. nov. et comb. nov.) and *Protolindenia deichmuelleri* Pritykina 1968 (in *Pritykiniella* gen. nov. et comb. nov.) (all Upper Jurassic taxa from Karatau, Turkestan, Russian Federation), are discussed. Also, the phylogenetic positions of *Miopetalura shanwangica* Zhang 1989 and *Miopetalura orientalis* (Hong 1985) (Middle Miocene of China) are discussed and these taxa are transferred from the Petaluridae to the Gomphides- Lindeniinae and Anisoptera incertae sedis respectively. The English Lower Cretaceous *Aeschnopsis perampla* (Brodie 1845) and *Cymatophlebiopsis pseudobubas* Handlirsch 1939 are revised, synonymised and considered to belong to Anisoptera incertae sedis. The Lower Cretaceous genus *Necrogomphus* Campion 1923 with two species *N. petrificatus* (Hagen 1850) and *N. jurassicus* (Giebel 1850) is revised and also referred to Anisoptera incertae sedis. The phylogenetic positions of *Protolindenia*, *Aeschnogomphus*, *Aktassia*, *Pseudocymatophlebia* gen. nov., and *Cretapetalura* gen. nov. within the Petalurida are discussed and a phylogenetic analysis of the fossil and extant Petalurida is presented. The Petalurida are identified as sister-group of all remaining extant Anisoptera (Euanisoptera). The new phylogenetic system of Anisoptera by Bechly (1996) is confirmed, and new phylogenetic definitions of the taxon names of Petalurida are proposed. The evolution and historical biogeography of Petalurida is discussed." (Authors)] Address: Nel, A., Lab. Ent., Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimr1.mnhn.fr

11401. Gaino, E.; Rebor, M. (2001): Apical antennal sensilla in nymphs of *Libellula depressa* (Odonata: Libellulidae). *Invertebrate Biology* 120(2): 162-169. (in English) ["In an ultrastructural study of the apical antenna of the last nymphal stages of *L. depressa*, we found long sensilla trichodea, 2 sensory pegs, and a coeloconic sensillum on the last article of the flagellum (the distal part of the antenna). The long sensilla trichodea are mechanoreceptors, almost identical to the long filiform hairs of some terrestrial insects and the first sensilla of this kind to be described in aquatic insects. Particular attention was given to the complex coeloconic sensillum, a compound sensillum innervated by 2 groups of 3 neurons wrapped in a dendritic sheath. A cuticular sleeve envelops the distal portion of the outer dendritic segment. The cuticle of the coeloconic sensillum shows

wide channels and is contiguous to the underlying granular and fibrillar layer. Similar structures on the antennae of the adults of other dragonflies were identified as chemoreceptors in previous studies. We hypothesize that this larval coeloconic sensillum might likewise have a chemosensory function, responding to molecules that diffuse through the cuticle and the underlying granular and fibrillar layer, as no clear pore or pore-tubule system is visible. Alternative functions are also explored on the basis of morphological details." 11403. Robson, B.; Sherwood, J.; McKay, S.F.; Kelly, L.M. (2002): Floodplain wetlands of the Gellibrand estuary: What type of invertebrate community?. *Ecological management & restoration* 3(2): 139-141. (in English) ["Along the south coast of Australia, wetlands on the floodplains of lowland rivers and estuaries have been severely altered by agriculture and urbanization. Efforts to restore or rehabilitate these wetlands are hampered by insufficient knowledge of the original condition of these wetlands, or their variability in time and space. This research describes the macroinvertebrate community of wetlands on the floodplain of the Gellibrand River and estuary, which has suffered comparatively few human impacts. The aim of the research was to describe the variability of macroinvertebrate communities as a baseline for the future management of these wetlands, and to contribute to the general understanding of estuary-floodplain wetlands, thereby improving the basis for their management. The Gellibrand River has a catchment area of approximately 1200 km² draining the western slopes of the Otway Ranges, and entering the Southern Ocean at Princetown. From a mean annual flow of 315 000 mL, 25 000 mL are removed per annum for agricultural and domestic use (O'May & Wallace 2001), and flows are closer to natural regimes than most other Western Victorian rivers. The estuary is a bar-built, salt-wedge estuary that becomes completely blocked by the sand bar in most years, during summer

and autumn. Over past decades, the estuary mouth has been opened artificially in most years. to prevent flooding of agricultural land and roads adjacent to the wetlands. At its maximum, the salt-wedge penetrates approximately 10 km upstream from the river mouth, but the estuary may also be completely fresh during high winter discharge (Mckay 2000). The wetlands surrounding Princetown cover 119 ha and are listed as nationally important (Environment Australia 2001). This listing regards the wetlands as an important habitat for animals at vulnerable stages of their life cycle and a refuge from adverse conditions, such as drought. They are a good example of coastal brackish and freshwater marshes, with an important ecological and hydrological role as part of a large wetland complex." (Authors) The list of taxa includes seven Odonata larvae, but no details are given.] Address: Robson, Belinda, School of Ecology & Environment, Deakin Univ., PO Box 423, Warrnambool, Vic 3280. 11405. Wakasugi, K.; Osada, M.; Mizutani, M.; Fukumura, K. (2002): Measurement of the dispersal distance of the *Ischnura asiatica*. Appropriate spacing of sanctuaries for aquatic animal life. *Transactions of the Japanese society of irrigation, drainage and reclamation engineering* 70(3): 421-426. (in Japanese, with English summary) ["One of the major concerns in rural areas these days is destruction of habitats of aquatic animal life and consequent loss of biodiversity, partly attributed to implementation of farmland consolidation projects. To cope with this problem, increasing efforts have been made to create animal sanctuaries in and around project areas. What we have yet to know, however, is how best to space these sanctuaries across the tracts of consolidated farmland. Obviously an index for their minimal spacing required is the dispersal distance of the aquatic life in question. In this study, we targeted at the aquatic dragonflies of the *Ischnura asiatica*, supposedly low in flight ability, and investigated how far they flew away from their breeding ground and what environmental factors affected where they reappeared, using the mark-and-recapture method. We conducted the field survey in Utsunomiya City during the August-September period, 2000. The survey revealed that they moved no farther than 1.1-1.2km and submerged fallow paddies greatly affected where they reappeared." (Authors)] Address: not available

2003

11407. Hutchinson, R.; Goulet, H. (2003): Book Reviews: Ontario Odonata. Volume 3 (including observations for the year 2001). Edited and compiled by Paul

M. Catling, Colin D. Jones and Paul Pratt. 2002. The Toronto Entomologists' Association, Toronto, Canada. *The Canadian Field-Naturalist* 117(3): 487. (in English) ["The third volume (208 pages) on Odonata (the order that includes dragonflies and damselflies) of Ontario is now available. About 25 papers are included, treating new Ontario records, notes on Odonata species rarely captured, changes in distribution patterns, annotated lists of Odonata from a region, characterization of species commonly confused, book reviews, an up-to-date checklist of 166 species (80% of the Canadian fauna!) and changes in abundance for many species since Walker's work in the 1940s, and a checklist of species. The lists of Ontario records are most impressive, comprising about 62% of Volume 3, and summarizing in a database format the information about species, locality, number of males, females and immatures for each record. Though the bulk of the records are for 2001, additional records not previously published cover the years 1996 to 1998. The total number for these four years is an impressive 6059 records. Including similar lists in volumes 1 and 2, 15370 records are now databased for 1996 to 2001. Specimens in collections previously added to about 13000 Ontario specimens. This is an exceptional contribution to the natural history of Ontario, providing a solid base to show the distribution of each species, and for the conservation of Ontario Odonata. Hopefully in time, this information could lead to books on Odonata of Ontario. About 1800 databased specimens of Odonata of Ontario are deposited as voucher in the Canadian National Collection, which has been massively upgraded in the past two years (Figure 1). Among the many articles, the one by Paul Catling on the characterization of males and females of *Lestes disjunctus* and *L. forcipatus* was most welcome. Both species have often been confused by many students. The editors intend to produce this type of document for another two years. By then it is hope that about 25000 records will have been entered. These records will become the base for future work on Odonata of Ontario as well as a time capsule at the very end of the 20th and beginning of the 21st century. We must congratulate the 31 contributors listed with their address and e-mail coordinates on page 105. Such a massive effort could not be done singly. To purchase copies of the 2000, 2001 and 2002 documents, contact Alan J. Hanks, 34 Seaton Drive, Aurora, Ontario, Canada L4G 2K1; Phone: (905) 727-6993, e-mail: A.Hanks@aci.on.ca." (Authors)] Address: Goulet, H., K. W. Neatby Building, 960 Carling Avenue, Ottawa, Ontario K1A 0C6 Canada

11411. Fore, L.S. (2004): Development and testing of biomonitoring tools for macroinvertebrates in Florida streams. Final Report. Prepared for: Russel Frydenborg & Ellen McCarron, Florida Department of Environmental Protection, 2600 Blair Stone Rd., Tallahassee, FL 32399-2400, USA: IV + 62 pp + app. (in English) ["Florida DEP assesses the chemical, physical and biological condition of hundreds of stream sites each year. This study used measures of hydrologic condition, riparian and channel habitat condition, water chemistry, and intensity of human land use to define a gradient of human disturbance for stream sites. I evaluated the sensitivity and tolerance of over 1000 stream macroinvertebrate taxa using the human disturbance gradient (HDG). I tested for correlation between the HDG and 36 biological measures of the stream macroinvertebrate assemblage (metrics) and selected the 10 most highly correlated metrics within six categories of biological organization. The six categories (and their selected metrics) were taxonomic richness (total number of taxa, number of Trichoptera taxa, and number of Ephemeroptera taxa); feeding group (percentage filterer individuals); voltinism (long-lived taxa richness); habit (clinger taxa richness); community structure (percentage dominance of the most abundant taxon and percentage Tanytarsini midges); and sensitivity and tolerance (sensitive taxa richness and percentage very tolerant individuals). Metrics were combined into an overall stream condition index (SCI) by transforming metric values into unit-less scores and summing the scores. The SCI was highly correlated with HDG for an independent data set (Spearman's $r = -0.81$, $p < 0.001$). SCI was independent of watershed size and geographic region (panhandle, peninsula and northeast). Across 10 years of sampling, the index showed a similar response to the HDG. SCI was somewhat higher for winter vs. summer samples (3.5%). A large portion of the variability of SCI was due to subsampling in the laboratory (49%). Confidence intervals based on estimates of SCI variance defined 3.7 categories of biological condition that the SCI could detect assuming a single sample. For two site samples, the SCI could detect five categories of biological condition. Biological metrics were also tested for a second stream macroinvertebrate sampling protocol (BioRecon) based on sorting of invertebrates in the field and taxonomic identification in the laboratory. Of the 10 SCI metrics, six taxa richness metrics were tested using BioRecon data; all were highly correlated with both SCI and HDG. From these metrics the BioRecon index was calculated as the sum of scores for the six metrics. The BioRecon index could detect 2.5 categories of biological condition for one sample and 3.5 categories for two

samples. ... Included in the list were all taxa in the Cordulegastridae and selected taxa in the families Aeshnidae, Gomphidae and Libellulidae ..."] (Authors)] Address: Fore, Leska, Statistical Design, 136 NW 40th St., Seattle, WA 98107, USA. E-mail: leska@seanet.com

11412. Rodrigues, D.J.; Uetanabaro, M.; Prado, C.P.A. (2004): Seasonal and ontogenetic variation in diet composition of *Leptodactylus podicipinus* (Anura, Leptodactylidae) in the southern Pantanal, Brazil. *Rev. Esp. Herp.* 18: 19-28. (in English, with Portuguese summary) ["The foraging strategies of amphibians allow them to capture a wide variety of prey, diet variation being generally associated with morphological, physiological, and behavioural traits that facilitate the location, identification, and digestion of food items. Herein we present the diet composition of *L. podicipinus* and variations regarding the number and type of prey consumed by juveniles, males and females during the wet and dry seasons, in the southern Pantanal, Brazil. Sampling was conducted at three different times during the dry season, and three different times during the wet season between June 1998 and May 1999. The quantitative analysis showed that the diet of *L. podicipinus* is composed mainly by Coleoptera (51.0%), Hymenoptera (9.1%), Diptera (8.7%), Aranae (5.3%), and Orthoptera (4.7%). In the wet season, males captured more prey than juveniles and females, but in the dry season there were no differences. Males and females ingested larger prey compared to juveniles. The frog *L. podicipinus* is an opportunist and generalist predator, and the availability of prey in the environment may be an important factor determining its diet composition in the Pantanal." (Authors) Odonata larvae occurred in low frequencies in the stomachs analyzed.] Address: Rodrigues, D.J., Departamento de Biologia, Universidade Federal de Mato Grosso do Sul, Caixa Postal 549, 79070-900, Campo Grande, MS, Brazil. 11413. Suh, A.N. (2004): Dragonfly assemblage dynamics and conservation at small reservoirs in KwaZulu-Natal, South Africa. Ph.D.-Thesis. University of KwaZulu-Natal, Pietermaritzburg: XX + 177 pp. (in English) ["A study of the odonate fauna was carried out at the edge of a major escarpment, in eastern South Africa, using the same methodology as has been used in the temperate regions to obtain a sub-tropical perspective. The study used the macroecology approach to compare patterns and responses of these animals (at the developmental stages of larva, teneral and adults) to seasonal, topographical and anthropogenic disturbances. The habitats used were small, but well-established reservoirs located at five elevational gradients: Stainbank Nature Reserve (100 m), Krantzklouf Nature Reserve (450 m), National Botanical Gardens Pietermaritzburg (790 m) Cedara (1050 m) and Mondi Goodhope Estate (1350 m). Although this is essentially a local component of a larger macroecological study, it is shown that even though species and identities differ between temperate, tropical and sub-tropical ecoregions, the general pattern of community response to these variables is similar. Odonate species phenologies in this sub-tropical study showed great similarity to their tropical counterparts by reason of their adults being highly elevation-tolerant, with long flight periods and over-lapping generations. Yet they also show temperate characteristics by overwintering principally as larvae and eggs. The Libellulidae, followed by the Coenagrionidae were the most abundant, elevation-tolerant families, with national ende-

mics constituting only 6.5% of the total species sampled. Classification and ordination methods identified and characterised sub-sites to ecologically meaningful biotopes for odonates. This also allowed inferences as to how the various landscape disturbances at the five elevations affect species richness and abundance. Species that responded to these impacts were potential indicator groups that can assist in the planning and management of the landscape for conservation of biodiversity. Some management recommendations for these landscapes are given. Individual odonate species developmental stages and their environmental relations were investigated using both univariate and multivariate analyses. The solutions to these analyses were then used to describe how odonate species are distributed along major environmental gradients. It was shown that regional processes e.g. elevation and insolation alongside local variables e.g. pH, marginal grasses, percentage shade, exposed rock, marginal forest, marsh and flow greatly accounted for adult (aerial stage) assemblage variation and distribution. Turbidity, floating/submerged vegetation and water depth (also influenced by regional factors), highly explained larval (aquatic stage) variation. Elevation has therefore, an indirect effect in that it determines climate, which in turn, determines soil and vegetation types which then determine species presence and absence. Also, although these artificial water bodies do not increase the 'extent of species occurrence', they are important in increasing their 'area of occupancy'. Dragonflies play a major role in conservation. The Japanese culture has strongly illustrated how dragonflies feature in everyday life more than any other country in the world. While many parks and Botanical Gardens feature dragonfly trails in their nature trails in Britain, this does not necessarily cater for threatened species. Conservation of invertebrates in urban environments in South Africa for example by ecological landscaping designed to encourage dragonflies has been particularly rewarding. A core of regularly occurring odonate species occupied the dragonfly trail at the National Botanical Gardens in Pietermaritzburg, while other species visited the study site at irregular periods. This is likely to be the case for a longer term, say ten years or more. Also, the trail, with updated information on species phenologies, variability and habitat preferences continues to play a valuable role in sensitising an increasingly urbanised population to biodiversity and conservation issues. Odonates remain a major component when assessing ecological components of aquatic biotopes, with the assemblage composition at anyone locality capable of changing over time. This has been extensively illustrated in the northern hemisphere. Medium to longer term changes in odonate population at established reservoirs as demonstrated in this study at the National Botanical Gardens in Pietermaritzburg, South Africa, makes it possible to determine whether a species in a conservation area is being given enough protection from local anthropogenic impacts and effects of unpredictable weather conditions. This in turn enables one to understand how concepts of residency and succession underpin conservation management decisions. In conclusion, this study has addressed some salient aspects of species inventory, monitoring and conservation practice at a local scale that also play a central role in conventional biodiversity conservation practice of a global nature. Information on species phenologies enhances their awareness-raising in addition to providing valuable insights into their population dynamics and conservation, especially for those under threat.

In addition, baseline data from this study and similar ones is useful in conserving biodiversity (as subjects) or in multi-taxa studies (as tools) in conserving ecosystems and/or landscapes. Finally, the macroecological approach employed in this study has great potential for teasing apart local effects from regional and/or global ones, and can contribute to the conservation of biodiversity at both small and large scales." 11433. Tsuyuki, K.; Sudo, S.; Igarashi, S. (2007): Aerodynamic characteristics of flapping motion of a two-dimensional wing model shaped like a dragonfly wing section. *Journal of the Japan Society for Aeronautical and Space Sciences* 55(No. 645): 459-466. (in English) ["This paper describes the aerodynamic characteristics of flapping motion of a dragonfly wing model. The orbit and feathering angle of a dragonfly wing were measured using a high-speed video camera. The measurement data was used to formulate two mathematical models: linear and Fourier models. The aerodynamic characteristics of a thin plate and dragonfly wing models, which were investigated using a numerical simulation, revealed that the linear model generated a high vertical force during descent and high thrust force during ascent. Although the Fourier model could not generate a high thrust force during ascent, it generated a higher vertical force than the linear model. During the flapping motion in both the models, a marginal difference was observed between the forces generated at the top and bottom. When the feathering angle approached the stroke angle, the resultant force direction acting on the wing models was reversed." 11435. Benard, M.F.; McCauley, S.J. (2008): Integrating across life-history stages: consequences of natal habitat effects on dispersal. *Am. Nat.* 171(5): 553-567. (in English) ["Ecological and evolutionary processes are affected by forces acting at both local and regional scales, yet our understanding of how these scales interact has remained limited. These processes are fundamentally linked through individuals that develop as juveniles in one environment and then either remain in the natal habitat or disperse to new environments. Empirical studies in a diverse range of organisms have demonstrated that the conditions experienced in the natal habitat can have profound effects on the adult phenotype. This environmentally induced phenotypic variation can in turn affect the probability that an individual will disperse to a new environment and the ecological and evolutionary impact of that individual in the new environment. We synthesize the literature on this process and propose a framework for exploring the linkage between local developmental environment and dispersal. We then discuss the ecological and evolutionary implications of dispersal asymmetries generated by the effects of natal habitat conditions on individual phenotypes. Our review indicates that the influence of natal habitat conditions on adult phenotypes may be a highly general mechanism affecting the flow of individuals between populations. The wealth of information already gathered on how local conditions affect adult phenotype can and should be integrated into the study of dispersal as a critical force in ecology and evolution." 11440. Martin, M. (2008): Diversity of dragonflies (Odonata) and protected species in Estonia. Ent. Tidskr. 129 (2008) Poster abstracts: 230-231. (in English) [Verbatim: Dragonflies are relatively large and conspicuously active insects. Despite of this more thorough data about ecological features of different species, including biotopical preferences and zoogeographical distribution is still not characterized in Estonia. The accumulation of new material is very occasional. Mainly only faunistic data has been collected and lists of species for several districts have been established. All data we have now is very fragmented and based only on occasional observations. There have been written only two more thorough papers concerning the dragonfly fauna in Estonia: First was made by H. Kauri in 1942 (MSc Theses, unpublished) second by Janika Ruusma in 1980 (Graduation Theses, unpublished). The first records about Estonian dragonflies can be found from year 1778. Nowadays 54 species of dragonflies have been registered. Among these species seven species - *Cordulegaster boltonii*, *Eitheca bimaculata*, *Libellula fulva*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia*, *Sympecma paedisca* (All category III, Rare) and *Anax imperator* (IV, Care demanding) are listed in our Red Databook. From year 2004 only 5 NATURA 2000 species – *Ophiogomphus cecilia* (II,IV category by EU habitats directive), *Aeshna viridis* (IV), *Leucorrhinia albifrons*, (IV) *L. caudalis*, (IV) and *L. pectoralis* II,IV). protected in Estonia (Category III). Among these protected species *Aeshna viridis* Eversman is the most rare one, whose distribution data has been rarely updated over past ten years. For *Ophiogomphus cecilia* more distribution data has been collected. Among protected *Leucorrhinia* species, *Leucorrhinia albifrons* is most common. This species is common inhabitant of all bogs water bodies over all territory except island Hiiumaa. Two other species *L. caudalis* and *L. pectoralis* have been very rare in Estonia until now. But in recent years these two species have become quite common in small water bodies in South-East and East Estonia. By opinion of authors there were two main reasons: 1) under changing social conditions fishing-nets were allowed to use to catch fish from small lakes. Before it was not allowed. After this from several lakes big fish, dangerous for dragonfly nymphs, were captured out; 2) distribution of beavers. These creatures have created several small water bodies. It seems that conditions in these water bodies were very acceptable for these two species.] Address: Martin, M., Institute of Zoology and Hydrobiology of University of Tartu, Estonia

11442. Sudo, S.; Takagi, K.; Tsuyuki, K.; Yano, T.; Nishida, K. (2008): The dragonfly flight by a pair of wings and frequency characteristics of wings. Proceedings of the

XIth International Congress and Exposition, June 2-5, 2008 Orlando, Florida USA. Society for Experimental Mechanics Inc.: 8 pp. ["This paper describes the dragonfly flight by a pair of wings and the frequency characteristics of dragonfly wings related to the aerodynamic characteristics. In the first place, free flight by two pairs of wings and a pair of wings of dragonflies was analyzed with a high-speed video camera system. It was confirmed that the dragonfly can fly by a pair of wings. In the second place, the tethered flight of a fly was also studied for comparison. It was confirmed that insect wings undergo strong deformation during the flight. In the third place, the surface shape of dragonfly wings was measured by the three-dimensional, optical shape measuring system. It was clear that the difference of elevation was especially remarkable between the longitudinal veins at the leading edge part. In the fourth place, the dynamic responses of dragonfly wings to the excitation vibration were examined over the relatively wide range of frequency. It was found that natural frequency of dragonfly wings was related to the flapping frequency of the dragonfly." (Authors) *Sympetrum infuscatum*] Address: Sudo, S., Akita Prefectural University, Ebinokuchi 84-4, Yurihonjo-shi 015-0055, Japan, E-mail sudo@akita-pu.ac.jp

11448. Lin, J.-L.; Wei, C.-Y.; Lin, C.-Y. (2009): Aerodynamic performance of thin wings at low Reynolds numbers. *Aircraft Engineering and Aerospace Technology* 81(1): 51-58. (in English) ["Purpose: The purpose of this paper is to explore the aerodynamic performance of wings with different shapes at low Reynolds numbers. Design/methodology/approach: The airfoils of these wings are made from aluminum plates, and the maximum chord length and wingspan are 15 cm. Wings A-D are plates with 6 percent Gottingen camber but different wing platforms. The forward-half sections of wings E and F are dragonfly-like, whereas the rear-half sections of wings E and F are flat and positively cambered, respectively. The aspect ratios of these wings are close to one, and the ratios of plate thickness to the maximum chord length are 1.3 percent. Experimental results indicate that the wings with Gottingen camber have a superior lift and lift-to-drag ratio, whereas the wings with dragonfly-like airfoils perform well in terms of drag and pitch moment. Findings: The aerodynamic measurements of the wings demonstrate that the wing with the Gottingen camber airfoil, a swept-back leading edge and a straight trailing edge is suitable for the use in micro aerial vehicle (MAV). An MAV is fabricated with this wing and the aerodynamic performance of the MAV is examined and compared with the bare wing data. Originality/value: This paper develops several criteria to the design of MAV-sized wings. For example, the thickness ratio of airfoil must be small, usually less than 2 percent. Besides, the airfoil must be cambered adequately. Furthermore, a wing platform with a swept-back leading edge and a straight trailing edge would contribute to the successful flights of MAVs." 11453. Moody, D. (2009): Mating behaviour in male territoriality *Enallagma vesperum* (Odonata: Coenagrionidae) on ponds in Ohio and northern Michigan. *Ohio Journal of Sciences* 109(3): 67-70. (in English) ["The crepuscular damselfly *E. vesperum*, was studied to document and clarify mating behaviour. This paper is a descriptive synthesis of observations which answer basic questions regarding mating behaviour of *E. vesperum*. Beginning in July 2004 and continuing in the summers through September 2009, approximately 140 hours of direct observation on a lake in Northern Michigan and a lake and two ponds in Ohio were logged to support the results and conclusions. The literature regarding mating behaviour in *E. vesperum* provides little information about male territoriality. The results from this six-year study offer strong evidence of male territory selection and territory defense. Copulatory behaviour and ovipositional behaviour were also recorded. In most coenagrionid species, males remain in tandem with ovipositing females unless the females submerge. In this study, however, females were observed ovipositing in tandem or individually into surface vegetation." (Author)] Address: Moody, D.L., Biology Dept, Univ. of Findlay, Findlay, OH, USA. 11457. Sircom, J. (2009): Determinants of the biodiversity and composition of stream insect communities. Ph. thesis. Dalhousie University Halifax, Nova Scotia: 111 pp. (in English) ["The North Mountain of the Annapolis Valley, NS, in eastern Canada, is a ~200 km basalt

ridge drained by many small first or second order streams in independent catchments. The area is fairly uniform geologically, presenting an opportunity to compare streams of similar chemistry, slope and aspect that vary in other respects, such as invertebrate community structure. In this thesis, I examine two macroinvertebrate functional groups to determine key factors influencing their abundance, composition and diversity across catchments. Chapters 2 and 3 are concerned with the predatory invertebrate guild in eight of the streams, in two groups separated by ~65 km. In Chapter 2, I assessed factors influencing composition of the predator guild using similarity matrices. Similarity in predator composition declined with distance, and streams that were more similar in disturbance (spates) were more similar in predator composition. Similarity within one family, Rhyacophilidae, was related to similarity in fish population. Chapter 3 reports the results of laboratory experiments involving two widespread species. Field data suggested an asymmetric interaction between *Sweltsa onkos* (Plecoptera: Chloroperlidae) and *Rhyacophila vibox* (Trichoptera: Rhyacophilidae); behavioural observations in artificial streams supported this. In the presence of *R. vibox*, *S. onkos* had higher mortality and injury rates, and grew less. The results of these chapters suggest that, although disturbance is important in shaping community structure, the results of interspecific interactions can be detected at large scales. *S. onkos* can only attain high numbers in streams where fish predation reduces the abundance of *R. vibox*. Chapter 4 examines biodiversity patterns in the macroinvertebrate detritivore guild in 25 streams encompassing ~80 km of the ridge. Using density and richness of the detritivore community, detrital resource quantity, and top predator abundance, I looked for evidence in support of several mechanisms that can lead to positive species-energy relationships. Patterns conformed to expectations of the 'More Individuals Hypothesis'. It appears that taxonomic richness of the detritivore guild increases with detrital resource availability because more taxa can attain their minimum viable population size where more resources are available." (Author) The thesis includes a few references to Odonata.] Address: not stated; Sircom, Julie

11462. Banerjee, S.; Aditya, G.; Saha, N.; Saha, G.K. (2010): An assessment of macroinvertebrate assemblages in mosquito larval habitats—space and diversity relationship. *Environmental Monitoring and Assessment* 168: 597-611. (in English) ["The aquatic bodies designated as mosquito larval habitats are diverse in size and species composition. The macroinvertebrate predators in these habitats are elements that influence the abundance of mosquito species, providing a basis for biological control. Assessment of species assemblage in these habitats will indicate the possible variations in the resource exploitation and trophic interactions and, therefore, can help to frame biological control strategies more appropriately. In the present study, the species composition is being investigated in five different mosquito larval habitats at a spatial scale. A random sample of 80 each of the habitats, grouped as either small or large, was analyzed in respect to the macroinvertebrate species assemblage. The species composition in the habitats was noted to be an increasing function of habitat size (species number = $1.653 + 0.819$ habitat size) and, thus, the diversity. The relative abundance of the mosquito immatures varied with the habitat, and the number of useful predator taxa was higher in the larger habitats. In the smaller habitats—plastic and earthen structures and sewage drains, the relative and absolute number of mosquito immatures per sampling unit were significantly higher than the pond and rice field habitats. This was evident in the cluster analysis where the smaller habitats were more related than the larger habitats. The principal component analysis on the species diversity yielded four and six components, respectively, for the smaller and larger habitats for explaining the observed variance of species abundance. The species composition in the habitats was consistent with the earlier findings and support that the abundance of coexisting macroinvertebrate species regulates the relative load of mosquito immatures in the habitats. The findings of this study may be further tested to deduce the relative importance of the habitats in terms of the productivity of mosquito immatures at a temporal scale." (Authors) The paper includes a reference to a zygopteran specimen.] Address: Banerjee, S., Dept of Zoology,

11466. Chen, Y.H.; Zhao, Y.; Huang, W.M.; Shu, D.W. (2010): Kinematics of dragonfly (*Sympetrum flaveolum*) flight. 6th World Congress of Biomechanics (WCB 2010). August 1-6, 2010 Singapore, IFMBE Proceedings 31(1): 56-59. (in English) ["The kinematics of the flapping flight of *S. flaveolum* is investigated. The flapping patterns of the hindwing are recorded and studied thoroughly using a high speed video camera with the highest shuttle speed and resolution as reported so far on study of insect flights. The overall results indicate that the flapping pattern of a dragonfly hindwing at the nodus and the pterostigma can be either a simple figure-eight or a double figure-eight, which is a new discovery. The angle of attack and the wing attitude are studied quantitatively. The relative position of the leading edge and trailing edge implies the presence of lift-enhancing mechanisms after stroke reversal. It is also found that the spanwise leading edge spar of a dragonfly wing is not one rigid piece, but two pieces hinged at the nodus with physical constraint of fort}' degrees. The elastic modulus of the costa of a hindwing is estimated through vibration tests using a vibrometer." (Authors)] Address: Chen, Y.H., School of Mechanical and Aerospace Engineering, Nanyang Technological University, Singapore

11467. Dmitriew, C. (2010): Evolutionary ecology of growth in insects: What maintains variation in growth trajectories at the phenotypic and genotypic levels? Doctoral thesis, Department of Ecology and Evolutionary Biology, University of Toronto: VI, 222 pp. (in English) ["Growth rates are highly variable, both within and among genotypes and populations. The resolution of the trade-off between size and age at maturity has been

the study of extensive research by life historians. The fitness advantages of large body size and rapid development time are well supported, leading to two predictions. First, realized growth rates should be maximized. Second, growth rate will be subject to strong stabilizing or directional selection, and consequently, low genetic variability. In real populations, despite the advantages of rapid growth, animals often, in fact, grow at rates lower than the maximum rate that is physiologically possible, even in the absence of external constraints on growth rate (e.g. resource restriction or risk of predation while foraging). This implies that growth may have direct fitness consequences that are independent of the size and age of maturity, thereby lowering the optimal rate of growth. In addition to inducing plastic declines in growth rate, such costs may also select for lower intrinsic rates of growth. Despite the strong fitness effects arising from attaining a large body size quickly, variation in growth rate persists at both the phenotypic and genetic levels. The evolutionary and ecological factors contributing to this variation in growth rate are the focus of this thesis. Growth rate variation in insect model species was produced by the manipulation of resource levels during development. By comparing fitness-associated traits and body composition of adults from different treatment groups, I identify direct costs of rapid growth that could explain why animals benefit from growth at submaximal rates. In the second part of the thesis, the relationship between environmental variation and genetic variance in growth rate is investigated by quantitative genetic analysis of body size at different ages and in different growth environments. The results of this analysis suggest that environmental stress can lead to increased genetic variance via decanalization. This has consequences for the evolvability of growth rates in changing environments." (Author) See also: Dmitriew, C., Cooray, M. & Rowe, L. 2007. 11468. Donnelly, N. (2010): Book Review: "Field Guide to the Dragonflies and Damselflies of New Jersey", by Allen E. Barlow, David M. Golden, and Jim Bangma. New Jersey Department of Environmental Protection, Division of Fish and Wildlife, 2009, 285 pages (many in color), spiral bound. The price is \$36 and it can be ordered through the Conserve Wildlife New Jersey Foundation, <<http://www.conservewildlifenj.org/support/cwf/publications.html>>. *Argia* 22(1): 18-19. (in English) [„This New Jersey guide now fills an important gap: thorough coverage of the heart of the Middle Atlantic states. It will be very useful from Maryland to southern New England, and west at least through Pennsylvania and New York. The guide is arranged in three parts. The first, and shortest, part is introductory and covers study techniques and basic morphology. The second, and longest, part covers the description, habits, habitat of each New Jersey species. The individual accounts are fairly exhaustive, including description, statement of abundance, similar species, where and when to find them, behaviour, and overall range. For a few confusing groups there are black and white illustrations of body parts necessary for identification. The third section consists of very good colour illustrations of each species, with a county-level range map for New Jersey. These il-

illustrations are all photos, and I think the printing has been faithful to the colours." (Author)] Address: Donnelly, T., 2091 Partridge Lane, Binghamton, NY 13903, USA. E-mail: tdonnel@binghamton.edu

11471. Goenendijk, D. (2010): Mysterious and beautiful, the Northern Emerald. *Vlinders* 3/2010: 18-21. (in Dutch, with English summary) ["*Somatochlora arctica* is one of the least known and rarest dragonflies of north-west Europe; in the Netherlands it is listed as a threatened species. One of the most characteristic species of living raised bog, its decline has been paralleled by the loss and degradation of such wetland habitat. We set up a Species Protection Plan which came into action in 2005. Seven Dutch populations are now known. Priority was given to locating the breeding grounds and understanding the adult's behaviour. Both males and females were seen frequenting small pools of about a metre deep. The surface was almost completely covered with rather dried out looking *Sphagnum* moss, often with other bog plants growing in it. We saw females ovipositing, and found larvae in various stages and their empty skins (exuviae). These pools have been targeted for conservation measures. On the short term, managers are given on-site advice either on how to protect them or how to dig new ones, depending on the local situation. On the long term, it is important that hydrological plans for the restoration of the bog include such pools, thus ensuring suitable breeding grounds for this rare and beautiful species." 11473. Hannon, E.R.; Hafernik, J.E. (2010): Reintroduction of the San Francisco fork-tail damselfly into an urban park, California, USA. In: Soorae, P. S. (ed.) (2010) *Global re-introduction perspectives: Additional case-studies from around the globe*. IUCN/SSC Reintroduction Specialist Group, Abu Dhabi, UAE, xii + 352 pp: 33-36. (in English) ["Feasibility: Most of the watershed that drains into Glen Canyon has been lost to

urbanization. However, *I. gemina* persists in small, isolated wetlands similar to those in the canyon. Because adults usually move only short distances during their lifetimes, damselflies released at a site have a good chance of remaining and reproducing at that site enhancing prospects for success. The Glen Park neighbourhood also is home to a group of citizens committed to maintaining native plants and animals in Glen Canyon. Their participation in active management of introduction sites could be key to future success. Implementation: We conducted a project during 1996 and 1997 to re-introduce *I. gemina* into Glen Canyon. The receiving site for adult damselflies was a linear asphalt channel on the rim of the easternmost slope of Glen Canyon Park. The channel carries water from a permanent seep. This channel was the sole breeding area for *I. gemina* in Glen Canyon prior to its local extinction (Garrison & Hafernik, 1981b; Hafernik & Garrison, 1986). We surveyed surrounding wetlands on the San Francisco Peninsula to find a source of stock for reintroduction. Our surveys indicated that the nearest large population of *I. gemina* was in a wetland approximately 12 km south of Glen Canyon. We assessed biotic and abiotic characteristics of the receiving site and found adequate larval food for *I. gemina* in the channel and in newly created ponds in the canyon bottom. Neither habitat contained fish, although the ponds contained larval dragonflies (*Aeshna* sp.), which could prey on *I. gemina* larvae. To restore habitat for *I. gemina*, we cleared aquatic vegetation that had grown in and over the channel. This work left the site relatively free of aquatic vegetation with open and sun-exposed areas. In addition, the California Conservation Corps implemented a habitat restoration project in the bottom of the canyon. They removed riparian trees and shrubs (e.g., *Salix* spp.) from a large seep and constructed three new pond-like habitats in Islais Creek near the seep. At the source site, we collected approximately 40 mating pairs on three separate days. This number was deemed appropriate since it was not likely to negatively impact the source population, it provided an adequate sample of genetic diversity of the source population, and it allowed new releases to approximate the number of adult damselflies previously found at the channel. We carefully transferred damselflies into small plastic vials with a source of moisture. We transported them to our laboratory in a cooler containing ice to limit stress from handling, warm temperatures, and light. In the laboratory, we marked individuals on their wings with a unique number using an indelible ink pen. We released the damselflies at the channel the following morning to give them a chance to feed before their midday peak mating period. We chose mating pairs because they provided an equal number of males and females for reintroduction. Secondly, it assured that individuals transferred were reproductively active, which increased the chance of oviposition at the receiving site. Thirdly, pairs are conspicuous while unpaired females are usually cryptically coloured and forage and rest away from the water (Hafernik, 1989). Lastly, we chose mating adults because juvenile damselflies are more easily damaged in handling than reproductively mature ones. We re-introduced captured adults instead of lab-reared adults because re-introducing mated females maximized the likelihood of establishing a new population quickly. Alternatively, another life history stage, such as eggs or larvae, could have been used for the reintroduction. However, this procedure would have been more labour intensive and would not have allowed comparison of the behaviour of newly released

adults with prior research in the canyon. Post-release monitoring: We monitored the re-introduced population daily to estimate mortality and movement patterns and to observe their behaviour. After a large initial decrease in recapture rate compared to previous years, survival and movement patterns were similar to those of previous studies. As in previous studies, some damselflies dispersed from the channel to the ponds below. We observed damselflies behaving normally and mating and ovipositing into aquatic vegetation. At least two generations of new adults were observed in 1996. In 1997, damselflies emerged in the spring, but did not persist into the fall. Subsequent yearly visits to Glen Canyon have found no individuals of *I. gemina*. Future plans by the City of San Francisco call for re-introducing the damselfly again if it is not observed in the next five years. Success will require active management of wetlands in the canyon to control invasive vegetation. Additional re-introductions are being considered in restored wetlands in the Presidio of San Francisco, a U.S. National Park. Reason(s) for success/failure: (1) Successfully trans-located the species. (2) Species behaviour upon release was not impacted. (3) Unable to maintain or "re-create" natural processes to keep habitat suitable through time." 11480. Kosterin, O.E.; Zaika, V.V. (2010): Odonata of Tuva, Russia. *International Journal of Odonatology* 13 (2): 277-327, pl. IVb. (in English) ["The odonate fauna of Tuva in Siberia, Russia, is documented, based mainly on data from expeditions in 1990, 2000 and 2004, and examination of collections preserved in Novosibirsk. The checklist of Tuvian Odonata presently includes 47 species. In the southern Ubsu-Nur depression 29 species were recorded (two just there); in the Central Tuvian depression 34 species (six just there) and in the Todzha depression 32 species (nine just there). The fauna of the more humid taiga region of Todzha, separated from the arid remainder of Tuva by the Obruchev Mts, contained some forest species but lacked seven species found elsewhere in Tuva. In spite of Todzha's position in the north-east, its fauna showed a more western character and included a population of *Calopteryx splendens* with a high proportion of androchromic females and males with wings coloured to the tips. Todzha was also inhabited by *Enallagma c. cyathigerum* with a variably melanized abdomen, while in the Central Tuvian and Ubsu-Nur depressions, *E. c.*

risi occurred. In Turan and the Upper Kaa-Khem basin, intergradation between both taxa took place. In Todzha, *Somatochlora exuberata* and *S. metallica abocanica* were sympatric without intermediate forms and with habitat segregation, thus proving their status as separate species. Todzha was also inhabited by *Ophiogomphus obscurus* while the rest of Tuva harboured *O. spinicornis*. (Authors)] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. E-mail: kosterin@bionet.nsc.ru

11481. Łabędzki, A.; Chrzanowski, A.; Kuźmiński, R.; Mazur, A.; Rutkowski, P. (2010): The Natura 2000 system and the problem of dragonfly protection in Poland. *Zarządzanie Ochroną Przyrody w Lasach IV*: 94-104. (in Polish, with English summary) ["As a result of forest habitat survey carried out in the years 2006-2007 in State Forests, it was found that many insect species are present in a much higher number of sites than previously thought. The success of the survey was much due to the composition of teams that carried out the survey. Prevention of forest damaging insects connected with performance of forest management tasks may pose a direct threat to dragonfly refuges. In Poland there exists a dissonance between the red list of Polish dragonflies and the protection measures with respect to these insects [Bernard et al. 2002, 2009]. The list of protected species includes all endangered species, but only to a limited extent it translates to real protection policy and practical protection measures. The species *Leucorrhinia pectoralis* and *Ophiogomphus cecilia* are among those unthreatened which was confirmed in the course of the survey carried out. The scope of survey did not include the *Coenagrion ornatum* (Selys) species. Currently, it is a critically endangered species in Poland which, in order to be preserved in national habitats, requires active protection measures that should be undertaken as a priority." (Authors) The Polish distribution of *Ophiogomphus cecilia*, *Coenagrion ornatum*, and *Leucorrhinia pectoralis* is mapped in detail.] Address: not stated

11482. López, L.I.; Gutiérrez, P.; Mora, J.M. (2010): Macrofauna Acuática de la Quebrada Santa Inés, Subcuenca del Río Yeguaré, Honduras. *Ceiba* 51(1): 17-28. (in Spanish, with English summary) ["Santa Inés is a stream of the Yeguaré River sub basin, located in the departments of Francisco Morazán and El Paraíso, Honduras. Santa Inés supplies water to several human communities. Three stations were sampled to study the macroinvertebrate community composition of the Santa Inés stream. A group of 3,525 individuals was collected in the stream belonging to 55 families. The dominant group was Ephemeroptera, an order generally abundant in mountain streams. On the trophic structure, predators were constant along the stream, while filter-feeding insects were the second dominant group in Santa Inés with 25% of the individuals. Santa Inés contains a high structural complexity, where all possible trophic groups of aquatic macroinvertebrates in a river system are represented. The micro basin geography of the Santa Inés stream, the current land use and the community of aquatic macroinvertebrates found in the stream makes it an ideal study subject under the River Continuum Concept." (Authors) 18% of specimens belong to the Odonata. All are treated at the genus level.] Address: López, Lucía Isabel, Consultora Ambiental, Zamorano, Honduras. E-mail: luciaisa2@gmail.com

11483. Lorenzo-Carballa, M. O.; Cordero-Rivera, A.; Andrés, J.A. (2010): Islands and parthenogenesis: genetical and ecological correlates of asexual reproduction in *Ischnura hastata* (Insecta: Odonata, Coenagrionidae). In: Pérez-Mellado, V. & Ramon, M. M. (eds.), *Islands and Evolution*, Institut Menorquí d'Estudis. *Recerca*, 19. Maó, Menorca: 281-307. (in English, with Spanish summary) ["The concept of "geographic parthenogenesis" refers to the observed pattern of non-overlapping distributions of sexual and parthenogenetic lineages of the same species. Hypotheses proposed to explain this phenomenon mostly lay on the idea that parthenogenetic lineages can persist in the long term if they are able to escape from the interaction with either sexual lineages and/or biological enemies (namely, predators and parasites). Therefore parthenogenetic reproduction will be more likely to occur in places that are difficult for sexuals to colonize or in stable environments. Islands have been traditionally regarded as ideal habitats for parthenogens, due mainly to their isolation and to the fact that they usually have less number of species than mainland (and thus the number of biological interactions in islands will be also lower). The analysis of patterns of mite ectoparasitism in sexual and parthenogenetic populations discards host-parasite interactions as the cause of geographic parthenogenesis in this species. The low incidence of parasitism observed in the parthenogenetic populations, where no mites have been found at most of the studied ponds, is likely to be due to the lack of parasites in the islands. Therefore, the habitat stability of the Azores, coupled with a low incidence of biological interactions must have allowed the persistence of this parthenogenetic population despite the lack of genetic variation observed, thus adding new evidence on the importance of islands as favorable habitats for parthenogenetic reproduction." 11484. Marinov, M. (2010): Spatial modelling of dragonfly habitats in New Zealand (Odonata: Insecta). Dissertation. Master of Applied Sciences, Environmental Management. Lincoln University: VI + 69 pp. (in English) ["While New Zealand is poor in Odonata species the 17 species thus far established have great natural importance (Moore 1989). Ten of them are endemic to the islands representing the country. Those include four genera known to occur only in this part of the world (Rowe 1987). This poses a great responsibility on New Zealand to protect this natural treasure. Damselflies and dragonflies are considered well protected within the national parks, but the loss of habitats could severely impact them in the future. This suggests that a habitat assessment should be prepared for the whole country that will serve as base-line data set for monitoring the development of the natural environment for the Odonata species in New Zealand. 14 species have been selected for this analysis. Their biological features and ecological requirements were considered in preparing a working habitat assessment methodology. Habitat models were developed using ArcGIS 9.2 software. Multistep spatial analysis was carried out to reclassify the layers containing the important information on the land topology representing crucial elements in the Odonata species habitats. The final outputs are individual species maps where the New Zealand territory is marked with four different colour classes corresponding to the ranks of im-

portance that each area is considered to have for individual species. The models are named probabilistic in that they reveal the areas where the ecological demands of the species are approached at a maximum level. However, they should not be used as distribution maps. Probabilistic models are contrasted against deterministic models used in other Odonata habitat models. The strengths and weaknesses are discussed and some important conclusions and recommendations are described and suggested." 11485. Marinov, M.; McHugh, P. (2010): Comparative study of the Chatham Islands Odonata: morphological variability, behaviour and demography of the endemic *Xanthocnemis tuanuii* Rowe, 1987. International Dragonfly Fund - Report 30: 1-44. (in English) ["Faunistic investigations on adult insects and molecular research on larvae have identified the existence of at least four species of Odonata on the Chatham Islands. The species resemble their New Zealand counterparts, although there are morphological deviations from the typical diagnostic features. Molecular evidence is not concordant with earlier morphological results as far as the genus *Xanthocnemis* is concerned. Genetic data suggest there are two species on the island while morphological investigations revealed just one. This topic needs further clarification and is given special attention in the present study. The main aim of the present study is to establish the taxonomic position of Chatham Island *Xanthocnemis* species and its relation to New Zealand main island fauna. It also provides some data on the biology of the local species and estimates of key demographic parameters (i.e., survival and abundance). The results show that Chatham Islands inhabitants are close morphologically to their New Zealand main island counterparts. Between-island differences in wing area and abdomen-to-body length ratio were found, but were largely attributable to the harsh environment on the Chatham Islands and its influence on body size. Chatham *Xanthocnemis* exhibited low survival rates and a great diversity of female colour morphs and certain behavioural traits (like underwater oviposition), which are suspected to be due to a composite influence of low summer temperatures, constant winds, and low pH. Ultimately, the taxonomic status of the Chatham Island *Xanthocnemis* species needs further confirmation based on molecular analysis of adults." (Authors)] Address: Marinov, M., 7/160 Rossall Str., Merivale 8014, Christchurch, New Zealand. E-mail: mgmarinov@yahoo.com

11486. Randsdale, N. (2010): Dragonflies of La Brenne & Vienne. Naturetrek Tour Report 23 - 30 June 2010: 13 pp. (in English) ["This two-centre holiday in central-western France gave us an excellent insight into both the dragonfly fauna and abundant butterflies, birds and other wildlife of the region. After spending the first few days in the Brenne, land of a thousand lakes, we visited the myriad ponds of the Pinail reserve on our way to Moulismes, where we spent two days visiting small étangs, gravel pits, rivers and streams in the southern Vienne. This wide range of sites and habitats yielded a final total of 41 species of dragonflies – an excellent total by European standards. The group also saw 40 species of butterflies, including 6 fritillary species, 14 orchid species, and 97 bird species, not to mention a wide range of other animals and plants that the combined talents of the group helped to find and identify. The cold

spring had not done us many favours when looking for one or two of the scarcer odonata species, but as ever, there were compensations, namely orchid species still in full bloom, and still lots of the 'early' butterflies." 11487. Sadeghi, S.; Kiani, M. (2010): The study of wing shape variation of *Calopteryx splendens* (Odonata: Calopterygidae) in Zagros Mountain sides. 16th National and 4th International Conference of Biology, Ferdowsi University of Mashhad, Mashhad, Iran, 14-16 September 2010: 591. (in bilingual in Farsi and English) [Verbatim: *Calopteryx splendens* Harris (1782) is a widespread damselfly, found in most of Europe, large parts of Siberia and much of west and central Asia. There is great variation among males in wing coloration. Traditionally subspecific taxa have been distinguished by the size and position of the pigmented wing spot, and by (mating) behavior. About a dozen of subspecies have been recognized, all of which are more or less geographically confined, but often with overlapping ranges and strong variation in wing spot size. We used geometric morphometrics method to quantify morphological data and analyze the wing shape of *C.splendens* populations irrespective of wing spot, than traditional morphometrics method, in Zagros Mountainsides. In this study six similar populations which are systematically known as *C.s.intermedia*, based on their wing spot size, were evaluated. Nineteen different points were digitized as landmarks on left fore wing of males using GPA (Generalized Procrustes Analysis). Our results in geometric morphometrics (regardless of wing spot) confirmed significant wing shape differences between entire populations except Markazi and Lorestan. These observations suggest that wing spot similarity necessarily cannot reflect the full genetic similarity and evolutionary grouping of populations and therefore, is not an infallible character in *Calopteryx splendens* subspecies.] Address: Kiany, M., Payam-e Noor University, Bam, Iran. 11488. Smith, P.H. (2010): Dragonflies and climate change. *Coastlines* 2010(1): 17. (in English) [Sefton Coast, North West of England, near Liverpool, UK. "Up to 1991, only 14 species had been recorded in the Sefton Coast sanddune system, ten of them breeding here. Today, the total number recorded is 20, of which 14 are probably breeding. This represents a 43% increase in dragonfly diversity in only 20 years. The extra species fall mainly into two groups: (a) Those with mainly southern British distributions that have moved north; (b) Long-distance migrants from continental Europe, these appearing during summer heat-waves. Of the first group, two dragonflies, *Anax imperator* and *Sympetrum sanguineum* had already arrived here by 1990. *A. imperator* was first seen during the hot summer of 1976 but did not become well-established until the mid-1990s. *S. sanguineum* first appeared in 1989 at a time when the nearest breeders were in south Cheshire. Again, by the mid-1990s, this attractive insect had viable breeding populations in several duneland ponds. More recent colonists are *Libellula depressa* (established mid-1990s), *Aeshna mixta* (early 2000s) and *Orithetrum cancellatum* (mid-2000s). Three species fall into the migrant group: *Sympetrum flaveolum*, *S. fonscolombii* and *Anax parthenope*. Occasional individuals have appeared here only in warm summers, such as those of 1995, 1999, 2003 and 2006. Most recently, the brief

heat-wave of early July 2009 saw an influx of *S. fonscolombii* up to eight being seen at Sands Lake, Ainsdale. *Calopteryx splendens* fits less easily into the above categories. Although it has greatly increased in north-west England, this seems more to do with improving water-quality in the slow-moving rivers and streams where it breeds, than to increasing temperatures. This distinctive insect now occurs abundantly on Downholme Brook, just inland of Formby, so it is perhaps not surprising that there have been two recent sightings in the dunes. Following their arrival on the Sefton Coast, most of the dragonflies mentioned above have continued to move north and are now becoming established in Scotland. Many studies, both in this country and in Europe, have linked these trends to climate change. Other species may soon follow, one possibility being *Erythromma viridulum*, which first appeared on the Essex coast in 1999. It now breeds over large parts of south-east England and, by 2006, had reached Derbyshire and Humberside. Recent poor summers have slowed its progress but it should get here eventually." 11491. Thompson, D.J. (2010): Re-introduction of the Southern Damselfly to Venn Ottery Common, Devon, UK. In: Soorae, P. S. (ed.) (2010) Global re-introduction perspectives: Additional case-studies from around the globe. IUCN/SSC Re-introduction Specialist Group, Abu Dhabi, UAE, xii + 352 pp: 29-32. (in English) ["Following the publication of the UK's Biodiversity Action Plan in 1994 a steering group was set up to look after the interests of the southern damselfly. It contained representatives from English Nature, the Countryside Council for Wales, the Environment Agency, the Wildlife Trusts and

Liverpool University, a centre of expertise in dragonfly and damselfly research. One of the aims of the plan devised by this group was to research the ecology of the species and ultimately to begin re-introductions into sites from which it had gone extinct in the UK. One of the early findings of a Studentship funded by the group was that southern damselfly sites had declined in number by more than 30% since 1960. Once the habitat requirements of the southern damselfly had been established the search began for sites from which it had gone extinct and for which habitat restoration was feasible. Venn Ottery Common, a Devon Wildlife Trust reserve lost southern damselfly in 1989, largely due to injudicious ditch digging which altered water courses to the detriment of southern damselfly, coupled with a relaxation of grazing which led to the spread of tussocks of *Molinia caerulea* which effectively covered the runnels passing down the site. It was chosen as the first re-introduction site for four reasons. First, it had lost southern damselfly relatively recently and water chemistry tests revealed that the water quality was within the range acceptable. Second, there was a strong resolve on the part of the site owners, Devon Wildlife Trust to restore southern damselfly to the site and to raise funds so to do. Third, there was enthusiastic local support from the two people most responsible for improving the status of southern damselfly on two other sites on the East Devon Pebble Beds, Aylesbeare and Colaton Raleigh Commons (Kerry, 1989). Finally there was the possibility that a meta-population structure might be established, and with it gene flow between populations (Thompson, Watts & Saccheri, 2007). From 2002 onwards researchers at Liverpool University had estimated genetic variation in all the known sites for southern damselfly in the UK and had determined population sizes and some of them. Beaulieu Heath in the New Forest was chosen as the donor site for the re-introduction on the grounds that it had the highest population density recorded in the UK and contained the most genetically diverse population. Licences to undertake the work were obtained at the national level from Natural England, from the Forestry Commission representing the donor site and from Devon Wildlife Trust representing the recipient site. On 10th June 2007, 57 mature individuals were taken from Beaulieu Heath to Venn Ottery Common in three modified cylindrical butterfly rearing cages. The water level at Venn Ottery had dropped surprisingly in the ten days since the site had been visited previously. The decision was taken to stop the re-introduction until the water supply at Venn Ottery was more reliable, but the animals transported were released in any case. Between the summer of 2007 and spring 2009 Devon Wildlife Trust make great efforts to secure the water supply to the runnels in which southern damselfly was likely to breed. Large numbers of birch trees were removed and Devon cattle were brought in to graze the site. In addition a fast-flowing, unsuitable stream on the edge of the site was transformed by the introduction of eleven dams which produced in parts conditions for southern damselfly similar to those at the other two East Devon Pebblebed sites. Growth of *Potamogeton polygonifolius*, a favoured oviposition plant for southern damselfly, was encouraged. By summer 2009 conditions at Venn Ottery were looking much better, with a steady flow of water down the runnels into which it was hoped that southern damselflies would breed. The re-introduction program was set to proceed. It was given a timely boost by the discovery of some breeding adults on the site, which must have been descendants of the

cohort introduced in 2007. Four hundred females and 100 males were transported from Beaulieu Heath to Venn Ottery Common over the course of ten days in six different batches. The car journey lasted roughly three hours but only three individuals did not survive the journey. Exclusively mated females (distinguishable by their muddy abdomen tips) were taken in the first two trips. Females store sperm and oviposit alone in the absence of males. As males were re-introduced later during the programme they would mate with females on site and by removing sperm deposited during previous matings in the New Forest (a unique feature of damselfly mating behaviour) would guarantee the highest genetic diversity per introduced female. Almost all individuals seemed unaffected by the car journey and many had begun to show reproductive behaviour within minutes of being released at Venn Ottery. Southern damselflies have a two-year life cycle in the UK. The first monitoring took place in 2009 in order to check whether any of the 2007 pilot introductions had bred. ... The pilot reintroduction in 2007 led to breeding adults being recorded on site in 2009, prior to the main re-introduction effort." 11493. Adnan, M.; Raza, S.A. (2011): Taxonomic studies of damselflies (Zygoptera: Odonata): With special emphasis on rice ecosystem of district Gujrat. VDM Verlag Dr. Müller: 56 pp. (in English) [nv, "Zygopterans are economically very important because they have a role in insect pest management; especially they mostly feed on the pests of rice like water fleas, larvae of mosquitoes and bugs. Rice is one of the major crops grown in Gujrat, so current project was designed to explore the Zygopterous fauna of District Gujrat. Adult samples were caught with a light and strong insect collecting net having a handle 2ft length and ring diameter of about 20 cm. Ethyl acetate as a killing chemical was used in glass jars. After softening with water bath, samples were placed and stretched over thermopore sheets and pinned properly and carefully. Identification was carried out by using standard keys. Seven species of damselflies were recorded from 14 different localities of Distt. Gujrat (July-August, 2010). The species recorded from the distt. Gujrat were *Agriocnemis pygmaea*, *Ceragrion coromandelianum*, *Pseudagrion hypermelas*, *Pseudagrion spencei*, *Enallagma parvum*, *Ischnura aurora* and *Rhodischnura nursei*. *Ischnura aurora* is the most common and abundant specie found in all localities of the district while *Pseudagrion spencei* is rare in this district." 11494. Almeida, E.; Nunes, A.; Andrade, P.; Alves, S.; Guerreiro, C.; Rebelo, R. (2011): Antipredator responses of two anurans towards native and exotic predators. *Amphibia-Reptilia* 32: 341-350. (in English) ["When faced with the risk of predation, tadpoles of many am-

phibian species are known to modify their phenotype. In this work we studied the effect of an exotic species, the red swamp crayfish (*Procambarus clarkii*), on the phenotype of two species of amphibians with different reproduction habitats: the Iberian painted frog, *Discoglossus galganoi*, that normally reproduces in temporary water bodies and the common toad, *Bufo bufo*, that reproduces in permanent water bodies. The responses were compared with the ones shown in the presence of a native predator, dragonfly (Aeshnidae) larvae. Behaviour, growth and morphology of tadpoles were monitored in a factorial experiment with five treatments. Our results showed that only the permanent habitat species altered its behaviour and life-history traits in the presence of *P. clarkii*; however, this was mediated by chemical cues from consumed conspecifics. Antipredator responses of *B. bufo* towards the exotic crayfish were similar to the ones towards the native predator, while *D. galganoi* responded to the dragonfly larvae but not to *P. clarkii*. This may be the result of infrequent colonization events of temporary habitats by the crayfish. Therefore, the consequences of the introduction of *P. clarkii* might be more serious for *D. galganoi* and other species living in temporary habitats. Species breeding in permanent habitats, more prone to having generalized antipredator responses, may be relatively protected against this exotic crayfish although the effectiveness of these responses still needs to be tested." 11495. Aluthwattha, R.G.S.T. (2011): Population structure and dynamics of *Nerothemis tullia* [sic] (Odonata: Libellulidae) with water availability in rice field ecosystem. Proceedings of 16th International Forestry and Environment Symposium 2011. Sixteenth Annual Symposium organized by Department of Forestry and Environmental Science, University of Sri Jayewardenepura, Nugegoda, Sri Lanka was held on 28 - 29 October 2011 at Golden Rose Recreation Complex, 261, Maharagama Road, Boralesgamuwa, Sri Lanka: (in English) [Verbatim: Dragonflies are important insects in rice field ecosystem (RFE) as pest predators. Rice fields in return serve as a good breeding and feeding ground for dragonflies though RFE undergo several changes during a crop cycle. However habitat conditions vary mainly on the climatic regions and farming practices. The selected RFE in wet zone lowland for sampling comprised deferent habitats, two shallow streams, non cultivated fields, cultivated fields, small water pools, ponds and water wells. The most common dragonfly in marshes and paddy fields, *Neurothemis tullia* was studied to understand its population structure and dynamics with the water availability. Sampling was conducted from May 2010 to November 2010 covering one cultivation cycle. Two sampling methods i.e., random sampling along 5m X 50m transects and systematic sampling in pre-identified colonies were used. Colonies were identified in advanced, numbered consecutively and every third colony was observed. *N. tullia* adult male, adult female, juvenile male and teneral female were distinguish by general morphological characters and recorded separately. Activeness of *N. tullia* individuals were recorded as number of catches (of prey) or tries for per 10 minutes. Other associated Odonata were also recorded. Water level and flow rate in streams were measured as indicators of water availability in RFE. Systematic sampling recorded higher density (2.50 individuals/m²)

while random sampling produced lesser density (0.19 individuals/m²). However random sampling method recorded higher diversity of Odonata in RFE. Number of individuals were positively correlated ($r = 7.68$) with water level. Flow rate had no significance relationship with individual density. Activity of colony peaks between 9.00 hr to 11.00 hr and minimum around 13.00 hr. Second peak occurred around 16.00 hr - 17.00 hr. Number of both male and female juveniles sharply reduced towards the drier months whilst number of both adult male and female increased. During the dry period in September, density reduced to minimum and juveniles became scarce. In November with the beginning of rain, number and activity of *N. tullia* increased and more colonies observed at water holes and in field proper of paddy fields. Sampling along transects can be recommended for study of Odonata diversity whilst systematic sampling is more suitable for study of population dynamic and structure. The study is being continued for second crop cycle. Though common species are neglected in conservation practices, consequences of sudden decline in common species that occur in higher number, such as *N. tullia* is unpredictable. This study implies the necessity of their conservation as they have complex ecosystem interactions and intense ecosystem service.] Address: not stated

11496. Arulprakash, R.; Gunathilagaraj, K. (2011): Impact of agrochemicals on the abundance and diversity of Odonata in rice fields. *Indian Journal of Plant Protection* 39(3): 191-195. (in English) ["A study was designed to ascertain the impact of agrochemicals on the biodiversity of Odonata in rice fields at a Wetland farm. Adult Odonata diversity was assessed at weekly intervals from two rice fields, one with normal application of agrochemicals and other without any agrochemicals application (control). Eighteen and ten species of Odonata were recorded in Control Rice Field (CRF) and Agrochemicals Applied Rice Field (AARF), respectively. Odonata abundance, diversity and species richness was higher in CRF than AARF. Among the different stages of the rice crop, active tillering stage had Maximum abundance, diversity and species richness of Odonata. Among the families, Libellulidae was dominant in both CRF and AARF. *Diplacodes trivialis* and *Pantala flavescens* were dominant in CRF and AARF, respectively and *Ischnura aurora* was abundant in both CRF and AARF. Eight species of Odonata, which were present in CRF and absent in AARF, may be identified as indicator Odonata species for agrochemicals contamination in rice ecosystem." 11501. Buy, DD.; Matushkina, N. (2011): Sex differences in the wing fluctuating asymmetry in a damselfly *Calopteryx splendens* (Odonata, Calopterygidae). Proceedings of the International Conference "Fundamental problems of entomology in the XXI century ". St. Petersburg, 16-20 May 2011. Edited by E. Kipyatkova and D.L. Musolina. - St. Petersburg: Publishing House of St. Petersburg State University, 2011, 198 pp: 23. (in Russian) [Verbatim: Fluctuating asymmetry (FA) is defined as small random deviations from perfect bilateral symmetry in living organisms (Van Valen, 1962). It is believed that elevated levels of FA may indicate that the stabilizing mechanisms are not able to fully compensate for the deviations of which are caused by negative factors such as extreme environmental conditions (including its pollution) or limited gene flow. The study of dragonflies in the FA aims to describe the state of the population as a whole, its individual members or to identify the signs, subject to a special press stabilizing selection. In the latter case, the study mainly relate to the wings of males who use drawing as a demonstration of a wing element or territorial and sexual behaviour. The aim of our work was to compare the level of dimensional parameters of wing FA in representatives of different sexes damselflies *Calopteryx splendens*. Males of this species have a spot on the distal halves of both pairs of wings, which, during the special demonstration flights are presented conspecific males (under the protection of the territory) and females (courtship). And in the process of courting the front wings of males *S. splendens* remain almost stationary. Wings of females of this species are transparent, and, apparently, the signal is not important. Material for our study included 36 females and 49 males selected on the river Vorskla (50°17'37 "N 34°49'40" E). We studied three characteristics lengths covered with the distance from the base of vein M before the end of bk (wing length), distance from base to knot M (the length of the proximal part of the wing), the distance from the knot before the end of R.2 (the length of the distal part of the wing). It is shown that the FA distal parts of the forewings of males was significantly (approximately 2.5-fold) than in females. However, within

the same sex FA of forewing most of the indicators was significantly higher than the rear. Length of the proximal and distal parts of the wing significantly correlated in females and males do not correlate. The results allow to conclude tentatively that male *C. splendens* dimensional characteristics of the distal part of the front wing, the carrier signal spot, may have a stronger influence of stabilizing selection, but this hypothesis requires further experimental verification.] Address: Matushkina, Natalia, Department of Zoology, Biological Faculty, Kyiv National University, vul. 11504. de Ávila, A.C.; Stenert, C.; Maltchik, L. (2011): Partitioning macroinvertebrate diversity across different spatial scales in southern Brazil coastal wetlands. *Wetlands* 31: 459-469. (in English) ["The main goals of this study were: (1) test how beta diversity of aquatic macroinvertebrates varies among samples from different spatial scales in permanent and intermittent wetlands; and (2) test how beta diversity of aquatic macroinvertebrates varies among different wetland habitat types. Four collections were carried out over 1 year in 16 freshwater coastal wetlands in southern Brazil. The habitat types identified were: 1) hydrophytes, represented by submersed and floating plants; 2) reed-like emergent plants; and 3) leafy emergent plants. Additive partitioning of diversity was used to decompose the total variation in macroinvertebrate composition (regional diversity) into alpha (fine spatial scale) and beta components (intermediate and broad spatial scales). A total of 51,290 macroinvertebrates distributed among 63 families were collected (including: Aeshnidae, Coenagri-

onidae, Libellulidae). Additive partitioning of diversity showed similar patterns for both permanent and intermittent wetlands. In general, alpha diversity component was much lower than beta components. The beta diversity was greater among wetlands than among distinct habitats within wetlands. We found a strong evidence of scale dependence on diversity partitioning of macroinvertebrate communities, with beta diversity at broad spatial scale making a large contribution to total diversity in coastal wetlands of southern Brazil." 11505. Edward, J.B.; Ugwumba, A.A.A. (2011): Macroinvertebrate fauna of a tropical southern reservoir, Ekiti State, Nigeria. *Continental Journal of Biological Sciences* 4(1): 30-40. (in English) ["A survey of the macroinvertebrate fauna of Egbe Reservoir, Ekiti State, Nigeria was carried out. Sampling of surface waters and macroinvertebrates was carried out twice in a month from September 2004 to December 2006. Physico-chemical parameters determined include pH, conductivity, alkalinity, dissolved oxygen and biochemical oxygen demand (BOD) using APHA methods. Macroinvertebrates were collected by kick sampling and with Van veen grab. Data analysis was done using descriptive statistics, Duncan multiple range, pearson correlation, paired t tests and diversity indices. 18 taxa of macroinvertebrates in two Phyla of Mollusca and Arthropoda were identified. Gastropods had the highest numerical abundance (41.8 %), diversity ($d=0.61$, $H=1.56$) and evenness ($J=0.87$). Odonata and Ephemeroptera (Insecta) had the lowest diversity ($d=0.00$, $H=0.00$ and $d=0.14$, $H=0.13$) and numerical abundance (0.4% and 6.3%, respectively). The gastropod, *Melanoides tuberculata*, which is the most abundant macroinvertebrate is an indicator of polluted water. This suggests that the reservoir may be tending towards organic pollution. This is further confirmed by the low abundance of Ephemeroptera and Odonata which are indicators of clean water. Measures should be taken to prevent the reservoir from further deterioration and eventual eutrophication." 11507. Ferreira, W.R.; Paiva, L.T.; Callisto, M. (2011): Development of a benthic multimetric index for biomonitoring of a neotropical watershed. *Braz. J. Biol.* 71(1): 15-25. (in English, with Portuguese summary) ["Biotic indices are important tools for evaluating water quality in Biomonitoring Programmes of river basins. The objective of this study was to develop a Benthic Multimetric Index (BMI) to evaluate the water quality in a Neotropical catchment in southeastern Brazil. Thirty metrics were evaluated and six were selected to calculate the BMI: family richness, % Oligochaeta, % Chironomidae + Oligochaeta (% CHOL), % EPT (Ephemeroptera, Plecoptera and Trichoptera), % Collector-gatherers, and BMWP-CETEC biotic index. Sampling was carried in triplicate at 21 sampling sites (8 in the river channel and 13 in the tributaries) during 4 annual collecting trips from June 2004 to November 2007, making a total of 945 samples. Scores (5, 3 or 1) were attributed to each chosen metric and were added up to establish the water quality criteria (a score of 6-12 – poor; 13-18 – intermediate; 19-24 – good; and 25-30 – very good water quality). Our results indicated that 48% of the sampling sites analysed in the catchment basin presented very good water quality, 14% good quality, 19% regular, and 19% poor water quality. This methodology proved to be an efficient tool for evaluating water quality in the Biomonitoring Programme of the Velhas River basin, and that it may serve to evaluate water quality in other river basins in South America." (Authors) The paper includes references to Odonata without giving any details.] Address: Ferreira, W., Laboratório de Ecologia de Bentos, Departamento de Biologia Geral, Universidade Federal de Minas Gerais – UFMG, Rua Marley Moura Abreu, 79, Vale do Jatobá, CEP 30668-530, Belo Horizonte, MG, Brazil. 11508. Feulner, G.; Karki, N. (2011): Damsel in disguise. *Gazelle*, Dubai 26(3): 4. (in English) [Verbatim: Damselflies of the genus *Ischnura* (bluetails) are notoriously difficult to distinguish in the field. For the three species present in the UAE and Northern Oman (*I. evansi*, *I. senegalensis* and *I. fountainae*), Bob Reimer of Al-Ain has recently sorted out visual identification of the males (see *Tribulus* vol. 18), but identification of *Ischnura* females continues to tax even experts. One reason is that the females of most species exhibit multiple colour patterns, including a pattern that mimics that of the male (androchrome colouration), featuring a blue band around the penultimate abdominal segment. We were forcefully reminded of the phenomenon of androchrome colouration in late January when we observed a 'male' *Ischnura* in a large irrigation ditch at the Ruwayah plantations. As we watched (and attempted to confirm an identification), the 'male' curled its abdomen and began to deposit eggs on a sloping reed stem, where it angled beneath the water. It was obviously a female! The same animal continued to edge backwards along the reed, still looping its abdomen and depositing eggs at increasingly lower levels, until its head was c.3cm below the water surface. The androchrome female remained fully submerged for approximately 5 minutes. When it

ascended the reed and re-emerged at the surface, a real male was waiting ahead of it; whether this was by design or inadvertence, we cannot say. Within another minute, the pair attempted copulation in the wheel position; the male grasped the female's neck but the (androchrome) female seemed only half-hearted and failed in her efforts to maintain a reciprocal hold on the male. Three times in the course of several minutes the tandem pair fell onto the surface of the water in the channel, but each time they were able to take flight and find a perch. In the end, however, they disengaged and went their separate ways, evidently without consummation. Another noteworthy point about this observation is that it was made in late January, and a second observation, of the sister species *I. senegalensis*, was made a day later at Dubai's "Pivot Fields". Thus, although it is sometimes said that the local damselflies emerge only "later in the season" than most of the dragonflies, this is not strictly true in all cases.] Address: Feulner, G.R., P.O. 11509. Fliedner-Kalies, T.; Fliedner, H. (2011): Libellen im Kanton Schwyz. *Ber. schwyz. naturf. Ges.* 16: 208 pp. (in German) [Following a long lasting inventory a total of 62 species of canton Schwyz (Switzerland) are presented monographically. The introductory chapters present an outline of the history of exploration of the regional Odonata fauna and of general Odonata biology, descriptions of Odonata biotopes and information on the impact of climate change. The concluding chapter is devoted to Odonata protection and conservation. An exhaustive regional bibliography is appended. Each species is presented with a brief description of the taxa, sections on distribution, habitats, biology and the conservation status, with photographs of both sexes, a phenology graph and a distribution map.] Address: Publishers: Arvenweg 10, CH-8840 Einsiedeln, Switzerland

11510. Fontaneto, D.; Tommaseo-Ponzetta, M.; Galli, C.; Riséd, P.; Glewe, R.H.; Paoletti, M.G. (2011): Differences in fatty acid composition between aquatic and terrestrial insects used as food in human nutrition. *Ecology of Food and Nutrition* 50(4): 351-367. (in English) [Italy; "Edible insects may be a source of long-chain polyunsaturated fatty acids (LC-PUFA). The aim of this article is to test for differences in aquatic and terrestrial insects used in human nutrition. We implemented linear models and discovered that differences in the proportion of LC-PUFA between aquatic and terrestrial insects do exist, with terrestrial insects being significantly richer in particular omega-6 fatty acids. In conclusion, any kind of insect may provide valuable sources of LC-PUFA. Because terrestrial insects are more abundant and easier to collect, they can be considered a better source of LC-PUFA than aquatic ones." The study includes *Gomphus vulgatissimus*. "Odonata were consumed in northern Italy in Piedmont region until the early 1940s. Children used to extensively collect adult dragonflies, mainly of the genus *Gomphus*, in May–June, open their thorax and suck the muscular content, known as the "dragonfly tuna" (Boano et al. 2007, and pers. comm. from C. Cerri and C. Cantoia)." (Authors)] Address: Fontaneto, D., Department of Invertebrate Zoology, Swedish Museum of Natural History, Stockholm, Sweden. E-mail: d.fontaneto@imperial.ac.uk

Sardineros Creek, Verde River drainage, upper Cauca, Colombia. *Rev. Invest. Univ. Quindío* 21: 21-28. (in Spanish, with English summary) ["We reviewed the composition and variation of aquatic insects from Sardineros Creek, a tributary of Verde river, Quindío river, Upper Cauca, Colombia. 2743 specimens were collected in low rainfall and 1020 during high rainfall. Diptera and Trichoptera were the most abundant. Diversity indices of Shannon-Wiener, Simpson's dominance were low in both climatic periods, while the Margalef richness was high. The index indicated a low diversity as a result of the reduced dissolved oxygen and increased conductivity during the period of high rainfall, which made the declining water quality as good (BMWP/Col: 191) during the low rainfall to acceptable (BMWP/Col: 65) at the high rainfall. Hotelling's T-Squared test probe significant differences between seasons in the community structure ($P=0,042$, $F= 4, 6$) and proportion test explain the structure change in 74% of the families analyzed; we propose that seasonality was the variable that most influences in the abundance and diversity of aquatic insects." (Authors) Taxa are treated at the family level and include Brechmorhoga, Progomphus, Phyllogomphoides, Hetaerina, and Aeshna.] Address: García-Alzate, C.A., Universidad del Quindío, Laboratorio de Ictiología, A. (in English) ["In Odonata, many species present sexual size dimorphism (SSD), which can be associated with male territoriality in Zygoptera. We hypothesized that in the territorial *A. reclusa*, male-male competition can favour large males, and consequently, drive selection pressures to generate male-biased SSD. The study was performed at a small stream in southeastern Brazil. Males were marked, and we measured body size and assessed the quality of territories. We tested if larger territorial males (a) defended the best territories (those with more male intrusions and visiting females), (b) won more fights, and (c) mated more. Couples were collected and measured to show the occurrence of sexual size dimorphism. Results indicated that males are larger than females, and that territorial males were larger than non-territorial males. Larger territorial males won more fights and defended the best territories. There was no difference between the mating success of large territorial and small non-territorial males. Although our findings suggest that male territoriality may play a significant role on the evolution of sexual size dimorphism in *A. reclusa*, we suggest that other factors should also be considered to explain the evolution of SSD in damselflies, since non-territorial males are also capable of acquiring mates." 11517. Honkanen, M.; Sorjanen, A.-M.; Mönkkönen, M. (2011): Deconstructing responses of dragonfly species richness to area, nutrients, water plant diversity and forestry. *Oecologia* 166(2): 457-467. ["Understanding large-scale variation in species richness in relation to area, energy, habitat heterogeneity and anthropogenic disturbance has been a major task in ecology. Ultimately, variation in species richness results from variation in individual species occupancies. We studied whether the individual species occupancy patterns are determined by the same candidate factors as total species richness. We sampled 26 boreal forest ponds for dragonflies and studied the effects of shoreline length, water vascular plant species density (WVPSD), availability of nutrients, intensity of forestry, amount of Sphagnum peat cover and pH on dragonfly species richness and individual dragonfly species. WVPSD and pH had a strong positive effect on species richness. Removal of six dragonfly species experiencing strongest responses to WVPSD cancelled the relationship between species richness and WVPSD. By contrast, removal of nine least observed species did not affect the relationship between WVPSD and species richness. Thus, our results showed that relatively common species responding strongly to WVPSD shaped the observed species richness pattern whereas the effect of least observed, often rare, species was negligible. Also, our results support the view that, despite of the great impact of energy on species richness at large spatial scales, habitat heterogeneity can still have an effect on species richness in smaller scales, even overriding the effects of area." 11520. Iserbyt, A.; Bots, J.; Van Dongen, S.; Ting, J.J.; Van Gossum, H.; Sherratt, T.N. (2011): Frequency-dependent variation in mimetic fidelity in an intraspecific mimicry system. *Proceedings of the Royal Society B: Biological Sciences* 278(1721): 3116-3122. (in English) [*Nehalennia irene*; "Contemporary theory predicts that the degree of mimetic similarity of mimics towards their model should increase as the mimic/model ratio increases. Thus, when the mimic/model ratio is high, then the mimic has to resemble the model very closely to still gain protection from the signal receiver. To date, empirical evidence of this effect is limited to a single example where mimicry occurs between species. Here, for the first time, we test whether mimetic fidelity varies with mimic/model ratios in an intraspecific mimicry system, in which signal receivers are the same species as the mimics and models. To this end, we studied a polymorphic damselfly with a single male phenotype and two female morphs, in which one morph resembles the male phenotype while the other does not. Phenotypic similarity of males to both female morphs was quantified using morphometric data for multiple populations with varying mimic/model ratios repeated over a 3 year period. Our results demonstrate that male-like females were overall closer in size to males than the other female morph. Furthermore, the extent of morphological similarity between male-like females and males, measured as Mahalanobis distances, was frequency-dependent in the direction predicted. Hence, this study provides direct quantitative support for the prediction

that the mimetic similarity of mimics to their models increases as the mimic/model ratio increases. We suggest that the phenomenon may be widespread in a range of mimicry systems." 11525. Kerst, C.; Gordon, S. (2011): Dragonflies and damselflies of Oregon. A field guide. Oregon State University Press. ISBN 978-0-87071-589-1: 304 pp. (in

English) ["Growing interest in watching and identifying dragonflies and damselflies has sharpened the need for an authoritative resource like *Dragonflies and Damselflies of Oregon*, a definitive field guide devoted solely to dragonflies and damselflies found in the state. Cary Kerst and Steve Gordon include information on identification, as well as biology and behaviour, using common terms useful to the novice and experienced enthusiast alike. The book features stunning colour photographs of male and female of all species currently known in Oregon, along with helpful illustrations and charts with important identification characteristics. *Dragonflies and Damselflies of Oregon* presents the life cycle and larval habits of dragonflies and damselflies, along with photographs of the larvae of families. The Oregon range for each species is mapped, and the size range of adults is provided in text and illustration. The book also includes a description of the best sites in Oregon to observe these amazing insects, a useful tool for viewing uncommon species in spectacular settings. *Dragonflies and Damselflies of Oregon* is an essential reference for odonatists, entomologists, birders, butterfly watchers, fishermen, wetland experts, naturalists, gardeners, artists, photographers, and all outdoor enthusiasts. 91 species descriptions, with ID charts; Full-colour photographs of all species known in Oregon, with illustrations and charts; Description of 30 best locations in Oregon to observe dragonflies; Tables of illustrations used as pictorial keys; Useful appendices and index" (Publisher)] Address: Publisher: Oregon State University Press, 121 The Valley Library, Corvallis, OR 97331, USA

11526. Ledger, M.E.; Edwards, F.K.; Brown, L.E.; Milner, A.M.; Ward, G. (2011): Impact of simulated drought on ecosystem biomass production: an experimental test in stream mesocosms. *Global Change Biology* 17(7): 2288-2297. (in English) ["Climate models predict widespread shifts in precipitation patterns and increases in the frequency of extreme events such as droughts, but consequences for key processes in affected ecosystems remains poorly understood. A 2-year manipulative experiment used a series of stream mesocosms to test the effect of recurrent drought disturbance on the composition and secondary production of macroinvertebrate consumer assemblages and functional groups. On average, secondary production in drought-disturbed communities (mean $4.5 \text{ g m}^{-2} \text{ yr}^{-1}$) was less than half of that that in controls (mean $10.4 \text{ g m}^{-2} \text{ yr}^{-1}$). The effects of the drought differed among functional feeding groups, with substantial declines for detritivore shredders (by 69%) and engulfing predators [including *Cordulegaster boltonii*] (by 94%). Contrasting responses were evident among taxa within most functional feeding groups, ranging from extirpation to irruptions in the case of several small midge larvae, but production of most species was suppressed. Taxon-specific responses were related to body mass and voltinism. The ratio of production to biomass (community P/B) increased under drought, reflecting a shift in production from large long-lived taxa to smaller taxa with faster life cycles. This research provides some of the first experimental evidence of the profound effects that droughts can have on both the structure and functioning of aquatic ecosystems." 11527. Liess, M.; Beketov, M. (2011): Traits and stress: keys to identify community effects of low levels of toxicants in test systems. *Ecotoxicology* 20(6): 1328-1340.

(in English) ["Community effects of low toxicant concentrations are obscured by a multitude of confounding factors. To resolve this issue for community test systems, we propose a trait-based approach to detect toxic effects. An experiment with outdoor stream mesocosms was established 2-years before contamination to allow the development of biotic interactions within the community. Following pulse contamination with the insecticide thiacloprid, communities were monitored for additional 2 years to observe long-term effects. Applying a priori ecotoxicological knowledge species were aggregated into trait-based groups that reflected stressor-specific vulnerability of populations to toxicant exposure. This reduces inter-replicate variation that is not related to toxicant effects and enables to better link exposure and effect. Species with low intrinsic sensitivity showed only transient effects at the highest thiacloprid concentration of 100 lg/l. Sensitive multivoltine species showed transient effects at 3.3 lg/l. Sensitive univoltine species were affected at 0.1 lg/l and did not recover during the year after contamination. Based on these results the new indicator SPEARmesocosm was calculated as the relative abundance of sensitive univoltine taxa. Long-term community effects of thiacloprid were detected at concentrations 1,000 times below those detected by the PRC (Principal Response Curve) approach. We also found that those species, characterised by the most vulnerable trait combination, that were stressed were affected more strongly by thiacloprid than non-stressed species. We conclude that the grouping of species according to toxicant-related traits enables identification and prediction of community response to low levels of toxicants and that additionally the environmental context determines species sensitivity to toxicants." (Authors) *Aeshna* sp., *Ischnura elegans*, *Leucorrhinia* sp., *Libellula quadrimaculata*, *Orthetrum coerulescens*, and *Sympetrum striolatum* are assessed as "non-sensitive univoltine taxa".] Address: Liess, M., Department System-Ecotoxicology, UFZ - Helmholtz Centre for Environmental Research, Leipzig 04318, Germany. 11529. Lüderitz, V.; Speierl, T.; Langheinrich, U.; Völkl, W.; Gersberg, R.M. (2011): Restoration of the Upper Main and Rodach rivers – The success and its measurement. *Ecological Engineering* 37(12): 2044-2055. (in English) ["Large-scale restoration of streams and rivers is a mandatory prerequisite for the implementation of the European Water Framework Directive (WFD) to reach good ecological status of water bodies. This contribution analyzes the success of the largest river restoration in Germany at the Upper Main (Bayern). Sections with a length of more than 18 km were restored be-

tween 1990 and 2008, including re-connection of former oxbow-lakes, multiple-channelling, and establishment of wide riparian buffer zones. Measuring the success of restoration by means of a multimetric assessment system, we found a clear success of restoration indicated by the status of hydromorphology and by the biological parameters, including macroinvertebrates, fishes, and macrophytes. Unlike non-restored reaches, the restored reaches attained a good ecological status. As such, the restoration of the Upper Main is shown to be a pilot project for the implementation of the WFD on a large scale." (Authors) With the exception of *Ophiogomphus cecilia*, all species listed below profit from restoration measures: *Aeshna cyanea*, *Calopteryx splendens*, *Coenagrion puella*, *Cordulegaster boltonii*, *Gomphus pulchellus*, *G. vulgatissimus*, *Ischnura elegans*, *Onychogomphus forcipatus*, *Platycnemis pennipes*, and *Pyrrosoma nymphula*.] Address: Lüderitz, V., University of Applied Sciences Magdeburg, Dept of Water and Waste Management, Breitscheidstr. 2, 39114 Magdeburg, Germany. E-mail: Volker.Luederitz@HS-Magdeburg.de

11530. Malikova, E.I.; Medvedev, A.F. (2011): New record of *Sympetrum risi* Bartenev, 1914 in Amur region. *Amurian zoological journal* III(3): 246-247. (in Russian, with English summary) [All *S. risi* specimens were collected in Amurskaya oblast in vic. of Blagoveshchensk (50°33'60"N, 127°39'27" E; 19.08.2011) and Raichikhinsk (49°47'36" N, 129°23'06" E; 15.09.2011). Diagnostic characters of *S. risi* and its relative *S. infuscatum* Selys, 1883 are discussed. Two colour morphs are noted in the females of *S. risi*, with heteromorph females closely resembling *S. infuscatum*.] Address: Malikova E.I., Department of Zoology, Blagoveshchensk State Pedagogical University, Lenina str. 104, Blagoveshchensk, 675000, Russia. 11531. Manger, R. (2011): Interspecific mating of *Sympetma fusca* (Vander L.) and *S. paedisca* (Brauer) observed for the second time in The Netherlands (Zygoptera: Lestidae). *Notul. odonatol.* 7(8): 74-75. (in English) ["On 26 April 2008, interspecific mating of *S. fusca* male and *S. paedisca* female, with oviposition ensuing, was observed in the Weerribben, in NE Netherlands. In 2007, a similar mating was brought on record from Drenthe, but its duration was shorter. It would seem that, in areas where both species reproduce, *S. fusca* behaves dominantly. The increasing expansion of *S. fusca* northward, as seen in the last few decades, could cause competition between the 2 species in the use of waters suitable for reproduction in the Weerribben and in similar areas. It is not known whether interbreeding could lead to viable progeny." (Author)] Address: Manger, R., Stoepveldsingel 55, 9403 SM Assen. The Netherlands. E-mail: rmanger@planet.nl

11532. Marinov, M. (2011): Damselflies and Dragonflies of the Nakorotubu Range, Ra and Tailevu Provinces, Viti Levu, Fiji. In: Morrison, C., Nawadra, S., and Tuiwawa, M. (ed.). A rapid biodiversity assessment of the Nakorotubu Range, Ra and Tailevu Provinces, Fiji. *RAP Bulletin of Biological Assessment* 59: 90-128. (in English) ["A total of 32 Odonata taxa were found during the RAP-Fiji in the Nakorotubu range, Ra and Tailevu Provinces, Fiji. These taxa represent more than 50% of the all species recorded for the whole Fijian archipelago and about 78% of the species established for Viti Levu. The significance of the group for environmental appraisals is discussed, individual behavioural traits and short ecological information are provided for each spe-

cies observed during the investigation, and a preliminary habitat classification scheme is suggested for the species collected from the study area. Due to problems with species taxonomy only general conservation recommendations are proposed without specifying local management actions that need to be taken." 11534. Neff, M.R.; Jackson, D.A. (2011): Effects of broad-scale geological changes on patterns in macroinvertebrate assemblages. *Journal of the North American Benthological Society* 30(2): 459-473. (in English) ["Understanding the broad-scale factors that influence biological communities has long been a goal of community ecology. We used benthic macroinvertebrate data to identify broad geographical patterns in macroinvertebrate community composition and specifically to examine the influence of the Precambrian Shield on stream abiotic and biotic conditions. The Precambrian Shield is a geological feature that encompasses most of northern North America. Geology differs between Shield and off-Shield areas, creating distinctly different physical and chemical conditions in aquatic systems. We focused our regional scale study on south-central Ontario, where both Shield and off-Shield conditions are found in adjacent areas. We used constrained and unconstrained multivariate analyses to examine patterns in biotic, abiotic, and spatial variables. Our results showed that, in low-order lotic systems, macroinvertebrate communities differ between Shield and off-Shield streams. Shield streams have higher dissolved O₂, velocity, and discharge, larger amounts of woody debris, and greater canopy cover than off-Shield streams. In contrast, off-Shield streams have higher conductivity, alkalinity, pH, turbidity, and water temperature, and frequently are surrounded by meadow, cultivated, or pastured land. In general, macroinvertebrate communities at off-Shield sites had a greater proportion of taxa preferring pool or depositional habitats, whereas macroinvertebrate communities at Shield sites contained taxa typically associated with riffles or erosional habitats. Analysis of spatial location indicated that the Shield/off-Shield distinction probably is the result of a combination of intertwined abiotic and spatial factors." (Authors) Taxa including

Odonata are treated at the family level.] Address: Neff, Margaret, Department of Ecology and Evolutionary Biology, University of Toronto, Toronto, Ontario M5S 3G5 Canada. E-mail addresses: maggie.neff@utoronto.ca

11535. Nesemann, H.; Sharma, G.; Sinha, R.K. (2011): Benthic macro-invertebrate fauna and "marine elements" sensu Annandale (1922) highlight the valuable dolphin habitat of river Ganga in Bihar - India. *TAPROBANICA: The Journal of Asian Biodiversity* 3(1): 18-30. (in English) ["From the main channel of River Ganga 95 invertebrate taxa (including *Asiagomphus* spec. and *Macrogomphus* spec.) have been recorded in the endangered Gangetic Dolphin (*Platanista gangetica*) habitat over an observation period of ten years. Mollusks, Annelids and Arthropods are the dominating benthic groups that constitute the detritivores, filter-feeders and sediment feeders, scrapers/grazers and herbivores. The benthic sediment fauna is rich in diversity and high in abundance. This enables carnivores to occupy a large variety of specialized ecological niches. ... Only two taxa are certainly recognized as non-indigenous neozoans, whereas the remaining fauna shows pristine and stable ecological conditions. In this aspect River Ganga differs from regulated large rivers, where faunal change has largely replaced the original species inventory. Despite the heavy pollution in parts of the river, the original composition of biological diversity is still persisting in the middle reaches of the Ganga. This provides hope for the survival of the Gangetic Dolphin." 11536. Nesemann, H.; Shah, R.D.T.; Shah, D.N. (2011): Key to the larval stages of common Odonata of Hindu Kush Himalaya, with short notes on habitats and ecology. *Journal of Threatened Taxa* 3(9): 2045-2060. (in English) ["The order Odonata is one of the most widely studied groups among insects from the oriental region. They colonize in both stagnant and running water bodies of wide water quality. Hitherto, the existing literature on the Odonata contained numerous publications with coloured figures of adults, helpful for identification. Identification key with figures on larval stages, using their coloration as distinguishing characters are largely missing. The current work attempts to provide an identification key to aquatic larvae of the most common families of Zygoptera, Anisoptera and Anisozygoptera with colour illustrations. The specimens were collected from Nepal and India (northern part). Each family is represented by several examples to demonstrate the range of morphological variability. This key helps determination of aquatic larvae Odonata up to family level without enormous efforts in field and laboratory." 11538. Nilsson, E.; Solomon, C.T.; Wilson, K.A.; Willis, T.V.; Larget, B.; Vander Zanden, M.J. (2011): Effects of an invasive crayfish on trophic relationships in north-temperate lake food webs. *Freshwater Biology* 57(1): 10-23. (in English) ["(1) The introduction of invasive species is one of the main threats to global biodiversity, ecosystem structure and ecosystem processes. In freshwaters, invasive crayfish alter macroinvertebrate community structure and destroy macrophyte beds. There is limited knowledge on how such invasive species-driven changes affect consumers at higher trophic levels. (2) In this study, we explore how the invasive rusty crayfish *Orconectes rusticus*, a benthic omnivore, affects benthic macroinvertebrates, as well as the broader consequences for ecosystem-level trophic flows in terms of fish benthivory and trophic position (TP). We expected crayfish to decrease abundance of benthic macroinvertebrates, making most fish species less reliant on benthic resources. We expected crayfish specialists (e.g. *Lepomis* sp. and *Micropterus* sp.) to increase their benthic dependence. (3) In 10 northern Wisconsin lakes, we measured rusty crayfish relative abundance (catch per unit effort, CPUE), macroinvertebrate abundance, and C and N stable isotope ratios of 11 littoral fish species. We used stable isotope data and mixing models to characterise the trophic pathways supporting each fish species, and related trophic structure to crayfish relative abundance, fish body size and abiotic predictors using hierarchical Bayesian models. (4) Benthic invertebrate abundance was negatively correlated with rusty crayfish relative abundance. Fish benthivory increased with crayfish CPUE for all 11 fish species; posterior probabilities of a positive effect were >95%. TP also increased slightly with crayfish CPUE for some species, particularly smallmouth bass, largemouth bass, rock bass and Johnny darter. Moreover, both fish body size and lake abiotic variables explained variation in TP, while their effects on benthivory were small. (5) Rusty crayfish abundance explained relatively little of the overall variation in fish benthivory and TP. Although rusty crayfish appear to have strong effects on abundances of benthic macroinvertebrates, energy flow pathways and trophic niches of lentic fishes were not strongly influenced by invasive rusty crayfish." (Authors) Odonata are represented in some of the studied lakes but not treated.] Address: Nilsson, E., Department of Biology /Limnology and Marine Ecology, Ecology Building, Lund University, SE-223 62 Lund, Sweden. 11539. Ohba, S.-Y.; Trang Huynh, T.T.; Le, L.L.; Ngoc, H.T.; Hoang, S.L.; Takagi, M. (2011): Mosquitoes and their potential predators in rice agroecosystems of the Mekong delta, southern Vietnam. *Journal of the American Mosquito Control Association* 27(4): 384-392. (in English) ["*Culex tritaeniorhynchus*, *Cx. gelidus*, and *Cx. quinquefasciatus*, known vectors of Japanese encephalitis (JE), are distributed in rice agroecosystems in Asian countries. Very few integrated studies on the breeding habitats of rice-field mosquitoes, including JE vectors, have been conducted in Vietnam. We investigated the mosquito fauna and potential predators (including 'Zygoptera' and 'Anisoptera') in 8 rice growing areas in the Mekong Delta region of southern Vietnam, during the wet and dry seasons of 2009. Mosquitoes and their predators were collected from a variety of aquatic habi-

tats (rice fields, ponds, wetlands, shrimp ponds, ditches, canals, and rivers). [...] Based on a stepwise generalized linear model, the abundance of mosquitoes and their predators in rice fields was high when the rice plant length was short and water depth was shallow. Therefore, the use of insecticides during the earlier stages of rice growth should be avoided in order to preserve the predator populations." 11541. Pfau, H.K. (2011): Functional morphology of the head movability and arrestment of *Aeshna cyanea* and some other dragonflies (Insecta: Odonata). *Entomologia generalis* 33(4): 217-234. (in English) ["The functional morphology of the neck sclerites and muscles, which are responsible for head movability and arrestment, is described. The musculature is divided (unsharp) in muscles for head-movements and muscles for head-arrestment and disengagement. A new mechanism of the cervicalia is described: the cervicalia-1/-3 constitute, together with the propleural suspension, a kinematic system with 5 links and 5 joints, which is activated by two pairs of antagonistic muscles. The muscles determine (on both sides) the distance between a pad of the cervical sclerite 2 and the head (which is articulated frontally to the cervicalia-1) by an alteration of both the lateral and longitudinal distances. -The head-suspension of dragonflies represents a serious mechanical weak point [Mittelstaedt 1950, Gorb 1998]. Since the head is continuously adjustable nearer or farther to the pads of the cervicalia-2, a gradual adaptation to risks of injury is possible. By strong contraction of the arrester-muscles an elastic bending property of the cervicalia-1 is utilized. The tangential approach and differently strong hooking of microtrichia fields effect a variable frictional damping of passive deflections of the head. Pressure-spring and tension-spring properties, mainly of the proximal bending zone of the cervicalia-1, also serve to protect the vulnerable head-joint. - The evolution of the punctiform head-articulation of the Odonata is reconstructed. Based on the different relative size of the cervical sclerites, the efficiency of different head-arrester systems is evaluated. Epallage fatigue, *Epiophlebia superstes* and the Anisoptera indicate an improved effectiveness of the head-arrester functions, which is possibly correlated to enhanced flight capabilities and increased risks of head-joint damage." 11542. Regan, E.; Nelson, B.M McCormack, S.; Nash, R.; O'Connor, J.P. (2011): Countdown to 2010: Can we

assess Ireland's insect species diversity and loss?. *Proceedings of the Royal Irish Academy* 110(2): 109-117. (in English) ["In light of the Convention on Biological Diversity, this paper summarises the known insect species numbers for Ireland and questions whether this is a true reflection of our insect diversity. The total number of known species for Ireland is 11,422. Using species accumulation curves and a comparison with the British fauna, this study shows that the Irish list is incomplete and that the actual species number is much higher. However, even with a reasonable knowledge of the species in Ireland, insects are such speciose, small, and inconspicuous animals that it is difficult to assess species loss. It is impossible to know at one point in time the number of insect species in Ireland and, although it is useful to summarise the known number of species, it is essential that biodiversity indicators, such as the Red List Index, are developed. ... For example, while 32 species of the Odonata have been recorded in Ireland, only 24 (75%) of these species are known to have established breeding populations (Nelson and Thompson 2004)."] Address: Regan, E., School of Natural Sciences, Trinity College Dublin, National Biodiversity Data Centre, Dublin 2, WIT West Campus, Waterford, Ireland

11547. Sano, K.; Miyoshi, K.; Ishikawa, S.; Liepvisay, N.; Kurokura, H. (2011): Impact of predation by water insects on fish seed production in Lao PDR. *Japan Agricultural Research Quarterly* 45(4): 461-465. (in English) ["The predation of cultured larval fish by water insects presents a serious issue for aquaculture development in rural areas of the Lao People's Democratic Republic (Lao PDR). In this study, the species composition of predatory water insects was monitored in a fish nursing pond. Laboratory predation experiments were then performed to examine the predation potential of water insects on 3 major cultured fish species, including *Barbonymus gonionotus*, *Cirrhinus cirrhosus*, and *Cyprinus carpio*. ... The results suggested that larvae of Coenagrionidae, Libellulidae, and Dytiscidae and adults and larvae of Notonectidae are potential predators of fish seed in nursing ponds. In this survey, predatory water insects were removed by drying the pond, and then filtering water using fine mesh nets after the pond had been refilled. The biomass of Coenagrionidae, Libellulidae, and Dytiscidae larvae was low 3 days after refilling and increased gradually over time, which suggests that the drying and filtering methods were effective for the removal of larvae of these 3 families, because they cannot fly. Coenagrionidae, Hydrophillidae and Dytiscidae individuals spawn the eggs on vegetation growing in the water. The removal of plants may therefore be more effective for the extirpation of these water insects than drying out the pond." (Authors)] Address: Sano, K., Fisheries and Aquaculture International Co. Ltd., Shinjuku, Tokyo 160-0004, Japan. E-mail: s-kousuke@mtj.biglobe.ne.jp

11552. Siesa, M.E. (2011): Freshwater communities and biological invasions: Odonata, Amphibia and *Procambarus clarkii*. Tesi di Dottorato. Scuola di Dottorato in Terra, Ambiente e Biodiversità, Corso di Dottorato di Ricerca in Scienze Naturalistiche e Ambientali, XXIII ciclo, Dipartimento di Biologia, Università degli studi di Milano: 144 pp. (in English) ["This research work analyses processes and dynamics occurring during the early stages of a biological invasion in freshwater habitats. I analysed processes determining the *Procambarus clarkii* invasion and the impact on native amphibians and odonates that have complex life cycles, I surveyed 148 among temporary and permanent wetlands of running and standing waters in a region that is at the edge of the invasion range of *P. clarkii*. I performed repeated sampling sessions in each wetland obtaining both qualitative and quantitative data on freshwater communities, I characterized each wetland using standard parameters, and I used GIS software for the description of the surrounding landscape. I analysed all data using spatial models and considering the spatial autocorrelation (for details see chapter 2). Data analysis showed that the environmental features are important in determining the early phases of the crayfish invasion; in the study area, *P. clarkii* spreads more frequently in association with large and permanent wetlands in human-altered landscapes, and the autocorrelation of its populations is stronger at distances up to 2500 m suggesting that dispersion affect invasion processes up to this distance (chapter 2). Further analysis showed that environment shapes both alien invasive species (AIS) and freshwater communities, but considering the optimal environmental features for *P. clarkii* and for amphibians and odonates, I observed important differences related to wetland size, depth, hydroperiod, exposition, presence of aquatic macrophytes, and surrounding landscape features (chapters 2, 3, and 5). The observed relationships among distribution and composition of native communities and distribution of *P. clarkii* suggests that the invasive crayfish has only a limited direct impact on adult amphibians and odonates, but the analysis of juvenile stages of native communities (larvae of amphibians, larvae and exuviae of odonates) showed the dra-

matic loss of their abundance and richness in wetlands invaded by the crayfish, indicating that, despite adults attempt reproduction in invaded sites, *P. clarkii* causes, with its activities, the fall down of their reproductive success (chapters 4 and 5). This research confirms the strong negative impact of AIS on native communities. My data indicate that *P. clarkii* determines the loss of reproductive sites, and the decrement of the reproductive success when native populations use the invaded sites for breeding (chapters 4, 5, and 6). This research highlights the importance of studying the early stages of an invasion, confirming that in this phase AIS populations have larger environmental needs that might make them more vulnerable at management actions (chapters 2, 3, and 6). Through the analysis and description of the mechanisms determining the AIS impact on native communities, this research helps to identify the ongoing processes at early stages of the AIS invasion, and the consequences that the invasive crayfish will have in the near future, allowing managers to start conservation actions before that the invasion consequences become irreversible." (Author)] Address: not stated

11553. Sivaperuman, C.; Kumar Shah, S.; Venkataraman, K. (2011): New records of odonates from Andaman and Nicobar Islands. *Biological Forum* 3(2): 69-70. (in English) [*Zygomma petiolatum*, *Tramea limbata similata*, *Diplacodes nebulosa*, and *Cratilla lineata* are listed without details; the first three species were probably found in 2007 and *C. lineata* in 2005.] Address: Sivaperuman, C., Zoological Survey of India, Andaman and Nicobar Regional Centre, Port Blair

11554. Souto, R.; Facure, K.G.; Pavanin, L.A.; Jacobucci, G.B. (2011): Influence of environmental factors on benthic macroinvertebrate communities of urban streams in Vereda habitats, Central Brazil. *Acta Limnologica Brasiliensia* 23(3): 293-306. (in English, with Portuguese summary) ["Aim: Veredas and the aquatic and semi-aquatic communities play a key role in watershed protection in the Cerrado Biome. Information about the effects of physical and chemical variables and habitat integrity on benthic communities has been increased in recent years; however, there is no study evaluating the influence of urbanization on macroinvertebrates of Vereda streams. Thus, improving the knowledge of the relationship between abiotic properties and benthic fauna is very important for understanding the functioning of ecological processes and health of aquatic ecosystems. This study investigated the influence of physical and chemical variables on benthic macroinvertebrate communities along a gradient of anthropogenic disturbance in four Vereda streams in Uberlândia (MG), one in a preserved area and three in the urban area; Methods: samplings were collected during the dry and rainy seasons; Results: principal component analysis separated the stream in the preserved area from those in the urban area by having lower values of BOD, COD, sediment size, conductivity, detergents, pH, deposited solids and total dissolved solids. Pollution sensitive groups (e.g., Ephemeroptera and Trichoptera) were associated to the stream in the preserved area, and more tolerant groups (e.g., Chironomidae and Oligochaeta) had greater abundance in the streams of the urban area. Canonical Correspondence Analysis indicated that dissolved oxygen, conductivity, BOD, oil and grease, and turbidity explained 56% of the variance in the distribution and abundance of macroinvertebrates; Conclusions: Benthic communities of Vereda streams in urban areas in

the Cerrado Biome seem to be highly affected by human activities that increase water organic pollution and sedimentation." (Authors) Odonata are treated at the family level.] Address: Pavanin, L.A., Instituto de uímica, Universidade Federal de Uberlândia-UFU, CEP 38408-100, Uberlândia, MG, Brazil. E-mail: pavanin@ufu.br

11555. Španić, R.; Cipčić, A.; Bogdanović, T.; Franković, M. (2011): State of research into dragonflies (Odonata) of Karlovac county, Croatia, with special reference to NATURA 2000 species. *Entomologia Croatica* 15: 209-221. (in English, with Croatian summary) ["42 dragonfly species were previously reported for Karlovac County. Historical as well as recently collected but unpublished records add seven more species to records for the analysed territory, raising the number of dragonfly species to 49. Analysis revealed uneven temporal and spatial distribution of records, showing that the SE part of the county (Kordun subregion) is the most underexplored. Although most of the published and unpublished data were collected during the last 25 years it is obvious that odonatological inventory was not conducted systematically but rather accidentally. Furthermore, only three NATURA 2000 species (*Cordulegaster heros*, *Leucorrhinia pectoralis* and *Ophiogomphus cecilia*) with very low number of records have been reported for Karlovac County." 11556. Stih, A.; Zdravec, M.; Hlavati, D.; Koren, T. (2011): First data about the dragonfly (Insecta, Odonata) fauna in the Vugrovec area, Zagreb and the first checklist of the dragonflies of Zagreb. *Entomologia Croatica* 15(1-4): 223-235. (in English) ["The fauna of Zagreb has been well investigated during the last two centuries, which is evident from a series of publications. Even so, only limited data on dragonfly fauna of Zagreb have been published, and there is no current checklist. During the three years period (2009-2011) we conducted a survey of the dragonfly and damselfly fauna (Insecta, Odonata) in Vugrovec village, located on the eastern slopes of Mt Medvednica. The aim of this study is to present the first data on dragonflies from the Vugrovec area and to compile the first checklist of dragonflies of Zagreb. The suborder Zygoptera is represented in Vugrovec by 4 families and 5 species, while the suborder Anisoptera is represented by 4 families and 9 species in the area. After a review of all the available literature, in conjunction with the newly collected data, a checklist of dragonflies of Zagreb was created, including 44 species, 14 of which are listed in the Red Book of Dragonflies of Croatia. This indicates a high richness in comparison to the 70 known species from Croatia." (Authors)] Address: Koren, T., Science and Research Centre Koper, University of Primorska, Koper, Slovenia

11558. Takahashi, Y.; Morita, S.; Yoshimura, J.; Watanabe, M. (2011): A geographic cline induced by negative frequency-dependent selection. *BMC Evolutionary Biology* 2011, 11:256: 10 pp. (in English) ["Background: Establishment of geographic morph frequency clines is difficult to explain in organisms with limited gene flow. Balancing selection, such as negative frequency-dependent selection (NFDS), is instead suggested to establish a morph frequency cline on a geographic scale at least theoretically. Here we tested whether a large-scale smooth cline in morph frequency is established by NFDS in the female-dimorphic damselfly, *Ischnura senegalensis*, where andromorphs and gynomorphs are maintained by NFDS. Results: We found a large-scale latitudinal cline in the morph frequency: andromorph frequency ranged from 0.05 (South) to 0.79 (North). Based on the empirical data on the numbers of eggs, the number of ovariole, abdomen length and latitude, the potential fitness of andromorphs was estimated to be lower than that of gynomorphs in the south, and higher in the north, suggesting the gene-by-environment interaction. From the morph-specific latitudinal cline in potential fitness, the frequency of andromorphs was expected to shift from 0 to 1 without NFDS, because a morph with higher potential fitness wins completely and the two morphs will switch at some point. In contrast, NFDS led to the coexistence of two morphs with different potential fitness in a certain geographic range along latitude due to rare morph advantage, and resulted in a smooth geographic cline of morph frequency. Conclusion: Our results provide suggestive evidence that the combination of NFDS and gene-by-environment interaction, i.e., multi-selection pressure on colour morphs, can explain the geographic cline in morph frequency in the current system." 11561. Uwimana, C. (2011): Impact of rice cropping on abundance of benthic macroinvertebrates in Nyanza, Sovu and Kibabara marshes, Huye district. Memoir submitted for partial fulfillment of the award of Bachelor's degree in Biology, National university of Rwanda,

Faculty of Science, Biology Department, Option: Zoology and conservation, Huye: 19 pp. (in English) [Rwanda; "The main purpose of this study was to assess the impact of rice cropping on water quality using benthic macroinvertebrates communities as bioindicators. The study was developed in Munyazi stream and surrounding rice irrigated fields in Nyanza, Sovu and Kibabara marshlands and the samples were collected in August during dry season and also maturation/cut period, three sites in Munyazi stream and other three sites in surrounding rice irrigated fields. 16 organisms were identified on order level, thus many of them could be identified on family level; Gastropoda of Planorbidae family were the most abundant taxa along with Ephemeroptera and Hemiptera, but the Ephemeroptera taxa was only found in Munyazi stream sample sites. The results showed a bare presence or absence of organisms sensitive to pollution in rice irrigated fields sample sites such as Ephemeroptera, Plecoptera and Trichoptera but also showed the presence, sometimes highly presented, in Munyazi stream sample sites. The rice cropping affected significantly the diversity and distribution of benthic macroinvertebrates organisms, meaning affecting water quality ($t=2.67, df=50, p=0.01$). The type of crops management and irrigation techniques, the use of pesticides are the main cause of the low diversity and low richness in benthic macroinvertebrates communities of rice irrigated fields. The benthic biodiversity loss observed in some sample sites, prove that environmental alteration is caused by rice cropping techniques, is at the origin of habitats reduction and degradation, simplification of ecosystem and impoverishment of water quality." (Author) In Munyazi Stream and surrounding rice fields Odonata accounted to 26% to sampled specimens.] Address: Uwimana, Catherine; no stated

(in Spanish, with English summary) ["The ubiquity of territorial defense in males of Calopterygidae is an interesting feature to evaluate the implications of morphological traits, sexual cues and ecological factors associated with territorial behaviour in odonates. The males of the genus *Hetaerina*, defend permanent territories in sunny areas close to riverbanks, through ritualized fights, chasing and displaying their wing against intruding males. It has been suggested that these traits have been evolved by sexual selection mainly because male's quality is expressed by honest signals, such as wing pigmentation levels, body size, thorax size (estimated of the amount of fat and muscle flight), and wings size. However, there is little evidence of variation in these traits among populations and alternative mating strategies which are common within *Hetaerina* genus. In this paper we document that

those traits not involved in territorial defense in males of *Hetaerina vulnerata* (Selys, 1853) not vary between populations, while the morphological traits involved in the success of male territorial behaviour are modified between populations and mating strategies. Our results highlight the importance of ecological features and levels of anthropogenic disturbance of natural populations in the reproductive success and the evolution of mating systems in Odonata." 11564. Wu, F.c.; Meng, W.; Cao, Y.-j.; Li, H.-x.; Zhang, R.-q.; Feng, C.-l.; Yan, Z.-g. (2011): Derivation of aquatic life water quality criteria for cadmium in freshwater in China. *Research of Environmental Sciences* 24(2): 172-184. (in Chinese, with English summary) ["Cadmium is a poisonous heavy metal which is toxic, hard to degrade and easy to reside. It can cause adverse effects on aquatic organisms and ecosystems. In order to control effectively the adverse effects which Cd might bring to aquatic life in Chinese freshwaters, it is urgent for China to derive regional aquatic life criteria for Cd, which could provide a basis for the establishment and revision of water quality standards. In this study, all available toxicity data of Cd to Chinese representative species in freshwater were collected in order to protect the freshwater ecosystem and biota system. Three widely used criteria derivation methods concerning the assessment factor method, toxicity percentile rank method and species sensitivity distribution method were used to derive aquatic life criteria for Cd. Meanwhile, the criteria values for freshwater in China and the derivation process were studied and compared among the three methods. The results showed that for the assessment factor method, the criteria of freshwater Cd was expressed by one value, which was 0.15 µg/L; for toxicity percentile rank method, the criteria included criteria maximum concentration and criteria continuous concentration, which were 7.30 µg/L and 0.12 µg/L, respectively; for species sensitivity distribution method, the criteria of short term hazardous concentration and long term hazardous concentration were 32.50 µg/L and 0.46 µg/L, respectively. Finally, this study analyzed the advantages and disadvantages of these three methods and compared the difference of the Cd criteria in this research and other existing reference values in China and abroad. In addition, the possible reasons which caused this difference and the key factors which influenced the aquatic life criteria were also discussed." (Authors) The paper refers Tollett et al. 2009. 11565. Xu, M.; Fincke, O.M. (2011): Tests of the harassment-reduction function and frequency-dependent maintenance of a female-specific color polymorphism in a damselfly. *Behav. Ecol. Sociobiol.* 65: 1215-1227. (in English) ["Colour polymorphisms have provided classical examples of how frequency-dependent selection maintains genetic variation in natural populations. Here

we tested for the first time, the hypothesized adaptive function of a female-specific colour polymorphism in odonates to lower male harassment towards females generally. Under conditions controlling for sex ratio, population density and morph frequency, we also tested two major frequency-dependent selection hypotheses for the maintenance of the polymorphism. Using groups of captive *Enallagma hageni*, whose females are either green or a male-like blue, we varied morph frequency at two sex ratios. We quantified sexual harassment towards females by visual observations, and by the presence of dust on females that was transferred from dusted males. Per capita harassment rate for the female-monomorphic treatments did not differ from that of the female polymorphic treatments. At a male-biased sex ratio, per capita harassment rate towards blue, but not green females increased with morph frequency, providing partial support for frequency-dependent selection resulting from male learning of female morphs. Even at high frequency, green females were not harassed more than blue, contrary to the prediction that males should always recognize green females as mates. Moreover, frequency-dependent harassment towards blue females was not detectable using harassment measured with dust evidence, which greatly underestimated the incidence of sexual harassment. Our findings identified problems with the use of insectaries and the dusting technique to quantify male sexual harassment towards females, as well as with a past insectary experiment on *Ischnura elegans* that failed to demonstrate frequency-dependent harassment." 11569. Ahn, S.J.; Park, C.G. (2012): Terrestrial Insect Fauna of the Junam Wetlands Area in Korea. *Korean Jour. Appl. Entomology* 51(2): 111-129. (in Korean, with English summary) ["Terrestrial insect fauna was surveyed in the Junam wetland area, which consists of the Junam, Dongpan, and Sannam wetlands, by visual

counting and pictures. A sweep net collection was conducted from May to October 2010. A neighboring artificial lotus wetland was also surveyed for comparison. A total of 5,730 insects were surveyed, representing 268 species in 85 families and 12 orders. Sixty-three species of coleopterans were surveyed, followed by 60 species of Lepidoptera, and 37 species of Hemiptera. Coleopteran individuals were 25.9% of the total insect numbers surveyed, comprising most abundant group. This was followed by Odonata, Lepidoptera, and Orthoptera at 22.3%, 15.4%, and 12.7%, respectively. In total, 197 species were surveyed in the Dongpan wetland, 175 in the Junam wetland, and 154 species in the Sannam wetlands. However, only 86 species were surveyed in the artificial lotus wetland. *Galerucella nipponensis* in Coleoptera, *Crocothemis servilia mariannae* in Odonata, and *Polygonia c-aureum* in Lepidoptera were the most abundant in all four wetlands. Community analyses showed that the dominance index was highest in the artificial lotus wetland at 0.25 and lowest in Junam wetland at 0.08. Diversity indices were relatively high in all wetlands at 4.48, 4.44, 4.28, and 3.87 in Junam, Dongpan, Sannam, and the artificial lotus wetland, respectively. The insect fauna similarity index was highest in the Junam and Dongpan wetlands at 0.96. The lotus wetland showed the lowest similarity of the three wetlands with values of 0.45-0.53." 11570. Altamiranda-S. M.; Ortega-M., O. (2012): Estructura poblacional de *Polythore gigantea* (Odonata: Polythoridae) en sistemas lóticos con diferentes estados de conservación en Antioquia, Colombia. *Rev. Biol. Trop.* 60(3): 1205-1216. (in Spanish, with English summary) ["Population structure of *Polythore gigantea* (Odonata: Polythoridae) in lotic systems with different conservation states in Antioquia-Colombia. The knowledge about population structure and dynamics of some Neotropical species, especially those living in lotic systems is still barely studied. This study had the aim to assess if the conservation status of some lotic systems, is related to some demographic variables of *P. gigantea*, so this may be used as a model for ecological monitoring. For this, we evaluated the population structure of *P. gigantea* three times per month (almost one sampling event every eight days) in four streams of the state of Antioquia, Colombia, from March-June 2009. The specimens were collected using entomological nets along a transect of 200m in the littoral zone of each stream. The insects were marked on the wings and the population size was estimated with the mark-recapture method. Our results showed that the largest population size was recorded for the stream "La Catedral" with approx 299 individuals, followed by the stream "La Doctora" with 218 individuals. Nevertheless, no significant differences in population size among the evaluated streams were found; and no statistical relationships were found between vegetation variables and the population size of *P. gigantea*. However, taking into account the limited dispersal capacity of *P. gigantea*, its survival in the studied streams was considered to be at risk, due to the continuous modification of large riparian forest areas, which cause the increase of forest patches, with different levels of interconnection, and hinder long-term permanence of populations." (in English) [Verbatim: This joint meeting of the BNHS, the Beds Bird Club and the British Dragonfly Society took place on one of those unfortunate days as far as dragonfly watching was concerned. The tempera-

ture was just 13°C and overcast, but 16 hardy souls assembled for the meeting. We started in the RSPB Reserve Reception area and were immediately rewarded with good views of two Otters, a fly-past pair of Bearded Tits and distant views of several Marsh Harriers. On leaving Reception we made our way out into the meadows and dykes, but very soon the rain came in increasing force with the most spectacular displays of rolling thunder and strong winds; not in any way dragonfly watching conditions! In the afternoon in only light rain we did find a few Azure, Blue-tailed and Large Red Damselflies and one each of Four-spotted Chaser, Scarce Chaser and Black-tailed Skimmers, but that was our total, with none of the hoped for Norfolk Chasers or Swallowtail Butterflies. We did see a few piles of Chinese Water Deer droppings, but that was about all. We will just have to go again another day, or another year, for Strumpshaw Fen is a great site.] Address: <http://www.bnhs.co.uk/main/docs/wab163.pdf>

11575. Andrew, R.J. (2012): Effect of paper mill effluent on the egg chorion of the dragonfly *Anax guttatus* (Burmeister) (Anisoptera: Aeshnidae). *Odonatologica* 41(1): 31-36. (in English) ["The egg of *A. guttatus* is endophytic and is cylindrical with a pointed anterior and a rounded posterior end. The chorion is divided into 2 layers, a thin, outer exochorion and a tough, thick, inner endochorion. The exochorion is modified anteriorly into a collar which is sculptured with 18-20 tiers of rectangular hexagonal impressions. Profound morphological and structural modifications are found in the eggs incubated in paper mill effluent for 5 days. The eggs became distorted due to swelling and the posterior rounded end became angular. The membranous exochorion degraded and transformed into thin, plate-like flakes which are shed, exposing the endochorion. The non-laminated, uniformly thick endochorion is converted into a laminated structure of overlapping plates with uneven thickness. The collar became pitted with minute perforations and started to disintegrate and detach from the egg and the hexagonal impressions became obliterated. 100% mortality was found in paper mill effluent treated eggs for 5 days, whereas eggs kept in pond water only had 10-13% mortality." (Author)] Address: Andrew, R.J., Post Graduate Dept of Zoology, Hislop College, Civil lines, Nagpur-440001, India. E-mail: rajuandrew@yahoo.com

11576. Andrew, R.J. (2012): Field notes on emergence of *Pantala flavescens* (Fabricius) in central India (Anisoptera: Libellulidae). *Odonatologica* 41(2): 89-90. (in English) ["A total of 611 exuviae were collected within a period of 45 days during April-May, 2004 from the walls of an open cement drain at Nagpur, India. The daily record of this collection revealed that 50% of the total emergence was completed by the 14th day and the sex ratio is considerably in favour of males (1.4:1). The females emerge earlier (protogyny) and the ME50 for female and male was observed on the 10th and 18th day, respectively. Protogyny probably provides adequate time for the female to develop her ovaries. 194 exuviae (31.75%) were collected from the north wall, which was completely in shade, and 417 (68.25%) from the south wall, which receives sunlight throughout the day. On the north wall, 44.7% exuviae were collected at a height of 30-45 cm from the water level, while from the south wall, 57.2% exuviae were collected at a height up to 15 cm and 28.4% between 15-30 cm. The present findings indicate that sunlight and temperature not only determi-

ne the choice of direction of the emerging larva but also initiate an early commencement of Stage I of metamorphosis (shortening the time between the surfacing of the larva and splitting its thoracic cuticle), which results in the shorter distance climbed by the larvae on the south wall for the final moult." (Author)] Address: Andrew, R.J., Dept of Zoology, Hislop College, Civil Lines, Nagpur- 440010, MS, India. E-mail: rajuandrew@yahoo.com

11577. Anonymus (2012): Tesco, the Lochan and the Damsel Fly. The Cairngorms Campaigner Spring 2012: 9. (in English) [Verbatim: Tesco, wanting to build a new supermarket Aviemore, have wanted the destruction of a small lochan on the site on grounds of safety. However the lochan, described by Aviemore Community Council as a "cesspit" and by ecological consultants for Tesco as having the very highest conservation value, harbours the northern damselfly (*Coenagrion hastulatum*). This species is on the Scottish Biodiversity List, which is a list of species considered by Scottish Ministers to be of principal importance to conservation. The Northern Damselfly is listed as 'endangered' on the Odonata Red Data List for Great Britain 2008. The solution recommended by CNPA planners is to relocate the species to other nearby sites prior to development. However, relocation can be a tricky thing. As the Park Authority's own Biodiversity Officer put it in his advisory paper on the issue, "...a translocation programme is not a quick or guaranteed option. It is handicapped by the lack of knowledge of the key habitat requirements for this species, and the need for a suitable donor site nearby. A donor site must not hold a current population of Northern damselfly and should meet the habitat requirements of the species. There is a complex process involved and this can take a number of years, hence the preference for retaining the population in situ." After all, if the species is present on one site and not others close by, there is probably a reason. In other words, you can relocate the species, but that is no guarantee it will thrive there. Therein lay the problem as the CNPA planner is recommending relocation, but that development would go ahead before it is known whether it has been successful. Badenoch and Strathspey Conservation Group, diligent as ever, wrote to the Authority questioning the legality of this procedure. Currently, it seems that Tesco may now have realised that translocating this species is a longer term project than formerly realised.] Address: Cairngorms Campaign, PO Box 10037, Alford, AB33 8WZ, UK

11578. Anonymus (2012): Bedfordshire's Steve Cham wins national conservation award. Wild about Beds - Newsletter of the Bedfordshire Natural History Society 163: 2. (in English) [Verbatim: The 2011 Marsh Award for Insect Conservation was given to Steve Cham for his outstanding and exemplary contribution to Insect Conservation. Steve Cham has had a lifetime fascination for Natural History with his interest in Entomology nurtured while working at Rothamsted Experimental Station during the early part of his career. Having moved on he continued his interest and personal research as a volunteer. He has been a member of the British Dragonfly Society (BDS) since its formation in 1983 and has published a number of papers in its journal. Steve became national co-ordinator for the Dragonfly Recording Network (DRN) after the scheme was transferred from the BRC. He was quick to see the benefits to conservation of providing Odonata data to the NBN and the

DRN dataset was used as a pilot during the development of the gateway. Steve has also been an active member of the Dragonfly Conservation Group of the BDS for over a decade and has been involved in a number of conservation initiatives that benefit these insects. Steve is author of several books on Dragonflies including the Dragonflies of Bedfordshire and a two volume field guide to the larvae and exuviae of British Dragonflies. He is also co-author of Dragonflies of Hampshire. Steve lectures on his favourite subject and is the leader on various courses. His photographs have been used widely. Steve is currently involved on the working party for the next national atlas of British Dragonflies.] Address: <http://www.bnhs.co.uk/main/docs/wab163.pdf>

11579. Anonymus (2012): A new partnership explores the world through the eyes of dragonflies. *flylines* July 2012: 6-7. (in English) [Verbatim: When one watches the stained-glass wings of dragonflies as they flit across ponds and alight upon reeds, it's hard to imagine that these seemingly fragile creatures can migrate thousands of miles. Many don't know that, in fact, there may be as many as 16 dragonfly species in North America that migrate at least occasionally, including five that are regular migrants. Large groups of dragonflies have frequently been documented heading south in the fall, some flying over large bodies of water despite their apparent fragility. The research, however, on the phenomenon of dragonfly migration is still in its infancy. There is so much more to learn. Therefore, a number of individuals and organizations have gotten together to form the Migratory Dragonfly Partnership (MDP), coordinated by The Xerces Society in Portland, Oregon, and sponsored by US Forest Service International Programs. The purpose of the partnership is to develop a network of citizen scientist monitors across Canada, Mexico, and the United States in order to track the spring and fall movement of the best-known migratory dragonflies in North America. The MDP will develop tools and resources to enable participants to monitor the timing, location, duration, and direction of travel of dragonfly flight and to identify the species involved. Regular monitoring and centralized reporting among participants across three nations will help us answer some of the many questions currently surrounding dragonfly migration and provide information needed to create cross-border conservation programs to protect and sustain the phenomenon. One of the first projects will be Dragonfly Pond Watch, a volunteer-based program to investigate the annual movements of two major migratory dragonfly species in North America: *Anax junius* and *Tamea lacerata*. By visiting the same wetland or pond site on a regular basis, participants will note the arrival of migrant dragonflies moving south in the fall or north in the spring, as well as record when the first resident adults of these species emerge in the spring. People should care about dragonflies for two reasons: First, they are great indicators of water quality in wetlands. Dragonflies are excellent species for monitoring the current biological condition of wetlands and for predicting future changes in those environments. Also, they are voracious predators on insect pests, including mosquitoes and a variety of biting flies. Dragonflies can't eliminate mosquitoes or other pesky flies, but the number would be much worse without hungry dragonflies eating their fill. Our studies will help us learn more about the life cycles of these critically important species. For information about the Migratory Dragonfly Partnership, please contact: Scott Hoffman Black, The Xerces So-

ciety, 628 NE Broadway, Suite 200, Portland, OR 97232. Tel: (503)232-6639, E-mail: dragonfly@xerces.org. You can also visit <http://migratorydragonflypartnership.org> and <http://www.xerces.org/dragonfly-migration/projects>.] Address: <http://gis.fs.fed.us/global/wings/newsletter/2012/july2012watanewsletter.pdf>

11580. Anusa, A.; Ndagurwa, H.G.T.; Magadza, C.H.D. (2012): The influence of pool size on species diversity and water chemistry in temporary rock pools on Domboshawa Mountain, northern Zimbabwe. *African Journal of Aquatic Science* 37(1): 89-99. (in English) ["The effect of pool size (area and depth) on species diversity and physicochemical characteristics of rock pool habitats on Domboshawa Mountain, northern Zimbabwe, was studied from December 2006 to May 2007. Pools were categorised based on maximum depth. Pool duration was a key factor structuring pool communities, driving their species diversity and nutrient content. Active predatory insects (Coleoptera, Odonata, Hemiptera) and zooplankton (Cladocera, Copepoda, Rotifera species) were associated with long-lived pools. As pool duration increased, early phytoplankton communities dominated by short-residence green algae were replaced by blue-green algae. The number of species present increased as pool area increased. Using depth as a proxy for disturbance, species composition in rock pools was influenced by the duration of inundation. A unique rock pool community with a filter-feeding component dominated by Cladocera, and from which large branchiopods were absent, is described. Nutrient status and community diversity in rock pools are determined by pool size, and pool depth, a proxy for habitat duration, is a major structuring factor in these temporary aquatic habitats." 11581. Balzan, M.V. (2012): Associations of dragonflies (Odonata) to habitat variables within the Maltese Islands: A spatiotemporal approach. *Journal of Insect Science* 12:87 available online: insectscience.org/12.87: 18 pp. (in English) ["Relatively little information is available on environmental associations and the conservation of Odonata in the Maltese Islands. Aquatic habitats are normally spatio-temporally restricted, often located within predominantly rural landscapes, and are thereby susceptible to farmland water management practices, which may create additional pressure on water resources. This study investigates how odonate assemblage structure and diversity are associated with habitat variables of local breeding habitats and the surrounding agricultural landscapes. Standardized survey methodology for adult Odonata involved periodical counts over selected water-bodies (valley systems, semi-natural ponds, constructed agricultural reservoirs). Habitat variables relating to the type of water body, the floristic and physiognomic characteristics of vegetation, and the composition of the surrounding landscape, were studied and analyzed through a multivariate approach. Overall, odonate diversity was associated with a range of factors across multiple spatial scales, and was found to vary with time. Lentic water-bodies are probably of high conservation value, given that larval stages were mainly associated with this habitat category, and that all species were recorded in the adult stage in this habitat type. Comparatively, lentic and lotic seminatural water-bodies were more diverse than agricultural reservoirs

and brackish habitats. Overall, different odonate groups were associated with different vegetation life-forms and height categories. The presence of the great reed, *Arundo donax* L., an invasive alien species that forms dense stands along several water-bodies within the Islands, seems to influence the abundance and/or occurrence of a number of species. At the landscape scale, roads and other ecologically disturbed ground, surface water-bodies, and landscape diversity were associated with particular components of the odonate assemblages. Findings from this study have several implications for the use of Odonata as biological indicators, and for current trends with respect to odonate diversity conservation within the Maltese Islands." (Author)] Address: Balzan, M.V., Institute of Life Sciences, Scuola Superiore Sant'Anna, Piazza Martiri della Libertà, Pisa, PI, Italy. E-mail: m.balzan@sss.up.it

11582. Barndt, D. (2012): Beitrag zur Kenntnis der Arthropodenfauna der Zwischenmoore Butzener Bagen, Trockenes Luch und Möllnsee bei Lieberose (Land Brandenburg) (Coleoptera, Heteroptera, Hymenoptera part., Auchenorrhyncha, Saltatoria, Diptera part., Diplopoda, Chilopoda, Araneae, Opiliones, u.a.). Märkische Entomologische Nachrichten 14(1): 147-200. (in German, with English summary) ["Two sphagnum-dominated mires and one calcareous fen in the eastern part of Germany were investigated. The paper presents 562 species of Arthropods identified in the years 2008 and 2009 using pitfall traps. The study determines the endangerment and dispersion of the species. 4 species were recorded for the first time in Brandenburg and 1 species was rediscovered. - 63 species that are typical for transitional mires or lagg zones were detected; of these, 19 species are critically endangered (CR) or endangered (EN). The calcareous fen Möllnsee could not be analyzed because of overflowing damage caused by mismanagement; the results of two alternative habitats are given. The aim of this research is to assist adequate restoration for those highly endangered fen systems." (Author) Odonata were not part of the study. The following species are reported based on historical data: *Coenagrion hastulatum*, *Aeshna juncea*, *Leucorrhinia albifrons*, *L. caudalis*, *L. dubia*, *L. pectoralis* and *L. rubicunda*.] Address: Barndt, D., Bahnhofstr. 40d, 12207 Berlin-Lichterfelde Ost, Germany. (in English) [Second record of *L. pectoralis* in UK: 16-VI-2012, Dunwich Heath, Walberswick, Suffolk] Address: Edwina & Alan Beaumont, 52 Squires Walk, Lowestoft, Suffolk, NR32 4LA, UK

11584. Bedjanič, M.; Vinko, D. (2012): New records of *Epallage fatime* (Charpentier, 1840) in Macedonia (Odonata: Euphaeidae). *Natura Sloveniae* 14(1): 15-22. (in English, with Slovenian summary) ["Formerly known from Macedonia only from two old records made in the southeasternmost part of the country, the species has been newly recorded on 20-VII-2008 at the Luda Mara stream south of Kavadarci (S Macedonia), on 24-VII-2008 at the Konska Reka stream west of Gevgelija (SE Macedonia) and on 26-IV-2010 at the Sermeninska Reka stream northwest of Gevgelija (SE Macedonia). At all localities, the species' development has been confirmed. Its currently known distribution in Macedonia and the neighbouring countries is presented and a short

zoogeographical discussion provided." (Authors)] Address: Vinko, D., Slovenska 14, SI-1234 Mengeš, Slovenia; E-mail: damjan.vinko@gmail.com

11585. Bitzer, L.J. (2012): Chronic toxicity testing in mining influenced streams of West Virginia. Theses and Dissertations. Paper 252: 119 pp. (in English) ["Whole effluent toxicity (WET) tests have become a common tool in the evaluation of effluent for discharge acceptability. In this study, four years of toxicity data from 119 sampling locations were analyzed to determine relationships with ions and conductivity as indicators of toxicity. West Virginia Stream Condition Index (WVSCI) scores were also examined to evaluate correlations between stream scores, conductivity, and IC25 endpoints from toxicity results. Conductivity was not an indicator of toxicity in the range of conductivities tested. Streams dominated by mining effluent sometimes exhibited toxicity to *Ceriodaphnia dubia*; however, toxicity was not found to be related to ionic concentration in the range tested. Although mortality and reproductive impairment were often demonstrated in the mining effluent dominated streams, there were no relationships established between survival and reproductive endpoints and the ionic concentrations. Benthic macroinvertebrate communities in the streams sampled indicated some level of impairment. Only a weak relationship was demonstrated between habitat assessment scores and WVSCI scores. No apparent relationship between conductivity and WVSCI was observed. ... The results showed that, under conditions of constant acid mine drainage, the Odonata, Ephemeroptera and Plecoptera were completely eliminated. The Trichoptera, Megaloptera and Diptera were reduced in number of species." (Author)] Address: not stated. Bitzer, Leah J.

11586. Borisov, S.N. (2012): Migrant dragonflies in Middle Asia. 3. *Pantala flavescens* (Fabricius, 1798) (Odonata, Libellulidae). *Eurasian Entomological Journal* 11(1): 37-41. (in Russian, with English summary) ["Data on the distribution, phenology and migrations of *P. flavescens* in Middle Asia are presented. The first spring-time generation is represented by immigrant specimens from the southern part of the range. Pre-imaginal development lasts about two months. Large numbers of specimens are recorded from rice fields. After emergence, adult dragonflies can accumulate locally, but in late summer or early autumn the second generation of dragonflies probably migrate in a southerly direction. Directional flights were recorded at the beginning of August in East Pamir." (Author)] Address: Borisov, S.N., Institute of Systematics and Ecology of Animals, Russian Academy of Sciences, Siberian Branch, Frunze Street 11, Novosibirsk 630091 Russia. 11587. Borisov, S.N. (2012): Translatitudinal migrations of dragonflies (Odonata) in Middle Asia. *Proceedings of the Russian Entomological Society* 83(1): 62-72. (in Russian, with English summary) ["Characteristic seasonal translatitudinal migrations are observed for three Middle Asian species of dragonflies (*Sympetrum fonscolombii*, *Pantala flavescens*, *Anax ephippiger*). In the spring, viripotent adults of dragonflies arrive from the southern parts of their ranges to Middle Asia where the second generation develops. In the autumn, descendants of immigrants come back to the south. Live strategy of *Anax p. parthenope* remains unknown, and at present we can ascertain only obligate character of the autumn southward migrations of these dragonflies. The

annual natural autumn migrations of *S. fonscolombii*, *A. ephippiger* and *A. p. parthenope* are observed during three seasons (2008–2010) on the pass Chokpak in Western Tien Shan with the help of ornithological traps. The autumn migrations of *P. flavescens* were also observed in August, 1980 in the East Pamir. Consecutive moving of different generations of dragonflies' migrants is the strategy achieves the fullest use of the environment resources. It also includes dwelling behind the northern limits of the basic ranges where overwintering of immature stages is impossible. Other adaptive importance of this strategy is hedge from possible disappearance (drying) of reservoirs suitable for larvae development. Initially this ability was probably developed in species migrants in the conditions of a monsoon climate where they develop in the seasonal temporary reservoirs filled with monsoon rains." 11591. Bried, J.T.; Hager, B.J.; Hunt, P.D.; Fox, J.N.; Jensen, H.J.; Vowels, K.M. (2012): Bias of reduced-effort community surveys for adult Odonata of lentic waters. *Insect Conservation and Diversity* 5(3): 213-222. (in English) ["(1) Repeat surveys are needed to capture a representative spectrum of adult odonate richness at a site, but specifics on frequency and duration of surveys and associated inferential biases are poorly understood. (2) Weekly 1 h surveys of mature male dragonflies and damselflies were repeated at least 15 times at 19 ponds, lakes and wetlands scattered throughout North America. For each site, we tallied the data remaining when the weekly frequency was reduced to 75% (every 1.5 weeks), 50% (biweekly), 33% (triweekly), and 25% (monthly) and the 1 h survey to 50, 40, 30, 20 and 10 min subsets. (3) Reducing the original effort by half (i.e. to 30 min biweekly) retained about 80% of the species on average. The smallest effort (10 min monthly) retained about 49% of species. The greatest rate of information loss occurred between 20 and 10 min. (4) Across-site analysis found that data subsets correlated to the original data set ($r > 0.81$) despite up to 50% species loss. Strong correlations ($r = 0.98$) remained with 10–15% species loss. (5) Biweekly surveys lasting 20–40 min each may provide a representative and cost-effective sample of adult odonate richness in lentic study sites. Losing a handful of species should not greatly undermine richness and compositional comparisons among sites." (Authors)] Address: Bried, J., Albany Pine Bush Preserve Commission, Albany, NY, USA. 11593. Brockhaus, T. (2012): Westpaläarktische Verbreitungsmuster von Libellen - Zeugnisse einer kaltzeitlichen Libellenfauna? Die Beispiele *Sympecma paedisca* und *Somatochlora metallica* (Odonata: Lestidae, Corduliidae). *Libellula Supplement* 12: 211-226. (in German, with English summary) ["Western Palaearctic distribution patterns of dragonflies - evidence of glacial faunal relicts? The examples of *Sympecma paedisca* and *Somatochlora metallica* (Odonata: Lestidae, Corduliidae) - The Western range margins of the transpalaearctic species, *S. paedisca* and *S. metallica*, have a particular shape and populations disjunct from the main range. Current theory suggests that these distribution patterns arose from a recolonisation after the Pleistocene. In this study I propose that these patterns are better explained by processes that happened during, rather than after, the Pleistocene. Specifically, *S. paedisca* probably recolonised the Western range during the warmer interglacial periods. *Somatochlora metallica* probably is a eurythermic glacial species whose historic Doggerland range was divided during the last glacial period in a Southern and a northern part. The testing of these hypotheses will be possible by genetic studies.

The colonisation hypotheses of the two species are supported by a number of shared ecological characters:

- They have a transpalearctic distribution with clearly disjunct populations at the range margins.
- They are cold stenothermic, or eurythermic. None are habitat specialists in their main range but become habitat specialists towards the range margins.
- These species are also able to survive under current, often anthropogenic, large-scale landscape changes and to colonise new habitats within their range.
- The species have reduced dispersal ability on their Western palearctic range margins, though the reasons are unknown." (Author)]

11594. Brucet, S.; Boix, D.; Nathansen, L.W.; Quintana, X.D.; Jensen, E.; Balayla, D.; Meerhoff, M.; Jeppesen, E. (2012): Effects of temperature, salinity and fish in structuring the macroinvertebrate community in shallow lakes: Implications for effects of climate change. *PLoS ONE* 7(2): e30877. doi:10.1371/journal.pone.0030877: 11 pp. (in English) ["Climate warming may lead to changes in the trophic structure and diversity of shallow lakes as a combined effect of increased temperature and salinity and likely increased strength of trophic interactions. We investigated the potential effects of temperature, salinity and fish on the plant-associated macroinvertebrate community by introducing artificial plants in eight comparable shallow brackish lakes located in two climatic regions of contrasting temperature: cold-temperate and Mediterranean. In both regions, lakes covered a salinity gradient from freshwater to oligohaline waters. We undertook day and night-time sampling of macroinvertebrates associated with the artificial plants and fish and free-swimming macroinvertebrate predators within artificial plants and in pelagic areas. Our results showed marked differences in the trophic structure between cold and warm shallow lakes. Plant-associated macroinvertebrates and free-swimming macroinvertebrate predators were more abundant and the communities richer in species in the cold compared to the warm climate, most probably as a result of differences in fish predation pressure. Submerged plants in warm brackish lakes did not seem to counteract the effect of fish predation on macroinvertebrates to the same extent as in temperate freshwater lakes, since small fish were abundant and tended to aggregate within the macrophytes. The richness and abundance of most plant-associated macroinvertebrate taxa decreased with salinity. Despite the lower densities of plant-associated macroinvertebrates in the Mediterranean lakes, periphyton biomass was lower than in cold temperate systems, a fact that was mainly attributed to grazing and disturbance by fish. Our results suggest that, if the current process of warming entails higher chances of shallow lakes becoming warmer and more saline, climatic change may result in a decrease in macroinvertebrate species richness and abundance in shallow lakes. ... The only taxa not related to salinity were Malacostraca, Odonata and Polychaeta, but the relative abundances of these taxon groups were low at all salinities. Diptera, one of the most salinity-tolerant groups, dominated in most of the lakes in the two climatic regions." (Authors)]

11595. Büsse, S.; von Grumbkow, P.; Hummel, S.; Shah, D.N.; Tachamo Shah, R.D.; Li, J.; Yoshizawa, K.; Wedmann, S.; Hörnschemeyer, T. (2012): Phylogeographic analysis elucidates the influence of the ice ages on the disjunct distribution of relict dragonflies in Asia. *PLoS ONE* 01/2012; 7(5):e38132. DOI:10.1371/journal.pone.0038132: 8 pp + suppl.. (in English) ["Unusual biogeographic patterns of closely related groups reflect events in the past, and molecular analyses can help to elucidate these events. While ample research on the origin of disjunct distributions of different organism groups in the Western Palearctic has been conducted, such studies are rare for Eastern Palearctic organisms. In this paper we present a phylogeographic analysis of the disjunct distribution pattern of the extant species of the strongly cool-adapted *Epiophlebia* dragonflies from Asia. We investigated sequences of the usually more conserved 18 S rDNA and 28 S rDNA genes and the more variable sequences of ITS1, ITS2 and CO2 of all three currently recognised *Epiophlebia* species and of a sample of other odonatan species. In all genes investigated the degrees of similarity between species of *Epiophlebia* are very high and resemble those otherwise found between different populations of the same species in Odonata. This indicates that substantial gene transfer between these populations occurred in the comparatively recent past. Our analyses imply a wide distribution of the ancestor of extant *Epiophlebia* in Southeast Asia during the last ice age, when suitable habitats were more common. During the following warming phase, its range contracted, resulting in the current disjunct distribution. Given the strong sensitivity of these species to climatic parameters, the current trend to increasing global temperatures will further reduce acceptable habitats and seriously threaten the existences of these last representatives of an ancient group of Odonata." 11597. Caesar, R.M. (2012): Phylogeny of the genus *Argia* (Odonata: Coenagrionidae) with emphasis on evolution of reproductive morphology. Dissertation, Doctor of Philosophy, The Ohio State University: XVIII + 191 pp. (in English) ["The damselfly genus *Argia* is found throughout the New World where some species are common and abundant members of lotic freshwater and adjacent ecosystems. *Argia* species are not only important predators of aquatic and terrestrial invertebrates but are themselves an important prey item to a variety of other insects and vertebrates. The distribution of species is highly variable within the genus and some species are locally threatened or endangered due to range limitation and habitat loss. Odonata may be use-

ful indicators of aquatic ecosystem health as well as indicators of climate change. There are approximately 120 species described with at least twenty suspected undescribed species. The taxonomy of the North American species is well known, but the Central and South American species are in need of revision. The phylogeny of the genus has never been studied using modern, repeatable methods. Therefore the evolutionary history of the genus has never been thoroughly explored. The reproductive biology of Odonata is unique among insects and provides a model system for testing hypotheses related to character evolution by sexual selection and other mechanisms of evolution. *Argia* species have unique morphologies of male and female secondary sexual characters, the modified cerci and paraprocts of males and the corresponding plates of the female pro- and meso-nota that are grasped by males during copulation and oviposition. The patterns of variation in these structures, both within and among species, may reveal the extent to which sexual and natural selection help shape the current diversity of the group. This dissertation presents phylogenetic hypotheses for the genus *Argia* using data from external morphology and ribosomal DNA. Maximum parsimony and maximum likelihood analyses were performed on the data, resulting in topologies that are mostly congruent, well-resolved, and moderately to highly supported. The variation in male cercus morphology is examined using three dimensional morphometrics where shape is quantified from computer tomography models. The phylogenetic hypotheses are used to examine patterns of cercus variation across the genus. The same methods are applied to populations of the widespread species *Argia moesta* in an attempt to test whether intrasexual selection applies to these important reproductive structures." 11598. Cham S. (2012): A study of Southern Hawker *Aeshna cyanea* emergence from a garden pond. *J. Br. Dragonfly Society* 28(1): 1-20. (in English) ["The construction in 2001 of a garden pond in close proximity to the author's house provided an opportunity for close study of emergence patterns, behaviour and predation of Southern Hawker *Aeshna cyanea*. This study discusses the impact of weather conditions and predation on emergence success over a period of several years. Exhaustive daily exuviae counts reveal differences in patterns of emergence in each year, influenced by larval development as well as periods of heavy rain and low temperatures. Predation by birds and wasps had a significant effect on the survival of emerging adults in some years." (Author)] Address: Cham, S., 24 Bedford Avenue, Silsoe, Bedford, MK45 4ER UK. 11599. Chand, S. (2012): Organophosphorus pesticides inflicted impairments in the midgut histo-architecture of naiad of *Trithemis aurora* (Burm.) (Odonata: Libellulidae). *Journal of Experimental Zoology, India* 15 (1): 213-218. (in English) ["A continuous forty hours of treatment of last instar naiad of *T. aurora* under LC50 concentration, 5.12×10^{-7} and 7.60×10^{-8} ppm of chlorpyrifos and quinalphos respectively has proved toxic and induced histopathological derangements in various tissues of midgut. The mesenteron has observed to be prone to both the pesticides. The chlorpyrifos separated the epithelial folds and widen the inter fold space up to the basement membrane. The quinalphos pene-

trated inside the epithelial folds and damaged cellular mass. Both the pesticides induced the movement of cytoplasmic contents at various degrees towards the apical end of the epithelial folds. This movement presumed to be the genesis of intense vacuolation at the basal ends of all the epithelial cells. The continuous pressure of the internal cellular contents and weekend cell boundaries have caused the violent exclusion of cell contents. The nuclear membrane at many places damaged by chlorpyrifos and severely affected by quinalphos." (Author)] Address: Chand, S., P G Department of Zoology, R.P.G. College Jamuhai, Jaunpur - 222 002, India.

11600. Chen, Y.; Wang, X.; Ren, H.; Yin, H.; Jia, S. (2012): Hierarchical dragonfly wing: Microstructure-bio-mechanical behavior relations. *Journal of Bionic Engineering* 9(2): 185-191. (in English) ["The dragonfly wing, which consists of veins and membrane, is of biological hierarchical material. We observed the cross-sections of longitudinal veins and membrane using Environmental Scanning Electron Microscopy. Based on the experiments and previous studies, we described the longitudinal vein and the membrane in terms of two hierarchical levels of organization of composite materials at the micro- and nano-scales. The longitudinal vein of dragonfly wing has a complex sandwich structure with two chitinous shells and a protein layer, and it is considered as the first hierarchical level of the vein. Moreover, the chitinous shells are concentric multilayered structures. Clusters of nano-fibrils grow along the circumferential orientation embedded into the protein layer. It is considered as the second level of the hierarchy. Similarly, the upper and lower epidermises of membrane constitute the first hierarchical level of organization in micro scale. Similar to the vein shell, the membrane epidermises were found to be a paralleled multilayered structure, defined as the second hierarchical level of the membrane. Combining with the mechanical behaviour analysis of the dragonfly wing, we concluded that the growth orientation of the hierarchical structure of the longitudinal vein and membrane is relevant to its biomechanical behaviour." 11602. Cicort-Lucaciu, A.-S.; Covaciu-Marcov, S.-D.; Bogdan, H.V.; Sas, I. (2012): Implication upon herpetofauna of a road and its reconstruction in Carei Plain Natural Protected Area (Romania). *Ecologia Balkanica* 4(1): 99-105. ["In autumn 2011 we monitored a 5 km

long road, paved with cobblestone, situated in Carei Plain Natural Protected Area, a road that is due to be modernized and continued across the border into Hungary. Dead bodies from eight different animal groups were observed on the road, amphibians presenting the greatest amount. The most frequent were the *Triturus dobrogicus* corps, a species with conservation importance. The amphibians were affected in the areas where the road is neighbouring the wetlands, while on the opposite pole sits the area with acacia plantations. The high number of mortalities recorded on the road, despite the low traffic speed, is alarming. It is likely that the modernization of the road that will surely increase its traffic and the speed of the vehicles, will make the situation even worse. However, the rebuilding could contribute to the reduction in the impact on amphibians, if certain measures are considered while planning the action. Thus, in the areas near the wetlands, there should be undercrossings, fences and speed limits. In this way, the modernization would at least represent an experiment regarding the diminution of the road's impact on amphibians." (Authors) The victims of traffic include Odonata which are not further specified or quantified.] Address: Cicort-Lucaciu, A.-S., University of Oradea, Faculty of Sciences, Department of Biology, Universitatii str. 1, Oradea 410087, Romania. 11603. Clapham, M.E.; Karr, J.A. (2012): Environmental and biotic controls on the evolutionary history of insect body size. *Proceedings of the National Academy of Sciences* 109(2): 10927-10930. (in English) ["Giant insects, with wingspans as large as 70 cm, ruled the Carboniferous and Permian skies. Gigantism has been linked to hyperoxic conditions because oxygen concentration is a key physiological control on body size, particularly in groups like flying insects that have high metabolic oxygen demands. Here we show, using a dataset of more than 10,500 fossil insect wing lengths, that size tracked atmospheric oxygen concentrations only for the first 150 Myr of insect evolution. The data are best explained by a model relating maximum size to atmospheric environmental oxygen concentration (pO_2) until the end of the Jurassic, and then at constant sizes, independent of oxygen fluctuations, during the Cretaceous and, at a smaller size, the Cenozoic. Maximum insect size decreased even as atmospheric pO_2 rose in the Early Cretaceous following the evolution and radiation of early birds, particularly as birds acquired adaptations that allowed more agile flight. A further decrease in maximum size during the Cenozoic may relate to the evolution of bats, the Cretaceous mass extinction, or further specialization of flying birds. The decoupling of insect size and atmospheric pO_2 coincident with the radiation of birds suggests that biotic interactions, such as predation and competition, superseded oxygen as the most important constraint on maximum body size of the largest insects." (Authors)] Address: E-mail: mclapham@ucsc.edu.

11604. Contador, T.A.; Kennedy, J.H.; Rozzi, R. (2012): The conservation status of southern South American aquatic insects in the literature. *Biodivers. Conserv.* 21: 2095-2107. (in English) ["We provide a comprehensive review of publications regarding the conservation of aquatic and terrestrial insects at a global scale and with an emphasis on southern South America. We reviewed three prominent conservation journals (*Conservation Biology*, *Biodiversity and Conservation*, and *Biological*

Conservation) and found that only 5 % of all the works published between 1995 and 2008 focus on the conservation of aquatic insects. The highest percentage of publications on the conservation of aquatic insects comes from Europe (2.3 %), while the lowest percentage comes from South America (0.1 %). To assess the trends of aquatic insect research in southern South America, we conducted a literature search using *Zoological Records*, *Biological Abstracts*, and *Current Contents*. We conclude that there is a gap in research regarding the conservation of freshwater and terrestrial insects, as reflected by the low amount of publications that specifically focus on the description and identification of new insect species and their conservation. In order to help overcome this gap in conservation research, we propose three ideas that could help enhance the research and conservation initiatives regarding these organisms: (1) focus research on understudied regions of the world, such as the Magellanic sub-Antarctic ecoregion, (2) increase the amount of funding available for taxonomic research focused on the description and identification of new aquatic and terrestrial insect species, and (3) increase the amount of public education programs which focus on field experiences and direct encounters with aquatic insect biodiversity and their habitats." (Authors) The total number of publications about the orders Plecoptera, Trichoptera, Ephemeroptera, Odonata, and Diptera (Chironomidae), published between the years 1975 and 2010 in southern South America is figured.] Address: Contador, Tamara, Dept of Biological Sciences, University of North Texas, Denton, TX, USA. 11605. Contreras-Garduno, J.; Villanueva, G.; Alonso-Salgado, A. (2012): Phenoloxidase production: The importance of time after juvenile hormone analogue administration in *Hetaerina americana* (Fabricius) (Zygoptera: Calopterygidae). *Odonatologica* 41(1): 1-6. (in English) ["It has been suggested that juvenile hormone (JH) negatively affects the phenoloxidase (PO), a key enzyme of the immune response in invertebrates. However, this negative effect has only been recorded over a short time period (2 to 3 h) after the administration of JH (or a JH analog). In the present study, using *H. americana*, it was corroborated that PO decreased a short time (3 h) after the administration of methoprene, a JH analog (JHa), but no effect was observed 24 h after the JHa application. This suggests that the time after the application of JHa should be taken into account in order to assess its actual effect on the immune response and PO expression and in studies that use the JH as a link between secondary sexual characters and immune response." (2012): No firm evidence of immunological costs of insect oviposition and copulation: A test with dragonflies (ygoptera). *Odonatologica* 41(1): 7-15. (in English) ["The immune response is a costly trait as investment in immunity is frequently traded off against life history components. In insects, for example, experimental tests have provided evidence that oviposition and copulatory activities impair immune ability in the form of encapsulation ability. Here such tests are repli-

cated by using four zygopteran spp., viz. *Argia joergenseni*, *Calopteryx splendens*, *C. virgo* and *Hetaerina americana* having encapsulation, phenoloxidase and nitric oxide activity 1 three key components in the insect immune response 1 as dependent variables. The results provide no consistent results. Only in *A. joergenseni* there was any evidence of oviposition activity (or, in the case of *H. americana*, submergence) affecting encapsulation, but neither in *C. splendens* nor in *H. americana* did copulation have any such effect. In *H. americana*, nitric oxide activity was lower in // that had been submerged but there was no effect on phenoloxidase activity. Thus, former observations indicating that oviposition and copulation negatively affect the immune response, cannot be generalized" (Authors)] Address: Cordoba-Aguilar, A., Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo, Apdo. 11608. Cothran, R.D.; Chapman, K.; Stiff, A.R.; Relyea, R.A. (2012): "Cryptic" direct benefits of mate choice: choosy females experience reduced predation risk while in precopula. *Behavioral ecology and sociobiology* 66(6): 905-913. (in English) ["Despite the central role that female mate choice plays in the production of biological diversity, controversy remains concerning its evolution and maintenance. This is particularly true in systems where females are choosy but do not receive obvious direct benefits such as nuptial gifts that increase a female's survival and fecundity. In the absence of such direct benefits, indirect benefits (i.e., the production of superior offspring) are often invoked to explain the evolution of mate choice. However, females may receive less obvious, or "cryptic," direct benefits, particularly in species with prolonged pre-mating interactions (e.g., precopulatory mate guarding). We assessed the "cryptic" direct benefits of female choice for large male size in two species of freshwater amphipods that do not receive obvious direct benefits. Females paired with large males experienced decreased predation from fish. However, we found that the size of a female's mate did not affect her predation risk against predatory dragonflies or the harassment she received

by single males while paired. Our results demonstrate that even when females receive no traditional direct benefits, female choice for large male size can still provide important direct benefits. Such "cryptic" direct benefits may be common, especially in species with prolonged mating interactions, and are likely important for fully understanding the evolution of mate choice." 11609. Couteyen, S.; Papazian, M. (2012): Catalogue et affinités géographiques des Odonata des îles voisines de Madagascar (Insecta: Pterygota). *Ann. soc. entomol. Fr. (n.s.)* 48(1-2): 199-215. (in French, with English summary) ["Catalogue and geographical affinities of the Odonata of the neighbouring islands of Madagascar (Insecta: Pterygota). A thorough bibliographic analysis shows that 71 species and sub-species of Odonata are recorded in the neighbouring islands of Madagascar, from the archipelagos of Mascarenes, Comoros and Seychelles. In these islands, the maximum endemism rate is about 34%, but more significant in Mascarenes (34%) than in Comoros (23%) or in Seychelles (19%). The odonatological fauna is dominated by the Libellulidae (36 taxa) and Coenagrionidae (18 taxa). Each archipelago owns at least one of the 23 endemic taxa found in these islands. Seychelles have two endemic monospecific genera: *Allolestes* et *Leptocnemis*. Mascarenes have two endemic genera: *Thalassothemis* and *Coenagriocnemis*. The last one demonstrated a progressive radiation in the archipelago. The neighboring islands of Madagascar are characterized by a radiation of two genera at regional level, viz. *Hemicordulia* and *Gynacantha*. The geographical affinities of this fauna are mainly Afrotropical. Colonization from Africa is not a random sample of the continental pool, but a selection of a few species with specific abilities. In the neighbouring islands of Madagascar, the specific richness of the populations of Odonata with African affinities decreases with the geographical isolation." 11613. Ellwood, E.R.; Diez, J.M.; Ibáñez, I.; Primack, R.B.; Kobori, H.; Higuchi, H.; Silander, J.A. (2012): Disentangling the paradox of insect phenology: are temporal trends reflecting the response to warming? *Oecologia* 168(4): 1161-1171. (in English) ["The strength and direction of phenological responses to changes in climate have been shown to vary significantly both among species and among populations of a species, with the overall patterns not fully resolved. Here, we studied the temporal and spatial variability associated with the response of several insect species to recent global warming. We use hierarchical models within a model comparison framework to analyze phenological data gathered over 40 years by the Japan Meteorological Agency on the emergence dates of 14 insect species (including *Orthetrum albistylum* and *Sympetrum frequens*) at sites across Japan. Contrary to what has been predicted with global warming, temporal trends of annual emergence showed a later emergence day for some species and sites over time, even though temperatures are warming. However, when emergence data were analyzed as a function of temperature and precipitation, the overall response pointed out an earlier emergence day with warmer conditions. The apparent contradiction between the response to temperature and trends over time indicates that other factors, such as declining populations, may be affecting the date phenological events are being recorded. Overall, the responses by insects were weaker than those found for plants in previous work over the same time period in these ecosystems, suggesting the potential for ecological mismatches with deleterious effects for both suites of species. And although temperature may be the major driver of species phenology, we should be cautious when analyzing phenological datasets as many other factors may also be contributing to the variability in phenology." 11618. Farag Mahmoud, M. (2012): Insects associated with Sesame (*Sesamun indicum* L.) and the impact of insect pollinators on crop production. *Pestic. Phytomed.* (Belgrade) 27(2): 117-129. (in English, with Serbian summary) ["A survey of insects associated with sesame, *Sesamun indicum* L. (Pedaliaceae) was conducted at the Agriculture Research Farm of The Faculty of Agriculture, University of Suez Canal during the growing seasons 2010 and 2011. All different insect species found on the experimental site were collected for identification. Sampling was done once a week and three times a day. Three methods were used to collect insects from the sesame plants (a sweep net, pitfall traps, digital camera and eye observation). A total of 31 insect species were collected and properly identified during the survey. Insects recorded on the plants were divided into four groups, true pollinators (Hymenoptera), other pollinators (Diptera, Coleoptera and Lepidoptera), pests (Orthoptera, Odonata [*Ischnura senegalensis*, *Crocotemis erythraea*], Hemiptera and Homoptera) and natural enemies (Coleoptera, Hymenoptera, Neuroptera and Dictyoptera). For studying the impact of insect pollination on sesame production, the experiment was divided in two: opened and non-opened pollination of sesame. 50 plants from nonopened pollination were covered with a perforated paper bag to allow the air to pass through and to prevent insects from approaching the plants. Quantitative and qualitative parameters were measured as follows: pod weight, number of seeds in each pod, weight of 1000 seeds, germination (%), seedlings vigour and oil content (%). Results clearly demonstrate that the opened pollination improved the

crop production." (Author)] Address: Farag Mahmoud, M., Suez Canal University, Faculty of Agriculture, Plant Protection Department, 41522 Ismailia, Egypt. E-mail: mfaragm@hotmail.com

11619. Fauchaux, M. (2012): Comparaison des antennes larvaires et de leurs sensilles chez deux espèces d'Argia, *A. concinna* (Rambur, 1842) et *A. telesfordi* Meurget, 2009, endémiques des Petites Antilles (Odonata: Zygoptera: Coenagrionidae). *Bull. Soc. Sc. Nat. Ouest de la France, nouvelle série* 34(2): 76-81. (in French, with English summary) ["The larvae of *A. concinna* and *A. telesfordi* live in different biotopes, the first in white water and on gravelly soil, the second in streams of almost stagnant water with a muddy bottom. The study of larval antennal sensilla of *A. telesfordi* has been carried out and compared with sensilla of *A. concinna* previously described so as to discover the impact of the biotope on sensory equipment. *A. telesfordi* possesses the same sensillum types as *A. concinna*, that is: sensilla chaetica, curved sensilla chaetica, flattened and curved sensilla chaetica, sensilla filiformia and sensilla campaniformia. These five types are all non-porous sensilla. The resemblance between the types, the location and number of sensilla of both species is so surprising that one might think that we have to do with the same species. The antennal larval sensory equipment of the two species is by no means influenced by the lives of the latter in different biotopes." 11622. Fraker, M.E.; Luttbeg, B. (2012): Predator-prey space use and the spatial distribution of predation events. *Behaviour* 149(5): 555-574. (in English) ["In many systems, predators and prey interact spatially. A number of game theoretic models (joint ideal free distributions, IFD) have suggested that a population-level distribution of mobile predators and mobile prey in which predators match the distribution of the prey's resources and prey are more evenly distributed will be stable. However, prey can often manage their exposure to predation risk by adjusting their space use and their level of apprehension or vigilance, while predators have been shown to behaviourally manage the risk level perceived by their prey. We used a system of predatory larval *Anax junius* and southern leopard frog (*Rana sphenoccephala*) tadpoles to explore how these species respond spatially to habitat features when alone (non-game situations) and together (game situations), then how predation events are distributed in relation to these features. In game and non-game situations, dragonflies avoided each other and showed no preference for tadpole resource patches, while tadpoles favoured their resource patches, avoided caged, feeding dragonflies, and used a combination of avoidance and activity reduction to reduce their predation risk. Predation events were generally distributed closer to resource patches and farther from caged predators. The results suggest that dragonflies and tadpoles do not directly follow joint IFD predictions, but manage fear and risk through their behavioural strategies. The results also suggest that stationary or slowly-changing habitat features can anchor predator-prey spatial distributions, but that they are likely to be temporally variable in some systems." 11625. Futahashia, R.; Kuritab, R.; Manoc, H.; Fukatsua, T. (2012): Redox alters yellow dragonflies into

red. Proceedings of the National Academy of Sciences 109(31): 12631-12626. (in English) ["Body colour change associated with sexual maturation—so-called nuptial coloration—is commonly found in diverse vertebrates and invertebrates, and plays important roles for their reproductive success. In some dragonflies, whereas females and young males are yellowish in colour, aged males turn vivid red upon sexual maturation. The male-specific coloration plays pivotal roles in, for example, mating and territoriality, but molecular basis of the sex-related transition in body coloration of the dragonflies has been poorly understood. Here we demonstrate that yellow/red colour changes in the dragonflies are regulated by redox states of epidermal ommochrome pigments. Ratios of reduced-form pigments to oxidized-form pigments were significantly higher in red mature males than yellow females and immature males. The ommochrome pigments extracted from the dragonflies changed colour according to redox conditions in vitro: from red to yellow in the presence of oxidant and from yellow to red in the presence of reductant. By injecting the reductant solution into live insects, the yellow-to-red colour change was experimentally reproduced in vivo in immature males and mature females. Discontinuous yellow/red mosaicism was observed in body coloration of gynandromorphic dragonflies, suggesting a cell-autonomous regulation over the redox states of the ommochrome pigments. Our finding extends the mechanical repertoire of pigment-based body colour change in animals, and highlights an impressively simple molecular mechanism that regulates an ecologically important colour trait." 11627. Gołąb, M.J.; Śniegula, S. (2012): Changes in reproductive behavior in adult damselfly *Calopteryx splendens* (Odonata: Calopterygidae) in response to flood. *Entomological Science* 15(3): 280-287. (in English) ["The reproductive behaviour *C. splendens* males and females inhabiting the Nida River, south Poland, was studied and compared during a pre-flood and a post-flood year. The flood disturbance in 2010 caused a decrease in aquatic macrophytes, thus reducing availability of potential territories and consequently, significantly influencing male behaviour towards a frequent non-territorial strategy. Many males in the post-flood population had damaged wings due to extremely aggressive contests. Male–male tandems were commonly observed; this is an uncommon behaviour in *C. splendens*. Although the sex ratio was male-biased throughout the whole study, we observed more males in the post-flood year. We also observed less-frequent copulations and ovipositions during the post-flood year. The only unchanged characteristic was population density, which did not differ before and after the flood disturbance. Floods have significant impact on damselfly reproductive sites and this, due to changes in behaviour and sex ratio, may result in further consequences on population dynamics." 11628. Golfieri, B.; Surian, N.; Hardersen, S.; Maiolini, B. (2012): Assessment of morphological and ecological conditions of Italian alpine rivers using the Morphological Quality Index (IQM) and Odonata. *IS.Rivers* 2012. 1ère conférence internationale sur les Recherches et Actions au service des fleuves et grandes rivières 26 au 28 juin 2012 / Lyon - FRANCE: 3 pp. (in English, with French summary) ["In the recent years many assessment methods have been developed to evaluate ecological and morphological conditions of rivers considering the requirements of the EU Water Framework Directive. Bioindicators are commonly aquatic organisms, but their use could lead to an incomplete evaluation of the status for the whole river corridor, for instance in large gravel-bed rivers. Dragonflies instead, as proposed in previous works, should offer a more complete evaluation of the ecological conditions of the river-floodplain system, due to the environmental characteristics that they indicate. In this study, the Italian Morphological Quality Index (IQM), joined with an Odonata based assessment system, are used to analyze the relationships between the ecological and morphological status of the fluvial environment. Another aim of the research is to test dragonflies as an ecological indicator over a set of reaches with different channel morphologies and human impacts. Preliminary results from five reaches show a good correspondence between the two assessment systems, confirming the positive correlation between ecological and morphological conditions of river reaches and the good potential of Odonata as bioindicators in riverine ecosystems." 11629. Gonçalves, J.F.; Rezende, F.; França, J.; Callisto, M. (2012): Invertebrate colonisation during leaf processing of native, exotic and artificial detritus in a tropical stream. *Marine and Freshwater Research* 63(5): 428-439. (in English) ["The relationship between leaf breakdown and colonisation by invertebrates in tropical aquatic ecosystems is poorly understood, especially in regard to the added problem of the potential effects of exotic species. To assess the colonisation by invertebrates during leaf breakdown in a third-order headwater stream in south-eastern Brazil, we conducted an experiment using the native species *Miconia chartacea*, the exotic species *Eucalyptus grandis* and artificial leaves. We hypothesised that the quality of the detritus and the leaf shape influence invertebrate colonisation because of the quality of the food and refuge offered by leaf detritus. Invertebrate density and richness were higher on leaves of *E. grandis* than on those of *M. chartacea*. Taxon richness did not differ among *M. chartacea* and the two sizes of artificial leaves offered, probably as a function of the chemical composition of *E. grandis*. Total invertebrate density was significantly higher in the organic detritus, suggesting that detritus provides food for the organisms. Our results indicate that the colonisation of invertebrates is probably affected by the chemical composition of detritus. Contrary to expectations, the community of invertebrates had no difficulty in colonising *E. grandis*, although it is an exotic species. In addition, the shredder activity did not influence leaf breakdown. These results may indicate that the invertebrates in this stream tend to behave as generalist feeders." 11630. Greig, H.S.; Kratina, P.; Thompson, P.L.; Pajunen, W.J.; Richardson, J.S.; Shurin, J.B. (2012): Warming, eutrophication, and predator loss amplify subsidies between aquatic and terrestrial ecosystems. *Global Change Biology* 18: 504-514. (in English) ["The exchange of organisms and energy among ecosystems has major impacts on food web structure and dynamics, yet little is known about how climate warming combines with other pervasive anthropogenic perturbations to affect such exchanges. We used an outdoor freshwater mesocosm experiment to investigate the interactive effects of warming, eutrophication, and changes in top predators (including 'Ischnura' and 'Libellula') on the flux of biomass between aquatic and terrestrial ecosystems. We demonstrated that predatory fish decoupled aquatic and terrestrial ecosystems by reducing the emergence of aquatic organisms and suppressing the decomposition of terrestrial plant detritus. In contrast, warming and nutrients enhanced cross-ecosystem exchanges by increasing emergence and decomposition, and these effects were strongest in the absence of predators. Furthermore, we found that warming advanced while predators delayed the phenology of insect emergence. Our results demonstrate that anthropogenic perturbations may extend well beyond ecosystem boundaries by influencing cross-ecosystem subsidies. We find that these changes are sufficient to substantially impact recipient communities and potentially alter the carbon balance between aquatic and terrestrial ecosystems and the atmosphere." 11635. Haislip, N.A.; Hoverman, J.T.; Miller, D.L.; Gray, M.J. (2012): Natural stressors and disease risk: does the threat of predation increase amphibian susceptibility to ranavirus?. *Canadian Journal of Zoology* 90(7): 893-902. (in English, with French summary) ["Emerging infectious diseases have been identified as threats to biodiversity, yet our understanding of the factors contributing to host susceptibility to pathogens within natural populations remains limited. It has been proposed that species interactions within communities affect host susceptibility to pathogens, thereby contributing to disease emergence. In particular, predation risk is a common natural stressor that has been hypothesized to compromise immune function of prey through chronic stress responses possibly leading to increased susceptibility to pathogens. We examined whether predation risk experienced during the development of four larval anuran species increases susceptibility (mortality and infection) to ranaviruses, a group of viruses responsible for amphibian die-offs. Using controlled laboratory experiments, we exposed each species to a factorial combination of two virus treatments (no virus or virus) crossed with three predator-cue treatments (no predators, larval dragonflies, or adult water bugs). All four amphibian species reduced activity by 22%-48% following continuous exposure to predator cues. In addition,

tion, virus exposure significantly reduced survival by 17%–100% across all species. However, exposure to predator cues did not interact with the virus treatments to elevate mortality or viral load. Our results suggest that the expression of predator-induced plasticity in anuran larvae does not increase ranaviral disease risk." (2012): Physicochemical characteristics and benthic macroinvertebrate communities in temporary surface waters of Northern Stark County, Ohio. *The Open Entomology Journal* 6: 1-12. (in English) ["Natural habitats located in urbanized regions are increasingly being impacted by residential, commercial and agricultural development, but little is known about their biotic and abiotic characteristics. Temporary aquatic habitats are less protected by environmental regulations than permanently flooded habitats, and they have been historically understudied. We sampled temporary aquatic habitats including vernal pools, other emergent wetlands and intermittent streams in northeastern Ohio over a two-year period to characterize the macroinvertebrate communities and abiotic characteristics of each habitat type. Duration of inundation of the habitat was the single largest contributing factor to benthic macroinvertebrate community structure. Macroinvertebrate community variability was greater among habitat types than within types suggesting that different habitats type do play a role in selecting for different invertebrate species. Macroinvertebrate abundance and diversity, and functional feeding group patterns differed among seasons. Dissolved oxygen, oxidation-reduction potential and conductivity explained a significant portion of the variability in macroinvertebrate community structure, and these differed among habitat types. Our results suggest that abiotic characteristics have a greater role in determining macroinvertebrate community structure than habitat type." (Authors) Taxa including Aeshnidae, Lestidae and Libellulidae are treated at family level.] Address: Hamilton, R., Dept of Biological Sciences, Kent State University at Stark, North Canton, OH 44720, USA

11637. Hartung, M. (2012): Bestimmung von Exuvien der Gattung *Aeshna* in Mitteleuropa mittels einer Matrix mit reellen Zahlen (Odonata: Aeshnidae). *Libellula Supplement* 12: 123-131. (in German, with English summary) ["Determination of the exuviae of the genus *Aeshna* in Central Europe using a matrix of real figures (Odonata: Aeshnidae) - The identification of exuviae is possible using different methods. Schmidt (1936) had published a table with measurement results of the exuviae belonging to the genus *Aeshna*. Based on this table an identification matrix was created using a modified calculation method according to Lapage et al. (1973). The modification consisted in the transformation of the calculation for the use of real figures, which are commonly used for the measurement of insects. Twenty exuviae of *Aeshna cyanea* controlled by adult emergence were measured according to Schmidt (1936). These measurements were standardized. The mean of results was used as a new value in the identification matrix. The newly identified exuviae were identified as *A. cyanea* in 19 of 20 specimens." 11638. Hassall, C. (2012): Predicting the distributions of under-recorded Odonata using species distribution models. *Insect Conservation and Diversity* 5(3): 192-201. (in English) ["(1) Absences in distributional data may result either from the true absence of a species or from a false absence due to lack of recording effort. I use general linear models (GLMs) and species distribution models (SDMs) to investigate this problem in North American Odonata and present a potential solution. (2) I use multi-model selection methods based on Akaike's information criterion to evaluate the ability of water-energy variables, human population density, and recording effort to explain patterns of odonate diversity in the USA and Canada using GLMs. Water-energy variables explain a large proportion of the variance in odonate diversity, but the residuals of these models are significantly related to recorder effort. (3) I then create SDMs for 176 species that are found solely in the USA and Canada using model averaging of eight different methods. These give predictions of hypothetical true distributions of each of the 176 species based on climate variables, which I compare with observed distributions to identify areas where potential under-recording may occur. (4) Under-recording appears to be highest in northern Canada, Alaska, and Quebec, as well as the interior of the USA. The proportion of predicted species that have been observed is related to recorder effort and population density. Maps for individual species have been made available online (<http://www.odonatacentral.org/>) to facilitate recording in the future. (5) This analysis has illustrated a problem with current odonate recording in the form of unbalanced recorder effort. However, the SDM approach also provides the solution, targeting recorder effort in such a way as to maximise returns from limited resources." (2012): Monitoring von Populationen der Helm-Azurjungfer *Coenagrion mercuriale* (Odonata: Coenagrionidae): Was taugen zwei Begehungen pro Saison? *Entomologia Helvetica* 5: 139-145. (in German, with English and French summaries) ["Conservation measures of endangered zygopteran species are frequently accompanied by minimal monitoring. Such a monitoring comprises two censuses per year, in which the number of imagines is determined. For *C. mercuriale* we have evaluated whether minimal monitoring results in a reliable assessment of population size. Therefore, we compared two different datasets, collected from the same populations on the Swiss Plateau in 2009. One dataset represented minimal monitoring with two censuses per year. The other dataset presented a more profound estimation of real population sizes. For this latter dataset, counts were conducted on every day with suitable weather conditions during the reproductive phase. Statistical evaluation showed a high agreement of the two methods. Therefore, we conclude that even minimal monitoring results in a reliable assessment of popula-

tion size. This result may also hold true for other damselfly species." (Authors)] Address: Hepenstrick, D., ZHAW Institut für Umwelt und Natürliche Ressourcen, Grüental, Postfach, CH-8820 Wädenswil, Switzerland. E-mail: daniel.hepenstrick@zhaw.ch

11641. Hettyey, A.; Rölli, F.; Thürlimann, N.; Zürcher, A.-C.; van Buskirk, J. (2012): Visual cues contribute to predator detection in anuran larvae. *Biological Journal of the Linnean Society* 106(4): 820-827. (in English) ["The ability of prey to detect predators directly affects their probability of survival. Chemical cues are known to be important for predator detection in aquatic environments, but the role of other potential cues is controversial. We tested for changes in behaviour of *Rana temporaria* tadpoles in response to chemical, visual, acoustic, and hydraulic cues originating from dragonfly larvae (*Aeshna cyanea*) and fish (*Gasterosteus aculeatus*). The greatest reduction in tadpole activity occurred when all cues were available, but activity was also significantly reduced by visual cues only. We did not find evidence for tadpoles lowering their activity in response to acoustic and hydraulic cues. There was no spatial avoidance of predators in our small experimental containers. The results show that anuran larvae indeed use vision for predator detection, while acoustic and hydraulic cues may be less important. Future studies of predator-induced responses of tadpoles should not only concentrate on chemical cues but also consider visual stimuli." (Authors)] Address: Buskirk, J. v., Inst. Zool., Univ. of Zürich, 8057 Zürich, Switzerland. E-mail: jvb@zool.unizh.ch

11642. Hobson, K.A.; Soto, D.X.; Paulson, D.R.; Wasenaar, L.I.; Matthews, J.H. (2012): A dragonfly ($\delta^2\text{H}$) isoscape for North America: a new tool for determining natal origins of migratory aquatic emergent insects. *Methods in Ecology and Evolution* 3(4): 766-772. (in English) ["(1) Tracking insect migration at continental scales is intractable using exogenous markers because of tiny body size and high improbability of recapture. Naturally occurring endogenous isotopic markers, such as tissue $\delta^2\text{H}$ and $\delta^{18}\text{O}$, are a means of assigning origins to both vertebrate and invertebrate populations, but the success depends upon derivation of a robust algorithm linking measured tissue isotope values with large-scale geospatial isotopic patterns (isoscapes) in the terrestrial hydrosphere. (2) We derived a North American dragonfly wing $\delta^2\text{H}$ and $\delta^{18}\text{O}$ isoscape from known-origin dragonflies of three species (*Aeshna interrupta*, *A. umbrosa* and *Pachydiplax longipennis*) obtained across North America. A strong relationship ($r^2 = 0.75$) was found between wing $\delta^2\text{H}$ and hydrologic geospatial $\delta^2\text{H}$ patterns, and between wing $\delta^2\text{H}$ and $\delta^{18}\text{O}$ ($r^2 = 0.92$). The strong coupling between emergent insect tissue and hydrologic spatial patterning suggested that this dragonfly isoscape may be applicable to other aquatic emergent migratory insects in North America and elsewhere. (3) As a proof of concept, we used the wing isoscape algorithm to map the probability of natal origin of *Anax junius* migrating through southern Texas. Results showed that these Texan dragonflies were a mix of local and far-distant migrant (e.g. northern United States) individuals. We suggest that this isoscape algorithm opens new opportunities to quantify the migration and natal origins of dragonflies and other aquatic emergent insects where conventional methods have failed." (2012): The reproductive biology and daily activity patterns of *Ischnura heterosticta* (Burmeister) in eastern Australia (Zygoptera: Coenagrionidae). *Odonatologica* 41(2): 99-107. (in English) ["The reproductive behaviour was observed at a pond in Fig Tree Pocket, Brisbane, Australia, from Oct. 2010 to Jan. 2011. In total, 769 individuals were marked in the field for observations pertaining to the daily activity patterns and reproductive cycle of this sp. Forty-one *I. heterosticta* pairs were collected and kept in the laboratory for detailed observations of the reproductive behaviours, copulation duration and oviposition, and to determine the duration of larval development. It started to form mating pairs from ca 5:00 to 9:00 am, foraged from ca 9:00 am to 13:00 pm, and finally females oviposited mainly from ca 13:00 pm to 16:30 pm. Oviposition usually occurred in the following days after mating. Mating pairs formed the tandem position for about 13 s, then copulated in the wheel position on average for 195 min, and upon completion of insemination formed a tandem position again for about 12 s. On average, females spent 145 min in actual oviposition, laying several hundred eggs on floating vegetation. Ovipositing females were not guarded by males. The eggs hatched within 10 to 21 days, and the larvae took 3 to 5 months to develop into adults." Trop.* 60(1): 291-303. (in English) ["Benthic macroinvertebrate fauna plays a major role in river ecosystems, especially those of tropical islands. Since there is no information on the distribution of benthic invertebrates along a Jamaican river, we report here on the composition of the benthic fauna of the Buff Bay river, on the Northern coast of Jamaica. A total of 14 samples were collected from five sites, using kick nets and a Surber sampler, between May 1997 and October 1998. We also examined the applicability of the rhithron/potamon model, and some of the premises of

the River Continuum Concept (RCC) in relation to the distribution of invertebrate taxa. The results showed a total of 38 taxa of identified invertebrates. A group of dominant taxa, composed mainly of immature stages of insects, occurred at all sites. Two notable characteristics of the river were the absence of a true potamonic fauna and the low representation of the shredder functional feeding group in the community. We conclude that, while there was minor variation in the composition of the benthic macroinvertebrate fauna among the sites, this was a response to local conditions within the river system. The characteristics of the community did not conform to either of the models." (Authors) The following taxa are listed: *Scapania frontalis*, *Dythemis rufinervis*, *Orthemis ferruginea*, and *Enallagma* sp.] Address: Hyslop, E.J., Department of Life Sciences, University of the West Indies, Mona campus, Kingston 7, Jamaica. 11647. Iorio, E. (2012): Nouvelles données sur la répartition et l'écologie de *Sympetrum depressiusculum* (Selys, 1841) dans les Bouches-du-Rhône (Odonata, Anisoptera: Libellulidae). *Martinia* 28(1): 25-36. (in French, with English summary) [In "2010 and 2011, the autochthony of *S. depressiusculum* has been emphasized in several new locations in Saint-Martin-de-Crau and Salon-de-Provence (Bouches-du-Rhône department, southern France). These locations are sedimentation tanks along motorways with clear and well brightened up waters on a muddy/rocky substratum, with many helophytes and with winter desiccation. The dominant plant species in the ponds where *S. depressiusculum* reproduces are, in decreasing order of frequency/abundance: *Typha domingensis*, *Cyperus eragrostis*, *Scirpoides holoschoenus* and *Schoenoplectus lacustris*. The Odonatological regular cortège is, in decreasing order of frequency/abundance: *Ischnura elegans*, *S. fonscolombii*, *Crocothemis erythraea*, *Orthetrum cancellatum* and *Anax imperator*. The odonatological occasional cortège is, in decreasing order of frequency/abundance: *S. sanguineum*, *O. coerulescens*, *O. brunneum*, *Anax parthenope*, *O. albistylum* and *S. striolatum*. Several cases of predation on *S. depressiusculum* and other Anisoptera species by *Argiope bruennichi* (Scopoli, 1772) (Araneae: Araneidae) have been observed. This spider seems to be an efficient predator in this kind of habitat." (Author)] Address: Iorio, E., ECO-MED (Ecologie & Médiation), Pôle Entomologie, Tour Méditerranée, 65 av. 11649. Iserbyt, A.; Van Gossum, H.; Stoks, R. (2012): Biogeographical survey identifies consistent alternative physiological optima and a minor role for environmental drivers in maintaining a polymorphism. *PLoS ONE* 7(2): e32648. doi:10.1371/journal.pone.0032648: 10 pp. (in English) ["The contribution of adaptive mechanisms in maintaining genetic polymorphisms is still debated in many systems. To understand the contribution of selective factors in maintaining polymorphism, we investigated large-scale (>1000 km) geographic variation in morph frequencies and fitness-related physiological traits in the damselfly *Nehalennia irene*. As fitness-related physiological traits, we investigated investment in immune function (phenoloxidase activity), energy storage and fecundity (abdomen protein and lipid content), and flight muscles (thorax protein content). In the first part of the study, our aim was to identify selective agents maintaining the large-scale spatial variation in morph frequencies. Morph frequencies varied considerably among populations, but, in contrast to expectation, in a geographically unstructured way. Furthermore, frequencies co-varied only weakly with the numerous investigated ecological parameters. This suggests that spatial frequency patterns are driven by stochastic processes, or alternatively, are consequence of highly variable and currently unidentified ecological conditions. In line with this, the investigated ecological parameters did not affect the fitness-related physiological traits differently in both morphs. In the second part of the study, we aimed at identifying trade-offs between fitness-related physiological traits that may contribute to the local maintenance of both colour morphs by defining alternative phenotypic optima, and test the spatial consistency of such trade-off patterns. The female morph with higher levels of phenoloxidase activity had a lower thorax protein content, and vice versa, suggesting a trade-off between investments in immune function and in flight muscles. This physiological trade-off was consistent across the geographical scale studied and supports widespread correlational selection, possibly driven by male harassment, favouring alternative trait combinations in both female morphs." 11650. Janssens, L.; Stoks, R. (2012): How does a pesticide pulse increase vulnerability to predation? Combined effects on behavioral antipredator traits and escape swimming. *Aquatic Toxicology* 110-111: 91-98. (in English) ["An increasing number of studies have documented that sublethal pesticide exposure can change predator-prey interactions. Most of these studies have focused on effects of long-term pesticide exposure on only one type of antipredator traits and have not directly linked changes in these traits to mortality by predation. To get a better mechanistic understanding of how short-term pesticide pulses make prey organisms more vulnerable to predation, we studied effects of 24 h exposure to a sublethal concentration of the insecticide endosulfan and the herbicide Roundup on the major antipredator traits and the resulting mortality by predation in larvae of the damselfly *Enallagma cyathigerum*. A pulse of both pesticides affected antipredator traits involved in avoiding detection by predators as well as traits involved in escape after detection. After a pesticide pulse, larvae increased activity levels and even further in-

creased the number of walks when predation risk was present. Further, an endosulfan pulse tended to reduce escape swimming speed. In contrast, previous exposure to Roundup caused the larvae to swim faster, yet less often when attacked. Importantly, although both studied pesticides induced maladaptive changes in overall activity, only for endosulfan this resulted in an increased mortality by predation. Our study highlights that considering changed predator-prey interactions may improve ecological risk evaluations of short pesticide pulses, yet also underscores the need (1) to consider effects on all important antipredator traits of the prey as trait compensation may occur and (2) to effectively score the outcome of predator-prey interactions in staged encounters." 11651. Kadoya, T.; Washitani, I. (2012): Use of multiple habitat types with asymmetric dispersal affects patch occupancy of the damselfly *Indolestes peregrinus* in a fragmented landscape. *Basic and Applied Ecology* 13: 178-187. (in English, with German summary) ["To appropriately predict the patch occupancy of animals, it is often essential to consider not only the habitat structure but also shifts in the habitat requirements of animals with changes in life stage. In addition, asymmetric dis-

persal among different types of habitat patches is likely to accompany use of multiple habitat types due to differences in the ease with which migrants can find the habitats, to changes in the dispersal ability of animals according to their life stage, or to both factors. However, few studies have explicitly elucidated the contribution of these processes to patch connectivity and to predictions of patterns of patch occupancy. In the present study, we evaluated the effects of multi-type habitat use on patch connectivity of the damselfly *Indolestes peregrinus*. After emergence, adults of this species move from their native ponds to woodlands for hibernation and return to aquatic habitats for oviposition in the next spring. We recorded the occurrence of *I. peregrinus* at newly created artificial ponds and attempted to explain patch occupancy using a series of Bayesian statistical models, which incorporate (1) local environment only, (2) both local environment and single-type habitat use connectivity, and (3) both local environment and multi-type habitat use connectivity. In addition, we considered two situations in the third model: symmetric or asymmetric dispersal. Comparing the performance of the candidate models revealed that the best model was the third model assuming asymmetric dispersal and it explained 18.8% of the deviance. The result suggests that multi-type habitat use is important for determining patch connectivity of *I. peregrinus*, and that there is asymmetry in the connectivity from pond to woodland patches and vice versa for the damselfly. Both multi-type habitat use and asymmetric dispersal processes are likely to apply to many other taxa and landscapes." 11653. Kalkman, V.J.; Orr, A.G. (2012): The Australian monsoon tropics as a barrier for exchange of dragonflies (Insecta: Odonata) between New Guinea and Australia. *Hydrobiologia* 693: 55-70. (in English) ["Recent studies show a remarkable scarcity of faunal exchange events between Australia and New Guinea in the Pleistocene despite the presence of a broad land connection for long periods. This is attributed to unfavourable conditions in the connecting area associated with the long established northern Australian Monsoon Climate. This would be expected to have impacted strongly on freshwater faunas with the following results: (1) limited overlap in species, (2) most higher taxonomic groups pre-

sent in both areas sharing no species or even genera and (3) shared species dominated by lentic species with high dispersal capacity. Testing these predictions for dragonflies showed the turnover in the family, genus and species composition between Australia and New Guinea to be higher than anywhere in the world with only 50% of families and subfamilies, 33% of the genera and 8% of the species being shared. Only one of the 53 shared species favours lotic waters compared with 64% of the 652 combined Australian–New Guinean species. These results agree with our predictions and indicate that the dragonfly fauna of Australia and New Guinea have effectively been separated during the Pleistocene probably due to the prolonged unfavourable climatic conditions in the intervening areas" (Authors)] Address: Kalkman, V.J., European Invertebrate Survey - Nederland, p/a Nationaal Natuurhistorisch Museum - naturalis, Postbus 9517, 2300 RA Leiden, The Netherlands. 11654. Keller, D.; van Strien, M.J.; Holderegger, R. (2012): Do landscape barriers affect functional connectivity of populations of an endangered damselfly? *Freshwater Biology* 57(7): 1373-1384. (in English) ["(1) Landscape genetic approaches were used to assess functional connectivity of populations of the endangered damselfly *Coenagrion mercuriale* in a fragmented agricultural landscape in Switzerland. Spatial genetic clustering methods combined with interpolation by kriging and landscape genetic corridor analysis were applied to identify landscape elements that enhance or hinder dispersal and gene flow. (2) Spatial genetic clustering analysis divided the sampled populations into a northern and a southern genetic group. The boundary between the two groups coincided with a hill ridge intersecting the study area. Landscape corridor analysis identified five landscape elements that significantly affected gene flow. Elevation change, Euclidian distance, patches of forest and flowing waterbodies acted as barriers, whereas open agricultural land enhanced gene flow between populations of *C. mercuriale*. (3) This study showed that movement of *C. mercuriale* was not restricted to its preferred habitat (i.e. streams). Populations linked via continuous open agricultural land were functionally well connected if they were not more than about 1.5–2 km apart. In contrast, substantial elevation change and larger forest patches separated populations. These findings may serve as a basis to define conservation units and should be considered when planning connectivity measures, such as determining the locations of stepping stones, or the restoration of streams." (2012): Clutch size and egg production in *Orthetrum nitidinerve* Selys, 1841 (Anisoptera: Libellulidae): effect of body size and age. *International Journal of Odonatology* 15(2): 51-58. (in English) ["Clutch size is an important fitness component often quantified artificially by inducing oviposition in libellulid females. Female behaviour and egg production of the yellow-veined skimmer, *Orthetrum nitidinerve*, were studied in northeast Algeria during its reproductive season. Data on reproductive

behaviour and biology of this Mediterranean endemic species has not been published previously. Males guarded territories within the wetland while females came only to lay their eggs and then went back to terrestrial habitat. In this study we induced oviposition, which depletes all the female eggs, to obtain estimations of egg deposition rate and subsequently clutch size. On average an induced clutch was ca. 2200 eggs while a natural one was about 970 eggs. Artificial clutches were positively correlated to body length but negatively related to mature lifespan. The rate of egg deposition was higher in the afternoon than in the morning, probably because of differences in temperature. During their mature lifespan females oviposited between one and three artificial clutches." 11658. Klecka, J.; Boukal, D.S. (2012): Who eats whom in a pool? A comparative study of prey selectivity by predatory aquatic insects. *PLoS ONE* 7(6): e37741: 13 pp. (in English) ["Predatory aquatic insects are a diverse group comprising top predators in small fishless water bodies. Knowledge of their diet composition is fragmentary, which hinders the understanding of mechanisms maintaining their high local diversity and of their impacts on local food web structure and dynamics. We conducted multiple-choice predation experiments using nine common species of predatory aquatic insects, including adult and larval Coleoptera, adult Heteroptera and larval Odonata, and complemented them with literature survey of similar experiments. All predators in our experiments fed selectively on the seven prey species offered, and vulnerability to predation varied strongly between the prey. The predators most often preferred dipteran larvae; previous studies further reported preferences for cladocerans. Diet overlaps between all predator pairs and predator overlaps between all prey pairs were non-zero. Modularity analysis separated all primarily nectonic predator and prey species from two groups of large and small benthic predators and their prey. These results, together with limited evidence from the literature, suggest a highly interconnected food web with several modules, in which similarly sized predators from the same microhabitat are likely to compete strongly for resources in the field (observed Pianka's diet overlap indices >0.85). Our experiments further imply that ontogenetic diet shifts are common in predatory aquatic insects, although we observed higher diet overlaps than previously reported. Hence, individuals may or may not shift between food web modules during ontogeny." (Authors) The following Odonata species were used in the experiment: *Coenagrion puella* (F-0) (water column), *Libellula depressa* (F-2), *Libellula depressa*

11659. Knillmann, S.; Stampfli, N.C.; Noskov, Y.A.; Bekeov, M.A.; Liess, M. (2012): Interspecific competition delays recovery of *Daphnia* spp. populations from pesticide stress. *Ecotoxicology* 21(4): 1039-1049. (in English) ["Xenobiotics alter the balance of competition between species and induce shifts in community composition. However, little is known about how these alterations affect the recovery of sensitive taxa. We exposed zooplankton communities to esfenvalerate (0.03, 0.3, and 3 lg/L) in outdoor microcosms and investigated the longterm effects on populations of *Daphnia* spp. To cover a broad and realistic range of environmental conditions, we established 96 microcosms with different treatments of shading and periodic harvesting. Populations of *Daphnia* spp. decreased in abundance for more than 8 weeks after contamination at 0.3 and 3 lg/L esfenvalerate. The period required for recovery at 0.3 and 3 lg/L was more than eight and three times longer, respectively, than the recovery period that was predicted on the basis of the life cycle of *Daphnia* spp. without considering the environmental context. We found that the recovery of sensitive *Daphnia* spp. populations depended on the initial pesticide survival and the related increase of less sensitive, competing taxa. We assert that this increase in the abundance of competing species, as well as sub-lethal effects of esfenvalerate, caused the unexpectedly prolonged effects of esfenvalerate on populations of *Daphnia* spp. We conclude that assessing biotic interactions is essential to understand and hence predict the effects and recovery from toxicant stress in communities." (Authors) The paper contains a passing reference to Odonata.] Address: Knillmann, Saskia, Department of System Ecotoxicology, Helmholtz Centre for Environmental Research, UFZ, Permoserstrasse 15, 04318 Leipzig, Germany. 11660. Koch, K.; Ziegler, D.A.; Griebeler, E.M. (2012): Nischenmodell für *Sympetrum striolatum* (Odonata: Libellulidae). *Libellula Supplement* 12: 151-160. (in German, with English summary) ["In this study, we assessed whether it is possible to establish ecological niche models for euryoecious species using *Sympetrum striolatum* as a model species. Presence-only data of this species, climate and land use data at the resolution of ordinance survey type maps (OSM) from six different Southern German federal states and from the time period 1950-2006 were used for modelling. Based on these data we calculated four different models applying the Software Max-Ent. Each model initially considered 19 pairwise uncorrelated environmental variables plus one climate and one precipitation variable based on different periods: "no egg or larval development", with averaged mean monthly temperatures below 4°C (December-February), "larvae", with averaged mean monthly temperatures above 4°C (March-November), "adult", the main flight season of *S. striolatum* (June-October), and "whole life cycle" the mean annual temperature. In general, model accuracy and performance was low. Nevertheless, all models identified the same variables as the most important predictors of the spatial distribution of *S. striolatum*. The different temperature variables showed the highest independent contribution to the overall vari-

ance explained by the models, whereas the contribution of the fraction of conifer forest, the fraction of soil with pH 7.5-8, and the difference between maximum and minimum altitude in meters within an OSM was lower. As the environmental variables identified by the models are consistent with the biology of our model species, we conclude that ecological niche models are reliable for euryoecious species." 11661. Kosterin, O.E. (2012): A rapid survey of Odonata on Bokor Plateau, Preah Monivong National Park, Cambodia. *Cambodian Journal of Natural History* 2012(1): 75-88. (in English, with Cambodian summary) ["Bokor Plateau, in the coastal area of Cambodia, supports a mixture of upper hill evergreen forest and wetlands, including Sphagnum peat-moss bogs, at approximately 1,000 m elevation. Despite being within Preah Monivong National Park, the recent construction of a resort on the plateau has destroyed most of its accessible wetlands before their biodiversity was fully investigated. The findings of three rapid surveys, which preceded the loss of the wetlands, are presented here. During six days in total, 45 species of Odonata were recorded on Bokor Plateau (1 Calopterygidae, 1 Euphaeidae, 2 Chlorocyphidae, 2 Lestidae, 11 Coenagrionidae, 1 Platycnemididae, 1 Protoneuridae, 1 Aeshnidae, 2 Corduliidae and 23 Libellulidae), comprising 10 lotic and 35 lentic species. Only four species, *Aciagrion tillyardi*, *Idyonyx ?thailandica*, *Lyriothemis elegantissima* and *Orthetrum pruinatum neglectum*, were not recorded at lower elevations during the same period. *Aciagrion tillyardi* appeared to breed in peat-moss habitats on the plateau, but no obligate peat-moss species were found. Numerous non-breeding individuals of the common species *Ceriagrion olivaceum*, *Neurothemis intermedia*, *Potamarcha congener* and *Tholymis tillarga* were found on the plateau in December, and *Pantala flavescens* in April and to a lesser extent in August, most of which had probably dispersed from lower elevations to forage. No very rare or localised endemic species were detected, but this may be explained by the short survey period." (2012): Do allopatric male *Calopteryx virgo* damselflies learn species recognition? *Ecology and Evolution* 2(3): 615-621. (in English) ["There is a growing amount of empirical evidence that premating reproductive isolation of two closely related species can be reinforced by natural selection arising from avoidance of maladaptive hybridization. However, as an alternative for this popular reinforcement theory, it has been suggested that learning to prefer conspecifics or to discriminate heterospecifics could cause a similar pattern of reinforced premating isolation, but this possibility is much less studied. Here, we report results of a field experiment in which we examined (i) whether allopatric *Calopteryx virgo* damselfly males that have not encountered heterospecific females of the congener *C. splendens* initially show discrimination, and (ii) whether *C. virgo* males learn to discriminate heterospecifics or learn to associ-

ate with conspecifics during repeated experimental presentation of females. Our experiment revealed that there was a statistically nonsignificant tendency for *C. virgo* males to show initial discrimination against heterospecific females but because we did not use sexually native individuals in our experiment, we were not able to separate the effect of innate or associative learning. More importantly, however, our study revealed that species discrimination might be further strengthened by learning, especially so that *C. virgo* males increase their association with conspecific females during repeated presentation trials. The role of learning to discriminate *C. splendens* females was less clear. We conclude that learning might play a role in species recognition also when individuals are not native but have already encountered potential conspecific mates." 11664. Lau, D.C.P.; Vrede, T.; Pickova, J.; Goedkoop, W. (2012): Fatty acid composition of consumers in boreal lakes – variation across species, space and time. *Freshwater Biology* 57(1): 24-38. (in English) [Sweden] "(1) Fatty acids (FAs) have been widely applied as trophic biomarkers in aquatic food web studies. However, current knowledge of inter- and intraspecific variation in consumer FA compositions across spatial and temporal scales is constrained to a few pelagic taxa. (2) We analysed the FAs of 22 taxa of benthic macroinvertebrates (including 'Aeshna spp., Corduliidae, Zygoptera'), zooplankton and fish collected from the littoral, pelagic and profundal habitats of nine boreal oligotrophic lakes over spring, summer and autumn. We quantified and compared the FA variance partitions contributed by species identity (i.e. an integrative effect of phylogenetic origin, life history and functional feeding guild of individual taxa), site and season using partial redundancy analysis both on all consumers and on benthic arthropods alone. (3) Species identity alone contributed 84.4 and 72.8% of explained FA variation of all consumers and benthic arthropods, respectively. Influences of site, season and all joint effects accounted for 0–11.3% only. Fatty acid profiles of primary consumers differentiated below class level, but those of predators were distinguishable only when they became more taxonomically distinct (i.e. among classes or higher). (4) Pelagic and profundal consumers showed stronger reliance on autochthonous resources than did their littoral counterparts as reflected by their higher x3 to x6 FA ratios. Polyunsaturated FAs (PUFAs) were increasingly retained with trophic levels, and saturated FAs (e.g. FA 16 : 0) gradually reduced. Ecologically, this trade-off enhances the trophic transfer efficiency and confirms the importance of PUFA-rich autotrophs in aquatic food webs. (5) Our findings indicate strong interspecific differences in FA requirements and assimila-

tion among aquatic consumers from a wide range of taxonomic levels, habitats and lakes. Consumers were able to maintain homeostasis in FA compositions across spatial and temporal changes in resource FAs, but consumer homeostasis did not limit the effectiveness of FAs as trophic biomarkers." 11665. Lee, Y.-H.; Lin, C.-P. (2012): Morphometric and genetic differentiation of two sibling gossamer-wing damselflies, *Euphaea formosa* and *E. yayeyamana*, and adaptive trait divergence in subtropical East Asian islands. *Journal of Insect Science* 12 | Article 53: 17 pp. (in English) ["Insular species frequently demonstrate different tendencies to become smaller or larger than their continental relatives. Two sibling gossamer-wing damselflies, *E. formosa* (Odonata: Euphaeidae) from Taiwan and *E. yayeyamana* from the Yaeyama Islands of Japan, have no clear structural differentiation, and can only be recognized by their geographical distribution, sizes, and subtle differences in wing shape and coloration. This study combined morphometric and genetic techniques to investigate the adaptive significance of trait divergence and species status in these two *Euphaea* damselflies. Phylogenetic analyses of the mitochondrial *cox2* sequences demonstrated that the two damselflies are monophyletic lineages and constitute valid phylogenetic species. The landmark-based geometric morphometrics indicated that the two damselflies are different morphological species characterized by distinctive wing shapes. The larger *E. formosa* exhibited broader hind wings, whereas *E. yayeyamana* had narrower and elongated forewings. The body size and wing shape variations among populations of the two species do not follow the expected pattern of neutral evolution, suggesting that the evolutionary divergence of these two traits is likely to be subjected to natural or sexual selection. The decreased body size, elongated forewings, and narrower hind wings of *E. yayeyamana* may represent insular adaptation to limited resources and reduced territorial competition on smaller islands." 11666. Lee, Y.-H.; Lin, C.-P. (2012): Pleistocene speciation with and without gene flow in *Euphaea* damselflies of subtropical and tropical East Asian islands. *Molecular Ecology* 21(15): 3739-3756. (in English) ["Climatic oscillations during the Pleistocene period could have had a profound impact on the origin of tropical species by the alternation of allopatric isolation and interpopulation gene flow cycles. However, whether tropical speciation involves strictly allopatric isolation, or proceeds in the face of homogenizing gene flow, is relatively unclear. Here, we investigated geographical modes of speciation in four closely related *Euphaea* damselfly species endemic to the subtropical and tropical East Asian islands using coalescent analyses of a multilocus data set. The reconstructed phylogenies demonstrated distinct species status for each of the four species and the existence of two sister species pairs, *Euphaea formosa*/*E. yayeyamana* and *E. decorata*/*E. ornata*. The species divergence time of the sibling *Euphaea* damselflies dates back to within the last one Mya of the Middle to

Lower Pleistocene. The speciation between the populous *E. formosa* of Taiwan and the less numerous *E. yayeyamana* of the Yaeyama islands occurred despite significant bidirectional, asymmetric gene flow, which is strongly inconsistent with a strictly allopatric model. In contrast, speciation of the approximately equal-sized populations of *E. decorata* of the southeast Asian mainland and *E. ornata* of Hainan is inferred to have involved allopatric divergence without gene flow. Our findings suggest that differential selection of natural or sexual environments is a prominent driver of species divergence in subtropical *E. formosa* and *E. yayeyamana*; whereas for tropical *E. decorata* and *E. ornata* at lower latitudes, allopatric isolation may well be a pivotal promoter of species formation." 11667. Leslie, A.W.; Smith, R.F.; Ruppert, D.E.; Bejleri, K.; McGrath, J.M.; Needelman, B.A.; Lamp, W.O.P (2012): Environmental factors structuring benthic macroinvertebrate communities of agricultural ditches in Maryland. *Environ. Entomol.* 41(4): 802-812. (in English) ["Agricultural drainage ditches are artificial structures used to optimize soil hydrology for crop production and secondarily have been co-opted as a tool to manage the quality of water draining from agricultural lands. We investigated the relationship between the aquatic macroinvertebrate community and environmental variables associated with physical and biogeochemical processes that affect water quality. Aquatic macroinvertebrates were sampled along with physical and chemical measures of the soil and water from 29 agricultural drainage ditches on the Eastern Shore of Maryland. Cluster analysis and multivariate ordination showed that ditches that had higher flow velocities supported communities of lotic invertebrates (i.e., Stenelmis, Prosimulium) versus those that had properties of linear wetlands, which supported communities of lentic invertebrates (i.e., Oligochaeta, Caecidotea). Taxon richness varied from four to 31 taxa per ditch, and was higher within ditches that had higher flow velocities. Small ditches had low diversity, but may have provided refugia from fish predators. Macroinvertebrate communities did not show a significant linear relationship with water quality or with nutrient concentrations within the soil or water. The addition of flow-control structures designed to improve the quality of water draining from agricultural lands may decrease the quality of ditches as habitat for certain aquatic macroinvertebrates. Management decisions for drainage ditches may consider tradeoffs between the benefits of ditches as a source of biodiversity and as a tool for improving water quality." (Authors) Taxa are treated at genus level and include *Dromogomphus*, *Libellula*, *Amphiagrion*, and *Argia*.] Address: Leslie, A.W., Dept of Entomology, Univ. of Maryland, College Park, MD 20742, USA. 11668. Letsch, H.O.; Meusemann, K.; Wipfler, B.; Schütte, K.; Beutel, R.; Misof, B. (2012): Insect phylogenomics: results, problems and the impact of matrix composition. *Proc. R. Soc. B* 279(1741): 3282-3290. (in English) ["In this study, we investigated the relationships among insect orders with a main focus on Polyneoptera (lower Neoptera: roaches, mantids, earwigs, grasshoppers, etc.), and Paraneoptera (thrips, lice, bugs in the wide sense). The relationships between and within these groups of insects are difficult to resolve because only

few informative molecular and morphological characters are available. Here, we provide the first phylogenomic expressed sequence tags data ('EST': short sub-sequences from a c(copy) DNA sequence encoding for proteins) for stick insects (Phasmatodea) and web-spinners (Embioptera) to complete published EST data. As recent EST datasets are characterized by a heterogeneous distribution of available genes across taxa, we use different rationales to optimize the data matrix composition. Our results suggest a monophyletic origin of Polyneoptera and Eumetabola (Paraneoptera + Holometabola). However, we identified artefacts of tree reconstruction (human louse *Pediculus humanus* assigned to Odonata or Holometabola (insects with a complete metamorphosis); mayfly genus *Baetis* nested within Neoptera), which were most probably rooted in a data matrix composition bias due to the inclusion of sequence data of entire proteomes. Until entire proteomes are available for each species in phylogenomic analyses, this potential pitfall should be carefully considered." (Authors) *Ischnura elegans* was included in analyses.] Address: Harald O. Letsch, H.O., Dept für Tropenökologie und Biodiversität der Tiere, Universität Wien, Rennweg 14, 1030 Wien, Austria. 11673. Lis, L.; Buczyński, P. (2012): *Leucorrhinia pectoralis* (Charpentier, 1825) (Odonata: Libellulidae) in secondary habitats in the former sulphur mine "Jeziórko" near Tarnobrzeg (Sandomierz Basin). *Odonatrix* 8(1): 19-22. (in Polish, with English summary) ["In the year 2011, *L. pectoralis* was recorded in the former borehole sulphur mine „Jeziórko” (E of Tarnobrzeg, south-eastern Poland). The species was observed in two drainage canals of mining subsidence (sites 1 and 3) as well as along the road running through the area of flood lands in mining subsidence (site 2). At sites 2 and 3 the species was very numerous (on May 28, more than 100 specimens per 100m of observation transect), at site 3 numerous territorial males were observed. For the *L. pectoralis* the examined areas are typical secondary habitats to which this species is being adapted and in the suitable stages of succession it often forms large populations in Poland. New data is essential for the knowledge about the distribution of this species in Poland (Bernard et al. 2009). It fills the gap on the map of distribution situated between central Poland and the Lublin Region. It is also the first one from the central part of the Sandomierz Basin, the area with very little data in general so far. This situation results mainly from the lack of respectively targeted studies on odonatofauna of this macroregion." 11674. Liu, V. (2012): Dragonflies and Damselflies of Las Galarias. *The Hum...* 7(1): 3-4. (in English) [Verbatim: Almost all dragonflies and damselflies (order: Odonata, or Odes for short) are dependent upon freshwater habitats in which the larval stages grow and develop, and we have plenty of those here at Reserva Las Galarias (RLG)! On sunny days they are often ob-

served throughout the reserve and can most frequently be found along the forest creeks and boggy areas of Peccary Trail, with the pond being a particular hotspot. Having been successful in obtaining identifications for many of the butterfly species on the reserve, we decided to try our luck with odes and sent off some photos to Bill Haber and Dave Wagner ("Odonata of Ecuador" project) with the ambitious hope that they might also be willing to help us identify what we have. With many thanks to Bill and Dave, we can report that 20 different species have been identified at RLG, with some additional 'interesting' species yet to be confirmed. Odes occur in greater abundance and higher diversity at lower elevations, but at higher elevations, such as RLG, there is a greater possibility of endemic species being found. We are still excitedly awaiting the identifications for our 'interesting' species. To check out Bill and Dave's on-going website-based inventory of the Odes of Ecuador, which will soon include records from RLG, visit their website at: <http://efg.cs.umb.edu/~whaber/OdonataofEcuador/index.html>] Address: Liu, Vicki, c/o Las Galarias Foundation Inc., 24140 Gessner Rd., North Olmsted, OH 44070, USA

11677. Lunde, K.B.; Resh, V.H. (2012): Development and validation of a macroinvertebrate index of biotic integrity (IBI) for assessing urban impacts to Northern California freshwater wetlands. *Environmental Monitoring and Assessment* 184(6): 3653-3674. (in English) ["Despite California policies requiring assessment of ambient wetland condition and compensatory wetland mitigations, no intensive monitoring tools have been developed to evaluate freshwater wetlands within the

state. Therefore, we developed standardized, wadeable field methods to sample macroinvertebrate communities and evaluated 40 wetlands across Northern California to develop a macroinvertebrate index of biotic integrity (IBI). A priori reference sites were selected with minimal urban impacts, representing a best-attainable condition. We screened 56 macroinvertebrate metrics for inclusion in the IBI based on responsiveness to percent urbanization. Eight final metrics were selected for inclusion in the IBI: percent three dominant taxa; scraper richness; percent Ephemeroptera, Odonata, and Trichoptera (EOT); EOT richness; percent Tanyptodinae/Chironomidae; Oligochaeta richness; percent Coleoptera; and predator richness. The IBI (potential range 0–100) demonstrated significant discriminatory power between the reference (mean=69) and impacted wetlands (mean=28). It also declined with increasing percent urbanization ($R^2=0.53$, $p<0.005$) among wetlands in an independent validation dataset ($n=14$). The IBI was robust in showing no significant bias with environmental gradients. This IBI is a functional tool to determine the ecological condition at urban (stormwater and flood control ponds), as well as rural freshwater wetlands (stockpools, seasonal wetlands, and natural ponds). Biological differences between perennial and nonperennial wetlands suggest that developing separate indicators for these wetland types may improve applicability, although the existing data set was not sufficient for exploring this option." (Authors) Taxa are treated at the genus level.] Address: Lunde, K.B., Environmental Science, Policy, and Management, University of California, Berkeley, 130 Mulford Hall #3114, Berkeley, CA 94720, USA. 11678. Maasri, A.; Gelhaus, J. (2012): Stream invertebrate communities of Mongolia: current structure and expected changes due to climate change. *Aquatic Biosystems* 2012, 8:18 doi: 10.1186/2046-9063-8-18: 24 pp. (in English) ["Background: Mongolia's riverine landscape is divided into three watersheds, differing in extent of permafrost, amount of precipitation and in hydrological connectivity between sub-drainages. In order to assess the vulnerability of macroinvertebrate communities to ongoing climate change, we consider the taxonomic and functional structures of stream communities in two major watersheds: The Central Asian Internal Watershed (CAIW) and the Arctic Ocean Watershed (AOW), together covering 86.1% of Mongolia's surface area. We assess the consequences of the hydrological connectivity between sub-drainages on the nestedness and distinctness of the stream communities. And accordingly, we discuss the expected biotic changes to occur in each watershed as a consequence of climate change. Results: Gamma and beta diversities were higher in the CAIW than the AOW. High community nestedness was also found in the CAIW along with a higher heterogeneity of macroinvertebrate assemblage structure. Assemblages characteristic of cold headwater streams in the CAIW, were typical of the drainages of the Altai Mountain range. Macroinvertebrate guilds of the CAIW streams exhibited traits reflecting a high stability and low resilience capacity for eutrophication. In contrast, the community of the AOW had lower nestedness and a combination of traits reflecting higher stability and a better resilience capacity to disturbances. Conclusion: Higher distinctness of stream communities is due to lower connectivity between the drainages. This was the case of the stream macroinvertebrate communities of the two major Mongolian watersheds,

where connectivity of streams between sub-drainages is an important element structuring their communities. Considering differences in the communities' guild structure, hydrological connectivity and different magnitudes of upcoming impacts of climate change between the two watersheds, respective stream communities will be affected differently. The hitherto different communities will witness an increasing differentiation and divergent adaptations for the upcoming changes. Accordingly, in an increasing awareness to protect Mongolia's nature, our results encourage adapting conservation planning and management strategies specifically by watershed." (Authors) The taxa list includes *Lestes*, *Ophiogomphus*, and *Leucorrhinia*.] Address: Maasri, A., The Academy of Natural Sciences of Drexel University, 1900 Ben Franklin Parkway, Philadelphia, PA 19103-1195, USA. 11681. Maltchik, L.; Schmidt Dalzochio, M.; Stenert, C.; Rolon, A.S. (2012): Diversity and distribution of aquatic insects in Southern Brazil wetlands: implications for biodiversity conservation in a Neotropical region. *Rev. Biol. Trop.* 60(1): 273-289. (in English) ["The selection of priority areas is an enormous challenge for biodiversity conservation. Some biogeographic methods have been used to identify the priority areas to conservation, and panbiogeography is one of them. This study aimed at the utilization of panbiogeographic tools, to identify the distribution patterns of aquatic insect genera, in wetland systems of an extensive area in the Neotropical region (~280 000km²), and to compare the distribution of the biogeographic units identified by the aquatic insects, with the conservation units of Southern Brazil. We analyzed the distribution pattern of 82 genera distributed in four orders of aquatic insects (Diptera, Odonata, Ephemeroptera and Trichoptera) in Southern Brazil wetlands. Therefore, 32 biogeographic nodes corresponded to the priority areas for conservation of the aquatic

insect diversity. Among this total, 13 were located in the Atlantic Rainforest, 16 in the Pampa and three amongst both biomes. The distribution of nodes showed that only 15% of the dispersion centers of insects were inserted in conservation units. The four priority areas pointed by node cluster criterion must be considered in further inclusions of areas for biodiversity conservation in Southern Brazil wetlands, since such areas present species from different ancestral biota. The inclusion of such areas into the conservation units would be a strong way to conserve the aquatic biodiversity in this region." (Authors)] Address: Maltchik, L., Lab. 11683. Martens, A.; Grabow, K.; Radkowsch, A. (2012): Ganzjährige Flugzeit von *Ischnura elegans* in Mitteleuropa durch Nutzung von Tropengewächshäusern (Odonata: Coenagrionidae). *Libellula* 31(1/2): 1-6. (in German, with English summary) ["In the water-lily house of the Botanical Garden of the KIT in Karlsruhe, Germany, adults of *I. elegans* were recorded several times between November 2010 and mid-January 2011, and on 13-i-2011 an egg clutch and several larvae. In the heated greenhouse of another Botanical Garden in Karlsruhe situated next to the palace of Karlsruhe, a female *I. elegans* emerged on 15-i-2012. Heated greenhouses with pools offer a good opportunity for year-round development in odonates. With open windows and gardening activities of the staff a good exchange with the free-living population is given. *Ischnura elegans* seems to be the only odonate species north of the Alps being able to survive under indoor conditions; this ability offers the opportunity for a habitat change, a continuous development and a year-round flight season of this species." (Authors)] Address: Martens, A., Biologie, Pädagogische Hochschule Karlsruhe, Bismarckstraße 10, D-76133 Karlsruhe, Germany. E-mail: martens@ph-karlsruhe.de

11684. Martin, S.; Bertaux, A.; Le Ber, F.; Maillard, E.; Imfeld, G. (2012): Seasonal changes of macroinvertebrate communities in a stormwater wetland collecting pesticide runoff from a vineyard catchment (Alsace, France). *Archives of Environmental Contamination and Toxicology* 62(1): 29-41. (in English) ["Agricultural land use may influence macroinvertebrate communities by way of pesticide contamination associated with agricultural runoff. However, information about the relation between runoff-related pesticides and communities of benthic macroinvertebrates (including not further de-

tailed Odonata) in stormwater wetland that receive agricultural runoff does not currently exist. Here we show changes in macroinvertebrate communities of a stormwater wetland that collects pesticide-contaminated runoff from a vineyard catchment. 16 runoff-associated pesticides, including the insecticide flufenoxuron, were continuously quantified at the inlet of the stormwater wetland from April to September (period of pesticide application). In parallel, benthic macroinvertebrate communities, pesticide concentrations, and physicochemical parameters in the wetland were assessed twice a month. Twenty-eight contaminated runoffs ranging from 1.1 to 114 m³ entered the wetland during the study period. Flufenoxuron concentrations in runoff-suspended solids ranged from 1.5 to 18.5 µg kg⁻¹ and reached 6 µg kg⁻¹ in the wetland sediments. However, flufenoxuron could not be detected in water. The density, diversity, and abundance of macroinvertebrates largely varied over time. Redundancy and formal concept analyses showed that concentrations of flufenoxuron, vegetation cover, and flow conditions significantly determine the community structures of stormwater wetland macroinvertebrates. This study shows that flow conditions, vegetation cover, and runoff-related pesticides jointly affect communities of benthic macroinvertebrates in stormwater wetlands." (Authors)] Address: Imfeld, G., Laboratory of Hydrology and Geochemistry of Strasbourg, Univ. of Strasbourg/ENGEES, UMR 7515 CNRS 1, rue Blessig, 67084 Strasbourg, France. E-mail: imfeld@unistra.fr

11685. Martínez-Sanz, C.; Cenzano, C.S.S.; Fernández-Aláez, M.; García-Criado, F. (2012): Relative contribution of small mountain ponds to regional richness of littoral macroinvertebrates and the implications for conservation. *Aquatic Conservation: Marine and Freshwater Ecosystems* 22(2): 155-164. (in English) ["Biodiversity is a central concept in conservation programme design. Until recently, ponds were neglected habitats probably owing to their small size and to the ignorance of their real conservation value. The classical theory of species-area relationship (SAR) might apparently support such a view by predicting low richness values in small habitat patches. SAR theory does not take into account the fact that groups of small habitat patches can significantly contribute to regional richness, regardless of their overall small area. This work intends to contribute to the SLOSS (single large or several small) debate with data on littoral macroinvertebrates from mountain ponds. Do groups of small ponds support communities with higher biodiversity than a single large lake? Littoral macroinvertebrate richness, both local and regional, were measured in 17 ponds and one large lake from Sanabria Natural Park (NW Spain). In order to guarantee valid comparisons among systems, observed and estimated richness, as well as rarefaction methods were used. Although local richness in the lake was much higher than in any single pond, regional richness of ponds widely exceeded the value measured in the lake regardless of their small overall area. Six to seven ponds were enough to obtain an accumulated average richness equivalent to that in the lake. This pattern may be caused partly by increased habitat heterogeneity as proposed by the niche theory. Metacommunity theory might help to explain the high regional richness measured in the group of ponds in the study area. Whatever the explanation, it is evident that groups of mountain ponds strongly contribute to regional richness, a conclusion that should be taken into account by management programmes. There is a gap in this re-

spect in European legislation (the EC Habitats Directive and Water Framework Directive), which fails to include groups of ponds as an additional habitat category." (Authors) The following taxa have been listed from these ponds, but their identification remains unclear because they are associated with running waters: *Coenagrion/Ischnura*, *Erythromma lindenii*, *Enallagma*, *Lestes*, *Boyeria irene*, *Cordulegaster*, *Gomphus*, *Onychogomphus* cf. *forcipatus*, and *Sympetrum*.] Address: Martínez-Sanz, C., Area of Ecol., Fac. 11688. Mickovic, B.; Lenhardt, M.; Đikanovic, V.; Skoric, S.; Strelnikova, A. (2012): Diet of juvenile sterlets (*Acipenser ruthenus* Linnaeus 1758) from the Danube river by Belgrade. *BALWOIS 2012 – Ohrid, Republic of Macedonia – 28 May, 2 June 2012*: 4 pp. (in English) [Serbia; "...stomach content in juvenile sterlets are presented. The fishes were collected during the period June – November 2003, at four sampling sites along the course of the Danube River through the Belgrade Region. A total of 178 fish of 0+ and 1+ age were examined. ... 37 species from 12 macrozoobenthic-groups have been found." In August, the diet included one specimen of *Gomphus* sp. "In general, the range of food items taken indicates that sterlet in Danube is a generalized invertebrate predator, which probably takes food items according to their abundance and seasonal occurrence." (Authors)] Address: Mickovic, B., Institute for multidisciplinary research, University of Belgrade, Belgrade, Serbia. E-mail: baneklej@imsi.rs

11689. Moisan, P.; Labandeira, C.C.; Matushkina, N.A.; Wappler, T.; Voigt, S.; Kerp, H. (2012): Lycopsid-arthro-

pod associations and odonatopteran oviposition on Triassic herbaceous Isoetites. *Palaeogeography, Palaeoclimatology, Palaeoecology* 344–345: 6-15. (in English) ["Associations between lycopsid and herbivorous arthropods are rare in the fossil record and equally sparse among the three surviving lineages of Lycopodiaceae, Selaginellaceae and Isoëtaceae. However, from the Middle–Upper Triassic Madygen Formation of southwestern Kyrgyzstan, we describe the first association between an isoetalean host, Isoetites (a quillwort), and a pattern of elliptical egg insertion scars that altered the host's live plant tissues. This ovipositional damage, in some cases deployed in a stereotypical zigzag pattern, was most likely caused by small damselfly-like insects from the extinct suborder Archizygoptera of the order Odonoptera (dragonflies). If this identification is correct, it indicates considerable behavioral stasis of dragonflies extending deep into the Mesozoic. Our detection of lycopsid ovipositional damage adds to the list of major plant hosts from the preangiospermous Mesozoic that were resources for host use by egg-laying dragonflies, particularly horsetails, ferns, and seed plants that included conifers, peltasperms, corystosperms, ginkgophytes, bennettitaleans and probably cycads. Highlights: We describe the first record of oviposition on lycopsids. This ovipositional damage was likely caused by small damselfly-like insects. Lycopsids are the least herbivorized group of vascular plants in time and space." 11691. Müller, O.; Schiel, H.-J. (2012): Description of the final instar larva of *Rhionaeschna elsia* (Calvert, 1952) (Odonata: Aeshnidae). *Libellula Supplement* 12: 133-142. (in English, with German summary) ["The final instar larva of *Rhionaeschna elsia*, a species endemic to the Coastal desert of Peru, is described and depicted for the first time and compared with the last larval instars /exuviae of the closely related species of the 'Neureclipta group'. Whereas the prementum is very similar in all five species, exuviae of *R. elsia* can be clearly distinguished from those of *R. absoluta*, *R. bonariensis* and *R. diffinis* by its comparatively long cerci and the very short lateral spines on segments 6 to 9. Especially, the lateral spine on segment 6 is significantly shorter than that of the other species and was even missing completely in two of the six exuviae investigated. In both features *R. elsia* is very similar to *R. galapagoensis*, as described by Needham (1904)." (Authors)] Address: Müller, O., Birkenweg 6d, 15306 Lin-

dendorf-Libbenichen, Germany. E-mail: mueller.ole@googlegmail.com

11692. Nation, J.L. (2012): Review: Paulson, Dennis. 2011. Dragonflies and Damselflies of the East. Princeton University Press, Princeton, NJ, USA. 538 pp. Paperback, ISBN 978-0-691-12283-0 (also available in hardback). \$29.95 (pbk). Florida Entomologist 95(2): 532. (in English) [Verbatim: With publication of Dragonflies and Damselflies of the East and the previously published Dragonflies and Damselflies of the West (2009), Dennis Paulson has made available the first comprehensive field guides to all the Odonata in the United States and Canada. One of the author's goals with these two volumes is to make it possible to "identify any of the 461 species of dragonflies and damselflies now known to occur in the United States and Canada." A second goal is to provide natural history about each species to stimulate both amateur and professional interest, perhaps making knowledge and pleasure in Odonata rival that of butterflies and birds. The present book is beautifully illustrated with colour photographs of the male and female of each species (no female photo available for a few species) and a colour coded map of the US and Canada where the species is found. The entire book is printed on acid-free glossy paper. The first 47 pages of the book give general background about dragonflies and damselflies, general natural history, colours, comments about common names that are only recently available for many of the species, how to collect and preserve odonates, threats to the conservation of odonates, and a couple of pages explaining the general nature of the species accounts given with each species. The section on how to collect, label, preserve, and store odonates will be valuable to young collectors, as is the section of labeled illustrations of the morphological and anatomical features needed to identify species in this introductory section. The photographer is identified with each photo, and where no name is given, the photo is by Paulson himself. In the 14 cm × 21.5 cm-format of the paperback volume that I have, the male and female color pictures with accompanying text typically comprise about 1 page (although a new species does not necessarily start at the top of each page). In a green colour bar across the page above the text about each species Paulson gives the common name, scientific name, total body length in mm and hindwing length in mm. Below the bar is the text including Description, Identification, Natural history, Habitat, Flight Season, Distribution (in addition to the colour coded map) and occasionally a comment about the species or former common name. Illustrations and text on damselflies, the Zygoptera, begin on page 49 (and continue to page 164) with damselflies organized into the Broad-winged Damsel family, the Spreadwing family, and the Pond Damsel family. Pages 165 to 517 comprise dragonflies, the Anisoptera, organized by families as follows: Petaltails, Darners, Clubtails, Spiketails, Cruisers, Emeralds, and Skimmers. On page 519 Paulson lists 4 species now found in the west that were not known there in his 2009 book on western dragonflies and damselflies. There is a list of books, some technical publications, and websites for Odonata on pages 521-522, a glossary on pages 523-525, and finally an index listing common and scientific names and page or pages where the species is described or illustrated. The photos are numbered, but apparently only indicate sequential position in the book. Dragonflies and Damselflies of the East is a valuable book for anyone interested in insect natu-

ral history and conservation. The price is fantastic for such a thorough and beautiful book. I recommend this book for every professional and amateur entomologist as a wonderful addition to a personal library; for collectors of odonates, it is indispensable.] Address: Nation, J.L., Univ. of Florida, Gainesville, USA. 11693. Nel, A.; Ilger, J.-M.; Brauckmann, C.; Prokop, J. (2012): *Bechala sommeri* Ilger & Brauckmann, 2012 enlightens the Namurian griffenfly diversity (Insecta: Odonoptera: Bechalidae). *Insect Systematics & Evolution* 43(2): 161-169. (in English) ["*B. sommeri* Ilger, the type species of the type genus of the early Late Carboniferous (Namurian) family Bechalidae Ilger & Brauckmann, 2012, is redescribed. It does not belong to the order Megaseoptera as previously proposed. The taxon is clearly attributable to Odonoptera for the typical venation characters as CuA separating from MP obliquely, a true arculus with concave RP and convex MA emerging from a composite vein R+MA, short ScP, and presence of convex intercalaries IR2 and IR1 between the main branches of RP3/4, RP2 and RP1. We transfer this taxon with the monospecific family Bechalidae to Odonoptera. A new diagnosis is given for Bechalidae and its type genus *Bechala*. Furthermore, the presence of an oblique subnodal crossvein very far from the ending of ScP and close to the base of RP2 confirms the hypothesis that the subnodus is a structure originally independent of the nodus with a different function in relation to wing tracheation. The Bechalidae are included in a clade (Meganeuridae-Sinierasipteridae-Bechalidae-Lapeyridae-Nodialata), in contrast to a sister group relationships between the two clades Meganisoptera (=Namurotypidae-Paralogidae-Kargalotypidae-Kohlwaldiidae-Meganeuridae) and Odonatoclada (=Lapeyridae-Nodialata), while the potential relationships between the Campylopteridae and the Lapeyridae and Nodialata are rejected. *Bechala* represents a 'damselfly-like' ecological niche in the Namurian, showing the high diversity of the earliest known Odonoptera, strongly suggesting an Early Carboniferous, if not Late Devonian age for this pterygote clade." 11696. Nilsson-Örtman, V.; Stoks, R.; De Block, M.; Johansson, F. (2012): Generalists and specialists along a latitudinal transect: patterns of thermal adaptation in six species of damselflies. *Ecology* 93(6): 1340-1352.

(in English) ["Tropical organisms colonizing temperate environments face reduced average temperatures and dramatic thermal fluctuations. Theoretical models postulate that thermal specialization should be favoured either when little environmental variation is experienced within generations or when among-generation variation is small relative to within-generation variation. To test these predictions, we study six temperate species of damselflies differing in latitudinal distribution. We developed a computer model simulating how organisms experience environmental variation (accounting for diapause and voltinism) and performed a laboratory experiment assaying thermal sensitivities of growth rates. The computer model showed opposing latitudinal trends in among- and within-generation thermal variability: within-generation thermal variability decreased towards higher latitudes, whereas relative levels of among-generation thermal variability peaked at mid-latitudes (where a shift in voltinism occurred). The growth experiment showed that low-latitude species were more thermally generalized than mid- and high-latitude species, supporting the prediction that generalists are favoured under high levels of within-generation variation. Northern species had steeper, near-exponential reaction norms suggestive of thermal specialization. However, they had strikingly high thermal optima and grew very slowly over most of the thermal range they are expected to experience in the field. This observation is at present difficult to explain. These results highlight the importance of considering interactions between life-history and environmental variation when deriving expectations of thermal adaptation." 11698. O'Donnell, E. (2012): Site guide: Cape Clear Island, West Cork, Ireland. *Atropos* 46: 15-25. (in English) [The site description includes a checklist of 11 Odonata species] Address: O'Donnell, E., Knockea, Lyre, Clonakilty, West Cork, Ireland. E-mail: Bobolink300@gmail.com

11699. Olberg, R.M. (2012): Visual control of prey-capture flight in dragonflies. *Current Opinion in Neurobiology* 22(2): 267-271. (in English) ["Interacting with a moving object poses a computational problem for an animal's nervous system. This problem has been elegantly solved by the dragonfly, a formidable visual predator on

fly. The dragonfly computes an interception flight trajectory and steers to maintain it during its prey-pursuit flight. This review summarizes current knowledge about pursuit behaviour and neurons thought to control interception in the dragonfly. When understood, this system has the potential for explaining how a small group of neurons can control complex interactions with moving objects. Highlights: *To catch prey the dragonfly computes an interception flight trajectory. *Target-Selective Descending Neurons (TSDNs) control prey capture flights. *Constant-angle strategies underlie interception of moving objects. *Proportional navigation results in a constant-bearing interception strategy. *This model illustrates control of complex behaviour by a small number of neurons." (Author)] Address: Olberg, R.M., Dept of Biological Sciences, Union College, 807 Union Street, Schenectady, NY 12308, USA. E-mail: olbergr@union.edu

11700. Orwa, P.O.; Raburu, P.; Njiru, J.; Okeyo-Owuor, J.B. (2012): Human Influence on macroinvertebrate community structure within Nyando wetlands, Kenya. *International Journal of Aquatic Science* 3(2): 21 pp. (in English) ["The study set out to investigate the changes in macroinvertebrate community along different disturbance gradients within Nyando wetlands with an aim of determining how macroinvertebrates in Nyando wetlands respond to human disturbances. Triplicate macroinvertebrate samples were collected monthly from October 2010 to April 2011 using a scoop net (500 µm mesh size) in three transects. They were sorted live, counted and identified to genus level. Water samples for total phosphorus and total nitrogen were collected and analyzed using standard methods. Physico-chemical parameters were taken in-situ using electronic meters. Macroinvertebrates were analyzed for richness, diversity, dominance, and abundance. The abundance and diversity was correlated with physico-chemical parameters using Pearson correlation analysis. Kruskal-Wallis test was used to test spatial differences in macroinvertebrate community and repeated measures ANOVA to test variation in water quality parameters. A total of 45 genera were identified with hemipterans dominating. The statistical analysis revealed significant spatiotemporal differences in macroinvertebrate abundance and water quality parameters. Macroinvertebrate abundance showed a strong negative correlation with nutrient levels. Sites with higher disturbance recorded lower richness and abundance compared to the less disturbed sites. The results indicated that macroinvertebrates in Nyando wetlands respond to human disturbance and can be used to monitor ecological integrity of the wetland." (Authors) Taxa identification (including Odonata) was made using two keys not specified for African taxa.] Address: Orwa, P.O., Department of Fisheries and Aquatic Sciences, Chepkoilel University College, Eldoret, Kenya. 11703. Pinto, N.S.; Juen, L.; Cabette, H.S.R.; De Marco, P. (2012): Fluctuating asymmetry and wing size of *Argia tinctipennis* Selys (Zygoptera: Coenagrionidae) in relation to riparian forest preservation status. Neotropical entomology 41(3): 178-185. (in English) ["Effects of riparian vegetation removal on body size and wing fluctuating asymmetry (FA) of *A. tinctipennis* studied in the River Suiá-Miçú basin, which is part of the Xingu basin in Brazilian Amazonia. A total of 70 specimens (n=33 from preserved and n=37 from degraded areas) was measured. Five wing measures of each wing (totalizing ten measured characters) were taken. Preserved and degraded points presented non-overlapped variations of a Habitat Integrity Index, supporting the environmental differentiation between these two categories. FA increases in degraded areas approximately four times for the width between the nodus and proximal portion of the pterostigma of forewings (FW), two times for the width of the wing in the region of nodus of FW, and approximately 1.7 times for the number of postnodal cells of FW. The increase is almost five times for the width between the nodus and the proximal portion of the pterostigma of hind wings (HW), three times for the number of postnodal cells of HW, and approximately 1.6 times the width between quadrangle and nodus of HW. Individuals of preserved sites were nearly 3.3% larger than for degraded sites, based on mean hind wing length. Our results supports that the development of *A. tinctipennis* in degraded areas is affected by riparian vegetation removal and may reflect in wing FA variations. Consequently, these FA measures may be a useful tool for bioassessment using Odonata insects as a model." (Authors)] Address: Pinto, A.P., Museu de Zoologia, Universidade de São Paulo, Av. Nazaré 481, Ipiranga 04263-000 São Paulo-SP, Brazil. E-mail: odonataangelo@hotmail.com

11704. Pokhrel, L.R.; Dubey, B. (2012): Potential impact of low-concentration silver nanoparticles on predator-prey interactions between predatory dragonfly nymphs and *Daphnia magna* as a prey. Environ. Sci. Technol. 46(14): 7755-7762. (in English) ["This study investigated the potential impacts of low-concentration citrate-coated silver nanoparticles (citrate-nAg; 2 µg L⁻¹ as total Ag) on the interactions of *Daphnia magna* Straus (as a prey) with the predatory *Anax junius* nymph using the behavioral, survival, and reproductive endpoints. Four different toxicity bioassays were evaluated: (i) horizontal migration; (ii) vertical migration; (iii) 48-h survival; and (iv) 21-day reproduction; using four different treatment combinations: (i) *Daphnia* + citrate-nAg; (ii) *Daphnia* +

Predator; (iii) *Daphnia* + citrate-nAg + Predator; and (iv) *Daphnia* only (control). *Daphnia* avoided the predators using the horizontal and vertical movements, indicating that *Daphnia* might have perceived significant risk of predation. However, with citrate-nAg + predator treatment *Daphnia* response did not differ from control in the vertical migration test, suggesting that *Daphnia* were unable to detect the presence of predator with citrate-nAg treatment and this may have potential implication on daphnids population structure owing to predation risk. The 48-h survival test showed a significant mortality of *Daphnia* individuals in the presence of predators, with or without citrate-nAg, in the test environment. Average reproduction of daphnids increased by 185% with low-concentration citrate-nAg treatment alone, but was severely compromised in the presence of predators (decreased by 91.3%). *Daphnia* reproduction was slightly enhanced by ca. 128% with citrate-nAg + predator treatment. Potential mechanisms of these differential effects of low-concentration citrate-nAg, with or without predators, are discussed. Because silver dissolution was minimal, the observed toxicity could not be explained by dissolved Ag alone. These findings offer novel insights into how exposure to low-concentration silver nanoparticles could influence predator-prey interactions in the fresh water systems." 11705. Pryke, J.S.; Samways, M.J. (2012): Conservation management of complex natural forest and plantation edge effects. Landscape Ecology 27(1): 73-85. (in English) ["Timber plantation forestry is a major threat to indigenous grassland biodiversity, with ecological networks (ENs) currently being used to mitigate this threat. Being composed mostly of linear corridors, ENs create more edge than would occur naturally. To determine the minimum width of corridors for maximising biodiversity conservation, we need first to establish the extent of edge effects from plantation blocks into corridors. We compared arthropod diversity along transects that ran from within plantation blocks into grassland corridors. We also studied the edge effects of natural forest adjacent to natural grasslands within ENs. Sites in grasslands of neighbouring protected areas acted as natural reference sites against which the biodiversity of the EN transects were compared. Two types of exotic plantation trees and various tree age classes were studied. We found a 32 m edge zone from plantation blocks into grassland corridors. Few significant edge effects from plantation blocks occurred at greater distances than this, which suggested that grassland corridors with a width <64 m are essentially all edge. However, and importantly, this situation was complex, as different arthropod taxonomic groups responded differently to edges of plantation blocks and natural forest patches. Natural forest supported many additional species, not just within the forest, but also in associated grassland corridors. This means that maintaining natural forest imbedded within the ENs will protect both indigenous grassland and indigenous forest species as well as help maintain biodiversity across this timber production landscape. ... Dragonflies responded in a similar way to butterflies, with an increase in species richness between the wooded areas and the open grassland corridors, although no edge effect was noticeable for either the plantation blocks or natural forest patches." (Authors)] Address: Samways, M.J., Dept Entomol. &

Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

11706. Raebel, E.M.; Merckx, T.; Feber, R.E.; Riordan, P.; Thompson, D.J.; Macdonald, D.W. (2012): Multi-scale effects of farmland management on dragonfly and damselfly assemblages of farmland ponds. *Agriculture, Ecosystems & Environment* 161: 80-87. (in English) ["Agricultural intensification has contributed to severe declines in odonate (dragonfly and damselfly) populations. Odonates require healthy waterbodies for their larval stages and resource-rich terrestrial landscapes as adults. As such, farmland management at both local and larger landscape scales may be needed to reverse population declines. We sampled odonate adults and exuviae from lowland farmland ponds in England, to investigate relationships between odonate species richness and surrounding land-use. The more mobile dragonflies (Anisoptera) were influenced most strongly by landscape variables at the largest scale (i.e. 1600 m radius), while less mobile damselflies (Zygoptera) were affected by variables at more local scales (i.e. 100/400 m radii). A greater number of landscape variables affected exuvial species richness compared to adult species richness. Exuvial species richness was higher when 2 m wide cross-compliance buffer strips around ponds were present. However, no ponds in the study had buffer strips that were established through England's basic agri-environment scheme (Entry Level Scheme: ELS) agreements, and we observed a negative relationship between ELS area and exuvial species richness. Exuvial species richness increased with the amount of water, but not the number of ponds, in the landscape surrounding a focal pond. The observed odonate responses to local and surrounding land-use lend support to the development of agri-environment scheme policies that encourage landscape-scale, as well as local, scheme implementation and management. We predict that both landscape-scale and quality-targeted management of farmland ponds would benefit odonates, irrespective of mobility level and life-stage." 11707. Reels, G.T. (2012): The curious case of the cannibal coenagrionid. *Insect news* 4: 13-14. (in English) [Verbatim: It has often struck me that members of the coenagrionid genus *Ceriagrion* appear to be unusually voracious predators of other zygopterans. However, an observation that I made two years ago indicated that one species, at least, is even capable of reckless acts of cannibalism. At ca 1030h on 25 July 2008 I was walking along a small stream at Luk Keng. N.T., Hong Kong (altitude ca. 20 m a.s.l.) when I noticed a male *Ceriagrion auranticum* grappling with a mature female of the same species. The male had seized the female's thorax just above the wing bases with his mandibles. At first I assumed that this was simply a clumsy mating attempt, particularly since the female was making little obvious effort to free herself. However, in the ensuing five minutes, the male, rather than letting go and trying to mate, proceeded to munch his way up the female's thorax, until he reached the pronotum. The entangled pair made several short flights during this period, possibly because I was disturbing them while trying to photograph the action, or maybe because the female, hav-

ing realised she was not hosting an amorous suitor, was belatedly attempting to escape. The male then spent some time chewing through the female's head attachment until her head fell off. Then he dragged the body to another perch to devour the thorax. Gruesome stuff.] Address: Reels, G., H-3-30 Fairview Park, Yuen Long, Hong Kong. E-mail address: gtreels@gmail.com

11708. Richardson, A. (2012): Assessment of locations of refugia for ancient and relictual invertebrate fauna within the proposed ENGO forest conservation areas. IVG FC Report 3A Ancient Fauna Refugia. A report for the Tasmanian Forest Agreement. 11711. Sadeghi, S.; Kiany, M. (2012): Wing shape variation in *Calopteryx splendens* (Harris) populations in the Zagros mountains, Iran (Zygoptera: Calopterygidae). *Odonatologica* 41(2): 123-134. (in English) ["*C. splendens* is found in most of Europe, large parts of Siberia and much of west and central Asia. There is great variation among males in wing coloration. Traditionally, sub-specific taxa have been distinguished by the size and position of the pigmented wing spot and by mating behaviour. About a dozen subspecies have been recognized, all of which are more or less geographically confined, but often with overlapping ranges and strong variation in wing spot size. Here, a geometric morphometrics is used to quantify morphological data and analyze the wing shape independent of wing spot size in 6 Zagros mountain populations, traditionally known as *C. s. intermedia*, based on wing spot size. 19 different points were digitized as landmarks on the left forewings of males, using GPA (Generalized Procrustes Analysis). The results reveal significant wing shape differences

between all populations except Markazi and Lorestan on the one hand and Fasa and Kazeroon on the other hand. These observations confirm the role of geographic (here Dena, Oshtoran Kooh and Zard Kooh mountains of more than 4000 m altitude) and climatic barriers in population isolation, but also suggest that wing spot similarity does not necessarily reflect the full genetic similarity and evolutionary grouping of populations. Based on the wing shape analyzed, *C. splendens* is split into 2 distinguishable population groups in central and southern Zagros with 2 different gene pools, even though they show the same wing spot size, i.e., a long-term isolation among the groups investigated has occurred and the wing spot is not an infallible character for identifying *C. splendens* subspecies." 11712. Saha, N.; Aditya, G.; Banerjee, S.; Saha, G.K. (2012): Predation potential of odonates on mosquito larvae: implications for biological control. *Biological Control* 63(1): 1-8. (in English) ["Predation potential of the larval odonates *Ceriatrigon coromandelianum* and *Brachydiplax chalybea* on the II and IV instar larvae of *Culex quinquefasciatus* was evaluated under simulated natural conditions in the laboratory. A type II functional response was exhibited by the odonates, with the attack rate and handling time differing significantly between prey sizes for *C. coromandelianum*. The per capita prey consumption varied between vegetated and open habitat conditions and between the days as reflected through the Clearance Rate (CR). Results of univariate ANOVA revealed that prey consumption varied significantly ($P < 0.05$) with the prey and predator densities for both the odonate predators, whereas habitat structure had significant effects only in case of *B. chalybea*. Thus, the use of larvae of *C. coromandelianum* and *B. chalybea* can facilitate conservation and biological control simultaneously under suitable habitat conditions." 11713. Sakai, M.; Natuhara, Y.; Imanishi, A.; Imai, K.; Kato, M. (2012): Indirect effects of excessive deer browsing through understory vegetation on stream insect assemblages. *Population ecology* 54(1): 65-74. (in English) ["Over the past decade, the abundance of sika deer has rapidly increased around Japan. Previous studies have showed overabundance of deer causes drastic reduction of forest understory vegetation, leading excessive soil erosion. However, no study has investigated the effects of excessive deer browsing on aquatic insect assemblages via sediment runoff. These effects are important to understand whether the terrestrial alteration by deer influences aquatic ecosystems. In a primary deciduous forest catchment in Ashiu, Kyoto, a deer exclusion fence has been in place since 2006. We compared forest floor cover, overland flow, stream environment, and aquatic insect assemblages in first-order streams and catchments inside and outside of the deer-exclosure from May-2008 to April-2009. The floor inside the deer-exclosure catchment was covered by lush understory vegetation, whereas outside was almost bare. The overland flow runoff rate at midslope and the dominance of fine sediment deposition in the streambed were higher outside than inside. Among aquatic insects, burrowers, which are tolerant against

fine sediment deposition, were significantly more abundant outside than inside, whereas clingers exhibited the opposite patterns. Collector-gatherers, which feed on fine detritus, were significantly more abundant outside than inside. Meanwhile, filterers were more abundant inside. The Simpson's diversity index of the aquatic insect assemblages was higher inside than outside. These results suggest that the demise of understory vegetation due to excessive deer browsing has indirectly caused changes in the aquatic insect assemblages of this catchment via increased sediment runoff and subsequent sandy sedimentation of the streambed." (Authors) Richness and abundance of aquatic insect during the course of the study resulted in Odonata as follows: Exclosure catchment (without deer): 7 taxa, 13 specimens; Control catchment (with deer): 8 taxa 39, specimens] Address: Sakai, M., Graduate School of Global Environmental Studies, Kyoto University, Japan

11714. Samraoui, F.; Nedjah, R.; Bouchecker, A.; Alfahhan, A.H.; Samraoui, B. (2012): Patterns of resource partitioning by nesting herons and ibis: How are odonata exploited? *Comptes Rendus Biologies* 335: 310-317. (in English, with French summary) ["Herons and ibis are colonially nesting waders which, owing to their number, mobility and trophic role as top predators, play a key role in aquatic ecosystems. They are also good biological models to investigate interspecific competition between sympatric species and predation; two processes which structure ecological communities. Odonata are also numerous, diverse, mobile and can play an important role in aquatic ecosystems by serving as prey for herons and ibis. A relationship between prey size and bird predator has been observed in Numidia wetlands (NE Algeria) after analyzing food boluses regurgitated by six species of birds (Purple Heron, Black-crowned Night Heron, Glossy Ibis, Little Egret, Squacco Heron and Cattle Egret) during the breeding period, which also shows a temporal gradient for the six species. Both the Levins index and preliminary multivariate analysis of the Odonata as prey fed to nestling herons and ibis, indicated a high degree of resource overlap. However, a distinction of prey based on taxonomy (sub-order and family) and developmental stage (larvae or adults) reveals a clear size dichotomy with large-sized predators (Purple Heron, Black-crowned Night Heron and Glossy Ibis) preying on large preys like Aeshnids and Libellulids and small-sized predators feeding mainly on small prey like Zygoptera. Overall, the resource utilization suggests a pattern of resource segregation by coexisting nesting herons and ibis based on the timing of reproduction, prey types, prey size and foraging microhabitats." (Authors)] Address: Samraoui, B., Laboratoire de Recherche des Zones Humides, Université d'Annaba, 4 rue Hassi-Beida, Annaba, Algeria. E-mail: bsamraoui@yahoo.fr

11715. Schiel, F.-J.; Buchwald, R. (2012): Parasitierung von *Lestes dryas* durch die Wassermilbe *Arrenurus papillator* in einer mittellitalienischen Karst-Hochebene (Odonata: Lestidae; Hydrachnidia). *Libellula* 31(1/2): 31-39. (in German, with English summary) ["Infestation of *Lestes dryas* by the water mite *Arrenurus papillator* in a karst high plain in central Italy (Odonata: Lestidae; Hydrachnidia) – A population of *L. dryas* was investigated between 06-vii-2009 and 11-vii-2009 in the Pian Piccolo di Castelluccio, Perugia province, Umbria, Italy. More than 49 % of the captured imagines (1,014 of 2,058) were infested by water mites. The degree of infestation

was 52 % of males, and 33 % of females. The proportion of infested individuals decreased during the six days' survey. The mite-load per adult ranged from one to 36 larval mites with a median value of nine mites ($n = 165$). The decreasing infestation rate in the observation period suggests an infection during emergence. The mite larvae, attached to both *L. dryas* and the syntopic *Sympetrum flaveolum*, were identified as *Arrenurus papillator*." 11716. Schmidt, E.G. (2012): Die ökologische Nische von *Sympetrum depressiusculum* in Nordwestdeutschland (Odonata: Libellulidae). *Libellula Supplement* 12: 161-176. (in German, with English summary) ["*S. depressiusculum* is a Southern Continental species of lowland river marshes and mires. The natural distribution area reaches Germany in the pre-alpine region and the Upper Rhine valley. Oviposition takes place in marsh ponds and mires, which are dry during winter and flooded late in spring, usually during May, when the sun is high. Then thermic conditions are best for development of eggs and larvae and also structure and food supply fit well. In other parts of Germany, similar conditions are simulated by breeding of carp, another Southern Continental species with a similar preference of micro-habitat for breeding. Therefore, at these carp breeding ponds *S. depressiusculum* is established far north of its natural margin of distribution. In northwestern Germany the warm Atlantic climate is rather unsuitable, and the species is dependent there on carp breeding ponds. For hunting and resting, the species prefers marshland with tall herb Vegetation and similar plants surrounding the breeding ponds. Here, the males search for females late in the morning and rest in tandem position until early noon. Then copulation takes place near the water, followed by egg-laying in tandem position over shallow water between the low bank weeds. Egg-laying can also be seen at unsuitable ponds (e.g. with permanent water) with similar bank Vegetation. Hence, the establishment of the species can only be proved by emergence, not solely by reproductive activities. The carp breeding ponds in northwestern Germany are stocked until autumn. Therefore egg-laying by *S. depressiusculum* on dry ground, as in its primary natural range, is unusual. These carp breeding ponds are also valuable for nature conservation because of rare Vegetation and birds. Carp breeding ponds are therefore an example for a classical management form that casually serves for nature conservation. Actually carp breeding in northwestern Germany cannot survive the cut-throat competition with cheap imports from climatically favoured countries as, e.g., Hungary. So nature conservation must help." 11721. Seehausen, M. (2012): *Ischnura ramburii* mit Wasserpflanzen nach Europa importiert (Odonata: Coenagrionidae). *Libellula* 31(1/2): 7-13. (in German, with English summary) ["The present study describes the first European record of the American damselfly *I. ramburii* (Selys, 1850). The larva was found on aquatic

plants from a pet shop in Wiesbaden, Hesse, Germany. Identification is specified in comparison to species of the quite similar-looking European *Ischnura elegans*-Group and the differences between *Ischnura ramburii* and the Afro-Asian *Ischnura senegalensis* (Rambur, 1842) are mentioned according to circa 50 individuals of each species from the Bavarian State Collection of Zoology in Munich. The main difference is the curve at the hind margin of the pronotum: It is much broader in *I. ramburii* than in *I. senegalensis*. Specific distribution routes of the aquatic plants are still unknown because the distributor predominantly imports plants from Asia and also has a nursery for rearing in the Netherlands. But maybe he had imported plants for rearing from America containing eggs of *I. ramburii*. The exuvia and the imago are stored in the zoological collection of the Wiesbaden Museum, Hesse, Germany." (Author)] Address: Seehausen, M., Museum Wiesbaden Hessisches Landesmuseum für Kunst und Natur, Friedrich-Ebert-Allee 2, 65185 Wiesbaden, Germany. E-mail: malte.seehausen@museum-wiesbaden.de

11722. Seidl, I. (2012): Management-intervention costs for damselfly *Coenagrion mercuriale* in the Oberaargau. In: Swiss Federal Institute for Forest, Snow and Landscape Research WSL (ed) 2012: ENHANCE. Enhancing ecosystem connectivity through intervention – benefits for nature and society? Final Report. Birmensdorf, Swiss Federal Research Institute WSL, 81 pp: 79-81. (in English) ["One of the species investigated in Oberaargau that potentially benefits management-interventions is *C. mercuriale*, a focus species of Smaragd. Thanks to the Smaragd-Project and its conservation schemes, there is detailed knowledge and experience about useful protection measures. Also data is available about the cost the various measures involve. Based on the study of the conservation cost for Swiss biotopes (Ismail et al. 2007), the management-intervention costs for the damselfly have been calculated. Cost data were gathered from reports of Trägerverein SMARAGD-Gebiet Oberaargau, from the Federal office of agriculture and in an interview with a conservation consultant. Preliminary costs are: 2500 CHF per year and municipality with rivers providing a habitat for the damselfly, and 3700 CHF per year and ha riverbank (buffer zone). Furthermore, there are non-recurring cost of 1500 CHF/ha riverbank. Thanks to the Smaragd-Project and generous funding by various organisations, suitable measures have been realised." (Author)] Address: Seidl, Irmi, Swiss Federal Research Institute WSL, Zürcherstr. 111; 8903 Birmensdorf, Switzerland

11723. Seifert, L.I.; Scheu, S. (2012): Linking aquatic and terrestrial food webs – Odonata in boreal systems. *Freshwater Biology* 57(7): 1449-1457. (in English) ["(1) It is increasingly realised that aquatic and terrestrial systems are closely linked. We investigated stable isotope variations in Odonata species, putative prey and basal resources of aquatic and terrestrial systems of northern Mongolia during summer. (2) In permanent ponds, $\delta^{13}\text{C}$ values of Odonata larvae were distinctly lower than those of putative prey, suggesting that body tissue comprised largely of carbon originating from isotopically light carbon sources. Presumably, prey consumed during autumn and winter when carbon is internally recycled and/or methanotrophic bacteria form an important basal resource of the food web. In contrast, in a temporary pond, $\delta^{13}\text{C}$ values of Odonata larvae were similar to those of putative prey, indicating that their

body carbon originated mainly from prey species present. (3) Changes in $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ values between larvae and adults were species specific and reflected differential replacement of the larval isotopic signature by the terrestrial diet of adult Odonata. The replacement was more pronounced in Odonata species of permanent ponds than in those of the temporary pond, where larvae hatched later in the year. Replacement of larval carbon varied between tissues, with wings representing the larval isotopic signature whereas thoracic muscles and eggs reflected the $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ values of the terrestrial diet of adults. (4) The results suggest that because of their long larval development, Odonata species of permanent ponds carry the larval signature, which is partly replaced during their terrestrial life. Terrestrial prey forms the basis for egg production and thus the next generation of aquatic larvae. In temporary ponds, in contrast, Odonata species rely on prey from a single season, engage in a prolonged aquatic phase and hatch later, leaving less time to acquire terrestrial prey resources for offspring production. Stable isotope analysis provided important insights into the food webs of the waterbodies and their relationship to the terrestrial system. ... Odonata species included *Aeshna crenata*, *A. juncea* and *Leucorrhinia orientalis* at site 1, *A. crenata*, *A. juncea*, *Coenagrion johanssoni* and *L. orientalis* at site 2, *A. crenata* and *L. orientalis* at site 3, and *Lestes sponsa*, *Symetrum danae* and *S. flaveolum*." 11725. Sharkey, C.R. (2012): The role of polarized light in prey capture in an aquatic predator. *Frontiers in Behavioral Neuroscience*. Conference abstract. Tenth International Congress of Neuroethology, College Park, Maryland USA, 5 Aug - 10 Aug, 2012 doi: 10.3389/conf.fnbeh.2012.27.00187: (in English) ["Sensitivity to polarized light has been demonstrated, through behavioural and electrophysiological studies, to be a common component of arthropod visual systems. Amongst terrestrial insects, polarized light has been shown to influence behaviours such as navigation (Dacke et al., 2011), signalling (Sweeney et al., 2003) and the detec-

tion of water bodies (Schwind, 1991). Different areas of insect eyes have evolved specialized polarization detectors for different visual tasks. The function of polarization sensitivity (PS) in aquatic insects, however, is less clear. Whilst dragonfly adults have been shown to possess PS in the ventral region of the eye, thought to aid water and horizon detection in the terrestrial environment (Laughlin, 1976), the visual system of dragonfly larvae is less well characterized, and the potential for aquatic insect larvae to possess polarization vision was previously unknown. The central aim of this study was to discover if polarization vision in dragonfly larvae is adapted to the specific visual environment of aquatic larvae versus its future aerial adult requirements. By removing the front analyser of a liquid crystal display (LCD) monitor, the intensity contrast of displayed objects and patterns is removed from the screen and, instead, only polarized light is emitted with the normal intensity contrast of displayed objects replaced by a polarization angle "contrast". We used this system to present polarized stimuli on a polarized background with a contrasting angle of polarization. This technology, first used by Pignatelli et al. (2011), allows us to manipulate the angles of polarization presented and to present moving polarization stimuli. The angular difference between stimuli and background was varied across trials to test the minimum angular difference dragonfly (*Anax* sp.) larvae are able to detect. Animals demonstrated tracking, hunting, and prey capture behaviours when presented with a moving polarization stimulus 0.4 by 0.4cm in size. The time for which animals tracked the stimulus decreased as angular polarization contrast was reduced. Results suggest that the minimum angular discrimination lies between 26 and 22 degrees, a value much higher than that known for cuttlefish, octopus and fiddler crabs (Pignatelli et al., 2011; How et al., 2012). Parallel experiments using a similar stimulus made visible as intensity contrast rather than a polarization angle contrast, showed that animals responded decreased as intensity contrast was lowered, but animals responded more strongly to intensity than polarization contrast. These findings will be discussed in light of the animal's visual environment and visual physiology. The structure of the larval retina has also been examined, using transmission electron microscopy, to locate potential polarization sensitive cells. Microvilli of photoreceptor cells show similarities in both structure and shape to adult ventral retinal photoreceptors. However, unlike the adult ventral retina, our behavioural work shows larval polarization spectral sensitivity lies outside the UV spectral range (Laughlin, 1976). This is the first behavioural data that suggests the innate use of polarization sensitivity in prey capture." (Author)] Address: Sharkey, Camilla, Univ. Bristol, Ecology of Vision Group, Bristol, BS8 1UG, UK, cs7750@bristol.ac.uk

11726. Shi, S.-x.; Liu, Y.-z.; Chen, J.-m. (2012): Journal of Hydrodynamics, Ser. B 24(3). An experimental study of flow around a bio-inspired airfoil at Reynolds number 2.0×10^3 : 410-419. (in English) ["The fluid flow around a bio-inspired airfoil with corrugated surfaces and its smooth counterpart at chord Reynolds number $Re = 2.0 \times 10^3$ and different Angle-Of-Attack (0° , 4° , 8° and 12°) were measured by using Particle Image Velocimetry (PIV). The global characteristics of the fluid flow around two airfoils were analyzed by ensemble-averaged velocity field, distribution of reverse flow intermittency, and time-series flow visualizations. At 0° , no significant variation of the global flow patterns was recog-

nized for both configurations. The statistical results of reverse flow intermittency results demonstrated that the protruding peaks of the corrugated airfoil delay flow separation occur at 4° . At large AOAs (8° and 12°), however, the flow is massively separated in both configurations, the combination of large separation bubble above the corrugated airfoil and small recirculation zones in the upstream upper valley results in earlier separation of the flow. At $AOA=8^\circ$, the wake region behind the corrugated airfoil is considerably shortened in comparison to the smooth one, indicating a remarkable reduction of the time-mean lift and drag forces, however, at 12° , the wake region behind the corrugated one is slightly larger than that behind the smooth one. For the case of 8° and 12° , the time-series flow visualizations demonstrate the intensified vortex shedding process of the corrugated airfoil, which would give rise to enhanced dynamic loading. Due to the fact that dragonfly wing is practically flexible, it is speculated that the wing structure of a gliding dragonfly might be sophisticatedly deformed in response to the periodic loading to reduce the drag." 11727. Simonis, P.; Berthier, S. (2012): How nature produces blue color. Photonic crystals - Introduction, applications and theory. In: Alessandro Massaro (Ed.): Electrical and Electronic Engineering. Publisher: InTech, March, 2012. ISBN 978-953-51-0431-5. 344 pp: 3-24. (in English) ["Tyndall scattering has long been recognized to be responsible for blue coloration of the sky (Tyndall, 1869) and the colour of blue eyes (Mason, 1924). It appears when small particles or voids with dimensions of the order of the wavelength of blue light (about 500 nm) are present in the propagation medium. In that case, the small wavelengths of the incident white light will be scattered and the longer wavelengths will pass undisturbed through the medium. Thus, the red and yellow wavelengths are transmitted and the blue and violet colours are scattered by the composite medium, giving out a non-iridescent light blue diffusion spectrum. In this phenomenon, the particle's sizes and refractive indexes control the coloration. As shown here above, the intensity of the reflected light by such a system is inversely proportional to the 4th power of the wavelength. The amplitude of the reflected light and its angular distribution will depend on the particle's sizes. [...] Scattered blues have early been assigned to insects. The scattering occurs in the epidermal cells beneath a transparent cuticle. In the odonate order such as aeschnids, agrionids and libelluloids (*Libellula pulchella*, *Mesothemis simplicicollis*, *Enallagma cyathigerum*, *Aeshna cyanea*, *Anax walsinghami*) the bright blue diffuse coloration on their body or wings (Mason, 1926; Parker, 2000; Parker, 2005; Veron, 1973) originates from scattering centers under the cuticle. Dragonflies (Mason, 1926) and some other adult insects can also develop a waxy bloom on the surface of their cuticle. The Tyndall effect is then produced by this waxy material and coloration can be destroyed by washing it with a wax solvent (Parker 2000)." 11728. Sivaperuman, C.; Kumar Shah, S. (2012): Species diversity and abundance of Odonata in Ritchie's

Archipelago, Andaman and Nicobar islands. *Biological Forum Spl. Iss.* 4(1): 65-69. (in English) ["The Ritchie's Archipelago is a cluster of smaller islands which lie some 25-30 km east of Andaman. This study was conducted during 2008-2011. Different islands in the Ritchie's archipelago were surveyed to assess the species diversity and distribution of Odonates. Total of thirty one species belong to 8 families were recorded during the study period. Highest number of species was observed from the family Libellulidae. The diversity index was varied in different islands. The distribution patterns and diversity of dragonflies are discussed in this paper. An extensive Odonatological survey needs to be carried out to explore the rich diversity of these graceful insects and come up with a representative checklist of Odonates for Ritchie's Archipelago." 11729. Śniegula, S.; Johansson, F.; Nilsson-Örtman, V. (2012): Differentiation in developmental rate across geographic regions: a photoperiod driven latitude compensating mechanism? *Oikos* 121: 1073-1082. (in English) ["Genetic differentiation and phenotypic plasticity in growth rates along latitudinal gradients may benefit our understanding of latitudinal compensating mechanisms in life history patterns. Here we explore latitudinal compensatory growth mechanisms with respect to photoperiod in northern and southern populations of two damselfly species, *Coenagrion puella* and *C. pulchellum*. In addition we compared size of field-collected adults from southern and northern populations. Eggs from females in copulating tandems were collected at two or three localities for each species in each geographic region. Eggs were transported to the laboratory and the experiment started when the eggs hatched. The role of photoperiod on the expression of larval growth rate was evaluated under controlled laboratory conditions. Both species had lower growth rate when reared in the northern photoperiod, which is counter to expectations if species use photoperiodic cues to trigger compensatory growth. Instead, both species displayed countergradient variation in growth rates, which probably enable northern populations to compensate for the shorter growth season in the north. The smaller size of field-collected adults from northern populations also supports the view that these species compensate for the shorter growth season by investing in growth and development but accomplish this at the expense of decreased final size." 11731. Stenert, C.; Maltchik, L.; Rocha, O. (2012): Diversity of aquatic invertebrates in rice fields in southern Brazil. *Biology and Conservation* 7(1): 67-77. (in Portuguese, with English summary) ["Irrigated rice fields have been cultivated for thousands of years, and a high diversity of invertebrate species has been associated with these agricultural areas. Investigations on the structure and diversity of aquatic invertebrates in rice fields are scarce in southern Brazil. Thus, the main goal

of this study was to conduct an inventory of the aquatic invertebrate diversity in rice fields and irrigation canals in an important rice cultivation area in Rio Grande do Sul to preserve the biota in these agroecosystems. Six collections were carried out along a cultivation cycle (June 2005 – June 2006) in six rice fields and four irrigation canals in the Coastal Plain of Rio Grande do Sul. A total of 26,579 individuals in 119 invertebrate taxa distributed among seven Phyla were collected over the cultivation cycle investigated in rice fields and irrigation canals. The arthropods were the invertebrates which showed the greatest amount of sampled taxa. Collectors, predators, and omnivores were the prevalent functional feeding groups in this study. Naididae, Chironomidae, Spongillidae, Libellulidae (differed at the genus level), and Tubificidae families were those which showed the highest number of genera and species. The invertebrate composition was different between rice fields and irrigation canals over the rice cultivation cycle. Besides, some were more frequent over the rice cultivation period whereas other ones were more associated with the non-cultivation period. Rice fields and irrigation canals are systems colonized by a variety of aquatic and terrestrial invertebrates, and they present a high biologic diversity which can be hardly found in other cultivation areas." 11732. Stoks, R.; Córdoba-Aguilar, A. (2012): Evolutionary ecology of Odonata: A complex life cycle perspective. *Annual Review of Entomology* 57: 249-265. (in English) ["Most insects have a complex life cycle with ecologically different larval and adult stages. We present an ontogenetic perspective to analyze and summarize the complex life cycle of Odonata within an evolutionary ecology framework. Morphological, physiological, and behavioural pathways that generate carry-over effects across the aquatic egg and larval stages and the terrestrial adult stage are identified. We also highlight several mechanisms that can decouple life stages including compensatory mechanisms at the larval and adult stages, stressful and stochastic events during metamorphosis, and stressful environmental conditions at the adult stage that may overrule effects of environmental conditions in the preceding stage. We consider the implications of these findings for the evolution, selection, and fitness of odonates; underline the role of the identified numerical and carry-over effects in shaping population and metapopulation dynamics and the community structure across habitat boundaries; and discuss implications for applied conservation issues." 11733. Subramanian, S.V. (2012): Application of auto-tracking to the study of insect body kinematics in maneuver flight. Master of Science in Engineering, Wright State University, Mechanical Engineering, Dayton: XI + 147 pp. (in English) ["There is a need to explain the complex phenomena that underlies the seemingly effortless flight modes of the dragonfly (Anisoptera). However, measuring the body kinematics during flight is labour intensive. Thus a robust system was developed that automatically tracks and quantifies the body kinematics of a dragonfly during voluntary and escape take-offs, as

well as maneuvers. Ultimately, the tool, which was developed using a custom code in C++ using the open source library OpenCV (Open Computer Vision), would be used to analyze bulk samples of high speed videos providing raw images at the rate of approximately 1000 frames per second from pair-wise orthogonal positions in space. As a result, there would be a considerably large database of information which may then be used to formulate, generalize and classify standard flight strategies used. Perceptibly, there is also a need to validate the outputs of this tool by comparing it to the outputs of a manual reconstruction." 11734. Suri Babu, B.; Sharma, G. (2012): On some aspects of territoriality and reproduction of *Pseudagrion microcephalum* (Rambur) (Insecta: Odonata: Zygoptera: Coenagrionoidea). *Biological Forum Spl. Iss.* 4(1): 25-31. (in English) ["The territoriality and reproductive behaviour of *Pseudagrion microcephalum* (Rambur) has been studied in detail in a temporary monsoon pond, Jagdalpur, District Bastar, State Chhattisgarh, India. The territoriality is strongly demonstrated by males towards both conspecific and heterospecific males. Precopulatory courtship display is present and brief, lasted for 8 to 13 seconds ($X=9.5$; $N=30$). Intramale sperm translocation has occurred after the seizure of the female only and lasted for 10 to 20 seconds ($X=14.25$; $N=10$). The copulatory wheel was formed during the perched condition and stage I lasted for 15 to 35 minutes ($X=25.15$; $N=20$) and stage II lasted for 05 to 08 minutes ($X=6.5$; $N=20$). The surface and below water oviposition is performed by both in tandem and female alone in underwater guarded by male on the above water surface. Behavioural comparisons of various stages have been drawn with other members of the genus *Pseudagrion* Selys." 11735. Takahara, T.; Kohmatsu, Y.; Maruyama, A.; Doi, H.; Yamanaka, H.; Yamaoka, R. (2012): Inducible defense behavior of an anuran tadpole: cue-detection range and cue types used against predator. *Behavioral Ecology* 23(4): 863-868. (in English) ["Inducible behavioural defense in response to predator cue detection is a key phenomenon in predator-prey interactions. The mechanisms by which prey use chemical/visual cues to avoid predation remain little known. We hypothesized that the distance at which prey species detect predator cues would be related to avoiding detection by the predator. To test this hypothesis, we performed laboratory experiments using an anuran tadpole (*Hyla japonica*) and a predatory dragonfly nymph (*Anax parthenope julius*). Tadpole activity level was reduced as a function of exposure to chemical cues from the dragonfly predator, but activity levels did not change when tadpoles were exposed to potential visual cues from the dragonfly. The distances over which tadpoles detected predator cues were longer than those over which the dragonfly predator detected tadpoles. The differences in cue-detection ranges between tadpoles and dragonfly predators are related both to predator avoidance by tadpoles and effective foraging strategies by dragonfly predators. Chemical cue detection as a trigger of inducible defense by prey species may shape predator-prey relationships in aquatic habitats." (Authors)] Address:

(holotype male: Sri Lanka, Ratnapura District, near Kudawe, 6°26'N, 80°25'E, 03 July 2007; paratype female, same location, 17 April 2008, to be deposited in the Sri Lanka National Museum, Colombo) is described and figured. Its phenotype differs from that of *M. d. donaldi* from India. This is the first record of the genus *Macromidia* from Sri Lanka. The habitat characteristics and species behaviour are briefly outlined." (Author)] Address: van der Poorten, Nancy, 17 Monkton Ave., Toronto, Ontario M8Z 4M9, Canada. E-mail: nmgvdp@gmail.com

11743. Van Praet, N.; Covaci, A.; Teuchies, J.; De Bruyn, L.; Van Gossum, H.; Stoks, R.; Bervoets, L. (2012): Levels of persistent organic pollutants in larvae of the damselfly *Ischnura elegans* (Odonata, Coenagrionidae) from different ponds in Flanders, Belgium. *Science of the total environment* 423: 162-167. (in English) ["We investigated the accumulation of persistent organic pollutants in *I. elegans* in 16 ponds in Flanders, widely differing in the surrounding land use. Concentrations of polychlorinated biphenyls (PCBs), polybrominated diphenyl ethers (PBDEs), p,p'-dichlorodiphenyldichloroethylene (p,p'-DDE) and hexachlorobenzene (HCB) were measured. From all targeted PBDE-congeners, only three congeners (IUPAC nos. 47, 99, 100) were above the limit of quantification (LOQ). The Σ PBDE concentrations ranged from < LOQ up to 0.51 ng g⁻¹ ww. From the targeted PCB-congeners, thirteen were detectable (IUPAC nos. 95, 99, 101, 105, 118, 138, 149, 153, 156, 170, 180, 183, and 187). A high variation in Σ PCB concentrations was observed between the ponds, ranging from < LOQ (0.67 ng g⁻¹ ww) up to 9.91 ng g⁻¹ ww in the damselflies from the pond at Sijsele. In all investigated Flemish ponds, p,p'-DDE concentrations were > LOQ (0.20 ng g⁻¹ ww) with values up to 3.30 ng g⁻¹ ww in the pond at Hamme. In fifteen ponds, the HCB concentrations were > LOQ (0.05 ng g⁻¹ ww) with values up to 0.24 ng g⁻¹ ww. For the available data in the literature a comparison with different species was done for some of the sampled ponds. The monitored ponds can be separated in three groups based on their contamination. The first group is characterised by a relative low POP content (Σ PBDEs, Σ PCBs, HCB). Group 2 contained more HCB and p,p'-DDE than the overall mean while this was the case for PBDEs and PCBs in group 3. The vectors of both contaminated groups are situated nearly perpendicular which is suggesting a different pollution sources." - 11744.** van Strien, M.J.; Keller, D.; Holderegger, R. (2012): A new analytical approach to landscape genetic modelling: least-cost transect analysis and linear mixed models. *Molecular Ecology* 21(16): 4010-4023. (in English) ["Landscape genetics aims to assess the effect of the landscape on intraspecific genetic structure. To quantify interdemelandscape structure, landscape genetics primarily uses landscape resistance surfaces (RSs) and least-cost paths or straight-line transects. However, both approaches have drawbacks. Parameterization of RSs is a subjective process, and least-cost paths represent a single migration route. A transect-based approach might oversimplify migration patterns by assuming rectilinear migration. To overcome these limitations, we combined these two methods in a new landscape genetic approach: least-cost transect analysis (LCTA). Habitat-matrix RSs were used to create least-cost paths, which were subsequently buffered to form transects in which the abundance of several landscape elements was quantified. To maintain objectivity, this analysis was repeated so that each landscape element was in turn regarded as migration habitat. The relationship between explanatory variables and genetic distances was then assessed following a mixed modelling approach to account for the nonindependence of values in distance matrices. Subsequently, the best fitting model was selected using the statistic. We applied LCTA and the mixed modelling approach to an empirical genetic dataset on the endangered damselfly, *Coenagrion mercuriale*. We compared the results to those obtained from traditional least-cost, effective and resistance distance analysis. We showed that LCTA is an objective approach that identifies both the most probable migration habitat and landscape elements that either inhibit or facilitate gene flow. Although we believe the statistical approach to be an improvement for the analysis of distance matrices in landscape genetics, more stringent testing is needed." - 11745.** Vandekerkhove, J.; Namiotko, T.; Hallmann, E.; Martens, K. (2012): Predation by macroinvertebrates on *Heterocypris incongruens* (Ostracoda) in temporary ponds: impacts and responses. *Fundamental and Applied Limnology / Archiv für Hydrobiologie* 181(1): 39-47. (in English) ["We conducted laboratory experiments to assess the potential impact of different macroinvertebrate taxa on populations and individuals of the ostracod *H. incongruens* a common inhabitant of temporary ponds. Our data show that nymphs of *Anax imperator* and adults of the pigmy backswimmer (*Plea minutissima* (Leach, 1817)), and to a lesser extent adults of the common backswimmer (*Notonecta glauca* Linnaeus, 1758), can dramatically reduce population densities of *H. incongruens*, and potentially also alter the size structure of the populations. Direct and indirect interactions among predators significantly reduced the predation efficiency of predators when multiple predatory species were combined. In consequence, predation pressure estimates should not be based on predator densities in biotically diverse systems. We also demonstrate that the predation pressure on *H. incongruens* is reduced through behavioral adaptations, such as migration to the open water and reduction of swimming activity. These behaviors are induced by taxon-specific chemical cues." (Authors)] Address: Namiotko, T., University of Gdańsk, Department of Genetics, Laboratory of Lim-
- nozoology, Kladki 24, 80-822 Gdańsk, Poland. E-mail: namiotko@biotech.ug.gda.pl

- 11747.** Vianna, D.M.; De Marco, P. (2012): Higher-taxon and cross-taxon surrogates for Odonate biodiversity in Brazil. *Natureza & Conservação* 10(1): 34-39. (in English) ["Odonate distributional patterns have recently become a focus of a global biodiversity evaluation, but it may present large gaps in biogeographical information, especially in tropical areas, which suggests the need of a surrogate approach for setting conservation priorities. Here we assemble available information of distribution of Brazilian odonate species and try to evaluate two different surrogate possibilities: i) a higher-taxon approach based on genera richness, and ii) a cross-taxon approach using the larger-sized Libellulidae species. The species richness distribution pattern shows a bias toward areas near research centers or with easy accessibility. Only 29% of the territory had any distributional information about odonates. A higher association of genera richness and species richness was observed and remained high even after controlling for differences in sampling effort. Libellulidae species richness was also a good surrogate, despite the low cover of available information of Brazilian territory. Our results support the use of higher-taxon over other approaches but highlight the importance of intensify sampling especially at the Cerrado, Caatinga and Amazonian biomes." A small species, *Diplacina paragua* sp. nov., is from Palawan Island (Tinadtad Falls, Irawan, Puerto Princesa, Palawan Island, Philippines, 29-i-2010, all six specimens leg. R.J. Villanueva & H. Cahilog)." (Author)] Address: Villanueva, R.J.T., D3C Gahol Apartment, Lopez Jaena St., 8000 Davao, Philippines. E-mail: rjtvillanueva@gmail.com

11751. Vyas, V.; Bharose, S.; Yousuf, S.; Kumar, A. (2012): Distribution of macrozoobenthos in River Narmada near water intake point. *Journal of Natural Sciences Research* 2(3): 18-24. (in English) ["...Presently, the study was carried out on a selected reach of river Narmada (India) near water intake point. Aim of the study was to assess the distribution of macrozoobenthos near water intake point on river Narmada. Loss in the distribution of macrozoobenthos fauna was recorded in lower reaches and in front of water intake point which indicates that ecological conditions are degrading and in near future situation can be alarming in the respect of ecology." (Authors) The paper includes the neotropical taxon *Aphylla*, and seems to be one of these increasing obscure papers without consideration of regional taxonomic literature.] Address: Kumar, A., Department of Environmental Sciences and Limnology, Barkatullah University, Bhopal- 462-026, India. E-mail: ankitlimno@yahoo.co.in

11752. Watanabe, M.; Kato, K. (2012): Oviposition behaviour in the dragonfly *Sympetrum infuscatum* (Selys) mistaking dried-up rice paddy fields as suitable oviposition sites (Anisoptera: Libellulidae). *Odonatologica* 41 (2): 151-160. (in English) ["Tandem oviposition behaviour of *S. infuscatum* was studied in rice paddy fields that were dried due to agricultural procedures in the cool temperate zone of Japan. Oviposition site selection is probably mainly visual because every tandem pair is attracted to structurally similar rice paddy fields without any water. Observations of flying behaviour of tandems was carried out on sunny days without winds. All pairs flew about to search for a suitable oviposition site in the rice paddy fields. They hovered to start oviposition while in tandem. Females of tandems flicked their abdomen while on the wing to aid egg release; each height of these oviposition flights was measured. They separated after completion of the oviposition bout. Vertical changes in the air temperature, relative humidities and light intensities above and below the top of the rice plants were measured. Oviposition site selection was related to the vertical decline of vapour pressure above the rice plants, suggesting that the horizontal surface of rice paddy fields horizontally reflects highly polarized light. Eggs that had fallen on dried-up rice paddy soil diapaused throughout the winter and started to develop the

following spring when the field was filled with enough water for rice planting. Therefore, there is a mechanism for suitable habitat selection for larval development under seasonal changes in man-made water supplies for the cultivation of rice plants." 11753. Wellenreuther, M.; Larson, K.W.; Svensson, E.I. (2012): Climatic niche divergence or conservatism? Environmental niches and range limits in ecologically similar damselflies. *Ecology* 93(6): 1353-1366. (in English) ["The factors that determine species' range limits are of central interest to biologists. One particularly interesting group are odonates (dragonflies and damselflies), which show large differences in secondary sexual traits and respond quickly to climatic factors, but often have minor interspecific niche differences, challenging models of niche-based species co-existence. We quantified the environmental niches at two geographic scales to understand the ecological causes of northern range limits and the co-existence of two congeneric damselflies (*Calopteryx splendens* and *C. virgo*). Using environmental niche modelling, we quantified niche divergence first across the whole geographic range in Fennoscandia and second only in the sympatric part of this range. We found evidence for interspecific divergence along the environmental axes of temperature and precipitation across the northern range in Fennoscandia, suggesting that adaptation to colder and wetter climate might have allowed *C. virgo* to expand further northwards than *C. splendens*. However, in the sympatric zone in southern Fennoscandia we found only negligible and non-significant niche differences. Minor niche differences in sympatry lead to frequent encounters and intense interspecific sexual interactions at the local scale of populations. Nevertheless, niche differences across Fennoscandia suggest that species-differences in physiological tolerances limit range expansions northwards, and that current and future climate could have large effects on the distributional ranges of these and ecological similar insects." (Authors)] Address: Wellenreuther, Maren, Dept of Biology, Univ. of Lund, Sweden. E-mail: maren.wellenreuther@biol.lu.se

11754. Wiederman, S.D.; O'Carroll, D.C. (2012): Feature saliency in a dragonfly neuron. *Front. Behav. Neurosci.* Conference Abstract: Tenth International Congress of Neuroethology, College Park, Maryland USA, USA, 5 Aug - 10 Aug, 2012. doi: 10.3389/conf.fnbeh.2012.27.00223: 1 p. (in English) ["*Hemicordulia tau* pursues moving prey, often against a cluttered, visual surround. This already complex small target detection task may even occur in the presence of multiple target-like features (e.g. other potential prey and conspecifics). Yet this is only one of many challenging visual behaviours exhibited by these impressive predators, despite a small brain. To understand the neural basis for such behaviour we use electrophysiological techniques to record intracellularly from feature detecting neurons, referred to as small target motion detectors (STMDs). STMDs likely underlie the dragonfly's ability to discriminate prey motion as they provide velocity-tuned responses selective for objects of no more than a few degrees size (O'Carroll 1993). One such neuron, the centrifugal STMD (CSTMD1) is a potential candidate for mediating higher-order mechanisms of attention towards targets in the presence of distractors. CSTMD1 gives a

locally enhanced response when a target moves along a continuous trajectory (Nordström et al. 2011). Furthermore, the neural response is entirely suppressed by the presence of a second object in a visual region of the other eye (Bolzon et al. 2009). CSTMD1 takes dendritic input from one eye and has an axon that traverses the brain. The neuron arborizes in two regions on the contralateral side, with one output aligning with the input of the mirror-symmetric CSTMD1. It is possible that the two CSTMD1 neurons work together in transferring target information from one side of the brain to the other during target pursuit, but the details of these mechanisms remain unclear. To elucidate a functional role for CSTMD1, we presented two target stimuli of varying sizes and contrasts. We found that a second 'distracter' target presented in the excitatory receptive field, suppresses the response of the neuron as its size is increased. Conversely, a second feature presented to the contralateral eye reveals inhibition that is itself size-tuned. Finally, we investigated how the saliency of two targets (of varying size and contrast) is encoded by the neuron through a simple form of selective attention. Putting this all together, the neuron is inhibited by either a large feature in the ipsilateral (excitatory) visual field or a small target in the contralateral eye. Additionally, if presented with multiple targets in the excitatory region, the neuron exhibits a simple form of visual attention via a competitive winner-takes-all interaction. This research was supported by the US Air Force Office of Scientific Research (FA2386-10-1-4114)." 11755. Wildermuth, H. (2012): *Aeshna caerulea* in den Schweizer Alpen (Odonata: Aeshnidae). *Libellula Supplement* 12: 77-106. (in German, with English summary) ["The present knowledge on the horizontal and vertical distribution, phenology, ecology and behaviour of *A. caerulea* in Switzerland is reviewed with a side glance on the remaining occurrences of the species in Europe. In the Swiss Alps *A. caerulea* has been recorded on 71 squares of 1 km² from 2000 to 2011 and observed to breed between 1318 m and 2230 m a.s.l. The lower vertical distribution is probably confined by the mild climatic conditions and interspecific competition while the upper limit is mainly restricted by the lack of suitable breeding habitats with lush Vegetation, organic matter and corresponding thermal conditions. Larval habitats, emergence, reproductive behaviour and thermoregulation are described in detail and photographically documented. The species is endangered prevailing by grazing livestock that destroys the breeding habitats, but also by tourism and climate change. Possible Conservation measures are suggested and discussed." 11768. Nilsson, A.N.; Malmqvist, B.; Báez, M.; Blackburn, J.H.; Armitage, P.D. (1998): Stream insects and gastropods in the island of Gran Canaria (Spain). *Annls Limnol.* 34(4): 413-435. (in English, with French summary) ["The current status of the stream-living insects and gastropods of the island of Gran Canaria in the Atlantic Canary Islands is documented. Data from semi-quantitative kick samples taken in 11 streams are supplemented by non-standardized collecting in the same and ten additional streams. The kick samples included some 9,000 specimens of 98 taxa, and in total 123 taxa were recorded from the studied streams in 1994 and 1995. The stream fauna was dominated by Diptera with some 80 taxa, followed by Coleoptera with 37 species known from the island. The kick samples yielded 11-36 species per stream and visit, whereas up to 48 species were scored when all collecting methods were included. Local diversity given as Fisher's α ranged from 3.2 to 10.3. Clustering showed only weak spatial patterns and resulted in much higher similarities among localities when based on the semi-quantitative samples than when based on presence/absence including records from all collecting methods. Species distributions among localities

were not significantly nested. The faunal similarity with the adjacent island of Tenerife is striking. Six of the Tenerife species are seemingly absent from Gran Canaria, whereas Gran Canaria has 13 species not found in Tenerife. Most of the 22 aquatic insect species in Gran Canaria only known from older records, prefer lentic habitats not included in our study. All except one of the five species endemic to Gran Canaria are considered extinct or on the edge of extinction. Increased future extinction rates are predicted as a response of the extreme habitat loss, with only three permanent streams known on the island today." (Authors) The following Odonata taxa are listed: Libellulidae indet., *Orthetrum chrysostigma*, *Sympetrum fonscolombii*, *Trithemis artemisa* and *Zygonyx torrida*.] Address: Nilsson, A.N., Department of Animal Ecology, University of Umea, SE-901 87 Umea, Sweden

from the sun, the polarization pattern of the sky offers insects a reference for visual compass orientation. Using behavioral experiments, it has been shown in a few insect species (field crickets, honey bees, desert ants, and house flies) that the detection of the oscillation plane of polarized skylight is mediated exclusively by a group of specialized ommatidia situated at the dorsal rim of the compound eye (dorsal rim area). The dorsal rim ommatidia of these species share a number physiological properties that make them especially suitable for polarization vision: each ommatidium contains two sets of homochromatic, strongly polarization-sensitive photoreceptors with orthogonally-arranged analyzer orientations. The physiological specialization of the dorsal rim area goes along with characteristic changes in ommatidial structure, providing actual anatomical hallmarks of polarized skylight detection, that are readily detectable in histological sections of compound eyes. The presence of anatomically specialized dorsal rim ommatidia in many other insect species belonging to a wide range of different orders indicates that polarized skylight detection is a common visual function in insects. However, fine-structural disparities in the design of dorsal rim ommatidia of different insect groups indicate that polarization vision arose polyphyletically in the insects." 11772. Wegner, E. (2000): Freshwater and land arthropods endangered with mosquito control treatments. *Wiad. entomol.* 18, Suppl. 2: 275-283. (in Polish, with English summary) ["Mosquito control in Poland is based almost solely on the use of broad-spectrum insecticides, which affect most arthropods. The tendency to control mosquitoes in Poland increases and there is a danger of annihilation of a great number of arthropod species in areas subject to mosquito control treatments unless modern microbial control means are employed in Poland. For this reason there is a necessity of a programme of mosquito control based on the environmentally aware methods. The specialists in biology and ecology of animals, especially those who deal with invertebrates, which co-occur with larvae or adult mosquitoes, would be very helpful to give their suggestions concerning protection for nontarget animals (including Odonata). On the basis of this information an environmentally acceptable programme and a detailed scenario of treatment actions would be proposed." 11777. Sformo, T. (2002): Minimum flight temperature and thermoregulatory performance of sub-arctic dragonflies. Society for Inetgrative and Comparative Biology 2002 Annual Meeting. Anaheim, California, January 2-6: (in English) [Verbatim: "Sub-arctic dragonflies (Odonata: Anisoptera), an order of insect previously not studied in Alaska, provide a unique system with which to examine questions of thermal biology. Two potential adaptations are the ability to initiate flight at low temperature and to thermoregulate. To establish minimum flight temperatures, I record the lowest temperature at which a species can maintain level flight, both in the lab and in the field. To determine thermoregulating ability, I measure thoracic temperature (T_{th}) of individual dragonflies using a thermocouple. T_{th} is then compared to the dragonfly model providing the operative environmental temperature (T_e). By regressing T_{th} on T_e, the slope of the regression line indicates thermoregulatory ability (Thermoregulation Performance Index). I predict that northern dragonflies will have lower minimum flight temperatures than comparable species from lower latitudes. I also predict a general pattern wherein more massive species are able to thermoregulate by both physiological and behavioural means, while less massive species rely solely on behavioural repositioning. The relationship between T_{th} of living specimens and T_e is examined for each species and compared across species to examine relative thermoregulating ability. I show, contrary to speculation by Vogt and Heinrich (1983), that minimum flight temperature of northern dragonflies are not different from comparable species from Maine, although they differ from species in Florida. Minimum temperatures range from 14°C for *S. danae* to 22°C for aeshnids. Finally, I conclude that the relative thermoregulating ability is a function of mass,

which ranges from 0.09g for the least to 0.86g for the most massive, while the Thermoregulatory Performance Index ranges from 0.90 (a thermal conformer) to 0.14 (a thermal regulator), respectively.]" Address: Sformo, T., Univ. Alaska, Fairbanks, AK, 99701, USA. E-mail: rfts@uaf.edu

2003

11778. Goudsmits, K. (2003): *Coenagrion scitulum*, the first record for the Netherlands. *Brachytron* 7(1): 27-29. (in Dutch, with English summary) [June 16, 2003, a male *C. scitulum* was captured near Tegelen in the south eastern part of The Netherlands.] Address: Goudsmits, K., Eerste Dorpstraat 7a, NL-3701 HA Zeist, The Netherlands

11779. Woods, M.; McDonald, R.A.; Harris, S. (2003): Predation of wildlife by domestic cats *Felis catus* in Great Britain. *Mammal Review* 33(2): 174-188. (in English) ["A questionnaire survey of the numbers of animals brought home by domestic cats *Felis catus* was conducted between 1 April and 31 August 1997. A total of 14 370 prey items were brought home by 986 cats living in 618 households. Mammals made up 69% of the items, birds 24%, amphibians 4%, reptiles 1%, fish <1%, invertebrates 1% and unidentified items 1%. A minimum of 44 species of wild bird, 20 species of wild mammal, four species of reptile and three species of amphibian were recorded." (Authors) Among the prey items, Odonata accounted to 25 specimens, representing 0.6% of all prey items.] Address: McDonald, R.A., The Game Conservancy Trust, Forest in Teesdale, Barnard Castle DL12 0HA, UK. E-mail: rmcdonald@gct.org.uk

2004

11780. Butler, H.J.B.; Kok, O.B. (2004): Dietary composition of cattle egrets (*Bubulcus ibis*) in the central Free State. *SA Tydskrif vir Natuurwetenskap en Tegnologie* 23(4): 90-98. (in Dutch, with English summary) ["Analysis of 152 stomach samples of adult *B. ibis* collected over a period of five years in the central Free State showed this species to be mainly insectivorous. The Insecta, occurring in almost all stomach samples, are represented by prey items from 13 orders of which the Orthoptera, followed by the Coleoptera, Isoptera, Diptera and Lepidoptera, showed the highest frequency of occurrence. Amongst the non-insect invertebrates, the Araneae and Solifugae occurred most frequently. Based on dry mass the Orthoptera and Isoptera constitute by far the most important components. Prey items of vertebrates combined represent only ca. 10% of the diet. Overall, the stomach contents of 75 chicks correspond with that of the adults, except that vertebrates make a significant contribution to the diet during the first week of the nesting phase. In general cattle egrets can be considered opportunistic feeders that concentrate on easily obtainable food sources which become sporadically available (partly because of their regular association with mammalian hosts)." (Authors) Odonata contribute only very little to the diet of *B. ibis*.] Address: Kok, O.B., Departement Dierkunde en Entomologie, Universiteit van die Vrystaat, Posbus 339, Bloemfontein, 9300, South Africa. E-mail: kokob.sci@mail.uovs.ac.za

11781. Dicke, M. (2004): From Venice to Fabre: insects in western art. *Proc. Neth. Entomol. Soc.* 15: 9-14. (in

English) ["Insects are not only special to entomologists, they have also been a source of inspiration to artists throughout the centuries. From the 13th century until present artists have depicted insects in twodimensional and three-dimensional works. Insects have often been used as symbols for the brevity of life, for the transcendence of the soul, but also because of the beauty of their forms and colours. Some artists paint or sculpt with insects themselves, either dead or still alive. Over the past 7 years I have visited 180 art museums and recorded the representation of insects in the works on display. As a result I have gained an entomological view of the history of art. This has provided insight both in the history of art itself as well as in the role of insects in its development. At present I have seen 3,045 works of art in which insects are represented. The majority occur in the Netherlandish still-lives of the 17th and 18th centuries, in surrealist works and in Jugendstil works. Some artists have depicted only a single insect while others have represented over 100 insects in a single work of art. Of some artists I know only a single work with insects, while of others more than 100 works are known." (Author) Approximately 450 paintings created between 13th-21st centuries include Odonata.] Address: Dicke, M., Laboratory of Entomology, Wageningen University, P.O. Box 8031, NL-6700 EH Wageningen, The Netherlands; E-mail: marcel.dicke@wur.nl

2005

11785. Brunelle, P.M. (2005): *Odonata Survey 2005: (Damselflies and Dragonflies)*, Whites Point Property, Digby County, Nova Scotia. Prepared for: Bilcon of Nova Scotia Corp., P.O. Box 2113, Digby, Nova Scotia, Canada B0V 1A0: 17 pp. (in English) [6-8-VIII-2005; "We visited all freshwater and brackish habitats at the appropriate time of day and weather condition for effec-

tive sampling of these insects. I documented all aquatic habitats, and we took 51 records of 21 species. Only one species we encountered is of some conservation concern - *Lestes forcipatus*, which is ranked as undetermined due to past confusion with the similar and common *L. disjunctus* - the balance being species common in Nova Scotia. I suggest in Table 1 other Odonata species which may be found in the aquatic habitats of the property, depending upon season of survey. The principal Odonata diversity on the property occurs in man-made habitats. Whether this diversity will persist through active industrial activities will be dependent upon the nature of those activities. During the reclamation phase of the project, efforts should be made to ensure that the freshwater aquatic habitats recover their diversity in Odonata. This may be beneficial, as small still-water habitats are rare along North Mountain, and that area of the province may host migratory Odonata (*Anax junius* in particular) which would benefit from the presence of those habitats. At this time, there is no indication of rare Odonata in the natural bog and stream habitats present on the property, and hence no particular concern that the still-water species will compete with them. If rare Odonata are discovered in the future outside of the man-made habitats, consideration should be given to removing the constructed still-water habitats during the reclamation phase." 11786. Febria, C.M.; Magnusson, A.K.; Williams, D.D. (2005): Seasonal abundance and prey selection of the nymphs of three sympatric species of *Sympetrum* (Odonata: Libellulidae) in an intermittent pond. *Canadian Entomologist* 137: 723-727. (in English) ["Odonates are obligate predators, and the composition of their diet is reflective of their microhabitat and effectiveness in detecting and capturing prey. In an intermittent woodland pond in southern Ontario, Canada, three species of *Sympetrum* were found to coexist: *S. internum*, *S. costiferum*, and *S. obtrusum*. *Sympetrum* species spend most of their life cycle in the aquatic stage and consume prey at all nymphal stadia. They overwinter in the egg stage, hatch in early spring, and typically emerge in late June to late July. To better understand the role of coexisting *Sympetrum* nymphs in this intermittent pond environment, and to evaluate potential mechanisms behind their coexistence, we collected seasonal abundance and body size data for 2 years and analyzed gut contents of each species. In addition, we experimentally tested the prey selection and predatory rate of two different size classes of *Sympetrum* nymphs and two of their potential competitors, *Lestes* sp. and *Acilius* sp. (Coleoptera: Dytiscidae), in laboratory microcosms." (Authors)] Address: Febria, Catherine, Surface and Groundwater Ecology Research Group, Dept Life Sciences, Univ. Toronto at Scarborough, Ontario, Canada M1C 1A4. E-mail: catherine.febria@utoronto.ca

11787. Nel, A.; Petrulevicius, J.F.; Jarzembowski, E.A. (2005): New fossil Odonata from the European Cenozoic (Insecta: Odonata: Thaumateuridae, Aeshnidae, ? Idionychidae, Libellulidae). *Neues Jahrbuch für Geologie und Paläontologie - Abhandlungen* 235(3): 343-380. (in English) ["A new genus and species of the fossil subfamily Thaumateuridae: *Dysagrioninae Primorilestes violetae* is described from the Early Oligocene of the Far East of Russia. The aeshnid *Aeschnophlebia andreasi* sp. n. is described from the Late Eocene/Early

Oligocene of the UK. *Oligoaeschna* (?) *anglica* Cockerell & Andrews, 1916 is redescribed on the basis of new, more complete material from the same strata. The hindwing structures of *Oligoaeschna jungi* Piton & Theobald, 1939 are described on the basis of a complete wing from the Oligocene of France. *Aeshna stavropolensis* sp. n. (Aeshnidae), *Mioidionyx stavropolensis* gen. n. sp. n. (?Idionychidae), two wings attributed to *Sympetrum* aff. *elongatum* Gentilini, 1989, and two unnamed Pantalinae (Libellulidae) are described from the Middle Miocene of Stavropol (North Caucasus, Russia). *Libellula ukrainensis* sp. n. is described from the Late Miocene of Crimea (Ukraine). The libellulid *Jeanlegrandia oligocenica* gen. n. sp. n. is described from the Late Oligocene of France. These new discoveries confirm the high diversity of the Cenozoic odonofauna of the Palaearctic Region." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. 11788. Holland, R.A.; Wikelski, M.; Wilcove, D.S. (2006): How and why do insects migrate? *Science* 313: 794-796. (in English) ["Countless numbers of insects migrate within and between continents every year, and yet we know very little about the ultimate reasons and proximate mechanisms that would explain these mass movements. Here we suggest that perhaps the most important reason for insects to migrate is to hedge their reproductive bets. By spreading their breeding efforts in space and time, insects distribute their offspring over a range of environmental conditions. We show how the study of individual long-distance movements of insects may contribute to a better understanding of migration. In the future, advances in tracking methods may enable the global surveillance of large insects such as desert locusts." (Authors) Several references to Odonata (*Rhionaeschna bonariensis*, *Anax junius*) are made.] Address: Wikelski, M., Department of Ecology and Evolutionary Biology, Princeton Univ., Princeton, NJ 08544, USA. (2007): Bioaccumulation of trace elements in omnivorous amphibian larvae: Implications for amphibian health and contaminant transport. *Environmental Pollution* 149: 182-192. (in English) ["Despite the influence that amphibians have on the flow of energy and nutrients in ecological systems, the role that amphibians play in transporting contaminants through food webs has received very little attention. This study

was undertaken to investigate bioaccumulation of trace elements (Mn, Se, V, As, Pb, Zn, Hg, Cd, Cu) in amphibians relative to other small aquatic organisms in a contaminated wetland. We collected bullfrog larvae (*Rana catesbeiana*) along with three other species of small vertebrates and four species of invertebrates (*Tramea* sp., *Erythemis* sp.) from a site contaminated with a wide array of trace elements and analyzed them for trace element concentrations and stable nitrogen and carbon isotope composition. We found that amphibian larvae accumulated the highest concentrations of most trace elements, possibly due to their feeding ecology. These results suggest that omnivorous amphibian larvae can serve as a critical link for trace element trophic transfer. Their propensity to accumulate trace elements may have important implications for amphibian health in contaminated environments and should be further investigated." 11796. Fulan, J.A.; Raimundo, R.; Figueiredo, D. (2008): Habitat characteristics and dragonflies (Odonata) diversity and abundance in the Guadiana River, eastern of the Alentejo, Portugal. Boln. Asoc. esp. Ent. 32(3-4): 327-340. (in English, with Spanish summary) ["In this study, we investigated the environmental variable that affected the dragonfly diversity and abundance in the Guadiana River in the period of March to July in 1999 and 2000. A total of 105 sites were investigated where 19 species of dragonflies, ten species of Anisoptera and nine species of Zygoptera were recorded. Canonical Correspondence Analysis (CCA) indicated that environmental factors were related to some species. *C. lindennii*, *C. tenellum*, *C. caerulescens*, *C. scitulum*, *E. viridulum* and *I. pumilio* (all Zygoptera) occurred in conditions of a relatively high percentage of cover of reeds. The occurrence of Anisoptera species such as *C. boltonii*, *O. caerulescens* and *O. nitidiverve* were influenced by shade." (Author)] Address: Fulan, J.A., Department of Zoology, Institute of Biosciences, State University of São Paulo, Campus of Botucatu, 18618-000 Botucatu, SP, Brazil; E-mail: joaofulan@ig.com.br

11797. Muramy, D.; Kovacs, T. (2008): Review and contribution to the Odonata fauna of Maramures, Romania. Studia Universitatis "Vasile Goldis", Seria Stiintele Vietii (Life Sciences Series) 18(Suppl.): 229-234. ["An annotated list of the 36 Odonata species reported from Maramures, Romania, and data of the Odonata material collected between 2004 and 2008 are given. Eleven species (*Lestes sponsa*, *Platycnemis pennipes pennipes*, *Enallagma cyathigerum*, *Ischnura pumilio*, *Anaciaeschna isosceles isosceles*, *Anax imperator*, *A. parthenope*, *Gomphus vulgatissimus*, *Onychogomphus forcipatus forcipatus*, *Orthetrum cancellatum cancellatum*, *Sympetrum danae*) are new records for the area. Taxonomical characters of the *Leucorrhinia dubia dubia* population found in the Rodna Mts are briefly discussed, and notes given on the faunistic rarities of the peat bogs of Maramures." (Authors)] Address: Murányi D., Hungarian Natural History Museum, Department of Zoology, Baross u. 13, H-1088, Budapest, Hungary, Tel. +36-1-267-7007, Fax. +36-1-3171-669, email: muranyi@zool.nhmus.hu

11798. Villeda Callejas, María del Pilar; Barrera Escorcia, Héctor; Lara Vázquez, José Ángel; Ruiz Puga, Pablo (2008): Histología del tubo digestivo de *Dythemis velox* (Libellulidae: Odonata). Revista de Zoología 19: 1-6. (in Spanish, with English summary) ["In the present work we analyze the morphology and the histology of digestive apparatus of *Dythemis velox*. It is observed that the estomodeo lacks of gastric caeca, and in a cross section are the layers of the circular muscle, the longitudinal muscle, epithelia that consist of a layer of cylindrical cells, and the intimate one that limits the lumen.

The mesodeo is limited by the cardiac valve in the previous end, and folds conformed by longitudinal muscle and followed of a columnar epithelia with microvilli that rest on a basal membrane, it lacks of a cuticular layer and in its place we observed a thin peritrophic membrane. The Proctodeo has great amount of folds towards the lumen of epithelial cells covered by a fine cuticular membrane. We conclude that the histology of the digestive tract of *D. velox* is very similar to that observed by other authors in saproxylofagous coleopterans." 2009

11799. Clarke, D. (2009): Males of the Common Blue Damselfly (*Enallagma cyathigerum*) targeting an ovipositing female Emperor Dragonfly (*Anax imperator*). *The Carlisle Naturalist* 17(1): 11-12. (in English) [Verbatim: On the calm sunny afternoon of 4th July 2008 a female Emperor Dragonfly was ovipositing near the edge of one of the pools on Scaleby Moss, Carlisle. Whilst watching her I noticed that she was being 'harassed' by several males of the Common Blue Damselfly, which were frequent, though not in 'swarming' numbers. I took some photographs, and two in particular confirm what I saw. In one shot, two Common Blue males are apparently 'buzzing' her (from in front and behind) and in the other a male is actually perched on her arched abdomen, facing forwards, his head just behind her wing bases, whilst she is laying eggs into vegetation just below the water surface. The Emperor showed no apparent response to this attention. At first glance this behaviour looked rather like aggression, but the biological advantage to a small weak predator of attacking a very much larger and aggressive one would seem limited, to say the least - and insects don't act like small birds mobbing raptors. My preferred explanation was that the coloration of this female Emperor - a typical greenish form with dark dorsal abdominal strip - was sufficiently similar to that of the normal colour phase of a female Common Blue as to present a 'super-stimulus' to males of that species, releasing a mating behavioural response. The alternative - which I am very reluctant to concede - is that what I saw was purely coincidental: the 'buzzing' Blues were just going about their business; the Emperor just happened to be a convenient perch for one of them. As opportunities to watch Emperors up here are still relatively few (though increasing), I had submitted this note to the Newsletter of the British Dragonfly Society. It appears in issue No. 54, along with a couple of very good images of the same behaviour taken in southern England, so this may actually be a frequent phenomenon.] Address: Clarke, D., Burnfoot, Cumwhitton, Brampton, Cumbria CA8 9EX, UK

11804. Jinguji, H.; Ueda, T.; Goka, K.; Hidaka, K.; Matsura, T. (2009): Effects of Imidacloprid and Fipronil insecticide application on the larvae and adults of *Sympetrum frequens* (Libellulidae: Odonata). *Transactions of the Japanese Society of Irrigation, Drainage and Rural Engineering* 77(1) (259): 35-41. (in Japanese) ["The insecticides fipronil and imidacloprid are effectively used against sucking insect pests of rice. Since these agents are absorbed by rice seedlings and stored in their tissues, they are usually applied to nursery boxes before planting. The effects of imidacloprid and fipronil on the life history of *S. frequens* larvae and adults were monitored using an experimental micro-paddy lysimeter (350mm× 500mm× 300mm (H)) for the duration of the cultivation period. Three lysimeters were treated with imidacloprid, three with fipronil, and the remaining three were left untreated and were used as controls. Three hundred eggs were laid on the soil surface of each of the nine lysimeters and the larval populations, larval development, and emergence patterns of *Sympetrum frequens* were observed in each lysimeter. The absence of *S. frequens* larvae from fipronil-treated-lysimeters

was most remarkable and exuviae were not observed. Imidacloprid-treated-lysimeters had approximately 60% of the larvae observed in control lysimeters. In addition, larvae in the imidacloprid lysimeter had lower mean specific growth rates and the length of adult wings was decreased relative to those observed in the control lysimeter. Emergence in imidacloprid lysimeters was also significantly lower than it was in the control. The application of fipronil and imidacloprid to seedling in the nursery box, and the subsequent transplanting of these into an experimental lysimeter, was associated with a decrease in the abundance of *S. frequens* larvae and adults." (Authors)] Address: Jinguji, H., School of Food, Agricultural and Environmental Sciences, Miyagi University, 2-2-1 Hatatate, Taihaku-ku. Sendai. Miyagi 982-0215, Japan. E-mail: jinguji@myu.ac.jp

11808. Rosset, V. (2009): Local biodiversity should increase with climate change: case-study for ponds from the Swiss National Park. 4th Symposium of the Hohe Tauern National Park, Conference Volume for Research in Protected Areas, September 17th to 19th, 2009, Castle of Kaprun: 283-286. (in English) ["Climate change is expected to have a significant impact on biodiversity worldwide (Thomas et al. 2004). Many studies focus on

responses to climate change at the regional level, such as species distribution shifts, and evidence that enrichment of regional biodiversity could happen in many areas of the world (Hickling et al. 2006). Less is known, however, about the consequences of climate change on the species richness in ecosystems (local scale). Alpine areas are particularly sensitive to climate change (Beniston 2003). Small waterbodies like ponds are abundant and widespread, and because of their small size they shelter simple communities, particularly at high altitude. Therefore, alpine ponds should play an important role as sentinel and early warning systems in the assessment of the future changes in local biodiversity. The Macun ponds of the Swiss National Park are part of a unique and exceptional area for such investigation and monitoring. ... predictions for alpine ponds evidence that a temperature increase would enhance pond diversity for the five taxonomic groups: +139% for vascular plants, apparition of Gastropoda, + 185% for Coleoptera, +454% for Odonata ..." 11810. Schröder, R.; Walguarnay, J.W.; Butler, M.A. (2009): The damselfly compound eye in stream habitat: Biological design for object detection in a dark complex habitat. *Proceedings of the Army Science Conference (26th)* Held in Orlando, Florida on 1-4, December 2008: 8 pp. (in English) ["Habitats characterized by high spatial variation in absolute light levels and spectral quality present a challenge to animals that rely on visual orientation and visual target discrimination. Insects, in particular, face several difficulties in visual performance related to the small absolute size and simplicity of visual components comprising their compound eyes, including the lack of a focusing mechanism, relatively limited light capture and coarse spatial resolution. Therefore, an understanding of the morphological and behavioural means by which insects overcome these limitations in order to perform highly demanding visual tasks can provide insight into both ecological specialization and artificial visual system optimization. We investigated optical geometry, perch orientation and microhabitat selec-

tion in the Hawaiian damselfly *Megalagrion xanthomelas*, a sit-and-wait predator that intercepts aerial prey among heterogeneous vegetation bordering streams and wetlands. We found that while the eyes of *M. xanthomelas* are roughly spherical, maximum visual acuity appears concentrated in an oblong region shifted below the equatorial frontal plane. This optical geometry corresponds well with typical orientations of damselflies resting on perches and suggests an arrangement maximizing detection of prey or conspecifics travelling along stream margins. We discuss the visual morphology and behaviour of *M. xanthomelas* in relation to available light environments and in comparison to the visual systems of other species." (Authors)] Address: Butler, Marguerite, University of Hawaii, Department of Zoology, 2538 McCarthy Mall, 96822 Honolulu, HI, USA. E-mail mbutler@hawaii.edu

11811. van Tol, J.; Reijnen, B.T.; Thomassen, H.A. (2009): Phylogeny and biogeography of the Platystictidae (Odonata). PhD Thesis. University of Leiden: 3-70. (in English) ["Conclusions: Methods. – We used both morphological and molecular characters for our phylogenetic analyses. Although the most parsimonious tree of the morphological character set showed many homoplasies, the strict consensus tree of the parsimony analysis was highly resolved, although the branches are poorly supported. However, we consider the significant congruence of this consensus tree with a tree based on molecular characters of a smaller taxon sample, a distinct indication of the robustness of the morphological character analysis. Relationships. – To establish the relationships and estimate the age of the odonate family Platystictidae, we studied a wide assemblage of species of southeast Asia representing the Zygoptera families Lestidae, Platystictidae, Platycnemididae, Protoneuridae, Megapodagrionidae and Coenagrionidae. Based on molecular characters, we ascertained that the Platystictidae represents an ancient monophyletic lineage of the Zygoptera. We confirmed the monophyly of the Platycnemididae, and the sister group relationship of the presently recognized subfamilies. The Protoneuridae were established as the sister group of the Platycnemididae. The family Megapodagrionidae seems to be a para- or even polyphyletic assemblage, which clearly needs further revision. Previous studies, such as Rehn (2003), found a different topology in the phylogenetic reconstruction of the Zygoptera, but our results agree broadly with Bybee et al. (2008), who added molecular characters to the morphological dataset of Rehn (2003). For a further understanding of the phylogeny of Zygoptera, we suggest inclusion of various small families of southeast Asia, such as the Isostictidae, a further expansion of the Coenagrionidae taxon sampling, and, in our set, addition of taxa of the New World. The subfamily Sinostictinae (only studied on morphology) 4 represents the most basal clade in the phylogeny of the Platystictidae. The Palaemnematinae of the New World are the sister group of the Platystictinae in our analysis based on a limited taxon sample. Based on our morphological study, it appeared that the Palaemnematinae are not monophyletic, but share a common ancestor with the genus *Platysticta* (Sri Lanka) and some species of *Drepanosticta* confined to New Guinea. Characters. – We have used the topology of the phylogenetic tree based on molecular characters to analyse the changes in character states of the morphological characters. We found that not many morphological characters exclusively define monophyletic groups as based on the mo-

lecular character set. Parallel development of the same character state appeared to be a common phenomenon. This conclusion was confirmed by our independent analysis of the morphological data set plotted on the tree based on molecular characters. Our results confirmed the supposition by Orr (2003) that *Protosticta Selys sensu Davies & Tobin (1984)* cannot be considered an monophyletic group. The reduction of the Ab vein has occurred several times during evolution (Fig. 51). On the other hand, some other wing venational character states, such as the position of the IR3, only developed once. Somewhat unexpectedly, also some characters of the anal appendages appeared to be very homoplastic. A long and conspicuous dorsal denticle on the superior appendage of the male evolved various times. For a further understanding of the phylogeny of the Platystictidae, we suggest a more extensive taxon sampling first, and an increased number of genetic markers in the molecular analyses. Biogeography. – The present 'tropical amphi-transpacific distribution' of the Platystictidae evolved from African ancestors that reached Asia via India, and the New World via the 'North Atlantic Land Bridge'. The evolution of the subfamily Platystictinae can be understood in relation to the palaeogeography of the Malesian region since the Eocene. Our limited taxon sample for molecular characters permitted only a very rough indication of a biogeographical scenario. Our reconstruction of the phylogeny based on the morphological characters, including more species of Platystictidae, permitted a more detailed scenario. Based on the occurrence of basal clades in southeast China (*Sinostictinae*) and Sri Lanka (*Platysticta* and some *Drepanosticta*), in combination with the presence of this family in the New World, we consider an origin of the ancestors of this family in Africa (where it does not occur at present) as the most likely scenario. The American taxa must have dispersed from Eurasia (Europe) via the North Atlantic Land Bridge during the Eocene, while the Asian clade dispersed into the region after India and Asia made their first contact about 50 Ma. Whether the species of New Guinea used a route via Asia (pre-Eocene Papuan Arc, suggesting evolution of the family in Asia), or via Australia (no recent representative in that continent), needs further study, including estimates of cladogenesis using a molecular clock. The cladogram of the Platystictinae and the present distribution of the species, indicate an eastward dispersal in which Sulawesi has played a prominent role. The widespread occurrence of one lineage from the Philippines to the northern Moluccas and New Guinea is presumably due to a geologically recent dispersal, probably during the Miocene or later. This study of the Platystictidae confirms the complicated nature of the historical biogeography of southeast Asia. A similar study of the Calicnemiinae (*Platycnemididae*) (Gassmann 2005, van Tol & Gassmann 2007) revealed a different scenario. The family *Platycnemididae* is very diverse at the genus level in New Guinea, is very speciose with two closely related genera in the Philippines, but is unknown from Sulawesi and Halmahera. New Guinea was apparently populated from the mainland of southeast Asia via the Izu-Bonin Arc, whereafter this group dispersed into western direction to reach the Philippines. Ancient lineages of the Calicnemiinae are found on New Guinea, as is also the case in the Platystictidae and various other groups of aquatic insects. Polhemus (1995) has stressed the role of a 'pre-Eocene' arc for aquatic Heteroptera. Such an arc may also have played a role in the origin of present distribu-

tion patterns in the Calicnemiinae and the Platystictidae. The historical biogeography of Malesia certainly asks for more, well-founded phylogenies of groups with similar ecology. The importance of estimates of timing of cladogenesis of those groups should be emphasized. This is considered the most reliable method to study the congruence between different cladograms, and area cladograms, in order to arrive at a reconstruction of the distributional history of the biotas of southeast Asia and the West Pacific. Species diversity. – Finally, it is an intriguing question how the huge diversity of the endemic flora and fauna of Malesia evolved. The present and palaeo-geography of the region strongly suggest that dispersal is the overwhelmingly universal mechanism in which the islands of Malesia were populated. Species with high dispersal power will be most successful in populating vacant islands, and are the most likely candidates as inhabitants of isolated islands. However, dispersive species frequently reach the same places, so that even such relatively isolated populations cannot evolve isolating mechanisms due to frequent gene flow between populations. Thus, dispersive species usually have large distributional ranges. On the other hand, it is unlikely that species with low dispersal power will ever reach isolated islands. The composition of island biotas was described in the dynamic equilibrium model of island biogeography by MacArthur & Wilson (1963, 1967), which is mainly a theory on an ecological time scale. Whittaker et al. (2008) recently proposed ‘a general dynamic theory of oceanic island biogeography’, in which also the geological life cycle of islands is incorporated. During the life cycle of an island, the complexity of habitats increases in relation to the development of an increasingly complex topography. Such conditions may provide opportunities for radiation of local plant and animal groups, as well as for individuals that newly reach the island. Small distributional ranges in Malesia are common in very different groups of plants and animals. The present distributional patterns of biotas are supposed to reflect events in the geological past, and congruent patterns of area relationships are frequently found in southeast Asia. Such patterns are usually attributed to vicariance events, but palaeogeographical data of southeast Asia hardly support the hypothesis that splitting of islands has frequently occurred. We presume that the dynamics of origin, movements with the continental plates, and final disappearance of the islands of the archipelago have been a more dominant driving force in the evolution of taxa. The resulting variation in proximity of islands to other islands or continental fragments during their geological history provided an environment in which completely different biotas could be ‘exchanged’. This aspect provides a further dimension in Whittaker’s et al. (2008) theory on island biogeography. Apparently, the biotas of Malesia evolved in a fragile balance, in which rare occasions of (common) dispersal events were interrupted with long periods without dispersal and radiation of local populations. The isolation of the islands in the Indo-Australian region during the Cenozoic strongly depended on the continuous reorganisation of the islands. During periods of low colonization rate, founder populations usually evolve isolating mechanisms (see Heaney, 2000). Specimens from new dispersal events, even from the same source population, may then no longer be able to mix with descendants of previous dispersal events, enabling the involvement of new species in the same area. In some cases, the flora and fauna of present-day larger islands, such as Sulawesi and New Guinea, which are them-

selves combinations of palaeo-islands that merged in the geological past, reflect the highly complex nature of evolution on the palaeo-islands, and the subsequent evolution of the biotas after the amalgamation of their habitats.” (Authors)] Address: Tol, J. van, National Museum of Natural History, P.O. 11812. Bouwman, J.H. (2010): Two new populations of *Somatochlora arctica* in Overijssel. *Brachytron* 13(1/2): 26-31. (in Dutch, with English summary) [“In 2008 two new populations of *S. arctica* were discovered in the southeastern part of the province for Overijssel, The Netherlands. These populations are the second and third for Overijssel. One population is located at the crossborder nature reserve Witte veen where it can be found in a peat area which is dominated by *Eriophorum angustifolium*, *Molinea caerulea* and *Sphagnum*-mosses. The second population is located in both the Overijssel as the Gelderland part of Het Lankeet. During the first visit the actual reproduction site couldn’t be found. In late summer 2008 the probable reproduction site was found. This beautiful peat area is dominated by *Narthecium ossifragum*, *Eriophorum angustifolium* and *Sphagnum* species like *S. cuspidatum* en *S. magellanicum*. On the 20th of May 2009 31 exuviae and several juveniles were found here, which shows that a big population is present here. Probably more populations can be found in the next years.” (Author)] Address: Bouwman, J.H., Vlinderstichting, Postbus 506, NL-6700 AM Wageningen, The Netherlands. E-mail: jaap.bouwman@vlinderstichting.nl

11813. Briggs, N.; Schneider, E.G.; Sones, J.; Puryear, K. (2010): Inventory of Odonata (Dragonflies and damselflies) at Gateway National Recreation Area. Natural Resource Technical Report NPS/NCBN/NRTR—2010/296: XV + 79 pp. (in English) [New York & New Jersey, USA; “In order to expand knowledge of odonate biodiversity and to make recommendations for management, we conducted a comprehensive baseline inventory of Odonata at Gateway National Recreation Area (GATE). During 2004 and 2005 we conducted a checklist inventory at sites where odonates could potentially breed, as well as at potential migratory and foraging sites. Checklist walks are unrestricted, complete searches that provide an efficient means for initial determination of species presence. During the combined 2004 and 2005 field seasons, 37 species of odonates were documented across 38 sites surveyed. Two New York state listed species were observed, *Ischnura ramburii* and *Libellula needhamii*. Of the 4,671 individuals sighted during 2004 and 2005, 353 were collected as voucher specimens, representing 35 of the 37 species recorded. The most abundant odonate species at GATE were *Enallagma civile*, *Pachydiplax longipennis*, *Ischnura hastata*, and *Epiaeschna heros*. GATE is located within the odonate migration corridor and offers critical habitat for migrating odonates. Migrating odonates were observed during both years of this study in the Jamaica Bay Unit at Fort Tilden and at Breezy Point. The Jamaica Bay Unit showed the greatest species richness of the three Park Units at GATE. In particular, Big John’s Pond and West Pond at Jamaica Bay Wildlife Refuge contained permanent water and supported considerable odonate activity, including two state-listed species, *I. ramburii* and *L. needhamii*. The Staten Island Unit generally lacks permanent water and abundant habitat that can be used for breeding by odonates. Nonetheless,

sites containing permanent water, such as Freshwater Pond and Peeper Road, provided good foraging and breeding habitat for a suite of odonate species, including two state-listed species, *I. ramburii* and *L. needhamii*. The Sandy Hook Unit contains several unique coastal habitats, including sand dunes, salt and freshwater marshes, and freshwater ponds that provided valuable foraging, breeding, and migratory habitats for odonate species. Of particular importance to breeding odonates were freshwater ponds such as Newest, North, and Exclamation Point Pond. Overall, GATE contains several marshes and coastal ponds that are appropriate for odonate reproduction, as well as several sites that offer good foraging and critical migration habitat." 11814. Brunelle, P.M. (2010): Dragonflies and damselflies (Odonata) of the Atlantic Maritime Ecozone. In: D.F. McAlpine and I.M. Smith (eds.). Assessment of Species Diversity in the Atlantic Maritime Ecozone. NRC Research Press, National Research Council Canada, Ottawa, ON: 333-369. (in English, with French summary) ["The 142 Odonata species recorded from the Atlantic Maritime Ecozone include 28% of the North American total, a large percentage for a comparatively small area. This diversity is due to the great breadth of aquatic habitat types in the ecozone. There has been a dramatic increase in knowledge of the odonates of the region in the last 20 years, much of it provided by informed amateur surveyors. Based on this information, federal and provincial governments and conservation authorities have recently been able to assign status ranks to odonate species. These ranks greatly facilitate consideration of the odonates when assessing human impact in the environment, and encourage further study of these insects. However, much remains to be done. Many species have not been adequately surveyed; subnational status ranks for numbers of odonates occurring in the Atlantic Maritime Ecozone are "undetermined", indicating the need for further focussed survey. This chapter includes a synopsis of species characteristics and conservation status, along with information on habitat preferences. A review of surveys and survey efforts is also provided, as are suggestions that should help guide future efforts that will increase our understanding of the order in the ecozone." (Author)] Address: Brunelle, P.-M., 2460 John Street, Halifax, Nova Scotia, B3K 4K7, Canada. E-mail: paulmbrunelle@gmail.com

11815. Chertoprud, M.V. (2010): Diversity and classification of rheophilic communities of macrobenthos in middle latitudes of European Russia. *Journal of General Biology* 72(1): 51-73. (in Russian, with English summary) ["Based on original data (450 samples from 115 streams of European Russia middle latitudes – from Pskov to Kostroma Regions) the attempt is made to describe the overall diversity of rheophilic communities dwelling on streams bottom and in macrophytes. In total, 39 community types were identified by the Braun-Blanquet method; their taxonomical and structural characteristics are described; the associations with biotopes are outlined; and a biotopical nomenclature is proposed. All communities are subdivided into four biotopical classes: crenal (springs and springbrooks with mixed substrates), rhithral (stony and woody substrates), phythal (macrophytes), and pelal (soft ground). It is shown that all communities may be divided by their organization as R-type or M-type community. 36 out of 39

studied communities belong to R-type and are characterized mainly by prevalence of insect, unstable dominance, and rather distinct association to the biotope. In M-type communities (3 out of 39 studied communities) eurybiontic mollusk *Viviparus viviparus* and amphipod *Dikerogammarus haemobaphes* predominate; these communities are interbiotopic, with stable species structure and high total abundance. The effect of the study spatial scale on the definition of communities is discussed along with problems of the communities dynamics." (Author) *Calopteryx splendens* is listed as species of the Hypoxylorhithral, Limnophytal and Rhizorheophytal coenoses and *Platycnemis pennipes* of the Rhizorheophytal coenosis.] Address: Chertoprud, M.V., Moscow Lomonosov State University, Faculty of Biology, 119992 Moscow, Leninskie Gory, Russia. 11817. Hamill, S.E. (2010): Recovery strategy for the Rapids Clubtail (*Gomphus quadricolor*) in Ontario. Ontario Recovery Strategy Series. Prepared for the Ontario Ministry of Natural Resources, Peterborough, Ontario: vi + 15 pp. (in English) ["*G. quadricolor* is a small, brightly coloured dragonfly which lives in clear, cool, medium to large rivers with wooded shorelines, gravel shallows, and muddy pools. Adult males perch on exposed rocks in the rapids. Adult females inhabit shoreline forests, moving to the rapids when ready to mate. Eggs are laid over the rapids and the nymphs live in quiet, muddy, downstream pools. This species is a globally rare to uncommon dragonfly found throughout Eastern North America, in a range extending from Maine to Minnesota, including southern Ontario. In Ontario it has been found in only four rivers: the Credit, the Thames, the Humber and the Mississippi. The population in the Credit River may be extirpated. The species is listed as endangered on the Species at Risk in Ontario (SARO) List under the Endangered Species Act, 2007. Threats to survival and recovery include dam construction, shoreline alteration, pollution, removal of shoreline forests, exotic predatory species, roadkill and climate change. Limiting factors include low population numbers, limited distribution and apparent sensitivity to specific habitat features. Knowledge gaps include a lack of understanding of the reasons for its limited distribution and for its habitat sensitivity. The recovery goal is to ensure the long-term survival of *G. quadricolor* in the

province by protecting existing populations and by restoring populations in appropriate habitat where feasible. The recovery objectives are to: (1.) protect, maintain and improve habitat in the four rivers in Ontario where *G. quadricolor* has been found; (2.) implement a monitoring program for the locations where *G. quadricolor* is known to exist; (3.) conduct additional inventory for *G. quadricolor* in suitable habitat; and, 4. initiate research to address knowledge gaps for *G. quadricolor*. It is important to ensure adequate protection of habitat and water quality for the species' survival and recovery. The locations where the species has been found in the Credit, Thames, Humber and Mississippi Rivers should all be prescribed as habitat in a habitat regulation. At each location, the area prescribed as habitat should include the section of the river containing the rapids and the pools below the rapids, plus the wooded shores on either side extending inland to include any forest which is within 800 metres of the shoreline."(Author)] Address: not stated

11818. Jinguji, H.; Tsuyuzaki, H.; Ueda, T. (2010): Effects of temperature and light on the hatching of overwintering eggs in three Japanese Sympetrum species. *Paddy and Water Environment* 8(4): 385-391. (in English) ["The aim of the present study was to obtain quantitative information on egg hatching with respect to temperature and light to clarify the effect of cultivation methods on three Japanese Sympetrum species. Eggs of three Sympetrum species were collected on October 2005 at Akita prefecture located at north of Japan, and the eggs had been laid on soil surface of paddy field till April 2006. The eggs (3 trays with 50 eggs each) were held under four constant temperatures (8, 13, 18 and 23°C) with a photoperiod (L:D 14:10; relative light intensity 3,000 Lux) and 23°C in darkness. No *S. infuscatum* eggs, but 67 and 60% *S. frequens* and *S. darwinianum* hatched in constant darkness. This result suggests that *S. frequens* and *S. darwinianum* do not require light for hatching, but *S. infuscatum* requires light for hatching. Eggs of *S. darwinianum* and *S. infuscatum* did not hatch at 8°C. In *S. frequens*, some eggs hatched but the hatching rate was significantly lower at 8°C than at higher temperatures ($P < 0.05$). At higher temperatures, the hatching rate did not differ significantly for three Sympetrum species. At 13°C, *S. infuscatum* hatched fastest, 0.18 for *S. infuscatum*, 0.11 for *S. darwinianum* and 0.08 for *S. frequens*. The mean head width of second stadium larva of *S. frequens*, *S. darwinianum* and *S. infuscatum* were 0.4 ± 0.01 , 0.4 ± 0.01 and 0.6 ± 0.01 mm (SD), respectively. These results suggest that *S. infuscatum* may have a competitive advantage over *S. frequens* and *S. darwinianum* under conditions that favour *S. infuscatum* through hatching speed." (Authors)] Address: Jinguji, H., School of Food, Agricultural and Environmental Sciences, Miyagi University, 2-2-1 Hatate, Taihaku-ku, Sendai. Miyagi 982-0215, Japan. E-mail: jinguji@myu.ac.jp

11819. Klymko, J. (2010): Odonate Surveys on the Tusket, Medway, and Lahave Rivers. Atlantic Canada CDC Canada Atlantique. Report to Nova Scotia Species at Risk Conservation Fund, December 21, 2010: 12 pp. (in English) ["The 2010 fieldwork on major rivers in southern Nova Scotia has significantly increased our understanding of the distribution and status of several rare dragonfly and damselfly species. The surveys demonstrate that exuvia-based collecting can detect elusive species, and can turn up new species on wa-

terways where adults have been well-surveyed. The occurrence of *Ophiogomphus anomalus* in Nova Scotia indicates appropriate habitat may occur for the COSEWIC Special Concern Pygmy Snaketail in Nova Scotia. Most importantly findings indicate there is still much to be learned about Nova Scotia's Odonata. Additional fieldwork on large Nova Scotia rivers would certainly produce new locations for rare species, and likely add species to the provincial list. Large Nova Scotia rivers that have received little attention to date include the St. Mary's (15 records, no exuvia), Clyde (41 records, 1 exuvia), Annapolis River (37 records, 1 exuvia), Roseway (5 records, no exuvia), Stewiacke (3 records, no exuvia), Musquodobit (3 records, 1 larva) (ADIP 2010)." 11824. Rebora, M.; Piersanti, S. Gaino, E. (2010): The antennal sensory function in the oldest pterygote in-

sects: an ultrastructural overview. In: A. Méndez-Vilas and J. Díaz (Eds.): *Microscopy: Science, Technology, Applications and Education*. Vol 4(1): 137-145. (in English) ["Paleoptera (Odonata and Ephemeroptera) represent the oldest pterygote insects. In consideration that antennae are one of the main site of not-visual insect perception, ultrastructural investigations under SEM and TEM have been recently performed on the flagellum of species belonging to several families of Odonata and Ephemeroptera, to clarify the sensory function of the antennae in Paleoptera. These antennae appear very reduced and are constituted by scape, pedicel and an aristate flagellum, mainly monoarticulated in Ephemeroptera and composed of 1-4 flagellomeres in Odonata. Several sensory structures have been identified on the ventro-lateral side of the flagellum in both orders with two main possible functions: thermo-hygroreception and olfaction. Studies on the sensory biology of these aquatic insects can contribute to clarify interesting aspects of their biology. In addition, studies on Paleoptera sensilla light into the evolution of insect sensory abilities." 11825. Rybak, J.; Pasternak, G. (2010): Analysis of water quality in the area of Wrocław's aquiferous layers with macroinvertebrates as bioindicators. *Ochrona Środowiska* 32(2): 27-34. (in Polish, with English summary) ["For the purpose of this study, seven biotic systems were chosen to assess the quality of wet pond water within the aquifer of Wrocław and in the bordering old Olawa river basin: BMWP-PL, ASPT, BBI, FBI, TBI, CBS and EPT. They all entail zoobenthic communities (including *Platycnemis pennipes*), whose composition changes with increasing pollution of the aquatic environment. The results obtained were compared with the values of some physicochemical parameters of the water, which enabled the applicability of the biotic systems to be evaluated. The water within the area under study was also analyzed for biodiversity. For this purpose calculations were performed to determine the domination and frequency of particular species and families at the sampling sites, as well as to establish the values of the Hurlbert and Margalef biodiversity indices. Both physicochemical and biological parameters make it clear that water quality in the area of the aquiferous layers is generally poor: species of comparatively high resistance to water pollutants were found to occur even at sampling sites characterized by great biodiversity. Water quality in all of the wet ponds examined has been classified either as acceptable or in some instances even as unacceptable. The results obtained support the applicability of the BMWP-PL index and recommend its use on a larger scale in Poland." (Authors)] Address: Rybak, Justyna, G. 11827. Tennessen, K (2010): Brief notes on *Ischnura* behavior. *Argia* 22(3): 17-18. (in English) [Verbatim: *Ischnura verticalis*: Females of some species of *Ischnura* mate only once in their lifetime, and they probably mate that one time early in their adult existence. Ola Fincke (1987) reported monogamy to be the norm in *Ischnura verticalis* (Say), the Eastern Forktail. She found that young females (mostly orange) and mature females (mostly grayish-blue) reject approaching males, whereas females that have aged and darkened somewhat but have not yet turned blue were often receptive, once, to mating attempts by males. Furthermore, females that copulated for more than 20 minutes could not be induced to mate again, apparently receiving enough sperm to serve their needs for the rest of their lives (i.e., to fertilize all eggs they may develop). This knowledge helps explain much of the behaviour of the two sexes of this species compared to most other coenagrionids, such as males being nonaggressive towards other males and females ovipositing alone and not being "bothered" much by intruding males. The signals that unreceptive females of *I. verticalis* show males are quite striking. Grieve (1937) was the first to observe females flexing their abdomen ventrally and fanning their wings at approaching males, but he misinterpreted this posturing as an attempt by females to attract males and assumed it was courtship behaviour. Bick (1966) correctly interpreted this behaviour as a signal to a male that the female was unreceptive to mating. I have seen this behaviour numerous times. The following photos (Fig. 1) I took in central Wisconsin show a male hovering near a female and the female wing-whirring and bending the apical half of her abdomen downward to refuse his approach. Males usually leave such females after a few seconds. This scenario (not the posture) is remindful of the age-old rejection at a high school dance, so it's hard for us fellows not to feel sorry for these "ambitious" males. *Ischnura hastata*: This species might also be monogamous, although literature on the natural history of this species is sparse. A population in the Azores is actually parthenogenetic (Lorenzo-Carballo & Cordero-Rivera, 2009); it is the only odonate known to be able to produce viable eggs without sperm, and all resulting offspring are female. However, all known mainland North American populations consist of both males and females. Very little is known about mating and oviposition in this species. Recently, I found several populations in Wisconsin Marquette, Shawano and Waushara counties) and so far have observed oviposition only once, at a ditch-like wetland in Marquette County. A female perched on the surface of the stem of a small rush that had fallen into the water and repeatedly poked her ovipositor into that stem and a nearby stem (Fig. 2). I was able to get two photographs before a male *I. verticalis* pounced on her, at which she flew into nearby vegetation. Further patient observation of this species will likely be rewarded with much-needed knowledge of its reproductive behaviour.] Address: Tennessen, K., 125 N. Oxford St, Wautoma, WI 54982, USA. 11832. Brook, J.; Brook, G. (2011): The Dainty Damselfly *Coenagrion scitulum* (Rambur) in Kent. Atropos 42:

9-13. (in English) [21-VI-2010, Isle of Sheppey, Kent, UK; discovery, identification and habits of the species are outlined.] Address: Brook, J., Barrack Cottages, Lower street, Broomfield, Maidstone, Kent, ME17 1PU, UK

11833. Buczyński, P.; Lewandowski, K. (2011): Dragonfly (Odonata) fauna of Olsztyn (Poland). In: Piotr Indykiewicz, Leszek Jerzak, Jörg Böhner, Brendan Kavanagh (eds.): URBAN FAUNA: Studies of animal biology, ecology and conservation in European cities: 109-119. (in English) ["The field studies presented in this paper were conducted in 1987-2004 and encompassed the Rivers Łyna and Wadąg, streams near Lake Skanda and in the Słoneczny Stok residential estate (usually regulated), eutrophic lakes Skanda, Redykajny and Tyrsko, small water bodies in various parts of the city (city center, Stoneczny Stok, Gutkowo, Municipal Forest, Mazurskie Estate, Jaroty), oxbow lakes, glacial lakes, and a fen near Lake Skanda. A total of 1 914 larvae (including 1 891 identified at the species level), 28 exuviae and 1 268 imagines of 49 dragonfly species were collected, accounting for 67% of the Polish dragonfly fauna. The finding of an imago of *Sympetrum striolatum* was an important faunistic discovery which confirmed the taxon's presence in the Masurian Lakeland. So far, this species had been sighted only in larval form, and, therefore, its occurrence was uncertain. *Sympetma paedisca*, *Lestes viridis* and *Aeshna cyanea* were recorded for the first time in the Olsztyn Lakeland. For all analyzed localities, the most diverse dragonfly fauna was found in small water bodies and streams. Rivers were characterized by the lowest faunistic diversity. The abundance of the odonata fauna in small water bodies can be attributed to a high number of small ponds in post-glacial regions, which differ in stability, trophy levels and vegetation cover. A comparison between the highly developed city center and suburban districts revealed that the qualitative diversity of dragonfly fauna in peripheral areas was twice as high as that reported for downtown Olsztyn." (Authors)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

11836. Chelmick, D. (2011): Vernacular names — Only for the Brits! Atropos 44: 49-50. (in English) [Verbatim: "Odonata is an insect order that has only come to public awareness in recent years. When I started my research

there were no vernacular names, but recent publications have changed all this and a range of English names have been invented, presumably, in order to popularise these insects and make them available to the wider world. I question the need and offer three examples. In the 1980s a particular project was to study the dragonfly *Epiheca bimaculata* in one of its key habitats, the Ardennes in northern France. I spent three days with Gennaro Coppa, who was a dedicated field-worker but whose English was non-existent. Fortunately, thanks to my 'menu French' and the fact that we both knew our dragonflies by their scientific names, we were able to converse and spent the evenings drinking beer and musing over the specific habitat requirements of *Sympetrum danae*, etc. Two years ago I was at a famous wetland in Central Spain known as the Tablas de Daimiel; it was thrashing down with rain but there on the boardwalk was a lone birdwatcher huddled behind his scope, ignoring the elements. 'I am studying *Locustella luscinioides*' he told me, then, realising that I was British, fumbled around in his notebook for his list and translated: Savi's Warbler. This autumn we took a trip to Romania (a walking holiday); the leader was a good birder but kept having to refer to a list whenever a new bird appeared. I found this strange, and upon enquiring I realised that he knew his birds by scientific names so when we found *Loxia curvirostra* he had to refer to his list in order to produce the name Crossbill. Normally he only needs the list for British groups. I am well aware that the British attitude to language is that 'we had to learn English so why shouldn't everyone else', but as a result we are becoming the naturalist laughing stock of Europe, relying upon names that nobody else needs. In addition to their irrelevance, vernacular names for dragonflies can be downright misleading. *Aeshna isosceles* (Norfolk Hawker) does occur in Norfolk but its range extends across central Europe to Mongolia. *Onychogomphus uncatatus* is known, confusingly, as the Large Pincertail and also as the Blue-eyed Hooktail. The species is virtually identical in size with its congener *Onychogomphus forcipatus*, which is known as the Small Pincertail. Even more confusing is the fact that the Blue-eyed Hooktail has green eyes in certain states and especially in females, and the Green-eyed Hooktail has blue eyes in the south of its range! Scientific names are not difficult to learn, are universal in use and provide common communication across all languages—why use anything else?" (Author)] Address: Chelmick, D., 31 High Beech Lane, Haywards Heath, West Sussex, RH16 1SQ, UK. E-mail: dgc@david-chelmick.com

11837. Cousins, L.; Tansley, D.; Hepburn, L. (2011): Investigation into the dietary habits of the Eurasian otter (*Lutra lutra*) in the county of Essex. IUCN Otter Spec. Group Bull. 28(2): 76-83. (in English, with French and Spanish summary) ["Monitoring throughout the county of Essex (UK) has shown annual widening of otter distribution. There is, however, room for expansion and some areas remain uncolonised. This paper reports a snapshot study of spraints collected from within the areas of known distribution, providing additional insight on a growing population. Prey remains were identified to family level and data used to calculate trophic breadths over the range of stream orders. Investigative comparisons were used to detect changes in diet with stream order. Further consideration was given to the importance of crayfish predation (e.g. the signal crayfish *Pacifastacus leniusculus*). Within the sample (n= 54)

from four stream orders (Strahler 2-5), fish occurred most frequently (67%). Other groups included; invertebrates 20%, birds 7% and mammals 6%. Crayfish comprised 4% of the sample. There were no significant differences between Trophic Niche Breadth and stream order ($H^* = 2.73$, $P > 0.05$), a finding strengthened by subsequent statistical analysis of the data. Dietary composition was consistent within the range and period studied. Extended research could determine seasonal variation and the extent to which available prey assemblage limits distribution against wider environmental and biological variables." (Authors) Odonata contributed with 6% to prey items extracted from otter spraint (n=54).] Address: Cousins, L., Essex Wildlife Trust, Abbots Hall Farm, Great Wigborough, Colchester. CO5 7RZ, UK. E-mail: lcousi@essex.ac.uk

11838. Da Silva, F.L.; Mayer Pauleto, G.; Ruiz, S.S.; Biscalquini Talamoni, J.L. (2011): Aquatic macroinvertebrates survey and assessment of two artificial reservoirs into conservation units from the southeast region of Brazil. *Pan-American Journal of Aquatic Sciences* 6(1): 57-64. (in English, with Portuguese summary) ["This study aims to inventory and assess the aquatic macroinvertebrates fauna in two artificial reservoirs into conservation units with differences regarding conservation level and to anthropogenic impacts. The samplings were carried out in Caetetús Ecological Station and Bauru City Zoological Park, where some physical and chemical variables also were measured. The results obtained indicated that the Caetetús Ecological Station is more effective in the conservation of the diversity of aquatic macroinvertebrates compared to Bauru City Zoological Park. These results can be attributed to the strong anthropogenic impact suffered by the reservoir in Bauru and demonstrate the importance of these areas in maintaining the diversity of aquatic macroinvertebrates community." (Authors) Odonata taxa are treated at family level.] Address: Da Silva, F.L., Universidade Federal de São Carlos – UFSCar, Programa de Pós-graduação em Ecologia e Recursos Naturais, Laboratório de Entomologia Aquática, Departamento de Hidrobiologia, Rodovia Washington Luís, km 235, 13565-905, São Carlos, SP, Brasil. 11840. Gómez-Anaya, J.A.; Novelo-Gutiérrez, R.; Campbell, W.B. (2011): Diversity and distribution of Odonata (Insecta) larvae along an altitudinal gradient in Coalcomán mountains, Michoacán, Mexico. *Rev. Biol. Trop. (Int. J. Trop. Biol.)* 59(4): 1559-1577. (in English) ["Evaluating components of landscape diversity is essential for the implementation of efficient conservation strategies. We evaluated the diversity of Odonata larval assemblages from the Coalcomán mountains (CM), Michoacán, Mexico, and related it to local (site-level) habi-

tat variables. Larvae were collected from shores, riffles and pools in five streams, counted and identified to species, twice per season during 2005. The Shannon Diversity Index (H'), Margalef's Richness Index (R), Simpson's Index as a dominance measure (D) and Pielou's Equitability (J) were used to describe the assemblages, and Renyi's Diversity Profiles were used to order diversity. A Bray-Curtis Similarity Index (BC) was used to evaluate beta diversity. Theoretical richness was estimated using non-parametric and parametric methods. A Canonical Correspondence Analysis (CCA) was applied to explore the relationships of species with site-level environmental variables. A total of 12 245 larvae from 75 species, 28 genera and 8 families were recorded. Over all sites, the dominant species were *Erpetogomphus elaps*, *Macrothemis pseudimitans* and *Argia pulla*. The number of species per locality ranged from 18 to 36, and a high number of species (76%) occurred with relative abundances lower than 1%. A differential distribution of species and abundance in streams, time and strata was observed. Renyi's diversity profiles showed diversity was higher in spring and on shores. Most BC similarity values were smaller than 25%, indicating a high turnover rate in the CM. The high turnover rate reflects a differential distribution of the species along the altitudinal gradient, supporting the hypothesis of Mexico as a betadiverse country. According to the slope of Clench's curve, a reliable list of species was gathered. The CM larval assemblage is currently the largest reported for Mexico, and our results support previous proposals of the CM as a species-rich area for conservation." (Authors)] Address: Gomez-Anaya, J.A., Instituto de Ecología, A.C., Apartado Postal 63, MX-91070, Xalapa, Veracruz, Mexico. E-mail: antonio.gomez@in-econol.edu.mx

11841. Hollingworth, L. (2011): A Bizarre Sighting of Common Blue Damselfly *Enallagma cyathigerum*. *Atropos* 44: 48. (in English) ["On 10 July 2011 I visited College Lake, Buckinghamshire. A Common Blue Damselfly *Enallagma cyathigerum* attracted my attention, which upon closer inspection appeared to have two bodies hinged at the top. When it flew the bodies opened like a pair of scissors. Can anyone explain what has caused this and whether it is very unusual? - The photo clearly shows a normal 'blue-phase' female Common Blue Damselfly that is also bearing the abdomen of a male, attached in the manner seen during mating i.e. with the male's claspers grasping around the rear of the female's pronotum (the small plate behind the head). What has actually happened is that a pair in tandem or in cop. has been caught by a predator, which has then removed/eaten the male's thorax. This has in turn allowed the female to escape, but with the abdomen of the male still attached. Although in most instances of pair predation a female can presumably escape simply by the pair separating, sightings of females with portions of a male abdomen attached are also reported from time to time. How long the link will persist is unknown but may apparently be some while, the male of course no longer being able to loosen his grip." (Eds.)] Address: Hollingworth, L., 23 Meadow Close, Trimley St Martin, Felixstowe, Suffolk, IP11 0UL, UK

11842. Holuša, O.; Dalecký, V.; Holušová, K. (2011): First record of larvae of *Cordulegaster heros* (Odonata: Cordulegastridae) in the Czech Republic. *Acta Musei Beskidensis* 3: 65-69. (in English, with Czech summary) [Two larvae of *C. heros* were found on 15-X-2011 at the

villages of Kudlovice (Kudlovický potok stream) and Jankovice (Jankovický potok stream) on the southern slopes of the Chriby Hills in the Czech Republic.] Address: Holuša, O., Muzeum Beskyd, přírodovědné oddělení, Zámecké náměstí 1264, CZ-738 01 Frýdek-Místek. E-mail: holusao@post.cz

11843. Just, J. (2011): *Australolestes* nom. nov. for *Austrolestes* Just, 1998 (Crustacea, Amphipoda, Ischyroceridae, Siphonocetini) homonym of *Austrolestes* Tillyard, 1913 (Insecta, Odonata). *Crustaceana* 84(3): 383. (in English) [Verbatim: "Just (1998) described *Austrolestes* subgen. nov. (type species: *Austrolestes berentsae* Just, 1998) in the siphonocetine amphipod genus *Ambicholestes* Just, 1998. Tillyard (1913) described *Austrolestes* gen. nov. (Odonata). Hence, *Austrolestes* Just, 1998 is a junior homonym of *Austrolestes* Tillyard, 1913. A new name is therefore required for *Austrolestes* Just, 1998. I hereby propose the name *Australolestes* for this subgenus. Component species: *Ambicholestes* (*Australolestes*) *berentsae* Just, 1998, *A. (Australolestes) minutus* Just 1998, *A. (Australolestes) thetis* Just, 1998. References: JUST, J., 1998. Siphonocetinae (Crustacea: Amphipoda: Ischyroceridae) 7: Australian concholestids, *Ambicholestes* n. gen., with a description of six new species, and a new, restricted diagnosis for *Caribboecetes* Just, 1983. *Records of the Australian Museum*, 50 (1): 27-54. TILLYARD, R. J., 1913. On some Australian Anisoptera, with descriptions of new species. *Proceedings of the Linnean Society of New South Wales*, 37: 404-479."] Address: Just, J., Museum of Tropical Queensland, 72-102 Flinders Street, Townsville, Queensland 4810, Australia. 11844. Karube, H. (2011): Two new species of the family Aeshnidae (Anisoptera) from central Vietnam. *Tombo* 53: 75-80. (in English, with Japanese summary) ["Two new species of the genera *Cephalaeschna* and *Planaeschna* are described from central Vietnam. *Cephalaeschna asahina* sp. nov. is related to *C. klotsi* Asahina, 1982 from Fukien, China. It is easily distinguished from the latter by its head structure, body maculation and male caudal appendages. It is the southernmost recorded occurrence of the genus. The *Planaeschna asahina* sp. nov. is the 7th member of the genus from Vietnam. It is easily separated from other members of the genus by its peculiar thoracic and abdominal maculation, but is clearly related to *P. tamdaoensis* Asahina, 1996. These two new species were discovered in the mountain zone of Bach Ma national park of central Vietnam, which is known for the rich diversity of its Odonata fauna." 11849. Lemke, M.; Germann, A. (2011): Ein Beitrag zur Libellenfauna (Insecta: Odonata) des ehemaligen Westwalls im Saarland. *Abhandlungen de Delattinia* 37: 155-170. (in German, with French and English summaries) ["This paper reports on dragonflies living in three anti-tank ditches that were part of the former Siegfried Line in the Saarland. Three anti-tank ditches were explored - Niederwürzbach, Lautzkirchen and Webenheim - inhabited by a great variety of species: 33 at Niederwürzbach, 27 at Lautzkirchen, and 29 at Webenheim. For several species evidence of reproduction was found by mating behaviour and ovipositions. On the other hand proof of reproduction success was found by observations of emergences and findings of exuviae. The very large population of *Libellula fulva* found in the anti-tank ditch at Niederwürzbach, the observation of *Ophiogomphus cecilia*, which is listed in the appendices II and IV of the FFH-Directive as well as the autochthonous population of *Epiheca bimaculata* in the anti-tank ditch at Webenheim are especially mentionable. In addition, several endangered species were found." (Authors)] Address: Lemke, M., Burgstr. 5, 66453 Medelsheim, Germany. E-mail: info@libelleninfo.de

11850. Lillo, F.; Faraone, F.P.; Lo Valvo, M. (2011): Can the introduction of *Xenopus laevis* affect native amphibian populations? Reduction of reproductive occurrence

in presence of the invasive specie. *Biol. Invasions*. 13: 1533-1541. (in English) ["Biological invasions are regarded as a form of global change and potential cause of biodiversity loss. *Xenopus laevis* is an anuran amphibian native to sub-Saharan Africa with strong invasive capacity, especially in geographic regions with a Mediterranean climate. In spite of the worldwide diffusion of *X. laevis*, the effective impact on local ecosystems and native amphibian populations is poorly quantified. A large population of *X. laevis* occurs in Sicily and our main aim of this work was to assess the consequences of introduction of this alien species on local amphibian populations. In this study we compare the occurrence of reproduction of native amphibians in ponds with and without *X. laevis*, and before and after the alien colonization. The results of our study shows that, when *X. laevis* establishes a conspicuous population in a pond system, the populations of *Discoglossus pictus*, *Hyla intermedia* and *Pelophylax synklepton esculentus* show clear signs of distress and the occurrence of reproduction of these native amphibians collapses. In contrast, the populations of *Bufo bufo* do not appear to be affected by the alien species. Since the Sicilian population of *X. laevis* shows a strong dispersal capacity, proportionate and quick interventions become necessary to bound the detriment to the Sicilian amphibians populations." (Authors) The diet of *Pelophylax esculentus* included 8,5%, that of *X. laevis*; no Odonata species were recorded.] Address: Lo Valvo, M., Dipartimento di Biologia Animale "G. Reverberi", Università di Palermo, Via Archira 18, 90123 Palermo, Italy. E-mail: mlovalvo@unipa.it

11851. Lopes Lionello, C.; José dos Santos-Wisniewski, M.; Zaitune Pamplin, P.A. (2011): Caracterização da fauna de insetos aquáticos e diagnóstico ambiental do Córrego dos Aflitos (Alfenas, MG). *Revista de biologia e ciências da terra* 11(1): 97-107. 11852. Masdeu, M.; Teixeira-de Mello, F.; Loureiro, M.; Arim, M. (2011): Feeding habits and morphometry of *Iheringichthys labrosus* (Lütken, 1874) in the Uruguay River (Uruguay). *Neotropical Ichthyology* 9(3): 657-664. (in English, with Spanish summary) ["Body size and diet of organisms are fundamental attributes which determine their ecology and natural history. *I. labrosus* is one of the most common fish species of the Uruguay River. However, its natural history is poorly known and there is little information about its diet and interactions with other species. This paper describes the feeding habits of this species, relating feeding patterns to the size classes and morphometry of individuals and to the temporal variations. Fishes were captured in May and November of 2006 in three zones of the lower Uruguay River. A total of 101 stomach contents was analyzed (standard length: 60-224 mm). The species exhibited a broad feeding spectrum with most items belonging to the benthic community. We found significant diet differences between size classes and studied months. However, we have not found a close relationship between changes in morphometric variables and diet shifts between size classes." (Authors) Odonata contributed little to the diet.] Address: Masdeu, M., Grupo de Ecología y Rehabilitación

11853. Maxell, B.J.; Piovoa-Scott, J.; Lawler, S.P.; Pope, K.L. (2011): Indirect effects of introduced trout on Cascade frogs (*Rana cascadae*) via shared aquatic prey. *Freshwater Biology* 56(5): 828-838. (in English) [California, USA; "(1) The introduction of trout to montane lakes has negatively affected amphibian populations across the western United States. In northern California's Klamath-Siskiyou Mountains, introduced trout have diminished the distribution and abundance of a native ranid frog, *Rana* (= *Lithobates*) *cascadae*. This is primarily thought to be the result of predation on frog larvae. However, if trout feed on larval aquatic insects that are available to *R. cascadae* only after emergence, then resource competition may also affect this declining native amphibian. (2) Stomach contents of *R. cascadae* were compared between lakes that contained trout and those from which introduced trout were removed. Total prey mass in stomach contents relative to frog body mass was not significantly different between lakes with fish and fish removal lakes, but in the former *R. cascadae* consumed a smaller proportion of adult aquatic insects. The stomach contents of fish included larvae of aquatic insects that are, as adults, eaten by *R. cascadae*. (3) *Rana cascadae* consumed fewer Trichoptera and more Orthoptera at lakes with higher densities of fish. At lakes with greater aquatic habitat complexity, *R. cascadae* consumed more Hemiptera: Gerridae and terrestrial spiders (Araneae). (4) We suggest that reductions in the availability of emerging aquatic insects cause *R. cascadae* to consume more terrestrial prey where trout are present. Thus, introduced trout may influence native amphibians directly through predation and, indirectly, through pre-emptive resource competition." (Authors) Stomach contents of *R. cascadae* averaged among fish-removal lakes (n = 3 lakes, 35 frogs) [A] and those with fish (n = 4 lakes, 13 frogs) [B] expressed as per cent by number (A: 11%; B: 3% in Odonata), per cent by estimated weight (A: 9.5%, B: 1.6% in Odonata)] Address: Maxell, B.J., Dept of Ecology & Evolutionary Biology, Campus Box 334, University of Colorado, Boulder, CO 80309-0334, USA. 11854. McLoughlin, S. (2011): New records of leaf galls and arthropod oviposition scars in Permian-Triassic Gondwanan gymnosperms. *Australian Journal of Botany* 59(2): 156-169. (in English) ["Single, midrib-positioned galls and midrib-flanking oviposition scars are described from four species of Permian glossopterid foliage from Australia and South Africa. Several of these traces have been mistaken previously for glossopterid reproductive organs or fructification detachment scars. A single Early Triassic corystosperm leaf from Australia is reported bearing multiple disc-like galls on both the midrib and pinnules. A Middle Triassic taeniopterid gymnosperm leaf from Australia is described hosting oviposition scars between consecutive secondary veins flanking the midrib. These fossils attest to a much richer record of plant-arthropod interactions in the late Palaeozoic and early Mesozoic of high-latitude Gondwana than previously reported, and indicate that herbivory and reproductive strategies involving galling and foliar ovipositioning were re-established relatively soon after the end-Permian mass extinction event that saw major

turnovers in both the flora and insect fauna." (Author) The paper includes references to Odonata.] Address: McLoughlin, S., Department of Paleobotany, Swedish Museum of Natural History, Box 50007, SE-104 05, Stockholm, Sweden. Email: steve.mcloughlin@nrm.se

11855. Miyake, M.; Miyashita, T. (2011): Identification of alien predators that should not be removed for controlling invasive crayfish threatening endangered odonates. *Aquatic Conservation: Marine and Freshwater Ecosystems* 21(3): 292-298. (in English) ["(1.) When multiple invasive species coexist in the same ecosystem and their diets change as they grow, determining whether to eradicate any particular invader is difficult because of complex predator-prey interactions. (2.): A stable isotope food-web analysis was conducted to explore an appropriate management strategy for three potential alien predators (snakehead *Channa argus*, bullfrog *Rana catesbeiana*, red-eared slider turtle *Trachemys scripta elegans*) of invasive crayfish *Procambarus clarkii* that had severely reduced the densities of endangered odonates (*Libellula angelina*) in a pond in Japan. (3.): The stable isotope analysis demonstrated that medium- and small-sized snakeheads primarily depended on crayfish and stone moroko *Pseudorasbora parva*. Both adult and juvenile bullfrogs depended on terrestrial arthropods, and juveniles exhibited a moderate dependence on crayfish. The turtle showed little dependence on crayfish. (4.): These results suggest that eradication of snakeheads risks the possibility of mesopredator release, while such risk appears to be low in other alien predators" (Authors)] Address: Miyashita, T., Laboratory of Biodiversity Science, School of Agriculture and Life Sciences, University of Tokyo, Yayoi, Tokyo 113-8656, Japan. 11858. Piersanti, S.; Rebor, M.; Almaas, T.J.; Salerno, G.; Gaino, E. (2011): Electrophysiological identification of thermo- and hygro-sensitive receptor neurons on the antennae of the dragonfly *Libellula depressa*. *Journal of Insect Physiology* 57(10): 1391-1398. (in English) ["Recent ultrastructural investigations on Odonata antennal flagellum describe two types of sensilla styloconica, T1 and T2. The styloconic sensilla are located in pits, at the bottom of deep cavities, and share common features typical of thermo-hygroreceptors. In order to ascertain if the Odonata antennae are involved in hygroreception and thermoreception, we carried out electrophysiological recordings (single cell recordings, SCR) from adult males and females of *L. depressa*. After con-

tact was established, the antenna was stimulated by rapid changes in temperature and humidity. The present research shows the occurrence of a dry (DC), a moist (MC) and a cold (CC) receptor neurons on the antennal flagellum of *L. depressa*. These data demonstrate for the first time the presence of functional thermo-hygroreceptors on the antennal flagellum of dragonflies. The present results extend our knowledge of the not visual sensory modalities of Odonata, a field of research unexplored so far." 11860. Pulfer, T.L.; Bahlai, C.; Mousseau, L. (2011): Recovery Strategy for Laura's Clubtail (*Stylurus laurae*) in Ontario. Ontario Recovery Strategy Series. Prepared for the Ontario Ministry of Natural Resources, Peterborough, Ontario: v + 23 pp. (in English) ["*S. laurae* is a member of the dragonfly family Gomphidae. It is found from Texas and the Florida Panhandle up to southwest Ontario, where it is found in the Norfolk Sand Plains physiographic region. Currently there are only two known populations in Ontario – Big Creek and Big Otter Creek. *S. laurae* is listed as an endangered species on the Species at Risk in Ontario (SARO) List and was assessed as endangered by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). *S. laurae* requires a high quality aquatic environment and a vegetated riparian area, preferably consisting of mature forests. It is generally found in or near small to medium sized streams with sand or silt substrate and overhanging trees or shrubs. Adults use riffles in the stream for foraging, mating and probably to lay eggs. Eggs or recently emerged larvae are carried downstream to pools. Adults are short-lived with breeding and egg-laying occurring within weeks of adult emergence. The main threat to the survival and recovery of *S. laurae* is habitat degradation or alteration to both the aquatic and terrestrial habitat. Aquatic habitat threats include changes to water flow rate, pH, dissolved oxygen, temperature, nutrient load, pollution, dam construction and changes to water quality. Terrestrial habitat threats include shoreline alteration and loss of riparian habitat. Invasive species (especially Round Goby) and road mortalities are also thought to negatively affect *S. laurae*, but the pressures these are exerting on the population are unknown and require further study. Limiting factors include a limited distribution and apparent sensitivity to specific habitat features. Knowledge gaps include an overall lack of species-specific information (including mating and foraging behaviours, physical tolerances to changes in stream condition and pesticides or herbicides), quantitative assessment of road mortalities and extent of the distribution in Ontario. The recovery goal is to ensure a viable, self-sustaining

population of *S. laurae* in Ontario. The protection and recovery objectives are to: *protect, maintain and enhance the quantity and quality of existing *S. laurae* habitat; *reduce or mitigate threats to *S. laurae* and its habitat where feasible; and *increase knowledge of *S. laurae* biology in Ontario including distribution, abundance, life history and habitat needs. It is recommended that all stream reaches (aquatic resource areas [Aquatic resource areas are aggregations of stream segments with similar physical and biological characteristics] as defined by OMNR) currently occupied by *S. laurae*, as well as the naturally vegetated areas on either side of the stream, extending inland 200 metres (the typical distance the dragonflies travel between reproductive and roosting habitats) be prescribed as habitat under the Endangered Species Act, 2007." (Authors)] Address: not stated

11861. Rivers-Moore, N.A.; Goodman, P.S.; Nel, J.L. (2011): Scale-based freshwater conservation planning: towards protecting freshwater biodiversity in KwaZulu-Natal, South Africa. *Freshwater Biology* 56(1): 125-141. (in English) ["(1.) River systems have strong linear linkages. Innovative solutions to capture these linkages are required from aquatic conservation planners. (2.) We apply an approach to freshwater conservation planning to freshwater ecosystems of KwaZulu-Natal (South Africa), using generic conservation planning software. We used a two-step, hierarchical process to capture catchment- and local-scale dynamics, where priority primary catchments were first identified and then used at a second level for selecting priority subcatchments, which served as planning units at a finer scale. (3.) We set quantitative targets for defined freshwater biodiversity features. Priority planning units at both catchment levels were selected using modified weighted cost discounts and penalties, which included the presence of priority estuaries and free-flowing rivers, planning units falling within priority primary catchments, planning units identified as important in an existing terrestrial conservation plan and the degree of catchment degradation. Ecological processes were incorporated by discounting planning units important for surface and groundwater yield. (4.) Upstream–downstream connectivity was achieved by linking adjoining subcatchments associated with main rivers and wetlands and enhanced by setting high targets for subcatchments through which eels (*Anguilla mossambica*) must migrate. (5.) The hierarchical approach of selecting priority primary catchments and using these to affect subcatchment costs, plus the use of high targets for migratory fish species, is applicable to any freshwater conservation plan to favour planning unit selection within selected basins, while facilitating connectivity in upstream–downstream subcatchments." (Authors) The list of freshwater features used in the plan to achieve gamma, beta and alpha biodiversity representation includes *Aciagrion pinheyi*, *Agriocnemis ruberrima ruberrima*, *Chlorolestes draconicus*, *Pseudagrion umsingaziense*, *Urothemis luciana*] Address: Rivers-Moore, N.A., Ezemvelo KZN Wildlife, PO Box 13053, Cascades 3202, South Africa. 11862. Rizzo, A.; Arcagni, M.; Arribère, M.A.; Bubach, D.; Ribeiro Guevara, S. (2011): Mercury in the biotic compartments of Northwest Patagonia lakes, Argentina. *Chemosphere* 84(1): 70-79. (in English) ["We report on total mercury (THg) concentrations in the principal components of food webs of selected Northern Patagonia

Andean Range ultraoligotrophic lakes, Argentina. The THg contents were determined using Instrumental Neutron Activation Analysis in muscle and liver of four fish species occupying the higher trophic positions (the introduced *Salmo trutta*, *Oncorhynchus mykiss* and *Salvelinus fontinalis*, and the native *Percichthys trucha*) accounted for eight lakes belonging to Nahuel Huapi and Los Alerces National Parks. We studied the food web components of both the West and East branches of Lake Moreno, including benthic primary producers such as biofilm, mosses, and macrophytes, three plankton fractions, fish, riparian tree leaves, and benthic invertebrates, namely decapods, molluscs, insect larvae, leeches, oligochaetes, and amphipods. Mercury concentrations in fish muscle varied in a wide range, from less than 0.05 to 4 µg g⁻¹ dry weight (DW), without a distribution pattern among species but showing higher values for *P. trucha* and *S. fontinalis*, particularly in Lake Moreno. The THg contents of the food web components of Lake Moreno varied within 4 orders of magnitude, with the lower values ranging from 0.01 to 0.5 µg g⁻¹ DW in tree leaves, some macrophytes, juvenile salmonids or benthic macroinvertebrates, and reaching concentrations over 200 µg g⁻¹ DW in the plankton. Juvenile *Galaxias maculatus* caught in the pelagic area presented the highest THg contents of all fish sampled, reaching 10 µg g⁻¹ DW, contents that could be associated with the high THg concentrations in plankton since it is their main food source. Although Lake Moreno is a system without local point sources of contamination, situated in a protected area, some benthic organisms presented high THg contents when compared with those from polluted ecosystems." (Authors) Taxa including Odonata are treated at order level.] Address: Rizzo, A., Laboratorio de Análisis por Activación Neutrónica, Centro Atómico Bariloche, CNEA, and CONICET, Av. 11865. Schwander, T.; Leimar, O. (2011): Genes as leaders and followers in evolution. *Trends in Ecology and Evolution* 26(3): 143-151. (in English) ["A major question for the study of phenotypic evolution is whether intra- and interspecific diversity originates directly from genetic variation, or instead, as plastic responses to

environmental influences initially, followed later by genetic change. In species with discrete alternative phenotypes, evolutionary sequences can be inferred from transitions between environmental and genetic phenotype control, and from losses of phenotypic alternatives. From the available evidence, sequences appear equally probable to start with genetic polymorphism as with polyphenism, with a possible dominance of one or the other for specific trait types. We argue in this review that to evaluate the prevalence of each route, an investigation of both genetic and environmental cues for phenotype determination in several related rather than in isolated species is required." 11867. Shin, I.K.; Yi, H.B.; Bae, Y.J. (2011): Colonization and community changes in benthic macroinvertebrates in Cheonggye Stream, a restored downtown stream in Seoul, Korea. *J. Ecol. Field Biol.* 34(2): 175-191. (in English) ["Colonization patterns and community changes in benthic macroinvertebrates in the Cheonggye Stream, a functionally restored stream in downtown Seoul, Korea, were studied from November 2005 to November 2007. Benthic macroinvertebrates were quantitatively sampled 15 times from five sites in the stream section. Taxa richness (59 species in total) increased gradually over the first year, whereas the density revealed seasonal differences with significantly lower values in the winter season and after flood events. The benthic macroinvertebrate fauna may have drifted from the upstream reaches during floods and from the Han River, arrived aerially, or hitchhiked on artificially planted aquatic plants. Oligochaeta, Chironomidae, Psychodidae, and Hydropterygidae were identified as major community structure contributors in the stream. Swimmers and clingers colonized relatively earlier in the upper and middle reaches, whereas burrowers dominated particularly in the lower reaches. Collector-gatherers colonized at a relatively early period throughout the stream reaches, and collector-filterers, such as the net-spinning caddisfly (*Cheumatopsyche brevilineata*), predominated in the upper and middle reaches after a 1-year time period. Cluster analyses and multi-response permutation procedures demonstrated that the Cheonggye Stream shares more similarities with the Jungnang Stream than with the Gapyeong Stream. Detrended correspondence analysis and nonmetric multidimensional scaling demonstrated that physical environmental factors (depth, current velocity, dissolved oxygen, and pH) as well as nutrients (total nitrogen and total phosphorous), water temperature, and conductivity could affect the distribution of benthic macroinvertebrates in the study stream... Larvae of *Anax parthenope julius*, *Orthetrum albistylum speciosum*, *Ischnura asiatica*, *Cercion calamorum*, *Cercion hieroglyphicum*, and *Coenagrionoidae* sp.), aquatic

bugs (*Ranatra chinensis*), and aquatic beetles (*Potamonectes hostilis*, *Potamonectes* sp., *Hydaticus* sp., and *Dytiscidae* sp.) were found among the artificially planted aquatic plants along the stream margins during the initial study period. These aquatic insects belong to a typical lentic fauna in Korea and were probably introduced with aquatic plants when they were planted in the restored stream section. The majority of these species disappeared several months after their occurrence. The restored Cheonggye Stream was opened to the public on October 1, 2005, but pilot operations were conducted prior to the opening ceremony while the channel was under construction with artificial plantations." 11868. Siepielski, A.M.; Mertens, A.N.; Wilkinson, B.L.; McPeck, M.A. (2011): Signature of ecological partitioning in the maintenance of damselfly diversity. *J. Anim. Ecol.* 80(6): 1163-1173. (in English) ["1. Ecological differences among co-occurring taxa are often invoked as an explanation for the maintenance of biodiversity. Whether these differences facilitate coexistence, which allows unequal competitors to remain in systems and thus maintain biodiversity, is still unclear. 2. Here, we used observational and experimental studies to test for ecological partitioning in ways that would promote coexistence among three co-occurring damselfly genera. We evaluated two necessary conditions for coexistence: (i) that the damselfly genera differ in their abilities to engage in interactions with other damselfly genera and environmental conditions such that their relative abundances covary differently along environmental gradients and (ii) that an increase in intrageneric abundance is more detrimental to performance-related demographic features of each genus than increases in intergeneric abundances. 3. Observational studies across 40 lakes showed that relative abundances of each genus covaried differently along an environmental gradient of lake abiotic and biotic features consistent with ecological partitioning. Field experiments in which we manipulated both intra- and intergeneric densities demonstrated that per capita growth rates of each genus are negatively density-dependent and are only limited by increases in intra- not intergeneric densities. 4. Collectively, these results show a clear signature of ecological partitioning among each genus, which should prevent competitive exclusion and maintain each genus in this system. The results do not guarantee local coexistence among the three genera but are consistent with criteria that should promote their coexistence. Our results also suggest that a food web model coupling keystone predation and apparent competition is likely necessary to explain the ecological dynamics of persistence among these genera." (2011): Terrestrial, benthic, and pelagic resource use in lakes: results from a three-isotope Bayesian mixing model. *Ecology* 92(5): 1115-1125. (in English) [Wisconsin-Michigan border region, USA; "Fluxes of organic matter across habitat boundaries are common in food webs. These fluxes may strongly influence community dynamics, depending on the extent to which they are used by consumers. Yet understanding of basal resource use by consumers is limited, because describing trophic pathways in complex food webs is difficult. We quantified resource use for zooplankton, zoobenthos, and fishes in four low-productivity lakes, using a Bayesian mixing model and measurements of hydrogen, carbon, and nitrogen stable isotope ratios. Multiple sources of uncertainty were explicitly incorporated into the model. As a result, posterior estimates of resource use were often broad distributions; nevertheless, clear patterns were evident. Zooplankton relied on terrestrial and pelagic primary production, while zoobenthos and fishes relied on terrestrial and benthic primary production. Across all consumer groups terrestrial reliance tended to be higher, and benthic reliance lower, in lakes where light penetration was low due to inputs of terrestrial dissolved organic carbon. These results support and refine an emerging consensus that terrestrial and benthic support of lake food webs can be substantial, and they imply that changes in the relative availability of basal resources drive the strength of cross-habitat trophic connections." 11872. Tunmore, M. (2011): An influx of insects along the north Norfolk coast. *Atropos* 42: 84-85. (in English) [Verbatim: "On 21 July 2010, whilst visiting friends in North Norfolk, I went for a walk along the nearby coast. It was a dry, warm and largely sunny day with a westerly breeze of approximately Beaufort Force 4. I began my walk at Brancaster beach, walking east along the dunes at the edge of the golf course to the beach chalets and returning via the same route to the car-park. As

I walked I disturbed small numbers of Common Darter *Sympetrum striolatum* (approximately four), a Migrant Hawker *Aeshna mixta* and the occasional Blue-tailed Damselfly *Ischnura elegans* (approximately six) and Common Blue Damselfly *Enallagma cyathigerum* in the dunes, there being no nearby freshwater. As I approached the beach chalets I disturbed several damselflies from a small Hawthorn *Crataegus monogyna*, which returned to alight on the branches of the bush. Upon closer investigation I found a total of 15 Small Red-eyed Damselfly *Erythromma viridulum* perched in this and two adjacent hawthorns, again with no nearby freshwater source. Later that afternoon I visited Titchwell RSPB reserve and walked down to the sea and west along the dunes. At the furthest point I disturbed an Anax imperator and a Painted Lady *Vanessa cardui* in the dunes and encountered an abundance of Silver Y *Autographa gamma* with an estimated 90,000 present in an area of sea lavender *Limonium* spp. At nearby Scott Head NNR summer warden Neil Lawton reported a similar mass arrival of Silver Y on this and the preceding day with 'several hundred thousand' present on 21 July. Via the Atropos Flight Arrivals webpage he also reported an arrival of Odonata on the island on 20/21 July with 10 Small Red-eyed Damselfly (including two in a moth-trap), two Emperor and small numbers of *S. striolatum*, *A. mixta*, *Orthetrum coerulescens*, *I. elegans* and *E. cyathigerum*. Overnight moth-trapping there on 20 July produced an estimated 6,000 Silver Y, one Small Mottled Willow *Spodoptera exigua* and seven Marbled Clover *Heliopsis virescens*. Clearly it was a significant period for insect immigration along this part of the North Norfolk coast." Address: Tunmore, M., 36 Tinker Lane, Meltham, Huddersfield, West Yorkshire HD7 3ES, UK. (2011): Recovering and succession of the species diversity of macrozoobenthos in Srebarna Biosphere Reserve (North-East Bulgaria). *Acta zool. bulg.* 63(1): 85-95. (in English) ["Development of the taxonomic composition of bottom macroinvertebrate fauna in Srebarna Lake Reserve is studied with a view to the changes in the environment after its reconnection with Danube River. A regime switching in the succession of the bottom invertebrate community in Srebarna Lake occurs expressed by considerable changes of its species composition after its reconnection of the with Danube by a new canal. Higher species richness in the peripheral pools of the wetland was recorded in comparison with the main open water body. Within the wetland area the local habitat parameters (modified by the flooding regime) are the leading factor that recently directly controls the bottom community development patterns and the spatial distribution of species. Succession of the faunistic complex of secondary aquatic organisms in Srebarna Lake are considered different than these in the communities of primary aquatic species being independent of the water flow." 11874. Verdonschot, R.C.M.; Keizer-Vlek, H.E.; Verdonschot, P.F.M. (2011): Biodiversity value of agricultural drainage ditches: a comparative analysis of the aquatic invertebrate fauna of ditches and small lakes. *Aquatic Conservation: Marine and Freshwater Ecosystems* 21(7): 715-727. (in English) ["Drainage ditches are a common aquatic habitat in the lowland agricultural landscape of north-western Europe. The invertebrate fauna of these waters is poorly known compared with that of the semi-natural wetland fragments found in this region. While most wetlands are designated as nature reserves, drainage ditches are generally viewed purely as hydrological infrastructure in support of agriculture. To assess the conservation value for aquatic invertebrates of these man-made habitats compared with that of wetland fragments, the taxonomic composition and life-history characteristics of invertebrate assemblages inhabiting nine small lakes and nine ditches in peatlands in the Netherlands were compared, as well as the environmental characteristics potentially influencing assemblage structure. Although ditches comprised a smaller water volume, contained less diverse vegetation, displayed larger fluctuations in nutrient concentrations and were regularly managed, the total number of invertebrate taxa recorded per taxonomic group was comparable with that in small lakes, as was the number of nationally uncommon to very rare taxa. Similarity in life-history characteristics between the two water-body types was high, except that a higher proportion of atmospheric air breathers was found in ditches, and more plant miners and collector-filterers in small lakes. On a regional scale, a relatively high inter-ditch taxon dissimilarity was observed, resulting in total diversity estimates for ditches exceeding those of small lakes. This study showed that drainage ditches can be a significant habitat type for aquatic invertebrates. In the Netherlands, water bodies in peatland agricultural areas can contain a diverse invertebrate fauna, similar to that of water bodies in nearby nature reserves. ... Heteroptera and Coleoptera accounted for a significantly larger proportion of the assemblage in drainage ditches, while Odonata and Chironomidae were relatively more abundant in small lakes. (2012): Spatiotemporal variation of macroinvertebrates in relation to canopy cover and other environmental factors in Eriora River, Niger Delta, Nigeria. *Environ. Monit. Assess.* 184(10): 6449-6461. (in English) ["Canopy cover is well known to influence the distribution of macroinvertebrates in temperate streams. Very little is known

about how this factor influences stream communities in Afrotropical streams. The effects and possible interactions of environmental factors and canopy cover on macroinvertebrate community structure (abundance, richness, and diversity) were examined in four stations in Eriora River, southern Nigeria bimonthly from May to November 2010. The river supported diverse macroinvertebrates in which the upstream sampling stations with dense canopy cover were dominated by Decapoda, Ephemeroptera, Odonata, Gastropoda, Trichoptera, and Coleoptera while Diptera and Coleoptera were the benthic organisms found predominant at downstream stations with less canopy cover. Some caddisfly species such as *Agapetus agilis*, *Trichosetodes* species and the stonefly *Neoperla* species were present upstream and were found to be potential bioindicators for a clean ecosystem. The blood worm *Chironomus* species and *Tabanus* sp. were abundant at the downstream of the river and are considered potential bioindicators for an organically degrading ecosystem. Some environmental factors varied temporally with significantly higher macroinvertebrate abundance and richness in May. We found out that canopy cover and environmental factors affected macroinvertebrates abundance, diversity, and richness and that the individual taxon had varying responses to these factors. These results help identify the mechanisms underlying the effects of canopy cover and other environmental factors on Afrotropical stream invertebrate communities." 11886. Armitage, P.A.; Hawczak, A.; Blackburn, H.H. (2012): Tyre track pools and puddles – Anthropogenic contributors to aquatic biodiversity. *Limnologia - Ecology and Management of Inland Waters* 42(4): 254-263. (in English) ["Twelve sites of tyre track pools and puddles situated in woodland, heath and pasture in Dorset UK were examined to determine their macroinvertebrate species richness and community changes over the course of one year. 174 taxa were found with Diptera (59) and Coleoptera (48) contributing 61% of the total. The most frequently occurring and ubiquitous groups were nematoceran dipterans, Oligochaeta, Coleoptera, Crustacea and Lamellibranchiata. Species richness varied with season and on average was highest in March and November samples. On average only 26% (range 16–40%) of the combined total number of taxa found in spring (March) and autumn (November) samples from a site were also found there in each of these seasons individually, indicating a high species turnover through the year. The tyre track pools contributed to local aquatic biodiversity by adding 29 taxa to previously published taxa lists from aquatic habitats in the area. The relative richness of the tyre track pools is attributed to their successional variation in a heterogeneous landscape. Conservation value of 9 of the 12 sites was rated Very high to High and nine regionally notable or rare taxa were recorded. It is suggested that the important conservation status of the tyre track pools warrants greater recognition and further intensive study." (Authors) The list of taxa includes *Pyrrhosoma nymphula*, *Aeshna cyanea*, *Libellula* sp., *L. depressa*, and *Sympetrum* sp.] Address: Armitage, P.A., Freshw. Biol. Ass., River Laboratory, East Stoke, Wareham, Dorset BH20 6BB, UK. E-mail: parmitage@fba.org.uk

11887. Asquith, C.M.; Vonesh, J.R. (2012): Effects of size and size structure on predation and inter-cohort

competition in red-eyed treefrog tadpoles. *Oecologia* 170: 629-639. (in English) ["Individual and relative body size are key determinants of ecological performance, shaping the strength and types of interactions within and among species. Size-dependent performance is particularly important for iteroparous species with overlapping cohorts, determining the ability of new cohorts to invade habitats with older, larger conspecifics. We conducted two mesocosm experiments to examine the role of size and size structure in shaping growth and survival in tadpoles of the red-eyed treefrog (*Agalychnis callidryas*), a tropical species with a prolonged breeding season. First, we used a response surface design to quantify the competitive effect and response of two tadpole size classes across three competitive environments. Large tadpoles were superior per capita effect competitors, increasing the size difference between cohorts through time at high resource availability. Hatchlings were better per biomass response competitors, and maintained the size difference between cohorts when resource availability was low. However, in contrast to previous studies, small tadpoles never closed the size gap with large tadpoles. Second, we examine the relationship between body size, size structure, and predation by dragonfly nymphs (*Anax amazili*) on tadpole survival and growth. Hatchlings were more vulnerable to predation; predator and large competitor presence interacted to reduce hatchling growth. Again, the size gap between cohorts increased over time, but increased marginally more with predators present. These findings have implications for understanding how variation in resources and predation over the breeding season will shape population size structure through time and the ability of new cohorts to invade habitats with older conspecifics." (Authors)] Address: Asquith, C.M., Department of Biology, Virginia Commonwealth University, 1000 West Cary Street, P.O. Box 842012, Richmond, VA 23284-2012, USA. E-mail: jrvolesh@vcu.edu

11888. Baird, I.R.C. (2012): The wetland habitats, biogeography and population dynamics of *Petalura gigantea* (Odonata: Petaluridae) in the Blue Mountains of New South Wales. PhD thesis, University of Western Sydney: (in English) ["*Petalura gigantea* is a poorly understood dragonfly with a long-lived fossorial larval habit that is unique to the Petaluridae. The species has been recorded from bogs, swamps and seepages of the coast and ranges of New South Wales, including a small number of records in the Blue Mountains. This topographically and hydrogeologically complex landscape includes a widely distributed network of wetlands characterised by considerable heterogeneity in patch size, quality and geographic separation. It provided the opportunity to elucidate the biogeography, and investigate population dynamics of this species at a landscape scale, within the context of metapopulation theory. This study was undertaken between late 2003 and early 2010. The objectives of the biogeographic component were to identify where *P. gigantea* occurs within the Blue Mountains and why it occurs there. Typologies of existing wetlands were reviewed, and a set of 22 types was identified for use in this thesis. A total of 284 swamps were surveyed, with *P. gigantea* recorded in 111 of these. The species was recorded from 6 swamp types, with potential habitat identified in an additional four swamp types. Hydrogeomorphically, these upland mires range from hanging swamps and localised seepage springs to valley-fill impeded-drainage swamps. *Petalura gigantea* has been observed utilising each of

these hydrogeomorphic expressions across a wide range of slopes and patch sizes. All of these swamp types may be considered groundwater dependent ecosystems. Hydrogeomorphic context and climate were found to be responsible for the development of peatland soils and suitable mire habitat, although selected wetland typologies varied in their usefulness as predictors of habitat suitability. Swamp types used by the species are characterised by considerable spatio-temporal heterogeneity in hydrology and spatial heterogeneity in the distribution of organic-rich soils, within and between swamps. Breeding sites are characterised by a groundwater regime that provides sufficient surface wetness to minimise risk of desiccation of eggs and early larval instars, supports the development of organic-rich peatland soils suitable for larval burrowing, and maintains some groundwater within the burrow throughout the larval stage. *Petalura gigantea* is considered to be an obligate, groundwater dependent, mire-dwelling species. Systematic exuviae surveys and modified 'Pollard Walk' imago surveys were used to study population dynamics at varying spatio-temporal scales, ranging from seasonal demographics within patches to comparison of changing relative abundance of imagines among years, both for and among patches. Seasonal demographics studied included sex ratio at emergence, pattern and duration of the emergence season, duration of the flying season and pattern of changing relative abundance of imagines across the flying season. This set of studies has identified a number of patterns in the landscape scale population dynamics of *P. gigantea* in the Blue Mountains. These include peak abundance years followed by a number of years of low or nil abundance in a large proportion of sites. The difference in relative abundance of male imagines among years was significant for each of the three main swamp types studied. Spatial synchrony in peak abundance years among sites in geographic proximity, and density-dependent male dispersal (in addition to female dispersal) from small sites with large emergence events that contributed to potential dispersal 'halo' effects, were also confirmed. These characteristics suggest a complex, spatially structured population, with patches of different sizes, quality and geographic distance, linked by variable between-patch movements across the network over varying temporal scales. These findings are consistent with metapopulation theory, and suggest a complex dynamic when the long larval stage, some likelihood of cohort splitting, landscape factors (patch size, patch quality, geographic distance, matrix effects) and stochastic exogenous factors (e.g., climate, fire) are considered. This longitudinal, landscape-scale study is the first for any petalurid and the first demographic study for any *Petalura* species. This research will further inform the dialogue in relation to the population dynamics of patchily distributed dragonflies in the context of metapopulation theory, including dynamics such as spatial synchrony, density-dependent dispersal, patch stepping stone and rescue effects. In addition to identified anthropogenic threats, a potential reduction in groundwater availability, a more intense fire regime and potential compounding effects of rapid climate change, may be the greatest threats to the persistence of these mire ecosystems and groundwater dependent species such as *P. gigantea*. The egg and early larval stages are identified as the critical phases, where climatic and fire effects may significantly reduce reproductive success. The improved understanding of the biogeography, habitat requirements and population dynamics of *P. gigantea* resulting from this

study provides a stronger foundation for conservation of the species and these mire ecosystems. *Petalura gigantea* is well placed to act as a flagship for their conservation." (Author) Available from: <http://handle.uws.edu.au:8081/1959.7/509925>.] Address: Baird, I.R.C., 3 Waimea St, Katoomba NSW 2780, Australia. ianbaird@mountains.net.au

11889. Bates, L.M.; Hall, B.D. (2012): Concentrations of methylmercury in invertebrates from wetlands of the Prairie Pothole Region of North America. *Environmental Pollution* 160(1): 153-160. (in English) ["Prairie wetlands may be important sites of mercury (Hg) methylation resulting in elevated methylmercury (MeHg) concentrations in water, sediments and biota. Invertebrates are an important food resource and may act as an indicator of MeHg exposure to higher organisms. In 2007–2008, invertebrates were collected from wetland ponds in central Saskatchewan, categorized into functional feeding groups (FFGs) and analyzed for total Hg (THg) and MeHg. Methylmercury and THg concentrations in four FFGs ranged from 0.2–393.5 ng·g⁻¹ and 9.7–507.1 ng·g⁻¹, respectively. Methylmercury concentrations generally increased from gastropods with significantly lower average MeHg concentrations compared to other invertebrate taxa. Surrounding land use (agricultural, grassland and organic agricultural) may influence MeHg concentrations in invertebrates, with invertebrate MeHg concentrations being higher from organic ponds (457.5 ± 156.7 ng·g⁻¹) compared to those from grassland ponds (74.8 ± 14.6 ng·g⁻¹) and ponds on agricultural lands (32.8 ± 6.2 ng·g⁻¹). Highlights: *MeHg concentrations ranged from 0.2 to 393.5 ng·g⁻¹ and generally increased with trophic level. *Gastropods had significantly lower average MeHg concentrations compared to other invertebrates. *Surrounding land use may influence MeHg concentrations in invertebrates. *MeHg concentrations were higher in organic ponds compared to grassland and agricultural ponds." (Authors) Taxa including Odonata are treated at family level. Average MeHg concentrations varied greatly among ponds for all four invertebrate groups. Average within pond invertebrate MeHg concentrations ranged from 3.3 - 1391.0 ng·g⁻¹ in Odonata.] Address: Hall, Britt, Dept of Biology, Univ. of Regina, 3737 Wascana Parkway, Regina, SK S4S 0A2, Canada. 11891. Bernard, R. (2012): East Palaearctic *Somatochlora graeseri* Selys occurs as a postglacial relict in Europe west of the Urals (Anisoptera: Corduliidae). *Odonatologica* 41(4): 309-325. (in English) ["The East Palaearctic *S. graeseri* is characterized by a current disjunct distribution. New data from northern European Russia significantly modify the earlier known pattern of its distribution. The first European record west of the Urals is reported from the environs of Pinega village (Arkhangelsk province, Pinega region). The distribution

range of this species presented here is similar to that of *Coenagrion hylas* and *C. glaciale*. Like these species, *S. graeseri* is a postglacial relict in Europe and representative of a cold-stenothermal fauna that probably colonized the continent during the late Pleistocene and early Holocene. During the Atlantic period they withdrew far to the East, remaining only as isolates in the Urals and in Europe. The survival of *S. graeseri* in the presumptive isolate of its distribution range in the Pinega region is probably a consequence of a specific combination of severe climate and habitat/microclimatic conditions, influenced by karst. The habitat conditions of the new locality are analysed in the context of the species' requirements. The spiny exuviae of *S. graeseri* and details of the female abdominal pattern are presented and compared with those of Siberian and Far Eastern individuals to show the morphological variation of the species. The diagnostic features of the exuviae, such as the large and specifically shaped lateral and dorsal spines, the thoracic banded pattern and the laterosternal sclerites on the fourth to sixth segments of the abdomen, are described." 11894. Bitsch, J. (2012): The controversial origin of the abdominal appendage-like processes in immature insects: Are they true segmental appendages or secondary outgrowths? (*Arthropoda hexapoda*). *Journal of Morphology* 273(8): 919-931. (in English) ["In this article, I review the major characteristics of different types of appendage-like processes that develop at the abdominal segments of many immature insects, and I discuss their controversial morphological value. The main question is whether the abdominal processes are derived from segmental appendages serially homologous to thoracic legs, or whether they are "secondary" outgrowths not homologous with true appendages. Morphological and embryological data, in particular, a comparison with the structure and development of the abdominal appendages in primitive apterygote hexapods, and data from developmental genetics, support the hy-

pothesis of appendicular origin of many of the abdominal processes present in the juvenile stages of various pterygote orders. For example, the lateral processes, such as the tracheal gills in aquatic nymphs of exopterygote insects, are regarded as derived from lateral portions of appendage primordia, homologous with the abdominal styli of apterygotan insects; these processes correspond either to rudimentary telopodites or to coxal exites. The ventrolateral processes, such as the prolegs of different endopterygote insect larvae, appear to be derived from medial portions of the appendicular primordia; they correspond to coxal endites. These views lead to the rejection of Hinton's hypothesis (Hinton [1955] *Trans R Entomol Soc Lond* 106:455-545) according to which all the abdominal processes of insect larvae are secondary outgrowths not derived from true appendageanlagen." 11895. Blanke, A.; Wipfler, B.; Letsch, H.; Koch, M.; Beckmann, F.; Beutel, R.; Misof, B. (2012): Revival of Palaeoptera—head characters support a monophyletic origin of Odonata and Ephemeroptera (*Insecta*). *Cladistics* 28: 560-581. (in English) ["The earliest branching event in winged insects, one of the core problems regarding early insect evolution, was addressed using characters of the head. The head is arguably one of the most complex body regions in insects and the phylogenetic information content of its features has been demonstrated. In contrast, the wings and other body parts related to the flight apparatus and sperm transmission are not useful in the context of this problem, as the outgroups (silverfish and bristletails) are wingless and transmit spermatophores externally. Therefore, they show profound differences in the organization of the postcephalic body, and assessment of homology and subsequent phylogenetic analysis of features of these body regions is extremely difficult. The core of this study is the investigation of head structures of representatives of the major clades of dragonflies. A detailed description of the head of *Lestes virens* is presented and was used as a starting point for the compilation of a character set and a character state matrix for the entire *Dicondylia* (winged insects + silverfish), with a main focus on the placement of dragonflies and consequently the basal branching event within winged insects. Our results indicate a sister-group relationship between a clade Palaeoptera (dragonflies + mayflies) and the megadiverse monophyletic lineage Neoptera. We show that despite considerable structural similarity between the odonate and neopteran mandible, the muscle equipment in dragonflies is more plesiomorphic with respect to *Dicondylia* than previously known. Odonata and Ephemeroptera also share presumably derived features of the antenna, maxilla, and labial musculature. Parsimony analyses of the head data unambiguously support a clade Palaeoptera." 11896. Bogdan, H.V.; Covaciu-Marcov, S.D.; Cupsa, D.; Cicort-Lucaciu, A.S.; Sas, I. (2012): Food composition of a *Pelophylax ridibundus* (*Amphibia*) population from a thermal habitat in Banat region (Southwestern Romania). *Acta zool. bulg.* 64(3): 253-262. (in English) ["The food of *Pelophylax ridibundus* population from the thermal habitat from Carpinis presents great differences depending on the period. The feeding of frogs was

more reduced throughout the winter, due to low temperatures, but also during autumn, due to the drought. Although the basic lines set by the previous studies on the feeding of amphibians in thermal waters are being followed, the facts here show more nuanced reality. Thus, not just low temperatures, but also other meteorological factors (drought or heavy rains) can induce important modifications in the feeding of amphibians. The feeding of *P. ridibundus* population was affected by the variation of such meteorological conditions throughout the entire year of our study. The trophic offer of the habitat was rather reduced, but the terrestrial environment had plenty of preys for the population to feed accordingly. Thus, the number of prey taxa was high, but also very variable among the study periods." (Authors) Odonata are of minor importance as diet of the frog species] Address: Bogdan, Horia, University of Oradea, Faculty of Sciences, Dept of Biology; 1, Universitatii, Oradea 410087, Romania. 11899. Bolotov, I.N.; Bepalaya, Yu.V.; Usacheva, O.V. (2012): Ecology and evolution of hydrobionts in hot springs of the subarctic and arctic: Formation of similar assemblages, adaptation of species, and microevolutionary processes. *Biology Bulletin Reviews* 2(4): 340-348. (in English) ["In the Subarctic and Arctic, the fauna of hydrothermal systems is considered to be an allochthonous, migration-mediated system comprised of the representatives of different taxa, which are characterized by a set of preadaptations to life in hot springs. These adaptations evolved before species had colonized this thermal anomalous environment. Hot springs characterizing by a constant temperature and hydrochemical regime appear to be the favourable sites compared to the usual local environment. The short-term existence of thermal springs on the geological time scale and their evolutionary evanescence serve as preconditions for the low fauna endemism that make up the taxa on the intraspecific and species levels. The taxonomical status of many of these forms has not yet been defined with certainty, since populations of new species and intraspecific taxonomic categories of molluscs that inhabit thermal pools may evolve similar morphological, physiological, and biochemical features independently; i.e., they may exhibit convergent similarity." (Authors) The paper refers on an older study with larval records of unidentified Odonata from thermals springs.] Address: Bolotov, I.N., Institute of Environmental Problems of the North, Urals Branch, Russian Academy of Sciences, Arkhangelsk, Russia. 11901. Bots, J.; Breuker, C.J.; Kaunisto, K.M.; Koskimäki, J.; van Gossum, H.; Suhonen, J. (2012): Wing shape and its influence on the outcome of territorial contests in the damselfly *Calopteryx virgo*. *Journal of insect science* 12:96: 13 pp. (in English) ["Male mating success is often determined by territory ownership and traits associated with successful territory defense. Empirical studies have shown that the territory owner wins the majority of fights with challenging males. Several physical and physiological traits have been found to correlate with resource holding potential. In addition, in aerial insects, wing design may also have a strong influence on resource holding potential, since it determines efficiency and precision during flight. However, this possibility has not yet been thoroughly evaluated using the modern technique of geometric morphometrics to analyze shape. Therefore, this study examined whether wing shape affects the outcome of male-male contests in the territorial damselfly, *Calopteryx virgo*. Wing shape and also traditional flight-related morphological measures were compared between 27 pairs of winners and losers from experimental territorial contests. Contrary to expectations, there were no differences between winners and losers in all studied wing traits (shape, length, width, total surface, aspect ratio, and wing loading). However, highly significant differences in wing shape and size were detected between the fore- and hindwing. It is currently not known how these differences relate to flight performance, since previous biomechanical studies in damselflies assumed fore- and hindwings to have an identical planform." (Authors)] Address: Bots, Jessica, Evolutionary Ecology Group, University of Antwerp, Antwerp, Belgium. E-mail: jessica.bots@ua.ac.be,

11902. Bried, J.T.; D'Amico, F.; Samways, M.J. (2012): A critique of the dragonfly delusion hypothesis: why sampling exuviae does not avoid bias. *Insect Conservation and Diversity* 5(5): 398-402. (in English) ["(1.) A recent study comparing adult and exuvial odonate richness concluded that adult surveys overestimate the number of species reproducing successfully. The authors called this phenomenon the "dragonfly delusion" and recommended that only exuviae be used for bio-monitoring and habitat quality assessment. However, they drew this conclusion from limited surveys and detection-naïve analysis and failed to acknowledge that exuvial richness is typically biased low. (2.) Here, we quantify the exuvial bias using two related metrics: (i) species detectability from concurrent adult and exuvial surveys and (ii) estimated exuvial species richness at a site based on imperfect detectability and the regional pool (cumulative total across study sites) of exuvial species observed. (3.) Using concurrent adult and exuvial data from lakes in south-west France, we found that detectability was generally lower in 1-h exuvial searches than in 20-min adult searches and that exuvial surveys may lead to strong negative bias in richness estimation. This suggests the alleged delusion of adult surveys was exaggerated. (4.) Controlling for species de-

tection probability is crucial in making unbiased inferences on how many odonate species occupy a site and, by extension, comparing adult and exuvial species richness. Exuviae sampling avoids positive bias, not bias in general, and requires either relatively intensive search effort, statistical accounting of false species absences, or acceptance of negatively biased richness." 11905. Burkle, L.A.; Mihaljevic, J.R.; Smith, K.G. (2012): Effects of an invasive plant transcended ecosystem boundaries through a dragonfly-mediated trophic pathway. *Oecologia* 170: 1045-1052. (in English) ["Trophic interactions can strongly influence the structure and function of terrestrial and aquatic communities through top-down and bottom-up processes. Species with life stages in both terrestrial and aquatic systems may be particularly likely to link the effects of trophic interactions across ecosystem boundaries. Using experimental wetlands planted with purple loosestrife (*Lythrum salicaria*), we tested the degree to which the bottom-up effects of floral density of this invasive plant could trigger a chain of interactions, changing the behaviour of terrestrial flying insect prey and predators and ultimately cascading through top-down interactions to alter lower trophic levels in the aquatic community. The results of our experiment support the linkage of terrestrial and aquatic food webs through this hypothesized pathway, with high loosestrife floral density treatments attracting high levels of visiting insect pollinators and predatory adult dragonflies. High floral densities were also associated with increased adult dragonfly oviposition and subsequently high larval dragonfly abundance in the aquatic community. Finally, high-flower treatments were coupled with changes in zooplankton species richness and shifts in

the composition of zooplankton communities. Through changes in animal behaviour and trophic interactions in terrestrial and aquatic systems, this work illustrates the broad and potentially cryptic effects of invasive species, and provides additional compelling motivation for ecologists to conduct investigations that cross traditional ecosystem boundaries." (Authors) The following Odonata species are included: Imagines: *Anax junius*, *Erythemis simplicicollis*, *Libellula luctuosa*, *Libellula saturata*, *Libellula pulchella*, *Pachydiplax longipennis*, *Tramea lacerata*. 11907. Bybee, S.M.; Johnson, K.K.; Gering, E.J.; Whiting, M.F.; Crandall, K.A. (2012): All the better to see you with: a review of odonate color vision with transcriptomic insight into the odonate eye. *Organisms diversity & Evolution* 12(3): 241-250. (in English) ["Although Odonata represent some of the most advanced visual systems among insects, odonate visual systems are not as well understood as those of model or more economically important insects. Yet, with their large and complex eyes, aquatic and terrestrial life stages, entirely carnivorous lifestyle, exceptional mating behaviours, diversity in coloration, occupancy of diverse light environments, and adult success that is completely dependent on vision, it would seem studying the visual system of Odonata at the molecular level would yield highly rewarding scientific findings related to predator/prey interactions, the physiological and molecular shifts associated with ecological shifts in light environments, and the role of vision on behavioural ecology. Here, we provide a review of odonate colour vision. The first odonate opsin sequences are published using a degenerate PCR approach for both dragonfly and damselfly lineages as well as a transcriptome approach for a single species of damselfly. These genetic data are combined with electrophysiology data from odonates to examine genotype/phenotype relationships in this visual system. Using these data, we present the first insights into the evolution and distribution of the visual pigments (opsins) among odonates. The integration of molecular and behavioural studies of odonate vision will help answer long-standing questions about how sensory systems and coloration may coevolve." (Authors)] Address: Bybee, S., Graduate Research Assistant: Branham Laboratory, Dept Entomology & Nematology, Univ. of Florida. Natural Area Drive, P.O.Box 110620, Gainesville, FL 32611-0620, USA. 11908. Camara, I.A.; Diomande, D.; Bony, Y.K.; Ouattara, A.; Franquet, E.; Gourene, G. (2012): Diversity assessment of benthic macroinvertebrate communities in Banco National Park (Banco Stream, Côte d'Ivoire). *African Journal of Ecology* 50(2): 205-217. (in English, with

French summary) ["In the present study, a first inventory of benthic macroinvertebrates in the Banco Stream, Côte d'Ivoire, and the correlations between environmental variables and taxonomic richness were analysed. Seven stations were sampled monthly over a 1-year period, using a hand net (10 × 10 cm, 250 µm mesh, 50 cm length). 132 macroinvertebrate taxa were recorded. These taxa were distributed among 74 families and 15 orders belonging to Insecta (118 taxa; 89% of total richness), Oligochaeta (seven taxa), Crustacea (five taxa) and Mollusca (two taxa). Kruskal-Wallis test revealed significant difference (at least $P < 0.05$) in macroinvertebrate richness between upstream stations (S1 and S2) and stations S4, S5 and S6. Chironominae and Tanypodinae (Insecta) were the two very frequent taxa in all the stations. Lumbriculidae (Oligochaeta), *Desmocarlis trispinosa* (Crustacea) and *Eurymetra* sp. (Insecta) were frequently found in the samples. Hierarchical cluster analysis revealed three groups of sampling stations according to taxonomic similarity. Taxonomic richness was significantly and negatively correlated with conductivity, while it was significantly and positively correlated with substrate types (woody debris and gravel). Due to the fact that Banco stream is the locality type of an endemic shrimp species (*Macrobrachium thysi*), this basin is of high conservation priority" (Authors) Samples were dominated by insects: Coleoptera (22%), Odonata (20.3%), Diptera (16.9%) and Trichoptera (14%)." (Authors)] Address: Camaral, Idrissa Adama, Laboratoire d'Environnement et de Biologie Aquatique, UFR-Sciences et Gestion de l'Environnement, Université d'Abobo-Adjamé, Abidjan 02, Ivory Coast. 11909. Carle, F.L. (2012): A new *Epiophlebia* (Odonata: Epiophlebioidea) from China with a review of epiophlebian taxonomy, life history, and biogeography. *Arthropod Systematics & Phylogeny* 70(2): 75-83. (in English) ["*Epiophlebia diana* sp.n. is described from larval specimens collected in the mountains of western Sichuan Province, China. Epiophlebian taxonomy, life history, and biogeography are reviewed, and keys provided for determination of the known adults and larvae of *Epiophlebia* Calvert, 1903. Classification of *Epiophlebia* is revised as follows: *Epiophlebia* s.str. with *E. superstes* (Selys, 1889) [type species] and *E. sinensis* Li & Nel, 2012; and *Rheoepiophlebia* subgen.n. with *E. laidlawi* Tillyard, 1921 [type species] and *E. diana* sp.n.. Behavioural, ecological and paleontological information is also evaluated and members of *Epiophlebia* acknowledged to have inhabited small high elevation streams of the east Palaearctic for possibly 180 million years. Likely reasons are proposed for the enduring survival of *Epiophlebia*, its lack of a fossil record and the extinction of related groups." opment of *Ischnura chingaza* Realpe under captivity conditions (Zygoptera: Coenagrionidae). *Odonatologica* 41(4): 327-335. (in English) ["The larval stages were observed and characterized under controlled conditions. The larvae were measured and described in order to establish the differences between them, using morphometric characters such as head and premental width and length, number of premental and labial setae, the length of wing pads and legs, and total length without gills, also the growth ratio of different body parts was calculated. The most important character to distinguish larval stages was the head width. There was an increase in the number of premental setae during ontogeny. Comparisons in terms of size were made, showing that females are larger than males in all observed structures. *I. chingaza* has 11 larval stages; except for the pro-larva, all of them were observed." 11913. Catling, P.M. (2012): Book reviews: Assessment of species diversity in the Atlantic Maritime Ecozone. Edited by Donald F. McAlpine and Ian M. Smith. 2010. National Research Council Press, 1200 Montreal Road, Ottawa, Ontario K1A 0R6 Canada. 785 pages. 94.00 USD. Cloth. *The Canadian Field-Naturalist* 126: 73-75. (in English) [Verbatim: "Chapter 16 by Paul-Michael Brunelle features the 142 Odonata species that are known from AME. This chapter includes such complete information on biology, habitat and systematics, all very well illustrated, that with a basic knowledge of its content, and using it as a reference, the reader is well on the way to being an expert on the group in the region. Brunelle has coordinated the Atlantic Dragonfly Inventory Program (ADIP) and has contributed about ten thousand records himself. The value of that program is immediately apparent in the extensive information available for the assessment. The section on recommendations for improvements on monitoring is especially useful. There is a little more to say on the subject of biogeography. Distributions are changing in this region as southern and western species (*Ischnura hastata*, *Enallagma civile*, *Tramea lacerata*), move north as they have further to the west (Catling 2008, Catling et al. 2009, and references therein). There are some notable patterns that correspond to those of other groups and could be obtained from Appendix Table 1. Distributions in saltmarsh have been discussed and more information on occurrence in this habitat is recently available (Catling 2009). There are a few websites that are useful for dragonflies in the region and one is devoted to a portion of the AME (<http://www.odonatanb.com>)."] Address: Catling, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. Maine Agricultural and Forest Experiment Station, the University of Maine. Technical Bulletin 206: 210 pp. (in English) [Records of Odonata are documented in appendix 2 on pages 76-77: *Aeshna interrupta*, *Coenagrion resolutum*, *Enallagma civile*, *Ischnura verticalis*, *Nehalennia irene*, *Lestes rectangularis*, *Leucorrhinia frigida*, *L. hudsonica*, *L. proxima*, *Libellula pulchella*, *L. semifasciata*, *Sympetrum obtrusum*, *S. rubicundulum* and *S. vicinum*.] Address: Chandler, D.S., Dept of Biological Sciences, Univ. of New Hampshire, Durham, NH, USA

11915. Chessman, B.C. (2012): Biological traits predict shifts in geographical ranges of freshwater invertebrates during climatic warming and drying. *Journal of Biogeography* 39(5): 957-969. (in English) ["Aim: To test the ability of biological traits to predict climate-related changes in geographical ranges of running-water invertebrates. Location: The Australian state of New South Wales and the Australian Capital Territory. Methods: I analysed data from 8928 biomonitoring samples collected during a 16-year period of generally rising air temperatures and declining precipitation. I used quantile regression to test for expansions and contractions on the climatically cooler, warmer, drier and wetter edges of the ranges of 120 invertebrate taxa, and correlated these shifts with the traits of thermophily (degree of preference for high versus low temperature) and rheophily (preference for flowing versus still water). Results: The most commonly inferred range shifts were cool-edge expansion plus warm-edge contraction (71 taxa) and wet-edge expansion plus dry-edge contraction (71), but contractions from both cool and warm extremes (36) and from both dry and wet extremes (28) were also frequent. High-temperature preference was associated with cool-edge expansion and low-temperature preference with wet-edge expansion and contraction from all other extremes. A preference for flow was associated with wet-edge expansion and dry-edge contraction. Main conclusions: Trait analysis has potential for predicting which species will expand their ranges and which will contract, but needs to be coupled with assessment of how the landscape provides each species with opportunities to track or avoid climate change. Improved quantification of climatically relevant traits and integration of trait analysis with species distribution modelling are likely to be beneficial." (Authors) Taxa (including Odonata) are treated at family level.] Address: Chessman, B.C., Office of Environment and Heritage, PO Box 3720, Parramatta, NSW 2124, Australia. 11916. Chuang, S.-W.; Lih, F.-L.; Miao, J.-M. (2012): Effects of Reynolds number and inclined angle of stroke plane on aerodynamic characteristics of flapping corrugated airfoil. *Journal of Applied Science and Engineering* 15(3): 247-256. (in English) ["The effects of the Reynolds number and inclined angle of stroke plane on the generating lift and thrust forces of a flapping corrugated airfoil was studied by numerical simulations with dynamic deformable meshes. The chord Reynolds number (Re) based on the incoming airstream velocity is varied from 10^3 to 10^4 with interval of 10^3 . Two different inclined angles of stroke plane on the aerodynamic forces of corrugated airfoil were also considered. Due to the corrugated shape of dragonfly wings varied depending on the cross section location chosen, present tested profile of airfoil was selected from the mid-span of wing of an *Aeshna cyanea* dragonfly forewing. Unsteady flows over a corrugated thin airfoil and a flat-

plate executing flapping motion are computed with time-dependent two-dimensional laminar incompressible Navier-Stokes equations. The dynamic mesh technique is applied to model the flow field of cyclical flapping motion of a corrugated airfoil under different combinations of pitch angle and stroke amplitude. Instant vorticity contours over a complete flapping cycle of a corrugated airfoil and a flat-plate clearly reveals the flow mechanisms for lift force generation are dynamic stall, rotational circulation, and wake capture. The thrust force is dominated by the formation of leading edge vortex (LEV) and trailing edge vortex (TEV) shedding downstream to form a reverse von Karman vortex. Results indicated that there is little difference on the aerodynamic force between corrugated airfoil and flat-plate under tested range of flapping frequency. The mean lift force coefficient of corrugated airfoil was enhanced with the increasing of Re . Visible changes in the mean lift force coefficient can be identified from the variation of inclined angle of stroke plane at a fixed Re . The critical products of reduced frequency and stroke amplitude to generate the positive mean thrust force output of a corrugated airfoil was given in present work." 11919. Cui, J.; Lackey, M.; Tew, G.; Crosby, A. (2012): Resilient synthetic PEG/PDMS hydrogels inspired by natural resilin. *Bulletin of the American Physical Society* 57(1) [APS March Meeting 2012, Monday–Friday, February 27–March 2 2012; Boston, Massachusetts]: 1 p. (in English) [Verbatim: Novel synthetic hydrogels are developed by incorporating hydrophobic polydimethylsiloxane (PDMS) into hydrophilic poly(ethylene glycol) (PEG)-based network using thiol-norbornene chemistry. The properties of these hydrogel are comparable to natural resilin, which is an elastic protein, exist-

ing in many insects, such as the tendons of flea and the wings of dragonfly, with extraordinary ability of mechanical energy storage. The energy storage efficiency (resilience) of the hydrogels is more than 97(%) even at tensile strains up to 170(%). In addition, the Young's modulus of the hydrogels ranges from 3 kPa to 300 kPa by increasing the volume fraction of the PDMS in the network. These unique properties are attributed to the well-defined network and negligible secondary structure, provided by the versatile and efficient chemistry.] Address: not stated

11920. Damm, S.; Hadrys, H. (2012): A dragonfly in the desert: genetic pathways of the widespread *Trithemis arteriosa* (Odonata: Libellulidae) suggest male-biased dispersal. *Organisms diversity & evolution* 12(3): 267-279. (in English) ["Water-dependent species inhabiting desert regions seem to be a contradiction in terms. Nevertheless, many species have evolved survival strategies for arid conditions. In Odonates, both larvae and adults require very different and complex water-associated habitat conditions. The present study investigates the genetic diversity, population structure and dispersal patterns of a desert inhabiting odonate species, *T. arteriosa*. Eight populations from the arid Namibia and four population sites in the more tropical Kenya were compared by using nine microsatellite loci, one non-coding nuclear fragment and the mtDNA fragment ND1. Microsatellite analyses as well as the nuclear fragment reveal a high allelic diversity in all populations with almost no genetic sub-structuring. In contrast, ND1 sequence analyses show sub-structuring and—with two exceptions—only private haplotypes. The conflicting patterns of nuclear versus mitochondrial markers suggest a male-biased dispersal in this species. Results indicate that male dispersal is dependent on the environmental stability of the habitat, while females are philopatric. This life history adaptation would allow females to save energy for mating and oviposition in the demanding environment of a desert region. The results give direct insights into the dispersal pathways of a desert-inhabiting, strongly water dependent flying insect." (in English) [Verbatim: "In our winter when I can not see odonates I carry out research into the use of marine chronometers on sailing ships in the early 19th century. I was recently reading the Ship's Log of an East India Company ship called the Bombay sailing from Malacca to Canton in 1810 (India Office Records, 1810). I was surprised to read that Captain Archibald Hamilton recorded in his log on the 5th October 1810, mid-ocean between Cambodia, Malaya and Borneo, seeing 'Dragonflies'. They were I would suggest almost certainly *Pantala flavescens*. "Friday 5 October 1810 8 am near to Latitude 5 17' N Longitude 106 8' E. Observed a great number of dragonflies on board which had not been on board before". "Wednesday 10 October Have continued to see a number of dragonflies about the ship ever since the 5th instant more or less sometimes only flying about the Vanes at the Mast Head". Reference: India Office Records, 1810. Captain's Log HEIC Bombay L/MAR/B/48B. British Library"] Address: Simon Davidson. E-mail: simoncathlyn@hotmail.com

11922. De Block, M.; Stoks, R. (2012): Phosphoglucose isomerase genotype effects on life history depend on latitude and food stress. *Functional Ecology* 26(5): 1120-1126. (in English) ["(1.) Phosphoglucose isomerase (Pgi) genotypes differ in life-history traits and shifts in their frequencies are thought to contribute to latitudinal gradients in life history. Yet, it is unstudied whether the life-history effects of Pgi are invariant across latitudes. Further, while genetic variation at the Pgi locus is thought to be maintained by genotype-by-environment interactions and by life-history trade-offs involving resource allocation, the effects of food stress on Pgi genotype effects are largely unstudied. (2.) We compared Pgi allozyme genotype effects on life history between northern and southern populations of the damselfly *Ischnura elegans* in a common garden experiment where we manipulated food stress. (3.) Pgi genotypes differed in larval development time and body mass, but neither in larval growth rates nor in adult life span. (4.) The effect of the Pgi genotype on larval development time differed between latitudes, suggesting interactions with the latitude-specific genetic background and/or maternal effects. Pgi genotype effects on both development time and body mass were dependent on food stress and indicated a trade-off between both fitness-related traits associated with the Pgi gene. (5.) The newly identified interaction between the Pgi genotype and latitude, the poorly studied Pgi genotype-by-food stress interactions and the observed life-history trade-offs associated with the Pgi genotypes can all potentially contribute to maintaining genetic variation at the Pgi locus and to latitudinal patterns in life history. Both types of interactions may also explain the poorly understood differences in the Pgi genotype effects on life history among studies of the same species." 11928. Dobrzańska, J. (2012): Global changes in the local scale, or about climate of cities and dragonflies (Odonata). Proc. 22th Congr. Pol. Hydrobiol., Cracow, Poland, 19–22 Sept. 2012 (www.iop.krakow.pl/zhp): (in English) [Verbatim: Odonata are presumed to be indicators of many environmental processes including climate change. It was already stated that increases in contribution, in terms of abundance and ranges, of Mediterranean species, in Poland, can be correlated with this global process. In my previous studies on dragonflies in Warsaw I suggested a possibility of analogous phenomenon in the local scale correlated with so-called „urban heat island”. In this study I continue researches at mentioned relationship analyzing species composition of chosen oxbow lakes of the Vistula River in Warsaw and surroundings. In the analysis I mainly focus on these factors which mostly can affect microclimate of studied reservoir. Among studied parameters the most important seem to be management of neighbouring land, size of the lake and distance from the city centre. City, as the specific ecosystem, influence on water ecosystems which are inside its borders and in the vicinity in special and multidimensional way. There are many aspects of dragonflies biology, out of which we can presume that these influence can sometimes be positive and in other cases negative. In presented deliberation chosen relationships related to city's influence on water ecosystems and their possible effects on dragonflies are going to be discussed.] Address: Dobrzańska, Julia, Warsaw Univ. of Life Sciences, Fac. of Civil & Environmental Engineering ul. Nowoursynowska 159, 02-776 Warszawa, Poland. E-mail: juliadobrzanska@sggw.pl

11929. Dolný A.; Harabiš F.; Bárta D.; Lhota, S.; Drozd, P. (2012): Aquatic insects indicate terrestrial habitat degradation: changes in taxonomical structure and functional diversity of dragonflies in tropical rainforest of East Kalimantan. *Tropical Zoology* 25(3): 141-157. (in English) ["As a group of freshwater invertebrates, dragonflies (Odonata) are commonly used as ecological indicators of freshwater ecosystems. Despite earlier studies suggesting that adult odonates may be good indicators for complex changes in a landscape, the utility of odonates as suitable indicators to indicate health of non-aquatic (forest) habitats remains poorly understood. This study analyses the adult dragonfly assemblage pattern against spatial and temporal disturbance characteristics in Indonesia's Sungai Wain Protection Forest. The core of this reserve comprises one of the few remaining fragments of primary rain forest along the East Kalimantan coast, whereas the rest of the reserve is covered by secondary forest, scrub, grassland, and farmland. Adult dragonfly assemblages at individual sampling sites were analysed

in relation to (1) their intensity, (2) frequency of human-caused disturbances, and (3) the time since the last such disturbance, while controlling random variables (type of aquatic and terrestrial habitat) were removed. This study tests the effect of these factors on (1) species richness, (2) proportion of Zygoptera, (3) proportion of forest specialists, and (4) proportion of Borneo's endemics. The human induced disturbances in the rain forest resulted in pronounced changes in the taxonomical composition and functional diversity of the odonate fauna. Results reported here demonstrate that gradual changes in the odonate assemblages correspond to the degree of anthropogenic influences on forest environments. Adult odonates comprise an appropriately sensitive and versatile indicator group for identifying changes in terrestrial forest environments as well as in freshwater habitats." 11930. Dorazio, R.M.; Rodriguez, D.T. (2012): A Gibbs sampler for Bayesian analysis of site-occupancy data. *Methods in Ecology and Evolution* 3(6): 1093-1098. (in English) ["(1.) A Bayesian analysis of site-occupancy data containing covariates of species occurrence and species detection probabilities is usually completed using Markov chain Monte Carlo methods in conjunction with software programs that can implement those methods for any statistical model, not just site-occupancy models. Although these software programs are quite flexible, considerable experience is often required to specify a model and to initialize the Markov chain so that summaries of the posterior distribution can be estimated efficiently and accurately. (2.) As an alternative to these programs, we develop a Gibbs sampler for Bayesian analysis of siteoccupancy data that include covariates of species occurrence and species detection probabilities. This Gibbs sampler is based on a class of site-occupancy models in which probabilities of species occurrence and detection are specified as probit-regression functions of site- and survey-specific covariate measurements. (3.) To illustrate the Gibbs sampler, we analyse site-occupancy data of *Aeshna cyanea*, a common dragonfly species in Switzerland. Our analysis includes a comparison of results based on Bayesian and classical (non-Bayesian) methods of inference. We also provide code (based on the R software program) for conducting Bayesian and classical analyses of site-occupancy data." 11935. Edmonds, S.T.; O'Driscoll, N.J.; Hillier, K.; Atwood, J.L.; Evers, D.C. (2012): Factors regulating the bioavailability of methylmercury to breeding rusty blackbirds in northeastern wetlands. *Environmental Pollution* 171: 148-154. (in English) [USA, Canada "Rusty blackbirds are undergoing rapid population decline and have elevated Hg concentrations while breeding in the Acadian ecoregion of North America. Factors regulating the bioavailability of methyl-Hg (MeHg) within this population's habitat were determined using water, invertebrates, and blood from adult rusty blackbirds collected for Hg-speciation, along with additional water column parameters: MeHg and THg, dissolved organic carbon, pH, dissolved oxygen, conductivity, redox potential, and temperature. Both DO₂ and pH were negatively related to biota MeHg, while water MeHg concentrations were positively related. Both invertebrate MeHg concentration and %MeHg increased with trophic level. Invertebrate MeHg concentrations were among the greatest reported when compared with those reported elsewhere for wetlands and waterbodies—often several times greater for similar taxa—while percent MeHg of THg

were similar. An environment with high bioavailability of MeHg in combination with a high trophic position best explains elevated Hg concentrations for this species regional population. Highlights: *DO₂ and pH negatively correlate with wetland biota methylmercury. *Water MeHg concentrations positively correlate with wetland biota methylmercury. *Rusty blackbird blood-Hg correlates with MeHg in Araneae, Ephemeroptera, and Trichoptera, but not Odonata. *Habitat with high MeHg bioavailability and a high trophic position explains regionally elevated Hg in the rusty blackbird." 11938. Farkas, A.; Jakab, T.; Tóth, A.; Kalmár, A.F.; Dévai, G. (2012): Emergence patterns of riverine dragonflies (Odonata: Gomphidae) in Hungary: variations between habitats and years. *Aquatic Insects* 34(Supplement 1): 77-89. (in English) ["In this paper the results of a six-year study on riverine dragonflies (Odonata: Gomphidae) emergence based on the systematic collection of exuviae are presented. The exuviae were counted to determine variations in species composition, abundance and emergence pattern of gomphids at four different sites along the rivers Tisza and Szamos, as well as at a selected site in five different years. While the number of species decreased, the abundance of exuviae increased downstream the river Tisza. The total numbers of exuviae differed significantly between the dammed and non-dammed sites. The emergence of gomphids varied in initiation, synchronisation and also in duration between sites as well as between years. The onset of emergence was dependent mainly on the species-specific temperature sums, consequently earlier or later emergence resulted from the differences in the spring water temperature. The duration of emergence in *G. flavipes* and *G. vulgatissimus* was twice as long at the dammed site, characterised by a higher larval density, as at the other sites. In the degree of synchrony *G. flavipes* showed the emergence characteristics both of the spring and the summer species. Such interyear variations at the same site might have been attributed to the differences in annual fluctuations in the water temperature, indicating that rising temperatures may influence not only the onset of emergence but the synchrony as well." (in English) ["Invasive alien species can have complex effects on native ecosystems, and interact with multiple components of food webs, making it difficult a comprehensive quantification of their direct and indirect effects. We evaluated the relationships between the invasive crayfish, *Procambarus clarkii*, amphibian larvae and predatory insects, to quantify crayfish impacts on multiple levels of food webs, and to evaluate whether crayfish predation of aquatic insects has indirect consequences for their preys. We used pipe sampling to assess the abundance of crayfish, amphibian larvae and their major predators (Ditiscidae, Notonectidae and larvae of Anisoptera) in invaded and uninvaded ponds within a human dominated landscape. We disentangled the multivariate effects of *P. clarkii* on different components of food web through a series of constrained redundancy analyses. The crayfish had a negative, direct impact on both amphibian communities and their predators. Amphibian abundance was negatively related to both predators. However, the negative, direct effects of crayfish on amphibians were much stronger than predation by native insects. Our results suggest that this crayfish impacts multiple levels of food webs, disrupting natural prey-predator relationships." 11941. Florencio, M.; Díaz-Paniagua, C.; Gomez-Mestre, I.; Serrano, L. (2012): Sampling macroinvertebrates in a temporary pond: comparing the suitability of two techniques to detect richness, spatial segregation and diel activity. *Hydrobiologia* 689: 121-130. (in English) ["Recent and increasing interest in temporary ponds as biodiversity reservoirs fosters our need to test sampling techniques for characterising their biological communities. We compared the efficiency of dip-netting to that of fyke nets in sampling the macroinvertebrate assemblage of a temporary pond in Doñana National Park (SW Spain). We sampled the pond at four different times -morning, afternoon, evening and night- distinguishing between deep and shallow zones. In our sampling, dip-netting captured a higher number of taxa, and higher abundances of individuals than fyke nets. However, both techniques captured exclusive taxa, not recorded with the other device. Fyke nets distinguished between nocturnal and diurnal macroinvertebrates, and hence are more appropriate to study macroinvertebrate diel activity. We detected nocturnal activity in *Gerris thoracicus* larvae, and adults of *Colymbetes fuscus*, *Rhantus suturalis*, *Rhantus hispanicus* and *Hydrochara flavipes*. Conversely, larvae of *Sympetrum fonscolombii* and *Notonecta* spp., and adults of *Notonecta glauca* were mainly diurnal. The overall diel activity pattern of the macroinvertebrate assemblage depended on the diel activities of their integrating taxa and stages. Although dip-netting was more appropriate to sample macroinvertebrate assemblages in different microhabitats, fyke nets better captured nocturnal and fast-swimming invertebrates. Consequently, the joint use of both sampling techniques would capture a better picture of the representative macrofauna of a temporary pond than either one on its own." (2012): Effectiveness of a newly created oxbow lake to mitigate habitat loss and increase biodiversity in a regulated floodplain. *Restoration Ecology* 20(3): 387-394. (in English) ["In 2005, an oxbow lake was constructed in a degraded floodplain area of the Ebro River (NE Spain) to mitigate habitat loss. In this study, we address the effectiveness of this restoration project through the analysis of the macroinvertebrate community that colonized the newly constructed lake, in comparison with a nearby natural oxbow lake and the adjacent river channel. To that end, water and macroinvertebrate samples were taken every 2 months in 2006. Ground movements during construction, wind-driven bottom resuspension, shore scouring, and lack of vegetation resulted in distinctive water chemistry in the constructed and natural lakes. Regarding biodiversity, only 8 months after the digging of the constructed lake the abundance, richness, Shannon, and trait diversity of macroinvertebrates exceeded that of the natural lake. It is suggested that the constructed lake provided habitat for new mobile species that rapidly dispersed to other wetlands, thus enhancing the biological diversity of the floodplain at a local scale. Furthermore, biodiversity is predicted to continue increasing in the following years, although isolation can lead to early clogging of the system. By showing a dramatic increase in aquatic biodiversity in constructed wetlands, our study suggests that wetland construction can be very effective in mitigating habitat loss and increasing biodiversity in highly degraded floodplain areas. Further monitoring is nevertheless needed to evaluate the sustainability of the newly created habitat in the long term." 11949. Gobbi, M.; Riservato, E.; Bragalanti, N.; Lencioni, V. (2012): An expert-based approach to invertebrate conservation: Identification of priority areas in central-eastern Alps. *Journal for Nature Conservation* 20(5): 274-279. (in English) ["The private and public agencies for nature protection often ask land managers to implement biodiversity conservation plans. Invertebrates constitute a substantial proportion of terrestrial and freshwater biodiversity and are critical to ecosystem functions. However, their inclusion in conservation planning and management is under represented, particularly in the Alps. In this paper we propose a new methodological solution and challenge for the identification of priority areas based on the integration of three approaches: invertebrate multi-taxa based; expert-based; and, GIS-based. The Trentino Province (eastern Italian Alps), was investigated as a case study. The first methodological step was to select a panel of nineteen experts which played a strategic role in the suggestion of 229 species (including Odonata), endangered or of

mandatory conservation interest. The second step was to find objective criteria for species prioritisation. These criteria, crossed with the experts taxonomical and ecological knowledge resulted in a list of 70 focal invertebrate species. The third step was to integrate with the GIS-based approach data layers from the habitat requirements of each of the 70 focal species to generate potential spatial-distributional maps. Potential distribution maps gave information about the sites (priority areas) in which the highest number of focal species could concentrate, thus suggesting where to focus future monitoring efforts. Several priority areas resulted outside the protected ones. Alluvial forest and hop-hornbeam woods were the habitats with the highest number of focal species, and thus they represent the habitats of major conservation interest and concern, because they are usually small, fragmented, and near urbanised areas located in the bottom of the valleys. The relatively simple processes involved in species and potential habitat distribution proposed in this paper can be conducted with a minimal amount of data, making it an attractive tool when time and funds are in short supply." (2012): Support for the immunocompetence handicap hypothesis in the wild: hormonal manipulation decreases survival in sick damselflies. *Evolution* 66(19): 3294-3301. (in English) ["The immunocompetence handicap hypothesis (ICHH) states that hormones enhance sexual trait expression but impair immunity. Previous

tests of the ICHH have been hampered by experimental design problems. Here, we report on an experimental test of the ICHH that includes manipulations of both hormones and infections in males of the territorial damselfly, *Hetaerina americana*, with accurate survival measurements. We conducted a fully factorial experiment subjecting each individual to one of three topical treatments: methoprene (a juvenile hormone analog), acetone, or control, and one of three injection treatments: bacteria, PBS, or control. We measured survival of manipulated males in both the wild and in captivity. As predicted, survival was most heavily impaired in methoprene-bacteria males than in the other groups in the wild, and no survival differences emerged in captive animals. This result confirms that survival is one cost an animal pays for increased hormonal levels. This corroborates theoretical predictions of the ICHH." 11954. Guan, Z.; Dumont, H.J.; Han, B.-p. (2012): *Archineura incarnata* (Karsch, 1892) and *Atrocalopteryx melli* (Ris, 1912) in southern China (Odonata: Calopterygidae). *International Journal of Odonatology* 15(3): 229-239. (in English) ["The calopterygines *Archineura incarnata* and *Atrocalopteryx melli* are subtropical habitat specialists, endemic to China, and sensitive to environmental change. We identified several sites with environmental deterioration from which the species seem to have disappeared; these species can be used as indicators of human disturbance. In this paper their distribution in China is mapped and information on their habitat is given, based on literature records (from 1892 until 2012) with supplements from field investigations in 2008–2011. We analysed Chinese literature, which contained much useful information. In all, 57 sites in 12 provinces were found to contain the two species. Suitable habitats occur in small shaded headwater streamlets for *A. melli*, in rocky streams for *Ar. incarnata*. The ranges of both species form an arc that descends from 30°N, then in the east curves inland at the level of the tropic. *Archineura incarnata* is clearly the more common species, but both are perhaps not so rare as hitherto believed. The majority of populations are situated in the provinces of Guangdong, Fujian and Guangxi. Several provinces merit more study, but the absence of both calopterygids from Yunnan might well be real. *Atrocalopteryx melli* populates the mountains of Hainan, while *Ar. incarnata* is absent from the island." 11955. Guareschi, S.; Gutiérrez-Cánovas, C.; Picazo, F.; Sánchez-Fernández, D.; Abellán, P.; Velasco, J.; Millán, A. (2012): Aquatic macroinvertebrate biodiversity:

patterns and surrogates in mountainous Spanish national parks. *Aquatic Conservation: Marine and Freshwater Ecosystems* 22(5): 598-615. (in English) ["In Spain, national parks represent the mainstay of conservation policies and attempt to protect the most representative natural ecosystems. However, studies on the ecology and conservation of aquatic biodiversity within protected areas are still scarce. This study aimed at compiling an inventory of the macroinvertebrate families inhabiting the aquatic ecosystems of each mountainous Spanish national park (Sierra Nevada, Cabañeros, Ordesa, Picos de Europa, Aigüestortes and Monfragüe). The results were used to answer two questions: (i) Which environmental variables are related to macroinvertebrate composition and richness in these protected ecosystems? (ii) Which taxon or group of taxa could act as biodiversity surrogates? Sampling was carried out in 81 aquatic ecosystems across the six national parks during the summers of 2008–2010. The national parks with the highest richness were Picos de Europa and Cabañeros. Overall, the six parks incorporated 66.2% of the taxa included in the Iberian checklist. Multivariate techniques showed that maximum altitude and the presence of lotic habitats were the most important variables related to different community compositions. The best richness model included the presence of a lotic habitat, together with the percentage of the catchment area with non-irrigated agriculture and siliceous geology. Selecting several diverse lotic and lentic water bodies at different altitudes provides the best way of representing Iberian macroinvertebrate diversity. Coleoptera family richness may be used as a macroinvertebrate biodiversity surrogate in Iberian mountainous protected areas because it displayed the highest correlation with the other taxonomic groups and remaining richness values. Such an indicator could be complemented with the use of Odonata family richness for standing waters. The adequacy of Coleoptera and Odonata as biodiversity surrogates should be tested at a wider geographic scale, and other surrogacy concepts (e.g. community composition) considered for assessing the role of this network in the protection of rare and endemic species." 11956. Guillermo-Ferreira, R.; Bispo, P.C. (2012): Male and female interactions during courtship of the Neotropical damselfly *Mnesarete pudica* (Odonata: Calopterygidae). *Acta ethologica* 15(2): 173-178. (in English) ["The courtship behaviour in calopterygid damselflies is well documented; however, the behaviour of the large Neotropical genus *Mnesarete* is still unknown. Thus, here we present the first description of male–female interactions in *Mnesarete pudica*, a common damselfly in the Neotropical savanna. The male–female interactions were composed of courtship displays, mounting, and chasing. The courtship behaviour lasted 5.23 ± 1.65 s and is very different from other calopterygids, consisting of hovering flights and the cross display made in front of females rather than on the oviposition site. The arrival and presence of females on a male territory are not sufficient to initiate sexual interactions; the male usually interacts with the female only after a patrolling flight. The females may present three distinct behaviours in response to male approach: (a) warding off signal (31.53%), (b) escape (28.83%), (c) and wing flipping (39.64%), which seems to stimulate male courtship. Females also may sit still, which induces males to react as if females were

signalling they are willing to mate. In this paper, we also suggest that male courtship behaviour is mediated by female signals." (Authors)] Address: Guillermo-Ferreira, R., Departamento de Biología, Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto, Universidade de São Paulo, Ribeirão Preto, São Paulo, Brazil. 11958. Guillermo-Ferreira, R.; Del-Claro, K. (2012): Reproductive behavior of *Acanthagrion truncatum* Selys, 1876 (Odonata: Coenagrionidae). *International Journal of Odonatology* 15(4): 299-304. (in English) ["Behavioural data on Neotropical coenagrionids is still scanty, with very few studies on their reproductive behaviour. Here we present the first description of the reproductive behaviour of *A. truncatum* in a high density population in the Brazilian Neotropical savanna. The observations were made at a pond in an ecological reserve. Males remain at the water searching for females. Females remain in the surrounding vegetation and only approach the water to mate and oviposit. The mean duration of copulation was 25.6 ± 3.26 minutes. Copulations are concentrated between 12:00 and 14:00 h (71%). Females oviposit in tandem with males, sometimes submerging to oviposit. Oviposition took 43.08 ± 22.17 minutes. Female underwater oviposition seems to disrupt male guarding and females emerge from the water by themselves. Male–male interactions usually consist of chases and "facing off". This damselfly species is apparently non-territorial, since males did not defend resources and searched for females in the area." 11960. Hadrys, H.; Simon, S.; Kaune, B.; Schmitt, O.; Schöner, A.; Jakob, W.; Schierwater, B. (2012): Isolation of Hox cluster genes from insects reveals an accelerated sequence evolution rate. *PLoS ONE* 7(6): e34682. doi:10.1371/journal.pone.0034682: 10 pp. (in English) ["Among gene families it is the Hox genes and among metazoan animals it is the insects (Hexapoda; including *Ischnura elegans* and *Sympetrum sanguineum*) that have attracted particular attention for studying the evolution of development. Surprisingly though, no Hox genes have been isolated from 26 out of 35 insect orders yet, and the existing sequences derive mainly from only two orders (61% from Hymenoptera and 22% from Diptera). We have designed insect specific primers and isolated 37 new partial homeobox sequences of Hox cluster genes (lab, pb, Hox3, ftz, Antp, Scr, abd-a, Abd-B, Dfd, and Ubx) from six insect orders, which are crucial to insect phylogenetics. These new gene sequences provide a first step towards comparative Hox gene studies in insects. Furthermore, comparative distance analyses of homeobox sequences reveal a correlation between gene divergence rate and species radiation success with insects showing the highest rate of homeobox sequence evolution." 11963. Haileselasie, T.H. Teferi, M. (2012): Influence of water quality on the diversity and distribution of macroinvertebrates in Hiwane second order stream, northern Ethiopia. *Research Journal of Environmental and Earth Sciences* 4(4): 475-481. (in English) ["Understanding

the pattern and process related to biodiversity is a greatest challenge to the science of biological conservation. Furthermore, diversity of tropical aquatic ecosystems is severely threatened by anthropogenic activities. What is more, the continuum of most of the tropical river is interrupted by several man-made activities contributing to adverse effects which hamper provision of good quality of water. Traditionally the quality of water is assessed by physico-chemical means but recent studies have focused on the use of organisms (biota) in water quality assessment for streams and lakes. Here we assessed the influence of water quality on the diversity and distribution of macroinvertebrates in Hiwane second order stream with primary objective to determine the ecological water quality status of Hiwane stream at different sampling sites using rapid field assessment screening methodology. A total of 5 sites (stream sections) were selected and 4 of the sampling sites were within the city Hiwane. However, a reference site outside of the city of Hiwane was included. There were 29 taxa of benthic invertebrates belonging to Ephemeroptera, Odonata, Plecoptera, Coleoptera, Trichoptera, Diptera and Hirudenia, among others, recorded from the river. Among these, members of Trichoptera and Ephemeroptera were predominant in density. Furthermore, species diversity is positively correlated with water quality. Since, man-made activities has lead to depletion of biota, any human activity in the drainage area which may cause changes among physico-chemical parameter could lead to a severe impact on the benthic invertebrates of Hiwane stream river. Thus, we recommend that effluent from the town should be carefully managed." 11965. Hamill, S.E. (2012): Recovery strategy for the Pygmy Snaketail (*Ophiogomphus howei*) in Ontario. Ontario Recovery Strategy Series. Prepared for the Ontario Ministry of Natural Resources, Peterborough, Ontario: v + 13 pp. (in English) ["*O. howei* is a small, brightly-coloured dragonfly which lives in large rivers with steady flow. Adults forage in the canopy of forests surrounding the rivers. Eggs are laid into the water where they are carried downstream and eventually sink. During the day the larvae burrow into sand or gravel sediments. At night they come to the surface, drift with the current, and prey on other invertebrates or small fish. This species is a globally rare dragonfly which occurs only in Eastern North America. In Canada it has

been found in 11 locations in New Brunswick and at one site in Ontario. The Ontario location is on the Namakan River in the Rainy River district of northwestern Ontario. The species is listed as endangered on the Species at Risk in Ontario (SARO) List under Ontario's Endangered Species Act, 2007 (ESA). The greatest potential threat to *O. howei* in Ontario is the impoundment of running waters, but others include forest harvesting and invasive species. Other threats common to dragonflies, such as road-kill, recreation, construction and pollution, may be of lower concern due to the remote northern location. Limiting factors include a need for pristine conditions and the species' short travel distance. Knowledge gaps are many, but major ones are the complete lack of information on population size and the unknown precise egg-laying location in Ontario. The recovery goal is to ensure the long-term survival of *O. howei* in Ontario by protecting the existing population. The protection and recovery objectives are to: • protect and maintain the quality and quantity of habitat on the Namakan River in Ontario where *O. howei* occurs; • implement a monitoring program at the location where *O. howei* is known to exist; • conduct additional inventories for *O. howei* in suitable habitat. When adult *O. howei* and breeding sites are found, a habitat regulation should be developed to protect those areas, including the river and sections of the surrounding forest. It is recommended that 300 metres of forested habitat on either side of the river, expanding to a radius of 500 metres around the breeding site, be prescribed as habitat in the regulation." 11966. Hammers, M.; van Gossum, H. (2012): Helping and misleading signals in female body coloration in *Ischnura elegans*. *Brachytron* 15(1): 16-24. (in Dutch, with English summary) ["Various animal species show coexistence of differently coloured and genetically inherited phenotypes. Sometimes these polymorphisms only occur in one sex, either only in males or only in females. When only occurring in females, this is considered to result from sexual conflict. Sexual conflict occurs when males and females differ in their optimal number of matings. In promiscuous species, male reproductive success typically increases with increasing numbers of matings, while for females just a few matings are optimal. Further matings are costly and reduce female reproductive success. In the damselfly *Ischnura elegans*, mature females occur as one of three differently coloured morphs. In addition, each of these morphs undergoes irreversible colour changes from immature to mature age. Intriguingly, one of the mature female morphs shows resemblance in phenotype to the conspecific male, specifically in body colouration (andromorph). The other two female morphs show different body colouration (gynomorphs). We explored three main questions concerning the occurrence and coexistence of these different female morphs in the damselfly *I. elegans*. Firstly, we asked whether variation in the relative frequencies of different female morphs occurs among populations and whether social or environmental factors can explain patterns in such variation. Among populations, large variation in female morph frequencies was observed, with andromorphs sometimes being the least, and sometimes being the most abundant female morph. Andromorph frequencies declined across populations with increasing ambient temperature. Secondly, we explored if males are aided by female body colouration to find and recognize suitable mating partners. Males appeared to avoid mating immature individuals, which

may be explained by differences in colour characteristics between immature and mature females. Thirdly, we asked whether andromorphs can be considered male-mimics that, as a result of their colour, succeed in reducing male harassment. Our work showed that andromorphs and males could not be distinguished based on colouration of their pale body parts. In line with this observation, males showed low mating interest for andromorphs, suggesting that andromorphs may indeed succeed in escaping from excessive male mating interest. Together our results show that colour signals by female damselflies may both help and hinder males in their mating decisions. Further, it appears that male harassment alone does not adequately explain female colour polymorphism in damselflies, and that other factors may play a significant role." 11967. Hannigan, E.; Kelly-Quinn, M. (2012): Composition and structure of macroinvertebrate communities in contrasting open-water habitats in Irish peatlands: implications for biodiversity conservation. *Hydrobiologia* 692: 19-28. (in English) ["The purpose of this study was to consider the relative importance of several habitat variables in explaining the patterns in the structure of macroinvertebrate assemblages in open-water habitats, in relatively intact bogs and fens, which should inform conservation strategies. It was hypothesised that variables relating to the size of the water body would differentiate the communities and that some species would be unique to certain conditions. The macroinvertebrate communities from pools >100 m², 10.1–100 m² and Sphagnum hollows were characterised using sweep sampling for eight intact peatland sites across four bog types, and related to habitat variables including pool size, Sphagnum cover and hydrochemistry. Results showed community composition and structure differed significantly between deep, permanent pools and shallow, drought-sensitive Sphagnum hollows, with larger invertebrates, such as Odonates and Dytiscinae, rarely found in the hollows. Sphagnum cover accounted for a substantial amount of the variation in community composition. An examination of life-history strategies found species dependent on predictable conditions for juvenile development to be more abundant in pools. In contrast, taxa that could delay juvenile development until conditions were favourable were more abundant in Sphagnum hollows. These results highlight the importance of habitat heterogeneity in maintaining macroinvertebrate diversity in peatlands. ... The overall faunal abundance of these sites was dominated by Diptera ([65%] whilst Coleoptera (*10%), Odonata (*10%), Trichoptera (*5%), Hemiptera (*5%) and Ephemeroptera (*5%) represented a small proportion of the fauna: *Lestes sponsa*, *Coenagrion puella/pulchellum*, *Enallagma cyathigerum*, *Ischnura elegans*, *Aeshna grandis*, *A. juncea*, *Libellula quadrimaculata* and *Sympetrum danae*." 11968. Hanson, M.A.; Herwig, B.R.; Zimmer, K.D.; Fieberg, J.; Vaughn, S.R.; Wright, R.G.; Younk, J.A. (2012):

Comparing effects of lake- and watershed-scale influences on communities of aquatic invertebrates in shallow lakes. *PLoS ONE* 7(9): e44644. doi:10.1371/journal.pone.0044644: 9 pp. (in English) ["Constraints on lake communities are complex and are usually studied by using limited combinations of variables derived from measurements within or adjacent to study waters. While informative, results often provide limited insight about magnitude of simultaneous influences operating at multiple scales, such as lake- vs. watershed-scale. To formulate comparisons of such contrasting influences, we explored factors controlling the abundance of predominant aquatic invertebrates in 75 shallow lakes in western Minnesota, USA. Using robust regression techniques, we modeled relative abundance of Amphipoda, small and large cladocera, Corixidae, aquatic Diptera, and an aggregate taxon that combined Ephemeroptera-Trichoptera-Odonata (ETO) in response to lake- and watershed-scale characteristics. Predictor variables included fish and submerged plant abundance, linear distance to the nearest wetland or lake, watershed size, and proportion of the watershed in agricultural production. Among-lake variability in invertebrate abundance was more often explained by lake-scale predictors than by variables based on watershed characteristics. For example, we identified significant associations between fish presence and community type and abundance of small and large cladocera, Amphipoda, Diptera, and ETO. Abundance of Amphipoda, Diptera, and Corixidae were also positively correlated with submerged plant abundance. We observed no associations between lake-watershed variables and abundance of our invertebrate taxa. Broadly, our results seem to indicate preeminence of lake-level influences on aquatic invertebrates in shallow lakes, but historical land-use legacies may mask important relationships" (Authors)] Address: Hanson, M.A., Wetland Wildlife Populations and Research Group, Minnesota Department of Natural Resources, Bemidji, Minnesota, USA. 11969. Harabiš, F.; Dolný, A.; Šipoš, J. (2012): Enigmatic adult overwintering in damselflies: coexistence as weaker intraguild competitors due to niche separation in time. *Population ecology* 54: 549-556. (in English) ["Odonata, like most freshwater invertebrates, tend to overwinter in water due to the thermal properties of a water environment. Winter damselflies (genus *Sympecma*), however, hibernate as adults in terrestrial habitats. The strategy of adult overwintering combined with high mortality is associated with several unique adaptations to semiarid conditions, but winter damselflies maintain this unique life history throughout almost the entire Palaearctic. We assume that the unique strategy of adult overwintering in temperate zones is indirectly maintained by niche separation in time. We used phenological data from the Czech Republic to compare the seasonal phenology of *Sympecma* spp. with other coexisting odonate species. Seasonal population growth patterns between *S. fusca* and other coexisting species representing different life histories were compared using GLMMs and LME. The models showed negative non-linear dependence between the population growth of *S. fusca* and the estimated abundance of compared species. We found that the specific strategy of adult overwintering makes it possible to avoid seasonal maxima of competition and predation in adult and larval stages. Adults may benefit from free niches during spring while larvae may benefit from size advantage among intraguild competitors and optimal conditions for development." (Authors)] Address: Hara-

11970. Hayasaka, D.; Korenaga, T.; Sánchez-Bayo, F.; Goka, K. (2012): Differences in ecological impacts of systemic insecticides with different physicochemical properties on biocenosis of experimental paddy fields. *Ecotoxicology* 21(1): 191-201. (in English) ["The environmental risks of pesticides are typically determined by laboratory single-species tests based on OECD test guidelines, even if biodiversity should also be taken into consideration. To evaluate how realistic these assessments are, ecological changes caused by the systemic insecticides imidacloprid and fipronil, which have different physicochemical properties, when applied at recommended commercial rates on rice fields were monitored using experimental paddy mesocosms. A total of 178 species were observed. There were no significant differences in abundance of crop arthropods among the experimental paddies. However, zooplankton, benthic and neuston communities in imidacloprid-treated field had significantly less abundance of species than control and fipronil fields. Significant differences in abundance of nekton community were also found between both insecticide-treated paddies and control. Influences on the growth of medaka fish were also found in both adults and their fries. Both Principal Response Curve analysis (PRC) and Detrended Correspondence Analysis (DCA) showed the time series variations in community structure among treatments, in particular for imidacloprid during the middle stage of the experimental period. These results show the ecological effect-concentrations (LOEC ~ 1 µg/l) of these insecticides in mesocosms, especially imidacloprid, are clearly different from their laboratory tests. We suggest that differences in the duration of the recovery process among groups of species are due to different physicochemical properties of the insecticides. Therefore, realistic prediction and assessment of pesticide effects at the community level should consider not only the sensitivity traits and interaction among species but also the differences in physicochemical characteristics of each pesticide." 11972. Herrmann, J. (2012): Chemical and biological benefits in a stormwater wetland in Kalmar, SE Sweden. *Limnologia* 42: 299-309. (in English) ["A manmade stormwater wetland in Kalmar, SE Sweden, sized 1 ha and receiving water from residential and road areas, was monitored over the first years after inundation with respect to chemistry and biology. Water flow and chemistry was analysed in years 2–4, mainly on a monthly basis, but, in the final year, every second month. This revealed that total nitrogen, according to the Swedish Environmental Quality Criteria (EQC), typically showed moderate or

high concentrations, whereas total phosphorous levels were very high or extremely high. Metal (Cd, Cr, Cu, Pb and Zn) concentrations were low or moderate in terms of EQC. Yearly average reduction of nitrogen was 173 kg ha⁻¹ y⁻¹, tending to increase over time, and for phosphorous 12.1 kg ha⁻¹ y⁻¹, tending to decrease. Vegetation analysis was performed in years 1–4 by noting all species in 27 consecutive zones around the wetland system. This showed that one year after filling with water, the vegetation was already well established with >30 plant species in the entire pond system, and this increased only slightly. After four years, the shoreline vegetation cover had become denser, especially with larger graminoids such as common reed (*Phragmites australis*) and sea club-rush (*Bolboschoenus maritimus*), and submersed vegetation almost disappeared. There was a tendency for common species to become more dominant, and for less common species to become rarer. Using sweep net sampling of benthic invertebrates during years 0–2, ca 50 species/higher taxa were observed during the first year, largely because of the appearance of many beetles, especially dytiscids. However, these decreased the following years. Apart from these animals, in the first few months the invertebrate colonisation was dominated by chironomids and corixids, whereas later prominent increases were noticed for the isopod *Asellus aquaticus*, the snail *Physa fontinalis*, and the mayfly nymph *Cloeon dipterum*. The results are discussed in terms of wetland values for biodiversity and nutrient reduction, suggesting that these objectives seem possible to combine in stormwater wetlands." 11973. Hof, C.; Brändle, M.; Dehling, M.; Munguia, M.; Brandl, R.; Araujo, M.B.; Rahbek, C. (2012): Habitat stability affects dispersal and the ability to track climate change. *Biology Letters* 8(4): 639-643. (in English) ["Habitat persistence should influence dispersal ability, selecting for stronger dispersal in habitats of lower temporal stability. As standing (lentic) freshwater habitats are on average less persistent over time than running (lotic) habitats, lentic species should show higher dispersal abilities than lotic species. Assuming that climate is an important determinant of species distributions, we hypothesize that lentic species should have distributions that are closer to equilibrium with current climate, and should more rapidly track climatic changes. We tested these hypotheses using datasets from 1988 and 2006 containing all European Odonata species. Bioclimatic envelope models showed that lentic species were closer to climatic equilibrium than lotic species. Furthermore, the models over-predicted lotic species ranges more strongly than lentic species ranges, indicating that lentic species track climatic changes more rapidly than lotic species. These results are consistent with the proposed hypothesis that habitat persistence affects the evolution of dispersal." 11976. Home, J. (2012): Emergence, maturation time and oviposition in the Common Darter *Sympetrum striolatum* (Charpentier). *J. Br. Dragonfly Society* 28(2): 66-74. (in English) ["The most successful period of oviposition in 2005 occurred during the last half of September. However, 9% of the emergences in 2006 occurred from a pond exposed from mid-October through November 2005, indicating a second, smaller, peak of oviposition. Over the period 1990-2011 the average date for the first sighting of individuals was 17 June and the average date when first seen patrolling was 14 July. The mean time between emergence and patrolling was 28 days." (Author)] Address: Home, J., 78 Spring Lane, Bishopstoke, Eastleigh, Hants, S050 6BB, UK

11977. Horváth, G. (2012): Assessment of riverine dragonflies (Odonata: Gomphidae) and the emergence behaviour of their larvae based on exuviae data on the reach of the river Tisza in Szeged. *Tiscia* 39: 9-15. (in English) ["Abundance, phenology, sex ratio, emergence pattern, mortality and larval emergence behaviour of riverine Gomphidae were studied at the Lower-Tisza

reach at Szeged (168–173 rkm) during the emergence period in 2011. Three 20 meter long sampling sites were chosen and searched systematically for exuviae, dead specimens and dragonfly wings, which were left behind by bird predators. At the studied reach of the river two species form stable populations: *G. flavipes* and *G. vulgatissimus*. *G. flavipes* was much more abundant than *G. vulgatissimus*. Exuviae indicated the excess of females in the *G. vulgatissimus* population (although there were no significant difference between sexes), while in the case of *G. flavipes* the number of individuals in both sexes were almost the same. *G. vulgatissimus* started to emerge first as a 'spring species', while *G. flavipes* started to emerge about a month later showing the characteristics of a 'summer species'. The rate of mortality in the *G. flavipes* population during emergence was slight and quite normal compared to the abundance of the species. Selection of emergence support of *G. flavipes* showed that the significant majority of the larvae chose soil, but this could have been caused by the notable minority of other types of substrates at the sampling sites. The distance crawled by the larvae from the water-front to the emergence site differed significantly between the two species, *G. vulgatissimus* crawled further, and in the case of *G. flavipes* the effect of the measured background variables to the distance had not been proven." 11978. Hossie, T.J.; Murray, D.L. (2012): Assessing behavioural and morphological responses of frog tadpoles to temporal variability in predation risk. *Journal of Zoology* 288(4): 275-282. (in English) ["Finely tuned adjustment of an individual's phenotype can offer substantial fitness benefits when it is closely matched with environmental change. For instance, prey may be safeguarded against unnecessary costs to growth or development when their responses to temporally variable predation risk include plastic anti-predator defences. Yet, the correspondence between perceived predation risk and related responses should differ between behavioural and morphological phenotypes when risk fluctuates because behaviour can be modified quickly, whereas morphological phenotypes require time to build. Theoretical models predict intermediate expression when risk fluctuates rapidly relative to the time required to mount a response, whereas traits that can be modified relatively quickly should more closely track current conditions. Using a tadpole-dragonfly larva system, we sought to compare the expression of behavioural and morphological defences following exposure to constant versus variable predation risk. By varying the pattern and total duration of predator cue exposure, but not cue concentration, we quantified phenotypic plasticity and trait reversibility. Our results show that strong behavioural responses were limited to early ontogeny but closely matched current level of risk. The morphology of prey experiencing a weekly changing predator environment was intermediate to that of prey in the no-predator and constantly exposed treatments. Yet, prey exposed to a predator environment for the same total duration as the weekly changing environment, but in a different exposure pattern, was morphologically unresponsive to the onset of predation risk. Finally, unexposed tadpoles gained deeper tails and smaller relative body size in late development, coincident with limb bud development. Such changes are consistent with anti-predator response and represent either an innate response when prey are more

vulnerable or shape optimization when faced with increased drag. We conclude that phenotypic expression depends critically on patterns of temporal variability in the environment, although the actual extent of expression depends on the specific trait in question." 11979. Huang, S.-C.; Reinhard, J. (2012): Color change from male-mimic to gynomorphic: a new aspect of signaling sexual status in damselflies (Odonata, Zygoptera). *Behavioral Ecology* 23(6): 1269-1275. (in English) ["Body colour variations are used by many animal species to communicate their sexual state and are believed to have evolved through sexual selection. In Zygoptera, females sometimes come in different colour morphs: gynomorphs and male-like andromorphs, pursuing different reproductive strategies. These distinct female colour morphs are usually mature females and their colour remains stable throughout the female's life. Here, we show for the first time that blue andromorph females of the Australian damselfly *Ischnura heterosticta*, are still sexually immature, and change their body colour to green-grey gynomorph when they are ready to mate. The colour change occurs within 24h and is irreversible. Males of *I. heterosticta* rarely recognize blue andromorphs as potential mates, but mistake them for other males. The andromorphs thus avoid male sexual harassment, giving them the advantage of additional time to forage and sexually mature. The colour change to gynomorph signals the readiness to mate, and the former andromorphs have equal mating success after the colour change as other gynomorph females. Our results demonstrate that andromorph *I. heterosticta* use a complete and unique body colour change from male-mimic to gynomorphic to signal sexual maturity and regulate reproduction. Our discovery gives rise to a novel hypothesis regarding maintenance of female-limited polymorphism in *Ischnura* damselflies via this colour change mechanism." 11980. Hughes, M.E.; Fincke, OM, (2012): Reciprocal effects between burying behavior of a larval dragonfly (Odonata: *Macromia illinoensis*) and zebra mussel colonization. *Journal of Insect Behavior* 25: 554-568. (in English) ["Invasive zebra mussels (*Dreissena polymorpha*) often colonize dragonfly larvae, especially spawning species whose survivorship to emergence as terrestrial predators is consequently reduced. Using individuals of the sprawler, *Macromia illinoensis*, as their own controls, we compared the burying behaviour of penultimate instar larvae before (i.e. baseline) and after their colonization by zebra mussels under ambient conditions. Individuals that took longer to bury themselves when mussel-free had a higher rate of colonization by mussels over a five-day period compared to those that buried faster. In contrast, the depth at which individuals buried when mussel-free was not predictive of subsequent colonization rate. Although mean bury time did not differ between baseline and when an individual carried one or more mussels, colonized larvae buried more shallowly than when mussel-free. Moreover, attached mussels increased the risk of subsequent colonization by zebra mussels. After naturally losing all of their attached mussels, bury time and depth of individuals did

not differ from their baseline behaviour, indicating that the changes in the behaviour of colonized individuals were due to mussel loads and not their time in captivity. Under natural conditions, the positive feed-back between mussel attachment and increasing vulnerability to colonization helps explain how mussel loads, which are lost at molting, can accumulate quickly over the duration of the final larval stadium. Because zebra mussel attachment decreases the crypsis that that a *M. illinoensis* gains from burying, the invasive mussel may also make dragonfly larvae more detectable to visual predators." 11982. Ingley, S.J.; Bybee, S.M.; Tennessen, K.J.; Whiting, M.F.; Branham, M.A. (2012): Life on the fly: phylogenetics and evolution of the helicopter damselflies (Odonata, Pseudostigmatidae). *Zoologica Scripta* 41(6): 637-650. (in English) ["Helicopter damselflies (Odonata: Pseudostigmatidae) form a relatively small, yet highly specialized group of odonates, including the largest extant odonate (wingspan of ~190 mm). Pseudostigmatids are found throughout Central and South America, with the exception of one species that is found exclusively in East Africa. Pseudostigmatids oviposit exclusively in phytotelmata and forage on orb-weaver spiders, which they pluck from webs. Pseudostigmatids also exhibit unique forms of both broad and narrow wings. Although the ecology of these behaviours and morphological features have been studied, their phylogenetic origins and evolutionary history are unknown. Here, we examine the origins of pseudostigmatid wing forms, oviposition in phytotelmata and spider feeding within a modern phylogenetic context, testing for single origins of each character. Phylogenetic analyses are based on 59 morphological characters and ~5 kb of sequence data. Our findings include a well-supported monophyletic Pseudostigmatidae and *Coryphagrion grandis* as sister to the Neotropical genera. The genus *Mecistogaster* is paraphyletic, with *Pseudostigma* nested within the clade. The genus *Microstigma* is supported as monophyletic and forms a sister group relationship to the clade of *Megaloprepus* and *Anomisma*. The sister group relationship to Pseudostigmatidae is less clear. On the basis of this phylogenetic analysis, we propose three new tribes (*Coryphagrionini*, *Microstigmatini* and *Mecistogastrini*). As Pseudostigmatidae is monophyletic, the behaviour of gleaning spiders from webs appears to derive from a single origin. There are two origins of broad wings within Pseudostigmatidae. Oviposition in phytotelmata most certainly evolved multiple times within Coenagrionoidea. These findings provide new insights into pseudostigmatid evolution that can be used to generate hypotheses regarding behaviour and morphological adaptation in this unique and threatened group of damselflies." ment of Biology, 401 WIDB, Brigham Young University, Provo, UT 84602. E-mail: sjingley@byu.edu

11983. Jacquemin, G.; Vein, D. (2012): The aquatic insects of a standard small plain river in NE France, with emphasis on remarkable species. *Aquatic Insects* 34, Supplement 1: 11-22. (in English) ["A five-year macroinvertebrate study was conducted on a 55 km river (le Rupt-de-Mad, Lorraine region, north-eastern France), a standard for the region. A list of 300 species was drawn up, and remarkable species were listed for some better known orders: Ephemeroptera, Plecoptera, Trichoptera and Odonata. Some faunistic results are emphasised: about 42% of the identified species were more or less ubiquitous, 26% were meso- to polysaprobic species of potamon, present only in the main course of the river, while 31% were rather stenoecious species restricted to certain tributaries. Fifty-one remarkable species were listed, taking into account their regional status, according to IUCN categories: more than three quarters were hosted in the small tributaries, and 55% found exclusively in these latter (versus 23.5% only present in the main course of the river). Calcareous lotic tributaries were hosting particularly original communities with many remarkable species. Ephemeroptera, Plecoptera and Trichoptera were pertinent groups to assess the global faunistic interest of lotic habitats, but lentic habitats are probably better evaluated using other groups, e.g. Odonata and Coleoptera; the latter unfortunately poorly known from an ecological point of view." 11984. Jaeschke, A.; Bittner, T.; Jentsch, A.; Reineking, B.; Schlumprecht, H.; Beierkuhnlein, C. (2012): Biotic interactions in the face of climate change: A comparison of three modelling approaches. *PLoS ONE* 7(12): e51472. (in English) ["Climate change is expected to alter biotic interactions, and may lead to temporal and spatial mismatches of interacting species. Although the importance of interactions for climate change risk assessments is increasingly acknowledged in observational and experimental studies, biotic interactions are still rarely incorporated in species distribution models. We assessed the potential impacts of climate change on the obligate interaction between *Aeshna viridis* and its egg-laying plant *Stratiotes aloides* in Europe, based on an ensemble modelling technique. We compared three different approaches for incorporating biotic interactions in distribution models: (1) We separately modelled each species based on climatic information, and intersected the future range overlap ('overlap approach'). (2) We modelled the potential future distribution of *A. viridis* with the projected occurrence probability of *S. aloides* as further predictor in addition to climate ('explanatory variable approach'). (3) We calibrated the model of *A. viridis* in the current range of *S. aloides* and multiplied the future occurrence probabilities of both species ('reference area approach'). Subsequently, all approaches were compared to a single species model of *A. viridis* without interactions. All approaches projected a range expansion for *A. viridis*. Model performance on test data and amount of range gain differed depending on the biotic interaction approach. All interaction approaches yielded lower range gains (up to 667% lower) than the model without interaction. Regarding the contribution of algorithm and approach to the overall uncertainty, the main part of explained variation stems

from the modelling algorithm, and only a small part is attributed to the modelling approach. The comparison of the no-interaction model with the three interaction approaches emphasizes the importance of including obligate biotic interactions in projective species distribution modelling. We recommend the use of the 'reference area approach' as this method allows a separation of the effect of climate and occurrence of host plant." 11985. Jardine, T.D.; Kidd, K.A.; Rasmussen, J.B. (2012): Aquatic and terrestrial organic matter in the diet of stream consumers: implications for mercury bioaccumulation. *Ecological Applications* 22: 843-855. (in English) ["The relative contribution of aquatic vs. terrestrial organic matter to the diet of consumers in fluvial environments, and its effects on bioaccumulation of contaminants such as mercury (Hg), remains poorly understood. We used stable isotopes of carbon and nitrogen in a gradient approach (consumer isotope ratio vs. periphyton isotope ratio) across temperate streams that range in their pH to assess consumer reliance on aquatic (periphyton) vs. terrestrial (riparian vegetation) organic matter, and whether Hg concentrations in fish and their prey were related to these energy sources. Taxa varied in their use of the two sources, with grazing mayflies (Heptageniidae), predatory stoneflies (Perlidae), one species of water strider (Metrobates hesperius) and the fish blacknose dace (*Rhinichthys atratulus*) showing strong connections to aquatic sources while *Aquarius remigis* water striders and brook trout (*Salvelinus fontinalis*) showed a weak link to in-stream production. The aquatic food source for consumers, periphyton, had higher Hg concentrations in low pH waters, and pH was a much better predictor of Hg in predatory invertebrates (including Odonata) that relied mainly on this food source vs. those that used terrestrial C. These findings suggest that stream biota relying mainly on dietary inputs from the riparian zone will be partially insulated from the effects of water chemistry on Hg availability. This has implications for the development of a whole system understanding of nutrient and material cycling in streams, the choice of taxa in contaminant monitoring studies, and in understanding the fate of Hg in stream food webs." tal of 26 species are reported.] Address: Johnson, J., 3003 Unander Avenue, Vancouver, WA 98660, USA. E-mail: jtjohnson@comcast.net

11988. Johnson, S.E.; Ugbah, N.K. (2012): The spatial games: investigating the spatial distribution of *Anax* and select prey as a function of predator-prey interactions. A Senior Project presented to the Faculty of the Biological Sciences Department California Polytechnic State University, San Luis Obispo in partial fulfillment of the requirements for the degree Bachelor of Science: 24 pp. (in English) ["Our study investigated the spatial distribution and movement behaviour of predatory dragonfly larvae (*Anax*) and of two prey types: mosquito larvae and amphipods. Predator-prey interactions have important consequences for the population dynamics of both predator and prey groups and these interactions can shape community structure. We measured behaviour of each prey type in the presence of the *Anax* predator and the behaviour of the predator in the presence of these alternative prey types. Observations were made in five-gallon aquaria where a grid pattern allowed us to track the number of moves made by individuals. We compiled data from ten, one hour trials for each predator-prey combination (*Anax* + amphipods and *Anax* + mosquito larvae). Prey species differed in their behaviour. Mosquito larvae spent more time near the water's surface, were more likely to utilize the artificial vegetation, and were more active than amphipods. On the other hand, amphipods utilized full range of the aquarium and had a greater number of moves than mosquito larvae. *Anax* behaviour was significantly different in the two prey treatments. *Anax* spent more time in the top portion of the aquarium during the mosquito treatments, utilized the artificial vegetation more in the amphipod treatments, had a greater number of moves in the amphipod treatments, and ate more amphipods than mosquito larvae. Our results indicate that *Anax* change their behaviour based on prey type." (Authors)] Address: not stated.

11989. Juen, L.; De Marco Jr, P. (2012): Dragonfly endemism in the Brazilian Amazon: competing hypotheses for biogeographical patterns. *Biodiversity and Conservation* 21(13): 3507-3521. (in English) ["Many hypotheses have been proposed to explain the origin and maintenance of the Amazonian diversity with special place for the theory of isolation by rivers and a set of hypothesis related to contemporary environmental dissimilarity. We explore those hypotheses here using the biogeographic distributional patterns of dragonflies in interfluvial areas of the Amazonian biome and also evaluate how differences among dispersal capabilities between the Anisoptera and Zygoptera suborders may contribute to those patterns. We used distributional information of 392 odonate species in the Amazonian forest in a cladistic analysis of distributions and endemism and the estimated faunistic similarity among interfluves with the Sorensen index. The environmental similarity among interfluves was analysed by discriminant analysis based on eight environmental metrics. Different metrics for geographic distance (connectivity) among interfluves were evaluated and their relation to the other variables tested by the Mantel test. The number of endemic species was linearly correlated to the area of the interfluves. General endemism patterns showed consistent resemblance to those reported for vertebrates, especially the similarity among the Rondônia and Inambari interfluves. Geographical distance has no predictive value for

dragonflies distribution, but the environmental similarity is a good predictor of proportion of shared species. The low dispersal group (Zygoptera) presented more clear patterns of distribution and a lower proportion of shared species among different interfluvies. The environmental similarity can be considered the determinant factor of the distribution of dragonflies, possibly due to environmental specificity evolved during a long history of some clades in this system. The low dispersal group (Zygoptera) retained more biogeographical information about possible historical factors that determine current distribution. Also, the transport of larvae by macrophyte banks, the lateral change of river courses, the reversal of the drainage basin, together with the capacity to disperse across rivers for some species may be explanations for the lack of effect of isolation by rivers, especially for Anisoptera." 11992. Karthika, P.; Vadivalagan, C.; Gunasekaran, C.; Anandhakumar, S. (2012): DNA Barcoding of selected dragonfly species (Libellulidae and Aeshnidae) for species authentication with phylogenetic assessment. *European Journal of Experimental Biology* 2(6): 2158-2165. (in English) ["Dragonflies are the bio indicators of the aquatic ecosystem. Knowledge and studies on the diversity of dragonflies in India is very high. Identification by traditional taxonomy often leads to misidentification. Incidence of sexual dimorphism is found to be high particularly in the Libellulidae and Aeshnidae family. In order to resolve the above mentioned problem, the accurate identification of the dragonflies was carried out by DNA barcoding using COI gene. In the present study,

selected dragonfly species (*Bradinopyga geminata*, *Crocothemis servilia*, *Diplacodes trivialis* and *Anaciaeschna jaspidea*) of the family of Libellulidae and Aeshnidae were taken and along with three other evident species (*Pantala flavescens*, *Orthetrum sabina*, and *Brachythemis contaminata*) were retrieved from GenBank. The phylogenetic tree was created using NJ (Neighbour Joining) method to determine the origin and evolutionary relationships of the species. Similarity search was performed and conformed species were submitted to the NCBI and BOLD database for species authentication. The present study concluded that the DNA barcoding is an invaluable tool for the authentication of the species. Storage of this nucleotide information in a database like BOLD would greatly help in the identification up to sub species level." 11994. Kefford, B.J.; Hickey, G.L.; Gasith, A.; Ben-David, E.; Dunlop, J.E.; Palmer, C.G.; Allan, K.; Choy, S.C.; Piscart, C. (2012): Global scale variation in the salinity sensitivity of riverine macroinvertebrates: Eastern Australia, France, Israel and South Africa. *PLoS ONE* 7(5): e35224. doi:10.1371/journal.pone.0035224: 12 pp. (in English) ["Salinity is a key abiotic property of inland waters; it has a major influence on biotic communities and is affected by many natural and anthropogenic processes. Salinity of inland waters tends to increase with aridity, and biota of inland waters may have evolved greater salt tolerance in more arid regions. Here we compare the sensitivity of stream macroinvertebrate species to salinity from a relatively wet region in France (Lorraine and Brittany) to that in three relatively arid regions eastern Australia (Victoria, Queensland and Tasmania), South Africa (south-east of the Eastern Cape Province) and Israel using the identical experimental method in all locations. The species whose salinity tolerance was tested, were somewhat more salt tolerant in eastern Australia and South Africa than France, with those in Israel being intermediate. However, by far the greatest source of variation in species sensitivity was between taxonomic groups (Order and Class) and not between the regions. We used a Bayesian statistical model to estimate the species sensitivity distributions (SSDs) for salinity in eastern Australia and France adjusting for the assemblages of species in these regions. The assemblage in France was slightly more salinity sensitive than that in eastern Australia. We therefore suggest that regional salinity sensitivity is therefore likely to depend most on the taxonomic composition of respective macroinvertebrate assemblages. On this basis it would be possible to screen rivers globally for risk from salinisation." (Authors) The analysed data sets include from Israel: *Platycnemis* sp., *Pseudagrion* sp., *Lesites virens* and *L. barbarus*, and from France: *Boyeria irene*, *Ischnura elegans*, *Calopteryx splendens*, *C. virgo*,

11995. Keller, D.; van Strien, M.J.; Ghazoul, J.; Holder-egger, R. (2012): Landscape genetics of insects in intensive agriculture: new ecological insights. In: Swiss Federal Research Institute WSL (ed) ENHANCE. Enhancing ecosystem connectivity through intervention - benefits for nature and society? Final Report. Birmensdorf, Swiss Federal Research Institute WSL: 27-35. (in English) ["Agricultural landscapes harbour various insect species, of which many became threatened due to fragmentation, habitat loss and agricultural intensification. Connectivity measures are being implemented to mitigate this trend. However, to determine whether structural connectivity measures are truly effective, the functional connectivity needs to be measured, which requires knowledge on species-specific migration rates as well as the identification of landscape elements enhancing or inhibiting migration. The latter is unknown for most insect species. Therefore, we studied the effects of landscape composition on migration and gene flow of insect species inhabiting an intensively managed agricultural landscape in the Oberaargau region in Switzerland. We focussed on five study species inhabiting different habitat types: ... [four grasshopper species] ... and a damselfly inhabiting ditches (*Coenagrion mercuriale*). For each of these species landscape elements that facilitated or inhibited migration and gene flow were assessed. Furthermore, we tested whether the reproductive habitat of a species was also the preferred migration habitat and whether this differed between short- and long-distance migration. Several landscape genetic approaches were applied to answer these issues. Transect analysis was used to identify landscape elements that enhance or inhibit gene flow within straight-line transects between pairs of populations. Because straightline transects assume rectilinear migration, we developed a new method, least-cost transect analysis (LCTA), which creates transects around least-cost paths to give a better representation of the landscape that a migrating individual may encounter. LCTA was used to assess most likely migration habitats for short- and long-distance dispersal and simultaneously identify landscape effects on gene flow. For both, the damselfly *C. mercuriale* and the wetland grasshopper *S. grossum*, short-distance migration occurred predominantly within their reproductive habitat. For long-distance dispersal, however, *C. mercuriale* preferred open agricultural landscapes, and *S. grossum* did not show any landscape preferences. This differentiation between short and long-distance dispersal was further analysed making use of population network topologies. With network topologies we discovered that the spatial configuration of populations may have influence on the detectability of a landscape effect on migration and should be considered in landscape genetic analyses. A simulation study is currently being set up to determine to what extent results from landscape genetic techniques are influenced by habitat fragmentation and abundance." 11996. Kerry, L.; Baker, R.A. (2012): The terrestrial mite *Leptus killingtoni* Turk (Acari: Erythraeidae) as a para-

site of the Small Red Damselfly *Ceragrion tenellum* and other odonates. *J. Br. Dragonfly Society* 28(1): 21-26. (in English) [Odonata from three commons on the East Devon Pebblebed Heaths (UK) were checked for mites. *L. killingtoni* was observed on the head, thorax, abdomen and legs of *C. tenellum*, *Pyrrhosoma nymphula*, *Coenagrion mercuriale*, *Orthetrum coerulescens* and *Cordulegaster boltonii*. *C. mercuriale* is a new host record. "The results for *C. tenellum* are - examined 123, infested 39, prevalence (percentage of individuals parasitized) 32%. Of the 56 mites observed, 23 (41%) were found on the legs and smaller numbers on other parts of the body; i.e. 2 (4%) on the head, 13 (23%) on the thorax, 10 (18%) on the abdomen and 6 (11%) on or near the eyes ... The majority of the odonates had only one mite per host." (Authors)] Address: Kerry, L., Mount Pleasant Cottage, Stoneyford, Colaton Raleigh, Sidmouth, Devon, EX10 OHZ, UK

11997. Klass, K.-D.; Matushkina, N.A. (2012): The exoskeleton of the female genitalic region in *Petrobiellus takunagae* (Insecta: Archaeognatha): insect-wide terminology, homologies, and functional interpretations. *Arthropod Structure & Development* 41(6): 575-591. (in English) ["The exoskeleton of the female genitalic region (abdominal venters 7-9) in *Petrobiellus takunagae* (Machilidae-Petrobiellinae) is studied using light microscopy and SEM. Sclerites are distinguished from membrane by the degree of cuticular flexibility. However, the microsculpture of the cuticle is shown to be useful in characterising the heterogeneity of the cuticle and in detecting weak sclerotisations. The morphology of *Petrobiellus* is compared with that in *Trigoniophthalmus alternatus* (Machilidae-Machilinae) described previously. While venter 7 is similar, venters 8 and 9 show many differences in the presence/absence or fusion/separation of particular sclerites. This suggests female genitalic morphology to be a valuable character system for phylogenetic and taxonomic work in Archaeognatha. Comparison with other insect orders is aimed at detecting homologous structures and conditions. Important points are: (1) *Petrobiellus* has a sclerotised genital lobe posteriorly on venter 7, similar to *Zygentoma* and *Dictyoptera*; it bears the gonopore. (2) *Petrobiellus* has a posterior sclerite on venter 9 that is very similar to a sclerite of Odonata. (3) The morphology of the coxal lobes of venter 9 (gonoplacs) suggests their function as a sheath of the ovipositor. From female genitalic morphology we deduce the process of oviposition, describing an external egg transportation tract." 11998. Koehler, C.; Liang, Z.; Gaston, Z.; Wan, H.; Dong, H. (2012): 3D reconstruction and analysis of wing deformation in free-flying dragonflies. *The Journal of Experimental Biology* 215(17): 3018-3027. (in English) ["Insect wings demonstrate elaborate three-dimensional deformations and kinematics. These deformations are key to understanding many aspects of insect flight including aerodynamics, structural dynamics and control. In this paper, we propose a template-based subdivision surface reconstruction method that is capable of reconstructing the wing deformations and kinematics of free-flying insects based on the output of a high-speed camera system. The reconstruction method makes no rigid wing assumptions and allows for an ar-

bitrary arrangement of marker points on the interior and edges of each wing. The resulting wing surfaces are projected back into image space and compared with expert segmentations to validate reconstruction accuracy. A least squares plane is then proposed as a universal reference to aid in making repeatable measurements of the reconstructed wing deformations. Using *Erythemis simplicicollis* as a demonstration, we quantify and visualize the wing twist and camber in both the chord-wise and span-wise directions, and discuss the implications of the results. In particular, a detailed analysis of the subtle deformation in the dragonfly's right hindwing suggests that the muscles near the wing root could be used to induce chord-wise camber in the portion of the wing nearest the specimen's body. We conclude by proposing a novel technique for modelling wing corrugation in the reconstructed flapping wings. In this method, displacement mapping is used to combine wing surface details measured from static wings with the reconstructed flapping wings, while not requiring any additional information be tracked in the high speed camera output." 11999. Korkeamäki, E.; Metsälä, P.; Parkko, P. (2012): *Isoukonkorenon (Aeshna crenata) elinympäristöt Salpausselän harjaluueella* [Habitat selection of *Aeshna crenata* in the Salpausselkä Ridge area]. *Crenata* 5: 29-33. (in Finnish, with English summary) ["*A. crenata*, is an impressive, but rare, localized and poorly known species in Europe. A total of 45 small ponds and lakes, situated within the Salpausselkä Ridge, north of Kouvola city in south-eastern Finland, were surveyed for populations of *A. crenata* during the period 30 June - 4 September 2011. Adults and exuviae were searched for in sunny weather. *A. crenata* was found in 18 ponds. The 16 other odonate species recorded in these ponds are listed in Table 1. *A. crenata* seems to have rather specialized habitat requirements in the study area. It occurs mainly in small, circular and oligotrophic ponds with slightly swampy shoreline. These ponds - 'suppa pits' - are typical glacial age formations in the Salpausselkä Ridge. Potential threats by the human activity to the populations of *A. crenata* are briefly discussed." (Authors)] Address: Korkeamäki, E., Karkunkatu 18 a 4 b, FIN-48600 Karhula, Finland.

12000. Kosterin, O.E.; Makbun, N.; Dawwrueng, P. (2012): *Burmagomphus asahinai* sp. nov., a new species from Cambodia and Thailand, with a description of the male of *B. graciosus* Chao, 1954. *International Journal of Odonatology* 15(4): 275-292. (in English) ["*Burmagomphus asahinai* sp. nov. (holotype male: Cambodia, Cardamom Mts., Koh Kong Province, Thma Bang District, 6 km SW of its centre, rapids at the Thma Bang River, 25 August 2011, RMNH) is described from Koh Kong Province of Cambodia and Nakhon Nayok, Chiang Mai and Parhuap Khiri Khan Provinces of Thailand and is compared with its nearest congeners. While the mesepisternum pattern is closest to that of *B. graciosus* Chao, 1954, the female head sculpture combines structures found separately in *B. graciosus* and *B. williamsoni* Forster, 1914. A redescription of *B. graciosus*, including the hitherto unknown male, is provided based on a pair from Guizhou Province, China." 12001. Krejčová, A.; Černohorský, T.; Pouzar, M. (2012): O-TOF-ICP-MS analysis of rare earth elements, noble elements, uranium and thorium in river-relating species. *International Journal of Environmental Analytical Chemistry* 92(5): 620-635. (in English) ["The determination of rare earth elements (REEs), Au, Pt, Ir, Pd, Th and U in various river species was performed by the orthogonal time-of-flight inductively coupled plasma mass spectrometry (o-TOF-ICP-MS). The method working conditions were optimised in order to minimise the presence and possible spectral interferences of oxides. Ratios MO⁺/M⁺ as well as interference of light REE and Ba oxides/hydroxides with high REEs were evaluated and confirmed to be insignificant. Using the internal standard Re, non-spectral matrix effects (originally decreasing of intensities up to 15%) were overcome and recoveries were found from 92 to 105% for all matrices analysed. For solutions, limits of detection (3s) were 0.14–0.82 for REEs, Th, U and Y, 1.18 for La, 4.3–5.6 for Au, Pt, Ir and Pd 11 for Sc (all in ng L⁻¹). The Principal component analysis was used for classification of samples according to their places of origin successfully. The o-TOF-ICP-MS was proved to be a very sensitive and suitable technique for bio-monitoring purposes and was employed in the analysis of biota samples (fish, insect, profiles, benthal growths) originated from five different places in the river Elbe (Czech Republic)." (Authors) The study includes four samples of 'Odonata'.] Address: Krejčová, Anna, Department of Environmental and Chemical Engineering, University of Pardubice, Studentská 573, CZ 532 10 Pardubice, Czech Republic. 12002. Kulijer, D.; Baker, R.A.; Zawal, A. (2012): A preliminary report on parasitism of Odonata by water mites from Bosnia and Herzegovina. *J. Br. Dragonfly Society* 28(2): 92-101. (in English) ["The following Odonata, infested with mites, have been collected from a number of sites in Bosnia and Herzegovina - *Aeshna isosceles*, *Sympetrum flaveolum*, *Coenagrion pulchellum*, *C. puella*, *C. scitulum*, *Enallagma cyathigerum*, *Erythromma najas*, *Ischnura elegans*, *I. pumilio*, *Lestes dryas*, *Platycnemis pennipes*, and *Pyrrosoma nymphula*. The preferred site of mite attachment on the body is the posterior ventral surface of the thorax, behind the third pair of legs. In all but one of the species of zygopteran, mites were also found between the first and second pair and/or the second and third pair of legs and, in several species, on the abdomen. Mite loads varied for different species but preliminary results suggest that the larger anisopteran can carry more mites (in *S. flaveolum* mean 42, range 1-91) than the zygopteran, the highest recorded in the latter being in *C. pulchellum* (mean 37, range 1-68) and the lowest in *L. dryas* (mean 4, range 1-11). More mites were found on female damselflies than on males. Three distinct sizes of larval mite have been noted, indicating stages in their engorgement on the host." (Authors)] Address: Kulijer, D., National Museum of Bosnia and Herzegovina, Zmaja od Bosne 3, 71000 Sarajevo, Bosnia and Herzegovina

12003. Kumar, C.S.; Nair, R.R.; Sivaramkrishnan, K.G.; Ganesh, D.; Janarthanan, S.; Arunachalam, M.; Sivaranban, T. (2012): Influence of certain forces on evolution of synonymous codon usage bias in certain species of three basal orders of aquatic insects. *Mitochondrial DNA* 23(6): 447-460. (in English) ["Forces that influence

the evolution of synonymous codon usage bias are analyzed in six species of three basal orders of aquatic insects. The rationale behind choosing six species of aquatic insects (three from Ephemeroptera, one from Plecoptera, and two from Odonata) for the present analysis is based on phylogenetic position at the basal clades of the Order Insecta facilitating the understanding of the evolution of codon bias and of factors shaping codon usage patterns in primitive clades of insect lineages and their subtle differences in some of their ecological and environmental requirements in terms of habitat–microhabitat requirements, altitudinal preferences, temperature tolerance ranges, and consequent responses to climate change impacts. The present analysis focuses on open reading frames of the 13 protein-coding genes in the mitochondrial genome of six carefully chosen insect species to get a comprehensive picture of the evolutionary intricacies of codon bias. In all the six species, A and T contents are observed to be significantly higher than G and C, and are used roughly equally. Since transcription hypothesis on codon usage demands A richness and T poorness, it is quite likely that mutation pressure may be the key factor associated with synonymous codon usage (SCU) variations in these species because the mutation hypothesis predicts AT richness and GC poorness in the mitochondrial DNA. Thus, AT-biased mutation pressure seems to be an important factor in framing the SCU variation in all the selected species of aquatic insects, which in turn explains the predominance of A and T ending codons in these species. This study does not find any association between microhabitats and codon usage variations in the mitochondria of selected aquatic insects. However, this study has identified major forces, such as compositional constraints and mutation pressure, which shape patterns of codon usage in mitochondrial genes in the primitive clades of insect lineages." 12005. Kyerematen, R.; Gordon, C. (2012): Aquatic insect fauna of three river systems in the Akyem Abuakwa traditional area of the eastern region of Ghana. *West African Journal of Applied Ecology* 20 (3): 73-82. (in English) ["Three river systems in the Akyem Abuakwa Traditional Area: Ayensu, Birim and Densu were sampled over a period of one year during the wet, dry and intermediate seasons for aquatic insect fauna. Fifteen sampling sites were chosen based on certain parameters such as accessibility as well as the inclusion of

high and low impact sites (i.e. close to or far from a town or village) or near areas with high human activity. and submerged Four sampling methods were employed: sweeping, core sampling, sieving and washing of stones, wood fragments objects as well as aquatic plants and leaves. Fifty seven (57) species of aquatic insects belonging to 26 families of 7 orders were recorded. Hemiptera, Ephemeroptera and Odonata were the most diverse and abundant orders with Hemiptera being the most diverse order with 17 species from 8 families. The most abundant species was *Rhagovelia obesa* (Hemiptera: Veliidae). The highest number of insects was collected in December while July recorded the lowest numbers. River Densu recorded the highest number of insects while River Birim recorded the highest diversity of insects with 36 species. River Ayensu had both the lowest numbers and diversity of insects." (Authors) The Odonata are a mixture from North-American/European and African taxa.] Address: Kyerematen, R., Dept of Animal Biology & Conservation Science, Univ. of Ghana, Legon, Ghana. 12006. Lai, G.-J.; Shen, G.-X. (2012): Experimental investigation on the wing-wake interaction at the mid stroke in hovering flight of dragonfly. *Science China. Physics, Mechanics & Astronomy* 55(11): 2167-2178. (in English) ["This paper focuses on flow structures of the wing-wake interaction between the hind wing and the wake of the forewing in hovering flight of a dragonfly since there are arguments whether the wing-wake interaction is useful or not. A mechanical flapping model with two tandem wings is used to study the interaction. In the device, two identical simplified model wings are mounted to the flapping model and they are both scaled up to keep the Reynolds number similar to those of dragonfly in hovering flight since our experiment is conducted in a water tank. The kinetic pattern of *Aeshna juncea* is chosen because of its special interesting asymmetry. A multi-slice phase-locked stereo particle image velocimetry (PIV) system is used to record flow structures around the hind wing at the mid downstroke ($t/T=0.25$) and the mid upstroke ($t/T=0.75$). To make comparison of the flow field between with and without the influence of the wake, flow structures around a single flapping wing (hind wing without the existence of the forewing) at these two stroke phases are also recorded. A local vortex identification scheme called swirling strength is applied to determine the vortices around the wing and they are visualized with the iso-surface of swirling strength. This paper also presents contour lines of ω_z at each spanwise position of the hind wing, the vortex core position of the leading edge vortex (LEV) of hind wing with respect to the upper surface of hind wing, the circulation of the hind wing LEV at each spanwise position and so on. Experimental results show that dimension and strength of the hind wing LEV are impaired at the mid stroke in comparison with the single wing LEV because of the downwash from the forewing. Our results also reveal that a wake vortex from the forewing traverses the upper surface of the hind wing at the mid downstroke and its distance to the upper surface is about 40% of the wing chord length. At the instant, the distance of the hind wing LEV to the upper surface is about 20% of the wing chord length. Thus, there must be a wing-wake interaction mechanism that makes the wake vortex become an additional LEV of the hind wing and it can partly compensate the hind wing for its lift loss caused by the downwash from the forewing. All Odonata species are legally protected; on pages 106 and 107 a few examples of species are figured, including *Oxygastra curtisii* which is not occurring in Austria.] Address: <http://www.land-oberoesterreich.gv.at/files/publikationen/ntiere.pdf>;

12009. Larson, M.D. (2012): Diet of the Cascades frog (*Rana cascadae*) as it relates to prey availability in the Klamath Mountains of Northwest California. M. Sc. thesis, Humboldt State University, Natural Resources: Wildlife, California State University Campus, Arcata: 71 pp. (in English) ["Frogs in the family Ranidae are considered generalist predators that consume prey as it is encountered in the environment. However, few studies have attempted to quantify the types and relative amounts of prey available to these frogs so a thorough understanding of their foraging ecology as it relates to prey availability is lacking. This study examined the diet of *R. cascadae* as it relates to prey availability in a Klamath Mountain basin in northern California during their active season of 2007. Based on the analysis of 275 stomach samples, *Rana cascadae* consumed 3052 prey items from 110 invertebrate taxa confirming that this species is a generalist predator. However, an Index of Relative Importance indicated that five prey categories were most important in the diet: Acrididae, Aranae, Formicidae, insect larvae, and Tipulidae. Differences in diet were detected between sexes, life stages, and seasons. Adult females consumed more Acrididae in the summer than males or juveniles. Adult male and juvenile frogs showed selection for insect larvae and Tipulid flies during the summer. In the spring adult females and juveniles also selected Tipulid flies and adult males selected Elaterid beetles. All life-stages and both sexes appeared to avoid very small prey. Shifts in prey use with changes in ontogeny were documented, with frogs consuming more large prey and less small prey as they grew." (Author) Odonata contributed very low to the diet of the species.] Address: Humboldt State University, California State University Campus, 1 Harpst Street, Arcata, CA 95521, USA

12010. Lease, H.M.; Wolf, B.O. (2012): Lipid content of terrestrial arthropods in relation to body size, phylogeny, ontogeny and sex. *Physiological Entomology* 36(1): 29-38. (in English) ["Energy storage in arthropods has

important implications for survival and reproduction. The lipid content of 276 species of adult arthropods with wet mass in the range 0.2–6.13 g is determined to assess how lipid mass scales with body mass. The relative contribution of lipids to total body mass is investigated with respect to phylogeny, ontogeny and sex. The lipid content of adult insects, arachnids, and arthropods in general shows an isometric scaling relationship with respect to body mass (M) (Marthropod lipid = $-1.09 \times M^{dry}$ 1.01 and Marthropod lipid = $-1.00 \times M^{lean}$ 0.98). However, lipid allocation varies between arthropod taxa, as well as with sex and developmental stage within arthropod taxa. Female insects and arachnids generally have higher lipid contents than males, and larval holometabolous insects and juvenile arachnids have higher lipid contents than adults." (Authors) With the exception of Odonata, female insects and arachnids had higher lipid content than males at the level of order. Odonata are treated at family level.] Address: Lease, Hilary, Department of Biology, University of New Mexico, Albuquerque, New Mexico, USA. E-mail: hlease@unm.edu

12011. Lemelin, H.; Williams, G. (2012): Blossoms & butterflies, waterfalls & dragonflies: Integrating insects in the hospitality and tourism industries through swarm supposition. In: Sloan, P., C. Simons-Kaufman & W. Legrand (eds.): Sustainable hospitality as a driver for equitable development. Case studies from developing regions of the world. XXXVII, 450 pp. Taylor & Francis: 198-211. (in English) ["It is now widely agreed that the climate is changing, global resources are diminishing and biodiversity is suffering. These changes pose huge challenges on nations, organizations, businesses, communities and ultimately individuals. Developing countries, many of them considered by the World Tourism Organization to be Top Emerging Tourism Destinations (UNWTO, 2009), are already suffering the full frontal effect of environmental degradation with the UN recently reporting the existence of nearly half a million climate refugees in Africa and Asia in addition to huge swathes of the world's farming land and oceans becoming infertile. The challenge for developing countries is a triple-edged sword, how can economic prosperity be achieved without the perpetual depletion of nature's reserves, the destruction of rural habitat and the dislocation of traditional societies? Many emerging nations are looking increasingly to the tourism industry as the motor for economic development with hospitality businesses at the forefront. In line with this increasing economic necessity is the growth of concern in the West for environmental and societal stewardship. Expectations are high, Western consumers want classy lodgings and unspoilt landscapes in the knowledge that the room maid has enough money to feed and educate her family. This book is designed to give students and practitioners a guide for best practices of sustainable hospitality operations in developing countries. Based on case studies, it provides a road map of how to achieve the goals of sustainability giving benchmark examples. The book not only taps in a contemporary business subject but provides readers with a better understanding on how sustainable theories can be operationalized in hospitality and tourism business practices in developing countries. Provides an enhanced view on sustainability beyond the borders of developed countries Case studies include hands-on activities, creative business practices and applied sustainable development strategies Includes case study questions, advanced reading list and online resource features." 12012. Lescak, E.A.; A. von Hippel, F.; Lohman, B.K.; Sherbick, M.L. (2012): Predation of threespine stickleback by dragonfly naiads. *Ecology of Freshwater Fish* 21(4): 581-587. (in English) [Alaska, USA; "Gasterosteus aculeatus populations that have evolved pelvic girdle reduction are most commonly found in lakes with low dissolved ion concentration, a lack of piscivorous fishes and abundant macroinvertebrate predators. Researchers have speculated that macroinvertebrates have a propensity to consume prey with pelvic spines. If this is true, perhaps macroinvertebrates use the stickleback's spines to facilitate capture and manipulation. This study tested whether dragonfly naiads ("Aeshna spp.") differentially prey upon stickleback possessing either a complete or reduced pelvis and documented naiad hunting and capturing behaviour. Results from an arena experiment suggest that naiads do not prey more heavily upon individuals with one pelvic phenotype over the other. However, results from trials where the naiads were presented with one stickleback with pelvic spines and another without suggest that naiads prey more heavily upon small stickleback with pelvic spines and large stickleback without pelvic spines and that they adjust their predatory behaviour based upon the pelvic phenotype of the prey." 12017. Locklin, J.L.; Huckabee, J.S.; Gering, E.J. (2012): Streamlining techniques for rearing large quantities of the damselfly, *Ischnura ramburii* (Odonata: Coenagrionidae) in the laboratory. The Preliminary Program for 97th ESA Annual Meeting (August 5-10, 2012): (in English) [Verbatim: "Background/Question/Methods: Dragonflies and damselflies often served as model organisms for answering a range of ecological and evolutionary questions. Although aquatic naiads and terrestrial adults can be readily collected in the field, laboratory rearing permits researchers to regulate variables during development that are difficult to control in the field. In addition, many laboratory-based experimental designs typically require large sample sizes of genetically-related organisms at the same developmental stage. Several rearing methods have been published for Odonata, but they recommend methods that become laborious when rearing large quantities simultaneously. We reared large numbers (1,000+) of the coenagrionid damselfly, *Ischnura ramburii*, from field-collected adults (N=8) that were mated in the lab through emergence of their offspring while streamlining some previously published recommendations. We also estimated the duration of naiad survivorship in the lab without food by starving a subset of naiads (N=170). Results/Conclusions: Of the eight mated females, 157± 33.9 naiads female-1 were produced. 66.4% of the naiads successfully emerged as adults with males and females emerging a median of 75 and 77 days, respectively, after hatching. Much naiad mortality (23%) occurred during emergence when they failed to locate emergence substrates and drowned. Naiads survived a mean of 14.2 days without food, demonstrating that naiads can be maintained in the lab with infrequent feedings. We found that several previously published rearing recom-

mendations for small damselfly cultures can be modified to improve rearing efficiency. Culturing large quantities of damselfly in the lab is manageable and broadens the experimental designs of many diverse research avenues." 12018. Logan, J.D.; Janovy Jr., J.; Bunker, B.E. (2012): The life cycle and fitness domain of gregarine (Apicomplexa) parasites. *Ecological Modelling* 233: 31-40. (in English) ["Theoretical demographic models with accompanying experimental programs provide an important framework to study the life history of organisms. In this paper we examine the fitness characteristics of gregarine parasites (Apicomplexa) and how these evolutionary long-lived parasites are shaped by their own life cycle stages inside and outside a definitive insect host. Although gregarines have been investigated in experimental works, their fitness and population characteristics have not been subject to modeling efforts to help understand their longevity or interactions with their host species. We develop a dynamic, mechanistic population model represented by a system of two differential equations for two of the parasite stages: the mature parasite, or trophont, inside a definitive insect host, and the infectious oocyst stage in the water environment of the host. In contrast to many classical macroparasite models, the force of infection between oocysts and hosts is of sigmoid type. Inside the host, production of the water borne infectious state is modeled by linear production rate in the trophont population with a density-independent trophont mortality. We examine stability of model's equilibria for different parameter values and different host populations. This leads to the definition of a fitness parameter that acts as a bifurcation parameter for the model. The model shows good cause for the establishment and long-time persistence of this common, widespread parasite. It is parameterized by extensive data gathered at Cedar Point Biological Station, and numerical calculations based on those parameters illustrate the dynamics. Possible applications include parasite control in aquacultures." 12019. Ma, L.; Gu, W.; Wang, L.; Zhang, C.; Ding, X.; Meng, Q. (2012): Insect community niche in the Zhalong wetland. *Scientia silvae sinicae* 48(5): 81-87. (in Chinese, with English summary) ["The Zhalong wetland nature reserve (46°40'—47°20'N, 123°59'—124°40'E), situated in the west of Heilongjiang Province of China, is the largest and the most important *Grus japonensis* wetland nature reserve in China, providing indispensable livelihood for the red-crowned crane as well as a temporary habitat for the migrating birds in severe danger such as *Grus leucogeranus*, *Ciconia nigra*, *Cygnus cygnus*, *Anser albifrons* and *Ciconia boyciana*. In this paper, the niche and competition among species of insect community in different habitat in Zhalong wetland were studied. The results showed that there were obvious niche overlaps and competitions in different species which used the same resources. Space niche breadth index of main groups were similar, the same as time niche breadth index. Niche similarity coefficient of insect community indicated that the difference between each group was not big. Spider groups were important regu-

lators in the Zhalong wetland insect ecological system. But Orthoptera and Coleoptera, Odonata group space niches were not significantly overlapped. Spider groups mainly affected Orthoptera, but hardly affected other groups of predatory. This study indicates that some measures should be implemented in the habitat when the number of Orthoptera individual is very big to maintain a balance relationship between insect groups." (Authors) Taxa are treated at order level.] Address: Ma, L., Forestry School, Northeast Forestry University Harbin 150040, China

12020. Machado, A.B.M. (2012): *Carajathemis simone*, new genus and species from Brazil (Odonata: Libellulidae). *Anais da Academia Brasileira de Ciências* 84(4): 1039-1049. (in English, with Portuguese summary) ["*Carajathemis simone* n. gen., n.sp. from the state of Pará, Brazil, is described and illustrated based on 22 specimens collected in a "canga" (laterite) lake within the forest at the Flona de Carajás, Parauapebas Municipality. The new libellulid genus fits in the subfamily Sympetrinae and the male keys out to *Erythemis* in Garrison et al. (2006). The new taxon has a combination of characters that makes it different from all genera of Sympetrinae including *Erythemis*. The species is remarkable by its large size, pleural striping and especially by the complex and strongly dimorphic leg armature. It seems to be restricted to shallow, rainfall-dependent, iron-rich lakes." (Author)] Address: Machado, A.B.M., Depto de Zoologia, Inst. Cienc, Biol., Univ. 12027. Matuszak, A.; Mörtl, M.; Quillfeldt, P.; Bauer, H.-G. (2012): Exclosure study on the exploitation of macrophytes by summering and moulting waterbirds at Lower Lake Constance. *Hydrobiologia* 697: 31-44. (in English) ["Owing to synchronous moult, most waterbird species are constrained by flightlessness and limited mobility for several weeks. As new feather production is

energy demanding, these birds need to choose a safe moulting site with appropriate food supply. Up to 20,000 waterbirds carry out moult at Lake Constance, gathering at sites where they find food close to safe hiding places from predators and human-caused disturbance. In this study, we focused on the food supply at one prominent moulting site, Mettnau Südbucht, at Lower Lake Constance. We aimed to determine the food items and quantity as well as their utilization by summering and moulting waterbirds. We conducted experiments with exclosure cages which protected macrophytes from bird grazing and compared these sites with unprotected grazed sites. In these experiments, we found that the summering and moulting waterbird community, dominated by Eurasian Coots (*Fulica atra* Linnaeus), caused a significant decline of the macrophyte biomass at 1.5-m depth (MWL), where they were responsible for a loss of over 40% of the total charophyte biomass. No grazing effect was found at a greater depth (2-m MWL). The available food consisted mostly of *Chara* spp. with a biomass density of about 350 g m². Animal food items were negligible: Macroinvertebrates, mainly *Asellus aquaticus* Linnaeus, that were associated with the macrophytes, made up only 2% of total biomass, and were very unevenly distributed." (Authors) Odonata are treated at suborder level.] Address: Matuszak, Anja, Max Planck Institute for Ornithology, Am Obstberg 1, 78315 Radolfzell, Germany. E-mail: matuszak@orn.mpg.de

12028. McCoy, M.W.; Touchon, J.C.; Landberg, T.; Warkeintin, K.M.; Vonesh, J.R. (2012): Prey responses to predator chemical cues: Disentangling the importance of the number and biomass of prey consumed. *PLoS ONE* 7(10): e47495. doi:10.1371/journal.pone.0047495: 5 pp. (in English) ["To effectively balance investment in predator defenses versus other traits, organisms must accurately assess predation risk. Chemical cues caused by predation events are indicators of risk for prey in a wide variety of systems, but the relationship between how prey perceive risk in relation to the amount of prey consumed by predators is poorly understood. While per capita predation rate is often used as the metric of relative risk, studies aimed at quantifying predator-induced defenses commonly control biomass of prey consumed as the metric of risk. However, biomass consumed can change by altering either the number or size of prey consumed. In this study we determine whether phenotypic plasticity to predator chemical cues depends upon prey biomass consumed, prey number consumed, or both. We examine the growth response of red-eyed treefrog tadpoles (*Agalychnis callidryas*) to cues from a larval dragonfly (*Anax amazili*). Biomass consumed was manipulated by either increasing the number of prey while holding individual prey size constant, or by holding the number of prey constant and varying individual prey size. We address two questions. (i) Do prey reduce growth rate in response to chemical cues in a dose dependent manner? (ii) Does the magnitude of the response depend on whether prey consumption increases via number or size of prey? We find that the phenotypic response of prey is an asymptotic function of prey biomass consumed. However, the asymptotic response is higher when more prey are consumed. Our findings have important implications for evaluating past studies and how future experiments should be designed. A stronger response to predation cues generated by more individual prey deaths is consistent with models that predict prey sensitivity to per capita risk, providing a more direct link between empirical and the-

oretical studies which are often focused on changes in population sizes not individual biomass." (Authors)] Address: McCoy, M.W., Department of Biology, East Carolina University, Greenville, North Carolina, USA. E-mail: mccoym@ecu.edu

12029. Meadows, A.J.; Owen, J.P.; Snyder, W.E. (2012): Complex predator effects on larval mosquitoes. The Preliminary Program for 97th ESA Annual Meeting (August 5 -- 10, 2012): [Verbatim: "The study of interactions among medically important mosquitoes and their predators has the potential to offer insight into patterns of population and disease outbreaks as well as control methods. The effects of predators on mosquitoes can be particularly complex: predators impact mosquitoes both by killing them, and by inciting predator-avoidance behaviors that carry energetic costs for those mosquitoes that avoid being killed. Here, we investigate the effects of a predator, *Erythemis simplicicollis* on varying densities of larval *Culex quinquefasciatus* (Diptera: Culicidae). First in laboratory microcosms and later in the field, we examined both mosquito survivorship and whether any non-lethal effects of predator exposure carry over to affect the size of adult mosquito. Survivorship from the larval to adult stage was measured along with wing length of adults. Results/Conclusions: We found, at most densities, dragonflies were successful in reducing survivorship of mosquito larvae as well as reducing wing length compared with no-predator controls. These data suggest larval predators can ultimately help regulate adult mosquito populations, both by reducing overall densities of mosquito adults and by reducing the robustness of those mosquitoes that evade predation. Ongoing field studies are examining how predator-community structure impacts mosquitoes through both lethal and non-lethal channels."] Address: Entomology, Washington State University, Pullman, WA, USA

12030. Melfi, J.; Lin, H.-t.; Mischiati, M.; Leonardo, A.; Wang, Z.J. (2012): Quantifying dragonfly kinematics during unsteady free-flight. *Bulletin of the American Physical Society* 57(17) [65th Annual Meeting of the APS Division of Fluid Dynamics, Sunday–Tuesday, November 18–20, 2012; San Diego, California]: 1 pp. (in English) [Verbatim: What make dragonflies such interesting fliers are the unsteady high-speed aerial maneuvers they perform. Until recently, the study of dragonflies in mid-flight has been limited to steady-state motions such as hovering and forward flight. In this talk, we report our kinematic analyses of the dragonfly flight recorded in a custom dragonfly arena at HHMI, Janelia Farm. Dragonfly's turning motions often involve all three degrees of freedom about its body axes: yaw, roll, and pitch. We examine the wing kinematics changes associated with different turning maneuvers, and seek the key variables in the wing kinematics that are responsible for each specific maneuver.] Address: Wang, Z. 12031. Melters, D.P.; Paliulis, L.V.; Korf, I.F.; Chan, S.W.L. (2012): Holocentric chromosomes: convergent evolution, meiotic adaptations, and genomic analysis. *Chromosome Research* 20: 579-593. (in English) ["In most eukaryotes, the kinetochore protein complex assembles at a single locus termed the centromere to attach chromosomes to spindle microtubules. Holocentric chromosomes have the unusual property of attaching to spindle microtubules along their entire length. Our mechanistic understanding of holocentric chromosome func-

tion is derived largely from studies in the nematode *Caenorhabditis elegans*, but holocentric chromosomes are found over a broad range of animal and plant species. In this review, we describe how holocentricity may be identified through cytological and molecular methods. By surveying the diversity of organisms with holocentric chromosomes, we estimate that the trait has arisen at least 13 independent times (four times in plants and at least nine times in animals). Holocentric chromosomes have inherent problems in meiosis because bivalents can attach to spindles in a random fashion. Interestingly, there are several solutions that have evolved to allow accurate meiotic segregation of holocentric chromosomes. Lastly, we describe how extensive genome sequencing and experiments in nonmodel organisms may allow holocentric chromosomes to shed light on general principles of chromosome segregation."(Authors) The study includes references to 'Odonata'.] Address: Chan, S.W.L., Howard Hughes Medical Institute, Chevy Chase, MD, USA. 12033. Michailova, P.; Warchalowska-Sliwa, E.; Szarek-Gwiazda, E.; Kownacki, A. (2012): Does biodiversity of macroinvertebrates and genome response of Chironomidae larvae (Diptera) reflect heavy metal pollution in a small pond? *Environmental monitoring and assessment* 184(1): 1-14. (in English) ["The investigation was carried out on a small pond situated on a recent mine spoil at Boleslaw in the Olkusz region with Zn–Pb ore deposits. Water of the pond had pH 7.2–8.5 and low concentrations of heavy metals. Concentrations of Pb ($487 \mu\text{g g}^{-1}$) and Zn ($1,991 \mu\text{g g}^{-1}$) in the sediment were very high and potentially could lead to toxicological effects. In the pond, 48 taxa of macroinvertebrates belonging to Oligochaeta and water stages of Ephemeroptera, Odonata, Megaloptera, Trichoptera, Heteroptera, Coleoptera and Diptera (mainly Chironomidae family) were found. The influence of heavy metals on macroinvertebrates diversity was not found. Effect of heavy metal pollution was observed on the appearance of chromosome aberrations in the polytene chromosomes of Chironomidae larvae. It was manifested by two ways: (1) in *Kiefferulus tendipediformis* and *Chironomus* sp. chromosome rearrangements in fixed state (tandem fusion and homozygous inversions), indicated intensive process of speciation; (2) in *Chironomus* sp., *K. tendipediformis*, *Glyptotendipes gripekoveni* (Chironomidae) somatic chromosome rearrangements (inversions, deficiencies, specific puffs, polyploidy) affected few cells of every individual. The somatic functional and structural alterations in Chironomidae species are particularly suitable as biomarkers—they can be easily identified and used for detecting toxic agents in the environment." 12035. Mirrasouli, E.; Ghorbani, R. (2012): The biological assessment of the Zaringol stream using the structure of benthic macroinvertebrates (Golestan Province). *Journal of Fisheries* 64(4): 357-369. ["This study was conducted to assess water quality level of Zarin Gol stream on macrobenthic invertebrates. Macrobenthic fauna were sampled from 9 selected sampling stations along the stream with an average distance of 22 km by using a Surber sampler every 45 days during the year. Sampling was replicated 9 times in each sampling station. Collected samples were fixed with 4% formalin, isolated, and then identified. The number of total abundance of macrobenthic fauna were counted to 2749.021 ± 1301.8 (ind/m²) belonging to 15 orders and 81 groups (families and genus). The minimum and maximum of total abundance (ind/m²) was at station 1 (370.63 ± 231.1) and at station 5 (215. 73 ± 101.75), respectively. The main orders of macro benthic invertebrate communities in Zaringol stream included Diptera, Ephemeroptera, Trichoptera, Plecoptera, Oligocheta, Odonata and Amphipoda. Population structure of macro benthic invertebrates were analyzed by biotic Indices and the results showed significant differences in EPT and EPT/CHIR indices at different sampling stations (p<0.05). Hilsenhoff and Shannon diversity indices indicated no significant differences (p>0.05) along the stream. Evaluation of indicators revealed less water quality at stations 2 and 5 where located at the lowermost of fish farms. This reduction might be implicated to the effluents of water dams from fish farms running into the stream as diversity and total abundance (%) of succible macro-invertebrates decreased and that of resistant macrofauna increased due to water pollution. Hence, from the obtained results, this can be concluded that the use of benthic macro-invertebrates as bioindicator for the assessment of water quality of the stream is desirable."(Authors)] Address: E-mail: elhammirasooli@yahoo.com

12036. Mlynarek, J.J.; Hassall, C., Forbes, M.R. (2012): Higher gregarine parasitism often in sibling species of host damselflies with smaller geographical distributions. *Ecological Entomology* 37: 419-425. (in English) ["(1.) This study investigated inter-specific variation in parasitism by gregarines (Eugregarinorida: Actinocephalidae), among sibling species of Zygoptera, in relation to relative size of geographical ranges of host species. (2.) Gregarines are considered generalist parasites, particularly for taxonomically related host species collected at the same sites or area. Prevalence and median intensity of gregarine parasitism was obtained for 1338 adult damselflies, representing 14 species (7 sibling species pairs) across 3 families within the suborder Zygoptera. Damselflies were collected at three local sites in South-

eastern Ontario, during the same periods over the season. (3.) Five out of seven species pairs had significant differences in parasitism between sibling species. The less widespread host species was the more parasitised for three species pairs with significant differences in gregarine prevalence, and for two species pairs with differences in median intensity. The more widespread host had a higher intensity of infection as expected, in two species pairs. (4.) Future studies on ecological determinants of parasitism among related species should examine robust measures of abundance of species and representation of species regionally." 12037. Mogali, S.M.; Saidapur, S.K.; Shanbhag, B.A. (2012): Tadpoles of the bronze frog (*Rana temporalis*) assess predation risk before evoking antipredator defense behavior. *Journal of ethology* 30(3): 379-386. (in English) ["Predation threat-associated behavioral response was studied in *R. temporalis* tadpoles to discover the importance of predators' visual and chemical cues (kairomones and diet-derived metabolites of consumed prey) in evoking antipredator behavior. The caged predators (dragonfly larvae) fed on prey tadpoles or insects (*Notonecta* spp.) and water conditioned with the predators provided the threat stimuli to the tadpole prey. The predators' visual cues were ineffective in evoking antipredator behaviors in the tadpole prey. However, exposure to caged tadpole-fed predators or water conditioned with tadpole-fed predators elicited predator avoidance behavior in the tadpoles; they stayed away from the predators, significantly reduced swimming activity (swimming time and distance traveled), and increased burst speed. Interestingly, exposure to water conditioned with starved predators did not elicit any antipredator behavior in the prey. Further, the antipredator responses of predator-experienced tadpoles were significantly greater than those exhibited by predator-naïve tadpoles. The study shows that *R. temporalis* tadpoles assess predation threat based exclusively on chemical cues emanating from the predators' dietary metabolites and that the inclusion of conspecific prey items in the diet of the predators is perceived as a threat. The study also shows that antipredator behavior in these tadpoles is innate and is enhanced during subsequent encounters with the predators." 12041. Mukherjee, S.; Ganguli, R. (2012): Nonlinear dynamic analysis of dragonfly inspired piezoelectric unimorph actuated flapping and twisting wing. *International Journal of Smart and Nano Materials* 3(2): 103-122. (in English) ["The nonlinear equations for coupled elastic flapping-twisting motion of a dragonfly-inspired smart flapping wing are used for a flapping wing actuated from the root by a PZT unimorph in the piezofan configuration. Excitation by the piezoelectric harmonic force generates only the flap bending motion, which, in turn, induces the elastic twist motion due to interaction between flexural and torsional vibration modes. An unsteady aerodynamic model is used to obtain the aerodynamic forces. Numerical simulations are performed using a wing whose size is the same as the dragonfly *Sympetrum frequens* wing. It is found that the value of average lift reaches its maximum when the smart flapping wing is excited at a frequency closer to the natural frequency in torsion. Moreover, consideration of the elastic twisting of the flapping wing leads to an increase in the lift force. It is also found that the flapping wing generates sufficient lift to support its own weight and carry a small payload. Therefore, the piezoelectrically actuated smart flapping wing based on the geometry of a *Sympetrum frequens* wing and undergoing flapping-twisting motions can be considered as a potential candidate for use in micro air vehicle applications." (Authors)] Address: Ganguli, R., Department of Aerospace Engineering, Indian Institute of Science, Bangalore-560012, India. E-mail: ganguli@aero.iisc.ernet.in

12042. Mukherjee, S.; Ganguli, R. (2012): A comparative study of dragonfly inspired flapping wings actuated by single crystal piezoceramic. *Smart structures and systems* 10(1): 67-87. (in English) ["A dragonfly inspired flapping wing is investigated in this paper. The flapping wing is actuated from the root by a PZT-5H and PZT-7%PT single crystal unimorph in the piezofan configuration. The nonlinear governing equations of motion of the smart flapping wing are obtained using the Hamilton's principle. These equations are then discretized using the Galerkin method and solved using the method of multiple scales. Dynamic characteristics of smart flapping wings having the same size as the actual wings of three different dragonfly species *Aeshna multicolor*, *Anax parthenope julius* and *Sympetrum frequens* are analyzed using numerical simulations. An unsteady aerodynamic model is used to obtain the aerodynamic forces. Finally, a comparative study of performances of three piezoelectrically actuated flapping wings is performed. The numerical results in this paper show that use of PZT-7%PT single crystal piezoceramic can lead to considerable amount of wing weight reduction and increase of lift and thrust force compared to PZT-5H material. It is also shown that dragonfly inspired smart flapping wings actuated by single crystal piezoceramic are a viable contender for insect scale flapping wing micro air vehicles." an Institute of Science, Bangalore-560012, India. E-mail: ganguli@aero.iisc.ernet.in

12043. Nava-Bolaños, A.; Córdoba-Aguilar, A.; Munguía-Steyer, R. (2012): A test of genital allometry using two damselfly species does not produce hypoallometric patterns. *Ethology* 118(2): 203-213. (in English) ["It is widely admitted that sexual selection is the responsible force behind genital traits. However, the particular mechanisms of genital evolution are still debated. Recently, studies of genital static allometry in insects have been used to elucidate such mechanisms. Insect genital traits are often reported to show negative allometry (i.e., a slope < 1), which has generated a number of ideas on how genital traits are selected. However, many studies that have inferred selection mechanisms have omitted consideration of the function of genital traits, used unreliable indicators of body size, and only rarely included female genitalia in their analysis. We investigated whether negative allometry operates for genitalia in *Protoneura cara* and *Ischnura denticollis*. Damselflies are suitable for genital allometry tests as their genital function and body size indicators (wing length and head width) are relatively well known and established. First, we show that the aedeagus is used to physically remove sperm from both sperm storage organs (bursa and spermatheca) and that wing length and head width correlate positively with other morphological traits for the two study species. Second, we estimated genital allometry by measuring aedeagal length, vaginal length, bursal volume, and spermathecal volume. Our results indicate no consistent allometric pattern. Allometry for aedeagal length and vaginal width was not the same. Thus, there was no support for a negative allometric relationship. We urge researchers investigating allometry to look directly at how genitalia function rather than inferring function from allometric relationships only." 12047. Odume, O.N.; Muller, W.J.; Arimoro, F.O.; Palmer, C.G. (2012): The impact of water quality deterioration on macroinvertebrate communities in the Swartkops River, South Africa: a multimetric approach. *Journal of Aquatic Science* 37(2): 191-200. (in English) ["A multimetric approach, using 21 metrics representing five categories — abundance, composition, richness, diversity and biotic indices — was applied to investigate the impacts of water quality deterioration on macro-invertebrate communities in the Swartkops River. Macroinvertebrates were sampled seasonally between August 2009 and July 2010 using the South African Scoring System version 5 (SASS5) protocol at one reference site upstream of Uitenhage and three downstream sites. Assessment of water quality impacts on macroinvertebrates was based on the discriminatory ability of metrics between the reference and impaired sites, and on their correlation with the physico-chemical variables. The metrics' discriminatory ability was explored using box plots, and their relationships with water chemistry variables elucidated with Pearson's correlation. Trichoptera abundance, %Chironomidae + Oligochaeta, %Ephemeroptera–Trichoptera–Odonata–Coleoptera (ETOC), %Trichoptera, Ephemeroptera–Plecoptera–Trichoptera (EPT) richness, ETOC richness, Margalef's family richness index, equitability, Shannon and Simpson diversity indices, SASS5 score and average score per taxon (ASPT) discriminated between the reference and impacted sites, and also exhibited significant correlations ($p < 0.05$) with water chemistry variables. Conversely, Gastropoda abundance, EPT abundance, ETOC abundance, EPT:Chironomidae ratio, %EPT, %Corixidae, %Oligochaeta + Hirudinae, Chironomidae + Oligochaeta abundance and Hemiptera + Diptera richness did not discriminate between the reference and impacted sites." 12048. Ott, J. (2012): Zum starken Auftreten der Großen Moosjungfer – *Leucorrhinia pectoralis* (CHARPENTIER, 1825) – im Jahr 2012 in Rheinland-Pfalz nebst Bemerkungen zu *Leucorrhinia rubicunda* (L.) (Insecta: Odonata). *Fauna Flora Rheinland-Pfalz* 12(2): 571-590. (in German, with English summary) ["The expansion of *L. pectoralis* in Rhineland-Palatinate in 2012, which is

classified as "extinct" in the Red List, is reported. In the Palatinate the species was found in 13 waters, in one of them as autochthonous and in five others with pairing activities or oviposition. The reasons of this expansion are migrations from the feeder populations in the north and east, also due to the favourable warm and sunny spring weather, a general increase of the populations in the stem areas, as well as more local migrations from small "outpost"-populations. The species, being listed on the annexes II and IV of the European habitats directive, has now to be monitored according to the EC law. Beside *L. pectoralis* in the Palatinate also two individuals of the very rare *L. rubicunda* were registered this year." (Author)] Address: Ott, J., Friedhofstr. 28, D-67705 Trippstadt, Germany. 12049. Outomuro, D.; Cordero-Rivera, A. (2012): Allometry of secondary, primary, and nonsexual traits in the beautiful demoiselle (*Calopteryx virgo meridionalis*). *Canadian Journal of Zoology* 90(9): 1094-1101. (in English) ["The static allometry between the size of a trait and the body size results from the net selection forces acting on the evolution of both the trait and the body size. An increased knowledge of the functional significance of traits is necessary to understand observed allometric patterns. We studied several traits of males of *C. virgo meridionalis*, for which there is a good functional knowledge of the genitalic traits and ornaments. We found positive allometry for the wing spot size (considered a secondary sexual trait) and for the distal width (but not length) of the anal appendages, which are used for grasping the female prior to copulation. Regarding the male secondary genitalia, the length but not the width of the big horns of the aedeagus showed an isometric pattern. The aedeagus shaft length showed a negative allometric pattern, while its distal width did not show a significant regression. The slopes of the regressions were higher when using wing length than when using body length as estimators of body size, with the exception of wing spot length. Results are discussed based on the functional significance of the study traits, as well as the pre- and post-copulatory selective pressures acting on them." (2012): Population structure in dry and rainy seasons in *Erythrodiplax umbrata* (Linnaeus) (Odonata: Libellulidae). *Odonatologica* 41(3): 245-249. (in English) ["Mark-recapture studies in adult Odonata have revealed that rainy periods have a negative impact on population size, recapture rate, survival probability and life expectancy. One reason for this is that rainy periods are usually associated with low temperatures which indirectly and directly affect individual condition. However, given that most studies have been

carried out in temperate environments it remains to be seen whether such phenomenon occurs in other places, i.e. tropical environments. Here, this question is approached by marking-recapturing the tropical *E. umbrata*, in a field site in central Colombia. Two seasons of opposite rainfall patterns were compared: a rainy and a dry season. After checking for no marking effects, no difference was found in population size and recapture rate. However, animals from the dry season had a higher survival and life expectancy compared to animals from the rainy season. These apparently conflicting results, suggest differential effects of seasonality. A population compensation may be occurring in the rainy season (with more animals emerging at this time compared to the dry season) despite the negative effects on survival. Thus, the principle that rainy periods have a negative impact in tropical odonate species seems supported." 12052. Parr, A.J. (2012): Migrant and dispersive dragonflies in Britain during 2011. *J. Br. Dragonfly Society* 28(2): 56-65. (in English) ["The year 2011 was noteworthy for the large, indeed unprecedented, numbers of *Anax ephippiger* noted throughout the year. There were at least three immigration waves - a slow trickle of sightings during the late winter of 2010/11, a surge of records during April and early May, and then a final run of records during October and November. Both the spring and autumn influxes were associated with spells of unseasonably hot weather with winds from the far south. Arrivals of *Sympetrum fonscolombii* were also noted during these periods. Although the summer weather was, by contrast, less spectacular, there were still significant immigrations of *Anax parthenope*, as well as of further *S. fonscolombii*. Three sightings of *Aeshna isosceles* were also made well away from the species' current UK stronghold. Many of the other key events of the year related to the consequences of immigrations seen not in 2011 but in the preceding few years, where new local breeding populations of a number of species might potentially have become established. The recently-identified colony of *Coenagrion scitulum* in Kent appeared to remain stable and there was to be proof of successful breeding by *Aeshna affinis* following the 2010 invasion, when small numbers of exuvia were discovered at Hadleigh Country Park, Essex, during June. Numbers of mature adults seen later in the year were, however, low and give some concern as to the long-term viability of this colony. Numbers of *Lestes barbarus* seen at Cliffe, Kent, following breeding attempts also noted during 2010 were, however, higher and hopefully a stable colony may develop here." 12055. Petzold, F.; Seifert, D.; (†); Zimmermann, W. (2012): Untersuchungen zur Libellenfauna (Insecta: Odonata) im Ostthüringer Holzland durch Dieter Seifert (†) – ein beeindruckendes Beispiel ehrenamtlicher Forschung für den Naturschutz. *Landschaftspflege und Naturschutz in Thüringen* 49(1): 26-34. (in German, with English summary) ["From 2003 to 2010 the late D. Seifert studied the dragonfly fauna of 35 localities in the Ostthüringer Holzland region (Thuringia, Germany). Additional surveys by Zimmermann & Petzold followed in 2011. Here we represent results from five selected and most intensely surveyed localities of the protected areas „NSG An den Ziegenböcken“ and „FND Rote Pfütze“ in detail. 46 species were recorded in total, 14 of them are red listed in Thuringia and further four species are of other conservation concern. The peat bog habitats of the two protected areas „NSG An den Ziegenböcken“ and „FND Rote Pfütze“ are the most important reproduction sites of threatened species within the Ostthüringer Holzland region. Of the moorland species *Somatochlora arctica* the only reproducing population in Thuringia has been found here which is of national importance. Other remarkable species are *Aeshna juncea*, *Leucorhinia pectoralis* and *L. rubicunda*. Despite much conservation effort the current situation within the protected areas is unsatisfactory. The main conservation issue is formed by the disturbance of the natural water balance of the moorland and peat bog habitats. The application of existing management plans is urgently necessary and would help to preserve the unique character of the important area." (Authors)] Address: Petzold, F., Pappelallee 73, D-10437 Berlin, Germany. E-mail: falkpetzold@web.de

12056. Pickwell, A.; Gennard, D.E.; Taylor, P.; Chadd, R. (2012): The Norfolk Hawker *Aeshna isosceles* (Muller): a step further from the brink? *J. Br. Dragonfly Society* 28(1): 44-55. (in English) ["The change in the range of the Norfolk Hawker *Aeshna isosceles* between 1970 and 2009 was investigated using historic records from the Dragonfly Recording Network and an increase in range was confirmed. It is apparent that this range increase has been sustained by an increase in the number of breeding populations of *A. isosceles* and was in a generally southerly direction, although some westerly and northerly expansion has also occurred. This contrasts with the general northern range shift of most other British Odonata. The increase in the range and population numbers are considered most likely to be due to a combination of habitat restoration and improvement initiatives and water quality improvements, even though increases in recorder effort may have had an effect. Aspects of the habitat requirements of *A. isosceles* (Muller) were investigated using historic aquatic vegetation and salinity data collated with records of its distribution.

It is shown to utilise a wider variety of vegetation communities and to be more tolerant of salinity than was previously thought." (Authors)] Address: Pickwell, A., School of Life Sciences, University of Lincoln, Brayford Pool, Lincoln, LN6 7TS, UK

12057. Pilgrim, E.M.; von Dohlen, C.D. (2012): Phylogeny of the dragonfly genus *Sympetrum* (Odonata: Libellulidae). *Organisms diversity & evolution* 12(3): 281-295. (in English) ["The libellulid dragonfly genus *Sympetrum* has been recognized since 1833, but lacks any morphological synapomorphies to unite the taxon. Previous researchers have disagreed over which species belong in *Sympetrum*, bringing the monophyly of the genus into question. We use DNA sequence data from 6 genetic loci (16S, tRNA-valine, 12S, elongation factor 1 alpha, cytochrome oxidase subunit I, and the second internal transcribed spacer region) and 25 morphological characters (mainly genitalic) to test the monophyly of *Sympetrum* with Bayesian inference and maximum likelihood analyses. Under Bayesian inference, all *Sympetrum* species included in this study form a clade, which also contains the Hawaiian monotypic genus *Nesogonia*, often considered a close relative of *Sympetrum*. Phylogenetic analyses also reveal at least six strongly supported clades (treated as species groups) within *Sympetrum*, but relationships between these species groups remain unresolved or unsupported. Although the relationships between *Sympetrum* species groups remain unresolved, several species groups include taxa from multiple biogeographic regions/continents, and the species group sister to the rest of *Sympetrum* contains migratory species from the New World and Africa. This pattern suggests a complex biogeographic history in *Sympetrum* shaped by vicariance and dispersal. Preliminary estimates of the divergence dates of *Sympetrum* species groups outline a rapid radiation of the groups approximately 32-38 million years ago, possibly influenced by cooling and drying climates of the late Eocene and early Oligocene." (Authors)] Address: Pilgrim, E., U.S. Environmental Protection Agency, Molecular Ecology Research Branch, 26 Martin Luther King Drive, Cincinnati, OH 45268, U.S.A. E-mail: pilgrim.erik@epa.gov

12058. Pryke, J.S.; Samways, M.J. (2012): Importance of using many taxa and having adequate controls for monitoring impacts of fire for arthropod conservation. *J. Insect Conserv.* 16(2): 177-185. (in English) ["Fire is a key natural and anthropogenic disturbance factor across many ecosystems, and also an important conservation management tool. However, little is known about arthropod responses to fire, particularly in Mediterranean-type ecosystems, including the biodiverse Cape Floristic Region (CFR). We investigate here the relative variety of responses by different arthropod taxa to fire, and ask whether single-taxon or multi-taxon approaches better suit post-fire biomonitoring for conservation management. Sampling involved multiple techniques and was conducted before fire, 1 year after fire, and 3 years after fire, with unburned areas as controls. Before-and-after statistics were used to identify changes in arthropod populations and assemblages as a result of fire, and between treatment and control sites. However, this was against a background of the annual effects having a major influence on the arthropods, irrespective of fire. Abundance was so variable, even in control plots, that we found it an unreliable indicator of the impact of fire. Overall, arthropods were remarkably resilient to fire, with most taxa recovering in species richness and as-

semblage composition within 3 years of the fire. Although all taxa showed resilience to fire, there was nevertheless little congruence in temporal recovery of the various taxa. Our results highlight the shortcomings of monitoring fire impacts using only a single-taxon without prior testing for complementarity or sensitivity to fire, while emphasizing the importance of sampling a wide range of taxa to represent overall responses of compositional biodiversity. From this, we recommend, at least for the CFR, that a cross-section of taxa, such as butterflies, ants, and scarab beetles, be used for monitoring arthropods in recovery/fire management conservation programmes. We also recommend that such monitoring be considered against the background of large annual variation seen in unburned areas." (Authors) Odonata have been included into the sample protocol, but no results are presented.] Address: Pryke, J.S., Department of Conservation Ecology and Entomology, Stellenbosch University, Private Bag X1, Matieland 7602, South Africa. E-mail: jpryke@sun.ac.za

12059. Pujol-Buxó, E.; San Sebastián, O.; Garriga, N.; Llorente, G.A. (2012): How does the invasive/native nature of species influence tadpoles' plastic responses to predators? *Oikos* 122(1): 19-29. (in English) ["Although the purely ecological impacts of biological invasions have been well studied, a less thorough effort has been made in terms of their evolutionary ecology. Previous studies show that anti-predator phenotypic plasticity may be one of the major ecological forces driving survival and rapid evolution of prey facing new predators. In turn, this means that biological invasions embody a perfect case for studying the tradeoffs and evolution of phenotypic plasticity per se. Here, we studied the plastic responses of native (*Pelodytes punctatus*) and invasive (*Discoglossus pictus*) anurans facing a native (dragonfly *Anax* sp.) and two invasive (fish *Gambusia holbrooki* and crayfish *Procambarus clarkii*) predators. Marked responses were reported against the native predator from both the native and the invasive anuran, but they both responded mildly to the exotic predators as well. Native *P. punctatus* displayed a morphological reaction to invasive *P. clarkii* after scarcely 30 years of coexistence with this predatory crayfish and responded behaviourally to the invasive fish *G. holbrooki*. Invasive *D. pictus* reacted behaviourally to all predators, but unexpectedly only reacted morphologically to native *Anax* sp. All these results support high prey-predator specificity in these reactions and an evolutionary dissociation between behavioural and morphological plasticity in anurans. Each species displayed a particular set of tradeoffs between plastic responses and their costs, which is probably due to differences in ecological niche and evolutionary history, but interestingly we usually detected unexpected patterns in combinations using introduced predators. This suggests that perhaps singular plastic shifts usually occur when tadpoles face recently introduced species. Given the speed in which these evolutionary changes become noticeable and their potential in avoiding predation risk, this study supports that phenotypic plasticity might play an important role in population dynamics during biological invasions" (Authors)] Address: Pujol-Buxó, E., Depto de Biología Animal, Facultat de Biología, Univ. de Barcelona, Av. Diagonal 643, ES-08028 Barcelona, Spain. E-mail: eudaldp@hotmail.com

12060. Pulfer, T.L.; Evans, C.G.; Featherstone, D.; Post, R.; McCarter, J.I.; Laverty, J.F. (2012): Recovery strate-

gy for the Hine's Emerald (*Somatochlora hineana*) in Ontario. Ontario Recovery Strategy Series. Prepared for the Ontario Ministry of Natural Resources, Peterborough, Ontario: vi + 27 pp. (in English) ["*S. hineana* is a globally rare dragonfly restricted to southern Ontario, Wisconsin, Michigan, Illinois and Missouri. In Ontario it is only known to occur in the Minesing Wetlands located in the County of Simcoe. It is listed as endangered under Ontario's Endangered Species Act, 2007 due to its habitat specificity, potential threats and extremely limited geographic range. It has also been listed as endangered or extirpated throughout its known global range. The key features used to distinguish *S. hineana* from other similar species are the unique conformations of its sexual appendages on the end of the abdomen, dark metallic green thorax with two creamy yellow lateral stripes and its relatively large size (60-65 mm long and 90-95 mm wingspan). *S. hineana* is restricted throughout its range to calcareous wetlands (marshes, sedge meadows and fens) dominated by graminoid vegetation and fed primarily by groundwater seeps. Adult males occur in seepage areas and fens and adjacent margins, whereas females are usually found in dry meadows, sometimes in adjacent forest openings, only coming into wetlands to lay eggs. Adults may also utilize adjacent forests, gravel roads, trails and fields for foraging before returning to the wetlands to mate and lay eggs. *S. hineana* deposit eggs in shallow channels or sheetflow in areas of herbaceous vegetation in marshes, meadow marshes and fens. The larvae remain in cool, shallow, slowly-moving waters of spring-fed marshes, alkaline fens, mineral-rich fens with shallow creeks, springs, small pools, marl deposits and calcareous marshy streams for three to five years before emerging as adults. In some locations, larvae use crayfish burrows, mainly of Digger Crayfish or of Devil Crawfish (also known as Meadow Crayfish), as refuge habitat in the summer and winter months. Crayfish burrows are thought to be a critical component of *S. hineana* habitat where seasonal drought and freezing occurs and may be a factor limiting its distribution. The main threats to this species in Ontario are habitat loss due to changes in surface and sub-surface hydrology (including water quality), competition from invasive species (Garlic Mustard, Purple Loosestrife, Glossy Buckthorn and the non-native genotype of Common Reed) and vegetation succession from native species. The inter-species dependency of *S. hineana* on Digger Crayfish indicates that threats to the persistence of burrowing crayfish in Ontario would have a severe negative effect on *S. hineana*. The recovery goal for *S. hineana* is to prevent any loss of population or habitat functionality at extant sites or at any other extant locations which may be identified in the future in Ontario. The recovery objectives outlined to achieve this goal are as follows: • protect and maintain the quantity and quality of *S. hineana* habitat and habitat functionality, including the hydrological and hydrogeological function; • reduce or mitigate threats to *S. hineana* and its habitat; • increase knowledge of *S. hineana* biology in Ontario including distribution, abundance, life history and habitat needs; • increase public awareness and understanding of *S. hineana* and its habitat in Ontario. It is recommended that the area regulated as habitat include all extant locations. In Ontario, this currently includes only the Minesing Wetlands. In order to protect both the adult and larvae stages of *S. hineana*, it is recommended that the area prescribed as habitat include fen and wetland meadows, (i) where Hine's Emerald have been observed and (ii) that are connected by surface or ground water

to areas where *S. hineana* have been observed. In addition to these areas the prescribed habitat should also include 500 metres beyond each of these habitats. For the purposes of perching, movement and dispersal, all forests and dry meadows that are connected to the areas described above by surface water or groundwater should also be prescribed as habitat. To allow for migration and dispersal between patches it is recommended that corridors used by *S. hineana* be prescribed as habitat. Corridors are believed to be both natural (creeks, swales and other water features) and anthropogenic features (trails, utility rights-of-way and gravel roads) that have forested edges or riparian habitat (C. G. Evans and D. Featherstone, pers. comm. 2012). Due to the dependence of *S. hineana* habitat on groundwater recharge it is recommended that prescribed habitat include the Snow Valley Uplands, where the current groundwater infiltration regime is maintained." (Authors)] Address: not stated

12061. Raebel, E.M.; Merckx, T.; Feber, R.E.; Riordan, P.; Macdonald, D.W.; Thompson, D.J. (2012): Identifying high-quality pond habitats for Odonata in lowland England: implications for agri-environment schemes. *Insect Conservation and Diversity* 5(6): 422-432. (in English) ["(1.) Agricultural intensification has contributed to severe declines in odonate populations. The objective of our study is to benefit current measures for the conservation of odonates by establishing the conditions favourable to Odonata and focusing on ponds within agricultural land. (2.) Our landscape-scale study used exuvial counts and habitat measurements from 29 ponds across a catchment in England, over 3 years, to determine key factors affecting odonate abundance and species richness. (3.) Ponds dominated by floating and submerged vegetation were the most transparent, supported the highest abundance and species richness of exuviae, and were always fully or partially surrounded by buffer strips. Ponds lacking vegetation were turbid, yielding no exuviae even if they were buffered. English agri-environment schemes (AES) currently support pond and buffer strip creation and management. (4.) Abundance of exuviae was higher in recently created ponds compared to older ponds, whereas ponds that had dried out the previous summer had fewer exuviae. (5.) Species richness of exuviae decreased with increasing distance to the nearest viable pond, falling by more than 40% for distances over 100 m. (6.) We conclude that odonate conservation would be more effective if AES would consider the spatial scale at which ponds are created and the location, type, and quality of ponds targeted for buffer strips." (Authors)] Address: Raebel, Eva, Wildlife Conservation Research Unit, The Recanati-Kaplan Centre, Dept of Zoology, Univ. of Oxford, Tubney House, Abingdon Road, Tubney, Oxfordshire OX13 5QL, UK. 12062. Ramos, O.; van Buskirk, J. (2012): Non-interactive multiple predator effects on tadpole survival. *Oecologia* 169(2): 535-539. (in English) ["Interactions among and within three species of predators were estimated in terms of their effects on prey survival using short-term predation experiments. The prey were tadpoles (*Rana temporaria*), and the predators were dragonfly larvae (*Anax imperator*), newts (*Triturus alpestris*), and backswimmers (*Notonecta glauca*). Mortality rate per predator imposed by *Triturus* and *Notonecta* did not decline with predator density, whereas the predation rate of *Anax* was strongly reduced when the number of preda-

tor individuals increased. Impacts of all three predators were not altered by the presence of other species in pairwise combinations. This system is therefore characterized by interference between individual dragonflies but relatively independent effects of predator species. These results were largely predictable based on the natural history of the predators and are encouraging for attempts to model communities as assemblages of interacting species." (Authors)] Address: Buskirk, J. van, Institute of Zoology, University of Zürich, CH-8057 Zürich, Switzerland. E-mail: jvb@zool.unizh.ch

12063. Rasool, N.; Jan, U.; Shah, G.M. (2012): Feeding habits and diet composition of Brown trout (*Salmo trutta fario*) in the upper streams of Kashmir Valley. *International Journal of Scientific and Research Publications* 2(12): 1-8. (in English) ["Coenagrionidae' contribute with 0,45% to the diet of the trout (n = 108).] Address: Rasool, N., Department of Zoology, University of Kashmir, Pin-190006, India. 12064. Rawi, C.S.; Al-Shamia, S.A.; Shah, A.S.R.; Ahmad, A.H.; Man, A. (2012): Effects of herbicides on Odonata communities in a rice agroecosystem. *Toxicological & Environmental Chemistry* 94(6): 1188-1198. (in English) ["The effects of the five herbicides propanil, quinclorax, molinate/propanil, 2,4-D amine, and bensulfuron on Odonata diversity and abundance at the experimental rice plots was investigated. A total of 13 Odonata morphospecies belonging to two families have been identified. Treated plots exhibited higher species richness (up to 12 species) than the control plot (8 species). *Ishnura* spp. was the most abundant species in the treated plots with a mean density of 194.2 individuals per m², (ind m²) followed by *Brachythemis contaminata* (152 ind m²) and *Agriocnemis* spp. (124 ind m²). In the control plots, *Agriocnemis* spp. was the dominant species (153 ind m²) followed by *Ishnura* spp. (143 ind m²) and *Neurothemis fluctuans* (59 ind m²). In the propanil-treated plot, the highest number of odonate species (10 species) was recorded followed by the plots treated with quinclorax and molinate/propanil (9 species). On the 2,4-D amine or bensulfuron-treated plots as well as the control plot, only eight odonate species were recorded. This study revealed that herbicide application had a positive effect on Odonata diversity. This seems reasonable as Odonata are non-target organisms for herbicides. Furthermore, the decomposed weeds resulting from herbicide application would enrich the water with necessary organic matter." 12065. Reels, G.; Dow, R.; Hämäläinen, M.; Do, M.C. (2012): Chapter 5. The status and distribution of dragonflies and damselflies (Odonata) in Indo-Burma. In: Allen, D.J., Smith, K.G., and Darwall, W.R.T. (Compilers). 2012. *The Status and Distribution of Freshwater Biodiversity in Indo-Burma*. Cambridge, UK and Gland, Switzerland: IUCN. x+158pp+4pp cover: 90-101. (in English) ["The present assessment covers some 473 odonate species (in 150 genera), of which approximately 160 (34%) are thought to be endemic or near-endemic in Indo-Burma (the real figure for endemics is uncertain, given that the region impinges on, and is biogeographically contiguous with, parts of Myanmar, China and the Malay Peninsula). 14 species are considered threatened. The region has a low proportion (30.5%) of species in the cosmopolitan families Coenagrionidae and Libellulidae, most members

of which are associated with open, lentic or slow-flowing waters. The majority of species are forest- and lotic-associated, reflecting the historical biogeography of the region. New species are still being described from Indo-Burma on a fairly regular basis (for example, Do 2011a, 2011b; Do & Karube 2011; Sasamoto et al. 2011) and it is likely that the real total exceeds 500 species (Hämäläinen 2004). Knowledge of Odonata across the region is very uneven. Hämäläinen (2004) briefly summarised the history of dragonfly studies in Thailand, Viet Nam, Lao PDR and Cambodia, noting that Thailand, the most accessible and best-studied country, had the most diverse odonate fauna (c.350 species), while Cambodia's odonate fauna was the most poorly known. This is largely still the case, with Cambodia and eastern Myanmar having the least-studied odonate faunas in Indo-Burma. Knowledge of the Cambodian fauna has however improved considerably in the last two years. Kosterin (2010, 2011) made two short surveys in the Cardamom Mountain foothills in southwestern Cambodia in April at the end of the dry season ('perhaps the worst time for Odonata') and November–December 2011, in which he made 29 new species records for that country – a powerful indication of how poorly known the Cambodian odonate fauna is. In combination with other recent work (Roland and Roland 2010, Day 2011, Kosterin and Holden 2011, Roland et al. 2011) this has brought the known total to 110 species, but there is clearly much still to be done. The Laotian fauna is rather better understood, mainly due to the efforts of Dr Naoto Yokoi, who added more than one hundred new species records over the period 1994 to 2003 (Hämäläinen 2004), bringing the Lao PDR total to in excess of two hundred species. Studies of Vietnamese Odonata have advanced considerably in recent years, to the point that a useful annotated checklist of 235 species was recently published (Do and Dang 2007), with maps showing species distributions at provincial level." 12066. Ren, Y.; Dong, H. (2012): On the optimal dynamic camber formation in insect flight. *Bulletin of the American Physical Society* 57(17) [65th Annual Meeting of the APS Division of Fluid Dynamics, Sunday–Tuesday, November 18–20, 2012; San Diego, California]: 1 pp. (in English) [Verbatim: "It is widely thought that wing flexibility and wing deformation could significantly affect aerodynamic force productions over completely rigid wings in insect flights. However, there is a lack of quantitative discussion of dynamic formation of wing camber and its effect on wing's aerodynamic performance. In this work, a deformable wing is used to model the wing camber and its dynamic formation. A Direct Numerical Simulation (DNS) based computational optimization frame has been developed to obtain the optimal dynamic camber formation of dragonfly in takeoff and cruising flight. Comparative study is then performed between the optimized flexible wing and real dragonfly wing. Results have shown the maximum camber happens around 30% (downstroke) and 80% (upstroke) of one wing beat. Force production and unsteady flows of the flexible wing are also discussed."] Address: not stated

12067. Roland, H.-J.; Grabow, K.; Martens, A. (2012): Aerial dispersal of freshwater gastropods by dragonflies (Odonata). *International Journal of Odonatology* 15(4): 317-318. (in English) [Mecklenburg-Vorpommern; Ger-

many; "At a ditch near Tribsees in northeastern Germany a young individual of the freshwater snail *Lymnaea stagnalis* was photographed while attached to the dorsum of the abdomen of a female *Aeshna viridis*, after the odonate took off after oviposition in *Stratiotes aloides*. This is the first known case for odonate-born dispersal of freshwater gastropods." (Authors)] Address: Roland, H.-J., Im Mühlahl 35, 61203 Reichelsheim, Germany. E-mail: Hjuergenroland@aol.com

12068. Rossaro, B.; Boggero, A.; Lods-Crozet, B.; Free, G.; Lencioni, V.; Marziali, L.; Wolfram, G. (2012): A benthic quality index for European alpine lakes. *Fauna norvegica* 31: 95-107. (in English) ["The development of benthic quality indices for European lakes is hindered by the lack of information concerning many national lake types and pressures. Most information is from north European lakes stressed by acidification and from deep lakes subjected to eutrophication; for other lake types (the ones included in the Mediterranean areas for example) and for other pressures (hydro-morphological alteration, toxic stress) there is practically no information about the response of benthic macro-invertebrates; this hinders the possibility of an intercalibration of the indices among the member states (MS) in the EU. In the present communication three benthic quality indices are proposed considering the littoral, sublittoral and profundal zone in 5 reference and 7 non reference lakes from the Alpine region in response to eutrophication. The sensitivity values of the 177 species (including *Somatochlora metallica*, *Gomphus vulgatissimus*, *Platycnemis pennipes*) found in these lakes were calculated taking a weighted average of the values of environmental variables from lakes in which the species were present. The indicator taxa which prevailed in these lakes were Chironomids and Oligochaetes. A coinertia analysis emphasized the importance of trophic variables (transparency, nitrates, total phosphorous) in explaining the species distribution, but geographic (altitude) and morphometric (depth, volume) variables were also important. The indices enabled a separation of reference from non-reference lakes and to assign the non-reference lakes to different quality classes in agreement with the Water Framework Directive." 12069. Rubach, M.N.; Baird, D.J.; Boerwinkel, M.-C.; Maund, S.J.; Roessink, I.; Van den Brink, P.J. (2012): Species traits as predictors for intrinsic sensitivity of aquatic invertebrates to the insecticide chlorpyrifos. *Ecotoxicology* 21: 2088-2101. (in English) ["Ecological risk assessment (ERA) has followed a taxonomy-based approach, making the assumption that related species will show similar sensitivity to toxicants, and using safety factors or species sensitivity distributions to extrapolate from tested to untested species. In ecology it has become apparent that taxonomic approaches may have limitations for the description and understanding of species assemblages in nature. Therefore it has been proposed that the inclusion of species traits in ERA could provide a useful and alternative description of the systems under investigation. At the same time, there is a growing recognition that the use of mechanistic approaches in ERA, including conceptual and quantitative models, may improve predictive and extrapolative power. Purposefully linking traits with mechanistic effect

models could add value to taxonomy-based ERA by improving our understanding of how structural and functional system facets may facilitate inter-species extrapolation. Here, we explore whether and in what ways traits can be linked purposefully to mechanistic effect models to predict intrinsic sensitivity using available data on the acute sensitivity and toxicokinetics of a range of freshwater arthropods exposed to chlorpyrifos. The results of a quantitative linking of seven different endpoints and twelve traits demonstrate that while quantitative links between traits and/or trait combinations and process based (toxicokinetic) model parameters can be established, the use of simple traits to predict classical sensitivity endpoints yields little insight. Remarkably, neither of the standard sensitivity values, i.e. the LC50 or EC50, showed a strong correlation with traits. Future research in this area should include a quantitative linking of toxicodynamic parameter estimations and physiological traits, and requires further consideration of how mechanistic trait-process/parameter links can be used for prediction of intrinsic sensitivity across species for different substances in ERA." 12070. Rudolf, V.H.W. (2012): Seasonal shifts in predator body size diversity and trophic interactions in size-structured predator-prey systems. *Journal of Animal Ecology* 81(3): 524-532. (in English) ["(1.) Theory suggests that the relationship between predator diversity and prey suppression should depend on variation in predator traits such as body size, which strongly influences the type and strength of species interactions. Prey species often face a range of different sized predators, and the composition of body sizes of predators can vary between communities and within communities across seasons. (2.) Here, I test how variation in size structure of predator communities (*Plathemis lydia*) influences prey survival using seasonal changes in the size structure of a cannibalistic population as a model system. Laboratory and field experiments showed that although the per-capita consumption rates increased at higher predator-prey size ratios, mortality rates did not consistently increase with average size of cannibalistic predators. Instead, prey mortality peaked at the highest level of predator body size diversity. (3.) Furthermore, observed prey mortality was significantly higher than predictions from the null model that assumed no indirect interactions between predator size classes, indicating that different sized predators were not substitutable but had more than additive effects. Higher predator body size diversity therefore increased prey mortality, despite the increased potential for behavioural interference and predation among predators demonstrated in additional laboratory experiments. (4.) Thus, seasonal changes in the distribution of predator body sizes altered the strength of prey suppression not only through changes in mean predator size but also through changes in the size distribution of predators. In general, this indicates that variation (i.e. diversity) within a single trait, body size, can influence the strength of trophic interactions and emphasizes the importance of seasonal shifts in size structure of natural food webs for community dynamics." Zool.* 102(3): 261-268. (in English, with Portuguese summary) ["The implantation of a hydroelectric power plant along a river alters the dynamics of the watercourse, transforming a lotic environment into a lentic or semilotic one, what can damage the otter's feeding. From April 2008 to March 2009 we analysed the otter's food habits in lotic (streamlet) and semilotic (hydroelectric reservoir) environments of Paranapanema Valley, in southeastern Brazil. Aiming to compare the otter's diet of these two environments, we analyzed statistically the frequency of occurrence of main items in the scats. Fishes represent the base of the diet both in the reservoir and in the streamlet and, despite of the total otter's diet showing up similarities in the two environments, the results evidenced modifications on the fish species consumed between them. In the reservoir the otters ate more exotic fish *Oreochromis niloticus* (Linnaeus, 1758) probably because it is an easy capture prey in this place. The fact that the otters get established and feed in the reservoir doesn't mean that this structure is benefic to the species because the food supplied for it consists mainly of exotic fish species." (Authors) In a single case, an unidentified dragonfly belongs to the diet of the otter.] Address: Santos, Livia, Universidade Estadual de Londrina, Rodovia Celso Garcia Cid, PR-445, Km 380, Caixa Postal 6001, 86051-980, Londrina, PR, Brasil. 12074. Schmit, O.; Martens, K.; Mesquita-Joanes, F. (2012): Vulnerability of sexual and asexual *Eucypris virens* (Crustacea, Ostracoda) to predation: an experimental approach with dragonfly naiads. *Fundamental and Applied Limnology / Archiv für Hydrobiologie* 181(3): 207-218. (in English) ["Through the animal kingdom,

sexual reproduction often increases predation risk. Sexual mates are usually more detectable by predators because of (visual, acoustic or chemical) sexual signalling, increased mobility during mate search, or higher visual detectability and reduced alertness of mating pairs, amongst other behaviours. In previous studies, we found that macroinvertebrate predator taxa were more common in ponds whose *Eucypris virens* ostracod populations were parthenogenetic than in populations with males present. Here, we investigate if there is a causal relationship between predation and the *E. virens* reproductive mode. We experimentally tested whether groups of sexual and parthenogenetic *E. virens* individuals were equally vulnerable to predation by dragonfly naiads. A first experiment with a balanced mixture of sexual and asexual ostracod prey was designed. In a second experiment, they were exposed separately to predation in distinct groups. Our results indicate an intense predation pressure on *E. virens*, which increased with predator size. No significant differences were found between parthenogens and sexual *E. virens* when offered mixed to *Sympetrum* odonate predators, and only a slightly higher vulnerability of asexuals was noted when offered separately. The absence of an adverse effect of sexual behaviour on predation vulnerability suggests that the association between mode of reproduction and predator abundance observed in the field is not due to the differential vulnerability of sexual and asexual *E. virens*. The faster population growth potential of parthenogens might allow them to persist in ponds where a strong top-down control could limit survival of sexuals. Alternatively, the observed field association may not indicate a causal relationship, rather the independent effects of habitat temporality on predator abundance and on the *E. virens* reproductive mode." 12076. Selvakumar, R.; Karthikeyan, K.; Radhakrishnan, P. (2012): Analysis on surface nanostructures present in hindwing of dragon fly (*Sympetrum vulgatum*) using atomic force microscopy. *Micron* 43(12): 1299-1303. (in English) ["The present study involves the analysis of surface nanostructures and its variation present in the hind wing of *S. vulgatum* using atomic force microscopy (AFM). The hindwing was dissected into 4 parts (D1-D4) and each dissected section was analyzed using AFM in tapping mode at different locations. The AFM analysis revealed the presence of irregular

shaped nanostructures on the surface of the wing membrane with size varying between 83.25 ± 1.79 nm to 195.08 ± 10.25 nm. The size and shape of the nanostructure varied from tip (pterostigma) to the costa part. The membrane surface of the wing showed stacked arrangement leading to increase in size of the nanostructure. Such arrangement of the nanostructures has led to the formation of nanometer sized valleys of different depth and length on the membrane surface giving them ripple wave morphology. The average roughness of the surface nanostructures varied from 18.58 ± 3.12 nm to 24.25 ± 8.33 nm. Surfaces of the wings had positive skewness in D1, D2 and D4 regions and negative skewness in D3 region. These surface nanostructures may contribute asymmetric resistance under mechanical loading during the flight by increasing the bending and torsional resistance of the wing. Highlights: *The atomic force microscopy of dragon fly wings (*Sympetrum vulgatum*) indicates the presence of distinct multilayers in the wing membrane with irregular shaped nanostructure with size varying from 89.91 ± 0.0195 nm to 345.36 ± 0.0471 nm. *The size of the nanostructure differed from the tip (pterostigma) to the costa part of wing attached to the abdomen. *The arrangement of the nanostructure resembled ripple wave morphology. *At present, the modelings of dragon fly wing are carried out considering only the venation and not the sub-micron to nano sized structures present in the wing. *This study clearly indicates that since the distribution and arrangement of nanostructure within the wing varies, its influence in flight mechanism should not be neglected during designing/modeling of wings." (in English) ["Human population on the University of Dar es Salaam, Mlimani Campus, has increased substantially in recent years. It is expected that the number of small animals trampled and killed by pedestrians is correspondingly increasing but no baseline study has hitherto been conducted. Between May 2007 and August 2008, over 1,000 animals trampled by humans walking along foot paths at the main Campus of the University of Dar es Salaam, Tanzania, were identified and enumerated. Human presence along foot paths was also recorded as well as animals killed by vehicles on roads of the campus and surrounding areas. Variations between foot paths, months, seasons and level of human abundance were examined. Invertebrates were the most common animal kills on foot paths while most vertebrate kills were along roads. Foot path deaths peaked during semester periods when pedestrian numbers increased. Types and numbers of animals killed differed between foot paths, apparently in relation to adjacent habitat. Tunnels placed at various sections of the paths would facilitate small animals crossings and reduce mortality. Despite having the highest concentration of pedestrians, a bridge path (path C) scored one of the lowest death tolls." (Author) Six out of eight studied foot paths contained no killed Odonata specimens. Each of the the other two paths had Odonata species which were approximately 1% of the total number of dead insect taxa established for for them.] Address: Senzota, R., Department of Zoology and Wildlife Conservation, University of Dar es Salaam, P.O. 12079. Sharma, I.; Dhanze, R. (2012): Evaluation of macrobenthic fauna in hill stream environment of Western Himalaya, India. *Journal of Threatened Taxa* 4(9): 2875-2882. (in English) ["The purpose of this study is to evaluate seasonal occurrence of macrobenthic fauna in the tributaries of river Beas. The seasonal diversity of macrobenthic fauna was calculated in relation with physico-chemical parameters which revealed that benthic diversity is largely controlled by temperature, water current and volume of water. The width and depth of the streams exhibited an inverse relation with benthic fauna. An inverse relation between temperature and benthos was recorded at the sites located at higher elevation whereas a direct relation was inferred at the lower elevation. The peak of benthic fauna was recorded during winter season at all sampling sites. The benthic fauna was mainly represented by eight groups out of which four are highly distributed at all the sites among which Ephemeroptera were most dominating taxa in the River. Simple correlations were applied for benthos and abiotic factors, which revealed that water temperature, dissolved oxygen, alkalinity, depth and width influenced the invertebrate's distribution and abundance. ...The Odonata were seen only at Tripal and Bathoo during winter season but their maximum population was reported from Tripal where it formed 0.16 to 40% of total benthos." 12080. Shull, D.R.; Chase, K.; Paulson, G.S. (2012): Phoretic relationship between *Hydra* sp. (Anthomedusae: Hydridae) and a damselfly nymph (Odonata: Calopterygidae). *Entomological News* 122(2): 154-156. (in English) [Verbatim: "During April 2007, we collected an immature *Calopteryx* sp. with a *Hydra* sp. attached to its dorsum in Burd Run, Shippensburg, Pennsylvania. This is the first record of phoretic behaviour by *Hydra* sp. ... *Hydra* sp. is attached by its basal disc near the base of the wing pads of the damselfly in a location that would probably not impede the mobility of the damselfly. The

permanence of this relationship is not determined. A moulting event could easily dislodge the Hydra sp. from the damselfly. However, the Hydra sp. is well located to switch to the newly emerged Calopteryx sp. The nature of the relationship between these two species is also unclear, but it is possible that the Hydra sp. may benefit from the relationship in a manner similar to that hypothesized by Dossdall and Parker (1998) for the phoretic association between *Nanocla dius branchicolus* (Diptera: Chironomidae) and *Argia moesta* (Odonata: Coenagrionidae). They suggested that the relationship benefited *N. branchicolus* by reducing interspecific competition for food, and reducing energy expenditure associated with relocation. Hydra spp. are relatively sedentary, typically found on rocks and vegetation. Lomnicki and Solbodkin (1966) describe an interesting mode of locomotion in response to overcrowding or lack of food where Hydra sp. produces a bubble and floats to the surface of the water to move short distances in relatively still waters. Much like the floating behaviour, Hydra sp. may utilize the damselfly nymph for dispersal over greater distances or perhaps forage in more prey-abundant areas on the back of a predatory insect." 12081. Simaika, J.P.; Samways, M.J. (2012): Using dragonflies to monitor and prioritize lotic systems: a South African perspective. *Organisms Diversity & Evolution* 12(3): 251-259. (in English) ["The ever-worsening condition of streams due to local, regional, and global demands on water has resulted in the development of increasingly streamlined, rapid assessment methods using macroinvertebrates. Biotic indices in particular are versatile and robust, although not always easy to use. For example, the family-level South African Scoring System is an effective water quality measure, but is time-consuming and requires high-level expert training. The index could be used alongside the species-level Dragonfly Biotic Index (DBI), originally developed for monitoring habitat integrity, with which it is significantly and strongly correlated. We review here the relevant biotic indices in stream biomonitoring and their advantages and disadvantages, and present a new extension of the DBI, the Habitat Condition Scale (HCS). The HCS enables comparison and ranking of sites in terms of their habitat condition. Indeed, the DBI is a very flexible index, having been used in site selection and prioritization for conservation, as well as the measurement of habitat recovery. The theoretical framework behind the index demonstrates the potential of the index to track biotic changes due to climate change. The index could also be easily adapted for use in other biogeographical regions, given that species distributions, threat levels and sensitivities are well-known, and that there is an adequate number of endemic species. However, like all benthic macroinvertebrate indices, the DBI cannot always identify exactly which in-water impacts have an effect and to what extent. The real power of the DBI lies in being able to quantify community response to known physical changes on the riverscape and across the region" (Authors)] Address: Simaika, J.P., Centre for Invasion Biology, Department of Conservation Ecology and Entomology, Stellenbosch University, P Bag X1, Matieland 7602, South Africa. 12083. Śniegula, S.; Nilsson-Örtman, V.; Johansson, F. (2012): Growth pattern responses to photoperiod across latitudes in a northern damselfly. *PLoS ONE* 7(9): e46024. doi:10.1371/journal.pone.0046024. (in English) ["Background: Latitudinal clines in temperature and seasonality impose strong seasonal constraints on ectotherms. Studies of population differentiation in phenotypic plasticity of life history traits along latitudinal gradients are important for understanding how organisms have adapted to seasonal environments and predict how they respond to climate changes. Such studies have been scarce for species with a northern distribution. Methodology/Principle Finding: Larvae of the northern damselfly *Coenagrion johanssoni* originating from semi-voltine central, partivoltine northern, and partivoltine northernmost Swedish populations were reared in the laboratory. To investigate whether larvae use photoperiodic cues to induce compensatory growth along this latitudinal gradient, larvae were reared under two different photoperiods corresponding to a northern and southern latitude. In addition, field adult size was assessed to test the strength of possible compensatory growth mechanisms under natural conditions and hatchling size was measured to test for maternal effects. We hypothesized that populations originating from lower latitudes would be more time constrained than high-latitude populations because they have a shorter life cycle. The results showed that low-latitude populations had higher growth rates in summer/fall. In general northern photoperiods induced higher growth rates, but this plastic response to photoperiod was strongest in the southernmost populations and negligible in the northernmost population. During spring, central populations grew faster under the southern rather than the northern photoperiod. On the other hand, northern and northernmost populations did not differ between each other and grew faster in the northern rather than in the southern photoperiod. Field sampled adults did not differ in size across the studied regions. Conclusion/Significance: We found a significant differentiation in growth rate across latitudes and latitudinal difference in growth rate response to photoperiod. Importantly, growth responses measured at a single larval developmental stage in one season may not always generalize to other developmental stages or seasons." 12084. Söndgerath, D.; Rummland, J.; Suhling, F. (2012): Large spatial scale effects of rising temperatures: model-

ling a dragonfly's life cycle and range throughout Europe. *Insect Conservation and Diversity* 5(6): 461-469. (in English) [(1.) Rising environmental temperature will likely affect life cycle and range of species. To forecast such effects in an odonate, we simulated the continent-wide life cycle distribution pattern and range of a dragonfly applying a dynamic population model. (2.) The model was used to investigate how much of the current voltinism patterns and distribution range of the species are correctly predicted by using temperature and day length as the only environmental factors. We forecasted the range and voltinism changes on a European extent for the year 2050 using one GCM (CSIRO) driven by one greenhouse gas emission scenario (b2a) according to the IPCC. (3.) The model run lead to 80% correctly predicted distribution range, with a sensitivity of 94% and a specificity of 55%, the latter because of high error in predicting absence in southern Europe. (4.) The projected voltinism ranged from 1 to 2 years per generation in southern latitudes to 5 years in the north. A comparison with field data indicated correct predictions in 50% of all cases, while the other 50% were slight over- or underestimates by half a year per generation. (5.) We conclude that the model led to sufficient predictions of range as well as of life cycle pattern in central and northern Europe. Wrong predictions of presence for southern Europe may be caused by factors not recognised in the model, likely competition by con generics, while incorrect voltinism was possibly because of habitat effects. (6.) Simulations with increased temperature scenarios implied a future northward shift of the fundamental niche and a decreased development duration towards the northern range." 12085. Steinhoff, P. (2012): Records of Odonata from Phong Nha-Ke Bang National Park and its Buffer Zone, Central Vietnam. *Entomologie heute* 24: 37-49. (in English, with German summary) ["From September 2010 until August 2011, the dragonfly fauna of several habitats in the Phong Nha-Ke Bang National Park and its buffer zone in Central Vietnam was investigated. It is the first time that research on dragonflies was undertaken in that area. The habitats surveyed in the buffer zone were rivers, water-filled bomb craters, paddy fields and forest streams, while the habitats where research on dragonflies was carried out inside the national park were forest rivers and forest streams. In total, 61 species were determined at 16 different sites, while the identification of 15 more species was possible just at genus level; an identification of the species requires further research. The species were identified either in the field, with the help of photographs or (when a specimen was collected) in the laboratory. The differences of the habitats surveyed and the species found at each location are discussed and compared with the knowledge of the dragonfly fauna of Vietnam. Furthermore, an outlook on further research in the future is given." (Authors)] Address: Steinhoff, P., Trelleborger Weg 1, 17493 Greifswald, Germany. E-Mail: philipsteinhoff@gmail.com

12088. Svensson, E.I. (2012): Non-ecological speciation, niche conservatism and thermal adaptation: how are they connected? *Organisms diversity & evolution* 12(3): 229-240. (in English) ["During the last decade, the ecological theory of adaptive radiation, and its corollary "ecological speciation", has been a major research theme in evolutionary biology. Briefly, this theory states that speciation is mainly or largely the result of divergent selection, arising from niche differences between populations or incipient species. Reproductive isolation evolves either as a result of direct selection on mate preferences (e.g. reinforcement), or as a correlated response to divergent selection ("by-product speciation"). Although there are now many tentative examples of ecological speciation, I argue that ecology's role in speciation might have been overemphasised and that non-ecological and non-adaptive alternatives should be considered more seriously. Specifically, populations and species of many organisms often show strong evidence of niche conservatism, yet are often highly reproductively isolated from each other. This challenges niche-based ecological speciation and reveals partial decoupling between ecology and reproductive isolation. Furthermore, reproductive isolation might often evolve in allopatry before ecological differentiation between taxa or possibly through learning and antagonistic sexual interactions, either in allopatry or sympatry. Here I discuss recent theoretical and empirical work in this area, with some emphasis on odonates and suggest some future avenues of research. A main message from this paper is that the ecology of species differences is not the same as ecological speciation, just like the genetics of species differences does not equate to the genetics of speciation." 12090. Tachamo Shah, R.D.; Narayan Shah, D.; Domisch, S. (2012): Range shifts of a relict Himalayan dragonfly in the Hindu Kush Himalayan region under cli-

mate change scenarios. *International Journal of Odonatology* 15(3): 209-222. (in English) ["Although understanding of geographic range shifts of many species in response to global climate change is expanding steadily, little is known about the Himalayan fauna, which in particular is affected by relatively faster warming rates than other parts of the world. Anticipated increases in temperature and changes in hydrological regimes will have significant adverse impacts on the habitat suitability for many species. This threat will even be higher to endemic and already threatened species due to their restricted distribution and narrow climate tolerance ranges. We investigated the range shifts of a relict Himalayan dragonfly (*Epiophlebia laidlawi*), a species that is endemic to the Hindu Kush Himalayan region. Currently, the species is only known from few localities in Bhutan, India and Nepal. For conservation of the species, it is necessary to foresee potential suitable habitat areas and range shifts due to global climate change. Here, we first estimated the current potential geographic distribution by identifying the suitable habitat area in the region using bioclimatic envelope models, by means of consensus projections of six algorithms as implemented in the BIOMOD-package in the software program R. We then used the current distribution to render future projections under the A2a and B2a IPCC emission scenarios for the years 2050 and 2080. Models predict that the suitable habitat area of the species will shift on average 374 m and 599 m uphill under the extreme (A2a) climate warming scenario, and 294 m and 342 m uphill under the moderate (B2a) scenario by 2050 and 2080, respectively. Future suitable habitat areas are projected to remain only in the high mountains of eastern Nepal. The results will help conservationists to delineate priority habitats in the first step towards the species conservation in the region." 12091. Takahashi, Y.; Morimoto, G.; Watanabe, M. (2012): Ontogenetic colour change in females as a function of antiharassment strategy. *Animal Behaviour* 84(3): 685-692. (in English) ["Mate choice by females is an important component of sexual selection in many species. Theoretically, female sexual traits may be influenced by selection acting on the females via male mate choice, while the evolutionary consequences of male mate preferences are largely unknown, especially in the context of sexual conflict. We tested whether male mate choice affects the evolution of female colour in the damselfly *Ischnura senegalensis* in which females exhibit dimorphism consisting of a gynomorph that experiences ontogenetic colour change and an andromorph that does not. We first quantitatively confirmed that only gynomorphs change their body colour in relation to sexual maturation. In field experiments, males were unwilling to mate with sexually immature gynomorphs, although they attempted to mate with immature andromorphs. This is because males changed their mating preference for female colour depending on previous copulation experiences with sexually mature females. As a result, immature andromorphs received more male harassment than sexually immature gynomorphs, and then showed decreased food intake. Immature-specific colour functioned to avoid costly male harassment during female prereproductive stages, suggesting that ontogenetic colour changes in females have evolved as an antiharassment strategy of females

via male mate choice. Highlights: *Female damselfly experienced ontogenetic colour change. *Females with immature-specific colour efficiently avoided male harassment. *Avoiding harassment increased food intake in females. *Male choice may lead to the evolution of antiharassment strategy in females." (2012): Description of the final stadium larva of *Erythrodiplax bromeliicola* Westfall 2000 (Odonata: Libellulidae) with notes on variation in adults from Cuba. *Zootaxa* 3545: 59-66. (in English, with Spanish summary) ["The final stadium larva of *E. bromeliicola* is formally described and illustrated. The light brown scape and pedicel and creamy pale flagellum of the antenna, plus the abundant short, reddish, spiniform setae on the integument of the body surface and epiproct, comprise an exclusive combination of characters in the larva of *E. bromeliicola*. Information on larval habitat and a key for the larvae of the five *Erythrodiplax* species occurring in Cuba are provided. Details on morphological variation

of an adult population from Cuba are also provided." (Authors)] Address: Trapero-Quintana, A., Universidad de Oriente. Patricio Lumumba s/n, Santiago de Cuba, 90500, Cuba. E-mail: atrapero@cnt.uo.edu.cu ;

12095. Tsui, M.T.K.; Blum, J.D.; Kwon, S.Y.; Finlay, J.C.; Balogh, S.J.; Nollet, Y.H. (2012): Sources and transfers of methylmercury in adjacent river and forest food webs. *Environ. Sci. Technol.* 46(20): 10957-10964. (in English) ["Nearly all ecosystems are contaminated with highly toxic methylmercury (MeHg), but the specific sources and pathways leading to the uptake of MeHg within and among food webs are not well understood. In this study, we report stable mercury (Hg) isotope compositions in food webs in a river and an adjacent forest in northern California and demonstrate the utility of Hg isotopes for studying MeHg sources and cross-habitat transfers. We observed large differences in both $\delta^{202}\text{Hg}$ (mass-dependent fractionation) and $\Delta^{199}\text{Hg}$ (mass-independent fractionation) within both food webs. The majority of isotopic variation within each food web could be accounted for by differing proportions of inorganic Hg [Hg(II)] and MeHg along food chains. We estimated mean isotope values of Hg(II) and MeHg in each habitat and found a large difference in $\delta^{202}\text{Hg}$ between Hg(II) and MeHg ($\sim 2.7\%$) in the forest but not in the river ($\sim 0.25\%$). This is consistent with in situ Hg(II) methylation in the study river but suggests Hg(II) methylation may not be important in the forest. In fact, the similarity in $\delta^{202}\text{Hg}$ between MeHg in forest food webs and Hg(II) in precipitation suggests that MeHg in forest food webs may be derived from atmospheric sources (e.g., rainfall, fog). Utilizing contrasting $\delta^{202}\text{Hg}$ values between MeHg in river food webs (-1.0%) and MeHg in forest food webs ($+0.7\%$), we estimate with a two-source mixing model that $\sim 55\%$ of MeHg in two riparian spiders is derived from riverine sources while $\sim 45\%$ of MeHg originates from terrestrial sources. Thus, stable Hg isotopes can provide new information on subtle differences in sources of MeHg and trace MeHg transfers within and among food webs in natural ecosystems. In the riparian zone, one of the two emerged aquatic insects (damselfly adults) displayed MeHg isotopic compositions similar to their river counterparts while another emerged aquatic insect (dragonfly adults) displayed much higher $\delta^{202}\text{Hg}$ MeHg. This suggests that damselfly adults may retain aquatic MeHg and perhaps continue feeding on other emerged aquatic insects, but dragonfly adults appear to feed on terrestrial insects that are enriched with $\delta^{202}\text{Hg}$ MeHg. This is possible because dragonflies are stronger fliers than damselflies (e.g., higher flying velocities 43), and dragonflies may spend more time integrating prey in forests (i.e., away from river), whereas damselflies likely remain around the river to feed." 12096. van Kleef, H.H.; van Duinena, G.-J.A.; Verberka, W.C.E.P.; Leuven, R.S.E.W.; van der Velde, G.; Esselink, H. (2012): Moorland pools as refugia for endangered species characteristic of raised bog gradients. *Journal for Nature Conservation* 20(5): 255-263. (in English) ["In intact raised bog landscapes transitions from ombrotrophic into minerotrophic conditions occur. These gradients are lost from many bogs due to peat harvesting and drainage, and are difficult to restore. To determine which endangered species are characteristic

of pristine raised bog gradients and their current status in degraded bogs, plants and macroinvertebrates were surveyed in Estonian intact raised bogs and Dutch degraded bog remnants. Dutch national distribution data were used to determine whether communities with these species occurred outside bog habitats. Water chemistry data were used to describe associated environmental conditions. Intact bog gradients were the preferred habitat for six plant species and fifteen macroinvertebrate species, all of which are endangered. In degraded bogs these species were scarce or not recorded. In intact bogs these species lived at sites where runoff from the bog massif came into contact with regional ground water resulting in a gradient in pH, alkalinity, Ca, Fe and ionic ratio. Analysis of Dutch national distribution data revealed aggregations of these endangered species in moorland pools. These pools contained water chemistry gradients similar to those found in pristine bogs, which occurred at sites where groundwater seepage and stream water came in contact. In the past, stream water has been used to increase pH and trophic status of moorland pools facilitating fisheries. Today, this practice offers a conservation strategy for the protection of endangered species for which no short-term alternatives are available." (Authors) The following Odonata species are included in the analysis: *Coenagrion hastulatum*, *Somatochlora arctica*, *S. flavomaculata*, *Aeshna subarctica*, *Leucorrhinia albifrons*, and *L. dubia*.] Address: van Klee, H.H., Bargerveen Foundation, Radboud University Nijmegen, P.O. 12097. Verberk, W.C.E.P.; Calosi, P. (2012): Oxygen limits heat tolerance and drives heat hardening in the aquatic nymphs of the gill breathing damselfly *Calopteryx virgo* (Linnaeus, 1758). *Journal of Thermal Biology* 37(3): 224-229. (in English) ["Thermal limits in ectotherms may arise through a mismatch between O_2 supply and demand. At higher temperatures, the ability of their cardiac and ventilatory activities to supply O_2 becomes insufficient to meet their elevated O_2 demand. Consequently, higher levels of O_2 in the environment are predicted to enhance heat tolerance, while reductions in O_2 are expected to reduce thermal limits. Here, we extend previous research on thermal limits and oxygen limitation in aquatic insect larvae and report critical upper temperatures in nymphs of *C. virgo* exposed to different levels of O_2 . In addition, we explore the potential for a mechanistic link between O_2 conditions and thermal plasticity by exposing nymphs to two consecutive extreme heat events, using different levels of O_2 in the second exposure. As predicted, hypoxia severely lowered critical temperatures. However, thermal tolerance was not improved under hyperoxia. Damselfly nymphs may be precluded to take advantage of hyperoxia if O_2 uptake and delivery is controlled locally near the caudal gills where most of the gas exchange occurs. The same asymmetrical effects of hypoxia and hyperoxia on heat tolerance in terrestrial insects could be similarly explained if tracheal opening and/or ventilation are not centrally regulated. Prior exposure to hypoxia enhanced critical thermal maxima in subsequent heat exposures and hyperoxia negated this hardening effect, indicating potential for oxygen-driven heat hardening in these aquatic insects. Our study provides broad confirmation for oxygen limitation as a key mechanism setting upper thermal limits, pointing to a vital role for heat shock proteins in reducing O_2 requirements by slowing down rates of protein denaturation." oocyte production has been assumed to be continuous, with periods of egg-laying interspersed with periods of resting/eating; however, recent work suggests that two types of oocyte production are common: either (a) continuous or (b) step-wise. These are mirrored in the arrangement of the ovarioles in the ovaries. Likewise, two types of mate-guarding behaviour have been observed in Libellulidae: (1) non-contact guarding and (2) tandem guarding in which the male either hovers above the female or is physically attached to her during oviposition. Using molecular (mitochondrial and nuclear) data we explored the evolution of female reproductive traits, focusing on ovariole morphology, as well as guarding behaviour, in Libellulidae. Continuous egg production appears to have evolved more than once, as have tandem and non-contact guarding. We discuss how the evolution of different ovariole types and guarding behaviour may have been influenced by habitat instability, dispersal and crowded oviposition sites; thus, migratory behaviour or habitat availability may have been the driving force of ovariole evolution." 12105. Wu, H. (2012): Huizhou Dragonflies. China Forestry Publishing House: 191 pp. (in bilingual in Chinese and English) ["Until relatively recent times, dragonflies were studied by only a few entomologists, but in this new century they are receiving ever increasing attention from nature lovers all over the world. Many now derive great pleasure from the hobby of observing and photographing dragonflies, in the way they have long watched and photographed birds. Numerous new books introducing dragonflies, enabling their identification and reporting their regional or local diversity are being published in many countries. The present book by Wu Hongdao is among the first of its kind from the mainland of China. The bilingual text is limited, but the superb colour photos provide an excellent introduction to the diverse and colourful world of south Chinese dragonflies. Although, the area of Huizhou City covers only 6% of the land area of Guangdong province and a tiny 0.11% of the whole of China, this area is home to at least 174 species of dragonflies -about 70% of species known from Guangdong and one quarter of the total Chinese dragonfly fauna. This is mainly because the area of Huizhou City includes several well preserved protected areas. The most famous is Nankunshan provincial reserve, which is especially rich in dragonfly species and has been particularly well studied. Within

Huizhou City there are also suitable wetland habitats outside protected areas, in both lowlands and mountain. The first book illustrating Chinese dragonflies was Edward Donovan's famous classic *AN Epitome of the Natural History of the Insects of China*, published in London in 1798. Two of its 50 fine hand-coloured copper-engraved plates illustrate six dragonfly species. All of these, including the beautiful *Neurobasis chinensis*, the first dragonfly from China and the whole of Asia to be scientifically named, are also to be founded in Wu's book. Since the time of Donovan the world has changed in many ways. However, the beauty and diversity of insects continues to fascinate us, and books showcasing their splendor are still being published." (from the preface of Matti Hämäläinen & publisher)]

12107. Yang, P.-s. (2012): A study of the geographical differentiation and conservation among *Psolodesmus mandarinus* populations (Calopterygidae: Odonata). Dissertation, Institute of Entomology, National Taiwan University: 115 pp. (in Chinese, with English summary) ["To investigate the phylogenetic relationship and geographical variation of wing colour among the *Psolodesmus mandarinus* three subspecies, a combination of molecular, morphological, and behavioural approaches was used to guide this research and develop the conservation strategies. Firstly, the molecular phylogenetic analysis of nuclear and mitochondrial genes revealed considerable divergence between Yaeyama's populations (subspecies *kuroiwa*) and Taiwanese populations (included subspecies *mandarinus* and *dorothea*). Furthermore, two mitochondrial lineages (east and west) existed in Taiwan. The eastern Taiwan lineage included these individuals belonging to *dorothea*, and the western Taiwan lineage included both *dorothea* and *mandarinus*. Because of the genetic diversity of mitochondrial gene was much lower in northwestern Taiwan region and two subspecies shared a common haplotype, it is probable the populations of *mandarinus* were derived from the northward expansion of *dorothea* populations. Secondly, Yaeyama's populations (*kuroiwa*) and Taiwanese populations (*mandarinus* and *dorothea*) could be exactly discriminated by the morphometrical analysis of wing pterostigma. Previous studies reported the wing colour differences between *mandarinus* and *dorothea*, our results illustrated that the wing colour traits gradually changed across the populations in northern Taiwan. It would be hard to discriminate two subspecies and determine the distribution limits. In contrast, the female wing size shifted dramatically at 24.19 degree (between central and northern Taiwan) which

was close to the current criteria (24.33 degree) for dividing two subspecies. Because of both the wing colour trait and female wing size changed across the populations of *mandarinus* in northern Taiwan, it is probable these traits may form co-adapted trait complexes and to cope with a different selection regime in northern Taiwan. Thirdly, the field observations of mating behaviour in *mandarinus* and *dorothea* populations demonstrated that two subspecies possessed the same kind of female preference for exaggerated male coloration. Thus, the differentiation of wing colour trait could not be interpreted only by using sexual selection. If the wing colour trait and life history trait formed co-adapted trait complexes in northern Taiwan, the fitness of female preference would be difference between *mandarinus* and *dorothea*. Because of the positive fitness effect in female preference for *mandarinus* populations, wing colour traits gradually changed across the northern Taiwan. On the contrary, the negative fitness effect in female preference for *dorothea* populations, the hyaline wing is maintained by a combination of sexual selection and natural selection. Finally, *Psolodesmus* is the only one endemic genus of damselflies in Taiwan and Yaeyama. The variety of wing colour provided an ideal explanation case for biodiversity education. It also could be used as a biological indicator for monitoring stream ecosystem and global warming. Above all, we suggested developing an educational and recreational program for pursuing the goals of research, conservation and sustainable utilization." (Author)] Address: not stated

12108. Zhang, H.; Hämäläinen, M. (2012): *Matrona annina* sp. n. from southern China (Odonata, Calopterygidae). *Tijdschrift voor Entomologie* 155 (2012) 285–290: 285-290. (in English) ["*Matrona annina* sp. n. from Guangdong and Guangxi (China) is described and illustrated for both sexes. The new species differs from its sympatric congener *M. basilaris* Selys, 1853 by its brown wings, reduced bluish-white reticulation at wing base and in details of the structure of the superior anal appendages. An NJ-tree derived from the ITS region (ITS1, 5.8S gene, and ITS2) of *M. annina* and *M. basilaris* specimens, collected from the same stream, is presented. A mean of 3.4% difference in the ITS sequences was found between the two species." 12109. Zhu, G.; Chmura, A.; Zhang, L. (2012): Morphology, echolocation calls and diet of *Scotophilus kuhlii* (Chiroptera: Vespertilionidae) on Hainan Island, South China. *Acta Chiropterologica* 14(1): 175-181. (in English) ["*S. kuhlii* is distributed in many urban environments, yet the ecology of this species is poorly known. The morphology, echolocation call structure, diet, and foraging areas of *S. kuhlii* were studied on Hainan Island, south China from March to November 2006. ... call shape suggests that this species is adapted to forage in open environments. Data from mist-netting and acoustic detection indicated that *S. kuhlii* foraged mainly around the crown of trees and street lights. Nine insect orders were recorded in its diet, with Lepidoptera (97.46%, by frequency) and Coleoptera (64.72 ± 2.37%, by volume) constituting the main prey, together with Hemiptera (19.99 ± 1.25%) and Hymenoptera (9.43 ± 1.14%). There was significant seasonal variation in the diet of *S. kuhlii*: Coleoptera increased from

March to May, and then decreased to August, while Hemiptera and Hymenoptera showed the inverse trend." (Authors) Odonata were occasionally recorded in the faeces, but no details are given.] Address: Zhang, L., Guangdong Entomological Institute, 105 Xingang Xi Road, Haizhu District, Guangzhou, 510260, China. 2013

12110. Almeida, D.; Merino-Aguirre, R.; Angeler, D.G. (2013): Benthic invertebrate communities in regulated Mediterranean streams and least-impacted tributaries. *Limnologia* 43(1): 34-42. ["Flow regulation is generally perceived to negatively influence fluvial ecosystems through alterations of natural habitat conditions, particularly in highly variable Mediterranean streams. However, the detection of impact may depend on chosen metrics, requiring a multiple-lines-of-evidence approach for ecologically relevant impact assessment. In this study, we compare the community structure, the trophic function, the microhabitat influence and the body condition of benthic invertebrates between the regulated Bullaque River and unregulated tributaries (Guadiana River basin, central Spain). Invertebrates and physical microhabitats were studied seasonally in 2010. Total abundance, EPT abundance, Rheoindex and LIFE metrics were higher in the regulated river during summer, whereas Shannon diversity was lower. Rheoindex and LIFE were higher in the tributaries during winter. Filterers were very abundant in spring and summer in the tributaries and the regulated stream, respectively. Deposit feeders dominated during summer in the tributaries. Despite these differences, ANOSIM revealed similar community structure and feeding groups characteristics in both fluvial system types. In addition, body condition, measured as fluctuating asymmetry level, indicated that damming created favourable developmental conditions for several invertebrate species in the Bullaque River. This suggests that damming surprisingly buffered from the adverse environmental conditions inflicted by seasonal summer droughts, which occur recurrently in Mediterranean areas. Results also suggest that the application of fluctuating asymmetry could therefore be promising for revealing integral ecological responses to different and often combined forms of anthropogenic and natural disturbance. ... A total of 12 species were selected to determine body conditions (fluctuating asymmetry (FA) levels): *Baetis fuscatus* (L.), *B. rhodani* (Pictet), *Caenis luctuosa* (Burmeister), *Ecdyonurus angelieri* Thomas, *Serratella ignita* (Poda), *Leuctra geniculata* (Stephens), *Platycnemis latipes* Rambur, *Onychogomphus uncutus* (Charp.), *Micronecta meridionalis* (Costa), *Hydropsyche exocellata* Dufour, *H. instabilis* (Curtis) and *Rhyacophila relicta* McLachlan." 12111. Barry, M.J.; Sval, S. (2013): Metabolic responses of tadpoles to chemical predation cues. *Hydrobiologia* 700: 267-276. (in English) ["Life-history theory predicts that predator-induced defences should incur fitness costs. In larval amphibians, the most frequently reported cost is reduced energy intake due to lower foraging rates; however, recent reports suggest that this trade-off may be uncoupled through morphological and physiological adaptations. Metabolism is a measure of

energy expenditure and plasticity in respiration may potentially offset other costs of predator-induction. The aim of this study was to measure the indirect effects of dragonfly larvae on the respiration rate of tadpoles of the Arabian toad (*Bufo arabicus*) over time and at different predator concentrations. We performed two experiments. In the first experiment (time-response), we exposed tadpoles either to the indirect presence of odonate larvae or predator-free conditions and measured respiration rates 3, 5, 8, 11, 13, 15, 19 and 26 days after the start of the experiment. In the second experiment (dose-response), we used three levels of predator chemicals, equivalent to 1 predator per 10, 100 or 1,000 l plus controls. The respiration rate of predator-exposed tadpoles varied initially, but was 56.3% of controls after 26 days. In the dose-response experiment, the respiration rate of all predator-exposed tadpole groups was reduced by between 19.1 and 27.2% after 21 days. The study demonstrates a mechanism by which tadpoles may be able to adjust their physiology to partially offset the costs of lower energy intake due to predator avoidance. ... Larval dragonflies were collected from a nearby wadi and maintained on a diet of tadpoles when not being used for experiments. In the time-response experiment, final instar Aeshnidae (*Anax* sp.) and final instar Libellulidae (*Trithemis* sp.) were used. In the dose-response experiment, only *Anax* sp. were utilised." 12112. Cañedo-Argüelles, M.; Kefford, B.J.; Piscart, C.; Prat, N.; Schäfer, R.B.; Schulz, C.-J. (2013): Salinisation of rivers: An urgent ecological issue. *Environmental Pollution* 173: 157-167. (in English) ["Secondary salinisation of rivers and streams is a global and growing threat that might be amplified by climate change. It can have many different causes, like irrigation, mining activity or the use of salts as deicing agents for roads. Freshwater organisms only tolerate certain ranges of water salinity. Therefore secondary salinisation has an impact at the individual, population, community and ecosystem levels, which ultimately leads to a reduction in aquatic biodiversity and compromises the goods and services that rivers and streams provide. Management of secondary salinisation should be directed towards integrated catchment strategies (e.g. benefiting from the dilution capacity of the rivers) and identifying threshold salt concentrations to preserve the ecosystem integrity. Future research on the interaction of salinity with other stressors and the impact of salinisation on trophic interactions and ecosystem properties is needed and the implications of this issue for human society need to be seriously considered." (Authors) The paper includes a reference to Odonata.] Address: Cañedo-Argüelles, M., Freshwater Ecology and Management (F.E.M.) 12113. Drinan, T.J.; Foster, G.N.; Nelson, B.H.; O'Halloran, J.; Harrison, S.S.C. (2013): Macroinvertebrate assemblages of peatland lakes: Assessment of conservation value with respect to anthropogenic land-cover change. *Biological Conservation* 158: 175-187. (in English) ["Small blanket bog lakes can contain many rare and threatened aquatic invertebrate species. Their conservation value, however, is threatened throughout Eu-

rope by peat extraction and particularly conifer afforestation, which can compromise the physico-chemical habitat quality of peatland lakes through excessive inputs of forestry-derived dissolved and particulate substances. To quantify the effect of conifer plantation forestry on the conservation value of these habitats, we compared the hydrochemistry and assemblages of aquatic Coleoptera, Heteroptera and Odonata of replicate lakes across three distinct catchment land uses: (i) unplanted blanket bog only present in the catchment, (ii) mature conifer plantation forests only present in the catchment and (iii) catchments containing mature conifer plantation forests with recently clearfelled areas. All three catchment land uses were replicated across regions of sedimentary and igneous geology. Lakes with afforested catchments, in both geologies, had elevated concentrations of plant nutrients, total dissolved organic carbon and heavy metals, the highest concentrations being recorded from the clearfell lakes. Coleoptera and Heteroptera assemblages responded strongly to forestry-mediated changes in water chemistry, whereas Odonata assemblages responded more to catchment geology – geology being confounded by altitudinal differences between lakes. The greatest species-quality scores (SQSs) and species richness were recorded from the clearfell lakes. Three of the four International Union for the Conservation of Nature (IUCN) nationally red-listed species recorded during this study were, however, absent from clearfell lakes. Our findings demonstrate that plantation forestry can have a profound impact on the aquatic macroinvertebrate assemblages and conservation value of small blanket bog lakes, primarily via eutrophication. Despite indices such as SQS scores and species richness appearing to reveal a beneficial response of blanket bog lake communities to habitat deterioration, they mask that certain 'emblematic' species are being severely negatively impacted by the disturbance caused by plantation forestry. Considering the need for fertiliser to produce economically viable plantation forest crops, coupled with the inefficiencies of peat soils in retaining applied nutrients, the degradation of peatland lakes is likely to become more prevalent as plantation forestry continues to expand worldwide." 12114. Herbst, D.B.; Medhurst, R.B.; Roberts, S.W.; Jellison, R. (2013): Substratum associations and depth distribution of benthic invertebrates in saline Walker Lake, Nevada, USA. *Hydrobiologia* 700: 61-72. (in English) ["Walker Lake, a terminal salt lake in western Nevada, is undergoing rapid changes because of falling lake level and rising salinity, affecting the potential habitat of benthic invertebrates that supply food to native fish and birds. Benthic invertebrate surveys were conducted within different substratum size classes and macrophyte beds in the nearshore littoral shallows (1 m) and in the deeper offshore littoral (2–10 m) and profundal ([10 m) zones of the lake. Samples were dominated by the chironomid midges *Cricotopus ornatus* and *Tanytus grodhausi*; the damselfly *Enallagma clausum*; and an oligochaete worm of the genus *Monopylephorus*. Midges showed distinct depth preferences, with *Cricotopus* found primarily in the shallow littoral, and *Tanytus* found in the lower littoral and profundal regions. *Enallagma* occurred throughout the littoral region but was reduced in abundance below 10 m. *Cri-*

cotopus and *Enallagma* were most abundant on cobble rock substratum and macrophytes. Sand and small gravel substrata supported few invertebrates except oligochaetes, which were most common in shallow littoral areas. The extent of *Ruppia* beds was determined using hydroacoustic sounding and showed that these beds were most well-developed in a zone from 1.25 to 5 m depth. The estimated area of productive shallow littoral zone habitat at different lake levels showed that coverage was lowest near the current surface elevation. Rising lake levels would result in expansion of suitable habitat area, and while falling levels could also expand nearshore habitat, this would likely occur on areas of poorer substratum quality and under high salinities that may inhibit growth." (Authors)] Address: Herbst, D.B., R. Jellison Sierra Nevada Aquatic Research Laboratory, Univ. of California, 1016 Mt. Morrison Road, Mammoth Lakes, CA 93546, USA. E-mail: herbst@lifesci.ucsb.edu

12115. Kosterin, O.E. (2013): Brief Odonata survey in North Ethiopia during heavy rainy season of 2012. *International Dragonfly Fund - Report 56: 1-54.* (in English) ["A survey of Odonata in North Ethiopia, on the route Debre Libanos – Bahir Dar – Woldia – Hayk – Mile – Awash – Debre Zeyit crossing the provinces of Oromia, Amhara and Afar, in July 29 - August 10, 2012 yielded 38 species, including two endemics of Ethiopia and five species not hitherto reliably reported for this country in the literature: *Pseudagrion commoniae*, *P. hamoni*, *P. salisburyense*, *Bradinopyga strachani* and *Ictinogomphus ferox*. The number of Odonata species recorded in Ethiopia thus reached 104. 17 main localities were visited, on average showing 4.9 species per locality. A small branch of Jara River, Amhara, was the richest one (15 species). Comments on specimens of *Pseudagrion spernatum* and *Nesciothemis farinosa* and notes on the country in general and particular habitats of Odonata are provided." 12116. Moller, A.P.; Nishiumi, I.; Suzuki, H.; Ueda, K.; Mousseau, T.A. (2013): Differences in effects of radiation on abundance of animals in Fukushima and Chernobyl. *Ecological Indicators* 24(1): 75-81. (in English) ["Radioactive contamination can negatively affect the abundance of living beings through the radiation and chemical toxic effects of radionuclides or the effects of mutation accumulation over time. If radiotoxic effects were the main determinant of the abundance of organisms, we should expect a reduction in abundance immediately following radioactive contamination, while we should expect a gradual increase in negative effects over time if mutation accumulation was the main determinant. In particular, we should expect the main effects at the recently contaminated site in Fukushima to mainly be due to radiotoxicity, while effects at Chernobyl which has been contaminated since 1986 should be a mixture of radiotoxic and mutation accumulation effects. We censused spiders, grasshoppers, dragonflies, butterflies, bumblebees, cicadas and birds at 1198 sites in Chernobyl and Fukushima-Daiichi, where major nuclear accidents happened 25 years and 6 months ago, respectively. The mean level of radiation was higher and less variable at Fukushima than at Chernobyl, implying that we should expect more negative effects on the abundance of animals at Fukushima if immediate ef-

fects of radiation were important. While all taxa showed significant declines in abundance with increasing level of background radiation in Chernobyl, only three out of seven taxa showed such an effect at Fukushima. The effect of radiation on abundance differed between the two areas for butterflies, dragonflies, grasshoppers and spiders, but not for birds or bumblebees. These findings are consistent with the main effects of radiation on the abundance of animals at Fukushima being due to radiotoxicity while those at Chernobyl may be due to a mixture of radiotoxicity and mutation accumulation, because chronic exposure have been present for many generations thereby allowing for accumulation of mutations." 12117. Nilsson-Örtman, V.; Stoks, R.; De Block, M.; Johansson, H.; Johansson, F. (2013): Latitudinally structured variation in the temperature dependence of damselfly growth rates. *Ecology Letters* 16(1): 64-71. (in English) ["The Metabolic Theory of Ecology predicts that the slope of the rate-temperature relationship, E, remains consistent across traits and organisms, acting as a major determinant of large-scale ecological patterns. Although E has recently been shown to vary systematically, we have a poor understanding of its ecological significance. To address this question, we conducted a common-garden experiment involving six damselfly species differing in distribution, estimating E at the level of full-sib families. Each species was sampled throughout its latitudinal range, allowing us to characterise variation in E along a latitudinal gradient spanning 3600 km. We show that E differs among populations and increases with latitude. E was right-skewness across species, but this was largely an artefact of the latitudinal trend. Increased seasonality towards higher latitude may contribute to the latitudinal trend in E. We conclude that E should be seen as a trait involved in local adaptation." 12118. Raubenheimer, D.; Rothman, J.M. (2013): Nutritional ecology of entomophagy in humans and other primates. *Annu. Rev. Entomol.* 58: 141-160. (in English) ["Entomophagy is widespread among nonhuman primates and is common among many human communities. However, the extent and patterns of entomophagy vary substantially both in humans and nonhuman primates. Here we synthesize the literature to examine why humans and other primates eat insects and what accounts for the variation in the extent to which they do so. Variation in the availability of insects is clearly important, but less understood is the role of nutrients in entomophagy. We apply a multidimensional analytical approach, the right-angled mixture triangle, to published data on the macronutrient compositions of insects to address this. Results showed that insects eaten by humans spanned a wide range of protein-to-fat ratios but were generally nutrient dense, whereas insects with high protein-to-fat ratios were eaten by nonhuman primates. Although suggestive, our survey exposes a need for additional, standardized, data." 12125. Hambrook, J.A.; Armitage, B.J.; Vis, M. (1999): Algal and macroinvertebrate assemblages of selected Ohio springs. *Ohio Biological Survey Notes* 2: 1-24. (in English) ["A qualitative study of the algal flora, macroinvertebrate fauna, and water quality of ten Ohio springs

was conducted during July-September 1996. The springs were primarily in central and northern Ohio on a variety of surficial geology settings including karst, till, and exposed bedrock. Water quality varied with the groundwater source and local environment (agriculture, woodland). The algal community varied greatly in diversity among sites. One woodland site (Styx River) had only three taxa. In contrast, Cedar Bog (an open alkaline fen) had a great diversity of diatoms (246 taxa) with a total of 258 taxa. At most locations, between 15 and 56 taxa were reported. Like the algal community, the diversity of the macroinvertebrate fauna differed considerably among sites, ranging from 2 to 40 identified taxa. This variation may have been due to the sitespecific differences in water chemistry and/or habitat. Computation of Jaccard similarity coefficients for both the algal and macroinvertebrate data resulted in low similarity values among sites. The data collected provide a basis for proposed sampling methods (spring biotic survey protocols) that could be used for the range of spring/seep types found in Ohio." 12133. Kelliher, E. (2004): Investigating fluctuating asymmetry of the larval damselfly, *Calopteryx maculata* (Odonata: Calopterygidae). *Undergraduate Review* 1(10). Available at: <http://vc.bridgew.edu/undergradrev/vol1>

/iss1/10: 29-40. (in English) ["Fluctuating asymmetry (FA), or subtle random deviations from perfect bilateral symmetry, has recently become a useful tool in allowing researchers to understand more about an organism's health, fitness, developmental stability and environmental stressors. Ultimately, FA studies can be used as an indirect measurement of the quality of an aquatic system over time. We measured and examined the femur segments of the larval damselfly, *C. maculata* from sites on the Town, Hockomock, and Salisbury Plain Rivers, of Plymouth County, Massachusetts to determine FA levels. After accounting for measurement error, preliminary results show that variations in symmetry are not correlated to individual trait size. Also, the Hockomock River site showed FA levels three times higher than the Salisbury Plain river, and twice that of the Town River. Finally, severe femur deformation of some individuals at all sites suggests that other, more serious developmental or environmental factors may be inhibiting normal development. Results from a simple two-way ANOVA of differences in right and left femur segments and a Kolmogorov Smirnov test for normality strongly suggest that the first femur of *C. maculata* is a useful trait for FA measurement." 12137. Smith, J. (2005): Complementarity between two metrics which use invertebrates to assess riparian conditions of rivers. M. S. Thesis. University of KwaZulu-Natal, Pietermaritzburg: 98 pp + app. (in English) ["Conservation of streams involves an understanding of their physical, chemical and biological entities. SASS5 is a

biomonitoring method developed to monitor the habitat quality of a water body. It is based on differential scores attributed to various macroinvertebrate families with varying degrees of sensitivity to anthropogenic impact. This method, however, does not assess impacts on particular species. Odonata are good candidates for study at the species level as they are well researched and males are easily identified. As adults, they are known to be sensitive indicators of both riparian and river conditions. Yet Odonata cannot be an umbrella taxon for all other taxa. Therefore, the main aim of this study is to determine the complementarity of the two metrics (Odonata assemblages and SASS5), establishing whether Odonata assemblages offer additional information on, or insight into, riverine habitat quality as portrayed by SASS5. To accomplish this, certain objectives were addressed. 1) The variation of SASS5 scores and 2) Odonata assemblages between river systems, structural habitat types (open or closed canopies) and compositional habitat types (indigenous or alien vegetation). 3) Whether SASS5 scores vary to the same extent, and, 4) on the same spatial scale (river system and point localities) as Odonata abundance and species richness. The relationship between these two metrics was determined along three rivers in the Pietermaritzburg basin. Sampling units (SUs) with extremes in vegetation structure (sunlight and shaded SUs) and vegetation composition (alien or indigenous) were selected. Using this range of environmental conditions placed environmental extremes on the macroinvertebrate populations at point localities and having three different river systems added the dimension of variation over a broader scale, thus stretching the two metrics to investigate whether both responded similarly or in different ways. Results indicated that both metrics provide a similar portrait of overall river conditions. At the smaller spatial scale, the Odonata assemblage, unlike SASS, was highly sensitive to the riparian vegetation. Odonata species were less sensitive to vegetation composition but differentially sensitive to vegetation structure. However, landscape context is also important, with point localities being affected by the neighbouring dominant habitat type. Larval Odonata alone did not provide this information. Overall, aquatic macroinvertebrates and adult Odonata provide a highly complementary pair of metrics that together provide large spatial scale (river system) and small spatial scale (point localities) information on the level of impact of stressors such as riparian invasive alien trees." 12138. Morris, K. (2006): Suffolk dragonflies 2005. *Trans. Suffolk Nat. Soc.* 42: 68. (in English) ["Not a great year for migrants but a few interesting records along the coast. More importantly at least five of our Odonates continued their territorial expansion in Suffolk. Both *Libellula fulva* and *Platycnemis pennipes* pushed further up the River Stour with the former well into Sudbury and the latter just short although another small colony has recently appeared north of Sudbury in the Glemsford area. *L. fulva* wasn't found on this river until the 1990s but is now abundant either side of Bures. *P. pennipes* seemed to disappear from Suffolk in the 1960s but was rediscovered by Arthur Watchman at Stratford St Mary in 1988. Two other hawkers are mak-

ing steady progress in establishing themselves in a wider area of our county. *Aeshna isosceles* can now be seen along the coast as far south as Aldeburgh with up to six hawking on the RSPB North Warren reserve – it was also reported as locally abundant further north and even found in central Lowestoft. Our earliest dragonfly – *Brachytron pratense* – only used to be found near the coast in Suffolk. Now it appears to be turning up almost anywhere. However it should be remembered that the hawkers normally take at least two years to go through their aquatic maturation process and therefore may not yet emerge every year in their new territories. Last but not least the new (1998) damselfly to England – *Erythromma viridulum* – can now be seen in most parts of the county where there is suitable habitat and certainly seems to have the ability to colonise faster than its larger relative *E. najas*." 12142. Ibrahim, H.; Dauti, E.; Gashi, A.; Trozic-Borovac, S.; Skrijelj, R.; Grapci-Kotori, L. (2007): The impact of sewage effluents in water quality and benthic macroinvertebrate diversity of the Prishtina river (Kosova). *Entomol. rom.* 12: 227-231. (in English) ["From December 2004 until November 2005 macrozoobenthos specimens were collected every month with Surber net in six selected stations of the Prishtina River. The Hilsenhoff Family Biotic Index (FBI) and Shannon Weaver Index of Diversity on family level were used to indicate organic and nutrient pollution. In total 7 947 specimens belonging to 56 families of macrozoobenthos groups were found, mainly consisting of aquatic insects. The FBI results during the one-year period show that station P3 has the lowest value (4.6) and thus the best quality of water, while the highest value of this index was regis-

tered in station P5 (8.1) where the impact from sewage input is huge and obvious. The lowest value of Shannon Weaver Diversity Index was registered in station P5 (0.33) while the highest value was found in station P3 (4.04). These results show that biodiversity of aquatic insects (and macrozoobenthos in general) is seriously threatened in the last three stations of Prishtina river because of the direct discharge of sewage waters." (Authors) Taxa (including Odonata) are treated at family level.] Address: Ibrahim, H., Faculty of Mathematical and Natural Sciences, University of Prishtina, Kosovo

12143. Rodrigues, R.C.; Teixeira, R.A.; Campos, L.A. (2007): Comunidade de insetos bentônicos em rio impactado por mineração de carvão em Treviso, Santa Catarina Community of benthic insects in a river impacted by coal mining in Treviso, Santa Catarina. *Tecnologia e Ambiente* 13: 14 pp-["The diversity of benthic insects under a pollution gradient by coal mining effluents was analyzed in the Mãe Luzia river, southern Santa Catarina (Brazil). Insects were collected biweekly from September 2004 to August 2005 at three sites presenting different contamination levels. Temperature, discharge, pH and conductivity were measured during field sampling. An entomological net (mesh of 1 mm) was used in transects of 20 m disturbing the substratum at each 1 m. The insects were identified to family level and for each site the diversity index of Shannon-Wiener and the equitability index of Pielou were calculated. Canonical Correspondence Analysis (CCA) was used to search for similarity patterns among the sites and the correlation between biotic and abiotic variables. A total of 14,025 specimens were registered belonging to 35 families of nine orders. Hydropsychidae (Trichoptera) was the most abundant family followed by Elmidae (Coleoptera) and Psephenidae (Coleoptera). Abundance and richness were inversely proportional to the pollution impact degree, whereas the highest values of diversity and equitability were found at the intermediary site. CCA indicated better correlation between the conductivity and the diversity of benthic insects. These analysis evidenced differences between the sample units of the two less disturbed sites, being useful to detect subtle variations in the lotic environment." (Authors) Taxa including Odonata are treated at family level.] Address: Rodrigues, R.C., Programa de Pós-Graduação em Ciências Ambientais, Universidade do Extremo Sul Catarinense, Av. 12144. Tamai, M.; Wang, Z.; Rajagopalan, G.; Hui, H.; He, G. (2007): Aerodynamic performance of a corrugated dragonfly airfoil compared with smooth airfoils at low Reynolds numbers. *Proceedings of the 45th AIAA Aerospace Sciences Meeting and Exhibit*, Reno, Nevada, 8-11 January 2007 (10.2514/6.2007-483): 12 pp. (in English) ["An experimental study was conducted to investigate the flow behaviour around a corrugated dragonfly airfoil compared with a traditional, streamlined airfoil and a flat plate. The experimental study was conducted at the chord Reynolds number of $Re_C = 34,000$, i.e., the regime where Micro-Air-Vehicles (MAV) usually operate, to explore the potential applications of such bio-inspired airfoils for MAV designs. The measurement results demonstrated clearly that the corrugated dragonfly airfoil has much better performance over the streamlined airfoil and the flat plate in preventing large-scale flow separation and airfoil stall at the test low Reynolds number

level. The detailed PIV measurements near the noses of the airfoils elucidated underlying physics about why the corrugated dragonfly airfoil could suppress flow separation and airfoil stall at low Reynolds numbers: Instead of having laminar separation, the protruding corners of the corrugated dragonfly airfoil were found to be acting as "turbulators" to generate unsteady vortices to promote the transition of the boundary layer from laminar to turbulent rapidly. The unsteady vortex structures trapped in the valleys of the corrugated cross section could pump high-speed fluid from outside to near wall regions to provide sufficient energy for the boundary layer to overcome the adverse pressure gradient, thus, discourage flow separations and airfoil stall." 12147. Chaput-Bardy, A. (2008): Structure des populations sur un réseau hydrographique dendritique. These de doctorat. Université d'Angers: VII + 139 pp. (in French, with English summary) ["River networks are characterised by a hierarchical branching structure and spatio-temporal heterogeneity. Indeed, longitudinal (physico-chemical parameters, water flow), lateral (connectivity between the main course and secondary channels) and time dimensions (seasonal variations) influence habitat heterogeneity. These variations in environmental parameters are gradual along branches (physico-chemical gradients) or discrete between branches (habitat heterogeneity) of the river network. Then landscape structure influences distribution, dispersal and gene flow of freshwater organisms. This work aimed to test (i) the effect of river network geometry on dispersal and gene flow, and (ii) the effect of environmental variations on distribution and phenotypic traits related to dispersal. We used empirical and theoretical approaches by studying a damselfly species, *Calopteryx splendens* across the River Loire and fitting an individual based-model to simulate gene flow in synthetic river networks. Then we showed a discontinuous distribution of individuals along watercourses and a morphological cline across the Loire River. This cline was due to physico-chemical characteristics of water. Morphological variations did not influence dispersal abilities but affected survival. Survival and densities were the main factors influencing dispersal in *C. splendens*. Genetical analyses showed an isolation by distance pattern and a strong genetic structure, but no genetic groups were defined in the catchment. These results can be ex-

plained by overland gene flow between watercourses and a metapopulation structure at the catchment scale. This is the first study performed in a large river network in environmental conditions. Furthermore we realised the Gene-Net software to test the effects of the river network on population genetic structure of freshwater organisms." 12154. Thaler, B. (2008): Die Wirbellosenfauna des Völser Weiher (Schlerngebiet, Südtirol). *Gredleriana* 8: 519-536. (in German, with English summary) ["In the frame of the "Habitat Schlem" project, the invertebrate assemblages of the Völser Weiher, meio- and macrozoobenthos as well as Zooplankton, were analyzed. Altogether 120 taxa were found, 33 of which not yet recorded for South Tyrol. Zoobenthos was composed of 99 crustacean and macroinvertebrate taxa, the majority of which found in the eulittoral. Tire richest group was the one of the Diptera with mainly Chironomidae taxa, followed by Oligochaeta and Crustacea. In terms of abundance the Crustacea clearly dominated in the eulittoral, mostly represented by *Macrotyclops albidus* and *Alonarfifinis*. Among the macroinvertebrates the highest relative abundance was shown by the Oligochaeta with *Sh/laria Incustris* as the most frequent species, the Diptera (*Dicrotendipcs tritonus*) and the Ephemeroptera (*Caenis horaria*). Tire zoobenthos of tire sublittoral zone was almost exclusively represented by Oligochaeta, Chironomidae and Crustacea. Tire Zooplankton was composed of 16 rotifer species, 10 cladoceran and 4 copepod species. Tire quantitatively most important species were *Keratella cochlearis* among rotifers, *Ceriodaphnia pulchella* among cladocerans and *Mesocyclops leuckarti* among copepods. Tire Zooplankton community was characterized by a high percentage of rotifers. Tire ecological status of Völser Weiher, according to the European Water Framework Directive (2000/60/EC), was found to be good both evaluating it with Zooplankton and with eulittoral zoobenthos." (Authors) The list of taxa includes *Coenagrion puella* group, *Ischnura* sp., *Anax imperator*, *Cordulia aenea*, *Libellula depressa*, and several early unidentified larval

stadia of different Odonata taxa.] Address: Thaler, Bertha, Biologisches Labor, Unterbergstr. 2, 39055 Leifers (BZ), Italy. E-mail: Bertha.Thaler@provinz.bz.it

12156. Dunkley, J. (2009): Red-veined Darter *Sympetrum fonscolombii* in Northamptonshire. Atropos 38: 64-65. (in English) ["A significant local find of six *S. fonscolombii* was made at Upton on 27 June 2009 by local stalwarts Nick Roberts and Mark Piper; these were hawking over a recently constructed pond serving as a stormwater balancing vessel for adjacent new roadworks, illustrating how Odonata may opportunistically make use of any available water offering favourable habitat. I visited the site the next day, but the sky had clouded over and despite searching there was no further sign that afternoon. I returned on 29 June at 08.00 hrs. It was already very warm, but it took another hour or more for the target to appear, by which time Bob Bullock had arrived and we were soon watching up to six *S. fonscolombii*, including an ovipositing pair in tandem. Following Mark Tyrrell's prediction that confirmation of breeding should be looked for from mid-September onwards, visits by he and I on 19 and 22 September respectively produced not only teneral but also exuviae. The species remained present into October with estimated numbers running into double figures, providing much pleasure to local Odonata enthusiasts. As a bonus Mark Tyrrell found a 'wandering' male of *S. danae* at the same site on 19 September, following a male in Northampton on 10 September (Doug Goddard), which I was also lucky to see. These constitute the first records for the County." (Author)] Address: Dunkley, J., 10 Stonelea Road, Syweil, Northampton, NN6 OAZ, UK

12157. Garzon Sanabria, C.; Realpe, E. (2009): Diversidad de Odonata (Insecta) en la reserva natural Cabildo-Verde (Sabana de Torres-Santander, Colombia), Una aproximación hacia la conservación (Dragonfly diversity (Insecta) in the natural reserve Cabildo-Verde (Sabana de Torres-Santander, Colombia), an conservation approach). *Caldasia* 31(2): 459-470. (in Spanish, with English summary) ["We studied the diversity of Odonata in six sampling stations in the Sabana de Torres county, department of Santander, Colombia. Four stations were located within the Natural reserve Cabildo Verde, an area long the western hall slope of the Eastern cordillera, in the Magdalena's river mid valley. The remaining two were located outside of this reserve. The species composition was analyzed using an euclidian distance analysis. We found 245 adult individuals belonging to seven families, 22 genera and 39 species in the Sabana de Torres; 33 species, most of them in the suborder Zygoptera were found in the Natural Reserve Cabildo verde. The Shannon-Weaver value for the natural reserve was of $H' = 2,972$ and outside of the reserve $H' = 2,645$, both relatively high in comparison to other studies. There was not significant differences in the number of species inside and outside of the reserve (Chi-squared, $X^2 = 1,51$, $Gl=1$, $p > 0.05$); however, the composition of dragonflies within the re-

serve was given mainly by stenotopic species, especially those in the families Protoneuridae and Perilestidae. Such species are abundant in the studied area, occurring in streams with high vegetal coverage in primary and secondary forests." (Authors)] Address: Garzon Sanabria, Carolina, Laboratorio de Zoología y Ecología Acuática (LAZOE), Universidad de los Andes, Apartado 4976, Bogotá D.C., Colombia. lc.garzon88@uniandes.edu.co

12164. El Haissoufi, M.; Bennis, N.; El Mohdi, O.; Millan, A. (2010): Analyse préliminaire de la vulnérabilité des odonates (Odonata) du Rif occidental (nord du Maroc). Boletín de la S.E.A. 46(1): 345-354. (in French, with Spanish and English summaries) ["The Odonata fauna of the Western Rif is well-known for its richness and diversity. In fact, 49 species out of the 61 which live in Morocco occur in this region alone. The analysis of the level of vulnerability shown by the species that occur in this region has shed light on those species most

vulnerable at the regional and national scale. *Hemianax ephippiger*, *Calopteryx exul*, *Oxygastra curtisii*, *Zygonyx torridus*, *Aeshna mixta* and *Orthetrum brunneum* are highly vulnerable at the regional scale and are therefore proposed for inclusion in the future red list of threatened species of the Western Rif. The degree of national vulnerability, studied here only for *C. exul* and *Gomphus simillimus maroccanus*, two Maghrebian and Moroccan endemics, respectively, revealed an average degree of vulnerability for both species. Protection measures should focus on these two species, especially because their natural habitats are being affected by different types and patterns of stress and disturbance." 12169. Martire, D. (2010): Les Libellules et Ephemeres de la Reunion. BIOTOPE. Mèze: 72 pp. (in French) [The book covers 21 Odonata and 2 Ephemeroptera species found on the island of Reunion. These are attractively illustrated with colour photos. The book presents an identification key to Odonata, many colour photos and distribution maps of the species.] Address: Biotope, 22, boulevard Maréchal Foch, BO 58, 34140 Mèze, France

12170. Meyabeme Elono, A.L.; Liess, M.; Duquesne, S. (2010): Influence of competing and predatory invertebrate taxa on larval populations of mosquitoes in temporary ponds of wetland areas in Germany. *Journal of Vector Ecology* 35(2): 419-427. (in English) ["Abundances of mosquito larvae and associated invertebrate communities were assessed in 27 temporary ponds during the spring season in wetland areas of Germany. Four genera of mosquitoes were identified: *Aedes*, *Anopheles*, *Culex*, and *Culiseta*. We focused our analyses on *Aedes* spp. because this genus was the most abundant (92% of total abundance) and frequently encountered mosquito (present in 65% of investigated sites). The abundance of *Aedes* spp. was negatively associated with the abundance of competitors for food, and to a lesser extent with those of intraguild predators and strict predators. The influence of these natural antagonists on larvae of *Aedes* was stronger in ponds with higher levels of dissolved oxygen ($53 \pm 4\%$) than in ponds with lower levels ($16 \pm 1\%$). The overall abundance of antagonists explained 42% of the variation in abundance of *Aedes* spp. at sites with higher levels of dissolved oxygen. Of this explained variation, competitors accounted for 34.7%, whereas the abundance of intraguild predators and strict predators accounted for only 6.8 and 0.5%, respectively. Therefore, the promotion of competing species might be an appropriate ecological approach for the control of *Aedes* spp. in temporary ponds in these areas." (Authors) Samples including Odonata originate from Rosslau (Sachsen-Anhalt), Spree-wald (Brandenburg) and Leipzig (Sachsen).] Address: Liess, M., UFZ – Helmholtz Centre for Environmental Research, Department of System Ecotoxicology, Permoserstr.15, 04318 Leipzig, Germany

12171. Molina, C.I.; Gibon, F.M.; Duprey J.L.; Dominguez E.; Guimarães, J.R.; Roulet, M. (2010): Transfer of mercury and methylmercury along macroinvertebrate food chains in a floodplain lake of the Beni River, Bolivian Amazonia. *Sci. Total. Environ.* 408(16): 3382-3391. (in English) ["We have evaluated the mercury and methylmercury transfers to and within the macroinvertebrate communities (including *Tremea* sp.) of a floodplain lake of the Beni River basin, Bolivia, during three hydrological seasons and in two habitats (open water and vegetation belt). Using the stable isotopes $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$, six trophic chains were identified during a previous study. Four are based on only one source: seston, organic matter from the bottom sediment, periphyton and macrophytes. Two are based on mixed sources (seston and periphyton in one case, periphyton and macrophytes in the other). During sampling, we found only one taxon that had surface sediment organic matter as food source and very few taxa whose trophic source was constituted by macrophytes. The periphyton was the most important source during all seasons; it produced the longest chain, with three trophic positions. Whatever the season and trophic source, all collected macroinvertebrates contained methyl mercury and the

latter was biomagnified in all trophic chains that we identified. The biomagnification of methylmercury through invertebrate trophic chains accurately reflected the existence and length of these chains. Biomagnification was virtually non-existent in the sediment-based chain, low and restricted to the dry season in the macrophyte-based chain. It was significant in the seston-based chain, but limited by the existence of only two trophic levels and restricted to the wet season. Finally, it was very effective in the periphyton-based chain, which offers the highest rate of contamination of the source but, above all, the largest number of trophic levels." (Authors)] Address: Molina, C.I., Instituto de Ecología, Unidad de Limnología, UMSA, Casilla postal #10077, La Paz, Bolivia. E-mail: camoar6088@gmail.com

12172. Specht, W. (2010): Zur Libellenfauna im Diabassteinbruch Wolfshagen, Landkreis Goslar (Niedersachsen) - ein Zwischenbericht (Odonata). *Mitteilungen des Naturwissenschaftlichen Vereins Goslar* 11: 81-164. (in German, with English summary) ["Dragonfly fauna of a quarry (Diabas-Steinbruch) near Wolfshagen, region Goslar (Lower Saxony, Germany) - an interim report (Odonata). During a number of studies in the quarry called "Diabas-Steinbruch" east of Wolfshagen in the time between 1992 and 2004, there was also carried out a survey of the occurrence of dragonflies within that quarry. On the basis of the results from those years, a total of 10 other species could be recorded in 2008 and 2009 raising the total number of species up to 33.18 out of these species are certainly indigenous to the place. This group includes the very rare *Leucorrhinia albifrons* and the Mediterranean species *Sympetrum fonscolombii* and *Crocothemis erythraea*. *Ischnura pumilio*, discovered in 2000 and 2004, was not found again. The rare dragonfly accounted to *Aeshna viridis* in 2004 could not be confirmed due to a mistake with identifying this specimen. The diversify and the large quantities of the dragonfly fauna in this protected biotope can possibly be explained with the presence of a micro-climate and a special water structure. The absence of fish and of human use are surely the most important reasons." (Author)] Address: Specht, W., Am Gemeindehof 6, 38690 Vienenburg, Germany. E-Mail: wolfgangspecht@web.de

12173. Thipaksorn, A.; Ruangsittichai, J. (2010): Diversity of rice Odonate insects in Lopburi Province, Thailand. *New Entomol.* 59(3,4): 37-42. ["From 2005 to 2008 in-season rice cropping period, 16 odonate insects were collected from pre-germinated direct seeded rice fields in Lopburi Province, an important rice field area of Central plain, Thailand. Within all rice odonate species, three predominant species, *Agriocnemis pygmaea*, *A. femina femina* and *Ischnura senegalensis*, had the highest numbers of individuals. The percentage of 3 species was 56.19% of the total collected. The sub-dominant species were *Diplacodes trivialis*, *I. aurora aurora*, *Crocothemis servilia servilia* and *Brachythemis contaminata*. The highest mean zygopteran species catch was founded from tillering to flowering rice growth stages and will decreasing of their number in milk grain to mature grain stages. On the other hand, the highest mean anisopteran species catch was founded from tillering to milk grain stages and rapidly decreasing of their number in dough grain stage. The number of species and individuals of rice odonates are increasing correlated to specific rice growth stages." (Authors)] Address: Thipaksorn, A., Department of Zoology, Faculty

of Science, Kasetsart University, Chatuchak, Bangkok 10900 Thailand. E-mail: athipaksorn@yahoo.com

12174. Trevor, D.; Caston, M.; Zwelabo, S. (2010): An assessment of the effect of industrial and sewage effluent on aquatic Invertebrates: A case study of a southern urban stream, Zimbabwe. *Journal of Sustainable Development* 3(2): 210-214. (in English) ["The impact of industrial effluent discharged in Mazai stream was assessed through physical-chemical parameters and also by bio-monitoring of benthic macro-invertebrates. Samples were collected at three sites, one before the effluent discharge point into the stream (site 3) and two sites which were located downstream after the discharge points (sites 1 and 2). High levels of chemical pollutants were recorded at sites 1 and 2 (ZINWA red category) whereas site 3 (reference site) consisted of relatively clean water (ZINWA blue category). This was confirmed by the biological evaluation process. The SASS4 scores at sites 1 and 2 indicated a deterioration of water quality while site 3 there was good water quality with high species diversity. Detrended correspondence analysis (DCA) showed that pollution sensitive taxa such as Hemiptera, Trichoptera, Coleoptera and Odonata were dominant at site 3 whilst the other sites were dominated by pollution tolerant species such as Chironomids. Continuous discharge of effluent could lead to extreme degradation of Mazai stream hence loss of biodiversity of macro-invertebrates." (Authors)] Address: Trevor, D., Dept Biol. Sci., Midlands State Univ., P. Bag 9055, Gweru, Zimbabwe. E-mail: tdube@msu.ac.zw

12175. van Swaay, C.A.M.; Groenendijk, D.; Termaat, T.; Plate, C.L. (2010): Vlinders en libellen geteld: jaarverslag 2009. Rapport VS2010.001, De Vlinderstichting, Wageningen: 36 pp. (in Dutch, with English summary) ["Butterflies and dragonflies are counted using a line-transect method. Butterfly transects are visited every week, dragonfly transects once every fortnight. The length of the transects is variable and depends on habitat quality and availability. In addition, single species transects are exclusively counted for a specific threatened butterfly or dragonfly. Indices were calculated using the computer program TRIM (Trends and Indices for Monitoring Schemes). This program was developed by CBS for the analysis of time series of counts with missing observations. The butterfly indices are calculated using a weighting procedure. The reference value of the year 2000 is set to 100. The dragonfly indices are not weighted yet and in most cases 2000 is used as the first year in the trend calculation and, therefore, set to a reference value of 100. Results of 2009: [...] Like in other years, in 2009 Odonata were counted every fortnight between May and September at 422 sites. The average number of dragonflies per transect was a little higher than in most previous years. Like in most other years *Enallagma cyathigerum* was the most common species (over 86,000 individuals). *Ischnura elegans*, with over 15,000 individuals, was the most widespread species. It was seen on about 81% of the plots. For most species indices are presented. As shown in previous years, an alarming decreasing trend was detected in 2009 again for *Aeshna viridis* and *Coenagrion hastulatum*. Other Red List species, like *Sympecma fusca*, *Lestes virens*, *Leucorrhinia dubia* and *Libellula fulva*, show a positive trend.(Authors)] Address: Termaat, T., De Vlinderstichting, Postbus 506, 6700 AM Wageningen, The Netherlands. 12180. Chalar, G.; Arocena, R.; Pacheco, J.P.; Fabián, D. (2011): Trophic assessment of streams in Uruguay: A Trophic State Index for Benthic Invertebrates (TSI-BI). *Ecological Indicators* 11: 362-369. (in English) ["In this study we assessed the trophic status of 28 wadeable stream reaches of the Santa Lucía basin, an important economic region of Uruguay. We developed a Trophic State Index of Benthic Invertebrates (TSI-BI), the first of its kind for South American lotic systems. The methodological approach consisted of determining the ambient trophic gradient via canonical correspondence analysis based on the benthic invertebrate abundance matrix and an environmental variable matrix. The rescaled site scores served as environmental variables in the weighted averaging model (WA), to weight the benthic abundances and then find the optimum and tolerance of each of the sampled genus. These data were used to estimate the TSI-BI scores. These scores, in conjunction with the total phosphorus concentrations (TP), were used to group the study reaches when running a cluster analysis. The basic statistical parameters of the defined groups serve as an input to identify the threshold values of TP and TSI-BI corresponding with the different trophic states. The boundaries of TSI-BI and TP demarcating mesotrophic and eutrophic states were 8 and 71 g/l, respectively, and can be considered the limits between impaired and less altered reaches. The results also indicated that the trophic status of the reaches is related to land use intensity. A change in land use management seems to be critical for the preservation of one of the most important water supply systems in Uruguay." (Authors) 15 Odonata genera are integrated into the index.] Address: Guillermo Chalar, G., Section of Limnology, Department of Ecology, Faculty of Science, University of the Republic, Iguá 4225, Piso 9, Montevideo CP: 11400, Uruguay. 12181. Contreras-Garduño, J.; Córdoba-Aguilar, A.; Azpilicueta-Amorín, M.; Cordero-Rivera, A. (2011): Juvenile hormone favors sexually-selected traits but impairs fat reserves and abdomen mass in males and females. *Evolutionary Ecology* 25(4): 845-856. (in English) ["The physiological mechanism underlying resource allocation in sexual selection studies has been little studied. One candidate is hormones as these favour resource allocation to reproductive traits but impair survival due to a resource over-expenditure directed to the former traits. We have investigated whether a juvenile hormone analog (JHa, methoprene) administered topically is involved in the resource allocation to wing pigmentation (an ornamental trait), fat reserves and flight muscle mass in both sexes of *Calopteryx haemorrhoidalis* and *C. virgo*. We also investigated the possible negative effect of such implementation on abdomen mass (an indirect measure of egg production) and field-based survival in adult males of *C. haemorrhoidalis* and *C. splendens*. We found that males and females treated with JHa, against a control group, developed higher wing pigmentation and showed reduced fat reserves

but had no change in muscle mass. In females, JHa decreased abdominal weight (an indicator of fecundity) and in males, survival was impaired only in *C. splendens*. These results support the idea that JH induces resource allocation to wing pigmentation, a sexually selected trait in both sexes. Thus, this study suggests that the action of JH could be a mechanistic link between ornaments and physiological condition in both males and females." (Authors)] Address: Córdoba-Aguilar, A., Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo, Apdo. 12185. Greven, H. (2011): Johann Leonhard Frisch (1666-1743) - ein wenig bekannter Pionier entomologischer Forschung. *Entomologie heute* 23: 145-206. (in German, with English summary) ["Johann Leonhard Frisch, pedagogue, linguist and entomologist, was born in 1666 in Sulzbach (Bavaria). He was a universal scholar of the Early Enlightenment. Among others he wrote aside from his job the "Description of various insects of Germany" („Beschreibung von allerley Insecten in Teutschland"), which was issued between 1721 and 1738 in 13 parts. Certainly, he was physico-theologically motivated, but this motivation is far less insistently expressed as by his contemporaries or subsequent "entomologists". The text often impresses with thorough descriptions of 300 "insects", in many cases including their developmental stages. Approximately 260 specimen are Hexapoda, from which many can be determined to the species level. The remaining "insects" belong to various "worms" such as arachnids, millipeds, molluscs, with careful observations of their living and

with ingenious and often amazing conclusions. In addition, he included 41 copper plates with 296 figures (tables; some with more than one figure) of different quality, which were engraved by his sons Philipp Jacob and Ferdinand Helfrich. Surely, meaningfulness of these plates (in combination with the text) is underestimated until now. Also noticeable are the short summaries, occasionally with critical annotations, of the entomological works of some famous naturalists of the Renaissance and the Early Enlightenment, among others Aldrovandi, Mofett, and Swammerdam. At the beginning of the 20th century Bodenheimer has thoroughly acknowledged Frisch, but later appreciations are either totally missing, are short, or focus on Frisch's main interest in parasites and store pests. Contrary to these approaches, I show exemplarily by some less spectacular details (e.g., striking legs of water scorpions, breathing of dragonfly-nymphs, parturition of aphids etc.), how precisely Frisch has observed his objects and how acutely he has commented his finding." (Author) The paper includes many figures and references to Odonata.] Address: Greven, H., Zoologie II, Heinrich-Heine-Universität, Universitätsstr. 1., 40225 Düsseldorf, Germany. Zimmermann was rewarded for his great contributions to knowledge of Odonata and Ephemeroptera. The laudatio was held by J. Müller.] Address: Klausnitzer, Hertha, PF 202731, 01193 Dresden, Germany

12188. Middlemis-Maher, J.; Werner, E.E.; Denver, R.J. (2011): Stress hormones mediate predator-induced phenotypic plasticity in amphibian tadpoles. Front. Endocrinol. Conference Abstract: ISAREN 2011: 7th International Symposium on Amphibian and Reptilian Endocrinology and Neurobiology. doi: 10.3389/conf.fendo.2011.03.00031: (in English) ["Amphibian tadpoles mount behavioural, physiological and morphological responses to predation. Tadpoles rapidly reduce activity level when exposed to chemical cues of predation; with chronic exposure, tadpoles develop relatively smaller bodies and larger tails. The larger tail may serve as a lure to distract predator strikes from the more vulnerable body, or may confer enhanced burst locomotion for escape. In many vertebrates, exposure to predators also influences the activity of the hypothalamo-pituitary-adrenal (interrenal; HPI) axis. Here we investigated the effects of predator cues on activity of the tadpole HPI

axis and the relation to predator-induced responses in tadpole behaviour and tail morphology. We exposed wood frog tadpoles (*Rana sylvatica*) to the nonlethal presence of a predator (dragonfly larvae fed conspecific tadpoles) in outdoor mesocosms, and measured whole body CORT content by radioimmunoassay. Exposure to predator cue reduced CORT by ~30% compared with controls at 4 hours, but increased CORT by ~2 fold after 4 or 8 days. In a laboratory experiment, exposure either to predator cue or to CORT for 3 days (130 nM added to the aquarium water), caused tadpoles to develop a larger tail relative to their body. Importantly, the effect of predator cue on tail morphology was blocked by treatment with the corticosteroid synthesis inhibitor metyrapone (110 µM). Short term treatment with CORT (1-3 hours) increased tadpole activity, and lead to higher mortality than controls in the presence of an unrestrained predator. By contrast, chronic exposure to CORT (8 days) showed a trend towards increased survivorship of tadpoles with free predators. Our results support the hypothesis that tadpoles mount a dual physiological and phenotypic response to predation, suppressing behaviour and CORT in the short term, but increasing CORT with longer exposure which induces changes in tail and body morphology." 12189. Naraoka, H. (2011): Reproductive behavior of *Coenagrion terue* (Asahina, 1949) (Zygoptera, Coenagrionidae), with special reference to repeated interruptions of the copulation and a long pre-ovipositional tandem linkage. Tombo 53: 101-109. (in Japanese, with English summary) ["The reproductive behaviour and prolonged pre-oviposition tandem in *C. terue* are described based on observations in northern Japan, in 2003-2007. The number of females was much smaller than that of males at the oviposition site. Tandem formation was observed at the roosting site in early morning and at the oviposition site in late morning, between 6:00-15:00h. However, males rarely succeeded in holding females, because most females avoided males by doing "face to face hovering". When a rejective female was seized by a male, she did a peculiar "abdominal oscillation", and consequently tandem was shortly dissolved. Copulation was observed from 6:10-14:30h. Oviposition started after 9:00h. When pairs were created early in the morning, they did not necessarily start to copulate soon, but did copulate at various time between 6:00-12:00h with a peak of 9:00-11:00h. The duration of copulation, observed in field and cage, before 9:00h (mean 41.7 ± 22.3 min), was longer than that after that time (mean 33.0 ± 12.1 min), but the difference was not significant. Mean copulation duration was 38.1 ± 19 min (n=34). Copulation was divided into 3 stages; I: 35.4 ± 19.1 min, II: 77.8 ± 32.7 sec, and III: 110.7 ± 43.4 sec. In copulations continuing over 24 min, "breaks" of 1-3 times were observed. Tandem pairs created before 9:00 h rested at 0.5-3 hours in some points of pre, mid and post-copulation, the same after 9:00 h did rarely rest until copulation and oviposition. Pre-oviposition rest was negatively and significantly correlated with tandem formation time during the day. Long tandem duration before oviposition can be regarded as pre-oviposition guarding." 12191. Pfau, H.K. (2011): Functional morphology and evolution of the male secondary copulatory apparatus of the Anisoptera (Insecta: Odonata). *Zoologica* 156: 103 pp. (in English) ["In this study, the functions and mechanical interactions of different parts of the secondary copulatory apparatus of Anisoptera are reconstructed in detail and possible evolutionary pathways are described. Whereas in Zygoptera and Anisozygoptera the vesica spermalis of the third abdominal segment is a single segmented intermediate sperm-storage, this organ is subdivided into four segments in the Anisoptera. The evolutionary consequences of acquiring new functions as secondary (in reality tertiary) "penis" and sperm-syringe are one focus of this study. The secondary copulatory apparatus of male dragonflies (Odonata), located at the second and third abdominal segment, consists of a number of sequentially arranged devices. These serve (1) as support of the female ovipositor, (2) for carrying out preparatory actions for filling an intermediate sperm-storage, (3) for levering and inserting a secondary "penis" (in the primitive case the ligula) and (4) as transmitter of sperm to the female vagina. Each subtask affords a sequence of actions of the corresponding sclerites and muscles of this apparatus. An impressive variety of different solutions to perform and secure the filling of the sperm-reservoir of the vesica spermalis in the Anisoptera is described. In the primitive case a laborious and time-consuming procedure - which probably depends on interrelated functions of the ligula and female ovipositor - is carried out. Reduction of the ovipositor in different lines of the Anisoptera apparently initiated evolutionary modifications, which finally led to more sophisticated modes of preparing filling and protection. Another focus are the auxiliary devices and techniques in the Anisoptera for emptying the sperm-reservoir of the vesica spermalis. For instance, two different types of sperm-pumps are incorporated in its distal segment ("glans"). These pumps - which extend the function of a hydraulically working gland-structure, the erectile organ - show an opposite co-ordination of sperm-suction and -ejection in connection with compression and decompression movements. It was tried to reconstruct a transitional system to close a serious gap in the phylogenetic interpretation. A comparative investigation of different "glans" led to the discovery of different "ways" of combining the emptying-mechanism of the sperm-reservoir with an intensification of the sperm-jet and a "washing out" of sperm of the male predecessor (sperm displacement). The different stages of evolution of the glans, which reflect phylogenetic splittings, are outlined and discussed. This study is of great interest to biologists interested in the functional morphology of the Odonata. It does not merely rely on painstaking comparisons of morphological details, but integrates func-

tional points of view to use the heuristic power of hypothetical approach." (Publisher)] Address: Pfau, H.K., Rathenastr. 14, D-65326 Aarbergen, Germany. E-mail: clauspfau@web.de

12193. Raescu, C.-S.; Dumbrava-Dodoaca, M.; Petrovici, M. (2011): Macrozoobenthic community structure and dynamics in Cerna River (western Romania). *Aquaculture, Aquarium, Conservation & Legislation* 4(1): 79-87. (in English, with Romanian and Hungarian summaries) ["In order to determine water quality in Cerna River, researchers carried out analyses into the structure and dynamics of benthic macroinvertebrates communities as well as into the physical-chemical factors. 12 Groups of macroinvertebrates were identified. Density, abundance and frequency values recorded for benthic communities varied according to the physical-chemical conditions specific to each sample collecting station. Researchers noticed a direct influence of Baile Herculane town and dam upon the community submitted to study, the maximum density and percentage numerical abundance being established for Oligochaeta and Diptera, benthic groups tolerant to changes in aquatic ecosystems qualitative parameters. The community of organisms including Ephemeroptera, Trichoptera, Plecoptera, Odonata and Coleoptera was characterized by a decrease in density and abundance values upstream - downstream as water quality is more and more degraded. This deterioration is also emphasized by the biotic index EPT/Ch values." 12203. Andrew, R.J.; Thakkar, N.; Verma, P. (2012): Ectoparasitism of anisopteran dragonflies (Insecta: Odonata) by water mite larvae of *Arrenurus* spp. (Arachnida: Hydrachnida: Arrenuridae) in central India. *Acarina* 20(2): 194-198. (in English) ["There is no report on the frequency, species selection and site specificity of water mites' ectoparasitism within and among dragonfly species of India. Here, we present a field survey of the species selection and site specificity of ectoparasite larval arrenurid mites on anisopteran adults at Nagpur city of central India. Since the female odonates returns to water to oviposit, it would be of some advantage for the mite to show a female-biased parasitism in order to return to water easily and continue the remaining aquatic part of their life cycle. A total of 204 specimens of anisopteran odonates belonging to 11 species were examined for the presence of larval *Arrenurus* spp. as ectoparasites during the post-monsoon (August–September 2010) and summer (March–April 2011) months from a large pond in central India. Only 14 dragonfly specimens of six species (*Acisoma panorpoides*, *Brachythemis contaminata*, *Crocothemis servilia*, *Diplacodes trivialis*, *Neurothemis t. tullia*, and *Trithemis pallidinervis*) were found to be parasitized (overall prevalence of 6.86%). The prevalence for *C. servilia* was 28.6%, followed by *T. pallidinervis* and *A. panorpoi-*

des at 21.4%. The total number of parasites recorded was 465 at an average of 33.26 per specimen. The parasite load per host species was the highest in *T. pallidinervis* (92.6) followed by *C. servilia* (24). In *C. servilia*, *A. panorpoides* and *D. trivialis* the mites were attached ventrally to the thorax and were mostly arranged in a 'v' or triangular shape, while in *B. contaminata* and *T. pallidinervis* the mites were found all over the ventral abdomen. In one *T. pallidinervis* male and one *C. servilia* female, mites were found both on the thorax as well as the abdomen. The maximum number of mites found on an individual dragonfly was on the female abdomen of *T. pallidinervis* (114), while only one mite was found on the thorax of a male *C. servilia*. Mite infestation was sex-biased — 71.0% and 85.7% of infested odonates were females in August–September and March–April, respectively." (Authors)] Address: Andrew, R.J., Post Graduate Department of Zoology, Hislop College, Nagpur, 440 001, India. E-mail: rajuandrew@yahoo.com

12205. Balter, M.; Zinman, A. (2012): The design, construction, and application of a 3D flying prey simulator to aid in the investigation of neuronal control in dragonflies. *Proceedings of The National Conference, On Undergraduate Research (NCUR) 2012, Weber State University, Ogden Utah, March 29 – 31, 2012: 61-68.* (in English) ["The goal of this interdisciplinary research project is to investigate the neuronal control of flying prey interception in dragonflies by designing, constructing, and programming an apparatus to simulate the complex motions of a flying insect. Our three-dimensional motion device is capable of mimicking a flying insect by moving a small glass bead accurately up to speeds of 1 m/s. Dragonflies are highly efficient aerial predators that have the remarkable capability of intercepting and capturing small insects in flight. This complex process generally occurs in less than 300 ms, with success rates as high as 97%1. Prey capture behaviour requires both rapid visual processing and information transmission, resulting in the evolution of large neurons in the control pathway. Eight pairs of large neurons, called Target-Selective Descending Neurons (TSDNs), are implicated in steering the interception flight. These neurons descend from the brain of the dragonfly to the wing motor regions of the thorax, transmitting visual information about prey movement. Our stimulus device will be used

to determine the way in which the TSDN's encode information about object movement in three dimensions. To date, visual neuron studies have been mostly restricted to two dimensions, the x-direction (left - right) and the y-direction (up - down), recording responses to images displayed on a flat projection screen. However, Dr. Olberg of the Biology Department at Union College hypothesized that the z-dimension (front - back) movement is vital to understanding the exact roles of these neurons in prey interception. An understanding of visually guided prey interception by dragonflies, could lead to the development of effective guidance mechanisms for military or civilian use. The device consists of 80/20 extruded aluminum parts, timing belts and pulleys, ball bearings, metal axles, and DC brushed motors with encoders. The device is computer controlled by Simulink and Real Time Windows Target, which are components of MATLAB." (Authors)] Address: Balter, M., Mechanical Engineering and Biology Departments, Union College, 807 Union Street, Schenectady, NY 12308 USA

12206. Balter, M. (2012): The design, construction, and application of a 3D flying prey simulator. Thesis. Rutgers University: (in English) ["The goal of this research project is to investigate the neuronal control of flying prey interception in dragonflies by designing, constructing, and programming an apparatus to simulate the complex motions of a flying insect. Our three-dimensional motion device is capable of mimicking a flying insect by moving a small bead accurately up to speeds of 1 m/s in any direction. Dragonflies are efficient aerial predators that can intercept and capture small insects in flight. Our stimulus device will be used to determine the way in which dragonfly neurons encode information about object movement in three dimensions. Sinusoidal position tracking experiments using multiple input frequencies were conducted using the apparatus. The results indicate that the machine operates smoothly with little variability between trials. Preliminary dragonfly testing with the apparatus showed favourable results, indicating proof of concept... This machine is programmed to move an analogue of a small flying insect (bead) in front of a dragonfly causing the dragonfly to react as if it were prey. Assists the research of Dr. Robert Olberg. Work has been presented and published at the 2012 National Conference on Undergraduate Research, while lead to an invitation into the Union College Chapter of Sigma Xi. Has currently been submitted for publication to the 2012 ASME Dynamic Systems and Controls Conference." 12208. Benchalel, W.; Samraoui, B. (2012): Caractérisation écologique et biologique de l'odonatofaune de deux cours d'eau méditerranéens: l'oued El-Kébir et l'oued Bouaroug (Nord-Est de l'Algérie). *Méditerranée* 118: 19-27. (in French, with English summary) [Algeria; "A total of 13 species were identified in Oued El-Kébir, and 11 in Oued Bouaroug. Reproduction was proved for 5 species in Oued El-Kébir and 8 species in Oued Bouaroug. In both sites of study, the flight period of the species extends from the beginning of spring to the end of autumn. The follow-up of the larval development of some species has proved the univoltinism of *Boyeria irene*, *Calopteryx haemorrhoidalis*, *Coenagrion puella*, *Lestes viridis*, *Orthetrum chrysostigma*, *Pseudagrion subdilatata*. Other species such as *Orthetrum anceps* *Onychogomphus costae* *Paragomphus genei* are probably univoltine. But we lack data that confirms their univoltinism because of the sampling problem. As for *Gomphus lucasi* and *Onychogomphus uncutus*, these species are probably not univoltines. A morphometric characterization of the different larval stages (metric and numerical characters) has also been established for every species which the reproduction has been proved. Given the intense anthropic pressure in the sampled areas especially in Oued El-Kébir, the regression of the species' total number seems to be unfortunately irreversible. These hydrographical basins need to be immediately and effectively protected in order to keep this natural heritage." (Authors)] Address: Benchalel, W., Université Badji Mokhtar -Annaba, B.P. 12, 23000 Algeria. E-mail: wafachalel@yahoo.fr

12209. Benson, D. H.; Baird, I. R. C. (2012): Vegetation, fauna and groundwater interrelations in low nutrient temperate montane peat swamps in the upper Blue Mountains, New South Wales. *Cunninghamia* 12(4): 267-307. (in English) ["Newnes Plateau Shrub Swamps are a series of low nutrient temperate montane peat swamps around 1100 m elevation in the upper Blue Mountains, west of Sydney (lat 33° 23' S; long 150° 13'E). Transect-based vegetation studies show a closely related group of swamps with expanses of permanently moist, gently sloping peatlands. Vegetation patterns are related to surface hydrology and subsurface topography, which determine local peat depth. While there is evidence that a group of the highest elevation swamps on the western side of the Plateau are more dependent on rainwater, the majority of swamps, particularly those in the Carne Creek catchment, and east and south of it, may be considered primarily groundwater dependent with a permanently high watertable maintained by groundwater aquifers. An integral part of the swamps are a number of threatened groundwater dependent biota (plants-*Boronia deanei* subsp. *deanei*, *Dillwynia stipulifera*, dragonfly- *Petalura gigantea*, lizard- *Eulamprus leuraensis*), which are obligate swamp dwellers. This association of dependence leaves the entire swamp ecosystem highly susceptible to threats from any loss of groundwater, the current major one being the impact of damage to the confining aquicludes, aquitards, aquifers and peat substrates as a result of subsidence associated with longwall mining. Impacts on the swamps may also result from changes to hydrology through damming of creeks, mine waste water discharge, increased moisture competition from pine plantations, recreational motorbike and off-road vehicle tracks and climate change. If these groundwater dependent ecosystems do not receive protection from activities such as longwall mining subsidence, significant ecolog-

ical damage is unlikely to be avoided or able to be mitigated even where provisions of the Commonwealth Environment Protection and Biodiversity Conservation and NSW Threatened Species Conservation Acts apply to groundwater dependent swamps and biota. The importance of the highest elevation part of the Plateau for a number of restricted (some endemic) plant species is also discussed. This paper includes a synthesis of results of a study (by IRCB) of larval burrow morphology and groundwater dependence in *P. gigantea*" (Authors) Available from <http://www.rbgsyd.nsw.gov.au/science/Scientificpublications/cunninghamia/contentsbyvolume/volume12#twelve%20four>] Address: Baird, I., 3 Waimea St, Katoomba NSW 2780, Australia. 12211. Bland, L.M.; Collen, B.; Orme, C.D.L.; Bielby, J. (2012): Data uncertainty and the selectivity of extinction risk in freshwater invertebrates. *Diversity and Distributions* 18(12): 1211-1220. (in English) ["Aim: To investigate the impact of different treatments of the IUCN Data Deficient (DD) category on taxonomic and geographical patterns of extinction risk in crayfish, freshwater crabs and dragonflies. Location: Global. Methods: We used contingency tables to evaluate taxonomic and geographical selectivity of data deficiency and extinction risk for three invertebrate taxonomic groups (crayfish, Odonata, and freshwater crabs) based on their IUCN Red List status. We investigated differences in patterns of data deficiency and extinction risk among taxonomic families, geographical realms and taxonomic families within geographical realms for each of the three groups. At each level, we evaluated the impact of uncertainty conferred by the conservation status of DD species on extinction risk patterns exhibited by that group. We evaluated three scenarios: excluding DD species, treating all DD species as non-threatened and treating all DD species as threatened. Results: At the global scale, DD species were taxonomically non-randomly distributed in freshwater crabs and dragonflies, and geographically non-randomly distributed in all three taxonomic groups. Although the presence of under- or over-threatened families and biogeographical realms was generally unchanging across scenarios, the strength of taxonomic and geographical selectivity of extinction risk varied. There was little consistent evidence for taxonomic selectivity of extinction risk at sub-global scales in freshwater crabs and dragonflies, either among biogeographical realms or among scenarios. Main conclusions: Global patterns of taxonomic selectivity and geographical selectivity were generally consistent with one another and robust to different treatments of DD species. However, sub-global scale conservation prioritization from these types of data sets will require increased investment to make accurate decisions. Given the current levels of data uncertainty, the relative importance of biological characteristics and threatening processes

in driving extinctions in freshwater invertebrates cannot be easily determined. We recommend that DD species should be given high research priority to determine their true status." 12212. Blanke, A.; Greve, C.; Wipfler, B.; Beutel, R.; Holland, B.; Misof, B. (2012): The identification of concerted convergence in insect heads corroborates Palaeoptera. *Systematic Biology* 62(2): 250-263. (in English) ["The relationships of the three major clades of winged insects - Ephemeroptera, Odonata and Neoptera - are still unclear. Many morphologists favor a clade Metapterygota (Odonata+Neoptera), but Chiasatomyaria (Ephemeroptera+Neoptera) or Palaeoptera (Ephemeroptera+Odonata) have also been supported in some older and more recent studies. A possible explanation for the difficulties in resolving these relationships is concerted convergence - the convergent evolution of entire character complexes under the same or similar selective pressures. In this study we analyse possible instances of this phenomenon in the context of head structures of Ephemeroptera, Odonata and Neoptera. We apply a recently introduced formal approach to detect the occurrence of concerted convergence. We found that characters of the tentorium and mandibles in particular, but also some other head structures, have apparently not evolved independently, and thus can cause artefacts in tree reconstruction. Our subsequent analyses, which exclude character sets that may be affected by concerted convergence, corroborate the Palaeoptera concept. We show that the analysis of homoplasy and its influence on tree inference can be formally improved with important consequences for the identification of incompatibilities between datasets. Our results suggest that modified weighting (or exclusion of characters) in cases of formally identified correlated cliques of characters may improve morphology based tree reconstruction." 12213. Bo, T.; Fenoglio, S.; López-Rodríguez, M.J.; Tierno de Figueroa, J.M. (2012): Trophic behaviour of the dragonfly *Cordulegaster boltoni* (Insecta: Odonata) in small creeks in NW Italy. *Entomologica Fennica* 22: 255-261. (in English) ["*C. boltonii* is a widespread Odonata in Europe, which usually inhabits small lotic systems. In this study we analysed the gut contents of *C. boltoni* immature stages, collected in the Rocchetta Tanaro Natural Park (Italy, Piemonte). Two hundred and eleven individuals were collected, and their diet analyzed by dissection or clearing. Larvae appeared to be opportunistic predators, feeding on a variety of prey. Aquatic insects dominated their diet, while crustaceans, annelids, molluscs and terrestrial invertebrates were sporadically observed in the gut contents. An ontogenetic shift in the diet was detected, as small larvae consumed different prey than large ones. Our study suggests that *C. boltonii* is one of the dominant predators in the benthic communities of lowland small order streams of Piemonte, which, because of their environmental characteristics, are devoid of fish and stoneflies." 12214. Boscardin, J.; Corrêa Costa, E.; Garlet, J.; Cunha Bolzan, L.; Nascimento Machado, D.; Pedron, L. (2012): Índices faunísticos para a entomofauna coletada em plantios de *Eucalyptus* spp. VII Congresso de Medio Ambiente de la AUGM: 14 pp. (in Portuguese, with English summary) ["The genus *Eucalyptus* has become important for the economy of Brazil. However with the increase in areas with *Eucalyptus* sp. entomological problems tend to increase in the same proportions, as crops with this kind provide conditions for adaptation of pests, thereby requiring constant monitoring through surveys of insect populations. The objective of this study is the population survey of entomofauna by using light traps in *Eucalyptus* spp. The study was conducted in three *Eucalyptus* stands, belonging to the species: *E. dunni*, *E. grandis* and *E. grandis* x *E. urophylla* (clone hybrid), with three years of age. located on the Taquari farm, in São Francisco de Assis, Rio Grande do Sul To collect entomofauna light traps were used, one in every species tested, with samples taken monthly from August 2008 to July 2009. The insects collected were analyzed using indices of frequency, abundance, diversity and constancy. During the survey, we collected 3054 individuals in eight orders (Blatodea. Coleoptera. Dermaptera, Hemiptera, Hymenoptera, Lepidoptera. and Odonata [Libellulidae], Mantodea) and 34 families. The orders with the highest number of insects were collected: Coleoptera. Lepidoptera and Hemiptera with 61.18 and 12% of the total sample respectively. The orders Coleoptera and Lepidoptera. presented the families with the most significant indices, especially the families Elateridae, Ptilodactylidae and Staphylinidae, Scarabeidae order Coleoptera and Arctiidae and Noctuidae of the Lepidoptera order. Considering the results obtained in this survey, it is concluded that the area presents major groups, some with potential to become pests, and others considered as a tool in integrated pest management of insect pests in *Eucalyptus*. contributing to reduced use of chemicals in your control." (in Spanish, with English summary) [Data on the reproduction in the Iberian Peninsula of the European endemic species *C. bidentata* is presented for the first time. Additionally, information about the composition of one of its larval colonies in Lerida is provided, pointing out that it shares its habitat with *C. boltonii*. This could be a sign of the deterioration of its colonies in the area." (Authors)] Address: Cano Villegas, F.J., C/Montemayor, 4 1º-2; 14003-Córdoba, Spain. E-mail: ficanovi2@hotmail.com

12219. Chae, J.S.; Park, M.K.; Kim, H.-C.; Jung, J.-Y.; Son, H.Y.; Ryu, S.-Y.; Shin, H.-J.; Sim, C.; Park, B.-K. (2012): Infection status of metacercaria in adult dragonflies from Republic of Korea. *International Journal of Veterinary Science* 1(2): 55-58. (in English) ["The dragonfly serves as a second intermediate host of some trematodes. Seven species of dragonflies, *Sympetrum darwinianum*, *Orthetrum albistylum*, *Lyriothemis pachygastra*, *Sympetrum eroticum*, *Crocothemis servilia*, *Pantala flavescens* and *Sympetrum pedemontanum* were surveyed. The most abundant species among these dragonflies were *S. darwinianum*, *S. eroticum* and *C. servilia* (2,118 and 620 and 334 individuals, respectively). And, the least abundant dragonflies were *S. pedemontanum*, *L. pachygastra* and *O. albistylum* (25, 57 and 62 individuals, respectively). Among these intermediate hosts, *S. eroticum* had the highest infestation rate of metacercaria per individual (11.71%). The infestation rates of two dragonflies, *S. darwinianum* and *S. pedemontanum* (8.58% and 4.56%, respectively) also were higher than those of the other four species. In artificial infection studies using animal hosts, we could identify the infections of adult *P. muris* and *P. japonicus* from only mouse, in which the infestation rates of *P. muris* and *P. japonicus* were 90% and 95% among 20-tested individuals, respectively. Interestingly, adult *L. liberum* was detected from only frog, *R. nigromaculata* and the rates of the infestation in frogs were 97.5% among 50-tested frogs. These results suggest that the population size of dragonfly is an important factor to carry high burden of metacercaria. Moreover, we discussed their epidemiological implications for human and animal infections." (Authors)] Address: Sim, Cheolho, Department of Biology, Baylor University, Waco, Texas 76798, USA. (2012): Wettability of dragonfly wings: the structure detection and theoretical modeling. *Surface and Interface Analysis* 45(2): 650-655. (in English) ["Hydrophobic surfaces have gained extensive attention in recent decades for their potential applications. The hydrophobic properties of dragonfly's (*Pantala flavescens*) wings were measured, and the water contact angles (WCAs) of the distal and basal part of a dragonfly's wing were 134.9° and 125.8°, respectively. Images obtained by optical microscopy and scanning electron microscopy showed the microstructures and nanostructures on the wing surface. Microstructures appeared as cell block patterns, and the size of the blocks decreased from the basal to distal part. However, no significant differences of chemical composition between the two parts were detected by X-ray photoelectron spectroscopy. To understand the correlation between the structures and WCA, a double roughness structure model was built theoretically with simplified lattice patterns, and the theoretical model was well fitted with empirical wettability of the dragonfly's wing." 12228. Foto, M.S.; Koji, E.; Ajeagah, G.; Bilong Bilong, C.; Njiné T. (2012): Impact of dam construction on the diversity of benthic macroinvertebrates community in a periurban stream in Cameroon. *International Journal of Biosciences* 2(11): 137-145. (in English) ["In the aim of evaluating the impact of a dam construction on the biodiversity of aquatic organisms, physicochemical variables coupled to benthic macroinvertebrates communities were analysed at the upstream and downstream of the Mefou stream dam from September 2009 to March 2010. Physicochemical results revealed a slightly acidic and well oxygenated water of the Mefou stream, being appropriated for the development of benthic macroinvertebrates organisms. Significant differences were observed for temperature and oxygen between the stations ($P < 0.05$). Of the 1801 individuals collected (4 phyla, 6 classes, 13 orders, and 47 families) arthropods (99.25%) dominated, while Annelids, Nematelminths and Mollusca were less represented (2 %). The Correspondence Canonic analysis (CCA) distinguished two sections on the stream: a superior section at the upstream of the dam which is characterised by much oxygenation and abundance of Atyidea (excellent bioindicators of good quality water) ($r = 0.04$; $P < 0.05$); an inferior section at the downstream of the dam, dominated by rheophil organisms (odonates). The relative abundance of odonates correlated with the values of water flow rates of each station ($r = 0.94$; $P < 0.01$). The presence of polluo-tolerant organisms (*Chironomidae* and *Haplotaenidae*) at station 3 could reflect anthropic action at the downstream of the dam. Shannon and Weaver ($H = 4.1 \pm 0.5$ bits) and Pielou index ($J = 0.8 \pm 0.1$ bits) revealed favourable conditions for the coexistence of

benthic macroinvertebrates. These results could provide viable information used in evaluating the water quality of lotic systems subjected to dam construction in Cameroon." (Authors)] Address: Foto, M.S., Dept of Animal Biology and Physiology, Faculty of Science, University of Douala, P.O Box 24157, Douala, Cameroon. E-mail: sfotomen@yahoo.fr

12229. Franzén, M.; Molander, M. (2012): Changes in the insect fauna in Padjelanta National Park. *Entomologisk Tidskrift* 132(2): 81-112. (in Swedish, with English summary) ["Arctic ecosystems and the trophic levels structuring them have recently been severely perturbed, although a relatively large proportion of the Arctic environment is protected. Temperatures have increased two to three times more rapidly in the Arctic compared to other regions, mammal populations have declined and the tree line has shifted to higher altitudes. However, knowledge of possible changes of the insect fauna in Arctic habitats is strikingly poor. In this study we compiled data from historical and recent surveys of six major insect taxa (Lepidoptera, Coleoptera, Hymenoptera (Aculeata), Odonata, Orthoptera and Diptera (Syrphidae) recorded in Padjelanta, the largest (1984 km²) National Park in Sweden. Padjelanta is situated in the Western part of the province Lule Lappmark and is dominated by alpine vegetation, with an average altitude of 800 m.a.s.l. (range: 550-1800 m.a.s.l.). Insects in Padjelanta have been studied occasionally since the beginning of the 1940s. We carried out a follow up study of the taxa listed above between 1998 and 2008 to study possible changes in the insect fauna. A total of 398 species belonging to the studied groups have been recorded in the park. Especially species rich groups are the bumblebees and butterflies, of which 16 and 26 species have been recorded. Red Listed species were represented by eight butterflies, but several other interesting and rare species were found, including the first records of the weevil *Dorytomus tortrix* and the chrysidid wasp *Chrysis angustula* in the province Lule lappmark. Only small changes in the fauna were detected; some species of Lepidoptera, Coleoptera and Aculeate wasps seem to have colonized the area over the last 65 years, but the overall rate of colonization has been low. We discuss changes in the alpine fauna, the Red List status of alpine insect species and threats to the environment. It is concluded that the alpine insect fauna warrants further attention and should be carefully monitored since environmental changes are expected to occur at an increased rate in the future." (Authors) *Aeshna caerulea*, *Somatochlora alpestris* and *S. arctica* are listed from the National Park.] Address: Franzén, M., UFZ Centre for Environmental Research, Dept of Community Ecology, Theodor-Lieser-Str. 4, 06120 Halle, Germany. 12231. Gaffin-Cahn, E. (2012): Neural responses to looming objects in the dragonfly. Thesis, Bachelor of Science in Neuroscience, University of Rochester: (in English) ["Dragonflies have high visual acuity, which, when combined with a remarkably fast visual response, allows them to hunt small insects with a high success rate. Rather than aiming at the prey's current location, the dragonfly predicts the prey's future location and intercepts the insect mid-flight. Eight bilateral pairs of large Target-Selective Descending Neurons (TSDNs) of the dragonfly ventral nerve cord respond to small, contrasting objects, which presumably represent potential prey. These interneurons are part of the neuronal circuitry that triggers small changes in wing angle and position to control flight during prey interception. In flight, dragonflies extend their legs out to catch the prey about 20 ms before contact. The current research investigates the role of the TSDNs in prey contact. Spiking traces from the nerve cord were recorded during the presentation of expanding black circles projected on a screen, which simulate approaching prey. Several loom sizes and speeds were used to cover a range of realistic and unrealistic rates of expansion. I hypothesized that the interneurons predict the time to contact (Tc) of the simulated looming stimuli. Looming-sensitive TSDNs fired at a consistent time before Tc, supporting the hypothesis." 12233. Hobbelen, P.H.F.; Samuel, M.D.; Foote, D.; Tango, L.; LaPoint, D.A. (2012): Modeling the impacts of global warming on predation and biotic resistance: mosquitoes, damselflies and avian malaria in Hawaii. *Theoretical Ecology* 6(1): 31-44. (in English) ["Biotic resistance from native predators can play an important role in regulating or limiting exotic prey. We investigate how global warming potentially alters the strength and spatial extent of these predator-prey interactions in aquatic insect ecosystems. As a simple model system, we use rock pools in streams of rainforests of Hawaii, which contain *Megalagrion calliphya* as predator and the invasive southern house mosquito *Culex quinquefasciatus* as prey. This abundant mosquito is the major vector of avian malaria transmission to native forest birds. We use mathematical modelling to evaluate the potential impacts of damselfly predation and temperature on mosquito population dynamics. We model this predator-prey system along an elevational gradient (749-1952 m elevation) and assess the effect of 1°C and 2°C climate warming scenarios as well as the effects of El Niño and La Niña oscillations, on predator-prey dynamics. Our results indicate that the strength of biotic resistance of native predators on invasive prey may decrease with increasing temperature because demographic rates of predator and prey are differentially affected by temperature. Future warming could therefore increase the abundance of invasive species by re-

leasing them from predation pressure. If the invasive species is a disease vector, these shifts could increase the impact of disease on both humans and wildlife." (Authors)] Address: Hobbelen, P.H.F., Rothamsted Research, Harpenden AL5 2JQ, UK. E-mail: peter.hobbelen@rothamsted.ac.uk

12234. Hobson, K.A.; Anderson, R.C.; Soto, D.X.; Wassenaar, L.I. (2012): Isotopic evidence that dragonflies (*Pantala flavescens*) migrating through the Maldives come from the northern Indian subcontinent. *PLoS ONE* 7(12): e52594. doi:10.1371/journal.pone.0052594: 4 pp. (in English) ["Large numbers of *P. flavescens* appear in the Maldives every October–December. Since they cannot breed on these largely waterless islands, it has recently been suggested that they are "falling out" during a trans-oceanic flight from India to East Africa. In addition, it has been suggested that this trans-oceanic crossing is just one leg of a multi-generational migratory circuit covering about 14,000–18,000 km. The dragonflies are presumed to accomplish this remarkable feat by riding high-altitude winds associated with the Inter-tropical Convergence Zone (ITCZ). While there is considerable evidence for this migratory circuit, much of that evidence is circumstantial. Recent developments in the application of stable isotope analyses to track migratory dragonflies include the establishment of direct associations between dragonfly wing chitin $\delta^2\text{H}$ values with those derived from long-term $\delta^2\text{H}$ precipitation isoscapes. We applied this approach by measuring wing chitin $\delta^2\text{H}$ values in 49 individual *P. flavescens* from the November–December migration through the Maldives. Using a previously established spatial calibration algorithm for dragonflies, the mean wing $\delta^2\text{H}$ value of -117 ± 16 ‰ corresponded to a predicted mean natal ambient water source of -81 ‰, which resulted in a probabilistic origin of northern India, and possibly further north and east. This strongly suggests that the migratory circuit of this species in this region is longer than previously suspected, and could possibly involve a remarkable trans-Himalayan high-altitude traverse." (in English) ["The most successful period of oviposition in 2005 occurred during the last half of September. However, 9% of the emergences in 2006 occurred from a pond exposed from mid-October through November 2005, indicating a second, smaller, peak of oviposition. Over the period 1990–2011 the average date for the first sighting of individuals was 17 June and the average date when first seen patrolling was 14 July. The mean time between emergence and patrolling was 28 days." (Author)] Address: Horne, J., 78 Spring Lane, Bishopstoke, Eastleigh, Hants, S050 6BB, UK

12239. Hull, R.; Katete, R.; Ntwasa, M. (2012): Therapeutic potential of antimicrobial peptides from insects. *Biotechnology and Molecular Biology Review* 7(2): 31–47. (in English) ["The first antimicrobial peptides were isolated from the cecropia moth *Hyalophora cecropia* in 1980. Since then a plethora of antimicrobial peptides have been isolated from other arthropods, invertebrates and chordates. With the emergence of antibiotic resistant bacterial pathogens and the promising activity of these peptides, attempts are being made to use these peptides as new antimicrobial agents. Other researchers are interested in using these peptides to improve the resistance of crops and livestock to infections, while another line of research is interested in using these peptides to control vector borne diseases. Despite the promising antibacterial, antiviral, anti-protozoan and anti-tumor activity of these peptides, relatively few peptides have made it to clinical trials. Problems associated with the development of these peptides into effective antimicrobial agents include their higher cost, proteolysis or decreased activity in physiological environments and mass production. This review (including a reference to *Aeshna cyanea*) will focus specifically on the development of insect antimicrobial peptides into useful chemotherapeutic agents." - 12241.** Jia, C.Y.; Wei, C.Y. (2012): Radio tracking of large Odonata species in forest fragments in Singapore. Project Report. Submitted to Nature Society (Singapore), Junior College Category, 2012; <http://www.nss.org.sg/documents/LGD%202012%20%20Radio%20Trackin%20Odonata%20NUS%20High%20Hwa%20Chong%20Inst.pdf>: 11 pp. (in English) ["Recent advances in technology allow radio tracking to be done for larger insects. Such studies have been done on Odonata, in the open fields of the UK. However, behaviour of larger Odonates in the tropical forests of the SE Asian region is not well known, especially when away from water bodies. Difficulty arises in following these large individuals through the dense forest undergrowth as the individuals fly or perch in the canopy foliage. This study thus aims to be a pilot study in the uses of radio tracking in collecting information on the spatial and temporal behaviour of large Singaporean Odonates, in particular the *Macrogomphus quadratus*. Radio tracking is done on foot and individuals are followed for as long as a signal is detected (an average of seven days). The *M. quadratus* is likely to be a percher in terms of its feeding behaviour as can be deduced from the signals received on the tracking receiver and also from visual observations of untagged individuals. As a pioneer work in the field of radio tracking in SE Asia, we hope that future work will be aided by our findings." - 12243.** Kang, S.-R.; King, S.L. (2012): Influence of salinity and prey presence on the survival of aquatic macroinvertebrates of a freshwater marsh. *Aquatic ecology* 46(4): 411-420. (in English) ["Salinization of coastal freshwater environments is a global issue. Increased salinity from sea level rise, storm surges, or other mechanisms is common in coastal freshwater marshes of Louisiana, USA. The effects of salinity increases on aquatic macroinvertebrates in these systems have received little attention, despite the importance of aquatic macroinvertebrates for nutrient cycling, biodiversity, and as a food source for vertebrate species. We used microcosm experiments to evaluate the effects of salinity, duration of exposure, and prey availability on the relative survival of dominant aquatic macroinvertebrates (i.e., *Procambarus clarkii*, *Cambarellus puer*, Libellulidae, Dytiscidae cybister) in a freshwater marsh of southwestern Louisiana. We hypothesized that increased salinity, absence of prey, and increased duration of exposure would decrease survival of aquatic macroinvertebrates and that crustaceans would have higher survival than aquatic insect taxon. Our first hypothesis was only partially supported as only salinity increases combined with prolonged exposure duration affected aquatic macroinvertebrate survival. Furthermore, crustaceans had higher survival than aquatic insects. Salinity stress may cause mortality when acting together with other stressful conditions." (Authors)] Address: Kang, S.R., School of Renewable Natural Resources, Louisiana State Univ. AgCenter, Rm. 307, RNR Building, Baton Rouge, LA, 70803, USA. E-mail:
- 12244.** Karube, H. (2012): Vietnamese Odonata collected in 1992-2003 surveys (3) Cordulegastridae, genus *Anotogaster* with note on its systematic grouping. *Tombo* 54: 55-69. (in English) ["Here I report the following five species of the genus *Anotogaster* from Vietnam with full descriptions; *A. sakaii* Zhou, 1988, *A. chaoi* Zhou, 1998, *A. sapaensis* sp. nov., *A. gigantea* Fraser, 1924 and *A. klossi* Fraser, 1919. Among them, *A. sapaensis* is new to science, and related for *A. nipalensis*. *A. sakaii*, *A. chaoi* and *A. gigantea* are new records for Vietnam. The female of *A. chaoi* and the male of *A. klossi* are described for the first time. In northern Vietnam, I recorded 4 species from the same mountain, such a high species diversity is a unique characteristics of Indochina region. In addition, the key for grouping of this genus is discussed." (Author)] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan. - 12245.** Kim, M.; Yoo, J.-c. (2012): Diet of yellow bitterns (*Ixobrychus sinensis*) during the breeding season in South Korea. *Journal of Ecology and Field Biology* 35(1): 9-14. (in English) ["Yellow bitterns (*Ixobrychus sinensis*) are a small wetland bird common to Asian countries including South Korea, Japan, and China. The aim of this study is to describe diet of yellow bitterns during the breeding season in artificial wetland of northeastern South Korea between May to August 1999-2001. For the purposes of this paper, we observe the frequency of nest visiting by parents during the chick rearing period. A total of 98 boluses regurgitated by 52 chicks aged 1 day to 11 days after hatching form the sample and are shown to contain 323 food items. A bolus contained mean 3.8 items and weighs 0.2 g to 7.7 g. The most regularly occurring food items recorded are fish (63%) and insets (33%). In terms of fish, top mouth minnows (*Pseudorasbora parva*) and crucian carps (*Carassius auratus*) are frequently observed. In terms of insects, there are mosquitoes (Diptera), instars of dragonfly (Libellulidae), damselflies Coenagrionidae) and water bugs (*Diplonychus japonicus*). Yellow bitterns were also shown to feed on bull frogs (*Rana catesbeiana*), shrimp (Palaemonidae), and spiders (Araneae). The size of fish in a bolus ranged from 15.56 mm to 93.73 mm (mean, 37.08 mm). The amount of food can be observed to increase with the age of chicks ($r = 0.279$, $P = 0.025$, $N = 64$) but parents did not provide larger fish as chicks grew. Parent birds visited nests more frequently when they have a larger brood ($F_{1,21} = 14.529$, $P = 0.001$). Our results suggest that fish is the most important prey during the breeding season and that age of chicks is related to amount of diet in yellow bitterns." (2012): Zur aktuellen Verbreitung der in Fließgewässer siedelnden Libellenarten in der Umgebung von Altenburg mit besonderer Berücksichtigung von Pleiße und deren Nebengewässern (Insecta: Odonata). *Mauritiana* 23: 148-174. (in German, with English summary) ["The recent distribution of lotic dragonfly species in the surrounding of Altenburg with special account on the Pleiße River and its tributaries (Insecta: Odonata). Along the Pleiße River and its tributaries in the Altenburger Land district and adjacent areas all members of the Odonata families Gomphidae and Calopterygidae were not known to occur or extinct since the 1960th. Pollution with industrial and urban waste water was probably the main reason for decline and extinction of these species. With the regional collapse of water polluting industry in the river catchment and increasing efforts in water purification after 1990 the situation turned to the better and from this time onwards some of the species resettled formerly abandoned river stretches. The paper presented here gives an up to date overview about the recent distribution of *Gomphus pulchellus*, *G. vulgatissimus*, *Ophiogomphus cecilia* and *Calopteryx splendens* and *C. virgo* in the region. Some of the mentioned species are nowadays widely distributed and locally common. In Germany the lentic *G. pulchellus* has its easternmost occurrence near Altenburg." (Author)] Address: Kipping, J., BioCart - Ökologische Gutachten & Studien, Albrecht-Dürer-Weg 8, D-04425 Taucha, Germany. E-mail: BioCartKipping@web.de

12248. Klaus, D. (2012): Die Besiedlung künstlich geschaffener Kleingewässer in der Pleißeau durch Wasserinsekten und Amphibien. *Mauritiana* 23: 54-77. (in German, with English summary) ["The colonisation of artificially created ponds in the Pleiße-Floodplain by aquatic insects and amphibians. The newly created small bodies of water on the meadows of the Pleiße between Windischleuba and Remsa in 2009 were examined for their colonization by dragonflies, water bugs, water beetles and amphibians. As a result 14 species of dragonflies, 8 taxa of water bugs and 27 representatives of aquatic beetles were detected. So far only three amphibian species were found in these ponds. The insects were predominantly eurytopic and widespread species in Thuringia. But with the Scarce Blue-tailed Damselfly (*Ischnura pumilio*) - Red List of TH 3 (= "Vulnerable"), the diving beetle *Laccophilus poecilus* - RL TH: R (= "Rare"), and the green toad (*Bufo viridis*) - RL TH 1 (= "Critically endangered"), these bodies of water also presented a habitat to three species endangered in Thuringia." (Author)] Address: Klaus, D., Naturkundliches Museum Mauritium Altenburg, Parkstr. 1, 04600 Altenburg, Germany. E-mail: klaus@mauritianum.de

12249. Koike, S. Morimoto, H.; Goto, Y.; Kozakai, C.; Yamazaki, K. (2012): Insectivory by five sympatric carnivores in cool-temperate deciduous forests. *Mammal Study* 37(2): 73-83. (in English) ["We studied insectivory by five carnivores—the Asiatic black bear (*Ursus thibetanus*), Japanese marten (*Martes melampus*), Japanese badger (*Meles meles*), red fox (*Vulpes vulpes*), and raccoon dog (*Nyctereutes procyonoides*)—in a cool-temperate deciduous forest in Japan. From May

2003 to April 2005, we assayed 373 fecal samples (91 from bear, 158 from marten, 43 from badger, 36 from fox, and 45 from raccoon dog) for insects. Each carnivore species consumed a variety of insect species, some preferentially. Bears preferred colonial insects like ants and wasps; martens ate a variety of forest insects, such as ground beetles and arboreal insects; badgers preferred forest ground beetles; foxes ate ground beetles and grassland insects; and raccoon dogs ate a variety of species. Dietary preferences may reflect the feeding strategy, behaviour, or habitat preference of each carnivore species. Based on the habitat preferences of the insects, we could assign carnivores to particular microhabitats: bears and martens used forest in three dimensions, badgers inhabited forest in two dimensions, foxes used grassland and forest in two dimensions, and raccoon dogs inhabited grassland and forest in three dimensions. Identification of insects in feces may provide information on the dietary and habitat preferences of these carnivores.... Foxes foraged only on Coleoptera, Hemiptera, Orthoptera, and Odonata. Only foxes ate Odonata (grassland insects)." (Authors)] Address: Koike, S., Tokyo University of Agriculture and Technology, 3-5-8 Saiwai, Fuchu, Tokyo 183-8509, Japan. E-mail: koikes@cc.tuat.ac.jp

12253. Kulijer, D.; Baker, R.A.; Zawal, A. (2012): A preliminary report on parasitism of Odonata by water mites from Bosnia and Herzegovina. *J. Br. Dragonfly Society* 28(2): 92-10. (in English) ["The following Odonata, infested with mites, have been collected from a number of sites in Bosnia and Herzegovina - *Aeshna isosceles*, *Sympetrum flaveolum*, *Coenagrion pulchellum*, *Coenagrion puella*, *Coenagrion scitulum*, *Enallagma cyathigerum*, *Erythromma najas*, *Ischnura elegans*, *Ischnura pumilio*, *Lestes dryas*, *Platycnemis pennipes*, and *Pyrrosoma nymphula*. The preferred site of mite attachment on the body is the posterior ventral surface of the thorax, behind the third pair of legs. In all but one of the species of zygopteran, mites were also found between the first and second pair and/or the second and third pair of legs and, in several species, on the abdomen. Mite loads varied for different species but preliminary results suggest that the larger anisopterans can carry more mites (in *S. flaveolum* mean 42, range 1-91) than the zygopterans, the highest recorded in the latter being in *C. pulchellum* (mean 37, range 1-68) and the lowest in *L. dryas* (mean 4, range 1-11). More mites were found on female damselflies than on males. Three distinct sizes of larval mite have been noted, indicating stages in their engorgement on the host." (Authors)] Address: Kulijer, D., National Museum of Bosnia and Herzegovina, Zmaja od Bosne 3, 71000 Sarajevo

12254. Kulijer, D.; Vinko, D.; Billquist, M.; Mekkes, J.J. (2012): Contribution to the knowledge of the Odonata fauna of Bosnia and Herzegovina – Results of the ECOO 2012. *Natura Sloveniae* 14(2): 23-38. (in English, with Slovenian summary) ["As a part of the 2nd European Congress on Odonatology (ECOO 2012), which was held in the beginning of July 2012 in Belgrade (Serbia), a post congress excursion to Bosnia and Herzegovina was organized. Between 6 and 12 August 2012, altogether 36 localities in three biogeographical regions throughout Bosnia and Herzegovina were surveyed, and 52 dragonfly species were found. This represents 83% of the hitherto recorded dragonfly species for the country. The most significant results are the second record and a new locality of *Somatochlora metallica*, second record of *Coenagrion hastulatum*, and first observation of the strong population of *Lindenia tetraphylla* for the country. New records of rare and/or threatened species, i.e. *Coenagrion ornatum*, *Ceriagrion tenellum*, *Caliaeschna microstigma*, *Cordulegaster heros* and *Selysiotermis nigra*, are also reported. The records of the most interesting species are briefly discussed from the aspects of biogeography and nature conservation." 12255. Laister, G. (2012): Ortstreue und Ortswechsel von *Cordulia aenea* an Fortpflanzungsgewässern (Odonata: Corduliidae). *Libellula* 31(3/4): 155-178. (in German, with English summary) ["In a five-year study, data on site fidelity and change of location in *C. aenea* during the pre-reproductive and reproductive period was

collected using capture mark-recapture method. Five ponds, which were preferentially investigated in pairs in different years, were included in the study. Teneral individuals of *C. aenea* were marked at the pond that harboured the largest population. Immigration, unequal probability of individuals to gain a territory and mortality during pre-reproductive period presumably had the widest influence on the recapture rate of males marked as tenerals. Emigration was proved only to a lesser degree towards nearby ponds. In summary, it can be concluded that in spite of low recapture rates of teneral marked males we cannot assume that emigration plays a major part in the composition of a large population. In adult males site fidelity including an exchange of individuals between closely neighbouring ponds was found." (Author)] Address: Laister, G., Stadtgärten Linz, Abteilung Botanischer Garten und Naturkundliche Station, Roseggerstr. 20-22, A-4020 Linz, Austria. E-mail: Gerold.Laister@mag.linz.at

12256. Laister, G. (2012): Ortstreue und Gewässerwechsel von *Cordulegaster boltonii* (Odonata: Cordulegastriidae). *Libellula* 31(3/4): 113-130. (in German, with English summary) ["Site fidelity and movement to other brooks in *Cordulegaster boltonii* (Odonata: Cordulegastriidae) – In the year 2000, at three brooks in the area of Linz, Austria, site fidelity and movement to other brooks has been investigated. The brooks have been of different width and because of their characteristics of different suitability for *Cordulegaster boltonii*. It has been shown that site fidelity and movement to other brooks depends on how much a habitat meets the ecological needs of the species. Site fidelity was highest for males at the apparently favoured habitat. Ratio of males moving to other brooks was highest at brooks which represented less typical habitats. Some males have been found more frequently and for a longer time at the brook than other males." 12258. Lankika, M.D.H.; Karunaratne, M.M.S.C.; Conniff, K. (2012): Species composition of Odonate fauna in Meegahawatta, a wetland Aaea in Hanwella, Sri Lanka. *Journal of Tropical Forestry and Environment* 2(2): 37-42. (in English) ["Approximately 120 species of Odonata have been recorded in Sri Lanka to date. There are many gaps in our knowledge of Odonata taxonomy and distribution. The present study, therefore, was carried out to investigate adult Odonata species present in Meegahawatta area (1000m²) in Hanwella. The study was carried out using two fixed quadrats (20m x 10m) randomly established in two selected sites. Total number of individuals belonging to each species was counted fortnightly by using binoculars. A total of 27 species,

11 Zygoptera and 16 Anisoptera representing eight families were recorded. This comprised of three endemic Zygopteran species (*Libellago adami*, *Pseudagrion rubriceps ceylonicum* and *Prodiasineura sita*) and three endemic anisopteran species (*Epophthalmia vittata cyanocephala*, *Cyclogomphus gynostylus* and *Macrogomphus lankanensis*). Among those identified was one recently discovered and yet un-described Archibasis species. Of the three endemic Anisopteran species recorded, *C. gynostylus* and *M. lankanensis* are listed as vulnerable species in the IUCN Redlist of 2010. Although the Zygopterans showed higher Diversity Index and Evenness Index ($H' = 1.99$, $E = 0.83$) than the Anisopterans ($H' = 1.96$, $E = 0.32$), their Richness Index ($R = 1.67$) was less than that of the Anisopterans ($R = 2.49$). The most common Zygopteran species recorded was *Pseudagrion malabaricum* whereas *Neurothemis tulia tulia* was the most common anisopteran species." 12259. Maag, N.; Gehrler, L.; Woodhams, D.C. (2012): Sink or swim: a test of tadpole behavioral responses to predator cues and potential alarm pheromones from skin secretions. *J. Comp. Physiol. A Neuroethol. Sens. Neural Behav. Physiol.* 198(11): 841-846. (in English) ["Chemical signalling is a vital mode of communication for most organisms, including larval amphibians. However, few studies have determined the identity or source of chemical compounds signalling amphibian defensive behaviours, in particular, whether alarm pheromones can be actively secreted from tadpoles signalling danger to conspecifics. Here we exposed tadpoles of the common toad *Bufo bufo* and common frog *Rana temporaria* to known cues signalling predation risk and to potential alarm pheromones. In both species, an immediate reduction in swimming activity extending over an hour was caused by chemical cues from the predator *Aeshna cyanea* (dragonfly larvae) that had been feeding on conspecific tadpoles. However, *B. bufo* tadpoles did not detectably alter their behaviour upon exposure to potential alarm pheromones, neither to their own skin secretions, nor to the abundant predator-defence peptide bradykinin. Thus, chemicals signalling active predation had a stronger effect than general alarm secretions of other common toad tadpoles. This species may invest in a defensive strategy alternative to communication by alarm pheromones, given that Bufonidae are toxic to some predators and not known to produce defensive skin peptides. Comparative behavioural physiology of amphibian alarm responses may elucidate functional trade-offs in pheromone production and the evolution of chemical communication." 12260. Machado, A.B.M. (2012): A new species of *Ischnura* (Odonata: Coenagrionidae) from high altitude eastern Andes, of Colombia. *Zoologia* 29(6): 598-600. (in English) ["*Ischnura mahechai* sp. nov. is described and illustrated based on specimens collected at the Eastern Andean mountain range of Colômbia. The species is close to *Ischnura cruzi* De Marmels, 1987 but differs from it by the structure of male anal appendages and female hind prothoracic lobe. The specimens were collected on a small Andine lake at 3,600 m, the 4th alti-

tudinal record for a resident odonate." (Author)] Address: Machado, A.B.M., Departamento de Zoologia, Instituto de Ciências Biológicas, Univ. Federal de Minas Gerais. Caixa Postal 486, 31270-901 Belo Horizonte, Minas Gerais, Brasil. E-mail: angelo@icb.ufmg.br

12261. Mäkinen, J. (2012): Eteläntytönkorento (*Coenagrion puella*) Suomessa [Coenagrion puella in Finland]. *Crenata* 5: 4-7. (in Finnish) [In Finland *C. puella* was a very rare and local species for many decades. It was first recorded in 1958 in Vehkalahti, where a population was found in a small river. The next two populations were also discovered in small streams in south-eastern Finland. *C. puella* was classified as endangered in the Finnish Red List between the years 1986 and 2001. In 2002 it began to expand its range rapidly. Within one decade it has become a common species in the Helsinki area. At present the northern border of the range (excluding the old population in Mäntyharju, still the northernmost in Finland) is 70-80 km north from the southern coast. The average speed of the expansion is estimated to have been 5-6 km per year during the past 11 years. (Asmus Schöter)] Address: makisenjussi@gmail

12262. Mäkinen, J., M. Friman, S. Karjalainen & J. (2012): Rahkonen (2012) Sudenkorentokatsaus 2011 [Report of dragonfly records made in Finland in 2011]. *Crenata* 5: 8-28. (in Finnish) [This article presents the most interesting Odonata records from Finland in 2011. Two new additions to the Finnish fauna were found: *Lestes virens* and *Sympetrum fonscolombii*. *L. virens* was recorded in Vantaa (27-28 August, by Miikka Friman) and *S. fonscolombii* in Helsinki (9 October, by Timo Päivinen). Only one individual of both species was observed. During 2011 seven new provincial records were made. These include the second observation of *Sympetrum pedemontanum* in Finland (Liperi, 27 July, by Kari Manner). A total of 59 dragonfly species have been recorded in the country by the end of 2011. (Asmus Schöter)] Address: makisenjussi@gmail

12263. Marinov, M. (2012): Description of female *Hemicordulia hilaris* Lieftinck, 1975 (Anisoptera: Corduliidae) with brief notes on the biogeography of the genus. *Rec. Auckland Mus.* 48: 97-105. (in English) ["Three *Hemicordulia* specimens in the Auckland Museum, collected from the Cook Islands and Fiji, were compared with recently sampled material from Fiji, Tonga and New Caledonia. They were determined to be conspecific with *H. hilaris*, originally described from New Caledonia and confirmed for other parts of the Pacific – Fiji, Samoa and Tonga. The female of *H. hilaris* is described here for the first time and morphological features that separate the species from other congeners are discussed." 12269. McTavish, E.J.; Smith, G.K.; Guerrero, R.F.; Gering, E.J. (2012): Flight morphology variation in a damselfly with female-limited polymorphism. *Evolutionary Ecology Research* 14: 325-341. (in English) ["Background: Female-limited colour polymorphisms occur in many species of Odonata. Often one female morph appears male-like in coloration (androchromes) whereas one or more others are distinct from males (gynochromes). These androchromes are hypothesized to be male-mimics, thereby avoiding the harassment of excessive male mating attempts. Organism: *Ischnura ramburii*, Rambur's forktail, is a widespread New World species with androchrome and gynochrome females. It was introduced to the Hawaiian Islands in the mid-1970s and females were thought to be exclusively gynochromatic there. Questions: How do males and females differ in their flight apparatus? Do females with different colour morphologies also differ in flight morphology? Hypothesis: Because male-like coloration is sometimes associated with male-like flight behaviours, androchrome females should have more male-like wings than gynochrome females. Methods: We caught individuals of *I. ramburii* in the field from seven populations on three of the Hawaiian Islands and three populations in Texas (part of its native range). Using digitized wing and body images, we compared body size, wing size, and wing shape between sexes, between female morphs, and among geographic regions. Results: Male *I. ramburii* are smaller than females and have smaller, more slender wings. Although androchromes are absent from the Big Island of Hawaii, both androchrome and gynochrome females are common on Oahu and Kauai. Androchrome females are indistinguishable from gynochrome females in all aspects of their flight apparatus except for forewing size, which is smaller than that of gynochromes and thus more-male like. Wing shape and size vary geographically. Body- and wing-size differences between males and females are consistent across regions, although the degree and direction of sexual dimorphism in wing shape are not." 12271. Mielewicz, M.; Liebisch, F.; Walter, A.; Greven, H. (2012): Infrarot (NIR)-Reflexion bei Insekten — phänetische Untersuchungen an 181 Arten. *Entomologie heute* 24: 183-216. (in German, with English summary) ["We tested a camera system which allows to roughly estimate the amount of reflectance properties in the near infrared (NIR; ca. 700-1000 nm). The effectiveness of the system was studied by taking photos of 165 insect species including some subspecies from museum collections (105 Coleoptera, 11 Hemiptera (Pentatomidae), 12 Hymenoptera, 10 Lepidoptera, 9 Mantodea, 4 Odonata, 13 Orthoptera, 1 Phasmatodea) and 16 living insect species (1 Lepidoptera, 3 Mantodea, 4 Orthoptera, 8 Phasmatodea), from which four are exemplarily pictured herein. The system is based on a modified standard consumer DSLR camera (Canon Rebel XSi), which was altered for two-channel colour infrared photography. The camera is especially sensitive in the spectral range of 700-800 nm, which is well-suited to visualize small scale spectral differences in the steep of increase in reflectance in this range, as it could be seen in some species. Several of the investigated species show at least a partial infrared reflectance. NIR-reflectance is especially pronounced in specimens of an overall white, red, orange and yellow colouration, but was also found in numerous green insects (e.g. the leaf katydids *Ancylecha fenestrata* and *Stipnochlora coulouiana* and the walking leaf *Phyllium celebicum*). In contrast, other green wings, as for example the metallic green wings of the butterfly *Troides priamus* or the metallic green elytra of several jewel beetles such as *Chrysaspis aurovittata*, do not reflect NIR-radiation... 3.2.5. Odonata (museum specimen): In contrast to the yellow spots on the abdomen of a female *Libellula depressa*, the dark body parts of Odonata species did not show any NIR-reflectance. Whitish transparent exuviae of various unclassified species generally showed a high reflectance (data not shown)." (Authors)] Address: Mielewicz, M., ETH Zürich, Institute of Agricultural Sciences, Universitätstr. 2, CH-8092 Zürich, Switzerland. E-Mail: michaemi@ethz.ch

12272. Moenickes, S.; Frassl, M.; Schlieff, J.; Kupisch, M.; Mutz, M.; Suhling, F.; Richter, O. (2012): Temporal patterns of populations in a warming world: a modelling framework. *Marine Biology* 159(11): 2605-2620. (in English) ["In this paper, we present an approach for describing the environmentally induced temporal pattern of structured populations by partial integro-differential equations. Populations are structured according to size or stage. Growth, energy allocation and stage transitions are affected by environmental conditions of which temperature, photoperiod, water depth and food supply were taken into account. The resulting modelling framework was applied to describe, analyse and predict alterations in populations with continuous development, populations with distinct state structures and interacting populations. Our exemplary applications consider populations of freshwater Amphipoda, Isopoda and Odonata. The model was capable of simulating life cycle altera-

tions in dependence on temperature in interaction with other environmental factors: (1) population dynamics, (2) seasonal regulation, (3) water depth-dependent dispersal, (4) intraguild predation and (5) consumer-resource dynamics." 12273. Mohamed, Z. Y.A.; Osman, K.S.M.; Mohamed, I.E.E.; Bakry, S.M. (2012): Impact of water-pH values on the consumption capacity of certain aquatic insects preying on different medical snails. *Journal of Evolutionary Biology Research* 4(3): 39-51. (in English) ["The main aim of this work was to determine the consumption capacity of five aquatic insects (as predators) on four species of medical snails (as preys) tested under four values of pH at a constant and controlling temperature in the laboratory. The predators were represented by adults of two hemipterous species (*Limnogeton fieberi* Mayr, *Sphaerodema urinator* Duf.) and three larval odonatus species (*Anax imperator*, *Crocothemis erythraea* and *Ischnura pumilio*). Moreover, the four water-pH values were 5, 7, 9, and 11 at 30°C. On the other hand, the four prey of the medical snails were *Bulinus truncatus* Audouin, *Biomphalaria alexandrina* Ehrenb, *Cleopatra bulimoides* Olivier and *Melanoides tuberculata* Muller. All of individual fauna were collected from the River Nile in Qena. The acidic media were adjusted as a mixture of three acids phosphoric acid acetic acid boric acid. In contrast, the alkaline solution was prepared by sodium hydroxide. The results illustrate that, the maximum predation occurred under 7 pH and 9 pH at 30°C regardless of the laboratory conditions. It appeared that *Bulinus truncatus* was highly preferable snail species to these predators. *Biomphalaria alexandrina* which is the intermediate host of *Schistosoma mansoni* Bilharz, may be the lastly preferable snail species to these predators. The belostomatids (*Limnogeton fieberi* and *Sphaerodema urinator*), and the odonats (*A. imperator*, *C. erythraea* and *I. pumilio*), could be the highest successful predators on the harmful snails (*Bulinus truncatus*, *Melanoides tuberculata*, *Biomphalaria alexandrina* and *Cleopatra bulimoides*). Therefore, its use should be encouraged to be reared in large numbers and then released in the natural places of snails under 7 to 9 range values of water pH." (Authors)] Address: Mohamed, Z. Y., Zoology and Entomology Dept, Faculty of Science in Qena, South Valley University Egypt

12274. Moreno Pallares, M.I.; Guillot Monroy, G.H., (2012): Distribución espacial y temporal de náyades de odonatos en los humedales La Vaca y Santa María del Lago, Bogotá, Colombia. *Acta biol. Colomb.* 17(2): 281-294. (in Spanish, with English summary) ["We evaluated the spatial and temporal variation in communities of dragonfly's naiads and their association to the habitat rehabilitation status in LaVaca and Santa María del Lagowetlands. Four samplings were carried out in several sites of each during a year. Macroinvertebrates were collected at the entry and exit flow, and in open waters of the wetlands using standard techniques. We found a gradient in the distribution of the abundance of nymphs in both wetlands, where naiads community had the highest number of individuals in the places located farther from the dumping sites. Comparing the community composition between wetlands La Vaca and Santa María del Lago through the beta diversity, heterogeneity was found in both ecosystems. The gradient in the

distribution of the abundance of naiads observed in both wetlands fits with to a response of the species in terms of tolerance to the environmental variables." 12275. Murashige, T. (2012): The record of an aberrant dark form of male *Ischnura senegalensis* (Rambur). Tombo 54: 70. (in Japanese, with English summary) ["An aberrant dark form of the male of *Ischnura senegalensis* was recorded from Kishiwada city, Osaka prefecture, Japan. This specimen has a uniformly black coloration on the whole head, synthorax, legs, basal abdomen and its dorsum, with only faintly bluish parts on the 8th and 9th segments. The green colour of typical specimens is totally absent and replaced by black." (Author)] Address: not stated

12276. Nilsson, V. (2012): Thermal adaptation along a latitudinal gradient in damselflies. Doctoral thesis. Umeå University, Faculty of Science and Technology, Department of Ecology and Environmental Sciences: XII + 35 pp. (in English) ["Understanding how temperature affects biological systems is a central question in ecology and evolutionary biology. Anthropogenic climate change adds urgency to this topic, as the demise or success of species under climate change is expected to depend on how temperature affects important aspects of organismal performance, such as growth, development, survival and reproduction. Rates of biological processes generally increase with increasing temperature up to some maximal temperature. Variation in the slope of the initial, rising phase has attracted considerable interest and forms the focus of this thesis. I explore variation in growth rate-temperature relationships over several levels of biological organization, both between and within species, over individuals' lifetime, depending on the ecological context and in relation to important life history characteristics such as generation length and winter dormancy. Specifically, I examine how a clade of temperate damselflies have adapted to their thermal environment along a 3,600 km long latitudinal transect spanning from southern Spain to northern Sweden. For each of six species, I sampled populations from close to the northern and southern range margin, as well from the centre of the latitudinal range. I reared larvae in the laboratory at several temperatures in order to measure individual growth rates. Very few studies of thermal adaptation have employed such an extensive sampling approach, and my findings reveal variation in temperature responses at several levels of organization." 12277. Nishadh, K.A.; Das, K.S.A. (2012): Metazoan community composition in tree hole aquatic habitats of Silent Valley National Park and New Amarambalam Reserve Forest of the Western Ghats, India. Journal of Threatened Taxa 4(14): 3312-3318. (in English) ["In a study of the metazoan community composition in tree hole aquatic habitat of a tropical rainforest, Silent Valley National Park, and the adjacent moist deciduous forest, New Amarambalam Reserve Forest, of the Western Ghats, 28 different species were recorded from 150 tree hole aquatic habitats with an average of 3-5 species per tree hole. Most of the recorded organisms (96.8%) belong to Odonata (no details on more detailed

taxonomic units), Heteroptera, Diptera, Coleoptera and Trichoptera. The study reports the first record of toe-winged beetle larvae (Ptilodactylidae) in a tree hole aquatic habitat. The most significant observation is the prolific occurrence of trichopteran larvae as the second most abundant taxa in tree holes of Silent Valley National Park, and this stands as the first comprehensive record of the entire order in the habitat studied. The study upholds the importance of less explored microhabitats in the Western Ghats region in terms of sustaining unique community composition in the most delicate and extreme habitat conditions. It also puts forward important ecological research questions on biodiversity ecosystem functionality which could impart important lessons for managing and conserving the diminishing tropical evergreen forests which are significant for these unique habitats." 12280. Novak, C.W.; Goater, T.M. (2012): Introduced bullfrogs and their parasites: *Haematoloechus longiplexus* (Trematoda) exploits diverse damselfly intermediate hosts on Vancouver Island. Journal of Parasitology 99(1): 59-63. (in English) ["The lung fluke, *Haematoloechus longiplexus*, is the most prevalent and abundant parasite of introduced bullfrogs on Vancouver Island, British Columbia, Canada. The ecological success of this trematode in invasive bullfrogs is related to the fluke's ability to utilize native intermediate hosts for transmission. The purpose of this study was to identify the odonate species involved in the transmission of *H. longiplexus* to the introduced bullfrog. The prevalences and mean intensities of 21 species of odonates (nymphs and adults) were examined for metacercariae infections. *Haematoloechus longiplexus* is a second intermediate host specialist, being found only in damselflies. Six damselfly species exhibiting the 'climber' ecological

habit were identified as second intermediate hosts of *H. longiplexus*. *Enallagma carunculatum* (prevalence = 75.0%, mean intensity = 17.2 ± 10.8), *Ischnura cervula* (65.2%, 8.9 ± 4.3), *Ischnura perparva* (45.5%, 15.4 ± 10.3), and *Enallagma boreale* (40.7%, 4.8 ± 7.8) were the most commonly infected damselfly species. Metacercariae were absent in damselflies collected from sites lacking bullfrogs. *Haematoloechus longiplexus* was likely introduced along with the bullfrog, and subsequently adapted to the physid snail and diverse damselfly intermediate hosts present in ponds on Vancouver Island." 12284. Omopariola, C.A. (2012): Survey of Aquatic Insects of Ogun River Nigeria and Its Physico-Chemical Properties. Undergraduate These, Biological Sciences, Federal University of Agriculture, Abeokuta: (in English) [Nigeria; "This study was carried out to determine the abundance, composition, distribution of aquatic insects

and physico - chemical factors of Ogun River. The aquatic insects were collected using sweep and pond net (0.5mm) from two study sites during February and middle April 2012. The water samples and insects were collected once in a week. Insects were sampled using standard entomological methods, while water samples was analysed using standard winkler's titrimetric and APHA methods to determine the chemical properties. Water analyses were conducted in the laboratory of Ogun State Water Corporation, Abeokuta, Ogun State. While insects identifications were done in the laboratory in the Department of Agricultural - Biology, University Of Ibadan. Results show that five orders and thirteen families were found with the highest number of aquatic insects from the order Odonata. The most abundant family were Coenagrionidae and Libellulidae respectively. Physico - chemical values, water temperature, pH, DO, Conductivity and Nutrient were measured. Only conductivity had the greater value among the water quality parameters. Bar chart were used to compare the physico - chemical parameters." (Author) Address: not stated

12291. Plotnikova, S.I.; Svidersky, V.L.; Gorelkin, V. S. (2012): Peculiarities of structural-functional organization of the motor neuropil in the dragonfly thoracic ganglia. *Journal of evolutionary biochemistry and physiology* 48(5-6): 568-573. ["The study considers structural-functional relations in motor neuropil of the thoracic ganglia in dragonflies-insects capable of performing very complex and fast maneuvering in flight. The motor neuropil in dragonflies was shown to be more differentiated than in less mobile insects, while its motor nuclei are more outlined and approached to each other. There were revealed dendrites of the leg muscle motoneurons (intermediate nucleus), running to the anterior and posterior nuclei that contain dendrites of the wing muscle motoneurons. A possible role of such a dendrite approaching is discussed for close functional cooperation of wing and leg muscles essential for dragonflies to catch a large prey in flight by using their legs. Peculiarities of structural organization of the wing muscle motoneurons in dragonflies and locusts are considered to suggest the greater functional capabilities of motoneurons in the dragonfly motor apparatus." 12292. Postler, E.; Postler, W.; Schiel, F.-J.; Martens, A. (2012): Die Quagga-Muschel *Dreissena rostriformis bugensis* als neuer Aufsitzer von Libellenlarven (Bivalvia: Dreissenidae; Odonata: Gomphidae, Libellulidae). *Libellula* 31(3/4): 237-241. (in German, with English summary) ["The quagga mussel *Dreissena rostriformis bugensis* as a new epizoon of odonate larvae (Bivalvia: Dreissenidae; Odonata: Gomphidae, Libellulidae) – Individuals of *Dreissena rostriformis bugensis*, an invasive species rapidly spreading in navigable inland waters of Central Europe, were reported from two exuviae of *Gomphus vulgatissimus* collected at the Datteln-Hamm-Kanal near Bergkamen, Germany, on 03-v-2012 and from an exuvia of *Orthetrum cancellatum* collected at a gravel-pit lake on 27-v-2012 next to the Upper Rhine River near Dettenheim north of Karlsruhe, Germany. These seem to be the first records of *D. r. bugensis* epizoic on odonate larvae; so far all reports from North America and from Western and Central Europe deal with the zebra mussel *Dreissena polymorpha*. Further findings of *D. rostriformis* settling epizoically on odonate larvae are expected." (Authors)] Address: Postler, W., Hammer Str. 39, D-59174 Kamen, Germany. E-mail: w.postler@t-online.de

12293. Prpic, N.-M. (2012): Nomenclatural note on the identity of *Agrion viridis* Vander Linden, 1820: a plea for the selection of a neotype (Odonata: Zygoptera, Libellulidae). *Nachrichtenblatt der Bayerischen Entomologen* 61(3/4): 76-79. (in German, with English summary) ["It has been recognized previously that the name for the Western Willow Spreadwing, *Lestes viridis*, in its original combination *Agrion viridis* Vander Linden, 1825, is a junior homonym of *Agrion viridis* Vander Linden, 1820, which is regarded as a junior synonym of *Lestes barbara*. The junior homonym normally must be replaced by its junior synonym *Agrion leucopsallis* De Charpentier, 1825, which would remove a well established and widely used name from the Odonata. Here I show that *Agrion viridis* Vander Linden, 1820, is no synonym of *Lestes barbara*, but has been based on a heterogeneous type series that also contained several other *Lestes* species. Since no types are extant, it is suggested that a topotypic neotype should be selected to establish the identity of *Agrion viridis* Vander Linden, 1820, with the species currently called *Lestes viridis*. This action would conform to the regulations of the International Code of Zoological Nomenclature and preserve the usage of *Lestes viridis*." (Author)] Address: Prpic, N.-M., Georg-August-Universität Göttingen, Johann-Friedrich-Blumenbach-Institut für Zoologie und Anthropologie, Abteilung für Entwicklungsbiologie, GZMB Ernst-Caspari-Haus, Justus-von-Liebig-Weg 11, 37077 Göttingen, Germany. 12295. Pugh, A.R. (2012): Effects of restoration on the waterways in the Styx River catchment. *The Weta* 44: 28-41. (in English) ["Riparian restoration of waterways is important in restoring, preserving, and enhancing their ecological and aesthetic values, particularly in lowland Canterbury where most waterways are severely degraded due to anthropogenic changes to the landscape. In order to assess the effects of riparian restoration in the Styx River catchment, aquatic macroinvertebrates were sampled at eight sites, seven within the Styx River catchment and a control site (there with *Xanthocnemis*). Comparisons were made between sites using the SQMCI biotic index, taxon richness and diversity, percentage EPT taxa, and by analysing macroinvertebrate community composition dissimilarity. The Styx River catchment is in relatively good condition compared to other lowland urban waterways in Canterbury; riparian restoration appears to be beneficial for the waterway macroinvertebrate communities, but currently unrestored sites require more than restoration of the riparian zone." (Author)] Address: Pugh, A.R., Dept of Ecology, Lincoln University, New Zealand. E-mail: Andrew.Pugh@lincolnuni.ac.nz

12296. Rebora, M.; Salerno, G.; Piersanti, S.; Dell'Otto, A.; Gaino, E. (2012): Olfaction in dragonflies: Electrophysiological evidence. *Journal of Insect Physiology* 58(2): 270-277. (in English) ["The problem of olfaction in Paleoptera (Odonata, Ephemeroptera) cannot be considered fully elucidated until now. These insects have been traditionally considered anosmic, because their brain lacks glomerular antennal lobes, typically in-

involved in Neoptera odor perception. In order to understand if the presumed coeloconic olfactory receptors described on the antennal flagellum of adult Odonata are really functioning, we performed an electrophysiological investigation with electroantennogram (EAG) and single cell recordings (SCR), using *Libellula depressa* as a model species. Odors representing different chemical classes such as (Z)-3-hexenyl acetate (acetate ester), (E)-2-hexenal, octanal (aldehydes), (Z)-3-hexen-1-ol (alcohol), propionic acid, butyric acid (carboxylic acids), and 1,4-diaminobutane (amine) were tested. Most of the tested chemicals elicited depolarizing EAG responses in both male and female antennae; SCR show unambiguously for the first time the presence of olfactory neurons in the antennae of *L. depressa* and strongly support the olfactory function of the coeloconic sensilla located on the antennal flagellum of this species. Electrophysiological activity may not necessarily indicate behavioural activity, and the biological role of olfactory responses in Odonata must be determined in behavioural bioassays. This study represents a starting point for further behavioural, electrophysiological, neuroanatomical and molecular investigation on Odonata olfaction, a research field particularly interesting owing to the basal position of Paleoptera, also for tracing evolutionary trends in insect olfaction. Olfaction in Paleoptera (Odonata/Ephemeroptera) is still an open question. *Libellula depressa* bears presumed olfactory sensilla on its antennae. We performed an electrophysiological investigation (EAG, SCR) on these antennae. Depolarizing EAG and SCR responses to chemicals were recorded in males and females. This is the first clear identification of olfactory receptor neurons in Odonata." 12297. Rosario, K.; Dayaram, A.; Marinov, M.; Ware, J.; Kraberger, S.; Stainton, D.; Breitbart, M.; Varsani, A. (2012): Diverse circular single-stranded DNA viruses discovered in dragonflies (Odonata: Epiprocta). *Journal of General Virology* 93: 2668-2681. (in English) ["Viruses with circular single-stranded DNA (ssDNA) genomes that encode a replication initiator protein (Rep) are among the smallest viruses known to infect both eukaryotic and prokaryotic organisms. In the past few years an overwhelming diversity of novel circular Rep-encoding ssDNA (CRESS-DNA) viruses has been unearthed from various hosts and environmental sources. Since there is limited information regarding CRESS-DNA viruses in invertebrates, this study explored the diversity of CRESS-DNA viruses circulating among insect populations by targeting dragonflies (Epiprocta), top insect predators that accumulate viruses from their insect prey over space and time. Using degenerate PCR and rolling circle amplification coupled with restriction digestion, 17 CRESS-DNA viral genomes were recovered from eight different dragonfly species collected in tropical and temperate regions. Nine of the genomes are similar to cycloviruses and represent five species within this genus, suggesting that cycloviruses are commonly associated with insects. Three of the CRESS-DNA viruses share conserved genomic features with recently described viruses similar to the mycovirus *Sclerotinia sclerotiorum* hypovirulence-associated DNA virus 1, leading to the proposal of the Gemycircularvirus genus. The remaining viruses are divergent species representing four novel CRESS-DNA viral genera including a gokushovirus-like prokaryotic virus (microphage) and

three eukaryotic viruses with Repts similar to circoviruses. The novelty of CRESS-DNA viruses identified in dragonflies using simple molecular techniques indicates that there is an unprecedented diversity of ssDNA viruses among insect populations." 12298. Rosset, V.; Simaika, J.P.; Arthaud, F.; Bornette, G.; Samways, M.J.; Oertli, B.; Vallod, D. (2012): Comparative assessment of scoring methods of the conservation value of biodiversity in ponds and small lakes. *Aquatic Conservation: Marine and Freshwater Ecosystems* 23: 23-36. (in English) ["Fresh waters are among the most endangered ecosystems in the world. Practical tools to measure their biodiversity value are needed for their effective conservation. Besides species richness, other aspects of biodiversity, including the threat level of species also need to be considered. Currently, existing scoring methods for assessing the conservation value of freshwater fauna and flora assemblages are varied, and guidelines to select an appropriate method are lacking. In this paper, it is hypothesized that scores to assess the conservation value of assemblages can vary markedly according to the type of method used. To test this, four types of scoring methods were applied differing in the weight given to Red List categories and in the expression of the score, i.e. either using mean per species or the assemblage as a whole, on sets of dragonfly and macrophyte data collected from varied types of small lakes and ponds in three different countries (France, Switzerland and South Africa). The comparison of the different types of methods showed that the type of method used had a marked impact on the assessment of the conservation value of a water body: the expression per species or per assemblage as the weight given to Red List categories changed the value of a given water body. Overall, results also confirmed that the different types of methods could be applicable in different geographical areas and types of standing water bodies, independently of the original area where the method was developed. Results illustrated that, besides the species richness assessment commonly used, calculating conservation value as a mean per species is useful because it provides additional information. Overall, using methods expressed as a mean per species and coupling the Red List with other criteria gave the best performance." (Authors) The analysis includes Odonata identified at the order level.] Address: Rosset, Véronique, University of Applied Sciences Western Switzerland, hepia Geneva technology, architecture and landscape, 1254 Jussy-Geneva, Switzerland. 12299. Rudolph, R. (2012): Die Libellen der Germanengöttin Frigga. *Odonatologica* 41(3): 251-266. (in English) ["In 1919, the German author Hermann Löns published 'Wasserjungfern. Von Sommerboten und Sonnenkundern' (Voigtländer-Verlag, Leipzig), a collection of thirteen dragonfly stories written in a particular emotional style. Here Löns stated that in paganian Germanic times dragonflies had been consecrated to the goddess Frigga and that, therefore, early missionaries had damned dragonflies as diabolic, imposing on them the names 'Satansbolzen' and 'Teufelsnadel'. The 'Wasserjungfern' were reprinted many times up to today and these statements have become widespread popular belief in Germany. Their diction being close to Nazi-terminology,

Löns's statements as to Frigga and the damnation of dragonflies were amended from the first edition following WW II but appeared again in all later editions. Here it is shown, by analyzing mythological and earliest clerical as well as ethnographic and old entomological literature, that dragonflies never have been consecrated to a Germanic goddess and that no clerical damnation ever took place." 12300. Sabagh, L.T.; Carvalho-e-Silva, A.M.P.T.; Rocha, C.F.D. (2012): Biota Neotropica 12(4). Diet of the toad *Rhinella icterica* (Anura: Bufonidae) from Atlantic Forest highlands of southeastern Brazil: 258-262. (in English, with Portuguese summary) ["In this study, we present some information of the regarding trophic niche from the anuran toad *R. icterica* living in high altitudes above 2000 m a.s.l. from a habitat of the Atlantic Forest Biome – the Altitude Fields in the Itatiaia National Park. We found 150 prey items in toad stomachs, belonging to five prey types, as well as skin remains and some remains of plant material. The index of relative importance indicated that most important prey types were beetles and ants, these last composing 70% of the diet numerically and the trophic niche breadth (B) was 1.81. The relatively low diversity of prey types we recorded in the diet of *R. icterica* of Itatiaia and numerically dominated by ants suggests some preference for this item. We do not found significant relationship between the toad measurements with the preys' measurements. We concluded that *R. icterica* toads at the highlands of Itatiaia feeds on arthropods, mainly ants and coleopterans and that the high consumption of preys with relatively small and similar size as ants in the diet prevents an expected relationship among frog body or mouth size and prey volume and size." (Authors) Odonata contributed with 1.3% (n=2) to the diet of 17 toad specimens.] Address: Sabagh, L.T., Laboratório de Ecologia de Vertebrados, Depto de Ecologia, Univ. do Estado do Rio de Janeiro – UERJ, Rua São Francisco Xavier, 524, Maracanã, CEP 20550-019, Rio de Janeiro, RJ, Brasil. 12303. Schneider, T.; Schneider, J. (2012): Sommerbeobachtungen von Libellen am unteren Nil in Ägypten (Odonata). *Libellula* 31(3/4): 257-266. (in German, with English summary) ["Summer observations of Odonata on the Lower Nile in Egypt – In June 2012, a total of 13 species was recorded on the River Nile south of Cairo. Of special interest was the first record of *Acisoma panorpoides* on the Nile in Egypt. This shows that the Nile can be used as a corridor by this species to reach the Mediterranean coast from tropical Africa. *Mesocnemis robusta*, a species which is classified as «critical relict» or «critically endangered» for North Africa, was found to be one of the most abundant dragonflies on the Nile. Some observations from the Nile Delta are added." (Authors)] Address: Schneider, T., Arnold-Knoblauch-Ring 76, 14109 Berlin/Wannsee, Germany. E-mail: thomas.rs@gmx.de

12304. Schorr, M.; Wolf, J. (2012): Bibliografie der für Deutschland publizierten Libellenliteratur (Odonata). *Libellula*, Supplement 11: 5-420. (in German, with English summary) ["This bibliography is a summary of over 6,400 titles about the Odonata of Germany. It starts with a quotation of 6,018 titles with relevance to Germany, including titles that originated in academic institutions. Besides individual studies, these were researched from about 1,000 periodicals from several countries. To ease the research on species, faunistic, biological, ecological, and geographical facts, all titles are tagged to approximately 1,000 words or phrases. Thanks to many parts also being in English, the contents of the quoted literature are also open to foreign users. The next chapter reviews around 400 quotations of unpublished titles about Odonata. Because of the nature of "grey literature" this chapter surely can only be a selection of an unknown amount of expertise and other unpublished literature." (Authors)] Address: Schorr, M., Schulstr. 7B, 54314 Zerf, Germany. E-mail: bierschorr@online.de

12305. Schröter, A.; Borisov, S.N. (2012): *Coenagrion scitulum* in Central Asia: a biogeographical analysis and rectification (Odonata: Coenagrionidae). *Libellula* 31(3/4): 267-283. (in English, with German summary) ["This study provides information on the occurrence of *Coenagrion scitulum* in Central Asia, in English for the first time. Based on critical evaluation of published and previously unpublished data, a schedule of records and an up-to-date distribution map is presented. With reference to occurrence of *C. scitulum* in Europe, specific chorological and ecological characteristics of Central Asian *C. scitulum* are discussed and by means of the example of a Kyrgyz population a regional habitat of *C. scitulum* is

described. *C. scitulum* is among those dragonfly species being widely distributed in Europe and whose eastern limit of distribution runs through Central Asia. Due to language barriers and insufficient communication, a considerable lack of knowledge of the proper distribution range of such species amongst European odonatologists seems to persist. This article addresses the knowledge gap and aims to rectify erroneous statements and establish the correct eastern limit of distribution of *C. scitulum* in European non-Russian-language odonatological literature." 12306. Selva Kumar, C.; Nair, R.R.; Sivaramakrishnan, K.G.; Ganesh, D.; Janarthanan, S.; Arunachalam, M.; Sivaruban, T. (2012): Influence of certain forces on evolution of synonymous codon usage bias in certain species of three basal orders of aquatic insects. *Mitochondrial DNA* 23(6): 447-460. (in English) ["Forces that influence the evolution of synonymous codon usage bias are analyzed in six species of three basal orders of aquatic insects. The rationale behind choosing six species of aquatic insects (three from Ephemeroptera, one from Plecoptera, and two from Odonata) for the present analysis is based on phylogenetic position at the basal clades of the Order Insecta facilitating the understanding of the evolution of codon bias and of factors shaping codon usage patterns in primitive clades of insect lineages and their subtle differences in some of their ecological and environmental requirements in terms of habitat-microhabitat requirements, altitudinal preferences, temperature tolerance ranges, and consequent responses to climate change impacts. The present analysis focuses on open reading frames of the 13 protein-coding genes in the mitochondrial genome of six carefully chosen insect species to get a comprehensive picture of the evolutionary intricacies of codon bias. In all the six species, A and T contents are observed to be significantly higher than G and C, and are used roughly equally. Since transcription hypothesis on codon usage demands A richness and T poorness, it is quite likely that mutation pressure may be the key factor associated with synonymous codon usage (SCU) variations in these species because the mutation hypothesis predicts AT richness and GC poorness in the mitochondrial DNA. Thus, AT-biased mutation pressure seems to be an important factor in framing the SCU variation in all the selected species of aquatic insects, which in turn explains the predominance of A and T ending codons in these species. This study does not find any association between microhabitats and codon usage variations in the mitochondria of selected aquatic insects. However, this study has identified major forces, such as compositional constraints and mutation pressure, which shape patterns of codon usage in mitochondrial genes in the primitive clades of insect lineages." 12308. Sheikh, E.M.; Douglas, M. (2012): Biodiversity, phenology, and thermoregulatory strategies of odonates at Pierce Cedar Creek Institute. Undergraduate Research Grants for the Environment Report, Grand Rapids Community College: 24 pp. (in English) ["Forty-three species of dragonflies from five families and sixteen species of damselflies from three families were identified at Pierce Cedar Creek Institute in Hastings, Michigan (latitude 42.6459 and longitude -85.2908) between May 7 and August 10, 2012. Our study showed that Pierce Cedar Creek Institute provides habitat to a greater number and variety of odonates than expected. The diurnal phenology of the odonates varied by species, with smaller and medium dragonflies generally out earlier in the day and active into the afternoon, and large dragonflies are more active near dusk. We found that dragonflies and damselflies use a variety of active and passive thermoregulatory strategies. We found that the mean ΔT (the difference between ambient and thoracic temperature) as well as the heating / cooling curves and preferred flight temperatures, are positively correlated with increasing thoracic size of the odonate. In addition, we found that the flow of haemolymph from the wings to the thorax does not function to significantly regulate thoracic temperature." (Authors)] Address: Sheikh, Elaine M.

12309. St. Clair, C. (2012): Effects of atrazine exposure on immune function and cannibalistic behavior of dragonfly larvae. M.S. thesis, Murray State University: 74 pp. (in English) ["Chapter 1: Agricultural runoff containing herbicide is known to have adverse effects on freshwater organisms. Aquatic insects are particularly susceptible, and herbicide runoff has the potential to affect immunity in this group. I examined the effect of atrazine, an herbicide commonly used in the United States, on immune function in larvae of *Plathemis lydia* during a long-term exposure at ecologically relevant concentrations. Larvae were exposed to concentrations of 0, 1, 5 and 10 ppb atrazine for three or six weeks. Haemocyte counts, haemolymph phenoloxidase (PO) activity, cuticular and gut PO, encapsulation ability and post-encapsulation PO were measured at the end of each trial period as indicators of immune system strength. Atrazine concentration had a significant effect on haemocyte counts after controlling for the effect of larva size. There was a significant interaction between time and concentration for haemolymph PO, cuticular PO, and a marginal interaction for gut PO. Therefore, atrazine affects both haemocyte numbers and phenoloxidase activity over time in *P. lydia*. The exact impact of the changes is unclear. However, the changed immune function demonstrated in this study is likely to modify susceptibility to pathogens, alter wound healing and may decrease available energy for growth and metamorphosis. Chapter 2: Agricultural runoff containing herbicide is known to have adverse effects on freshwater organisms. Aquatic insects are particularly susceptible, and herbicide runoff has the potential to affect behaviour in this group. Here I examine the effects of short-term exposure to the herbicide atrazine on cannibalistic behaviour in larvae of *Libellula luctuosa*. Large focal larvae (> 12 mm length) were exposed to 0, 1, 10, or 100 ppb atrazine for 96 hours. A smaller (< 8 mm) conspecific was then placed with the focal larva, and its behaviour observed for 30 minutes. Time until

initiation of stalking and time until strike were noted. After the initial 30 minutes, each pair was checked at 2, 4, 6, 24 and 48 hours. Time of consumption and amount consumed were noted. The number of larvae that engaged in cannibalistic activity within the initial 30-minute observation period was significantly higher for controls compared to all experimental treatments. When stalking, striking and consumption times were examined together (a measure of overall response time) concentration had a significant effect, with the 10 ppb group taking significantly longer to cannibalize than the control group." 12310. Stavenga, D.G.; Leertouwer, H.L.; Hariyama, T.; De Raedt, H.A.; Wilts, B.D. (2012): Sexual dichromatism of the damselfly *Calopteryx japonica* caused by a melanin-chitin multilayer in the male wing veins. PLoS ONE 7(11): e49743. doi:10.1371/journal.pone.0049743: 7 pp. (in English) ["Mature male *C. japonica* damselflies have dark-blue wings, due to darkly coloured wing membranes and blue reflecting veins. The membranes contain a high melanin concentration and the veins have a multilayer of melanin and chitin. Female and immature *C. japonica* damselflies have brown wings. We have determined the refractive index of melanin by comparing the differently pigmented wing membranes and applying Jamin-Lebedeff interference microscopy. Together with the previously measured refractive index of chitin the blue, structural colour of the male wing veins could be quantitatively explained by an optical multilayer model. The obtained melanin refractive index data will be useful in optical studies on melanized tissues, especially where melanin is concentrated in layers, thus causing iridescence." 12311. Stewart, S.S. (2012): Variation in fluctuating asymmetry among nine damselfly species. M.S. thesis. Dept. of Biology. Baylor University: (in English) ["Fluctuating asymmetry (FA), measured as random deviations from bilateral symmetry, likely results from developmental disturbances by internal or environmental stresses. However, comparisons of FA in single damselfly species from stressed environments have often been inconclusive. We measured levels of FA among multiple species of damselflies from the same environment to determine the relative roles of environmental stress and species specific developmental instability. Damselflies of nine species were collected from a central Texas wetland. Calculations of their FA were based on cell counts of four venation patterns in fore and hind wings. Significant FA of venation occurred in both sexes, both wing positions, and in each of four venation patterns of all nine species. Levels of FA were not significantly different between sexes or between wing positions for any of the nine species. However, FA varied significantly among the four venation patterns. Patterns with lowest mean cell counts had significantly higher FA than the other patterns, despite scaling to remove size bias. More broadly, a three-fold difference in overall FA occurred among the nine species and was not correlated with species mean weight or abdomen length. The wide range of FA levels among multiple species in the same environment casts doubt on the effective use of FA of a single species to indicate of environmental stress. Future research must examine the relative roles of species-specific predispositions for FA from internal genetic

stresses as well as external stressors." (Author) For a published version of the thesis see: Stewart, S.S.; Vodopich, D.S. 12313. Suhonen, J.; Suutari, E.; Kaunisto, K.M.; Krams, I. (2012): Patch area of macrophyte *Stratiotes aloides* as a critical resource for declining dragonfly *Aeshna viridis*. *Journal of Insect Conservation* 17(2): 393-398. (in English) ["Currently, many rare and endangered species occur in fragmented habitats. Habitat patch size is often used as an easily measured surrogate of habitat quality and local population size. We investigated whether habitat patch size affects the presence and density of larvae of the endangered dragonfly *Aeshna viridis*, which for a large part of their life history depend on the macrophyte *Stratiotes aloides* rosette. The study was performed in four populations, two from Finland and two from Latvia. Our main result was that density of *A. viridis* and patch occupation increased with area of *S. aloides* patch. The results may be due to larvae actively avoiding enemies (higher survival) and/or to the possibility that females laid higher number of eggs in the large *S. aloides* patches. Our results indicate that local abundance and persistence of *A. viridis* population may depend on the few, large *S. aloides* patches rather than several small patches of equal total area." 12314. Taylor, D.J.; Titus-Mcquillan, J.; Bauer, A.M. (2012): Diet of *Chalcides ocellatus* (Squamata: Scincidae) from southern Egypt. *Bulletin of the Peabody Museum of Natural History* 53(2): 383-388. (in English) ["We studied the diet of the skink *C. ocellatus* (Forskål, 1775) from southern Egypt using stomach contents from a large series of specimens collected during the Yale University Prehistoric Expedition to Nubia. Only 2.5% of specimens contained identifiable prey items. Insect larvae, coleopterans and orthopterans were the most important prey items. The first two of these prey categories are typically among the most important in the diet of this species in other areas of its broad distribution. Males and females differed somewhat in their diets and had a dietary overlap of 0.607. Males had relatively larger head widths than females, but this is likely to be related to sexual selection rather than dietary segregation.

12315. Termaat, T.; Kalkman, V.J. (2012): De nieuwe Rode Lijst Libellen. *Vlinders* 2 2012: 4-7. (in Dutch, with English summary) ["The new Red List for dragonflies: Red Lists have to be updated every ten years, and as the previous Red List for dragonflies of the Netherlands was written in 1997, a new one was finally made in 2011. As the current method for evaluating species differs, the 1997 data had to be re-evaluated to make comparison of the lists possible. During the last fourteen years, the status of Dutch dragonflies has improved. Three nationally extinct species reappeared. Eight species have increased, now considered to be of least concern. Six more species have become less threatened. The downside is that two species which used to be of least concern are now vulnerable and one other species shifted from endangered to critically endangered. Environmental and nature conservation measures have mediated the positive picture for most dragonflies, but the improvements are not large enough for some of the most critical species. Climate change also plays a positive role for many species, but might be a risk for others. Dragonfly data collected by voluntary observers are crucial to be able to make Red Lists, now and in the future." 12318. Thipaksorn, A.; Apiwathnasorn, C.; Ruangsittichai, J. (2012): Modified molecular techniques for detecting rice odonate insects in Thailand. *Munis Entomology & Zoology* 7(2): 852-856. (in English) ["Rice odonates are beneficial predators that can help control insect pests in rice, so playing a valuable role in the rice eco-

system. Morphological classification is not reliable at the taxonomic level for some species. Thus, molecular techniques may be used to resolve species more accurately. Normally, genetic DNA sequence amplification is used in molecular identification. This study modified and developed one stage of the DNA extraction process to permit DNA extraction from a single insect leg. After cytochrome oxidase subunit 1 (COI) amplification, nucleotide banding was conducted to determine the efficiency of the extracted DNA. The results showed that this modification to DNA extraction could yield sufficient DNA to amplify the COI gene, and thus be a practical tool for detecting odonates using molecular techniques." 12320. Tyrrell, M. (2012): The impact of spring temperature on emergence patterns in five 'spring' species. *J. Br. Dragonfly Society* 28(2): 102-107. (in English) ["The first emergence dates for five 'spring' species were monitored at a single site over a seven season period. During this time, average spring temperature was also monitored and the two related to determine the impact of average air temperature on the first emergence of each species. It was noted that during warm springs, for example 2007 and 2011, the five species emerged significantly earlier than in an average spring, for example 2010. During a cold spring, for example 2012, first emergence coincided with the dates for average springs. This implies that, for these species, spring air temperature is only a critical factor determining emergence if it is high, in which case day length is not a trigger but sun intensity may be. Cooler temperatures in spring have little or no impact on first emergence compared to an average spring, in which case day length may then be the critical factor determining emergence." (Author)] Address: Tyrrell, M., 8 Warwick Close, Raunds, Northants, NN9 6JH, UK

(2012): When asymmetrical fitness costs select for suboptimal traits: the cliff-edge hypothesis revisited. *PLoS ONE* 7(4): e34889. doi:10.1371/journal.pone.0034889: 9 pp. (in English) ["The cliff-edge hypothesis introduces the counterintuitive idea that the trait value associated with the maximum of an asymmetrical fitness function is not necessarily the value that is selected for if the trait shows variability in its phenotypic expression. We develop a model of population dynamics to show that, in such a system, the evolutionary stable strategy depends on both the shape of the fitness function around its maximum and the amount of phenotypic variance. The model provides quantitative predictions of the expected trait value distribution and provides an alternative quantity that should be maximized ("genotype fitness") instead of the classical fitness function ("phenotype fitness"). We test the model's predictions on three examples: (1) litter size in guinea pigs, (2) sexual selection in damselflies, and (3) the geometry of the human lung. In all three cases, the model's predictions give a closer match to empirical data than traditional optimization theory models. Our model can be extended to most ecological situations, and the evolutionary conditions for its application are expected to be common in nature.... Our second example deals with a secondary sexual trait in *Calopteryx splendens*, using survival and mate choice data obtained in the field ([30], M. Wellenreuther, E. Vercken and E. Svensson, unpublished data)." (Authors)] Address: Vercken, Elodie, Institut Sophia Agrobiotech, UMR 1355 ISA, Institut National de la Recherche Agronomique, Sophia-Antipolis, France. (2013): Neue Ansätze digitaler Artenerfassung für den ehrenamtlichen Naturschutz Ergebnisse der Entwicklung mobiler Lösungen in Niedersachsen. *Naturschutz und Landschaftsplanung* 45(4): 101-107. (in German, with English summary) ["The collection of data on flora and fauna by honorary nature conservation has been subject of changes in terms of techniques in the field and the flow of data. During the last years web portals have been established supported by open source software including free usable maps and forms for the recording of the observations as well as identification keys, species profiles and internet platforms. The portals are hosted by NGOs and public authorities. The method of Citizen Science seems to be very effective for data collection in a broad geographical range. Voluntary data collection has been additionally facilitated by the use of mobile devices such as smartphones, simplifying data flow from the field to the NGOs or nature conservation authorities. The paper summarises the current developments of voluntary data collection. It illustrates software developments such as the DragonflyApp (LibellenApp) and the web-based GIS portal eMapper. As an additional example the paper explains the standardized digital flow of data from the field up to the Lower Saxony Water Management, Coastal Defense and Nature Conservation Agency (NLWKN) which has also been implemented within the joint research project ARDINI. The apps have been developed to run on both operating systems (iOS/ Android). The application of modern techniques of the IT sector may encourage young people to participate in honorary nature conservation." 12338. Arle, J.; Wagner, F. (2013): Effects of anthropogenic salinisation on the ecological status of macroinvertebrate assemblages in the Werra River (Thuringia, Germany). *Hydrobiologia* 701: 129-148. (in English) ["For more than 100 years, the Werra River has been severely affected by intensive salinisation caused by potash fertilizer industries. We show considerable differences in macroinvertebrate assemblages between reaches without salinisation impact and downstream reaches with intense anthropogenic salinisation in the Werra. This is true for almost all biological metrics relevant for ecological status classification under the EU-Water Framework Directive (EU-WFD) (European Community, Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy, No. L 327/1, of 22 December 2000) and diversity measures (taxon richness, evenness). Macroinvertebrate assemblages at salinisation sites were completely dominated by three halophile neobiotic macroinvertebrate species (*Gammarus tigrinus*, *Corophium lacustre* and *Potamopyrgus antipodarum*). We compared anthropogenically salinised sites from the Werra with disturbed but non-salinised sites from the Werra and other German rivers. We used biological metrics developed for classifying the ecological status according to the EU-WFD. This comparison indicated a severe degradation at salinisation sites on the Werra and these fell into the worst ecological status class 'bad' according to the EU-WFD. Multivariate statistical analyses revealed anthropogenic salinisation as a key factor causing the differences in composition of macroinvertebrate assemblages in the Werra between salinisation and reference sites. Analyses of the long-term presence-absence data of macroinvertebrate assemblages indicated no marked improvement in the ecological status in the past 20 years." (Authors) The assessment also includes the Odonata-EPTCBO (Eph., Ple., Tri., Col., Bivalv., Odo.) index.] Address: Wagner, F.,

12343. Beatty, S.J.; Morgan, D.L.; Keleher, J.; Allen, M.G.; Sarre, G.A. (2013): The tropical South American cichlid, *Geophagus brasiliensis* in Mediterranean climatic south-western Australia. *Aquatic Invasions* 8: 21-36.

(in English) ["The highly endemic (82%) freshwater fishes of south-western Australia are imperiled due to severe habitat and water quality declines and impacts of introduced species. As a case study of the recent tropical aquarium fish introductions, the biology and ecology of the pearl cichlid *Geophagus brasiliensis* was determined in the Swan River catchment south-western Australia. Unlike endemic freshwater fish species of this Mediterranean climatic region, *Geophagus brasiliensis* underwent a protracted spawning period during the warmer period from December to May. It appeared that recruitment only occurred in lentic habitats; however the species also persists in downstream lotic habitats. Growth rate and maximum size (245 mm TL) of the species exceed all but one of the region's native freshwater fishes. Whilst minimum water temperature may help limit its establishment in many aquatic ecosystems, its salinity tolerance and omnivorous diet would facilitate its colonisation in this region, including freshwaters and estuaries. Past and future habitat and climatic change is predicted to continue to favour species from sub-tropical and tropical regions." 12347. Bertoluci, J.; da Rocha, P.L.B.; Trefaut, R.M. (2013): Field evidence of coupled cycles of arthropod predator-tadpole prey abundance in six aquatic systems of an Atlantic Rainforest site in Brazil. The Herpetological Journal 23(1): 63-66 (in English) ["We evaluated the patterns of abundance association between tadpoles and their aquatic arthropod predators (including *Anax amazili*, *Aeshna punctata*, *Libellula herculea*) in natural communities of Atlantic Forest in south-eastern Brazil. We distributed 10 traps in each one of six aquatic systems and counted the numbers of tadpoles and of predators captured monthly for 13 months. For each system, we quantified the temporal association between tadpoles and predator abundances and measured its strength (using Spearman's rho coefficient) for time-lags ranging from -6 to +6 months, followed by testing the hypothesis that the strength of the association differs among time-lag values. The associations were always stronger in streams than in ponds, and strongest ($r^2 > 0.42$) and always significant ($p < 0.016$) when time-lag was zero months, resulting in significant differences of mean values of r^2 across time-lags ($p < 0.001$). A time-lag shorter than one month agrees with predictions from the model of predator-prey coupled cycles. The results also suggest that the importance of secondary factors driving abundance values in streams is stronger than in ponds, where conditions tend to be more unstable. To our knowledge, this is the first evidence of coupled cycles of predator-prey abundance with delayed dependence demonstrated with tadpoles and insects in aquatic forest systems." 12348. Bhandarkar, S.V.; Bhandarkar, W.R. (2013): A study on species diversity of benthic macro invertebrates in freshwater lotic ecosystems in Gadchiroli district Maharashtra. Int. J. of Life Sciences 1(1): 22-31. (in English) ["A study was conducted to evaluate the potential of benthic macro-invertebrates community assemblages in predicting the water quality status. Three sampling stations with various environmental quality gradients were selected at the Wainganga, Gadhavi and Khobragadhi River in Gadchiroli district in order to determine differences or changes in the benthos community associated with variability in water quality. The diversity indices like Shannon-Wiener index, Evenness or Shannon equitability index and Margalef's index were calculated. According to Shannon-Wiener index of species diversity, all the selected sampling sites fall under moderate pollution. The Shannon equitability index values showed a greater equitability in the apportionment of individuals among the species in all the sites while Margalef's index of species richness reveals that the site-I had more healthy body and have higher species diversity among all sampling sites. The species diversity of site-II is greater than site-III. The site-III had poorer in species diversity and nutrient material." (Authors) The taxa list includes "Aphylla nymph (Aeshnidae)", Gomphidae and Libellulidae.] Address: Bhandarkar, S.V., Department of Zoology, M. B. Patel College, Deori. Dist. Gondia. 441 901. MS. India. E-mail: sudhirsense@rediffmail.com

12349. Bin, L.; Mao, S. (2013): Aerodynamic interactions between wing and body of a model insect in forward

flight and maneuvers. Journal of Bionic Engineering 10(1): 19-27. (in English) ["The aerodynamic interactions between the body and the wings of a model insect in forward flight and maneuvers are studied using the method of numerically solving the Navier-Stokes equations over moving overset grids. Three cases are considered, including a complete insect, wing pair only and body only. By comparing the results of these cases, the interaction effect between the body and the wing pair can be identified. The changes in the force and moment coefficients of the wing pair due to the presence of the body are less than 4.5% of the mean vertical force coefficient of the model insect; the changes in the aerodynamic force coefficients of the body due to the presence of the wings are less than 5.0% of the mean vertical force coefficient of the model insect. The results of this paper indicate that in studying the aerodynamics and flight dynamics of a flapping insect in forward flight or manoeuvre, separately computing (or measuring) the aerodynamic forces and moments on the wing pair and on the body could be a good approximation." (Authors) The paper includes a reference to dragonflies.] Address: Bin, L., Ministry-of-Education Key Laboratory of Fluid Mechanics, Beihang University, Beijing 100191, P. R. China

12350. Bischof, M.M.; Hanson, M.A.; Fulton, M.R.; Kolka, R.K.; Sebestyen, S.D.; Butler, M.G. (2013): Invertebrate community patterns in seasonal ponds in Minnesota, USA: Response to hydrologic and environmental variability. Wetlands 33(2): 245-256. (in English) ["Seasonal ponds are common throughout forested regions of the north central United States. These wetlands typically flood due to snow-melt and spring precipitation, then dry by mid-summer. Periodic drying produces unique fishless habitats with robust populations of aquatic invertebrates. A basin's physical/chemical features, the absence of vertebrate predation, and especially the duration of seasonal flooding, have long been viewed as the major structuring influences on these communities, but previous studies have shown only limited effects of environmental variables on pond invertebrates. Applying ordination methods to data from weekly collections of invertebrates during 2008–2009, we tested influences of site-level environmental gradients on the presence and relative abundance of aquatic invertebrate communities in 16 seasonal ponds in a forested region of north central Minnesota, USA. We assessed invertebrate (including Odonata) community patterns in relation to pond size and depth, soil nutrients, canopy closure, hydroperiod, and predominant groundwater function (recharge, discharge, or flow-through). Patterns in pond invertebrate community composition were consistently related to pond depth, overhead canopy closure, and hydroperiod. Site-level hydrologic function showed weak relationships to seasonal patterns of invertebrate abundance. Although physical features of ponds had only modest influence on presence and abundance of invertebrates, weekly sampling improved models relating environmental variables to pond invertebrates." 12353. Bomfleur, B.; Decombeix, A.-L.; Escapa, I.H.; Schwendemann, A.B.; Axsmith, B. (2013): Whole-plant concept and environment reconstruction of a *Telemachus* conifer (Voltziales) from the Triassic of Antarctica. *International Journal of Plant Sciences* 174(3): 425-444. (in English) ["We present a whole-plant concept for a genus of voltzialean conifers on the basis of compression/impression and permineralized material from the Triassic of Antarctica. The reconstruction of the individual organs is based on a combination of organic connections, structural correspondences, similarities in cuticles and epidermal morphologies, co-occurrence data, and ex situ palynology. The affiliated genera of organs include trunks, branches, and roots (Notophytum); strap-shaped leaves with parallel venation (*Heidiphyllum* compressions and permineralized *Notophytum* leaves); seed cones (*Telemachus* and *Parasciadopitys*); pollen cones (*Switzianthus*); and bisaccate pollen of *Alisporites* type. Structural similarities lead us to suggest that *Parasciadopitys* is the permineralized state of a *Telemachus* cone and should be treated as a junior synonym. Biotic interactions involving the reconstructed conifer genus include plant-insect interactions (oviposition by Odonata) and not less than five different types of plant-fungal interactions, including two distinct endomycorrhizal associations, two probable seed parasites, and epiphyllous fungi. A representative whole plant is reconstructed as a 10–15-m-tall, seasonally deciduous forest tree with a vertical, narrow-conical crown shape. We interpret these *Telemachus* trees as the dominant components of peat-forming conifer swamps, forest bogs, and immature bottomland vegetation in the Triassic high-latitude river basins of southern Gondwana. In architecture, growth habit, and many ecological characteristics, the *Telemachus* conifers appear to be comparable to extant larch (*Larix*). Owing to the large amount and often exquisite preservation of the material, this conceptual whole-plant genus represents one of the most completely reconstructed ancient conifer taxa to date." tionary Biology, University of Kansas, Lawrence, Kansas 66045, U.S.A., and Natural History Museum and Biodiversity Institute, University of Kansas, Lawrence, Kansas 66045, USA

12354. Bose, A.P.H.; Robinson, B.W. (2013): Invertebrate predation predicts variation in an autotomy-related trait in larval damselfly. *Evolutionary Ecology* 27(1): 27-38. (in English) ["Autotomy, the discarding of a prey appendage grasped by a predator, may evolve when the benefits of immediate survival outweigh the costs of appendage loss. In larval damselflies, joints connecting lamellae to the abdomen vary in size and shape within and among taxa suggesting that they may evolve under selection by invertebrate predators, such as dragonfly larvae. Assuming that joint width is proportional to the force required for autotomy, we tested if invertebrate predation favours smaller lamellar joints for autotomy or larger joints for structural support of lamellae for swimming. We compared the maximum joint widths of larval *Lestes* and *Enallagma* among ponds that varied in risk of invertebrate predation. Relative predation risk estimated as the frequency of regenerated lamellae within ponds was weakly and positively related to the relative abundance of larval dragonflies. The allometry of lamellar joint size decreased with increasing risk of invertebrate predation across ponds after controlling for variation in body size in *Lestes* congener but not in *Enallagma* species. Both species of *Lestes* had larger joint sizes than the five species of *Enallagma*, suggesting that the ancestral divergence of lamellar joints between these genera may influence contemporary responses to invertebrate predation." (Authors)] Address: Bose, Aneesh, Department of Integrative Biology, University of Guelph, 50 Stone Road East, Guelph, ON, N1G-2W1, Canada. E-mail: abose@uoguelph.ca

12355. Brandon, A. (2013): Odonata news and events from across the vice counties of Anglesey, Merionethshire, Caernarvonshire, Denbighshire and Flintshire. *Y Fursen - North Wales Dragonfly Newsletter* 70: 3 pp. (in English) [The author reports from the British Dragonfly Society Recorders Conference at CEH, Wallingford, UK in March 2013, and presents a brief report on the recent trends in UK species ranges: "The records show that since 1970 they are doing much better as a group than, say, butterflies. There are more species actually increasing their range than those in decline - 14% are increasing and 5% decreasing. The winners, i.e. those species that have expanded their ranges or are colonising new sites are: *Aeshna mixta*, *A. cyanea*, *Anax imperator*, *Brachytron pratense*, *Calopteryx splendens*, *Erythromma viridulum*, *Libellula fulva*, *L. quadrimaculata*, *Orthetrum cancellatum*, *Platynemis pennipes*, *Sympetrum sanguineum*. Distinct losers are: *Aeshna grandis*, *Coenagrion puella*, *C. pulchellum*, *Enallagma cyathigerum*, *Ischnura elegans* – this includes three of our most common damselflies!" Details on the current distribution of *C. pulchellum* in North Wales, UK are presented. The journal also advises to Odonata larva videos.] Address: Brandon, A., North Wales Dragonfly Recorder, Bryn Heilyn, Rowen, Conwy LL32 8YT., UK. E-mail: allanrowenconwy@antispam.sky.com

12356. Büsse, S.; Genet, C.; Hörschemeyer, T. (2013): Homologization of the flight musculature of Zygoptera (Insecta: Odonata) and Neoptera (Insecta). *PLoS ONE* 8(2): e55787. doi:10.1371/journal.pone.0055787: 16 pp, suppl. (in English) ["Among the winged insects (Pterygota) the Dragonflies and Damselflies (Odonata) are

unique for several reasons. Behaviourally they are aerial predators that hunt and catch their prey in flight, only. Morphologically the flight apparatus of Odonata is significantly different from what is found in the remaining Pterygota. However, to understand the phylogenetic relationships of winged insects and the origin and evolution of insect flight in general, it is essential to know how the elements of the odonatan flight apparatus relate to those of the other Pterygota. Here we present a comprehensive, comparative morphological investigation of the thoracic flight musculature of damselflies (Zygoptera). Based on our new data we propose a homologization scheme for the thoracic musculature throughout Pterygota. The new homology hypotheses will allow for future comparative work and especially for phylogenetic analyses using characters of the thoracic musculature throughout all winged insects. This will contribute to understand the early evolution of pterygote insects and their basal phylogenetic relationship." (2013): Nachweise der Gestreiften Quelljungfer *Cordulegaster bidentata* Selys, 1843 (Odonata: Cordulegastriidae) in Quellbächen des Unteren Lennetales (Märkischer Kreis, NRW). *Natur und Heimat* 73(1): 1-10. (in German) [Märkischer Kreis, Nordrhein-Westfalen, Germany; *C. bidentata* was recorded in the crenal of ten from 33 studied running water bodies.] Address: Bußmann, M., Märkischer Kreis, Untere Landschaftsbehörde, Heedfelder Str. 45, 58509 Lüdenscheid, Germany

12358. Butcher, G. (coord.) (2013): The Mysterious Migratory Dragonfly. *Flylines Spring 2013*: 7-8. (in English) [Verbatim: For centuries, people around the world have reported seeing large swarms of dragonflies, migrating mostly in early fall. In the United States, up to 16 different species have been spotted in these autumnal flights. In spite of these numerous sightings and the fascination with dragonflies, these flights still remain a mystery. The US Forest Service and its partners, however, are working to increase our knowledge of this remarkable phenomenon. They are working together to delve deeper into the mystery of dragonfly migration, their biology and their breeding patterns. One partner organization, the Xerces Society, has convened a group of experts to form the Migratory Dragonfly Partnership. One of the first products of the partnership is a scientific review paper by Michael L. May: "A critical overview of progress in studies of migration of dragonflies (Odonata: Anisoptera), with emphasis on North America," in the *Journal of Insect Conservation* (www.migratorydragonflypartnership.org). In his review, the author discusses the task of greatly increasing our understanding of this phenomenon. Citizen science is another way in which we are gaining more than a glimpse into the world of dragonflies. Celeste Mazzacano, dragonfly partnership coordinator, is organizing a project, Pond Watch (www.migratorydragonflypartnership.org), which encourages the public to visit local dragonfly ponds often to determine which species are present and at which life-cycle stage. The project focuses on five major migratory species: *Anax junius*, *Tramea lacerata*, *Pantala flavescens*, *P. hymenaea*, and *Sympetrum corruptum*; however, the

study's techniques can be used on any dragonfly species of interest. Another project, Migration Monitoring Project (www.migratorydragonflypartnership.org) encourages people to report sightings during fall migration. Many observations of their flight have occurred at well-known sites for observing raptor migration, so it may be possible to combine efforts to monitor hawks, eagles, kites, and dragonflies from the same sites. Migratory Dragonfly Partnership researchers are taking the lead on a third major project that uses latitudinal differences in stable isotopes to determine the geographic origin of adult dragonflies. The scientists study emerging adults and exuviae (the "skin" that the emerging adults discard) to create an isotopic map of North America. Then they can compare the isotopes of migrating adults to determine their geographic origin. If all of this makes you want to get involved, be sure to visit the web site and start contributing your data. In addition, visit the web site to see if there will be a Migratory Dragonfly Short Course taught in your area. These short courses are a great way to learn how to participate firsthand.] Address: For more information on the Wings Across the Americas, visit <http://www.fs.fed.us/global/wings>

12359. Carlson, B.E.; Langkilde, T. (2013): A common marking technique affects tadpole behavior and risk of predation. *Ethology* 119(2): 167-177. (in English) ["In many studies, it is necessary for researchers to mark individual animals for later identification. It is often assumed in the interpretation of these studies that marks have no effects on the biology of the animals. This assumption is insufficiently tested, and, when it is, coarse assessments of negative effects are often used, such as survival and growth under simplified laboratory conditions. We examined the consequences of a common larval amphibian marking technique (staining with methylene blue) for wood frog tadpole behaviour and survival in an ecologically realistic scenario (predation). We measured a number of tadpole behavioural variables, under baseline conditions and in the presence of olfactory cues of a predator, for marked and unmarked tadpoles. We then exposed pairs of tadpoles (one marked and one unmarked) to one of two predators and tested for the effects of marking on the susceptibility of tadpoles to predation. We found that marking suppressed the increase in movement rate that typically occurred in (unmarked) tadpoles in the presence of predator cues. Marked tadpoles were significantly more likely to be captured by predators, an effect that could not be attributed to this difference in movement rate. These results raise concern about the use of this staining method and highlight the need for studies involving marked animals to thoroughly address any relevant effects the marks may have on the biology of the subjects." (Authors) Dragonfly predators were predominantly larvae of *Anax junius*.] Address: Carlson, B.E., Dept of Biology, The Pennsylvania State University, 208 Mueller Laboratory, University Park, PA 16802, USA. 12360. Chambers, D.L.; Wojdak, J.M.; Du, P.; Belden, L.K. (2013): Pond acidification may explain differences in corticosterone among salamander populations. *Physiological and Biochemical Zoology* 86(2): 224-232. (in English) ["Physiological tolerances play a key role in determining species distributions and abundance across a landscape, and understanding these tolerances can therefore be useful in predicting future changes in species distributions that might occur. Vertebrates possess

several highly conserved physiological mechanisms for coping with environmental stressors, including the hormonal stress response that involves an endocrine cascade resulting in the increased production of glucocorticoids. We examined the function of this endocrine axis by assessing both baseline and acute stress-induced concentrations of corticosterone in larvae from eight natural breeding populations of Jefferson's salamander *Ambystoma jeffersonianum*. We surveyed individuals from each pond and also examined a variety of environmental pond parameters. We found that baseline and stress-induced corticosterone concentrations differed significantly among ponds. Population-level baseline corticosterone concentrations were negatively related to pH and positively related to nitrate, and stress-induced concentrations were again negatively related to pH, positively related to nitrate, and positively related to temperature. We followed the field survey with an outdoor mesocosm experiment in which we manipulated pH and again examined baseline and acute stress-induced corticosterone in *A. jeffersonianum* larvae. As in the field survey, we observed an increase in the baseline corticosterone concentration of individuals exposed to the lowest pH treatment (pH 5–5.8). Examining physiological indices using a combined approach of field surveys and experiments can be a powerful tool for trying to unravel the complexities of environmental impacts on species distributions. [...] After 24 h, tadpoles from high-latitude populations, compared with those from low-latitude populations, had increased baseline corticosterone levels when reared with a nonlethal dragonfly predator, but this difference disappeared after 15 d of cohousing with a predator." 12361. Chen, Y.H.; Skote, M.; Zhao, Y.; Huang, W.M. (2013): Stiffness evaluation of the leading edge of the dragonfly wing via laservibrometer. *Materials Letters* 97: 166-168. (in English) ["The material property of the leading edge vein (LEV) of the dragonfly wing is investigated. A new vibration method is developed using a laser vibrometer and mini-shaker. The natural frequency of a cantilevered LEV is determined via lateral oscillation. As a result, the elastic modulus of a LEV sample from a dragonfly wing is found to be in the range of the elastic hydrocarbon polymer, while a dead dragonfly is similar to low density polyethylene. The loss of water contents in the veins increases the stiffness of the LEV by approximately 20times. Highlights: *Material property of the costa of the dragonfly hindwing is investigated. *New vibration method is developed to obtain the elastic modulus of the costa. *Elastic modulus is 20 times lower for a fresh costa than a dead sample. *Material for an artificial model should be an elastic hydrocarbon polymer." 12366. De Block, M.; Pauwels, K.; Van Den Broeck, M.; De Meester, L.; Stoks, R. (2013): Local genetic adaptation generates latitude-specific effects of warming on predator-prey interactions. *Global Change Biology* 19(3): 689-696. (in English) ["Temperature effects on predator-prey interactions are fundamental to better understand the effects of global warming. Previous studies never considered local adaptation of both predators and prey at different latitudes, and ignored the novel population combinations of the same predator-prey species system that may arise because of northward dispersal. We set up a common garden warming experiment to study predator-prey interactions between *Ischnura elegans* damselfly predators and *Daphnia magna* zooplankton prey from three source latitudes spanning >1500 km. Damselfly foraging rates showed thermal plasticity and strong latitudinal differences consistent with adaptation to local time constraints. Relative survival was higher at 24 °C than at 20 °C in southern *Daphnia* and higher at 20 °C than at 24 °C, in northern *Daphnia* indicating local thermal adaptation of the *Daphnia* prey. Yet, this thermal advantage disappeared when they were confronted with the damselfly predators of the same latitude, reflecting also a signal of local thermal adaptation in the damselfly predators. Our results further suggest the invasion success of northward moving predators as well as prey to be latitude-specific. We advocate the novel common garden experimental approach using predators and prey obtained from natural temperature gradients spanning the predicted temperature increase in the northern popula-

tions as a powerful approach to gain mechanistic insights into how community modules will be affected by global warming. It can be used as a space-for-time substitution to inform how predator-prey interaction may gradually evolve to long-term warming." 12368. Degefu, F.; Lakew, A.; Tigabu, Y.; Teshome, K. (2013): The water quality degradation of upper Awash River, Ethiopia. *Ethiopian Journal of Environmental Studies and Management* 6(1): 58-66. (in English) ["Benthic macroinvertebrate based assessment of water quality in the upper Awash River, along the river course of about 500 kms was conducted on quarterly bases between September 2009 and August 2010. This paper reports the complete identification of macroinvertebrates together with measurements of physico-chemical parameters and heavy metal concentrations which were considered as a tool for assessing the water quality status of upper Awash river, Ethiopia. Benthic animals and water samples were collected from three different sampling sites located in the upper Awash River, and analyzed to evaluate stressor sources and the general stream water quality. The percentage abundance of families of various macroinvertebrates taxonomic groups was identified from all sites. Accordingly, Koka bridge site of the upper Awash River had low water quality status which is likely to be due to poor farming, untreated effluents from factories and poor provision of sanitation facilities to the riparian communities. Apparently, the concentrations of the selected nutrients and heavy metals did not differ significantly among the sampling sites (ANOVA, $P > 0.05$), presumably due to pollution of the whole stream reach by the catchment nutrient

sources. Ten orders of benthic macroinvertebrates consisting of 36 families were identified. The highest family richness was observed in Ginchi, slightly impacted site (1) whilst the least faunal diversity was observed in Koka Bridge (7 families) indicating the effect of water quality class differences among the sampling sites." 12370. Domisch, S.; Araújo, M.B.; Bonada, N.; Pauls, S.U.; Jähnig, S.J.; Haase, P. (2013): Modelling distribution in European stream macroinvertebrates under future climates. *Global Change Biology* 19(3): 752-762. (in English) ["Climate change is predicted to have profound effects on freshwater organisms due to rising temperatures and altered precipitation regimes. Using an ensemble of bioclimatic envelope models (BEMs), we modelled the climatic suitability of 191 stream macroinvertebrate species from 12 orders across Europe under two climate change scenarios for 2080 on a spatial resolution of 5 arc minutes. Analyses included assessments of relative changes in species' climatically suitable areas as well as their potential shifts in latitude and longitude with respect to species' thermal preferences. Climate-change effects were also analysed regarding species' ecological and biological groupings, namely (1) endemicity and (2) rarity within European ecoregions, (3) life cycle, (4) stream zonation preference and (5) current preference. The BEMs projected that suitable climate conditions would persist in Europe in the year 2080 for nearly 99% of the modelled species regardless of the climate scenario. Nevertheless, a decrease in the amount of climatically suitable areas was projected for 57-59% of the species. Depending on the scenario, losses could be of 38-44% on average. The suitable areas for species were projected to shift, on average, 4.7-6.6° north and 3.9-5.4° east. Cold-adapted species were projected to lose climatically suitable areas, while gains were expected for warm-adapted species. When projections were analysed for different species groupings, only endemics stood out as a particular group. That is, endemics were projected to lose significantly larger amounts of suitable climatic areas than nonendemic species. Despite the uncertainties involved in modelling exercises such as this, the extent of projected distributional changes reveals further the vulnerability of freshwater organisms to climate change and implies a need

to understand the consequences for ecological function and biodiversity conservation." (Authors) The analysis includes *Calopteryx haemorrhoidalis*, *C. splendens*, *Gomphus pulchellus* and *Onychogomphus uncatu*.] Address: Domisch, S., Senckenberg Research Institute and Natural History Museum Frankfurt, Department of River Ecology and Conservation, Gelnhausen, Germany. 12376. Ferry, E.E.; Hopkins, G.R.; Stokes, A.N.; Mohammadi, S.; Brodie, E.D.; Gall, B.G. (2013): Do all portable cases constructed by caddisfly larvae function in defense? *Journal of Insect Science*: Vol. 13 | Article 5: 9 pp. (in English) ["The portable cases constructed by caddisfly larvae have been assumed to act as a mechanical defense against predatory attacks. However, previous studies have compared the survival of caddisflies with different cases, thereby precluding an analysis of the survival benefits of "weaker" case materials. The level of protection offered by caddisfly cases constructed with rock, stick, or leaf material, as well as a no-case control, was investigated against predatory nymphs of *Anax junius*. A valid supposition is that the cases made of stronger material are more effective at deterring predators. Yet, observations revealed that there was no difference in survival between the case types. All caddisflies with a case experienced high survival in comparison to caddisflies removed from their case. In addition, larvae with stick-cases experienced fewer attacks and captures by dragonflies. These results showed that the presence of a case, regardless of the material used in its construction, offers survival benefits when faced with predatory dragonfly nymphs." (Authors)] Address: Ferry, Emily, Dept of Biology, Utah State Univ., 5305 Old Main HL, Logan UT 84322, USA.

12380. Fuller, C.A.; Gilmore, A.F. (2013): The combined effects of Atrazine and predation on the larval dragonfly *Ladona deplanata*. Kentucky Water Resources, Annual Symposium, March 18, 2013, Marriott's Griffin Gate Resort, Lexington, Kentucky: 57-58. (in English) [Verbatim: Agricultural pesticide contamination is ubiquitous in freshwater habitats and predicting the fate of these chemicals in natural communities is an important goal for ecologists. Atrazine is a common herbicide found in freshwater habitats worldwide with numerous negative effects on aquatic wildlife. Typical concentrations are relatively low (~100 ppb), yet have the ability to impair wildlife behaviour, physiology, and fitness traits. Recent research indicates that these effects are often magnified in the context of other community interactions. Because invertebrates are a keystone species in aquatic habitats we sought to determine how sublethal concentrations of atrazine (80 ppb) and predator cues (*Anax junius*) affect larval dragonflies (*Ladona deplanata*) throughout development. We used a split-plot experimental design with aquatic mesocosms to test the interaction of these stressors over a six-week period. We

examined the effects of both stressors on immune parameters, growth, and fat storage, phenotypically plastic traits that have fitness implications for adult dragonflies. Preliminary analyses using two-way ANOVAs indicate that both treatment effects on larvae were evident after two weeks of exposure with predator cues affecting growth and immune parameters over the entire six weeks. After two weeks of exposure, there was a significant treatment interaction on immune parameters, however by the end of the six-week period, treatment effects depended on the specific immune response measured. The effect of predator presence on hemocyte numbers persisted throughout the experiment, as did the effect of atrazine on phenoloxidase (PO) activity. The results of our study indicate that sublethal atrazine exposure affects immune function in larval dragonflies with implications for parasite resistance and the potential for tradeoffs between growth and immune investment. In the context of a natural community, sublethal herbicide exposure may be intensifying the effects of predators with implications for survival to metamorphosis and adult fitness. This study highlights the importance of conducting long-term exposure experiments of multiple stressors, in detecting differences in the sublethal effects of contaminants on aquatic invertebrates.] Address: Fuller, Claire, A., Department of Biology, Murray State University, Murray, KY 42071, USA. 12384. Goertzen, D.; Suhling, F. (2013): Promoting dragonfly diversity in cities: major determinants and implications for urban pond design. *Journal of Insect Conservation* 17(2): 399-409. (in English) ["Urbanisation is increasing and it is essential to integrate biodiversity into the spatial planning of urban areas. This requires deeper understanding of biodiversity patterns in cities. We investigated which habitat variables are major determinants of dragonfly diversity and species assemblage structure in the municipal area of Dortmund (Germany). We sampled dragonfly larvae in 33 ponds situated in city parks, commercial, residential and agricultural areas. We recorded 30 autochthonous dragonfly species with species richness ranging from zero to 17. Additionally, we surveyed a set of environmental variables including habitat size, water level, pond structures

and vegetation as well as surrounding landscape and potential disturbances like waterfowl and fish. Multivariate methods were used to identify the major determinants of dragonfly diversity, abundance and assemblage structure. Analysis indicated that diversity of aquatic and terrestrial vegetation affected dragonfly diversity positively. City park ponds had low diversity, but *Ischnura elegans* was obviously promoted by the specific park pond conditions, including high waterfowl density. We found five assemblages mostly determined by generalistic species which were related to different pond types. Moderately disturbed ruderal and pioneer ponds in residential and agricultural areas also contained increased numbers of rare species. Our results indicate that urban ponds may have a great value for maintaining biodiversity, but various disturbances have negative impact. To promote urban biodiversity we suggest a natural design of well-vegetated ponds as well as a high diversity of different pond types and particularly a more-natural redesign of city park ponds." 12385. Gonzalez-Bellido, P.T.; Peng, H.; Yang, J.; Georgopoulos, A.P.; Olberg, R.M. (2013): Eight pairs of descending visual neurons in the dragonfly give wing motor centers accurate population vector of prey direction. *Proceedings of the National Academy of Sciences* 110(2): 696-701. (in English) ["Intercepting a moving object requires prediction of its future location. This complex task has been solved by dragonflies, who intercept their prey in midair with a 95% success rate. In this study, we show that a group of 16 neurons, called target-selective descending neurons (TSDNs), code a population vector that reflects the direction of the target with high accuracy and reliability across 360°. The TSDN spatial (receptive field) and temporal (latency) properties matched the area of the retina where the prey is focused and the reaction time, respectively, during predatory flights. The directional tuning curves and morphological traits (3D tracings) for each TSDN type were consistent among animals, but spike rates were not. Our results emphasize that a successful neural circuit for target tracking and interception can be achieved with few neurons and that in dragonflies this information is relayed from the brain to the wing motor centers in population vector form." (Author) *Libellula luctuosa* was studied; additional results were obtained by using specimens of *L. lydia* and *L. pulchella*.] Address: Gonzalez-Bellido, Paloma, Allen Institute for Brain Science, Seattle, WA 98103, USA. 12386. Harabiš, F.; Tichanek, F.; Tropek, R. (2013): Dragonflies of freshwater pools in lignite spoil heaps: Restoration management, habitat structure and conservation value. *Ecological Engineering* 55: 51-61. (in English) ["Although numerous studies of several terrestrial groups have revealed high conservation potential of post-industrial sites, freshwater habitats in post-mining sites still remain little explored. Here we present a study of Odonata colonizing 61 freshwater pools newly established at 9 lignite spoil heaps in the north-western Czech Republic, Central Europe. We aimed mainly on effects of the three prevailing pool restoration methods (spontaneously inundated depressions at non-reclaimed sites, at reclaimed sites; and novel technically constructed ponds) along with several factors of the local habitat and surrounding landscape on species richness,

conservation values, and species composition of the dragonfly communities. By recording of 32 species of lentic dragonflies (including 8 threatened ones) and 2 additional threatened lotic species, we documented the conservation value of post-industrial habitats also for aquatic arthropods. None of the three restoration methods supported dragonfly communities of distinctly higher conservation value than did the two others, each method generated habitats for different threatened species. Similar patterns were revealed also for vegetation heterogeneity, bottom substrate, water shading, and surrounding terrestrial habitats. We thus conclude that a mosaic-like combination of the restoration methods and creating of heterogeneous water pools will be most effective for restoring of freshwater biodiversity in highly degraded sites." 12387. Heino, J. (2013): Environmental heterogeneity, dispersal mode, and co-occurrence in stream macroinvertebrates. *Ecology and Evolution*: 12 pp. (in English) ["Both environmental heterogeneity and mode of dispersal may affect species co-occurrence in metacommunities. Aquatic invertebrates (including Odonata; all taxa are treated at order level) were sampled in 20–30 streams in each of three drainage basins, differing considerably in environmental heterogeneity. Each drainage basin was further divided into two equally sized sets of sites, again differing profoundly in environmental heterogeneity. Benthic invertebrate data were divided into three groups of taxa based on overland dispersal modes: passive dispersers with aquatic adults, passive dispersers with terrestrial winged adults, and active dispersers with terrestrial winged adults. The co-occurrence of taxa in each dispersal mode group, drainage basin, and heterogeneity site subset was measured using the C-score and its standardized effect size. The probability of finding high levels of species segregation tended to increase with environmental heterogeneity across the drainage basins. These patterns were, however, contingent on both dispersal mode and drainage basin. It thus appears that environmental heterogeneity and dispersal mode interact in affecting co-occurrence in metacommunities, with passive dispersers with aquatic adults showing random patterns irrespective of environmental heterogeneity, and active dispersers with terrestrial winged adults showing increasing segregation with increasing environmental heterogeneity." 12390. Jancowski, K.; Orchard, S.A. (2013): Stomach contents from invasive American bullfrogs *Rana catesbeiana* (= *Lithobates catesbeianus*) on southern Vancouver Island, British Columbia, Canada. *NeoBiota* 16: 17-37. (in English) ["Invasive alien American bullfrog populations are commonly identified as a pernicious influence on the survival of native species due to their adaptability, proliferation and consequent ecological impacts through competition and predation. However, it has been difficult to determine conclusively their destructive influence due to the fragmentary and geographically dispersed nature of the historical database. An expanding meta-population of invasive American bullfrogs, became established on southern Vancouver Island, in the mid- to late 1980s. An on-going bullfrog control program begun in 2006 offered a unique opportunity to examine the stomach contents removed from 5,075 adult and juvenile bullfrogs collected from 60 sites throughout the active season (April to October). Of 15 classes of organisms identified in the diet, insects were numerically dominant, particularly social wasps and odonates. Seasonality and site-specific habitat characteristics influenced prey occurrence and abundance. Native vertebrates in the diet included fish, frogs, salamanders, snakes, lizards, turtles, birds, and mammals, including some of conservation concern. Certain predators of bullfrog tadpoles and juveniles are commonly preyed upon by adult bullfrogs, thereby suppressing their effectiveness as biological checks to bullfrog population growth. Prey species with antipredator defences, such as wasps and sticklebacks, were sometimes eaten in abundance. Many prey species have some type of anti-predator defence, such as wasp stingers or stickleback spines, but there was no indication of conditioned avoidance to any of these. Results from this study reinforce the conclusion that, as an invasive alien, the American bullfrog is an opportunistic and seemingly unspecialized predator that has a uniquely large and complex ecological footprint both above and below the water surface." 12391. Janssens, L.; Stoks, R. (2013): Exposure to a widespread non-pathogenic bacterium magnifies sublethal pesticide effects in the damselfly *Enallagma cyathigerum*: From the suborganismal level to fitness-related traits. *Environmental Pollution* 177: 143-149. (in English) ["While there is increasing concern that pesticide stress can interact with stress imposed by antagonistic species including pathogens, it is unknown whether this also holds for non-pathogenic bacteria. We exposed *Enallagma cyathigerum* damselfly larvae to the pesticide chlorpyrifos and a non-pathogenic *Escherichia coli* strain. Both exposure to chlorpyrifos and *E. coli* reduced growth rate and fat storage, probably due to the observed energetically costly increases in physiological defence (glutathione-S-transferase and Hsp70) and, for *E. coli*, immune defence (phenoloxidase). Moreover, these stressors interacted for both fitness-related traits. Most importantly, another fitness-related trait, bacterial load, increased drastically with chlorpyrifos concentration. A possible explanation is that the upregulation of phenoloxidase in the presence of *E. coli* changed into a downregulation when combined with chlorpyrifos. We

argue that the observed interactive, partly synergistic effects between pesticides and widespread non-pathogenic bacteria may be common and deserves further attention to improve ecological risk assessment of pesticides. Highlights: *Non-pathogens such as the bacterium *E. coli* are ignored in ecotoxicology. *Both *E. coli* and chlorpyrifos impaired fitness-related traits in damselfly larvae. **E. coli* modulated and magnified effects of chlorpyrifos on physiology and fitness. *Bacterial load was magnified >10× in the presence of chlorpyrifos. *Risk assessment of pesticides should consider synergisms with non-pathogens." 12392. Janssens, L.; Stoks, R. (2013): Synergistic effects between pesticide stress and predator cues: conflicting results from life history and physiology in the damselfly *Enallagma cyathigerum*. *Aquatic Toxicology* 132–133: 92-99. (in English) ["There is increasing awareness that the negative effects of anthropogenic stressors may be magnified in the presence of natural stressors. Very few of these studies have included physiology, yet including physiological studies may help learning about the mechanistic base of such synergisms at the life history level and identify synergistic interactions not translated in life history traits. We studied in *Enallagma cyathigerum* damselfly larvae potential synergistic effects between exposure to the pesticide glyphosate and predator cues on a key life history trait, growth rate, its associated behavioral trait, food intake, and three types of physiological traits known to be affected by both stressors in isolation: the stress protein Hsp70, energy storage and variables related to oxidative stress and damage. The pesticide and predator cues reduced growth rate in an additive way. Food intake increased under pesticide exposure and was not affected by the predator cues, indicating physiological mediation of the growth reduction. One potential physiological mechanism was that both stressors additively increased Hsp70 levels, this may also have contributed to the reduced levels of total carbohydrates when exposed to predator cues. Chronic exposure to predator cues reduced oxygen consumption, possibly to avoid too high costs of an increased metabolic rate. This reduction did not occur in the presence of the pesticide, reflecting the need for energetically expensive defence mechanisms (such as Hsp70 upregulation). When both stressors were combined, there was a reduction of the antioxidant enzyme superoxide dismutase activity (SOD) and an associated increase of oxidative damage in lipids. While synergistic interactions were not present for growth rate and food intake, they were identified for antioxidant defence and oxidative damage. This novel type of "hidden" synergistic interaction may have profound fitness implications, and when ignored will lead to underestimations of the impact of pollutants in natural populations where predators are omnipresent. Highlights: *Interactions between natural stressors and pesticides remain poorly understood. *Predation risk and glyphosate additively affected life history and behaviour. *We showed a novel type of synergistic interaction in terms of oxidative damage. *This hidden synergism can have severe fitness consequences and may be widespread." 12393. Jinguji, H.; Quoc Thuyet, D.; Uéda, T.; Watanabe, H. (2013): Effect of imidacloprid and fipronil pesticide application on *Sympetrum infuscatum* (Libellulidae: Odonata) larvae and adults. Paddy and Water Environment 11: 277-284. (in English) ["The effect of imidacloprid and fipronil on *S. infuscatum* larvae and adults during the rice cultivation period was monitored using an experimental micro-paddy lysimeter (MPL) system. Twenty-two hatched larvae were laid on the soil surface of each MPL. MPLs were treated with imidacloprid, fipronil, and the control MPL was left untreated. The pesticide concentration, *S. infuscatum* larval and adult populations, and larval emergence time were monitored in each MPL. The maximum imidacloprid and fipronil concentration in paddy water was 52.8 µg/l at 1 day, and 1.3 µg/l at 6 h, respectively, after the pesticide application. Both pesticides dissipated quickly in paddy water, with half-lives of 8.8 and 5.4 days for imidacloprid and fipronil, respectively. The absence of *S. infuscatum* larvae and exuviae in the fipronil-treated MPL was remarkable. The larval survival decreased to 63.6 ± 18.2, 15.2 ± 2.6, and 0% in the control, imidacloprid-treated, and fipronil-treated MPLs, respectively, by 9 days after pesticide application. Emergence in the imidacloprid-treated MPL was also significantly lower than that in the control MPL. The observed decrease in the abundances of *S. infuscatum* larvae and adults in MPLs seems to be both directly and indirectly associated with nursery-box application of fipronil and imidacloprid." 12394. Johansson, F.; Nilsson-Örtman, V. (2013): Predation and the relative importance of larval colour polymorphisms and colour polyphenism in a damselfly. Evolutionary Ecology 27(3): 579-591. (in English) ["Intraspecific body colour variation is common in many animal species. Predation could be a key selective agent giving rise to variation in body colour, and such variation could be due to genetics (polymorphisms) or phenotypic plasticity (polyphenisms). In this study we examined the degree of colour polymorphism and polyphenism in background colour matching in larvae of *Coenagrion armatum*. In addition, we tested if predation risk is reduced when larvae are exposed to a matching compared to a non-matching background. By raising families of larvae at three different background colours we showed that polymorphism explained about 20 % of the total variation and polyphenism about 35 %. In a predation experiment with fish, we showed that larvae with a body colour matching the background had a higher survival success compared to larvae with a non-matching background colour. We suggest that the background matching is adaptive in terms of survival from predation and that colour diversity is maintained because of spatial and temporal variation in the background experienced by damselfly larvae under field conditions." 12395. Johnson, L.; Mantle, B.L.; Gardner, J.L.; Backwell, P.R.Y. (2013): Morphometric measurements of dragonfly wings: the accuracy of pinned, scanned and detached measurement methods. ZooKeys 276: 77-84. (in

English) ["Large-scale digitization of museum specimens, particularly of insect collections, is becoming commonplace. Imaging increases the accessibility of collections and decreases the need to handle individual, often fragile, specimens. Another potential advantage of digitization is to make it easier to conduct morphometric analyses, but the accuracy of such methods needs to be tested. Here we compare morphometric measurements of scanned images of dragonfly wings to those obtained using other, more traditional, methods. We assume that the destructive method of removing and slide-mounting wings provides the most accurate method of measurement because it eliminates error due to wing curvature. We show that, for dragonfly wings, hand measurements of pinned specimens and digital measurements of scanned images are equally accurate relative to slide-mounted hand measurements. Since destructive slide-mounting is unsuitable for museum collections, and there is a risk of damage when hand measuring fragile pinned specimens, we suggest that the use of scanned images may also be an appropriate method to collect morphometric data from other collected insect species." 12400. Kaunisto, K.M.; Suhonen, J. (2013): Parasite burden and the insect immune response: interpopulation comparison. *Parasitology* 140(1): 87-94. (in English) ["The immune response affects host's survival and reproductive success. Insurmountable immune function has not evolved because it is costly and there is a trade-off between other life-history traits. In previous studies several factors such as diet and temperature have been proposed to cause interpopulation differences in immune response. Moreover, the insect immune system may be functionally more protective upon secondary exposure, thus infection history may associate with the immune response. Here we measured how geographical location and Parasite burden is related to variation in immune response between populations. We included 13 populations of *Coenagrion hastulatum* in Finland over a latitudinal range of 880 km to this study. We found that water mites associated strongly with the

immune response at interpopulation level: the more the mites, the higher the immune response. Also, in an alternative model based on AIC, latitude and individual size associated with the immune response. In turn, endoparasitic gregarines did not affect the immune response. To conclude, a positive interpopulation association between the immune response and the rate of water mite infection may indicate (i) local adaptation to chronic Parasite stress, (ii) effective 'induced' immune response against Parasites, or (iii) a combined effect of both of these." (Authors)] Address: Suhonen, J., Department of Biology, Section of Ecology, University of Turku, FI-20014 Turku, Finland. E-mail: jukseh@utu.fi

12401. Keränen, I.; Kahilainen, A.; Knott, E.; Kotiaho, J.S.; Kuitunen, K. (2013): High maternal species density mediates unidirectional heterospecific matings in *Calopteryx* damselflies. *Biological Journal of the Linnean Society* 108(3): 534-545. (in English) ["Hybridization is a well-known phenomenon, but there are still relatively few studies addressing the question of reproductive isolation between related sympatric animal species with largely overlapping ranges. Population density, relative abundance, and operational sex ratio (OSR) are among the factors known to have an influence on the frequency of heterospecific matings in sympatric populations. Here we had two aims. First, we used microsatellite markers and field observations to study the frequency of hybrids, and backcrosses, and the rate of heterospecific matings between two sympatric damselfly species *Calopteryx splendens* and *C. virgo*. Second, we investigated the role of population densities, relative abundances, and OSRs on conspecific and heterospecific mating rates. Altogether we genotyped 2104 individuals from both species and found four hybrids (0.19%), one of which was a backcross. Of all the 272 matings observed, 17 (6%) were between heterospecifics, and all of these were between a *C. splendens* male and a *C. virgo* female. In addition, all of the hybrids contained mitochondrial DNA (mtDNA) of *C. virgo*. We show that the population density of *C. virgo*, which was the maternal species of all the heterospecific matings and hybrid individuals, was the only significant factor covarying with the rate of the heterospecific matings. The OSRs did not correlate with the rate of con- or heterospecific matings. Studies on interspecific interactions in sympatric species can give information about the maintenance of reproductive isolation, and thus speciation." 12403. Khairiyah, M.H.S.; Izzati, M.R.N.; Faezah, P. (2013): Species richness and temporal variation in the dragonfly and damselfly fauna at National Botanical Garden Shah Alam. Humanities, Science and Engineering (CHUSER), 2012 IEEE Colloquium on 3-4 Dec. 2012: 442-447. (in English) ["A study on the species richness and temporal variation of insect under order Odonata was conducted at National Botanical Garden Shah Alam (NBGSA), Selangor. Samplings were conducted for three months from January 2012 to March 2012 using sweep net. Two trails were chosen at two different lakes and two different sessions which were morning session and evening session. Trail one was located at the innermost part of the forest that far human activities while trail two was located at middle of the forest with open area and near to human activities. A total of 420 odonates were successfully collected consist of four families and 23 morphospecies. The families identified were Lestidae, Libellulidae, Coenagrionidae and Gomphidae. The most abundant family was the Libellulidae with 341 individuals followed by Lestidae, Coenagrionidae and Gomphidae with 54, 16, and 9 individuals respectively. Trail one recorded the highest number of individuals collected with 250 individuals while trail two with 170 individuals had the lowest number of individual collected. Morning session was identified as the most active time for Odonata with 236 individuals collected rather than evening session with only 184 individuals. From the data analysis, Shannon-Weiner Diversity Index showed that there was no significant different ($p > 0.05$) between both trails and sessions. Overall study had shown area with high vegetation and located far away from human activities had the highest diversity of Odonata." 12404. Kim, Y.H.; Lee, S.H. (2013): Which acetylcholinesterase functions as the main catalytic enzyme in the class Insecta? *Insect Biochemistry and Molecular Biology* 43(1): 47-53. (in English) ["Most insects possess two different acetylcholinesterases (AChEs) (i.e., AChE1 and AChE2; encoded by *ace1* and *ace2* genes, respectively). Among the two AChEs, AChE1 has been proposed as a major catalytic enzyme based on its higher expression level and frequently observed point mutations associated with insecticide resistance. To investigate the evolutionary distribution of AChE1 and AChE2, we determined which AChE had a central catalytic function in several insect species across 18 orders. The main catalytic activity in heads was determined by native polyacrylamide gel electrophoresis in conjunction with Western blotting using AChE1- and AChE2-specific antibodies. Of the 100 insect species examined, 67 species showed higher AChE1 activity; thus, AChE1 was considered as the main catalytic enzyme. In the remaining 33 species, ranging from Palaeoptera to Hymenoptera, however, AChE2 was predominantly expressed as the main catalytic enzyme. These findings challenge the common notion that AChE1 is the only main catalytic enzyme in insects with the exception of

Cyclorrhapha, and further demonstrate that the specialization of AChE2 as the main enzyme or the replacement of AChE1 function with AChE2 were rather common events, having multiple independent origins during insect evolution. It was hypothesized that the generation of multiple AChE2 isoforms by alternative splicing allowed the loss of *ace1* during the process of functional replacement of AChE1 with AChE2 in Cyclorrhapha. However, the presence of AChE2 as the main catalytic enzyme in higher social Hymenoptera provides a case for the functional replacement of AChE1 with AChE2 without the loss of *ace1*. The current study will provide valuable insights into the evolution of AChE: which AChE has been specialized as the main catalytic enzyme and to become the main target for insecticides in different insect species." 12405. Kin, A.; Gruszczynski, M.; Martill, D.; Marshall, J.D.; Błażejowski, B. (2013): Palaeoenvironment and taphonomy of a Late Jurassic (Late Tithonian) Lagerstätte from central Poland. *Lethaia* 46(1): 71-81. (in English) ["A rich assemblage of exceptionally preserved marine and terrestrial fossils occurs in finegrained limestones in the upper part of the Late Tithonian (Middle Volgian) shallowing upward carbonate sequence in Central Poland. The richest horizon, a deposit known locally as the Corbulomima horizon, is named after the shallow burrowing suspension feeding bivalve *Corbulomima obscura*, moulds of which occur in densities of up to 500 per square metre on some bedding planes. The fauna in this bed also includes organic and phosphatic remains of a wide range of other creatures including the exuviae of limulids and decapods, disarticulated fish skeletons and rare isolated pterosaur bones and teeth. There are also perfectly preserved dragonfly wings and beetle exoskeletons. The average stable carbon and oxygen isotope values for ostracod shells and fine-grained sediment from this horizon suggest precipitation of the calcium carbonate from warm seawater of normal marine salinity. The carbonate sediments overlying the fossiliferous horizon have been interpreted as nearshore to shoreface facies. These pass abruptly into coarse reworked intraclastic sediments interpreted as possible tsunami or storm surge over-wash deposits. The clasts in this deposit have more positive oxygen isotope values than those in the underlying limestone, which may indicate that they were lithified in a slightly more evaporative, perhaps intertidal, setting. The succession terminates with silicified fine-grained limestones likely to have formed in extremely shallow lagoonal environments. In contrast with the Solnhofen limestones of Lower Tithonian age in south-central Germany the Corbulomima horizon is interpreted as a transitional deposit formed in a shallow marine setting by rapid burial with elements of both Konservat- and Konzentrat-Lagerstätte preservation." - 12408.** Kulkarni, A.S.; Subramanian, K.A. (2013): Habitat and seasonal distribution of Odonata (Insecta) of Mula and Mutha river basins, Maharashtra, India. *Journal of Threatened Taxa* 5(7): 4084-4095. (in English, with Marathian summary) ["Catchment landscape degradation and habitat modifications of freshwater ecosystems are a primary cause of biodiversity loss in riverine ecosystems all over the world. Many elements of the flora and fauna of freshwater ecosystems are sensitive to the changes in catchment land use and habitat modification. These sensitive taxa are also reliable indicators of freshwater ecosystem health. In the current study we investigate the seasonal and habitat distribution of Odonata across riparian land use types in Mula and Mutha river basins, northern Western Ghats, Maharashtra. There was a difference in the species composition across land use types and across seasons with highest diversity and abundance during the post monsoon period. The highest Odonata diversity was observed in urban areas followed by forest and agriculture fields. There was a loss of 31% of the odonate fauna in the study area over 50 years which could be due to rapid industrialization and urbanization of the region and consequent degradation of freshwater ecosystems. The significance of catchment land use on Odonata diversity and its value in landscape monitoring is discussed." - 12409.** Li, Y.; Béthoux, O.; Pang, H.; Ren, D. (2013): Early Pennsylvanian Odonatoptera from the Xiaheyan locality (Ningxia, China): new material, taxa, and perspectives. *Fossil Record* 16(1): 117-139. (in English) ["Data on Odonatoptera species from the Xiaheyan locality (Ningxia, China; Early Pennsylvanian) described so far are complemented based on abundant new material. Several taxonomic and nomenclatural adjustments are proposed. The species *Tupus readi* Carpenter, 1933 is transferred to the genus *Shenzhousia* Zhang & Hong, 2006 in Zhang et al. (2006), and therefore should be referred to as *Shenzhousia readi* (Carpenter, 1933) n. comb. The monotypic genus *Sinomeganeura* Ren et al., 2008 is synonymized with *Oligotypus* Carpenter, 1931. As a consequence the type species of the former must be referred to as *Oligotypus huangheensis* (Ren et al., 2008) n. comb. The monotypic genus *Paragilsonia* Zhang, Hong & Su, 2012 in Su et al. (2012) is synonymized with *Tupus* Sellards, 1906. As a consequence the type-species of the former is to be referred to as *Tupus orientalis* (Zhang, Hong & Su, 2012 in Su et al. (2012)) n. comb. The monotypic genus *Sinierasiptera* Zhang, Hong & Su, 2012 in Su et al. (2012) is synonymized with *Erasipterella* Brauckmann, 1983. As a consequence the type-species of the former is to be referred to as *Erasipterella jini* (Zhang, Hong & Su, 2012 in Su et al. (2012)) n. comb. In addition *Aseripterella sinensis* n. gen. et sp. and *Sylphalula laliquei* n. gen. et sp. are described. The 'strong oblique distal' cross-vein, located in the area between RA and RP is found to occur more extensively than previously expected. It is believed to be a structure distinct from the subnodal cross-vein, and therefore deserves to be referred to by a distinct name (viz. 'postsubnodal cross-vein'). Odonatoptera from the Xiaheyan locality cover a broad range of sizes. Factors that could have promoted the evolution of large-sized Odonatoptera are briefly reviewed. The permissive conditions prevailing during the Pennsylvanian, and the existence of an elaborated food web, are emphasized as putative positive factors. The new taxonomic treatment suggests that genera documented in the Lower Permian, such as *Shenzhousia* and *Oligotypus*, stem from the early Pennsylvanian, and implies a high resilience of these taxa when facing the Pennsylvanian-Permian environmental perturbations." ology 82(2): 522-537. (in English) ["The diets (including Odonata) of 99 pumpkinseed sunfish *Lepomis gibbosus* from a pair of small, adjacent lakes in Ontario, Canada, were estimated from their stomach contents, trophically transmitted parasites and stable isotopes of carbon and nitrogen in fish tissue. The three methods provided virtually unrelated information. There was no significant correlation in the importance of any prey item across all three methods. Fish with similar diets according to one method of estimating diet showed no tendency to be similar according to other methods. Although there was limited variation in fish size and the spatial scale of the study was small, both fish size and spatial origin showed comparatively strong associations with diet data obtained with all three methods. These results suggest that a multidisciplinary approach that accounts for fish size and spatial origins is necessary to accurately characterize diets of individual fish." 12412. Lopes Junior, R.S.; Peixoto, P.E.C. (2013): Males of the dragonfly *Diastatops obscura* fight according to predictions from game theory models. *Animal Behaviour* 85(3): 663-669. (in English) ["Agonistic interactions between males for the ownership of mating territories are common among animal species. There are at least three theoretical models aimed to clarify the rules used by rivals to decide the contest winner: war of attrition model (WOA), sequential assessment model (SAM) and cumulative assessment model (CAM). However, few empirical investigations have simultaneously tested predictions from these three models, reducing our ability to infer each model's explanatory power. In this study, we used males of *D. obscura* to identify traits that affect individual fighting ability (resource-holding potential, RHP) and to test predictions derived from WOA, SAM and CAM models. For this, we identified morphological and physiological male traits related to chances of victory, timed contests between males and evaluated the relationship between male traits, contest duration and performance of costly behaviours. Individual body mass represented the main trait affecting RHP. Contest duration decreased with increasing winner body mass and increased with increasing loser body mass, rejecting the WOA model. The probability of physical contact increased with decreasing mass differences between rivals. Additionally, when considering pairs of rivals that showed similar mass differences, contest duration was unrelated to loser body mass. Since fights can lead to physical contact, body mass may affect the capacity to inflict costs on the rivals. Also, the relationships between contest duration and RHP and between the probability of physical contact and RHP difference between rivals indicate that males perform mutual assessment of fighting ability, as presumed by SAM. Highlights: *We identified male traits in *Diastatops obscura* that determine fighting ability. *We tested predictions from three game theory models regarding rules used by rivals. *Males previously present in territories were more likely to win. *Greater body mass was related to greater chances of victory in contests. *Males seem to perform mutual evaluation of fighting ability during the contest." 12413. Lou, M. (2013): Improving specimen identification: Informative DNA using a statistical Bayesian method. Open Access Dissertations and Theses. Paper 7637. <http://digitalcommons.mcmaster.ca/opedissertations/7637>: XI + 99 pp. (in English) ["This work investigates the assignment of unknown sequences to their species of origin. In particular, I examine four questions: Is existing (GenBank) data reliable for accurate species identification? Does a segregating sites algorithm make accurate species identifications and how does it compare to another Bayesian method? Does broad sampling of reference species improve the information content of reference data? And does an extended model (of the theory of segregating sites) describe the genetic variation in a set of sequences (of a species or population) better? Though we did not find unusually similar between-species sequences in GenBank, there was evidence of unusually divergent within-species sequences, suggesting that caution and a firm understanding of GenBank species should be exercised before utilizing GenBank data. To address challenging identifications resulting from an overlap between within- and between species variation, we introduced a Bayesian treeless statistical assignment method that makes use of segregating sites. Assignments with simulated and *Drosophila* (fruit fly) sequences show that this method can provide fast, high probability assignments for recently diverged species. To address reference sequences with low information content, the addition of even one broadly sampled reference sequence can increase the number of correct assignments. Finally, an extended theory of segregating sites generates more realistic probability estimates of the genetic variability of a set of sequences. Species are dynamic entities and this work will highlight ideas and methods to address dynamic genetic patterns in species." 12415. Lupi, D.; Rocco, A.; Rossaro, B. (2013): Benthic macroinvertebrates in Italian rice fields. *J. Limnol.* 72(1): 184-200. (in English) ["Rice fields can be considered man-managed temporary wetlands. Five rice fields handled with different management strategies, their adjacent channels, and a spring were analysed by their benthic macroinvertebrate community to i) evaluate the role of rice agroecosystem in biodiversity conservation; ii) find indicator species which can be used to compare the ecological status of natural wetlands with rice agroecosystems; and iii) find the influence of environmental variables on biodiversity. Different methods of data analysis with increasing degree of complexity – from diver-

sity index up to sophisticated multivariate analysis – were used. The investigation provided a picture of benthic macroinvertebrates inhabiting rice agroecosystems where 173 taxa were identified, 89 of which detected in rice paddies. Among them, 4 phyla (Mollusca, Annelida, Nematomorpha, and Arthropoda), 8 classes (Bivalvia, Gastropoda, Oligochaeta, Hirudinea, Gordioida, Insecta, Branchiopoda, and Malacostraca), 24 orders, 68 families, 127 genera and 159 species have been found. Ten threatened and 3 invasive species were detected in the habitats examined. The information obtained by the different methods of data analysis allowed a more comprehensive view on the value of the components of rice agroecosystems. Data analyses highlighted significant differences between habitats (feeding channel and rice field), with higher diversity observed in channels, and emphasised the role of the water chemical-physical parameters. The period of water permanence in rice fields resulted to be only one of the factors influencing the community of benthic macroinvertebrates. The presence of rare/endangered species allowed characterising some stations, but it was less informative about management strategies in rice paddies because most of these species were absent in rice fields." (Authors) The list of taxa includes 15 Odonata species.] Address: Lupi, Daniela, Univ. of Milan, Dept of Food, Environmental and Nutritional Sciences (DeFENS), Via Celoria 2, 20133 Milano, Italy. 12416. MacNeil, C.; Beets, P.; Lock, K.; Goethals, P.L.M. (2013): Potential effects of the invasive 'killer shrimp' (*Dikerogammarus villosus*) on macroinvertebrate assemblages and biomonitoring indices. *Freshwater Biology* 58(1): 171-182. (in English) ["(1.) Water quality monitoring data from 10 watercourses and laboratory mesocosm studies were used to assess the potential impacts of the crustacean amphipod invader *D. villosus* on resident macroinvertebrate assemblage structure in Central European fresh waters. (2.) The presence of *D. villosus* was associated with a decline in the prevalence of many native species, pollution sensitive as well as pollution tolerant, and changes in biotic indices, despite the trends of improved water quality coinciding with the invasion period. A general increase in the prevalence of other invaders was also noted. The potential impacts of *D. villosus* were substratum dependent, differing between stone, concrete and sand-dominated sites. (3.) Mean Multimetric Macroinvertebrate Index Flanders (MMIF) values were marginally lower when *D. villosus* was present ($P < 0.06$), as opposed to when other amphipod species or no amphipods were present, despite the improved water quality. Mesocosm studies showed that several macroinvertebrate taxa were completely eliminated in treatments with *D. villosus*, oligochaete worms, Caenidae mayfly, chironomids and tipulids being particularly vulnerable to *D. villosus* predation. Biological Monitoring Working Party (BMWP) scores were lower in mesocosms with *D. villosus* as opposed to the native *Gammarus pulex* or no amphipods at all. (4.) We predict that resident macroinvertebrate assemblages in both Central Europe and Britain will come under increasing pressure as *D. villosus* invasions progress. Consequently, macroinvertebrate biotic indices, such as the MMIF or BMWP, may need to be revised to account for changes in taxa sensitivities to water quality as well as increased predation and competition." (Authors) Larvae of *Ischnura elegans* were used for the experiments. They were preyed less frequently by *D. villosus* and only very rarely by *G. pulex*, opposite to worms, chirono-

mids and tipulids which were predated in all amphipod replicates. In field samples based on the samples from 1990 to 2009, Platycnemididae were effected negatively by invasive *D. villosus* especially in rivers with concrete substratum or stone substratum.] Address: MacNeil, C., Department of Environment, Food and Agriculture, The Isle of Man Government, Thie Slieau Whallian, Foxdale Road, St. Johns IM4 3AS, Isle of Man. 12417. Majumder, J.; Das, R.K.; Majumder, P.; Ghosh, D.; Agarwala, B.K. (2013): Aquatic insect fauna and diversity in urban fresh water lakes of Tripura, Northeast India. *Middle-East Journal of Scientific Research* 13(1): 25-32. (in English) ["Freshwater lakes are integral part of urban ecosystem and provide numerous benefits to human beings directly or indirectly. An inventory was carried out to study the aquatic entomofauna, their diversity and distribution in three urban freshwater lakes of Tripura, northeast India during January to May, 2012. A total of 2159 individuals representing 31 species belonging to 23 genera, 15 families and 4 orders were recorded. Maximum of 30 species and 1191 individuals of aquatic insects were recorded in vegetation rich Maharaja Bir Bikram College Lake and minimum of 11 species and 215 individuals were recorded in vegetation poor Laxminarayan Bari Lake. Insects belonging to the orders Hemiptera (32.26%) and Odonata (32.25%) showed higher species richness followed by those belonging to Coleoptera (25.81%) and Diptera (9.68%), respectively. Maximum diversity ($H_s = 3.03$) and least dominance ($D_s = 0.06$) and minimum diversity ($H_s = 1.50$) and maximum dominance ($D_s = 0.06$) of aquatic insects was recorded in Maharaja Bir Bikram College Lake and Laxminarayan Bari Lake, respectively. Richness estimators Chao 1 and Chao 2 provided the best predicted value of species richness. Three species are reported here for the first time from the state. Dominance of hemipteran and coleopteran insects suggested that urban lakes of Tripura are relatively less polluted." (Authors)] Address: Agarwala, B.K., Department of Zoology, Ecology and Biodiversity Laboratories, Tripura University, Suryamaninagar, Tripura 799 022, India

12418. Marinov, M.; Donnelly, N. (2013): *Teinobasis fatakula* sp. nov. (Zygoptera: Coenagrionidae), found on 'Eua Island, Kingdom of Tonga. *Zootaxa* 3609(6): 589-592. (in English) ["A recent study of the 'Eua Island in the Kingdom of Tonga has yielded a small Odonata fauna including the new species *Teinobasis fatakula* (Holotype male: Kingdom of Tonga, 'Eua Island, 21.3781° S, 174.9346° W, elevation 175 m; 14 July 2012, M. Marinov leg.). Because 'Eua has aquatic habitats unique within the Kingdom of Tonga, the new species is very likely endemic to that island and represents an extension of the verified range of the genus of at least 2800 km." 12423. Moon, D.C.; Silva, D. (2013): Environmental heterogeneity mediates a cross-ecosystem trophic cascade. *Ecological Entomology* 38: 23-30. (in English) ["(1.) The flow of energy and nutrients across ecosystem boundaries can have significant community-wide effects, but the role of productivity of the recipient habitat in mediating these effects remains unclear. This is especially true when organisms moving across ecosystem boundaries serve simultaneously as predators and prey. (2.) In this study, the effects of odonates, primarily *Enallagma civile*, on a salt marsh system were examined. Cages were used to exclude odonate predators, but not other arthropods, from experimental plots of the sea oxeye daisy, *Borrchia frutescens* (L.) in high and low productivity areas. The effects were assessed on the in situ arthropod community and the host plant. (3.) There were strong direct effects of predation on the herbivores *Pissonotus quadripustulatus* Van Duzee and *Asphondylia borrichiae* Rossi and Strong, with higher densities where damselflies were excluded. Damselflies also served as prey for web-building spiders. This resulted in lower spider densities inside cages, and a positive indirect effect on grasshopper densities. (4.) Direct and indirect effects of odonates were greater in the high productivity area, resulting in a trophic cascade, with greater damage and reduced flowering and density of the host plant inside cages. (5.) The results of this study support the subsidy hypothesis and show that theoretical models of trophic dynamics, which were developed to explain exchanges within ecosystems, may have predictive and explanatory value for exchanges across ecosystems as well." (Authors)] Address: Moon, D.C., Dept of Biology, University of North Florida, Jacksonville, Florida, USA. E-mail: dmoon@unf.edu

12424. Murphy, J.F.; Davy-Bowker, J.; McFarland, B.; Ormerod, S.J. (2013): A diagnostic biotic index for assessing acidity in sensitive streams in Britain. *Ecological Indicators* 24(1): 562-572. (in English) ["Despite the history of freshwater biomonitoring, there is still a dearth of proven indices that allow accurate status assessment while simultaneously diagnosing the cause of impairment, particularly when stressors are multiple. Here, we present an approach to developing diagnostic indices where the sensitivity of biota (including *Cordulegaster boltonii*) is quantified using multivariate ordination. We applied the approach to the development of an index to detect acidity in British streams. Using a 197-site calibration dataset, we quantified variation in macroinvertebrate assemblages and determined which environmental variables best described the pattern. We then ranked taxa along an acid-base gradient, having first considered the merits of factoring out confounding variation from natural environmental factors. The response of the new species-level Acid Water Indicator Community (AWICsp) index to variation in base-flow and storm-flow pH and acid neutralising capacity (ANC) was quantified using independent data. Performance was also compared with existing family-level and species-level indices. AWICsp was consistently the species-level diagnostic index most clearly related to base-flow pH, storm-flow pH and ANC, accounting for 38–56% of the variation in acid conditions among the 76

test sites. Given the need to develop bio-diagnostic indicators, these data illustrate how organisms can indicate causes of stream impairment using robust and objective procedures, and when applied to strong environmental gradients such as acid–base status. We suggest that given the necessary calibration data, this approach could be applied successfully to other widespread stressors with equally strong biological effects such as organic pollution and fine sediment deposition, particularly if used in combination with RIVPACS-type predictive bioassessment models." 12425. Nautiyal, P.; Shivam Mishra, A. (2013): Variations in benthic macroinvertebrate fauna as indicator of land use in the Ken River, central India. *Journal of Threatened Taxa* 5(7): 4096-4105. (in English, with Marathian summary) ["Examination of benthic macroinvertebrates in semi-natural, urban and agricultural land use along the highland Ken River in central India reveals a significantly higher density in semi-natural compared with other two landuse. Insects dominate the fauna at seminatural (90%) and urban locations (93%) compared to agriculture sites (48%) where annelid share increases to 32%. The seminatural location characterized by rocky substrate support high relative abundance of Caenidae and Neoephemeridae. Their abundance decreases at urban locations. Brachycentridae, Chironomidae, Glossocolecidae, Nephthyidae, Thiariidae and Corbiculidae increased at urban and agriculture locations characterized by small-sized sediments, suggesting important role for substrate also. Ordination shows that the Caenidae and Heptageniidae are characteristic at semi-natural location, Leptophlebiidae, Hydroptychidae, Glossosomatidae at urban while Thiariidae and Chironomidae at agricultural locations. Functionally, the collectors dominate the fauna, as all three landuse, especially large tracts of agriculture, are a continuous source of particulate organic matter (POM) in the river." 12426. Nixon, M.R.; Orr, A.G.; Vukusic, P. (2013): Subtle design changes control the difference in colour reflection from the dorsal and ventral wing-membrane surfaces of the damselfly *Matronoides cyaneipennis*. *Optics Express* 21(2): 1479-1488. (in English) ["The hind wings of males of *M. cyaneipennis* exhibit iridescence that is blue dorsally and green ventrally. These structures are used semiotically in agonistic and courtship display. Transmission electron microscopy reveals these colours are due to two near-identical 5-layer distributed Bragg reflectors, one placed either side of the wing membrane. Interestingly the thicknesses of corresponding layers in each distributed Bragg reflector are very similar for all but the second layer from each outer surface. This one key difference creates the significant disparity between the reflected spectra from the distributed Bragg reflectors and the observed colours of either side of the wing. Modelling indicates that modifications to the thickness of this layer alone create a greater change in the peak reflected wavelength than is observed for similar modifications to the thickness of any

other layer. This results in an optimised and highly effective pair of semiotic reflector systems, based on extremely comparable design parameters, with relatively low material and biomechanical costs." An experimental approach with an odonate predator. *Ethology Ecology & Evolution* 25(2): 185-198. (in English) ["Predation is a primary driver of tadpole assemblages, and the activity rate is a good predictor of the tadpoles' tolerance for predation risk. The conflicting demands between activity and exposure to predation can generate suboptimal behaviours. Because morphological components, such as body colouration, may affect the activity of tadpoles, we predict that environmental features that enhance or match the tadpole colouration should affect their survival or activity rate in the presence of a predator. We tested this prediction experimentally by assessing the mortality rate of tadpoles of *Rhinella schneideri* and *Eupemphix nattereri* and the active time on two artificial background types: one bright-coloured and one black-coloured. We found no difference in tadpole mortality due to the background type. However, *R. schneideri* tadpoles were more active than *E. nattereri* tadpoles, and the activity of *R. schneideri* was reduced less in the presence of the predator than that of *E. nattereri*. Although the background colouration did not affect the tadpole mortality rate, it was a stimulus that elicited behavioural responses in the tadpoles, leading them to adjust their activity rate to the type of background colour." 12429. Nunes, A.L.; Richter-Boix, A.; Laurila, A.; Rebelo, R. (2013): Do anuran larvae respond behaviourally to chemical cues from an invasive crayfish predator? A community-wide study. *Oecologia* 171(1): 115-127. (in English) ["Antipredator behaviour is an important fitness component in most animals. A co-evolutionary history between predator and prey is important for prey to respond adaptively to predation threats. When non-native predator species invade new areas, native prey may not recognise them or may lack effective antipredator defences. However, responses to novel predators can be facilitated by chemical cues from the predators' diet. The red swamp crayfish *Procambarus clarkii* is a widespread invasive predator in the Southwest of the Iberian Peninsula, where it preys upon native anuran tadpoles. In a laboratory experiment we studied behavioural antipredator defences (alterations in activity level and spa-

tial avoidance of predator) of nine anurans in response to *P. clarkii* chemical cues, and compared them with the defences towards a native predator, the larval dragonfly *Aeshna* sp. To investigate how chemical cues from consumed conspecifics shape the responses, we raised tadpoles with either a tadpole-fed or starved crayfish, or dragonfly larva, or in the absence of a predator. Five species significantly altered their behaviour in the presence of crayfish, and this was largely mediated by chemical cues from consumed conspecifics. In the presence of dragonflies, most species exhibited behavioural defences and often these did not require the presence of cues from predation events. Responding to cues from consumed conspecifics seems to be a critical factor in facilitating certain behavioural responses to novel exotic predators. This finding can be useful for predicting antipredator responses to invasive predators and help directing conservation efforts to the species at highest risk." Explicando a riqueza de espécies pela variabilidade ambiental. *Entomobrasilia* 6(1): 1-8. (in Portuguese, with English summary) ["Variations in Odonata (Insecta) community in streams may be predicted by the plankton paradox? Explaining species richness by environmental variability: The theory of Plankton Paradox postulates that environments that exhibit regular temporal fluctuations would present a high diversity of species, since such fluctuations would prevent the occurrence of competitive exclusion. This work aimed evaluate variations in adult Odonata community in catchment of River Suiá-Miçú, testing the hypothesis that sites with environmental variables with the largest amplitude of variation would present the highest species richness. Were sampled 11 water bodies in an area of transition Cerrado-Amazon Forest in east-central Mato Grosso state, Brazil. Environmental variables evaluated were: environmental integrity (HII) and range of variation of pH, conductivity, air temperature, water temperature, dissolved oxygen, ammonia, phosphorus and Mg⁺. Were collected 2.144 specimens, distributed in eight families, 41 genera and 78 species. Our hypothesis was not confirmed, since the multiple regression analysis performed between the estimated kind of richness Anisoptera and Zygoptera with range of variation of physical-chemical was not significant for any of the eight variables, as well as for HII. Our results suggest that variations in the community of Odonata in streams cannot be explained by Plankton Paradox. We believe that this result may have occurred due mainly to the low variations in environmental conditions discussed, action of other local processes such as competition and predation or differ-

ences ecophysiological result of body size variation and capacity of thermoregulation in the order of the adults studied." (Authors)] Address: Juen, L. Universidade Federal do Para, Brasil. E-mail: leandrojuen@ufpa.br

12437. Ramirez-Gonzalez, R.; Yu, D.W.; Bruce, C.; Heavens, D.; Caccamo, M.; Emerson, B.C. (2013): PyroClean: Denoising pyrosequences from protein-coding

amplicons for the recovery of interspecific and intraspecific genetic variation. *PLoS ONE* 8(3): e57615. doi:10.1371/journal.pone.0057615: 11 pp. (in English) ["High-throughput parallel sequencing is a powerful tool for the quantification of microbial diversity through the amplification of nuclear ribosomal gene regions. Recent work has extended this approach to the quantification of diversity within otherwise difficult-to-study metazoan groups. However, nuclear ribosomal genes present both analytical challenges and practical limitations that are a consequence of the mutational properties of nuclear ribosomal genes. Here we exploit useful properties of protein-coding genes for cross-species amplification and denoising of 454 flowgrams. We first use experimental mixtures of species from the class Collembola to amplify and pyrosequence the 5' region of the COI barcode, and we implement a new algorithm called PyroClean for the denoising of Roche GS FLX pyrosequences. Using parameter values from the analysis of experimental mixtures, we then analyse two communities sampled from field sites on the island of Tenerife. Cross-species amplification success of target mitochondrial sequences in experimental species mixtures is high; however, there is little relationship between template DNA concentrations and pyrosequencing read abundance. Homopolymer error correction and filtering against a consensus reference sequence reduced the volume of unique sequences to approximately 5% of the original unique raw reads. Filtering of remaining non-target sequences attributed to PCR error, sequencing error, or numts further reduced unique sequence volume to 0.8% of the original raw reads. PyroClean reduces or eliminates the need for an additional, time-consuming step to cluster reads into Operational Taxonomic Units, which facilitates the detection of intraspecific DNA sequence variation. PyroCleaned sequence data from field sites in Tenerife demonstrate the utility of our approach for quantifying evolutionary diversity and its spatial structure. Comparison of our sequence data to public databases reveals that we are able to successfully recover both interspecific and intraspecific sequence diversity." 12439. Ren, H.; Wang, X.; Li, X.; Chen, Y. (2013): Effects of dragonfly wing structure on the dynamic performances. *Journal of Bionic Engineering* 10(1): 28-38. (in English) ["The configurations of dragonfly wings, including the corrugations of the chordwise cross-section, the microstructure of the longitudinal veins and membrane, were comprehensively investigated using the

Environmental Scanning Electron Microscopy (ESEM). Based on the experimental results reported previously, the multi-scale and multi-dimensional models with different structural features of dragonfly wing were created, and the biological dynamic behaviours of wing models were discussed through the Finite Element Method (FEM). The results demonstrate that the effects of different structural features on dynamic behaviours of dragonfly wing such as natural frequency/modal, bending/torsional deformation, reaction force/torque are very significant. The corrugations of dragonfly wing along the chordwise can observably improve the flapping frequency because of the greater structural stiffness of wings. In updated model, the novel sandwich microstructure of the longitudinal veins remarkably improves the torsional deformation of dragonfly wing while it has a little effect on the flapping frequency and bending deformation. These integrated structural features can adjust the deformation of wing oneself, therefore the flow field around the wings can be controlled adaptively. The fact is that the flights of dragonfly wing with sandwich microstructure of longitudinal veins are more efficient and intelligent." 12442. Rizo-Patron, F.; Kumar, A.; McCoy Colton, M.B.; Springer, M.; Trama, F.A. (2013): Macroinvertebrate communities as bioindicators of water quality in conventional and organic irrigated rice fields in Guanacaste, Costa Rica. *Ecological Indicators* 29: 68-78. (in English) ["The purpose of this study was to compare how aquatic macroinvertebrates are affected by certain management practices and agrochemicals in organic and conventional rice cultivations (treatments) in northwestern of Costa Rica. We sampled macroinvertebrates in both treatments, at the water entrances (irrigation) and exits (drainage) during two cycles (8 months total) of rice field cultivation. We employed a water quality index using macroinvertebrates (BMWP/CR) as bioindicators in both management treatments. Insect family mean ($P = 0.0019$) and species mean richness ($P = 0.0340$) were greater in the organic vs. the conventional treatments as well as at the entrances rather than their exits. Both macroinvertebrates mean abundance ($P = 0.0281$) and insects mean abundances ($P = 0.0065$) were greater at the organic vs. the conventional treatments. The water quality index (BMWP/CR) was greater in the organic treatment at the entrance (124) comparing with the exit (72), and also at the conventional entrance (92) vs. the exit (66), thus showing that the management practices affected the macroinvertebrate community. The organic treatment showed the settlement of a greater number of families and species of macroinvertebrates both in general and in those considered sensitive to pollution than in the conventional treatment. This sensitive group of macroinvertebrates (Baetis sp., Fallceon sp., Leptohyphes sp., Tricorythodes sp., Farrowes sp., Phyllogomphoides sp., Hydroptila sp., Mayatrichia sp., Neotrichia sp., Oxyethira sp., Nectopsyche sp.1, Nectopsyche sp.2, Oecetis sp.) can be used as a bioindicators of water quality in these agroecosystems. On the contrary, more macroinvertebrates resistant to pollution were found in the conventional compared to the organic treatment, showing that aquatic macroinvertebrates respond to the type of management/products that are applied to the rice field." (Authors)] Address: Rizo-Patrón, F., Organization for Tropical Studies, Palo Verde Biological Station, Guanacaste, Costa Rica. E-mail: frizopatron@ibcperu.org

12443. Rosario, K.; Padilla-Rodriguez, M.; Kraberger, S.; Stainton, D.; Martin, D.P.; Breitbart, M.; Varsani, A. (2013): Discovery of a novel mastrevirus and alphasatellite-like circular DNA in dragonflies (Ephemeroptera) from Puerto Rico. *Virus Research* 171: 231-237. (in English) ["Geminiviruses have emerged as serious agricultural pathogens. Despite all the species that have been already catalogued, new molecular techniques continue to expand the diversity and geographical ranges of these single-stranded DNA viruses and their associated

satellite molecules. Since all geminiviruses are insect-transmitted, examination of insect vector populations through vector-enabled metagenomics (VEM) has been recently used to investigate the diversity of geminiviruses transmitted by a specific vector in a given region. Here we used a more comprehensive adaptation of the VEM approach by surveying small circular DNA viruses found within top insect predators, specifically dragonflies (Ephemeroptera). This 'predator-enabled' approach is not limited to viral groups transmitted by specific vectors since dragonflies can accumulate the wide range of viruses transmitted by their diverse insect prey. Analysis of six dragonflies collected from an agricultural field in Puerto Rico culminated in the discovery of the first mastrevirus (Dragonfly-associated mastrevirus; DfasMV) and alphasatellite molecule (Dragonfly-associated alphasatellite; Dfas-alphasatellite) from the Caribbean. Since DfasMV and Dfas-alphasatellite are divergent from the limited number of sequences that have been reported from the Americas, this study unequivocally demonstrates that there have been at least two independent past introductions of both mastreviruses and alphasatellites to the New World. Overall, the use of predacious insects as sampling tools can profoundly alter our views of natural plant virus diversity and biogeography by allowing the discovery of novel geminiviruses and associated satellite molecules without a priori knowledge of the types of viruses or insect vectors in a given area." (Authors)] Address: Varsani, A., School Biol. Sci., Univ. Canterbury, Private Bag 4800, Christchurch 8140, New Zealand. E-mail: arvind.varsani@canterbury.ac.nz

12444. Ruhi, A.; Boix, D.; Gascon, S.; Sala, J.; Quintana, X.D. (2013): Nestedness and successional trajectories of macroinvertebrate assemblages in man-made wetlands. *Oecologia* 171(2): 545-556 (in English) ["Current successional models, primarily those based on floral succession, propose several distinct trajectories based on the integration of two key hypotheses from succession theory: convergence versus divergence in species composition among successional sites, and progression towards versus deviation from a desired reference state. We applied this framework to faunal succession, including differential colonization between active and passive dispersers, and the nested patterns generated as a consequence of this peculiarity. Nine man-made wetlands located in three different areas, from 0–3 years from wetland creation, were assessed. In addition, 91 wetlands distributed throughout the region were used as references for natural macroinvertebrate communities. We predicted the following: (1) highly nested structures in pioneering assemblages will decrease to lower mid-term values due to a shift from active pioneering taxa to passive disperser ones; (2) passive idiosyncratic taxa will elicit divergent successional trajectories among areas; (3) the divergent trajectories will provoke lower local and higher regional diversity values in the mid-term assemblages than in pioneer assemblages. Our results were largely congruent with hypotheses (1) and (2), diverging from the anticipated patterns only in the case of the temporary wetlands area. However, overall diversity trends based on hypothesis (3) did not follow the expected pattern. The divergent successional trajectories did not compensate for regional biodiversity losses that occurred as a consequence of pioneering colonizer decline over time. Consequently, we suggest reconsidering wetland construction for mitigation purposes within mid-term time frames

(B3 years). Wetlands may not offset, within this temporal scenario, regional biodiversity loss because the ecosystem may not support idiosyncratic taxa from natural wetlands." (Authors) Supplementary data provide information at the species level, while the main paper analyses the taxa (including Odonata) at family level.] Address: Ruhí, A., Catalan Institute for Water Research (ICRA), Scientific and Technological Park of the University of Girona, H2O Building, Emili Grahit 101, 17003 Girona, Catalonia, Spain. 12445. Rychła, A. (2013): New sites of the Golden-ringed Dragonfly *Cordulegaster boltonii* (Donovan, 1807) (Odonata: Cordulegasteridae) in the mid-western Poland. *Odonatrix* 9(1): 21-28. (in Polish, with English summary) ["*C. boltonii* has been known from 133 sites in Poland so far. Currently, the largest metapopulations are present in the Pomarenian's Lake District, Lubusz Land, Upper Silesia and Lesser Poland. However, the knowledge about the distribution of *C. boltonii* is still incomplete and any information is required since it has been vulnerable and consequently protected species in Poland. Therefore, new records of *C. boltonii* from mid-western Poland (southern Lubusz Land) are presented in this paper. The investigated area is situated on territories of communes Brody, Gubin, Lubsko and Tuplice in the Lubuskie District. In brief, it is lowland locally with varied relief structure of numerous morainic hills (altitudes to 120 a.s.l.) and depressions (altitudes to 50 a.s.l.), particularly covered by pine cultures with small participation of leaf forests. The main running waters like Pstrąg, Tymnica, Golec and Wełnica represent the type of lowland rivers dominated by sandy channel substrates and receive flows from numerous small tributaries in the area. The investigation was carried out from April to October 2011 in selected sections (length of 100–500 m) of all running waters. The occurrence of larvae, exuviae and imagines, as well as the general hydromorphological features of each habitat were noted. For larvae, 15 to 20 samples were taken with a hydrobiological scoop at each site. As result, *C. boltonii* was observed at 16 sites in 11 running waters (small rivers and streams). Larvae were found at 12 sites localized in 7 running waters, providing a breeding success of *C. boltonii* in these habitats. The highest number of larvae was found in small forest streams at sites 6 and 9, with 21 and 22 larvae respectively. The habitats of *C. boltonii* are small-mid lowland streams, rivers, and rarely ditches with the width range of 0,5–3,5 m and depth range of 10–100 cm; with swift current, sandy and sand-gravelled bottom partially covered with fine and grob detritus deposits. The flowing water is clear, but at the most sites brown coloured probably as a result of large iron content. Currently, the surface waters in the investigated are only under slight anthropogenic pressure, manifesting in low risk of dispersed nutrients inflows from the drainage basin and in temporary changing hydrological regime and water quality by fish ponds. Locally, the hydrological regime of some running waters is changed by beaver's dam constructions, which slow down the current. In fact, only imagines could be found at some sites downstream from the fish ponds (No. 2 and 7), suggesting that the larvae might avoid habitats localized directly beyond fish ponds. (sites No. However, with increasing distance from ponds, larvae could be observed again (sites No. 4a, 4b, 4c). Additionally, the significant hydromorphological changes occurred only locally (sites No. 3, 4a, 8 and 10) as a result of beaver's activity (several meters

above the dams). The larvae of *C. boltonii* weren't observed only the still water bodies. It indicates, that the beavers might have a negative influence only on short sections of habitats used by *C. boltonii* in this area. To conclude, the data indicate that the southern part of Lubusz Land is currently an important area for the development and protection of an intact population of *C. boltonii* in Poland." 12446. Sacchi, R.; Hardersen, S. (2013): Wing length allometry in Odonata: differences between families in relation to migratory behaviour. *Zoomorphology* 132(1): 23-32. (in English) ["In insects, wing shape and body size are correlated with several aspects of behaviour, and the optimal morphology of wings is a trade-off between a number of functional demands in relation to behaviour (e.g. foraging, migration and sexual display). Dragonflies are spectacularly skilful flyers and present a range of different wing shapes, but to date, no detailed studies have been conducted in this group on wing length allometry in relation to body size. In this paper, we use published data on body length and wing length in all European and North American dragonflies to investigate differences in wing length allometries among Odonata taxa (suborders and families) and to relate these to behavioural patterns. We found different wing allometries between Zygoptera and Anisoptera, which are probably related to the flight mode and wing form of the two suborders. Among the Anisoptera, the Libellulidae showed a distinct wing length allometry from all other anisopteran families and migrants differed from non-migrant species. The first dichotomy is likely to reflect the adaptation of wing morphology of Libellulidae to sit-and-wait behaviour and to brief foraging flights (most species of this family are perchers) with respect to all other families, members of which are typically flyers. The second dichotomy reflects the trend of migrating species to have relatively longer wings than non-migrating members of the same family. Finally, wing length allometry differed among all the zygopteran families analysed, and this pattern suggested that each family evolved a particular wing morphology in response to peculiarities in behaviour, habitat and flight mode." (2013): Maintenance of polymorphic females: do parasites play a role? *Oecologia* 171(1): 105-113. (in English) ["The role of parasites in explaining maintenance of polymorphism is an unexplored research avenue. In odonates, female-limited colour polymorphism (one female morph mimicking the conspecific male and one or more gynochromatic morphs) is widespread. Here we investigated whether parasitism contributes to colour polymorphism maintenance by studying six species of female dimorphic damselflies using large databases of field-collected animals. We predicted that androchrome females (male mimics) would be more intensively parasitized than gynochrome females which is, according to previous studies, counterbalanced by the advantages of the former when evading male harassment compared to gynochrome females. Here we show that in *Ischnura denticollis* and *Enallagma no-*

vahispaniae, androchrome females suffer from a higher degree of parasitism than gynochromatic females, and contrary to prediction, than males. Thus, our study has detected a correlation between colour polymorphism and parasitic burden in odonates. This leads us to hypothesize that natural selection, via parasite pressure, can explain in part how androchrome and gynochrome female colour morphs can be maintained. Both morphs may cope with parasites in a different way: given that androchrome females are more heavily parasitized, they may pay a higher fecundity costs, in comparison to gynochrome females." (in English) ["Damselfly larvae, important predators and prey in many freshwater communities, may be particularly sensitive to hypoxia because their caudal lamellae (external gills) are frequently lost. In this study, we address how lost lamellae interact with low oxygen to affect respiration and behaviour of the widespread North American damselfly *Ischnura posita*. Results showed no effect of lost lamellae on resting metabolic rate or critical oxygen tension. Ventilation behaviours increased only when dissolved oxygen (DO) was at or below 25% saturation, and these behaviours were not affected by the number of lamellae. Use of the oxygen-rich surface layer occurred almost exclusively at the lowest dissolved oxygen level tested (10% saturation, 2.0 kPa). Damselflies that were missing lamellae spent more time at the surface than individuals with intact lamellae. The negative relationship between body size and time at the surface, and the negative relationship between body mass and critical oxygen tension suggest that larger *I. posita* may be more hypoxia tolerant than smaller individuals. Overall, *I. posita* was minimally affected by missing lamellae and seems well adapted to low DO habitats. Average critical oxygen

tension was very low (0.48 kPa, 2.4% saturation), suggesting that individuals can maintain their metabolic rate across a broad range of DO, and behaviours changed only at DO levels below the hypoxia tolerance thresholds of many other aquatic organisms." 12451. Siepielski, A.M.; McPeck, M.A. (2013): Niche versus neutrality in structuring the beta diversity of damselfly assemblages. *Freshwater Biology* 58(4): 758-768. (in English) ["(1.) Differences among communities in taxonomic composition – beta diversity – are frequently expected to result from taxon-specific responses to spatial variation in ecological conditions, through niche partitioning. Such process-derived patterns are in sharp contrast to arguments from neutral theory, where taxa are ecologically equivalent and beta diversity results primarily from dispersal limitation. (2.) Here, we compared beta diversity among assemblages of Zygoptera, for which previous experiments have shown that niche differences maintain genera within a community, but patterns of relative abundance for species within each genus are shaped primarily by neutral dynamics. (3.) Using null-model and ordination-based methods, we find that both genera and (in contrast to neutral theory) species assemblage composition vary across the landscape in a deterministic fashion, shaped by environmental and spatial factors. (4.) While the observed patterns in species composition conflict with theory, we suggest that this is a result of weak ecological filters acting to produce spatial variation in assemblages of ecologically similar species undergoing ecological drift within communities. Such patterns are especially likely in systems of relatively weak dispersers like damselflies." 12452. Sim, L.L.; Davis, J.A.; Strehlow, K.; McGuire, M.; Traylor, K.M.; Wild, S.; Papas, P.J.; O'Connor, J. (2013): The influence of changing hydroregime on the invertebrate communities of temporary seasonal wetlands. *Freshwater Science* 32(1): 328-342. (in English) ["Community dynamics in temporary waters are constrained by the hydroregime (depth, timing, duration, frequency, and predictability of water in an aquatic habitat), which in turn is influenced by climatic patterns and anthropogenic use of water in the landscape. Declining rainfall in regions with a Mediterranean climate, such as southwestern Australia, has decreased the depth and duration of water in temporary wetlands, potentially altering the composition of invertebrate communities. We used a long-term data set (6–25 y) to examine temporal changes in hydroregimes and aquatic invertebrate diversity (based on species presence/absence) at 9 seasonal wetlands. The study wetlands maintained distinctly seasonal hydroregimes, despite declining rainfall and the contraction of wetland hydroperiods. Distance-based redundancy analysis (dbRDA) indicated that conductivity, NO₃-+NO₂-, and turbidity were the most important factors explaining the changes in invertebrate community composition over time. Allocation of species into 4 trait-based groups based on their resilience to or

resistance of drought and their mode of recolonization of a water body upon rewetting revealed that the fauna is dominated by active dispersers. This result suggests that the proximity of source wetlands from which mobile invertebrate species and vertebrate vectors, such as waterbirds, can recolonize seasonal wetlands is an important factor influencing the invertebrate community response to rewetting. Despite the decline in water availability, we found little evidence of a shift to a more arid-adapted fauna. We suggest that the maintenance of a mosaic of wetlands of varying hydroregimes at the whole-landscape scale will be critical to the future persistence of aquatic invertebrate communities in Mediterranean regions where the frequency and intensity of droughts is predicted to increase... Group-3 taxa (colonists that do not need water for egg laying) were relatively rare. Those recorded included damselflies (Lestidae), mosquitoes (Culicidae), and dragonflies (Libellulidae)." 12453. Simaika, J.P.; Samways, M.J.; Kipping, J.; Suhling, F.; Dijkstra, K.-D.B.; Clausnitzer, V.; Boudot, J.-P.; Domisch, S. (2013): Continental-scale conservation prioritization of African dragonflies. *Biological Conservation* 157: 245-254. (in English) ["Indicators on the state of global biodiversity illustrate continued decline, while pressure on biodiversity keeps rising. This necessitates revisiting site prioritization and species protection for conservation. Patterns of richness and threat of four well-studied aquatic taxa, the fishes, crabs, molluscs and dragonflies largely coincide at the continental scale, at least in Africa. For this study, we focus on dragonflies, for which there is a point locality database, as a surrogate taxon, modelling the species at the fine-scale, using species distribution modelling. With this approach, we built a protected areas network using spatial planning software. Priority areas for dragonfly conservation largely coincided with analyses of global biodiversity hotspots. The Zambian swamps and woodlands, as well as the rainforests of the Lower Guinea and Congo Basin are emphasized as hotspots of dragonfly diversity. Among globally threatened species, 72% were recorded at least once in a protected area. Although the current reserve network covers 10.7% of the landscape, the proportional representation of species geographic distributions in reserves is only 1.2%. The reserve network is therefore inefficient concerning freshwater species, and many areas of conservation priority that are not formally protected remain. The advantage of operating at the fine scale, while covering a large geographic area is that it shifts the focus from the large-scale hotspots to smaller priority areas within and beyond hotspots. Also, by operating at the fine-scale for a large geographical area, the potential exists for local conservation managers to consider campaigning for the inclusion of the priority areas that are not formally protected, while adjacent to the existing reserve networks. Where this is not possible, we recommend monitoring these areas to detect future threats to the habitats that these might face." of incongruence using new transcriptomic data. *Genome Biol Evol.* 4(12): 1295-1309. (in English) ["The evolution of the diverse insect lineages is one of the most fascinating issues in evolutionary biology. Despite extensive research in this area, the resolution of insect phylogeny especially of inter-ordinal relationships has turned out to be still a great challenge. One of the challenges for insect systematics is the radiation of the polyneopteran lineages with several contradictory and/or unresolved relationships. Here, we provide the first transcriptomic data for three enigmatic polyneopteran orders (Dermaptera, Plecoptera and Zoraptera) to clarify on of the most debated issues among higher insect systematics. We applied different approaches to generate three data sets comprising 78 species and 1,579 clusters of orthologous genes. Using these three matrices we explored several key mechanistic problems of phylogenetic reconstruction including missing data, matrix selection, gene and taxa number/choice and the biological function of the genes. Based on the first phylogenomic approach including these three ambiguous polyneopteran orders we provide here conclusive support for monophyletic Polyneoptera, contesting the hypothesis of Zoraptera+Paraneoptera and Plecoptera+remaining Neoptera. In addition, we employ various approaches to evaluate data quality and highlight problematic nodes within the Insect Tree that still exist despite our phylogenomic approach. We further show how the support for these nodes or alternative hypotheses might depend on the taxon- and/or gene-sampling." 12457. Stewart, S.S.; Vodopich, D.S. (2013): Variation in fluctuating asymmetry among nine damselfly species. *International Journal of Odonatology* 16(1): 67-77. (in English) ["Fluctuating asymmetry (FA), measured as

random deviations from bilateral symmetry, likely results from developmental disturbances by internal or environmental stresses. However, comparisons of FA in single damselfly species (Odonata: suborder Zygoptera) from stressed environments have often been inconclusive. We measured levels of FA among multiple species of damselflies from the same environment to determine the relative roles of environmental stress and species-specific developmental instability. Damselflies of nine species (*Argia sedulum*, *A. nahuana*, *A. immundum*, *Ischnura ramburii*, *I. hastata*, *I. posita*, *Enallagma civile*, *E. basidens*, *Telebasis salva*) were collected from a central Texas wetland. Calculations of their FA were based on cell counts of four clearly defined areas (venation patterns) in fore and hind wings. Significant FA of venation occurred in both sexes, both wing positions, and in each of four venation patterns of all nine species. Levels of FA were not significantly different between sexes or between wing positions for any of the nine species. However, FA varied significantly among the four venation patterns. Patterns with lowest mean cell counts had significantly higher FA than the other patterns, despite scaling to remove size bias. More broadly, a three-fold difference in overall FA occurred among the nine species and was not correlated with species mean weight or abdomen length. The wide range of FA levels among multiple species in the same environment calls for caution in designing studies that select a single species expected to be sensitive to environmental stress. Future research must examine the relative roles of species-specific predispositions for FA from internal genetic stresses as well as external stressors." 12458. Suhling, I.; Suhling, F. (2013): Thermal adaptation affects interactions between a range-expanding and a native odonate species. *Freshwater Biology* 58(4): 705-714. (in English) ["(1.) Increasing temperature and invading species may interact in their effects on communities. In this study, we investigated how rising temperatures alter larval interactions between a naturally range-expanding dragonfly, *Crocothemis erythraea*, and a native northern European species, *Leucorrhinia dubia*. Initial studies revealed that *C. erythraea* grow up to 3.5 times faster than *L. dubia* at temperatures above 16 C. As a result, we hypothesised that divergent temperature responses would lead to rapid size differences between coexisting larvae and, consequently, to asymmetric intraguild predation at higher ambient temperatures. (2.) Mortality and growth rates were measured in interaction treatments (with both species present) and non-interaction controls (one species present) at four different temperature regimes: at an ambient temperature representative of central Germany, where both species overlap in distribution, and at temperatures increased by 2, 4 and 6 C. (3.) The mortality of *C. erythraea* did not differ between treatment and control. In contrast, mortality of *L. dubia* remained similar over all temperatures in the controls, but increased with temperature in the presence of the other species and was significantly higher there than in the controls. We concluded that *L. dubia* suffered asymmetric intraguild predation, particularly at increased temperature. Reduced growth rate of *L. dubia* in the interaction treatment at higher temperatures also suggested asymmetric competition for prey in the first phase of the experiment. (4.) The results imply that the range expansion of *C. erythraea* may cause reduction in population size of

syntopic *L. dubia* when temperature rises by more than 2°C. The consequences for future range patterns, as well as other factors that may influence the interaction in nature, are discussed." 12459. Sundermann, A.; Gerhardt, M.; Kappes, H.; Haase, P. (2013): Stressor prioritisation in riverine ecosystems: Which environmental factors shape benthic invertebrate assemblage metrics? *Ecological Indicators* 27: 83-96. (in English) ["Aquatic ecosystems are amongst the most heavily altered ecosystems and exhibit a disproportional loss of biodiversity. Numerous stressors, such as nutrient enrichment, contaminant pollution, sedimentation and alterations in stream hydrology and habitat structure, account for these losses. Understanding these forces is of utmost importance to prevent riverine ecosystems from further deterioration and to provide helpful insights for restoration practices. In the present study, we analyse the response of biological indicators to a large number of environmental factors. For this, benthic invertebrate assemblages (including Odonata at the order level) from 83 sites in Germany were described based on 25 metrics from four different metric types. The condition of the sites was described using 27 environmental factors: 13 for water quality, 4 for land use in the catchment and 10 for local scale habitat structure. The relative importance of single environmental predictors or predictor combinations for benthic invertebrate assemblages was analysed with single and multiple linear regression models. The results for the latter models were statistically supported via a bootstrap approach. The models revealed the importance of water quality and catchment-scale land use in explaining benthic invertebrate assemblages; in particular, chloride, oxygen, total organic carbon and the amounts of artificial surfaces and arable land were the most important predictors. Models including solely structural variables such as plan form, bank structures and substrate diversity had lower goodness of fit values than those for other variables. Regarding the four different assemblage metric types, functional metrics had on average lower goodness of fit values than composition/abundance, richness/diversity and sensitivity/tolerance metrics. Among the richness/diversity metrics, however, the model results for the Shannon–Wiener and Simpson diversity indices and evenness were poor. Our results show that catchment-related factors and water quality were of overriding importance in shaping biodiversity patterns and causing species loss. In contrast, structural degradation at a local scale was not the most significant stressor. This finding might explain why structural restoration at a reach scale often yields a low benefit–cost ratio and may be considered to represent inappropriate investment prioritisation." 12460. Takahara, T.; Doi, H.; Kohmatsu, Y.; Yamaoka, R. (2013): Different chemical cues originating from a shared predator induce common defense responses in two prey species. *Animal Cognition* 16(1): 147-153. (in English) ["In freshwater ecosystems, inducible defenses that involve behavioural or morphological changes in

response to chemical cue detection are key phenomena in prey–predator interactions. Many species with different phylogenetic and ecological traits (e.g., general activity patterns and microhabitats) use chemical cues to avoid predators. We hypothesized that prey species with a shared predator, but having different ecological traits, would be adapted to detect different chemical cues from the predator. However, the proximate mechanisms by which prey use chemical cues to avoid predation remain little known. Here, we tested our hypothesis by using fractionated chemical components from predatory dragonfly nymphs (*Anax parthenope julius*) to trigger anti-predator behavioural responses in two anuran tadpoles, the wrinkled frog *Glandirana* (*Rana*) *rugosa* and the Japanese tree frog *Hyla japonica*. *Glandiranarugosa* detected chemical cues that had either high or low hydrophobic properties, but *H. japonica* responded only to chemical cues with hydrophilic properties. During the normal behaviours of these tadpole species, *G. rugosa* remains immobile in benthic habitats, whereas *H. japonica* exhibits active swimming at the surface or in the middle of the water column. As we had hypothesized, these tadpole species, which have different general activity levels and microhabitats, detected different chemical cues that were exuded by their shared predator and responded by changing their activities to avoid predation. The specific chemical cues detected by each tadpole species are likely to have characteristics that optimize effective predator detection and encounter avoidance of the shared dragonfly predator." 12461. Takahashi, Y.; Watanabe, M. (2013): Time constraints related to sexual maturation and prolonged copulation in the female-dimorphic damselfly *Ischnura senegalensis*. *Entomological Science* 16(1): 34-39. (in English) ["Time constraints are critical for reproductive success. To understand the spatiotemporal dynamics of morph frequency in the female-dimorphic damselfly *Ischnura senegalensis*, we compared two different morphs for two important time constraints on female reproductive output, i.e. post-emergence sexual maturation and prolonged copulation. The females of both morphs achieved sexual maturation 4–5 days after emergence, suggesting that the rate of sexual maturation does not result in morph-specific fitness. The copulation durations declined with the time of onset of copulation in both morphs. Consequently, all copulations terminated at approximately 12:00 hours. Because females show foraging and oviposition activity only after copulation, the copulation duration does not result in morph-specific time constraints. These two important time constraints do not account for morph-specific reproductive success and do not affect the evolutionary equilibrium of morph frequency in *I. senegalensis*." 12466. Thomas, J.A.; Trueman, J.W.H.; Rambaut A.; Welch, J.J. (2013): Relaxed phylogenetics and the palaeoptera problem: Resolving deep ancestral splits in the insect phylogeny. *Systematic Biology* 62(2): 285 - 297. (in English) ["The order in which the three groups

of winged insects (the Pterygota) diverged from their common ancestor has important implications for understanding the origin of insect flight. But despite this importance, the split between the Odonata (dragonflies and damselflies), Ephemeroptera (mayflies) and Neoptera (the other winged orders) remains very much unresolved. Indeed, previous studies have obtained strong apparent support for each of the three possible branching patterns. Here, we present a systematic reinvestigation of the basal pterygote split. Our results suggest that outgroup choice and limited taxon sampling have been major sources of systematic error, even for datasets with a large number of characters (e.g., in phylogenomic datasets). In particular, a dataset of 113 taxa provides consistent support for the Palaeoptera hypothesis (the grouping of Odonata with Ephemeroptera), while results from datasets with fewer taxa give inconsistent results, and are highly sensitive to minor changes in data and methods. We also focus on recent methods that exploit temporal information using fossil calibrations, combined with additional assumptions about the evolutionary process, and so reduce the influence of outgroup choice. These methods are shown to provide more consistent results, for example, supporting Palaeoptera, even for datasets that previously supported other hypotheses. Together, these results have implications for understanding insect origins and for resolving other problematic splits in the tree of life." 12467. Tiitsaar, A.; Kaasik, A.; Teder, T. (2013): The effects of seasonally variable dragonfly predation on butterfly assemblages. *Ecology* 94(1): 200-207. (in English) ["Where predation is seasonally variable, the potential impact of a predator on individual prey species will critically depend on phenological synchrony of the predator with the prey. Here we explored the effects of seasonally variable predation in multispecies assemblages of short-lived prey. The study was conducted in a landscape in which we had previously demonstrated generally high, but spatially and seasonally variable dragonfly-induced mortality in adult butterflies. In this system, we show that patterns of patch occupancy in butterfly species flying during periods of peak dragonfly (in >90% *Orthetrum cancellatum*) abundance are more strongly associated with spatial variation in dragonfly abundance than patch occupancy of species flying when dragonfly density was low. We provide evidence indicating that this differential sensitivity of different butterfly species to between-habitat differences in dragonfly abundance is causally tied to seasonal variation in the intensity of dragonfly predation. The effect of dragonfly predation could also be measured at the level of whole local butterfly assemblages. With dragonfly density increasing, butterfly species richness decreased, and butterfly species composition tended to show a shift towards a greater proportion of species flying during periods of off-peak dragonfly abundance." 12469. Touchon, J.C.; McCoy, M.W.; Vonesh, J.R.; Warkentin, K.M. (2013): Effects of plastic hatching timing carry over through metamorphosis in red-eyed treefrogs. *Ecology* 94: 850-860. (in English) ["Environmentally cued plasticity in hatching timing is widespread in animals. As with later life-history switch points, plasticity in hatching timing may have carryover effects that affect subsequent interactions with predators and competitors. Moreover, the strength of such effects of hatching plasticity may be context dependent. We used red-eyed treefrogs, *Agalychnis callidryas*, to test for lasting effects of hatching timing (four or six days post-oviposition) under factorial combinations of resource levels (high or low) and predation risk (none, caged, or lethal *Pantala flavescens* dragonfly naiads). Tadpoles were raised in 400-L mesocosms in Gamboa, Panama, from hatching until all animals had metamorphosed or died, allowing assessment of effects across a nearly six-month period of metamorphosis. Hatching early reduced survival to metamorphosis, increased larval growth, and had context-dependent effects on metamorph phenotypes. Early during the period of metamorph emergence, early-hatched animals were larger than late-hatched ones, but this effect attenuated over time. Early-hatched animals also left the water with relatively longer tails. Lethal predators dramatically reduced survival to metamorphosis, with most mortality occurring early in the larval period. Predator effects on the timing of metamorphosis and metamorph size and tail length depended upon resources. For example, lethal predators reduced larval periods, and this effect was stronger with low resources. Predators affected metamorph size early in the period of metamorphosis, whereas resource levels were a stronger determinant of phenotype for animals that metamorphosed later. Effects of hatching timing were detectable on top of strong effects of larval predators and resources, across two subsequent life stages, and some were as strong as or stronger than effects of resources. Plasticity in hatching timing is ecologically important and currently underappreciated. Effects on metamorph numbers and phenotypes may impact subsequent interactions with predators, competitors, and mates, with potentially cascading effects on recruitment and fitness." 12470. Tweedy, B.; Drenner, R.W.; Murray Chumchal, M.; Kennedy, J.H. (2013): Effects of fish on emergent insect-mediated flux of methyl mercury across a gradient of contamination. *Environ. Sci. Technol.* 47: 1614-1619. (in English) [Texas, USA; "We examined the effects of fish predation on emergent insect-mediated methyl mercury (MeHg) flux across a gradient of MeHg contamination in experimental ponds. Emergent insects were collected from ponds with (n=5) and without fish (n=5) over a six-week period using floating emergence traps. We found that the potential for MeHg flux increased with Hg contamination levels of the ponds, but that the realized MeHg flux of individual insect taxa was determined by fish presence. Fish acted as size-selective predators and reduced MeHg flux by suppressing emergence of large insect taxa (Odonata) but not small insect taxa (chironomids and micro-caddis-

flies). MeHg flux by small insect taxa was correlated with concentrations of MeHg in terrestrial spiders along the shorelines of the study ponds, demonstrating for the first time the cross-system transport of MeHg by emergent insects to a terrestrial spider." 12471. van Strien, A.J.; Termaat, T.; Kalkman, V.; Prins, M.; De Knijf, G.; Gourmand, A.-L.; Xavier Houard, X.; Nelson, B.; Plate, C.; Prentice, S.; Regan, E.; Smallshire, D.; Vanappelghem, C.; Vanreusel, W. (2013): Occupancy modelling as a new approach to assess supranational trends using opportunistic data: a pilot study for the damselfly *Calopteryx splendens*. *Biodivers. Conserv.* 22(3): 673-686. (in English) ["There is limited information available on changes in biodiversity at the European scale, because there is a lack of data from standardised monitoring for most species groups. However, a great number of observations made without a standardised field protocol is available in many countries for many species. Such opportunistic data offer an alternative source of information, but unfortunately such data suffer from non-standardised observation effort and geographical bias. Here we describe a new approach to compiling supranational trends using opportunistic data which adjusts for these two major imperfections. The non-standardised observation effort is dealt with by occupancy modelling, and the unequal geographical distribution of sites by a weighting procedure. *C. splendens* was chosen as our test species. The data were collected from five countries (Ireland, Great Britain, the Netherlands, Belgium and France), covering the period 1990–2008. We used occupancy models to estimate the annual number of occupied 1 x 1 km sites per country. Occupancy models use presence-absence data, account for imperfect detection of species, and thereby correct for between-year variability in observation effort. The occupancy models were run per country in a Bayesian mode of inference using JAGS. The occupancy estimates per country were then aggregated to assess the supranational trend in the number of occupied 1 x 1 km². To adjust for the unequal geographical distribution of surveyed sites, we weighted the countries according to the number of sites surveyed and the range of the species per country. The distribution of *C. splendens* has increased significantly in the combined five countries. Our trial demonstrated that a supranational trend in distribution can be derived from opportunistic data, while adjusting for observation effort and geographical bias. This opens new perspectives for international monitoring of biodiversity." (Authors)] Address: van Strien, A.J., Statistics Netherlands, P.O. Box 24500, 2490 HA The Hague, The Netherlands. Rapport VS2013.003, De Vlinderstichting, Wageningen: 37 pp. (in Dutch, with English summary) ["The number of dragonfly transects has stabilized around 330 sites. About 40% of these transects are counted for one target species only. In 2012, 21 transects had more than 20 species. The most speciose transects had 27 species (2 transects, both in eastern Overijssel). The number of counted dragonflies per transect was below the long-term average, but a little higher than the previous two years. Like previous years, *Coenagrion*

puella was the most abundant species, *Ischnura elegans* was the most widespread species. Population indices are presented for most species in chapter 8. 22 species show a significant increase, 6 species are stable and 18 others are declining. For the first time significant trends are presented for three very rare species: *Coenagrion armatum*, *Leucorrhinia albifrons* and *L. caudalis* (all declining). *L. albifrons* was not observed in 2012. The coming field season will indicate if this species still exists in the Netherlands or not." postela Valley Province, Mindanao Island, Philippines, K. Jumawan leg." (Authors)] Address: Villanueva, R., D3C Gahol Apartment, Lopez Jaena St., PH-8000 Davao, Philippines. E-mail: rjtvillanueva@gmail.com

12476. Wang, C.; Zhou, H.; Zhang, Z.; Zhao, Y.; Cong, D.; Menga, C.; Zhang, P.; Ren, L.b (2013): Mechanical property of a low carbon steel with biomimetic units in different shapes. *Optics & Laser Technology* 47: 114-120. (in English) ["Inspired by the superior biomechanical properties of some biological compositions, an attempt to improve the mechanical property of low carbon steel with biomimetic units was made by using a laser remelting process. Three kinds of shapes including 'striation', 'spot' and 'gridding', were chosen for forming the biomimetic units. Microstructure and microhardness examinations demonstrated that desirable microstructural changes and regular hardness distribution were acquired in the units. The results of tensile tests indicated that the biomimetic specimens had an improvement in the strength and ductility simultaneously. The beneficial influence of laser processed biomimetic units on tensile behaviour can be attributed to the combined effects of the microstructural characteristics within the unit zone and the stress redistribution derived from the efficient stress transfer. By investigating the variation of plastic deformation in different regions of the specimens, the effect of unit shapes on tensile property was also compared and discussed. Highlights: *Low carbon steel with biomimetic units in different shapes was processed by laser. *Good combination of strength and ductility was obtained in biomimetic samples. *Mechanical property improvement was analyzed on basis of microstructural changes and stress transfer. *Effect of unit shapes on tensile property was compared and discussed.... Typical structural shapes of constriction units in biological compositions: (a) striation-shaped units in the tree leaf; (b) spot-shaped units in the elytrum of ground beetle; (c) gridding-shaped units in the dragonfly wing; (d) gridding-shaped units in the scale of butterfly wing." 12477. Wang, Y.; Engel, M.S.; Rafael, J.A.; Dang, K.; Wu, H.; Wang, Y.; Xie, Q.; Bu, W. (2013): A unique box in 28S rRNA is shared by the enigmatic insect order Zoraptera and Dictyoptera.. *PLoS ONE* 8(1): e53679. doi:10.1371/journal.pone.0053679: 13 pp. (in English) ["The position of the Zoraptera remains one of the most challenging and uncertain concerns in ordinal-level phylogenies of the insects. Zoraptera have been viewed as having a close relationship with five different groups of Polyneoptera, or as being allied to the Paraneoptera or even Holometabola. Although rDNAs have been widely used in phylogenetic studies of insects, the application of the complete 28S rDNA are still scattered in only a few orders. In this study, a secondary structure model of the complete 28S rRNAs of insects was reconstructed based on all orders of Insecta. It was found that one length-variable region, D3-4, is particularly distinctive. The length and/or sequence of D3-4 is conservative within each order of Polyneoptera, but it can be divided into two types between the different orders of the supercohort, of which the enigmatic order Zoraptera and Dictyoptera share one type, while the remaining orders of Polyneoptera share the other. Additionally, independent evidence from phylogenetic results support

the clade (Zoraptera+Dictyoptera) as well. Thus, the similarity of D3-4 between Zoraptera and Dictyoptera can serve as potentially valuable autapomorphy or synapomorphy in phylogeny reconstruction. The clades of (Plecoptera+Dermaptera) and ((Grylloblattodea+Mantophasmatodea)+(Embiodea+Phasmatodea)) were also recovered in the phylogenetic study. In addition, considering the other studies based on rDNAs, this study reached the highest congruence with previous phylogenetic studies of Holometabola based on nuclear protein coding genes or morphology characters. Future comparative studies of secondary structures across deep divergences and additional taxa are likely to reveal conserved patterns, structures and motifs that can provide support for major phylogenetic lineages." 12479. Wellenreuther, M.; Sánchez-Guillén, R.A.; Cordero-Rivera, A.; Svensson, E.I.; Hansson, B. (2013): Male-biased recombination in odonates: insights from a linkage map of the damselfly *Ischnura elegans*. *Journal of Genetics* 92(1): 5 pp. (in English) ["Results: The two-point analyses detected that 13 of the 19 markers were linked to at least one other in our *I. elegans* mapping data set. These markers built up four linkage groups with two to five markers (figure 1). No markers were linked to more than one linkage group, and thus no conflicting assignments occurred. The parsimonious sex-average autosomal linkage map spanned 211.5 cM. A moderate degree of heterochiasmy was found, with a female map of 179.2 cM and a male map of 331.7 cM (paired t-test on log₁₀ map distances at the four linkage groups: $t = 3.295$, $df = 3$, $P = 0.046$). The female-to-male map ratio was 0.54, i.e. -0.27 on a log₁₀-scale. To compare the pattern of recombination in insects, we compiled data of sex-specific recombination, either from linkage mapping studies or recombination nodule counts, for 30 insect species (including *I. elegans*) (figure 2; details and references are given in table 2 in electronic supplementary material). Comparison of recombination rates within the class of Insecta showed that most species have higher recombination in females, contrasting the pattern found for *I. elegans*, and that achiasmatic recombination is widespread across multiple orders." 12480. Wheat, C.W.; Wahlberg, N. (2013): Explosion, the colonization of land and the evolution of flight in arthropoda. *Systematic Biology* 62(1): 93-109. (in English) ["The timing of the origin of arthropods in relation to the Cambrian explosion is still controversial, as are the timing of other arthropod macroevolutionary events such as the colonization of land and the evolution of flight. Here we assess the power of a phylogenomic approach to shed light on these major events in the evolutionary history of life on earth. Analyzing a large phylogenomic dataset (122 taxa, 62 genes) with a

Bayesian-relaxed molecular clock, we simultaneously reconstructed the phylogenetic relationships and the absolute times of divergences among the arthropods. Simulations were used to test whether our analysis could distinguish between alternative Cambrian explosion scenarios with increasing levels of autocorrelated rate variation. Our analyses support previous phylogenomic hypotheses and simulations indicate a Precambrian origin of the arthropods. Our results provide insights into the 3 independent colonizations of land by arthropods and suggest that evolution of insect wings happened much earlier than the fossil record indicates, with flight evolving during a period of increasing oxygen levels and impressively large forests. These and other findings provide a foundation for macroevolutionary and comparative genomic study of Arthropoda." 12485. Wong-Muñoz, J.; Anderson, C.N.; Munguía-Steyer, R.; Córdoba-Aguilar, A. (2013): Body size and morph as drivers of copulation duration in a male dimorphic damselfly. *Ethology* 119(5): 407-416. (in English) ["Copulation duration is often highly variable within and among species. Here, we explore the roles of body size, male morph, morph frequency, and alternative reproductive tactics to explain copulation duration in the damselfly *Paraphlebia zoe*. *P. zoe* has two male morphs (pigmented or hyaline wings) which differ in reproductive tactics (territorial or non-territorial behaviours). We also analyze the effects of season as the frequencies of both morphs tend to vary along the reproductive season. In the first non-experimental year, we found that the relationship between body size and copulation duration depended on the time of year. Early in the season, body size positively correlated with copulation duration, while late in the year, body size negatively correlated with copulation duration. In the second experimental year (when we reversed the frequency of male morphs in the middle of the season: making pigmented males less frequent than hyaline males), size influenced copulation duration as well as morph – body size positively correlated with copulation duration, and hyaline males mated for longer than pigmented males. Contrary to our prediction, changes to the relative abundances of morphs did not influence copulation duration. Hyaline males may be under selection for longer copulation durations to compensate for their reduced access to females, as long copulations potentially lead to more rival sperm to be removed from the female sperm storage organs and/or increased mate guarding. We do not discard, however, other explanations that drive variation in copulation duration such as cryptic female choice and/or predation." 12486. Yang, J.; Gonzalez-Bellido, P.T.; Peng, H. (2013): A distance-field based automatic neuron tracing method. *BMC Bioinformatics* 2013, 14:93 (in English) ["Background: Automatic 3D digital reconstruction (tracing) of neurons embedded in noisy microscopic images is challenging, especially when the cell morphology is complex. Results: We have developed a novel approach, named DF-Tracing, to tackle this challenge. This method first extracts the neurite signal (foreground) from a noisy image by using anisotropic filtering and automat-

ed thresholding. Then, DF-Tracing executes a coupled distance-field (DF) algorithm on the extracted foreground neurite signal and reconstructs the neuron morphology automatically. Two distance-transform based "force" fields are used: one for "pressure", which is the distance transform field of foreground pixels (voxels) to the background, and another for "thrust", which is the distance transform field of the foreground pixels to an automatically determined seed point. The coupling of these two force fields can "push" a "rolling ball" quickly along the skeleton of a neuron, reconstructing the 3D cell morphology. Conclusion: We have used DF-Tracing to reconstruct the intricate neuron structures found in noisy image stacks, obtained with 3D laser microscopy, of dragonfly thoracic ganglia. Compared to several previous methods, DF-Tracing produces better reconstructions." 12487. Yang, Y.; Wang, L.; Wei, S.; Song, G.; Kenoyer, J.M.; Xiao, T.; Zhu, J.; Wang, C. (2013): Nondestructive analysis of dragonfly eye beads from the Warring States Period, excavated from a Chu tomb at the Shenmingpu Site, Henan Province, China. *Microscopy and microanalysis* 19(2): 335-343. (in English) ["Dragonfly eye beads are considered to be the earliest types of glass objects in China, and in the past have been considered as evidence of culture interaction or trade between West and East Asia. In this article, synchrotron radiation microcomputed tomography and μ -probe energy dispersive X-ray fluorescence were used to determine the chemical composition, microstructure, and manufacturing technology of four dragonfly eye beads, excavated from a Chu tomb at the Shenmingpu site, Henan Province, China, dated stylistically to the Middle and Late Warring State Period (475 bc-221 bc). First, a nondestructive method was used to differentiate the material types including faience (glazed quartz), frit, glazed pottery (clay ceramic), and glass. Three beads were identified as faience and one bead as glazed pottery. The glaze recipe includes quartz, saltpeter, plant ash, and various copper, and is classified as belonging to the K₂O-CaO-SiO₂ glass system, which indicates that these beads were not imported from the West. Based on computed tomography slices, the manufacturing technology of the faience eye beads appears to include the use of an inner core, molding technology, and the direct application glazing method. These manufacturing features are consistent with the techniques used in China during this same time period for bronze mold-casting, proto-porcelain, and glass." 12496. Tuxhorn, C.; McShaffrey, D. (1998): Flight velocities of Odonata measured using video techniques. Bull.

North American benthological society 15(1): 152. [Verbatim: We determined the flight velocity, based on over 2,800 flight segments of individuals of 4 spp. near Marietta, Ohio. A Panasonic Palmsight PV-1557 16x Optical Zoom camcorder was used to record flight of individuals at a pond on 3 dates in 1997. Recording was done between 1-4 pm. Distances on the monitor were determined by reference to mean lengths of individuals caught at the time of filming. The distance a specimen flew between frames was calculated by measuring the on-screen distance and dividing by the magnification factor. This distance was then multiplied by the time between video frames (0.03 sec) to determine velocity. Average flight velocity for all flight segments of the 4 spp. was 1.9 m/s (n=2844, sigma=0.59). Mean velocities were: Libellula luctuosa 1.7 m/s (n=737, sigma=0.48), L. lydia 2.0 m/s (n=1963, sigma=0.49), Pachydiplax longipennis 1.5 m/s (n=59, sigma=0.53), Tramea lacerata 2.5 m/s (n=85, sigma=0.85). Significant differences (t-test, alpha=0.05) were found between the flight velocities of all 4 spp. A positive correlation exists between the length of the species and average flight velocity. Address: not stated.

12501. Malikova, E.I.; Seidenbusch, R. (2001): Description of a female *Macromia manchurica* Asahina, 1964 (Macromiidae). *Tombo* 43: 21-22. (in English) [Southern Primorje, Oktyabrsky region, v. Novo-Georgievka, Russia, 6. VIII. 1989, S. Kulchitsky leg; the female of this rare Far Eastern species was unknown until present. "One female specimen of this species identified as *M. sibirica* Djakonov, 1926 (= *M. amphigena fraenata* Martin, 1905) was mentioned and depicted by Dr. S. Gorb (1991) and then sent to one of us (R. S.) together with a male specimen of true *M. amphigena fraenata*....The species can be easily distinguished from co-occurring *M. amphigena* by more developed yellow body mark-

ings : the yellow rings on the tergites IV-VII are not interrupted ; by a pale brown or chestnut labium, and the labrum with a pair of yellow spots; and by the shape of the genital plate. Asahina (1964) supposed that the larvae of *Macromia* sp. from the River Sintuhe (now R. Komissarovka) near village Ijinka, Primorje Territory, described by Popova (1953), were in fact *M. manchurica*. The finding of imago from a neighbouring locality confirmed this supposition." (Authors)] Address: Malikova, E.I., Dept of Zoology, Blagoveshchensk State Pedagogical University, Lenin Street, 104, Blagoveshchensk, 675000, Russia

12502. Matsuki, K. (2001): Description of the last instar larva of *Euphaea ochracea* Selys, 1859 from Thailand (Euphaeidae). *Tombo* 43: 23-24. (in English) [7-V-1985, Huey Kaeo, N. Thailand, K. Matsuki, leg.; the female exuvia is figured.] Address: Matsuki, K., 3-1575-14 Hasama-cho, Funabashi, Chiba, 274-0822, Japan

12503. Sasamoto, A. (2001): Description of a new subspecies of *Stylogomphus lawrenceae* Yang et Davies, 1996 from the Malay Peninsula (Anisoptera: Gomphidae). *Tombo* 43: 14-18. (in English) ["The adult and larva of *Stylogomphus lawrenceae malayanus* ssp. n. are described and illustrated (holotype: male, allotype: female, Tapah to Tana Rata, 19 miles point, Perak, Malaysia; 31. III. 1999, captured at larval stage and reared in room until emergence, and deposited in the National Science Museum, Tokyo). This is the first record of the genus *Stylogomphus* from the Malay Peninsula. This subspecies is almost identical with nominotypical subspecies in the shapes of male anal appendages, female valvula vulvae and occiput, although discriminated in the shapes of hamulus anterior and posterior, and thoracic markings. The genus *Stylogomphus* was established by Fraser in 1922 and contains 10 species, 2 of which have one subspecies each (Tsuda, 2000). *Stylogomphus* species hitherto have been known from E. Asia, N. India, Bangladesh, Nepal, continental China, Taiwan, N. Vietnam, and Japan, as well as one species from N. America. From N. Thailand only unidentified exuviae were reported by Matsuki (1988). In spring of 1999 in Cameron Highland, the Malay Peninsula, the larvae supposed as *Stylogomphus* were caught from a clean stream in tropical jungle, and then, reared in room until adult emergence. This species is not only a new record from the Malay Peninsula, but is also believed to be a new subspecies." (Author)] Address: Sasamoto, A., 190-4 Yakuoji, Tawaramoto-chô, Shiki-gun, Nara, 636-0341, Japan. E-mail: akssmt@sea.plala.or.jp

12504. Lynch, R.J.; Bunn, S.E.; Catterall, C.P. (2002): Adult aquatic insects: Potential contributors to riparian food webs in Australia's wet-dry tropics. *Austral Ecology* 27(5): 515-526. (in English) ["Changes in the abundance and biomass of aquatic and terrestrial aerial in-

sects with distance (mid-stream, 0, 10–15 and 160 m) from lowland streams were examined across the dry season landscape in Kakadu National Park, northern Australia. Malaise traps and sticky intercept traps were used to sample the insects at four streams, spaced over an area of 1650 km². Malaise and intercept catches were dominated by Diptera (flies and midges), both numerically and by biomass. Chironomid midges were the most abundant taxon, making up 43.4 and 51.0% of the malaise and intercept trap catches, respectively. However, most chironomids were small (less than 3 mm body length), contributing 34.9% to intercept trap biomass, but only 5.2% in malaise traps. Ceratopogonid midges and caddisflies (Trichoptera) accounted for most of the remaining adult aquatic insects. Major terrestrial components were Diptera and Hymenoptera in malaise traps and Coleoptera and Diptera in intercept traps. The total abundance and biomass of insects were much greater over streams and along the water's edge than in riparian (10–15 m) and savanna (160 m) habitats primarily because of the presence of large numbers of adult aquatic insects. The abundance and biomass of terrestrial insects in malaise traps showed no relationship with distance, but intercept trap catches suggested slightly greater abundances over the water and at the water's edge. The great abundance of aquatic insects relative to terrestrial insects close to streams suggests that they have the potential to be an important component of the diets of riparian insectivores, and predation may be an important pathway by which aquatic nutrients and energy are moved into terrestrial food webs." (Authors) The aquatic classification included those insects with at least one fully aquatic life stage: Odonata, Ephemeroptera, Trichoptera, Diptera (Chironomidae, Culicidae, Simuliidae), Neuroptera (Sisyridae) and Hemiptera (Veliidae, Corixidae). ... 523 odonates were caught in malaise traps.] Address: Bunn, S.E., Faculty of Environmental Sciences, Griffith University, Nathan, Queensland 4111, Australia. 12510. Brunelle, P.M.; deMaynadier, P. (2005): The Maine Damselfly and Dragonfly Survey: A Final Report. No-

vember 1 2005. Edition 2 (Revised). Prepared for: Maine Department of Inland Fisheries and Wildlife (MDIFW), 650 State Street, Bangor, Maine, USA 04401: 31 pp. (in English) ["MDDS Final Results: The goals of the MDDS project were two-fold: (1) To raise public awareness and concern for damselflies and dragonflies specifically, and invertebrate conservation generally, and, (2) To improve the Maine Department of Inland Fisheries and Wildlife's ability to protect those odonate species of greatest conservation concern. Underlying the achievement of both goals was the need for an improved understanding of the distribution and status of Odonata in Maine. The balance of this report provides a graphical and tabular summary of MDDS's final results. In summary, the project exceeded initial expectations for public participation and scientific contributions, as evidenced by the following summary statistics: Outreach Contributions: Volunteer participation statewide: >200; Volunteers trained in MDDS seminars: 95; Newsletters published (Mainensis): 4; Major press articles covering the project: 5; Website hits (<http://mdds.umf.maine.edu/~odonata/>): >16,000; Scientific Contributions: Total records submitted (% increase on 1999 baseline): 17,264 (229%); New Rare, Threatened, and Endangered species records: 297; New state species records: 10; New U.S. species records (Québec Emerald and Canada Whiteface): 2; Scientific publications completed or in progress (4 articles; 1 book): 5." (Authors) For details see: <http://mdds.umf.maine.edu/MDDS%20Final%20Report.pdf> Address: Brunelle, P.M., 6044-1 Compton Avenue, Halifax, Nova Scotia, Canada, B3K 1E7

12512. Labandeira, C.C. (2005): The fossil record of insect extinction. New approaches and future directions. *American Entomologist* • Spring 2005: 14-29. (in English) ["The fossil record of insect extinction at the family level is characterized by two basic modes: background extinction, which represents an ambient level of taxa extirpation, and mass extinctions, which are occasional severe events in which taxa are eliminated significantly above background levels. The most significant mass extinction, at the end-Permian (Permian-Triassic; P-T), divides the history of insects into two major evolutionary faunas: an earlier Paleozoic Evolutionary Fauna of apterygotes, paleopterans, and basal clades of or-

thopteroids and hemipteroids; and a subsequent Modern Evolutionary Fauna of more derived clades of orthopteroids and hemipteroids and especially holometabolous insects. In addition to the P-T event, four other extinctions are documented by multipletypes of data: Late Pennsylvanian, Late Jurassic, later Early Cretaceous; and the end-Cretaceous (Cretaceous-Paleocene; K-P). There also is an analogous record of insect origination that is characterized by major, above-background events. Four methods are used to detect insect extinction in the fossil record. The taxic approach is widely used, whereby the temporal durations of fossil taxa are tallied for each geologic unit of interest and analyzed in a manner analogous to demography used in ecology. By contrast, the phylogenetic approach uses clades as the basic units of interest. A recent approach uses proxy data such as quantification of plant-insect associations across major boundaries in lieu of an insect body-fossil record. Last, the clustering of times of origin from modern coevolved plant-insect associations provides data for likely interruptions from major paleoenvironmental perturbations. Pluralism, emphasizing multiple approaches to determine the ecological dynamics of insects during an extinction, is the best strategy to evaluate insect demise or survival in the fossil record." (Author) The paper includes several references to dragonflies.] Address: Labandeira, C., Dep Paleobiology, National Museum of Natural History, Smithsonian Institution, Washington, DC 20560-0121, USA. 12514. Jocqué, M.; Martens, K.; Riddoch, B.; Brendonck, L. (2006): Faunistics of ephemeral rock pools in southeastern Botswana. *Arch. Hydrobiol.* 165(3): 415-431. (in English) ["Rock pools on granite outcrops occur worldwide and are poorly studied, despite their intrinsic biological interest. In semi-arid Botswana, such habitats occur mainly on the granite outcrops in the southwestern Hardveld zone. To date, studies on these systems have focused mainly on individual species or particular interactions. By means of frequent sampling (every other day) during an entire wet phase (hydrocycle), we attempted to get a time integrated overview of invertebrate species composition in a set of 18 rock pools from two clusters (meta-communities). A faunal list (including *Pantala flavescens*) is presented and described. Rock

pool species were separated in permanent and ephemeral inhabitants, based on their strategy to survive or escape the frequent dry phases of their habitat, respectively. A new chydorid species, four new turbellarian taxa and two new ostracod species were discovered. All new taxa were permanent inhabitants, illustrating the need for more intense and time-integrated studies of these ephemeral systems and especially the permanent residents with specific adaptations to the vagaries of their variable habitat. The best sampling strategy to assess species richness in these rock pool systems is to randomly sample three to four pools in a cluster, each in the final phase of their hydrocycle." 12520. Goncalves, F.B. (2007): Análise comparativa de índices bióticos de avaliação de qualidade de água, utilizando macroinvertebrados, em um rio litorâneo do Estado do Paraná. Dissertação apresentada ao Programa de Pós-Graduação em Ecologia e Conservação, Setor de Ciências Biológicas Universidade Federal do Paraná, como requisito parcial para obtenção do grau de Mestre em Ecologia e Conservação: IX + 43 pp. [Brazil; this work aimed to compare four different biotic indices of water quality using benthic macroinvertebrate, in order to verify if there is one better to be applied in the coastal streams in the Paraná state; describe its communities and analyse its environmental condition through the functional feeding groups. Five biotic indices were chosen to it: 1- EPT INDEX (Percent of Ephemeroptera, Plecoptera and Trichoptera); 2- BMWP' (Biological Monitoring Work Party System); 3- BMWP'-ASPT (Average Score Per Taxon) and 4-HFBI (Hilsenhoff Family Biotic Index). They were applied in two different sites in a coastal stream in the Paraná state. The "do Pinto" stream headwaters' are placed in a protected area.

There are many input materials from headwaters to the mouth as organic house material, craps and funny activities. Five samples were taken between April of 2005 and April of 2006. It was observed the HFBI index does not represent the real conditions of the stream. This way, no one of the indices can be suggested as a better one, since everyone presented many differences among their scores and the structure of community. The functional feeding groups protocol suggested the stream as a not structured one, mainly in the inferior site that has an human influence." (Author) Odonata are treated at the family level.] Address: not stated

12522. Torralba Burrial, A.; Ocharan, F.J. (2007): Comparación del muestreo de macroinvertebrados bentónicos fluviales con muestreador surber y con red manual en ríos de Aragón (NE Península Ibérica). *Limnetica* 26(1): 13-24. (in Spanish, with English summary) ["Comparison between Surber and hand net sampling methods to survey benthic macroinvertebrates in rivers of Aragon (NE Iberian Peninsula) When monitoring the ecological state of rivers and other surface waters, the Water Framework Directive (Directive 2000/60/CE) establishes that the methods used should guarantee that the information given be of an equivalent scientific quality and comparability; for rivers and communities of benthic macroinvertebrates in shallow waters, it remits to the standards for the biological sampling with Surber and hand net. These sampling methods were compared in 15 sites located in the fluvial network of Aragon (NE Spain), including the different types of rivers and ecological states existent in it. Both methods provided similar results when employed with the same community, showing high correlation coefficients and slopes near 1, for number of taxa captured, number of EPT groups (Ephemeroptera, Plecoptera and Trichoptera), number of taxa included in the index IBMWP (formerly known as BMWP'), value of this index and of the IASPT. In spite of this high correlation, the Surber sampler presented a higher average efficiency in the total number of taxa captured than the hand net, capturing a slightly greater number of taxa, taxa included in the IBMWP among them (increasing the value of the index a little). Other advantages of Surber versus hand net are commented, especially that of allowing quantitative samplings." (Authors) Samples include Coenagrionidae, Calopterygidae, Aeshnidae, and Gomphidae (all at the family lev-

el).] Address: Torralba Burrial, A., Depto de Biología de Organismos y Sistemas, Universidad de Oviedo, E-33071 Oviedo, Spain. E-mail: antoniotb@hotmail.com

12524. Johansson, F.; Crowley, P.H. (2008): Larval cannibalism and population dynamics of dragonflies. In: Lancaster, J. & R.A. Briers (eds): *CAB International 2008. Aquatic insects: Challenges to populations. Proceedings of the Royal Entomological Society's 24th symposium*: 36-54. (in English) ["Cannibalism, the process of killing and eating conspecifics, is common among odonate larvae and is believed to influence odonate population dynamics. Here we attempt to summarize and consider interactions among key factors linked to cannibalism at both the individual and population levels. Through cannibalism, odonate larvae receive energy directly from the consumption of the conspecific, and indirectly from reduced exploitation competition because the per capita food supply may increase. Cannibalism might, however, also incur costs such as risk of death and pathogen infections. Alternative food availability, population density and size structure of the cannibalistic population, and habitat structure are environmental factors that affect cannibalism rate in odonate larvae on a short-term basis. Theoretical models predict that cannibalism reduces size variation under most cannibalism intensities and life histories. The models also show that cannibalism can – but will not always – stabilize population dynamics. Unfortunately few long-term studies examining the population dynamics on dragonfly larvae have been performed, and we urge more such studies." 12525. Bingham, S.N. (2009): Aquatic macroinvertebrate use of rootmat habitat created by eight woody riparian species. M.Sc. thesis, Graduate School of The Ohio State University: XII + 61 pp. (in English) [oas 38;"Rootmats are an instream habitat type created by fine roots of riparian vegetation that are exposed through natural erosion at the stream bank. Previous research indicated that rootmats may be important habitats for aquatic invertebrates and may have a distinct inverte-

brate composition compared to other instream habitat types. The objective of this study was to examine the invertebrate communities inhabiting rootmats of eight common woody riparian species in Cuyahoga Valley National Park, Ohio (CVNP). I collected 47 rootmat samples from pools across 10 CVNP streams. Coarse particulate organic matter, root morphology, and physicochemical variables were measured to characterize the local habitat at each location. Invertebrate community indices, multivariate techniques and univariate techniques were used to investigate the role of rootmats as habitat and determine whether any associations existed between invertebrate communities and eight woody riparian species. Additionally, invertebrate communities of rootmats were compared to adjacent riffles for eight sites. A total of 138 taxa were collected from rootmats across all woody species. Most (59%) of the taxa were gathering collectors and this suggests that fine particulate organic matter may be a dominant food source within or near rootmats. Additionally, 15% of the captures were predators, while scrapers, shredders and filtering collectors were present in similar proportions (8-9% each). *Paratanytarsus dissimilis* was the most abundant organism across the samples at nearly 250 organisms m². Other abundant taxa were Chironomidae *Calopteryx maculata*, *Caecidotea communis* (isopod), *Stenelmis* sp. and *Dubiraphia bivittata* (riffle beetles). Invertebrate diversity, species composition and functional feeding guilds differed among certain tree species. Specifically, rootmats of two willow species (*Salix interior* and *S. nigra*) were consistently similar to each other, and different from rootmats of *Carpinus caroliniana*, *Fraxinus pennsylvanica*, and *Acer saccharum*. Additionally, invertebrate species composition was different in adjacent rootmat and riffle habitats, but the habitats were similar in terms of diversity and abundance." 12526. Bolzon, D.M.; Nordström, K.; O'Carroll, D.C. (2009): Local and large-scale inhibition in feature detection. *Journal of Neuroscience* 9(45): 14143-14150. (in English) ["Lateral inhibition is perhaps the most ubiquitous of neuronal mechanisms, having been demonstrated in early stages of processing in many different sensory pathways of both mammals and invertebrates. Recent work challenges the long-standing view that assumes that similar mechanisms operate to tune neuronal responses to higher order properties. Scant evidence for lateral inhibition exists beyond the level of the most peripheral stages of visual processing, leading to suggestions that many features of the tuning of higher order visual neurons can be accounted for by the receptive field and other intrinsic coding properties of visual neurons. Using insect target neurons as a model, we present unequivocal evidence that feature tuning is shaped not by intrinsic properties but by potent spatial lateral inhibition operating well beyond the first stages of visual processing. In addition, we present evidence for a second form of higher-order spatial inhibition—a

long-range interocular transfer of information that we argue serves a role in establishing interocular rivalry and thus potentially a neural substrate for directing attention to single targets in the presence of distracters. In so doing, we demonstrate not just one, but two levels of spatial inhibition acting beyond the level of peripheral processing." 12527. Donohue, I.; Donohue, L.A.; Ní Ainín, B.; Irvine, K. (2009): Assessment of eutrophication pressure on lakes using littoral invertebrates. *Hydrobiologia* 633(1): 105-122. (in English) ["Until the E.U. Water Framework Directive listed benthic invertebrates as a biotic element to be used for ecological classification of lakes, techniques for the assessment of the response of littoral invertebrates to anthropogenic pressures were extremely limited compared with those of rivers and lake profundal zones. We describe here the development of an ecological classification model based on changes of littoral invertebrate assemblages across a gradient of eutrophication, which is the most widespread anthropogenic pressure on lakes across Europe. The model comprises three derived parameters, two of which were developed from taxon-specific optima along a total phosphorus gradient calculated using canonical correspondence analysis, and the third based on invertebrate abundance. Combining the parameter metrics, we can estimate the ecological quality ratio (EQR), relative to those from paleolimnologically-confirmed reference lakes. The model was tested using independent samples collected from both hard and soft substrata and across two seasons from 45 lakes, comprising three alkalinity groups (n = 15 in each), and across gradients in water column total phosphorus concentrations. For hard substrata, EQRs were related consistently and highly significantly to water column concentrations of total phosphorus, accounting for the majority of the variance in every alkalinity group. For samples taken from soft substrata, a significant relationship was found only for high alkalinity lakes, accounting for a moderate proportion of the variability in water column total phosphorus concentrations. Our results compare highly favourably with those from other aquatic ecological assessment methods, irrespective of the faunal or floral group upon which they are based, demonstrating that littoral invertebrate assemblages can provide a statistically robust prediction of nutrient status when samples are collected from hard substrata. While the method was developed specifically to assess nutrient pressures on littoral invertebrates, many lakes are subject to multiple pressures. The development of classification models that incorporate multiple pressures presents a particularly significant challenge for the implementation of the Water Framework Directive, requiring both reliable identification of minimally-impacted reference states and incorporation of pressures that are unlikely to interact in predictable

ways." (Authors) Taxa classified as 'sensitive' to total phosphorus used in the calculation of the %Sensitive to TP Metric include *Brachytron pratense*, *Coenagrionidae*, *Libellulidae*, *Orthetrum cancellatum*, and *O. coerulescens*.] Address: Donohue, I., School of Natural Sciences, Dept of Zoology, Trinity College Dublin, Dublin 2, Ireland. 12529. DuBois, R.B.; Pleski, J.M.; Smith, W.A.; Epstein, E.J. (2009): Odonata of coastal peatland habitats adjacent to Lake Superior in Wisconsin. *Great Lakes Entomologist* 42(3/4): 158-172. (in English) ["We sampled adults and exuviae of Odonata in eleven coastal fens and poor fens near Lake Superior in Douglas, Bayfield, and Ashland counties in Wisconsin to determine species that were breeding in these areas, and gain knowledge about their relative abundances, flight periods, and nymphal habitats. The flora in these fens was characterized by mats of *Sphagnum* mosses, a variety of ericaceous shrubs, and a number of sedges, among which *Carex lasiocarpa* was most dominant. We averaged seven visits per site from early June through September, 2004, to cover the flight periods of most species of Odonata at this latitude. Fifty species of Odonata were identified at the sites, 33 of which exhibited evidence of breeding. Species commonly breeding in the fens included *Lestes disjunctus*, *Coenagrion resolutum*, *Enallagma hageni*, *Nehalennia irene*, *Aeshna canadensis*, *Williamsonia fletcheri*, *Leucorrhinia frigida*, *L. glacialis*, *L. hudsonica*, *Libellula quadrimaculata*, *Sympetrum obtrusum*, and *S. vicinum*. Eight uncommon species were found to breed in at least one of the fens, including *L. eurinus*, *A. sitchensis*, *A. tuberculifera*, *A. verticalis*, *Somatochlora incurvata*, *W. fletcheri*, *Nannothemis bella*, and *S. danae*. *W. fletcheri* and *S. danae* were found to be more common in these habitats than previously thought, causing their rarity status with the Natural Heritage Inventory of the Wisconsin Dept of Natural Resources to be relaxed, and they will no longer be actively tracked. Emergence and flight periods of Odonata in coastal peatlands began at least a week later than in similar inland peatlands in these counties." 12536. Torralba-Burrial, A.; Alonso-Naveiro, M. (2009): Las comunidades de libélulas (Odonata) del Parque Natural de Sierra de Cebollera (La Rioja, N España). Zulia 27: 7-52. (in Spanish, with English summary) ["Odonata communities were sampled in 22 locations in Natural Park Sierra de Cebollera (La Rioja). 21 species were found; eleven have been not recorded before from La Rioja. Records of threatened dragonflies *Coenagrion caerulescens* and *Sympetrum flaveolum* are very interesting. The last species has great populations in Sierra de Cebollera. Dragonfly communities are analysed showed differences between running and stagnant waters. Biogeographical analysis shows a low percentage of Ethiopic elements and high percentage of West-

Mediterranean elements. A provisional checklist of La Rioja odonates is included." (Authors)] Address: Torralba Burrial, A., Departamento de Biología de Organismos y Sistemas, Universidad de Oviedo, E-33071 Oviedo, Spain. E-mail: antoniotb@hotmail.com

12537. Walia, G.K. (2009): The impact of industrial effluent on moulting and emergence in the damselfly *Ceriagrion coromandelianum* (Fabricius) (Odonata: Zygoptera: Coenagrionidae). National journal of Life Sciences 6(1): 99-102. (in English) ["The antipenultimate and penultimate larval instars of *C. coromandelianum* were reared in effluent free medium. The antipenultimate larvae required 32 days to become adult and penultimate larvae needed 9 days to become final instars. In sub lethal concentration of industrial effluent the moulting is arrested and all the antipenultimate larvae died in 25-32 days, while in case of penultimate larvae, all of them died within 15 days. However, few of them exhibited incomplete moulting but died without eclosion on the same day. Rate of oxygen consumption and various biochemical constituents in the tissues were decreased significantly in the effluent treated larvae. These could be the probable cause for the mortality of larvae under the toxicity of industrial effluent. As industrial effluent inhibits moulting thus juvenomimetic action could be attributed to it." 12538. Henderson, C.L.; Adams, S. (il.). (2010): Butterflies, moths, and other invertebrates of Costa Rica: a field guide. Mariposas, polillas y otros invertebrados de Costa Rica: una guía de campo. Editorial Austin, TX, University of Texas Press, US: 173 pp. (in English) ["At the biological crossroads of the Americas, Costa Rica hosts an astonishing array of plants and animals-over half a million species! Ecotourists, birders, and biologists come from around the world, drawn by the likelihood of seeing more than three or four hundred species of birds and other animals during even a short stay. To help all these visitors, as well as local residents, identify and enjoy the wildlife of Costa Rica, Carrol Henderson published Field Guide to the Wildlife of Costa Rica in 2002, and it instantly became the indispensable guide. Now Henderson has created a dedicated field guide to more than one hundred tropical butterflies, moths, and other invertebrates that travelers are most likely to see while exploring the wild lands of Costa Rica. He includes fascinating information on their natural history, ecology, identification, and behaviour gleaned from his forty years of travels and wildlife viewing, as well as details on where to see these remarkable and beautiful creatures. The butterflies, moths, and other invertebrates are illustrated by over 180 stunning and colourful photographs, most of which were taken in the wild by Hen-

person. A detailed and invaluable appendix that identifies many of Costa Rica's best wildlife-watching destinations, lodges, and contact information for trip-planning purposes completes the volume." (Publisher) The book includes a brief chapter on Pseudostigmatidae.] Address: not stated

12539. Indermuehle, N.; Angélibert, S.; Rosset, V.; Oertli, B. (2010): The pond biodiversity index "IBEM", a new tool for the rapid assessment of biodiversity in ponds from Switzerland. Part 2. Method description and examples of application. *Limnetica* 29(1): 105-119. (in English, with Spanish summary) ["Ponds are now widely recognized to contribute significantly to regional freshwater biodiversity. Therefore, tools to easily and rapidly assess biological quality specifically for these aquatic habitats have been increasingly requested by conservation planners and nature managers. In close association with practitioners, we developed such a method for Switzerland; the pond biodiversity index "IBEM". The IBEM-Index is based on the assessment of the taxonomic richness of 5 groups: aquatic vegetation, Gastropoda, Coleoptera, adult Odonata and Amphibia. No abundance data are necessary and genus level identification is required for all groups except Amphibia (species level). The sampling methodology is a stratified random strategy and allows the use of richness estimators to transform the observed taxonomic richness (Sobs) into true taxonomic richness (Strue). As the IBEM assessment follows the methodology presented in the Water Framework Directive, it is based on the calculation of the ratio of true taxonomic richness (Strue) to reference-based predicted richness (Sref). Each of the five taxonomic groups is assessed separately and the overall biological quality of any given pond (i.e. the IBEM-Index) is the average of the five ratios. This score is later converted into one of five quality classes for each pond: bad (0 to 0.2), poor (> 0.2 to 0.4), moderate (> 0.4 to 0.6), good (> 0.6 to 0.8), and high (> 0.8 to 1). In this paper, the implementation of the IBEM-Index is described in detail. The sampling methodologies are developed (for the biodiversity and the environmental variables) as well as the assessment methodology. Finally, two examples are presented in detail, for a "good" quality pond and for a "bad" quality pond. The method implementation also includes a website (<http://campus.hesge.ch/ibem>) which allows the online calculation of the index, and provides support for both sampling and assessment methodologies to users. The IBEM-Index is a rapid assessment method which gives an overall value of pond biodiversity in terms of taxa richness and can be used, for example, in regional screenings or site monitoring in Switzerland. Moreover, as biodiversity is generally recognized as a good indicator of global ecological quality, the IBEM-Index can also be used to investigate ecosystem quality.] Address: Oertli, B., HEPiA Geneva, Univ. of Applied Sciences Western Switzerland, technology, architecture and landscape. 1254 Jussy-Geneva, Switzerland. 12541. Scott, R.W. (2010): The diversity and composition of benthic macroinvertebrate assemblages in streams in the Mackenzie River System, Northwest Territories. M.Sc. thesis, University of Waterloo, Ontario, Canada: X + 138 pp. (in English) [Impending natural resources development and concern about the effects of climate change have spurred increased efforts to study and monitor aquatic habitats in the Mackenzie River system. As part of Environment Canada's attempt to survey the system in advance of the construction of the Mackenzie Gas Pipeline, benthic macroinvertebrates were sampled at 50 streams spanning the geographical range of the Mackenzie system in the Northwest Territories, Canada, to assess spatial patterns in diversity and assemblage structure and the environmental factors driving them. Replicated, quantitative D-net samples were collected during the late summer of 2005 through 2008, mostly at crossings of the proposed pipeline route. 373 macroinvertebrate taxa were recorded, mainly aquatic insects, which were identified to the genus or species levels; other groups were identified to higher taxonomic levels. Ephemeroptera and Plecoptera diversity declined along a latitudinal gradient, while Trichoptera diversity declined in the middle of the latitudinal range and rose towards the far north. Chironomidae (Diptera) increased in diversity and abundance towards the far north, becoming dominant in the northern subarctic forest and lowland tundra of the Mackenzie Delta. Diversity, measured as the average generic richness per stream, correlated with a composite environmental variable representing stream size, but not much else; spatial trends in local generic richness were only apparent in the far north of the study area. Regional diversity was assessed using rarefaction curves and showed a clear decrease from south to north across the study area for most taxa; the major exception was the chironomid subfamilies Orthocladiinae and Chironomini, the former being diverse throughout the study area and the latter increasing in diversity on the tundra. Odonata, Hemiptera and Coleoptera were well-represented in the south of the study area, but decreased sharply in diversity and abundance in the north; another common order, Megaloptera, was entirely absent from the study area, as were crayfish. Community composition varied along a latitudinal gradient, with some species restricted to northern latitudes and many more species restricted to the southern areas. Composition varied by region, as did the environmental factors that control it. Streams in the north of the system are connected to hundreds of small lakes and tend to freeze in the winter,

which increases habitat stability; assemblages in this region were characterized by relatively large chironomids that are usually associated with lentic habitats and by a lack of taxa that are intolerant to freezing. Substrate was the main factor explaining differences in assemblage composition in this region. Just to the south, alluvial streams are more common and permafrost is continuous with very shallow active layers, which likely results in intense discharge peaks and ice scour in the spring and flashy summer hydrographs. Invertebrates in this region were mainly short-lived, small sized orthoclads, baetids and chloroperlids; the annual disturbance regime seems likely to be an important factor shaping community composition in this region. Many streams in this region received input from saline springs, resulting in perennial flow, and these streams harboured several taxa that were absent or rare in other streams at similar latitudes, including several stoneflies (e.g. *Pteronarcys*, *Sweltsa*); the presence of flow during the winter was found to be a major factor affecting community composition in this region, which surrounded the town of Norman Wells, NT. Nutrient dynamics appeared to be important in structuring benthic assemblages in the southern portion of the study region, with high-nutrient streams supporting a diverse fauna which included many taxa that were absent in the north, while communities in low-nutrient streams were more similar to the northern alluvial stream fauna. There was no spatial distinction between low- and high-nutrient streams in the southern region, and the difference may be due to the local conditions of permafrost, which is patchy and discontinuous in the region. Evidence that winter ice and permafrost conditions are important drivers of benthic invertebrate diversity and community composition in the Mackenzie system, along with the latitudinal gradients which are consistent with a temperature/climate gradient, raises the possibility that benthic assemblages may be useful as indicators of effects of global climate change on freshwater habitats in the Canadian north. More immediately, construction of the Mackenzie Gas Pipeline may affect stream habitat due to sedimentation, and plans for the operation of the pipeline have raised concerns about potential effects on permafrost conditions. Implications for development of a biomonitoring program utilizing benthic invertebrates and their potential as indicators of climate change are discussed." (Author) Mainly in table 10, the following Odonata taxa are listed: *Aeshna* sp., *Somatochlora minor*, *Epitheca canis*, *Amphiagrion* sp., *Coenagrion/Enallagma* sp., *Lestes unguiculatus*, *Ophiogomphus severus*.] Address: not stated

12555. Burwell, C.J.; McDougall, A.; Nakamura, A.; Lambkin, C.L. (2011): New butterfly, hawkmoth (Lepidoptera) and dragonfly (Odonata) records from vegetated coral cays in the southern Great Barrier Reef, Queensland. *Australian Entomologist* 38(2): 75-88. (in English) [Cays, including the first data from Lady Elliot and North Reef Islands, are presented and previously published records summarised. ... Not surprisingly, the Odonata fauna of the Capricornia Cays is depauperate, with only 10 species recorded from our survey. Most are strong-flying species and/or species that are known to disperse or be blown long distances from their larval breeding sites. Seven are distributed throughout most or all of Australia with the other three occurring in northern and eastern Australia: *Diplacodes trivialis* occurring as far south as southern NSW, *Orthetrum sabina* as far south as south-eastern Queensland and *O. serapia* as far south as Rockhampton, central Queensland (Theischinger & Endersby 2009). Odonata are probably regular visitors to islands of the Capricornia Cays, but the absence of permanent water bodies means that they are unable to establish resident populations. However, on Lady Elliot Island there is a sizable depression which fills with rainfall and might provide temporary larval habitat for some dragonflies and damselflies. All 10 odonate species we collected from Lady

Elliot Island are known to breed in temporary water bodies (Watson et al 1991, Theisinger and Hawking 2006). We recorded only two dragonfly species from other islands: *Ischnura aurora* from Lady Musgrave and North Reef Islands and *Pantala flavescens* from North Reef Island."
