12559. DuBois, R.B. (2011): Comparison of field- and classroom-based forms of environmental education to motivate adult learner involvement in Citizen-Based Monitoring of Odonata. Master of Science in Education, University of Wisconsin – Superior: VII + 74 pp. (in English) ["Environmental education has been one of the primary means used to recruit volunteers for citizen-based monitoring partnerships. However, little research has been done to investigate the forms of environmental education that are most effective in promoting these partnerships or how to effectively motivate adult learners who will become meaningfully involved in them. This study sought to determine the relative effectiveness of two forms of short-term environmental education in motivating adult learners to become involved in a citizen-based monitoring activity related to dragonflies and damselflies (Odonata), called the Wisconsin Odonata Survey (WOS). The two forms of environmental education examined were 1) a classroom-based interactive lecture form in which PowerPoint presentations of learning content and accompanying question and answer periods were used in conjunction with exploration of display items and live specimens, and 2) a field-based guided discovery form in which learning content was delivered orally and with illustration poster boards, after which students observed odonate behaviour in the wild, captured and handled live specimens, and practiced making field identifications. Three replications of each form of education were examined during summer of 2010, and student intent to become involved with WOS was measured using survey questionnaires given to willing volunteers immediately after each education event and again through the mail after six weeks. Re-

sults were largely equivocal, but suggested the possibility of a weak advantage with the use of field-based guided-discovery learning over classroom-based interactive lecturing when recruiting citizen volunteers for WOS. Both forms of education had value in other areas including building a greater understanding of the need to protect odonates and their habitats, increasing interest in odonates, and prompting participants to learn more about them." (in English) ["The Odonata diversity and species composition in the surrounding areas of Poondi reservoir in Tiruvallur district of Tamil Nadu were studied from January 2009 to November 2010. The specimens were collected from agricultural crops, grasses, herbs and shrubs by sweeping net. Eighteen different species of Odonates belonging to 15 genera and four families were recorded during the study period. Family Libellulidae was predominant in this area with 11 species. Family Coenagrionidae was represented by five species. Other families viz., Lestidae and Gomphidae were represented by only one species each. The Shannon's and Simpson's diversity indices were maximum during Sep-Nov. 2009 with 2.381 and 0.8817 scores respectively. Maximum evenness of 0.6306 was recorded during Jun-Aug. 2010." Annual Report of the Miyazaki Prefectural Institute for Public Health and Environment 23: 112-118. (in Japanese, with English summary) ["The estimation of water quality based on ASPT (Average Score Per Taxon) is used a lot as an investigation indicating the river conditions. And the biological indicator by the zoobenthos is very important to make up for the chemical properties. Therefore, we have examined the water quality and biota of rivers flowing through Miyazaki prefecture since 1993. We investigated 3 points downward along the stream of Sakatani and Hiroto Rivers situated in the south part of the prefecture. In order to evaluate the river environment based on zoobenthos, we used ASPT and DI. Compared to the research in 1994, BOD (Biochemical Oxygen Demand) was significantly reduced. More species of zoobenthos were found, ASPT value was higher than 7.0 at all points except Obi. The result indicated that both rivers have generally maintained the water quality, biological condition and biodiversity at a good level." (Authors) The list of species includes *Sieboldius albarda*, *Sinogomphus flavolimbatus*, and *Onychogomphus viridicostus*.] Address: Kawano, M., Environmental Science Division, Miyazaki Prefectural Museum of Nature and History, 2-4-4 Jingu, Miyazaki, Miyazaki Prefecture 880-0053, Japan

12574. Premachandran, S.; Giacobello, M. (2011): The effect of wing corrugations on the aerodynamic performance of low-Reynolds number flapping flight. 17th Australasian Fluid Mechanics Conference, Auckland, New Zealand, 5-9 December 2010: 4 pp. (in English) ["The effect of wing corrugations on the aerodynamic performance of low Reynolds number hovering flight is investigated using two-dimensional Computational Fluid Dynamics. Corrugated sections with peaks that follow the contours of NACA sections are compared with the corresponding NACA airfoils, a flat plate of the same wall thickness as the corrugated sections, and a 1:4 ellipse. Simplified kinematics comprising combined heaving and pitching motions were simulated, and it was found that the thinner airfoil-type sections produced more lift than the thicker sections. The corrugated sections were found to perform similarly regardless of the size of the corrugated peaks and the orientation of the leading edge. The net vertical force in all of the corrugated cases was approximately the same as for the flat plate, indicating that wing corrugations produce no direct benefit in the generation of net vertical force for wings operating with hovering kinematics." 12576. Rojas-Riano, N.C. (2011): Sistemática del género *Polythore* Calvert, 1917 (Odonata: Polythoridae). Maestría thesis, Biología, línea Sistemática, Universidad Nacional de Colombia: 118 pp. (in English, with Spanish summary) ["The Neotropical damselfly genus *Polythore* is mainly distributed in western South America, in the foothills of the eastern slope of the Andes between Bolivia and Venezuela and in the Amazon region. In the present study, the 19 species of *Polythore* are revised based on morphological adult male characters from wing venation, wing pattern coloration, and genital ligula. Only general characters of females are included due to their polymorphism and to the limited availability of specimens in collections. Presence of supplementary sectors between RP2 and IR2 proximal to the pterostigma was found as a character that taxonomically defines the genus. Based on this character the new combination *P. chiribiquete* is proposed. The status of the populations proposed in the literature for species of the *picta* group is assessed by morphometric and multivariate analyses. Clear differentiation was found in populations of *P. procera* and *P. gigantea*. Populations of the remaining species differ only by characters proposed in the literature but not by other characters studied. Descriptions, illustrations, and an identification key to adult males are provided. A phylogenetic analysis of 49 species, including all the species of *Polythore* plus 29 out-group species, was performed based on wing venation, wing pattern coloration of male and female, and male genital ligula. Character coding and managing was conducted through DELTA package. Heuristic search tree was developed under the Ratchet method using NONA of the WinClada package. Partitioned analysis using male and female characters were designed and were compared with a total evidence analysis. Also, the relationship between morphological intraspecific variability and phylogenetic signal was studied using the species of *Polythore* as a model, through lineal and geometric morphometrics approach in two body regions: wings and genitalia. Total evidence analysis had the lowest percentage of strict homologies (22%), being near the percentage of partitioned analysis of female

characters (32%), while partitioned analysis of male characters had the highest percentage of strict homologies with 37%. The statistical support for individual clades was assessed with Bootstrap and Bremer values. A strict homology as support of the monophyly of Polythore was found. Of the six species groups proposed in the literature, only three were found to be natural groups. The sister group of Polythore is Euthore. Polythore williamsoni is registered for the first time for Colombia" (Author)] Address: Rojas-Riano, Nancy, Biologist. (2011): Hábito alimentar de *Oligosarcus robustus* Menezes, 1969 e de *Oligosarcus jenynsii* (Günther, 1864), no sul do estado do Rio Grande do Sul. *Atlântica*, Rio Grande 33(1): 73-86. (in Portuguese, with English summary) ["The characiform fishes *O. robustus* and *O. jenynsii* inhabit the coastal lagoons of the extreme southern Brazil. They "were characterized according to their morphologic variation and feeding structures as well as to their feeding habit. Specimens were collected in two periods (July and December 2001) in the Flores, Nicola, Jacaré and Mangueira lagoons. The food range was determined using the frequency of occurrence (FO%) and gravimetric methods (G%). A total of 164 specimens were analyzed, 67 of which had empty stomachs. The most frequent food items for *O. robustus* were insects FO=58,6%, fish FO=46,3% and crustaceans FO=12,2%. For *O. jenynsii* insects were dominant FO=83,9%, followed by crustaceans FO=35,7% and fish FO=26,8%. Insects were more frequent during summer for both species, Ephemeroptera and Odonata were the dominant groups. Fish were the main item in the diet of *O. robustus* during winter while *O. jenynsii* maintained the preference for the same group of insects during the cold season. The feeding strategy determined by the Amundsen graphic method showed that *O. jenynsii* is generalist preferring insects throughout the year while *O. robustus* is generalist opportunistic choosing insects during summer and fish in the wintertime." 12579. Simaika, J.P. (2011): Practical conservation planning from local to continental scales using freshwater invertebrates. Dissertation presented for the degree of Doctor of Philosophy in Conservation Ecology at the University of Stellenbosch: XVI + 123 pp. (in English)

["Dragonflies are a valuable tool for assessing aquatic systems and have been used as indicators of ecological health, ecological integrity, and environmental change, including climatic change. In four separate studies I explored the usefulness of dragonflies as surrogates in biomonitoring, site prioritization and indication of global climate change. In the use of dragonflies for biomonitoring, I field-tested a freshwater ecological integrity index, the Dragonfly Biotic Index (DBI), based on dragonfly assemblages at the local scale, and compared the DBI to a standard freshwater benthic macroinvertebrate-based freshwater health index. Overall, dragonflies were more sensitive to changes in river condition than were macroinvertebrates, and the DBI site value and macroinvertebrate scores were highly significantly correlated. I conclude that dragonfly assemblages in the form of a DBI are an excellent tool for environmental assessment and monitoring freshwater biodiversity, with the potential to replace benthic macroinvertebrate-based freshwater quality assessments. In the second study, I used the DBI to prioritize sites for conservation action in South Africa. Using a selected set of top prioritized sites, I compared the DBI's performance to that of a rarity-complementarity algorithm. Site prioritization using the DBI reveals that CFR sites protect Red Listed taxa rather well. The rarity-complementarity algorithm represents all species, but without greater emphasis on the rare and threatened species. I conclude that the DBI is of great value in selecting biodiversity hotspots, while the algorithm is useful for selecting complementarity hotspots. The third study was made possible by the recent completion of a continental assessment of freshwater biodiversity, which revealed that patterns of richness and threat of four well-studied aquatic taxa largely coincide at the continental scale. Using only dragonflies, I built a protected areas network for Africa using spatial planning software. I then compared the performance of the existing African reserve network and that of known global biodiversity hotspots against the model, and identified sites of conservation concern. Although the current reserve network covers 10.7% of the landscape, the proportional representation of species geographic distributions in reserves is only 1.1%. The reserve network is therefore inefficient, and many areas of conservation priority that are not formally protected remain. The advantage of operating at the fine scale, while covering a large geographic area is that it shifts the focus from the large-scale hotspots to smaller priority areas within and beyond hotspots. In the fourth study, I created species distribution models of dragonflies in an El Niño-prone biodiversity hotspot in South Africa, and predicted the changes in species richness, geographic range and habitat suitability, forty and eighty years from now. According to the model results of two different emissions scenarios, at least three species will be lost from the area by 2050, and four by 2080. The remaining species are predicted to persist with reduced geographical ranges, at generally higher elevations. Most species presented here thrive quite well in artificial

environments, that is, engineered ponds or dams. It is therefore unlikely that loss in connectivity will play a role for these species." 12584. Subramanian, K.A.; Kakkassery, F.; Nair, M.V. (2011): Chapter 5 "The status and distribution of dragonflies and damselflies (Odonata) of the Western Ghats. In: Molur, S., Smith, K.G., Daniel, B.A. and Darwall, W.R.T. (Compilers). 2011. *The Status and Distribution of Freshwater Biodiversity in the Western Ghats, India*. Cambridge, UK and Gland, Switzerland: IUCN, and Co-

imbatore, India: Zoo Outreach Organisation: 63-72. (in English) ["Conclusions and conservation recommendations: The river basins and associated freshwater ecosystems of the Western Ghats are global hotspots for odonates with high levels of endemism. Even though only 3.2% (four species) of the species are known threatened, over a quarter of the odonates in the region (46 species) have been assessed as DD. Many of these species are likely to be threatened as they are only known from historical records, often just the type specimens, and urgently need more survey work to identify their current ranges, populations and threats. Research is also required in those large areas where there is insufficient information on odonate diversity and distributions such as those south and north of the southern Karnataka–northern Kerala habitats and eastwards into the Deccan plateau. Many of the endemic odonates such as *Disparoneura apicalis* (VU) (Protoneuridae), *Platysticta deccanensis* (VU) (Platystictidae), *Melanoneura bilineata* (NT) (Protoneuridae) or *Idionyx* spp. (Cordulidae) are very narrowly distributed within the Western Ghats. The destruction of riverine habitats by hydro-electric and irrigation projects threatens the survival of these odonates, which depend on fast flowing torrential streams or stream associated habitats such as *Myristica* swamps. Destruction or alteration of a small catchment means likely extinction of these species. The protection of key habitats (fast flowing streams) for these species is an immediate priority. This is particularly urgent for species such as *Disparoneura apicalis*, *Calocypha laidlawi* and *Melanoneura bilineata*. Long term conservation of the odonate fauna of the region depends upon: (1) conservation of riparian forest cover, (2) prevention of flow modifications in streams and rivers, (3) conservation of *Myristica* swamps and high altitude peat bogs, and (4) prevention of use of pesticides and other agrochemicals in upper catchments of rivers." 12585. Tabugo, S.R.M.; Torres, M.A.J.; Demayo, C.G. (2011): Determination of developmental modules and conservatism in the fore- and hind-wings of two species of dragonflies, *Orthetrum sabina* and *Neurothemis ramburii*. *International journal of agriculture & biology* 13: 541-546. (in English) ["The wings of dragonflies are highly compartmentalized as shown by the major and minor veins separating the different compartments or modules. There is a long term hypothesis that compartments of the wings as bounded by the veins may correspond to units of "gene regulation". Are the different compartments 'units of gene regulation' and is there genetic conservatism on the wings of the dragonfly? This study was therefore, conducted to evaluate whether there is a number and pattern of developmental modules in dragonfly wings and determine whether there exists genetic conservatism based on intra and inter-modular variations in the wings. The study was con-

ducted in two cosmopolitan species of Libellulid dragonflies. Different hypotheses were formulated and tested as to the possible spatial boundaries based on major wing venations. A priori models applying the tools of geometric morphometrics were constructed and statistically tested for the goodness of fit test (GoF) statistic by comparing the observed and expected covariance matrices. Jackknife support values for each variational model were also computed using Y^* as the GoF statistic. Results showed fair consistency in the observed number and patterns of hypothesized developmental modules implying that the wings of these species of dragonflies are highly conserved. It is concluded that there is genetic conservatism in the morphological spaces in the wings of the two species." (Authors)] Address: Demayo, C.G., Dept of Biol. 12588. Zhao, H.X.; Yin, Y.J.; Zhong, Z. (2011): Assembly modes of dragonfly wings. Microscopy Research and Technique 74(12): 1134-1138. (in English) ["The assembly modes of dragonfly wings are observed through FEG-ESEM. Different from airplane wings, dragonfly wings are found to be assembled through smooth transition mode and global package mode. First, at the vein/membrane conjunctive site, the membrane is divided into upper and lower portions from the center layer and transitioned smoothly to the vein. Then the two portions pack the vein around and form the outer surface of the vein. Second, at the vein/spike conjunctive site, the vein and spike are connected smoothly into a triplet. Last, at the vein/membrane/spike conjunctive site, the membrane (i.e., the outer layer of the vein) transitioned smoothly to the spike, packs it around, and forms its outer layer. In short, the membrane looks like a closed coat packing the wing as a whole. The smooth transition mode and the global package mode are universal assembly modes in dragonfly wings. They provide us the references for better understanding of the functions of dragonfly wings and the bionic manufactures of the

wings of flights with mini sizes." (Authors)] Address: Zhong, Z., School of Aerospace Engineering and Applied Mechanics, Tongji University, Shanghai 200092, China. E-mail: zhongk@tongji.edu.cn

12589. Abdelsalam, K.M. (2012): Benthic macro- and meso-invertebrates of a sandy riverbed in a mountain stream, central Japan. Limnology 13(1): 171-179. (in English) ["Quantitative samples of benthic invertebrates were collected from a sandy riverbed of a mountainous stream (Kozu site of Takami-gawa stream, Nara Prefecture), central Japan by core samplers in five sampling occasions through the years 2008–2009. A total of 120 taxa (including 'Davidius') were identified, representing 55 families and 97 genera. Insects formed about 92% of the total recorded taxa and 88% of individuals' abundance. A total of 111 taxa of aquatic insects, belonging to 49 families and 92 genera, were identified and represented by ten orders. Oligochaeta and Acari were dominant non-insect invertebrates. Diptera was the most diverse insect group, followed by Trichoptera and Ephemeroptera. Dominant taxa were mesoinvertebrates, younger stages of macroinvertebrates, both of which predominantly inhabit the interstitial zone of a sandy riverbed. Both taxon richness and invertebrate abundance were higher in February 2009 and lower in April and August 2008. A few major invertebrate taxa demonstrated distinct seasonal trends; i.e. Nymphomyia alba, Rheosmittia, and Corynoneura were abundant in February 2009. Newly hatched larvae of Larcasia akagiae were abundant in May 2008. This study also demonstrated the effectiveness of core samplers to collect small-sized benthic fauna that inhabit the interstitial or hyporheic zone of the sandy riverbed." 12593. Balachandran, C.; Anbalagan, S.; Dinakaran, S. (2012): Influence of environmental parameters on the aquatic insect assemblages in Meghamalai hills, South India. *Life sciences Leaflets* 9: 72-81. (in English) ["In order to develop discreet management practices for lotic ecosystems, it is inevitable to gather subsequent information on their ecological status which involves monitoring the environmental parameters and biodiversity attributes. The distribution and composition of aquatic insect communities in streams at a local scale are considered to be primarily determined by environmental factors and interactive relationships within the system. The current study was carried out to investigate the effects of environmental variables on the assemblages of aquatic insects in the streams of Meghamalai hills. Six different streams in Meghamalai hills were selected as sampling sites and were examined for the water quality and aquatic insect assemblages. A total of 2139 individuals of aquatic insects, belonging to 10 orders, 28 families and 30 genera (including *Heliogomphus*), were collected from six streams. The collectors occupied a predominant group amongst all the functional feeding groups of insects followed by scrapers, predators and shredders. Higher diversity of aquatic insects was found at the middle order streams. The BMWP scores revealed that among the six sites studied, Site VI had the best water quality while Site III had the least water quality. Among the 12 environmental variables taken into account for the study, riparian vegetation, pH, conductivity, atmospheric temperature and stream order were found to be influencing the distribution of aquatic insects." 12595. Bogan, M.T.; Boersma, K.S. (2012): Aerial dispersal of aquatic invertebrates along and away from arid-land streams. *Freshwater Science* 31(4): 1131-1144. (in English) [Arizona, USA; "Dispersal is an essential process in metapopulation and metacommunity dynamics. Most studies of aquatic invertebrate dispersal in streams have focused on in-stream drift of larvae. However, understanding aerial dispersal is important for predicting community assembly in isolated habitats after disturbance or stream restoration. We used artificial pools placed at 3 distances (5, 75, and 250 m) from 1 perennial and 1 ephemeral arid-land stream to examine aerial-dispersal dynamics of aquatic invertebrates over a 6-wk period in summer 2009. We also conducted a 2-wk experiment to examine the relationship between daily rainfall and disperser abundance at the perennial site. Sixty-six aquatic invertebrate taxa colonized the artificial pools. They represented 1/3 of taxa documented from neighbouring perennial streams. Abundance and species richness declined with distance away from both streams. This result suggests that ephemeral stream channels may serve as important aerial dispersal corridors for aquatic invertebrates even when no surface water is present. Mean species richness tripled after 58 mm of rain during the 4th wk of the experiment. Data from the 2-wk experiment highlighted the role of rainfall as a dispersal cue in this system. Amount of daily rainfall explained 48 to 77% of the variation in disperser abundance at 5, 75, and 250 m from the perennial site. We used spatiotemporal dispersal patterns observed in our study to identify 5 modes of aerial dispersal among 56 taxa: 1) widespread common, 2) widespread hap-hazard, 3) range-restricted, 4) cue-limited, and 5) infrequent. Classification of specific aerial-dispersal modes provides a conceptual framework for modelling spatially explicit community responses to disturbance, stream restoration, and climate-change-induced habitat contraction or expansion." em *Biología Celular e Estructural*, para obtenção do título de *Doctor Scientiae*: x + 61 pp. (in Spanish, with English summary) ["... The ultrastructural features of the sperm has shown promise for phylogenetic analyzes in many insect groups, but such studies are still lacking for Odonata. Thus, this study aimed to describe the structure and ultrastructure of spermatozoa of species of Odonata suborders: Zygoptera and Anisoptera, searching for information that would assist in understanding the systematics of this group of insects. For this, sperm from seminal vesicles and testes of adult males of the *Ischnura fluviatilis*, *Pantala flavescens*, *Tramea abdominalis* and *Micrathyrja hesperis* were prepared for light and transmission electron microscopy. The sperm of these species have some characteristics similar to those presented by the sperm of most Pterygota. However, some differential characteristics stand out: lack of perforatorium in the acrosome and of paracrystalline material in the mitochondrial derivatives; flagellum very short, possibly immobile with small mitochondrial derivatives inspecies of Libellulidae; and lack of accessories bodies and microtubule arrangement 9+9+0 in species of the Trameinae subfamily. The analysis of the ultrastructure of spermatozoa enabled the differentiation of the two suborders of Odonata, as well as, the species of two Libellulidae subfamilies studied." Mitt. Niederösterreich. Landesmuseum* 23: 83-112. (in German, with English summary) ["Hydromorphological reference conditions as basis for deriving river-type-specific dragonfly communities (Insecta: Odonata): a case study at the rehabilitated downstream stretch of the Weidenbach (Lower Austria): The ecological status of the rehabilitated downstream stretch of the Weidenbach in the lowland areas of Lower Austria was assessed by dragonfly surveys at three sections. Key element of the assessment procedure, which is in compliance with the EU Water Framework Directive (WFD), is a comparison between the current situation and river-type-specific reference conditions. Hydromorphological references served as basis for deriving the reference dragonfly community. The section with the smallest deviation from the hydromorphological reference was colonised by a near river-type-specific dragonfly

community. Species composition, the Odonata Habitat Index, species-specific habitat values and flow preferences were considered in the assessment. A total of 27 species were recorded, 19 species of them were classified as autochthonous. All four species of the genus *Orthemtrum* occurring in Central Europe were found. The river stretch was ranked as class II ("good ecological status"), which represents the second best class and the quality target in the 5-tiered WFD classification scheme." 12601. Csányi, B.; Szekeres, J.; György, Á.I.; Szalóky, Z. (2012): Macrozoobenthon investigations along the Lower Danube between Calarasi and Braila, Romania. *Acta Biol. Debr. Oecol. Hung.* 28: 47-59. (in English, with Hungarian summary) [In the framework of the improving the navigability of the Lower Romanian Danube between Calarasi and Braila (375 fkm – 175 fkm) a detailed survey program of aquatic macroinvertebrates and fish was performed. On-site sampling of macroinvertebrates was carried out in early summer of 2011 between 31 May and 4 June. Altogether 16 Kick and Sweep multi-habitat samples in the littoral zone and 18 dredged samples in the deep water zone were collected. A motor boat was used in 11 sites of the main arm. Mussel populations were estimated along the banks with free diving method. There were Cnidaria (1), Annelida and leeches (7), snails (10), mussels (9), Malacostraca (18), Ephemeroptera (4) Odonata (2), Heteroptera (6), Trichoptera (4), Coleoptera (3) and Diptera (3) taxa detected. Results illustrate that in deep zones characterized by uniform moving sand fraction only has very scarce community with low taxon numbers. The littoral zone of the low discharge conditions that has low bed erosion and not significant sediment deposition contains very rich macroinvertebrate communities, especially at those sections that are having rocky habitats, as well. Interesting faunistic results were the detection

of the leech (*Batracobdelloides moogi*), a snail (*Theodoxus transversalis*), a very rare mussel (*Unio crassus*) and a brackish water invader Crustacea species (*Pseudocuma longicorne ponticum*) on this Danube section." (Authors) Stylurus flavipes] Address: Csányi, B., Environmental & Water Management Research Institute Non-profit Ltd., Nonprofit Kft., H-1095 Budapest, Kvaszay Jenő út 1, Hungary. 12603. Futahashi, R.; Sasamoto, A. (2012): Revision of the Japanese species of the genus *Rhipidolestes* (Megapodagrionidae) based on nuclear and mitochondrial gene genealogies, with a special reference of Kyushu-Yakushima population and Taiwan-Yaeyama population. Tombo 54: 107-122. (in English, with Japanese summary) ["Here we report a revision of Japanese *Rhipidolestes* (Megapodagrionidae) species based on nuclear and mitochondrial gene genealogies, along with morphological findings. In Japan, six *Rhipidolestes* species (*R. aculeatus* Ris, 1912, *R. okinawanus* Asahina, 1951, *R. hiraoui* Yamamoto, 1955, *R. asatoi* Asahina, 1994, *R. shozoi* Ishida, 2005, and *R. amamiensis* Ishida, 2005) and two subspecies (*R. aculeatus yakusimensis* Asahina, 1951, and *R. amamiensis tokunoshimensis* Ishida, 2005) have been described so far. Because the differences in morphological characteristics between each species/subspecies are subtle, it has been difficult to determine the phylogenetic classification of these groups. Based on the results of our molecular phylogenetic analyses using nuclear DNA (1TS1 and ITS2 regions) and mitochondrial DNA (16S ribosomal RNA and COI regions) sequences, we newly show that Kyushu-Yakushima and Taiwan-Yaeyama Islands populations apparently belong to different clades, *R. yakusimensis* stat. nov. and *R. aculeatus* (sensu stricto), respectively. We confirmed that *R. shozoi* and *R. okinawanus* in the Okinawajima Island can be clearly distinguished, whereas the differences between nominotypical *R. amamiensis* and *R. amamiensis tokunoshimensis* were rather obscure. We also recognized genetic differences between Kyushu and Yakushima populations of *R. yakusimensis*, between Yaeyama and Taiwan populations of *R. aculeatus*, and between middle Okinawajima and Tokashikijima populations of *R. okinawanus*, though we do not discuss them in detail at present. Overall, the results of molecular phylogeny in Japanese *Rhipidolestes* group coincided with the closeness of geographic distribution rather than the similarity of genital

morphology." (Authors)] Address: Futahashi, R., Fujiwara Lab., Univ. Tokyo, Biosci. Bldg 501, Kashiwa, Chiba, 377-8562, Japan

12604. Gashaw, H.; Mengistu, S. (2012): Ecological assessment of lake Hora, Ethiopia, using benthic and weed-bed fauna. Momona - Ethiopian Journal of Science 4(2): 3-15. (in English) ["Urbanization and human settlement in close proximity to the Ethiopian lakes are among the potential causes of changes in water quality and quantity. The drastic changes occurred into one of the Bishoftu crater lakes (Kilole) best exemplify this phenomenon. The purpose of this study was ecological assessment of Lake Hora using benthic and weed-bed fauna. Samples of benthic and weed-bed were collected monthly from September 2009 to March 2010 at 3 sampling stations (A, B, C), with a standard Ekman grab. Station A is in front of Ras Hotel, Station B is place of Irecha and station C was to the south crater of the lake. The benthic and weed-bed fauna of Lake Hora included a total of 6958 individuals within 27 taxa belonging principally to Copepod (2812) and Chironomidae (1460) and Ecdyonuridae (735). A high number of organisms were observed mainly at stations B and A (3198 and 2342 respectively). The correlation result indicates that oxygen showed strong relation to benthic and weed bed fauna distribution and abundance. There were high number of individuals, taxa diversity, evenness and grate number of rare taxa of benthic and weed-bed fauna at stations A and B, but these stations were affected by the community around the lake area for different reasons (for example washing clothes, boat parking and others). However low density and abundance of macroinvertebrates at station C could be due to: low organic matter load at station C which was free of human interactions; steeply slope geographical setting of the profoundly and its catchment and low vegetation cover. The Family Biotic Index result for all the sampling stations was 7.55, according to Hilsenhoff Family Biotic Index this value is indicating likely severe organic pollution and very poor water quality in all sampling sites. As this research finding indicates Lake Hora needs protection management strategies to maintain its sustainable use." (Authors) Taxa including Coenagrionidae and Lestidae are treated at family level.] Address: Gashaw, H., Dept of Biology, Addis Ababa University, Addis Ababa, Ethiopia. E-mail: habibag2@gmail.com

12608. Henderson, B.L.; Chumchal, M.M.; Drenner, R.W.; Deng, Y.; Diaz, P.; Nowlin, W.H. (2012): Effects of fish on mercury contamination of macroinvertebrate communities of grassland ponds. *Environmental Toxicology and Chemistry* 31(8): 870-876. (in English) ["Mercury is an environmental contaminant that negatively affects the health of vertebrate consumers such as fish, birds, and mammals. Although aquatic macroinvertebrates are a key link in the trophic transfer of Hg to vertebrate consumers, Hg contamination in macroinvertebrate communities has not been well studied. The purpose of the present study was to examine how Hg in macroinvertebrate communities is affected by the presence of fish. We sampled macroinvertebrates from five ponds with fish and five ponds without fish, at the Lyndon B. Johnson National Grassland in north Texas, USA. Ponds without fish contained a higher biomass of macroinvertebrates and taxa with higher concentrations of Hg, which led to a higher Hg pool in the macroinvertebrate community. A total of 73% of the macroinvertebrate biomass from ponds without fish was composed

of taxa with the potential to emerge and transport Hg out of ponds into terrestrial food webs. The results of the present study suggest that small ponds, the numerically dominant aquatic ecosystems in the United States, may be more at risk for containing organisms with elevated Hg concentrations than has been appreciated." (Authors) Taxa include Odonata and are treated at the genus level.] Address: Henderson, B.L., Institute for Environmental Studies & School of Geology, Energy, & the Environment, Texas Christian Univ., Fort Worth, Texas, USA.

12611. Jacquemin, J.; Vein, D. (2012): The aquatic insects of a standard small plain river in NE France, with emphasis on remarkable species. *Aquatic Insects* 34 (Suppl): 11-22. (in English) ["A five-year macroinvertebrate study was conducted on a 55 km river (le Rupt-de-Mad, Lorraine region, north-eastern France), a standard for the region. A list of 300 species was drawn up, and remarkable species were listed for some better known orders: Ephemeroptera, Plecoptera, Trichoptera and Odonata (31 species). Some faunistic results are emphasised: about 42% of the identified species were more or less ubiquitous, 26% were meso- to polysaprobic species of potamon, present only in the main course of the river, while 31% were rather stenoecious species restricted to certain tributaries. 51 remarkable species were listed, taking into account their regional status, according to IUCN categories: more than three quarters were hosted in the small tributaries, and 55% found exclusively in these latter (versus 23.5% only present in the main course of the river). Calcareous lotic tributaries were hosting particularly original communities with many remarkable species. Ephemeroptera, Plecoptera

and Trichoptera were pertinent groups to assess the global faunistic interest of lotic habitats, but lentic habitats are probably better evaluated using other groups, e.g. Odonata and Coleoptera; the latter unfortunately poorly known from an ecological point of view." 12614. Jung, K.-S.; Park, D.-H.; Lee, J.-E. (2012): A study of the arrangements of wing and thoracic muscu-

lar structures on flight behavior of Odonata, with a note on backward flight of Zygoptera. *Tombo 54*: 133-138. (in English, with Japanese summary) ["The two suborders of Odonata, Zygoptera and Anisoptera, show different modes of flight behaviours, e.g. capturing their prey. In suborder Anisoptera, most species fly dynamically and are good at capturing preys in flight by grasping them in their legs. On the contrary, in suborder Zygoptera, species usually fly delicately and often use their mandibles to capture their prey. In addition, we observed that zygopteran species were sometimes flying backwards when they cannot advance forward in small space. Such backward flight is observed rarer in Anisoptera. For purpose to reveal the differences of these flight modes between two suborders, we compared the arrangement of wing and pterothorax with measuring the angles between dorsal carina to costal margin of wing or posterior thorax, and dissected pterothoracic muscular structures of both Zygoptera and Anisoptera. From our results, both suborders have six muscles are attached to each wing, however, differed in the attachment to wing and thorax, and distinct in thoracic proportion as angles of wing to pterothorax. Each arrangement is supposed to be suitable for the flight behaviour in each suborder, especially Zygoptera is better at delicate turning in flying including backward flight." 12617. Keller, D. (2012): Insect dispersal in fragmented agricultural landscapes. Diss. ETH No. 20663. A dissertation submitted to ETH Zürich: 142 pp. (in English) ["Preserving biodiversity and enhancing connectivity are two major goals of current conservation strategies in fragmented agricultural landscapes. Therefore, many European countries have implemented agri-environment schemes in order to foster biodiversity and connectivity. The expected positive effects on biodiversity could, however, not consistently be detected, and for many agricultural species, it remains unknown whether populations are functionally connected. As functional connectivity is sustained by dispersal and gene flow, connectivity measures should be based on knowledge of species-specific dispersal potential, dispersal habitats and landscape elements that impede or facilitate gene flow. However, such information is not available for most species, and especially so for many insect species. In this thesis, I wanted to gain knowledge on insect dispersal in intensively managed and fragmented agricultural landscapes, where diverse connectivity measures had been implemented. The main goals were to assess the reproductive habitats, dispersal abilities, dispersal habitats and landscape effects on gene flow of five insect species inhabiting an agricultural landscape in the Oberaargau region on the Swiss plateau. In chapter 1, I analysed dispersal ability and dispersal habitats of the threatened damselfly *Coenagrion mercuriale*, which inhabits streams and ditches flowing through agricultural land. With a mark-resight study, I detected frequently occurring dispersal over short distances (= 500 m). This short-distance dispersal was restricted to streams, i.e. the reproductive habitat of *C. mercuriale*. In a landscape genetic analysis, I also detected long-distance dispersal showing that populations were functionally connected by individuals moving over larger distances. While short-distance dispersal was confined to streams, this long-distance dispersal seemed to be more directed and seemingly followed more or less straight lines across agricultural land. Functional connectivity of populations of *C. mercuriale* as well as the effects of several landscape elements on gene flow were further analysed in chapter 2, where I applied spatial genetic clustering methods combined with interpolation by kriging and landscape genetic corridor analysis (= transect analysis). The analysed populations were divided into a northern and a southern genetic cluster, separated by a hill ridge intersecting the study area. Similarly, landscape corridor analysis identified elevation change, but also Euclidian distance, patches of forest and flowing water bodies as barriers to gene flow. Only open agricultural land seemed to enhance dispersal in *C. mercuriale*. This again 2 showed that dispersal was not restricted to the reproductive habitat of *C. mercuriale* and that populations separated by open agricultural land were well connected. To analyse how landscape elements affect dispersal and gene flow in another specialised insect species, I developed ten polymorphic microsatellite markers for the wetland grasshopper *Stethophyma grossum*, using the 454 next generation sequencing technol-

ogy (chapter 3). These newly developed markers were then applied to identify dispersal habitats of *S. grossum* and to assess the effects of population network topology and spatial scale (geographical distance thresholds) on landscape genetic analysis in chapter 4. Both spatial scale and population network topology proved to be important factors in landscape genetic analysis and all three approaches applied (i.e. isolation by distance patterns, population network topology, least-cost transect analysis) identified a scale threshold of 3-4 km, up to which landscape composition and configuration greatly influenced dispersal and gene flow. For dispersal among neighbouring populations (defined by a Gabriel graph) that were within its maximum dispersal distance (0-3 km), *S. grossum* preferred its reproductive habitat as dispersal habitat. In contrast, no clear most likely dispersal habitat could be identified when population network topology and spatial scale were not considered. [...] In conclusion, this thesis presented several approaches to assess landscape effects on dispersal and gene flow in agricultural insects. Moreover, it detected various aspects of insect dispersal in intensively managed fragmented agricultural landscapes, which should be considered in future studies. The analyses of five insect species showed that landscape effects on dispersal and gene flow mainly depend on species-specific dispersal ability, reproductive habitat specialisation and spatial population configuration. The latter phenomenon has, however, hardly been used in landscape genetic studies. Furthermore, I found that populations of all analysed species were functionally connected, even in the fragmented landscape of the study area. The species were well able to cross intensively managed open agricultural land and dispersal was not restricted to their reproductive habitats. For both specialised study species (i.e. *C. mercuriale* and *S. grossum*), dispersal habitats changed at different thresholds of spatial scale. Moreover, the consideration of population network topology as applied in the analysis of *S. grossum* (i.e. restricting the dataset to neighbouring populations within maximum dispersal distance) further improved results. For future landscape genetic analyses, these studies suggest a more thorough consideration of spatial scale, by differentiating between short- and long-distance dispersal, as well as by incorporating population network topology. All these findings, i.e. the identification of species-specific reproductive habitats, dispersal habitats, dispersal ability and the detection of landscape elements hindering or facilitating gene flow, will help planning future connectivity measures for the study species and can also give general guidelines for the conservation of insects in fragmented agricultural landscapes." 12620. Klass, K.-D.; Matushkina, N.A.; Kaidel, J. (2012): The gonangulum: A reassessment of its morphology, homology, and phylogenetic significance. *Arthropod Structure & Development* 41(4): 373-394. (in English) ["The gonangulum is a sclerite in the female genitalic region of insects. Its presence or full development has long been considered an apomorphy supporting Zygentoma + Pterygota. Recent studies of female genitalia in several insect orders (K.-D. Klass and co-workers) revealed many new data on the gonangulum and homologous sclerotisations (laterocoxa LC9). Herein the gonangulum area is described (including articulations, muscle attachments, sulci) and compared among Archaeognatha, Zygentoma, Odonata, Dermaptera, Dictyoptera, and Notoptera. A wider perspective is provided to the topic by addressing some novel issues: identification of LC9 sclerotisations in non-insect taxa and in insects that secondarily lack an ovipositor; occurrence of homonomous sclerotisations in other abdominal segments of both sexes; morphological interpretation of LC9; and the role of paedomorphosis in LC9 evolution. As a result, there is currently no support for any insect lineage from this character system. For gonangulum-related characters both a significant intra-ordinal variation and frequent homoplasy are demonstrated using various Odonata, Dermaptera, and Dictyoptera as examples. Divergent fates of LC9 in simplified genitalia are shown using a dermapteran and an odonatan. We view all this as a showcase of how a renewed and more

detailed examination of a character system can dramatically change the phylogenetic evidence drawn from it." (Authors)] Address: Matushkina, Natalia, Department of Zoology, Biological Faculty, Kyiv National University, vul. Volodymirs'ka 64, Kyiv, 01033, Ukraine. E-mail: odonataly@gmail.com

12622. Kraemer, L.D.; Evans, D. (2012): Uranium bioaccumulation in a freshwater ecosystem: Impact of feeding ecology. *Aquatic Toxicology* 124-125: 163-170. (in English) ["The objectives of our study were: 1) to determine if there was significant uranium (U) bioaccumulation in a lake that had been historically affected by a U mine and 2) to use a combined approach of gut content examination and stable nitrogen and carbon isotope analysis to determine if U bioaccumulation in fish was linked to foodweb ecology. We collected three species of fish: smallmouth bass (*Micropterus dolomieu*), yellow perch (*Perca flavescens*) and bluegill (*Lepomis macrochirus*), in addition to several invertebrate species including freshwater bivalves (family: Sphaeriidae), dragonfly nymphs and snails (class: Gastropoda) and zooplankton (family: Daphniidae). Results showed significant U bioaccumulation in the lake impacted by historical mining activities. Uranium accumulation was 2-3 orders of magnitude higher in invertebrates than in the fish species. Within fish, U was measured in operculum (bone), liver and muscle tissue and accumulation followed the order: operculum > liver > muscle. There was a negative relationship between stable nitrogen ratios ($^{15}\text{N}/^{14}\text{N}$) and U bioaccumulation, suggesting U biodilution in the foodweb. Uranium bioaccumulation in all three tissues (bone, liver, muscle) varied among fish species in a consistent manner and followed the order: bluegill > yellow perch > smallmouth bass. Collectively, gut content and stable isotope analysis suggests that invertebrate-consuming fish species (i.e. bluegill) have the highest U levels, while fish species that were mainly piscivores (i.e. smallmouth bass) has the lowest U levels. Our study highlights the importance of understanding the feeding ecology of fish when trying to predict U accumulation. Highlights: *Significant U accumulation in

Bow Lake biota *U accumulation was higher in invertebrates than in fish *U biodilution occurred in the food-web *In fish U bioaccumulation: bluegill > yellow perch > smallmouth bass *U accumulation in fish is linked to feeding ecology." 12625. Mahabal, A.; Rane, P.D. (2012): Large-scale night congregation of Yellow-tailed Ashy Skimmers Po-

tamarcha congener (Rambur) at Gaganbawada, Maharashtra State: with notes on their camouflage and roosting behaviour. *Bugs R All* 19: 16-17. (in English) [Verbatim: "During the faunistic survey of Maharashtra State, we had camped at Gaganbawada (16°32'48"N 73°50'06"E) PWD Rest House, Kolhapur district, from 7-9 January, 2007. Gaganbawada is a small town situated in the Northern Western Ghats at a height of 614 meters asl, with an average rainfall of 2500 to 3000 mm. Surrounding this town a mixture of agricultural cropland, hilly areas with dry deciduous – mixed forest, medium and large - sized ponds and streams were noticed. Along these ponds and streams there was dense vegetation that included shrubs, trees and aquatic plants with some marshy areas. On the first evening (7/1/2007) we came across a large congregation of *P.* congener, on cultivated, medium sized 'Australian Pine' *Casuarina equisetifolia* Linnaeus (Casuarinaceae). On close observation it was noticed that these skimmers had chosen only the dry branches of the tree. Further, it was also observed that the resting position of the skimmers was the same as the branching pattern of needle-shaped green leaves. From a distance the colony of skimmers was totally camouflaged and this behaviour could be related to avoid predation of the colony at night time. The congregation of skimmers was also noticed on two other near-by *Casuarina* trees. We counted the number of dry branches occupied by these *P.* congener on all the trees as well as number of individuals resting on such branches. Roughly we then estimated the congregation to be of about 4000 skimmers. On this first day, the skimmers roosted in these trees overnight and next morning around 9 am they vacated the roost in swarms of 50 to 200 individuals. On second day (8/1/2007) in the evening they came back and roosted again on the same trees in similar fashion. During this night, with the help of torch light we collected few samples of these skimmers using insect net for confirming their identity. The roost was disturbed and some of them dispersed and got attracted to the light at verandah of the rest house. In general here we noticed that the females were much more than the males in such congregations (in the ratio of 7:3 approx.). On 9/1/2007 we moved to the next camp. We then contacted the caretaker of the Gaganbawada rest house and enquired about these skimmers and he informed us that the insects were still roosting on the trees on 9th January. *P.* congener are medium sized dragonflies with bluish black thorax and yellow tail with black markings. Their large colonies are often found within patches of forest or scrub associated with weedy ponds and marshes. These insects breed in marshes but their flight season is not known (Fraser, 1936; Subramanian, 2009). It is uncertain whether such large-scale congregation and overnight roosting of these skimmers is temporary or permanent or a local winter migratory behaviour. However, it can be inferred that because of agricultural crops and marshy places, plenty of food and breeding areas might be available to them along with

proper trees for safe roosting in this area of Gaganbawda." (Authors)] Address: Rane, P.D., Zoological Survey of India, W.R.C, Akurdi, Pune 411044, India

12626. Matsuda, I.; Umesaki, H. (2012): Records of the migrating species *Anax guttatus* caught in SaKai City and Taism-cho, Osaka Prefecture in 2004 and 2011. Tombo 54: 145-146. (in Japanese, with English summary) ["One of the authors, Matsuda, caught by "buri" (thread and stones for catching flying dragonflies) 3 males in 2004 and 3 males in 2011 (one male each on June 11, July 3 and 9) of *Anax guttatus* in Oizumi Park, Sakai City, Osaka Prefecture. Umesaki netted a male of the same species in Taishi-cho, Osaka Prefecture on July 9, 2011. This species is considered to be an immigrant from the south, and the first typhoon visited mainland Japan on July 12 in 2011. Thus, it seems noteworthy that 4 males were recorded before the typhoon visited." (Authors)] Address: Matsuda, I., 583 -087, 6 -11 Osaka Habikino Momoyamada 1-chome, Japan

12627. Mayon, N.; Terweduwe, S. (2012): Différents patterns d'émergence chez deux libellules rhéophiles: effet station ou mécanisme pour limiter la compétition? Les Naturalistes belges 93(4): 45-64. (in French, with English summary) ["We have compared the emergence patterns of *Gomphus vulgatissimus* and *Onychogomphus forcipatus* in different sites along a downstream gradient in the Sûre River (southern Belgium). Results confirm that *G. vulgatissimus* reacts as a spring species while *O. forcipatus* shows emergence characteristics of a summer species. In *G. vulgatissimus*, results suggest cohort splitting to take place at different levels in the various study sites. We discuss such differences with special focus on non-biotic (mainly temperature) and biotic (competition) parameters. In sites where both species are present, results show that the emergence cycles can be either contiguous or separated, suggesting an effect of interspecific competition. This work shows that emergence patterns in dragonflies are under the combined influence of numerous parameters. Therefore, they can be rather different even at a very local scale (i.e. a stream section)." (Authors)] Address: Mayon, N., Parc Naturel Haute-Sûre et Forêt d'Anlier. Chemin du Moulin 2, B-6630 Martelange, Belgium. E-mail: nicolas@parcnaturel.be

12628. McLamb, S. (2012): Not a total washout! The red-veined darter *Sympetrum fonscolombii* Selys, 1840 in Shropshire. Shropshire entomology 6: 9-10. (in English) [Recent records of *S. fonscolombii* in Shropshire, UK are compiled and briefly discussed. Though it is too early to summarise the field season with respect to dragonflies and damselflies I felt it important to point out that despite a largely soggy summer not all was lost and whilst the May monsoons briefly abated Red-veined darters *Sympetrum fonscolombii* Selys 1840, were spotted by Jim Almond at Venus Pool (SJ5406). Days later I was lucky enough to see them accompa-

nied by the experienced eyes of Bob Kemp who confirmed the identification. The darters stubbornly remained some distance out from the main bird hide though with the aid of a telescope the single pale stripe on the side of the thorax was clearly visible. This is illustrated here in Jim's photographs and one can also make out Shropshire Entomology – October 2012 (No.6): 10 the blue coloration in the lower half of the eye. The darters were clearly ovipositing and though this species is regarded as a scarce migrant there has been an increase in the number of breeding records in recent years (Smallshire & Swash, 2010). *S. fonscolombii* has been recorded in a number of locations this year including Staffordshire where interestingly it has been recorded for the last few years suggesting possible successful breeding as opposed to an influx of new migrants (British Wildlife, 2012). This is definitely a species to look out for and thanks to Jim is a great record for Shropshire. The only previous record was an anonymous sighting made at Whixall Moss in 1940.] Address: not stated

12629. Mediani, M.; Boudot, J.-P.; Benazzouz, B.; El Bella, T. (2012): Two dragonfly species (Insecta: Odonata) migrating at Dakhla (region of Oued Ad-Dahab Lagouira, Morocco). International Journal of Odonatology 15(4): 293-298. (in English) ["Large numbers of migrating imagos of *Anax ephippiger* were observed from the end of January to March 2012 at Dakhla Bay, Southern Morocco, in an area where long-lasting fresh and brackish waters are lacking, and thus which is unfavourable for the reproduction of Odonata. This supports well the classical scheme of northward mass migration of the species along the Atlantic coast of Africa, induced by autumnal mass emergences in the Sahel as a result of the summer African monsoon. Small numbers of *Sympetrum fonscolombii* were previously temporarily recorded from the same area in July 2011. They were probably nomadic individuals of which the origin could not be verified, but which could have been involved in long distance vagrancy, typical of the species, due to the scarcity of fresh and brackish water in the area." 12631. Michalski, J. (2012): A Manual for the Identification of the Dragonflies and Damselflies of New Guinea, Maluku, & the Solomon Islands. Khanduanum Books: 561 pp. (in English) ["First comprehensive guide to all 620 species of dragonflies of New Guinea and the neighbouring islands, which is home to ten percent of the world's dragonfly fauna. Nearly half of the species are found nowhere else on Earth. Includes 1,275 illustrations and eight pages of colour plates showing representative species and habitats. Includes introductory sections on structure, habitat, history, collection and photography, as well as appendices discussing taxonomic questions and a full bibliography. Illustrated keys to all taxa, and illustrations of larval forms where known. Over the past ten years there has been a growing interest in the dragonflies of this remarkable part of the world. This manual brings together all of the published research on this fauna from its origins in the 1800s to the present." (Author)] Address: Michalski, J., 1223 Mount Kemble Avenue, Morristown New Jersey 07960, USA. E-mail: huonia@aol.com

12632. Motte, G., Vadevyvre, X.; Dufrene, M. (2012): Evolution des populations d'odonates des mares de Ben-Ahin 20 ans après la création de la Réserve Naturelle. *Les Naturalistes belges* 93(4): 65-84. (in French, with English summary) ["Twenty years after the establishment of Ben-Ahin Nature Reserve (1993), we followed the evolution of the dragonfly fauna between 1993 and 2011. A comparison of the data collected before and after 2003 shows that the species richness of the site remained stable. Four species were no longer observed (*Erythromma lindenii*, *E. viridulum*, *Lestes sponsa*, *Sympetrum vulgatum*) but this is attributed to sampling bias. And two new species have recently been recorded (*A. isosceles*, *O. brunneum*) but these observations were only of erratic individuals. No obvious changes in species phenology could be documented in relation to global warming. Recommendations for site management are also proposed at the end of this paper." (Authors)] Address: Dufrière, M., Service Public Wallon (SPW) - Direction Générale Opérationnelle (DG03) - Département de l'Etude du Milieu naturel et agricole (DEMna), Av. Maréchal Juin, 23, B-5030 Gembloux, Belgium. E-mail: Marc.Dufrene@spw.wallonie.be

12633. Naraoka, H. (2012): Discovery of *Platycnemis echigoana* Asahina (*Platycnemididae*) in Aomori Prefecture. *Tombo* 54: 139-141. (in Japanese, with English summary) ["The Japanese endemic species *Platycnemis echigoana* Asahina was previously recorded from only 4 prefectures; Niigata, Yamagata, Fukushima and Nagano. Here I report records of this species from Rok-

kasho village, Aomori Prefecture, more than 280 km away from the known habitats. On June 25, 2011, I discovered one immature male and one immature female of this species in a forest at Rokkasho village. I also found many mature adults during July and August, 2011 and observed reproductive behaviours. After September, I could not find any adult specimens." (Author)] Address: Naraoka, H., Motoizumi 36-71, Fukunoda, Itayanagi, Kitatsugaru-gun, Aomori 038-3661, Japan. E-mail: sbnkq127@ybb.ne.jp

12634. Nordström, K.; Bolzon, D.; O'Carroll, D. (2012): Underlying neuro-physiological mechanisms. *Front. Behav. Neurosci. Conference Abstract: Tenth International Congress of Neuroethology*. doi: 10.3389/conf.fnbeh.2012.27.00234: (in English) [Verbatim: As an animal moves through the world, its own movement generates widefield optic flow across the visual field that it can use for several behavioural tasks, such as maintaining a straight trajectory or avoiding obstacles. Behavioural evidence shows that many animals can also disambiguate the motion of discrete objects that move independently of the remaining visual surround from such self-generated optic flow. In the insect optic ganglia, we find neurons specialized for detecting these two types of motion: Some respond optimally to widefield optic flow whereas others are specifically tuned to the relative motion of discrete figures (Olberg, 1981). In the dragonfly lobula there are two types of neurons tuned to the relative motion of discrete figures: Small target motion detectors (STMDs) and bar cells (O'Carroll, 1993). Whereas STMDs are tuned to small figures (Nordström, 2012), the bar cell response increases with bar height, but there is no response to the type of widefield stimuli generated during ego-motion (O'Carroll et al., 2012). Bar cells thus respond specifically to the motion of elongated, discrete figures. We here investigate the neurophysiological mechanisms that underlie this tuning. In the vertebrate visual cortex bar sensitivity is generated by aligning output from rows of neurons with small receptive fields (simple cells). Vertebrate simple cells share several physiological properties with elementary STMDs (ESTDMs), the input elements to STMDs (Wiederman et al., 2008). To investigate whether dragonfly bar cells generate their specific sensitivity to elongated features by spatially pooling the input from a row of elementary small target tuned motion detectors, we quantify responses to key parameters involved in ESTMD tuning (Wiederman et al., 2008). We show that whereas the velocity tuning and the high gain to sub-pixel targets suggest that bar cells share input mechanisms with STMDs, other responses point to a different type of input. For example, as opposed to STMDs, bar cell responses are often contrast polarity invariant, and they respond equally well to a bar and to a single edge moving across the visual field. The neurons also show a surprisingly strong spatial summation. Early anatomical studies of the fly optic lobes showed that the column underlying each facet is represented by

up to 100 unique interneurons, leading to the suggestion that visual input is processed in many parallel streams (e.g. Fischbach & Dittrich, 1989). In support of this notion, local motion is computed differently in the inputs to SMTDs (Wiederman et al., 2008) and to the neurons coding for widefield optic flow (Hassenstein & Reichardt, 1956). Our findings that bar cells generate their specific sensitivity to discrete, elongated figures by using different visual input from the STMDs provide further evidence for the notion of parallel visual input pathways.] Address: Nordström, Karin, Uppsala University, Department of Neuroscience, Uppsala, 75124, Sweden. 12638. Ottburg, F.G.W.A.; Henkens, R.J.H.G. (2012): Combinatie van vaarrecreatie en beek gebonden natuur in Noord-Brabant. Kennis over ecologische effecten van kano's en fluisterboten, kwetsbaarheid van flora en fauna en handelingsperspectieven voor beheerder en gebruiker. alterra-rapport no. 2375: 113 pp. (in Dutch) ["Combining water recreation and stream-related nature in Noord-Brabant. Knowledge of the ecological effects of canoes and whisper-boats, sensitivity of flora and fauna and management prospects for manager and end user: Two small river systems (R5 and R6) in this Dutch province are suitable for canoes and whisper-boats. These streams also include several Habitat 2000 areas and are important for Red List species. A literature study was made of the ecological effects of this type of water recreation on habitats, vegetation, fish populations, waterfowl, and Odonata. Several species of water birds and Odonata were very susceptible to disturbance by boats. Two case studies, the Dommel and Bovenmark, were used in a local workshop to apply this knowledge to a local stream management plan. Supportive measurements included fixed stopping points for boats, zoning of streams for recreative use, and more education for users and staff." 12639. Parr, A.J. (2012): Migrant and dispersive dragonflies in Britain during 2011. *J. Br. Dragonfly Society* 28(2): 56-65. (in English) ["The year 2011 was noteworthy for the large, indeed unprecedented, numbers of Vagrant Emperor *Anax ephippiger* noted throughout the year. There were at least three immigration waves - a slow trickle of sightings during the late winter of 2010/11, a surge of records during April and early May, and then a final run of records during October and November. Both the spring and autumn influxes were associated with spells of unseasonably hot weather with winds from the far south. Arrivals of *Sympetrum fonscolombii* were also noted during these periods. Although the summer weather was, by contrast, less spectacular, there were still significant immigrations of *Anax parthenope*, as well as of further *S. fonscolombii*. Three sightings of *Aeshna isosceles* were also made well away from the species' current UK stronghold. Many of the other key events of the year related to the consequences of immigrations seen not in 2011 but in the preceding few years, where new local breeding populations of a number of species might potentially have become established. The recently-identified colony of *Coenagrion scitulum* in Kent appeared to remain stable and there was to be proof of successful breeding by *Aeshna affinis* following the 2010 invasion, when small numbers of exuvia were discovered at Hadleigh Country Park, Essex, during June. Numbers of mature adults

seen later in the year were, however, low and give some concern as to the long-term viability of this colony. Numbers of *Lestes barbarus* seen at Cliffe, Kent, following breeding attempts also noted during 2010 were, however, higher and hopefully a stable colony may develop here." 12643. Raposeiro, P.M.; Cruz, A.M.; Hughes, S.J.; Costa, A.C. (2012): Azorean freshwater invertebrates: Status, threats and biogeographic notes. *Limnetica* 31(1): 13-22. (in English, with Spanish summary) ["This paper presents an updated catalogue of the freshwater invertebrates (including Odonata) of the Azores archipelago and reviews the published records to account for the current taxonomic status and changes in the nomenclature of the listed taxa. The number of freshwater invertebrate species that has been recorded in the Azores has risen sharply throughout the 20th century to 241 species based on field collections and the identification by several generations of local and foreign researchers. The freshwater fauna has been described as the following: (i) being "disharmonic", i.e., lacking taxa commonly found in continental freshwater systems such as the Plecoptera, and (ii) possessing a relatively high degree of endemism in selected groups. As expected, most recorded invertebrates are primarily of Palaearctic origin. However, endemic species make up 11 % of the freshwater invertebrate fauna, which emphasises the unique character of Azorean freshwater habitats, the importance of conservation measures and the need to continue the study of these systems." The island offers no suitable breeding habitat for the species, and this individual was presumably a wanderer. The nearest known site for this Irish rarity is some 24km away in County Kerry, though closer sites may yet be discovered. (A. Parr)"] Address: Regan, E., National Biodiversity Data Centre, WIT west campus, Waterford, Ireland

12645. Roberts, D. (2012): Responses of three species of mosquito larvae to the presence of predatory dragonfly and damselfly larvae. *Entomologia Experimentalis et Applicata* 145(1): 23-29. (in English) ["Although predators have been extensively used in the biological control of mosquito larvae, their efficacy will be reduced if the larvae are able to detect and respond to their presence.

This ability to detect and respond to the unseen presence of dragonfly or damselfly larvae was investigated for the larvae of three mosquito species (all Diptera: Culicidae) to see whether they either altered their rate of development or their feeding behaviour. The development of *Culex quinquefasciatus* Say and *Culiseta longiareolata* Macquart larvae was not affected by exudates from either predator, but *Culex sinaiticus* Kirkpatrick developed significantly slower when reared in the presence of a caged dragonfly larva and produced adults that were significantly smaller, indicating that they probably reduced feeding activity to make themselves less detectable to the predator. This only occurred when the dragonflies were fed in situ (in the presence of the mosquito larva) and not when removed for feeding, so that although this removed predator kairomones, other cues such as vibrations caused by movement of the predator may also be involved. In addition, the mosquito larvae responded to dragonfly larvae, but not to damselfly larvae. The depth of the water in which the mosquito larvae were reared had no effect on their response to the dragonfly. All three mosquito species significantly increased surface filter-feeding, when a predator was present in the water (compared with controls where no predator was present), at the expense of bottom scraping. In *Cx. sinaiticus* (but not the other two species), surface filter-feeding was greater when a dragonfly was present, compared with a damselfly. In the experimental conditions of one predator per 250 ml water, all three mosquito species were thus able to detect dragonfly and damselfly larvae (and distinguish between the two), but their response varied among species." 12652. Sinclair, K.A.; Xie, Q.; Mitchell, C.P.J. (2012): Methylmercury in water, sediment, and invertebrates in created wetlands of Rouge Park, Toronto, Canada. *Environmental Pollution* 171: 207-215. (in English) ["Thousands of hectares of wetlands are created annually because wetlands provide beneficial ecosystem services. Wetlands are also key sites for production of the bioaccumulative neurotoxin methylmercury (MeHg), but little is known about MeHg production in created systems. Here, we studied methylmercury in sediment, water, and invertebrates in created wetlands of various ages. Sediment MeHg reached 8 ng g⁻¹ in the newest wetland, which was significantly greater than in natural, control wetlands. This trend was mirrored in several invertebrate taxa, whose concentrations reached as high as 1.6 µg g⁻¹ in the newest wetland, above levels thought to affect reproduction in birds. The MeHg concentrations in created wetland invertebrate taxa generally decreased with increasing wetland age, possibly due to a combination of deeper anoxia and less organic matter accumulation in younger wetlands. A short-term management intervention and/or improved engineering design may be necessary to reduce the mercury-associated risk in newly created wetlands." (Authors) Most Odonata taxa in the newest constructed wetland had concentrations in excess of 1 µg g⁻¹, which is twice the current fish warning level for human consumption.] Address: Mitchell, C., Department of Physical and Environmental Science, University of Toronto Scarborough, 1265 Military Trail, Toronto, ON, Canada M1C 1A4. 12653. Stoks, R.; Swillen, I.; De Block, M. (2012): Behaviour and physiology shape the growth accelerations associated with predation risk, high temperatures and southern latitudes in *Ischnura damselfly* larvae. *Journal of Animal Ecology* 81(5): 1034-1040. (in English) ["(1) To better predict effects of climate change and predation risk on prey animals and ecosystems, we need studies documenting not only latitudinal patterns in growth rate but also growth plasticity to temperature and predation risk and the underlying proximate mechanisms: behaviour (food intake) and digestive physiology (growth efficiency). The mechanistic underpinnings of predator-induced growth increases remain especially poorly understood. (2) We reared larvae from replicated northern and southern populations of *Ischnura elegans* in a common garden experiment manipulating temperature and predation risk and quantified growth rate, food

intake and growth efficiency. (3) The predator-induced and temperature-induced growth accelerations were the same at both latitudes, despite considerably faster growth rates in the southern populations. While the higher growth rates in the southern populations and the high rearing temperature were driven by both an increased food intake and a higher growth efficiency, the higher growth rates under predation risk were completely driven by a higher growth efficiency, despite a lowered food intake. (4) The emerging pattern that higher growth rates associated with latitude, temperature and predation risk were all (partly or completely) mediated by a higher growth efficiency has two major implications. First, it indicates that energy allocation trade-offs and the associated physiological costs play a major role both in shaping large-scale geographic variation in growth rates and in shaping the extent and direction of growth rate plasticity. Secondly, it suggests that the efficiency of energy transfer in aquatic food chains, where damselfly larvae are important intermediate predators, will be higher in southern populations, at higher temperatures and under predation risk. This may eventually contribute to the lengthening of food chains under these conditions and highlights that the prey identity may determine the influence of predation risk on food chain length." (2012): Functional role of dragonfly legs before and after hatching: reorganization of coordinating interactions. *Rossiiskii fiziologicheskii zhurnal imeni I.M. Sechenova* 98(11): 1432-1440. (in Russian, with English summary) ["The characteristics of a structure-functional organization of leg apparatus were examined in the dragonfly *Aeshna grandis*: larvae of the final stadium, which legs perform a locomotion function and adults (imago) rising on a wing, which legs lose a locomotion function and are used mainly for catching a prey in the air. It has been demonstrated that legs of the imago practically do not differ from those of the larva either in shape or in proportion of segments of the leg and all changes in the functional role of legs of the imago are implemented due to modifications of mechanisms of limb muscle control and an appropriate reorganization or coordinating interactions. As it is proved by the obtained data, this reorganization concerns

mechanisms of the generation of motor commands as well as close coordination of the activity of wing and leg apparatus and some others. The above mentioned mechanisms are discussed." 12658. Tiple, A.D. (2012): Odonata (damselflies and dragonflies) fauna of Tadoba National Park and surroundings, Chandrapur, Maharashtra (Central India). *Bionano Frontier* 5: 149-152. ["A survey of fresh water body sites such as ponds, streams, fields grassland, and forests areas of Tadoba National Park, Chandrapur district area of 623 sq. km. from 2008 to 2010 to collect and record the Odonate faunal diversity and their status. A total of 64 species of Odonata belonging to 41 genera and 9 families viz. Gomphidae, Aeshnidae, Cordulidae, Libellulidae, Coenagrionidae, Platycenemididae, Protoneuridae, Chlorocyphidae and Lestidae were recorded. The checklist adds 24 new records for Tadoba National Park. The Odonates belong to the Libellulidae (33 species), followed by Coenagrionidae (14 species), Aeshnidae (5 species), Gomphidae, (3 species), Platycenemididae and Lestidae (3 species each), Protoneuridae (2), Macromiidae (1 species) and Chlorocyphidae (1 species). Of the total 64 species, 23 were abundant or very common, 24 were common, 12 rare and 5 very rarely in occurrence. The observations support the val-

ue of the National park (reserve forest) area in providing valuable resources for Odonata." (Author)] Address: Tiple, A.D., Dept of Zoology, Vidyabharti College, Seloo, Wardha 442104, Maharashtra, India. E-mail: ashishdtiple@yahoo.co.in

del tipo de hábitat, genética y selección sexual sobre la morfología alar en *Hetaerina* (Odonata: Calopterygidae). *Biológicas* 14(1): 53-60. (in Spanish, with English summary) ["Odonates exhibit distinctive behaviour among insects, particularly flight types associated with mating systems and therefore have been widely used as ecological and evolutionary models. As in other flying insects, the wing shape is under strong selective pressures because it determines not only flight efficiency but also their reproductive success. We evaluated the factors that shape the evolution of wing shape in three species of *Hetaerina*: *H. americana*, *H. cruentata* and *H. titia*, which have a wide geographical distribution in Mexico and can settle in different habitat types. These species also converge in a territorial lek mating system, where males gather in exhibition arenas where they perform ritualized flights, long-lasting and energy-demanding. We apply geometric morphometric techniques to independently evaluate the shape and size of individuals. Also genetic relationship analysis was made between populations of the three species using nuclear DNA sequences (ITS1, 5.8S and ITS2). Our results suggest that although there is convergence in the mating system and a genetic similarity within populations, the evolution of the forms of the wings in these three species is determined by the pressures associated to habitat similarity. Analysis of deformation show that the structural complexity and levels of competition for resources and sexual partners that are characteristic of tropical rain forests favour the evolution of wing designs that increase the maneuverability of individuals." 12669. Weissinger, R.H.; Perkins, D.W.; Dinger, E.C. (2012): Biodiversity, water chemistry, physical characteristics, and anthropogenic disturbance gradients of sandstone springs on the Colorado plateau. *Western North American Naturalist* 72(3): 393-406. (in English, with Spanish summary) ["Springs located on the Colorado Plateau are highly threatened and represent a small percentage of the landscape; yet they are disproportionately important to diverse native flora and fauna. The relationships between anthropogenic disturbance, aquatic macroinvertebrate species composition, and environmental variables at these springs have received little study. We selectively visited 40 sandstone springs in southeastern Utah and southwestern Colorado to span a range of impacts. We classified the springs into impact categories based on a spring impact score, and we measured biodiversity (aquatic macroinvertebrates), water chemistry (nutrients, dissolved O₂, pH, specific conductivity, temperature, turbidity, coliform bacteria [*Escherichia coli*]), physical characters (solar radiation, substrate, vegetation cover, bank stability, discharge), and presence of anthropogenic disturbance. *Escherichia coli* abundance was higher in high impact categories, and turbidity increased with increasing disturbance. No differences in total N, total P, specific conductivity, flow, dissolved O₂, pH, or substrate were found among the

impact categories. Vegetation cover was higher in low impact categories than in moderate and high impact categories, while potential annual and growing-season solar radiation was lower in low impact categories than in high impact categories. Global and subsequent multiple response permutation procedure (MRPP) comparisons suggested strong differences in aquatic macroinvertebrates between low and high impact springs and no difference at moderate impact springs. Mean taxa richness (α -diversity), total taxa richness (γ -diversity), and percent of taxa richness composed of shredders peaked at moderate disturbance levels. The percentage of non-insect taxa richness was reduced in high impact categories, and Odonata were higher in low impact categories than in high impact categories. All high impact springs had both livestock use and vehicle use (roads or off-highway vehicles), and our data suggest that disturbances caused by one or both of these uses alter the aquatic macroinvertebrate assemblage. We suggest that disturbance may increase macroinvertebrate richness, where a mix of tolerant and intolerant species co-occur, until macroinvertebrate richness reaches a threshold; after surpassing this threshold, macroinvertebrate diversity decreases." 12670. Yapó, M.L.; Atse, B.C.; Kouassi, P. (2012): Inventaire des insectes aquatiques des étangs de piscicoles au sud de la Côte d'Ivoire. *Journal of Applied Biosciences* 58: 4208-4222. (in French, with English summary) ["Objective: The main objective of this study was to determine the diversity of aquatic insect species in five fish farms ponds in the Southern Ivory Coast. It contributes to our knowledge of this ecosystem, which is not well known. Methods and Results: The samples were taken using a hand net and a Van veen grab. Specimens were identified to the lowest possible taxonomic level, by use of systematic and classification keys (Dejoux et al., 1981; Tachet et al., 2003; de Moor et al., 2003 a; 2003 b). Seventy-nine taxa belonging to 8 orders and 35 families were identified. Hemiptera and Coleoptera were the major insect taxa collected (with 21 taxa each). They were followed by Diptera (15 taxa), Odonata (11 taxa), Ephemeroptera (5 taxa) and by Trichoptera (4 taxa). Megaloptera and Lepidoptera (1 taxon each) were the less diversified. Conclusion and application: Eight new taxa for the Ivory Coast were harvested. Most of these taxa are cosmopolitan. They were found in most of the stations. This is a contribution to the list of aquatic insects for the scientific community." 12673. Abbott, J. (2013): Morph-specific and sex-specific temperature effects on morphology colour polymorphic damselfly *Ichnura elegans*. Animal Biology 63(2): 149-167. (in English) ["Colour polymorphic species with extensive ranges often exhibit large-scale geographic patterns of morph frequency variation. Because colour polymorphism is associated with correlated differences in multiple traits, such as thermal performance, a likely proximate explanation for such patterns is morph-specific responses to temperature variation. The colour polymorphic *Ichnura elegans* exhibits large-scale geographic variation in morph frequencies, but the possibility that temperature is a proximate explanation for the latitudinal cline in morph frequencies has only ever been tested within a single developmental stage (egg survival and hatching time), where no difference between the morphs was found. I therefore carried out a temperature manipulation on larvae of *I. elegans* which I raised to maturity in the laboratory. I found that individuals exhibited incomplete compensatory growth after being exposed to cold temperatures, and that individuals which did not emerge successfully and those that experienced cold temperatures had more juvenile morphology in the last instar. In addition, there were sex-specific and morph-specific effects of temper-

ature on adult morphology, such that sexual size dimorphism was increased when individuals experienced warm temperatures throughout the larval stage, and that cold temperatures tended to result in larger size of androchromes and their offspring compared to the other morphs. These results are generally consistent with the large-scale geographic variation in morph frequencies found in this species." (Author)] Address: Abbott, Jessica, 1. 12674. Abed, R.M.M.; Barry, M.J.; Al Kindi, S.; Golubic, S. (2013): Structure and cyanobacterial species composition of microbial mats in an Arabian Desert stream. African Journal of Microbiology Research 7(15): 1434-1442. (in English) ["Microbial mats are often the dominant benthic biotype in desert streams, however information on such mats is very scarce. We investigated the gross morphology of microbial mats and their cyanobacterial species composition in a perennially flowing wadi in Northern Oman, in relation to current flow and other biotic and abiotic variables. Physical and chemical parameters at the six sites were generally similar with low concentrations of soluble phosphorus and nitrogen; however, flow rates varied greatly with the highest velocity being 50 cm/s. The mats varied greatly in their gross morphology with the four sites with the highest current velocities forming low laminated structures attached to cobbles, and the two sites with minimal or no flow forming complex three-dimensional structures or free floating balls 1 to 3 cm in diameter. The concentration of chlorophyll a varied between 2.6 (± 0.02) and 1.4 (± 0.11) mg chlorophyll a g⁻¹ mat fresh weight, with the highest concentration detected in the free floating balls. 21 cyanobacterial morphotypes belonging to 14 genera ... were identified with *Calothrix* and *Leptolyngbya* spp. as the most abundant. Cluster analysis of the cyanobacterial species composition showed that mats could have very different morphologies despite similar species compositions suggesting a high degree of plasticity of mat form. We conclude that microbial mats are important elements in Wadi ecosystems and have great variety of structure and community composition." (Authors) Odonata are treated as morphospecies.] Address: Abed, R.M.M., Biology Dept, College of Science, Sultan Qaboos Univ., P.O. Box: 36, postal code 123, Al Khoud, Sultanate of Oman. 12675. Al-Shami, S.; Heino, J.; Che Salmah, M.R.; Hassan, A.A.; Suhaila, A.H.; Madrus, M.R. (2013): Drivers of beta diversity of macroinvertebrate communities in tropical forest streams. Freshwater Biology 58(6): 1126-1137. (in English) ["(1.) There has recently been increasing interest in patterns of beta diversity but we still lack a comprehensive understanding of these patterns in various regions (e.g. the tropics), ecosystems (e.g. streams) and organism groups (e.g. invertebrates). (2.) Our aim was to investigate the patterns of beta diversity of stream ma-

croinvertebrates in relation to key environmental (i.e. stream size, pH and habitat degradation) and geographical variables (i.e. latitude, longitude, altitude) in a tropical region. We surveyed a total of 8–10 riffle sites in each of 34 streams (altogether 337 riffle sites were sampled) in Peninsular Malaysia to examine variation in macroinvertebrate community composition at within-stream and among-stream scales. (3.) Based on test of homogeneity of dispersion, we found that the streams studied differed significantly in within-stream variation in community composition (i.e. among-site variation of within stream beta diversity). The patterns were similar based on Bray–Curtis coefficient on abundance data, Sorensen coefficient on presence–absence data and Simpson coefficient on presence–absence data. We also found that within-stream beta diversity was significantly related to stream size, pH and latitude, with each of these variables individually accounting for around 20% of the variation in beta diversity in simple regressions, while the total variation explained by the three significant variables amounted to around 50% in multiple regressions. By contrast, habitat degradation, longitude and altitude were not significantly related to beta diversity. We also found that the factor drainage basin accounted for much of the variation in beta diversity in general linear models, suppressing the effects of environmental variables. (4.) We concluded that within-stream beta diversity is mainly related to a combination of the identity of a drainage basin and stream environmental factors. Our findings provide important background for stream environmental assessment and conservation planning by emphasising that (i) macroinvertebrate communities within streams are not homogeneous, but show considerable beta diversity, (ii) streams differ in their degree of within-stream beta diversity, (iii) stream size and water pH should be considered in applied contexts related to within-stream beta diversity and (iv) historical effects may be different in different drainage basins and may affect present-day patterns of within-stream beta diversity. ... However, dragonflies, fish and frogs showed negative responses to latitude, whereas caddisflies and salamanders showed no relationships with latitudinal gradients. ..." 12676. Alvarez, H.A.; Serrano-Meneses, M.A.; Reyes-Márquez, I.; Jiménez-Cortés, J.G.; Córdoba-Aguilar, A. (2013): Allometry of a sexual trait in relation to diet experience and alternative mating tactics in two rubyspot damselflies (Calopterygidae: Hetaerina). *Biological Journal of the Linnean Society* 108(3): 521-533. (in English) ["Several arguments have been put forward to explain how sexual selection drives the evolution of sexual trait allometry, especially hyperallometry. The 'positive allometry theory' suggests that hyperallometry is a rule in all-secondary sexual traits, whereas the 'display hypothesis' suggests that only males in good condition will exhibit hyperallometric sexual display traits. In the present study, we investigated: (1) the condition-dependence nature (by

using two diet treatments that varied in the amount of food provided to the larvae) of a sexually selected trait (wing pigmentation; WP) in recently-emerged adults of *Hetaerina americana*, and (2) the scaling relationship between WP and body size (wing and body length) in *H. americana* and *H. vulnerata*, according to alternative reproductive tactics (ARTs; territorial and nonterritorial males). First, we found support that indicated that diet positively affected WP length, although there was no significant WP allometric pattern in relation to diet regimes. Second, WP was hyperallometric in both *Hetaerina* species. WP size was similar between ARTs and, in *H. americana* (but not *H. vulnerata*), nonterritorial males showed steeper slopes than territorial males when wing length was used. The results obtained support the notion that sexual traits are hyperallometric, although there is no clear pattern in relation to ARTs." 12679. Anonymus (2013): Keynsham landmark appears on new book cover. *The Week in Bitton*, Corston,

Downend, Emersons Green, Hanham, Keynsham, Kingswood, Longwell Green, Mangotsfield, Oldland Common, Pucklechurch, Salford, Staple Hill, Stockwood, Warmley, Whitchurch, Wick & Willsbridge • Thursday 8 August 2013: 29. (in English) [Verbatim: "Keynsham landmark appears on new book cover The chimney of Cadbury's former power house appears in a painting on the front cover of a new book published by the Bristol Regional Environmental Records Centre (BRERC). Called Dragonflies and Damselflies of the Bristol Region, it is the fourth in a series of books that document local wildlife. Why put Keynsham on the front cover? The stretch of the River Avon along with the River Chew and other water-courses are particularly good sites for Odonata (an order of carnivorous insects that includes dragonflies and damselflies). Specialist species include the Scarce Chaser, that is often seen now but was not discovered in the Bristol area until 1986, and the delicate White-legged Damselfly that needs good, clean water to complete its life cycle. John Aldridge, from Keynsham and a volunteer for the BRERC, said: "A key message that should be taken forward is that the redevelopment at the former Cadbury site must be sympathetic to dragonflies and damselflies; this should not be too difficult as the flood plain is impossible to build on anyway. However, steps should be taken to ensure that the habitat is not damaged when work takes place." The hardback book contains many photographs, maps and text describing each species. It costs £19.50 and is available from BRERC. For more information call 0117 934 9833 or visit www.brerc.org.uk] Address: <http://theweekin.co.uk/wp-content/uploads/2013/08/Issue0281.pdf>

12680. Anonymus (2013): Beauties from the above skies. Journal - Parc National du Mont-Orford 2013-2014: 4 (in English) [Verbatim: The parc national du Mont-Orford team is very pleased with new discoveries made over time in the park that allow the team to pursue the mission of conservation, protection and development of our heritage. During the 2012 summer season, based on an exploratory survey of Odonata, a preliminary list of 26 species was drawn up in 3 field visits in the Lac-Stukely sector. This first summary-inventory showed a species not yet mentioned in the Estrie region: *Somatochlora tenebrosa*, a dragonfly rarely observed in Quebec. Another wonderful discovery was *Perithemis tenera*. This latter species was mentioned for the first time in Quebec in 2007. This is the second mention of this species for the Estrie region. ...] Address: <http://www.sepaq.com/dotAsset/35697.pdf>

12681. Bagworth, T. (2013): Reports from coastal stations - 2012: Gibraltar Point NNR, Lincolnshire. *Atropos* 48: 67-68. (in English) [UK, *Sympetrum fonscolombii*, *Calopteryx splendens*, *Aeshna grandis*] Address: not stated

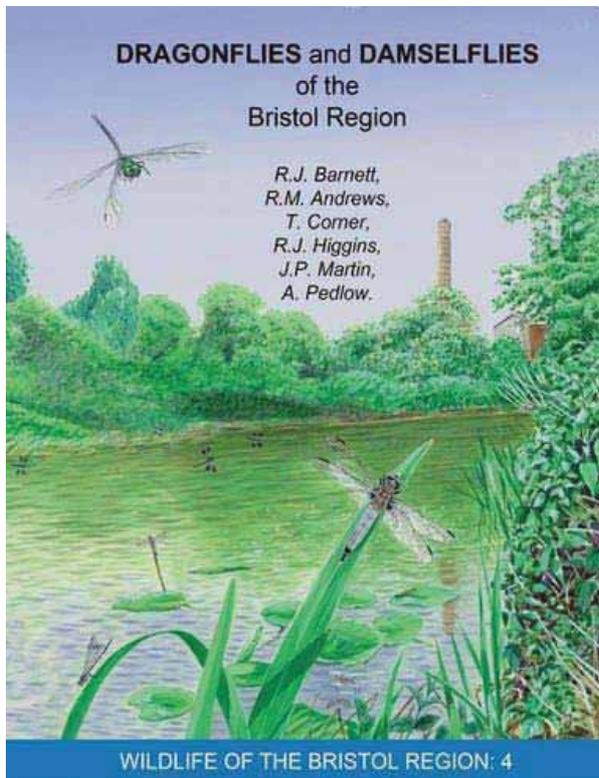

12682. Baker, R.A. (2013): Cynthia Evelyn Longfield (1896-1991) - the Irish connection and collections. *J. Br.*

Dragonfly Society 29(1): 23-39. (in English) ["Cynthia E. Longfield (1896-1991), traveller, explorer and dragonfly expert, was a remarkable woman in many ways. Internationally known as an odonatologist, she travelled throughout the five continents, most importantly sailing with other scientists to the South Pacific on the St. George expedition in 1924. She taught herself natural history at home and had wide interests including ornithology and botany. She always regarded herself as Irish, with her family estate in County Cork, to which she was to return on 'retirement' in 1957. She deposited her library and scientific papers at the Royal Irish Academy and a collection of her Odonata was donated to the Natural History Museum in Dublin. She worked for many years at the Natural History Museum in London as a volunteer, where she eventually specialized on African species of dragonflies and was made an Honorary Associate in 1948. Author or co-author of several books on dragonflies, she was elected the first Honorary member of the British Dragonfly Society and is remembered with affection and high regard by those who knew her." (Author)] Address: Baker, R.A., The Bungalow, St Johns Park, Menston, Ilkley, LS29 6ES, UK.

12683. Baker, R.A. (2013): Malcolm Burr (1878-1954) and Robert McLachlan (1837-1904), British workers on the Balkan fauna in 1898, with notes on the Odonata collected and identified. *Notul. odonatol.* 8(1): 1-3. (in English) ["2 British naturalists, a young student from Oxford University and an older expert on Odonata, collaborated on material from SE Europe in 1898. The first of these, M. Burr, collected the material while on a tour of the Balkans, Romania and Hungary in that year and R. McLachlan identified the specimens and published the work in the same year. The species list provides some of the earliest information on the Odon. from this part of the world, and is updated with additional notes." 12684. Barnett, R.; Andrews, R.; Corner, T.; Higgins, R.J.; Martin, J.P.; Pedlow, A. (2013): Dragonflies and Damselflies of the Bristol Region. Bristol Regional Environmental Records Centre (BRERC): 214 pp. (in English) ["This book presents the culmination of thousands of sightings by both professional ecologists, biologists and amateur naturalists, brought together by BRERC to enable the status of our species in the region to be assessed. Wonderful colour photographs accompany the distribution maps which reveal where the different species occur around Bristol, Bath and the surrounding countryside. Expert authors analyse the threats and opportunities to the dragonfly populations; they have been subject to great changes over the last two hundred years, and will no doubt continue to change into the future. For example, the restoration of boating on the Kennet & Avon Canal has reduced the numbers of dragonflies, but at the same time, new species such as

Erythromma viridulum are colonising our area." (Publisher, <http://www.brerc.org.uk/services/publications.htm>) Address: BRERC: Bristol Central Library, College Green, Bristol, BS1 5TL, UK

12685. Bashar, K.; Reza, M.S. (2013): Dragonflies & damselflies in Bangladesh. Faunistic study of Odonata. Lambert Academic Publishing AG & Co. KG: 128 pp. (in English) [inv, "A faunistic study of Odonata was carried out in Bangladesh. A total of forty eight (48) species of Odonates belonging to thirty one genera, eight families and two sub-orders were recorded from the sampling areas. Among them, twenty five (25) species of Dragonflies under three families and twenty three (23) species of Damselflies under five families were recorded. The highest and lowest numbers of Odonata species were observed in Jahangirnagar university campus (31 species) and Bandarban (23 species) respectively. The diversity of Odonata species was peak during the post-monsoon season (45 species). Highest numbers of species were identified in Libellulidae family whereas lowest numbers were observed in Gomphidae, Lestidae, Calopterygidae and Protoneuridae family. Rhyothemis variegata was the dominant species (13.03%) of dragonfly but in damselfly, Agriocnemis pygmaea was the abundant species (13.97%) among all collected Odonata." (Authors)]

12686. Batty, P.M. (2013): The Brilliant Emerald Somatochlora metallica (Vander Linden) in Scotland, with particular reference to the Argyll sites and to larval habitat. J. Br. Dragonfly Society 29(1): 55-64. (in English) ["Since 2000, new S. metallica sites have been found in the Loch a' Chrion-doire area in Argyll. The sites are de-

scribed. The apparent range expansion is likely to be the result of increased recording in the area. Larvae were first found in Scotland in 2000. Their habitat is discussed. They are found in water 20-40 cm deep, underneath heather or sphagnum banks amongst sparse fibrous detritus. The banks are at water level and overhanging or undercut for between 30 and 150 cm. Larvae have also been found under stones in Slovenia." (Author)] Address: Batty, Pat M., Kirnan Farm, Kilmichael Gien, Lochgilphead, Argyll PA31 8QL, UK

(in French) [After 150 years of absence, G. stylurus was discovered at 27-VII-2007 in the region Rhône-Alpes, France.] Address: Bazin, N., Chemin d'Aurelle, le village, 07700 Bidon, France

12688. Bechly, G.; Poinar, G. (2013): Burmaphlebia reifi gen. et sp. nov., the first anisozygopteran damsel-dragonfly (Odonata: Epiophlebioptera: Burmaphlebiidae fam. nov.) from Early Cretaceous Burmese amber. Historical Biology: An International Journal of Paleobiology 25(2): 233-237. (in English) ["A new family, genus and species of damselfly, Burmaphlebia reifi gen. et sp. nov. (Burmaphlebiidae fam. nov.), is described as the second fossil odonate from Early Cretaceous Burmese amber. Its phylogenetic position is discussed and the fossil is attributed to a new family at the base of the anisozygopteran grade, probably closely related to the Recent relict group Epiophlebiidae. It is the first record of the 'anisozygopteran' grade from amber and the smallest known representative of this group." (Authors)] Address: Bechly, G., Staatliches Museum für Naturkunde, Abt. Paläontologie, Rosenstein 1, D-70191 Stuttgart, Germany. E-mail: guenter.bechly@smns-bw.de

12689. Blanke, A.; Greve, C.; Mokso, R.; Beckmann, F.; Misof, B. (2013): An updated phylogeny of Anisoptera including formal convergence analysis of morphological characters. Systematic Entomology 38(3): 474-490. (in English) ["Family interrelationships among Anisoptera (dragonflies) are unresolved. Molecular markers applied thus far have not been particularly useful for resolving relationships at the family level. Previous morphological studies have depended heavily on characters of wing venation and articulation which are believed to display considerable degrees of homoplasy due to adaptations to different flight modes. Here, we present a comprehensive anatomical dataset of the head morphology of Anisoptera focusing on muscle organization and endoskeletal features covering nearly all families. The characters are illustrated in detail and incorporated into an updated morphological character matrix covering all parts of the dragonfly body. Phylogenetic analysis recovers all families as monophyletic clades except Corduliidae, Gomphidae as sister group to all remaining Anisoptera, and Austropetaliidae as sister group to Aeshnidae (=Aeshnoidea). The position of Petaluridae and

Aeshnoidea to each other could not be resolved. Libelluloidea is monophyletic with Neopetalia and Cordulegastridae as first splits. Chlorogomphidae is sister to monophyletic [Synthemistidae + ('Corduliidae + Libellulidae)]. In addition, we applied a recently published formal approach to detect concerted convergence in morphological data matrices and uncover possible homoplasies. Analyses show that especially head and thorax characters may harbour homoplasies. After exclusion of possible homoplastic characters, Gomphidae is corroborated as sister group to all remaining Anisoptera." 12690. Blinova, I.V. (2013): A brief review of studies of insects and spiders in Murmansk region since 1900. Herald of the Kola Science Centre of the Russian Academy of Sciences 2013(1): 58-65. (in Russian, with English summary) ["Faunistic studies of insects and spiders on the Kola Peninsula have always been sporadic and were mostly conducted by visiting scientists. These studies were begun mostly by Finnish workers and were pursued actively between 1840 and 1934. Since 1930, arthropod exploration has been undertaken by some scientists at the Kola Science Centre, at regional Nature Reserves and by visiting zoologists as well. The number of arachnid and insect species in the region is c.4000, which is only a half of the corresponding number in Karelia. At least 400 species can be described as rare ones. The regional distribution of all arthropods is insufficiently known. The better explored areas include the Barents and White Sea coasts and the Khibiny Mountains. Soil invertebrates and amphibiotic & aquatic insects are among the most thoroughly studied. Invertebrate-plant interactions in the region's ecosystems, including life cycles and consortia, require for further study." (Author) The extensive list (n = 144) of regional publication also includes odonatological titles.] Address: Blinova, Ilona V., Head. Lab. population biology of plants. E-mail: ilbli@yahoo.com

12691. Booth, A.J.; Kadye, W.T.; Vu, T.; Wright, M. (2013): Rapid colonisation of artificial substrates by macroinvertebrates in a South African lentic environment. African Journal of Aquatic Science 38(2): 175-183. (in English) ["Macroinvertebrate colonisation patterns on artificial substrates were investigated in a small reservoir in the Eastern Cape, South Africa. Semi-closed 1 000 cm³ polythene netting cages filled with either brick, gravel, shredded plastic, or equal proportions of these three materials, were suspended above the benthic substrate. Gravel was preferred by caenid mayflies and chironomids, plastic by odonates, and brick by potamonautid crabs. Colonisation rates were rapid, with half the substrate-specific asymptotic diversity and richness being attained within a week. Overall, taxon richness on the substrates was similar to that in samples

collected with a sweep net, but diversity was almost half. Taxon richness was found to be highest on the gravel and brick substrates, and lowest on plastic. By contrast, macroinvertebrate communities on the plastic and mixed substrates were the most diverse and the most even. All substrates, with the exception of gravel, showed that the number of odonates was significantly positively correlated with the number of potential prey that included chironomid midges, caenid mayflies and caddisfly larvae. It is recommended that plastic be used to construct artificial substrates if a high macroinvertebrate diversity is required for monitoring purposes within lentic environments." 12695. Brochard, C.; van der Ploeg, E. (2013): Searching for exuviae of endemic Odonata species in Greece. Brachytron 15(2): 83-101. (in English, with Dutch summary) ["During two field trips to Greece in 2012, the first to Corfu in May 2012 and the second to Crete in June 2012, 37 species of dragonflies were observed. On Corfu, many larvae and exuviae of Pyrrhosoma elisabethae were found, both unknown to science. On Crete

a fair number of exuviae of *Coenagrion intermedium* and *Boyeria cretensis* were collected. *C. scitulum* and *Erythromma lindenii* are reported for the first time for Corfu and *Lindenia tetraphylla* was a new species of the dragonfly fauna of Crete. Also on Crete, *C. scitulum* is rediscovered at two localities after an apparent absence of more than 100 years. The identification of *Gomphus schneiderii* and the use of searching for exuviae are discussed near the larval habitat." (Authors)] Address: Brochard, C., Marsstraat 77, 9742EL Groningen, The Netherlands. E-mail: info@cbrochard.com

12696. Brochard, C.; van der Ploeg, E. (2013): A first acquaintance with the larvae of *Ceriagrion georgifreyi* and *Pyrrhosoma elisabethae*. *Brachytron* 15(2): 133-139. (in Dutch, with English summary) ["The larva of *Ceriagrion georgifreyi* was found for the first time during a field trip in South West Turkey (May 2011), while searching for exuviae for the project of creating a photographic guide of exuviae of European dragonflies. Also larvae of *Pyrrhosoma elisabethae* were found for the first time during a field trip on the island Corfu, Greece, for the same project in May 2012. Both species are very rare in Europe and both have a more common look-alike: *Ceriagrion tenellum* and *Pyrrhosoma nymphula*. The larvae of *Ceriagrion georgifreyi* and *Pyrrhosoma elisabethae* have been captured, photographed in an aquarium and then released again into their habitat. The habitat that the larvae use is described succinctly. Comparison for each species with its common look-alike shows that they have a very similar morphology. To identify them, many measurements of the exuviae collected during the field trips will be made. The results will be published in the key of the photographic guide of the exuviae of European dragonflies." (Authors)] Address: Brochard, C., Marsstraat 77, 9742EL Groningen, The Netherlands. E-mail: info@cbrochard.com

12697. Brown, A. (2013): Variation in the flexibility of potential anti-predator behaviours among larval damselflies. MSc thesis, Department of Integrative Biology, The University of Guelph, Ontario, Canada: VII + 53 pp. (in English) ["Heterogeneous environments play an important role in the evolution of traits when selection is diversifying between different conditions. One response is the capacity of individuals to beneficially adjust their phenotype to local conditions, such as different predators. In larval *Enallagma* damselflies, diversifying selection from predatory dragonfly larvae or predatory fish favours opposing traits, respectively high or low levels of activity, and so appears to drive the adaptive divergence of anti-predator specialists. However, little work has addressed: i) if anti-predator generalist species exist; ii) if anti-predator generalist species express adaptive flexible behaviour; iii) if adaptive flexible behaviour is influenced by prior experience with predators. I compared individual larval behaviour in the presence of fish, dragonfly larvae, or no predators, in four *Enallagma* species groups from ponds with and without fish preda-

tors. Ecological distributions suggest variation in degree of anti-predator generalization, and this was associated with increased responsiveness to predator treatment in the most likely ecological generalist. Responses to predators varied across different behaviours and sometimes were shaped by prior predation experience. Thus, a variety of adaptive strategies may have evolved to cope with heterogeneity in predation risk in larval damselflies." (Author)] Address: not stated

12698. Buczyński, P.; Ciechanowski, M.; Karasek, T. (2013): A peat bog in Martenki (the East-Pomeranian Lake District) – an interesting refugium of aquatic insect fauna. *Chrońmy Przyr. Ojcz.* 69(4): 315-321. (in Polish, with English summary) ["The peat bog in Martenki (the East-Pomeranian Lake District, northern Poland, 54°25'N, 18°20'E) is located at the bottom of the glacial drainage channel. It covers 2.29 ha. Transition mires and quaking bogs with *Sphagnum* spp., *Vaccinium oxycoccus*, *Drosera rotundifolia*, *Typha latifolia* and *Menyanthes trifoliata* are dominant vegetation. About half of the bog is covered with post-excavation peat pits filled with dystrophic waters, overgrown by *Potamogeton natans*. The site is a refugium for an interesting assemblage of aquatic insects, rich in tyrphobionts and tyrphophiles, thus requires legal protection. During preliminary hydrobiological studies, 24 species were recorded, belonging to Odonata (7), Heteroptera (5), Coleoptera (10), Trichoptera (1) and Lepidoptera (1)." 12700. Bush, A.; Theischinger, G.; Nipperess, D.; Turak, E.; Hughes, L. (2013): Dragonflies: climate canaries for river management. *Diversity and Distributions* 19(1): 86-97. (in English) ["Aim: Freshwater ecosystems are highly vulnerable to the effects of climate change. Where long-term datasets are available, shifts in species phenology, species distributions and community structure consistent with a climate change signal have already been observed. Identifying trends across the wider landscape, to guide management in response to

this threat, is limited by the resolution of sampling. Standard biomonitoring of macroinvertebrates for water-quality purposes is currently not well suited to the detection of climate change effects, and there are risks that substantial changes will occur before a management response can be made. This study investigated whether dragonflies, frequently recommended as general indicators of ecological health, are also suitable as indicators of climate change. Location: Data were analysed from standard bio-assessment monitoring at over 850 sites spanning a 9° latitudinal gradient in eastern Australia. Methods: Using variation partitioning, we analysed the proportion of assemblage turnover in dragonflies and other macroinvertebrate assemblages that can be explained by climate and other environmental drivers. We also tested whether the utility of dragonflies as indicators improved at higher taxonomic resolution and whether the turnover of dragonfly assemblages was congruent with that of other groups. Results: Climate explained three times as much variation in turnover of dragonfly species than dragonfly and other macroinvertebrate assemblages at family level. The dissimilarity of dragonflies and varying turnover in each macroinvertebrate assemblage meant surrogacy amongst groups were low. Main conclusions: On the basis of the influence of climate on turnover of macroinvertebrate assemblages, dragonfly species distribution appears highly sensitive to climatic factors, making this taxon a potential useful indicator of climate change responses. However, the low surrogacy amongst assemblages also suggests that a shift in the focus of conservation management from specific taxa to the functional composition of assemblages across a diverse range of habitats is needed." (2013): Thermoregulation and microhabitat choice in *Erythrodiplax latimaculata* Ris males (Anisoptera: Libellulidae). *Odonatologica* 42(2): 97-108. (in English) ["It was assessed whether solar incidence affects the spa-

tial distribution, microhabitat choice, territorial defense, time spent in behavioural categories, activity patterns, and abundance of *E. latimaculata*. The study was conducted in a semi-lotic area in the Cerrado in Aparecida de Goiânia, Goiás, Brazil, using the scan procedure with a fixed area, sampling 3 environments, viz. shade, partial shade, and an area with constant solar incidence. There was a higher abundance and activity concentration of this species. in areas with higher solar incidence than in other areas ($H = 19.180$; $P < 0.001$). This can be explained by the ecophysiological requirements of *E. latimaculata*, in which individuals need to be exposed to solar radiation to warm their bodies, allowing the beginning of their activities. Diurnal variation did not affect the behavioural pattern, indicating that individuals are ectothermic and need direct solar incidence on their bodies ($H = 12.193$; $P = 0.160$). They spend most of the time perching with wings dropped (41.448 ± 21.781 ; mean \pm SD) and displaying a territorial behaviour, making defense flights around the perch. In lentic water bodies females seem only to mate and oviposit (exophytic, directly into the water)." 12705. Cayasan, R.D.; Limitares, D.E.; Gomid, J.V.S.; Nuñez, O.M.; Villanueva, R.J.T. (2013): Species richness of Odonata in selected freshwater systems in Zamboanga del Sur, Philippines. *Aquaculture, Aquarium, Conservation & Legislation. International Journal of the Bioflux Society* 6(4): 378-393. (in English) ["In this study, the species richness and relative abundance of Odonata were determined in 12 sampling sites in Zamboanga del Sur. Field work was conducted in August-December, 2012 using the random sampling method. Thirty-six species belonging to 10 families were docu-

mented of which 16 (44%) species are Philippine endemic. High species richness was recorded in Cabilinan Stream which is considered to be the most undisturbed site in the 12 sampling sites. Species richness was also considerably high in eight sampling sites despite habitat modification and water pollution from agricultural run-offs. The presence of Oriental species which are indicators of degraded environments suggests that the streams are disturbed. However, the presence of some endemic species indicates that these endemic fauna can thrive in disturbed habitats." 12706. Chahl, J; Dorrington, G.; Mizutani, A. (2013): The dragonfly flight envelope and its application to micro UAV research and development. 15th Australian International Aerospace Congress. Melbourne, Vic.: Australian International Aerospace Congress, 2013: 278-287. (in English) ["In this paper we present quantitative analysis of three dimensional trajectories of dragonflies under free flight conditions. The trajectories were captured while male insects were engaged in their normal behaviour of combat to protect oviposition sites along a stream. For the first time we have unambiguous measurements of speed, acceleration and turn rate of large dragonflies and the means by which comparative studies can be done against other species and in different environments. Using physical scaling laws we propose means by which this data set can be used to provide a comparison for larger flapping wing UAV concepts. Our ultimate goal is to provide a robust standard against which flapping wing aircraft performance can be compared so that appropriate evolutionary pressure can also be applied to technological developments, thus freeing resources for the truly viable designs." (Authors) *Hemianax papuensis* was studied, and peak speeds of 6.0 m/s (21.6 km/h) are observed.] Address: Chahl, J., Defence and Systems Institute, University of South Australia, Mawson Lakes, South Australia, 5095, Australia. 12708. Cho, J.-Y.; Kim, G.; Kim, S.; Lee, H. (2013): Replication of surface nano-structure of the wing of dragonfly (*Pantala flavescens*) using nano-molding and UV nanoimprint lithography. *Electronic Materials Letters* 9(4): 523-526. (in English) ["The hydrophobicity of a dragonfly's wing originates from the naturally occurring nano-structure on its surface. The nano-structure on a dragonfly's wing consists of an array of nano-sized pil-

lars, 100 nm in diameter. We re-create this hydrophobicity on various substrates, such as Si, glass, curved acrylic polymer, and flexible PET film, by replicating the nano-structure using UV curable nano-imprint lithography (NIL) and PDMS molding. The success of the nano-structure duplication was confirmed using scanning electron microscopy (SEM). The hydrophobicity was measured by water-based contact angle measurements. The water contact angle of the replica made of UV cured polymer was $135^\circ \pm 2^\circ$, which was slightly lower than that of the original dragonfly's wing ($145^\circ \pm 2^\circ$), but much higher than that of the UV cured polymer surface without any nano-sized pillars (80°). The hydrophobicity was further improved by applying a coating of Teflon-like material." (2013): High global diversity of cycloviruses amongst dragonflies. *Journal of general virology* 94(8): 1827-1840. (in English) ["Members of the *Circoviridae* family, specifically the *Circovirus* genus, were thought to infect only vertebrates; however, members of a sister group under the same family, the proposed *Cyclovirus* genus, have been detected recently in insects. In an effort to explore the diversity of cycloviruses and better understand the evolution of these novel single stranded DNA (ssDNA) viruses, here we present five cycloviruses isolated from three dragonfly species (*Orthetrum sabina*, *Xanthocnemis zealandica* and *Rhionaeschna multicolour*) collected in Australia, New Zealand and the United States of America. The genomes of these five viruses share similar genome structure to other cycloviruses, with a circu-

lar ~1.7 kb genome and two major bidirectionally transcribed open reading frames (ORFs). The genomic sequence data gathered during this study were combined with all cyclovirus genomes available in public databases to identify conserved motifs and regulatory elements in the intergenic regions, as well as determine diversity and recombinant regions within their genomes. The genomes reported here represent four different cyclovirus species, three of which are novel. Our results confirm that cycloviruses circulate widely in winged insect populations; in eight different cyclovirus species identified in dragonflies to date, some of these exhibit a broad geographical distribution. Recombination analysis revealed both intra- and inter-species recombination events among cycloviruses, including genomes recovered from disparate sources (e.g., goat meat and human faeces). Similar to other well-characterised circular ssDNA viruses, recombination may play an important role in cyclovirus evolution." 12719. Dolný, A.; Mižicová, H.; Harabiš, F. (2013): Natal philopatry in four European species of dragonflies (Odonata: *Sympetrinae*) and possible implications for conservation management. *J. Insect Conserv.* 17(4): 821-829. (in English) ["In Europe, the species *Sympetrum depressiusculum* is classified as vulnerable with a high risk of extinction in the wild. It is a habitat specialist, the presumed main reason for its vulnerability is the destruction of its natural habitats. Other causes of its general extinction are unknown. Published information regarding dispersal rate and philopatry is not available, although these are evolutionary strategies that can play key roles in susceptibility to environmental change. We compared the rate of philopatry in *S. depressiusculum* and three other related, abundant but not endangered species of the same genus (*S. sanguineum*, *S. striolatum*, *S. vulgatum*). We collected data in a very isolated site in the Czech Republic, more than 100 km distant from another known population of the species. Using exuviae collection (total of 6,157 exuviae) and capture-mark-recapture (total of 2,188 adults marked) methods, we acquired data allowing us to compare the numbers of emerged individuals and adults returning to the ma-

ternal site. We found a difference of nearly an order of magnitude between the philopatry of *S. depressiusculum* and the three other species. While in *S. depressiusculum* philopatry was almost 100 %, in the other species it was 10 %. We suggest the high rate of philopatry can influence the vulnerability of *S. depressiusculum* in landscape altered by humans. Strict protection of the natal sites is very important for preserving species having this evolutionary strategy, and reintroductions and translocations should also be undertaken to reduce the extinction risk of this endangered species." (2013): Diversity in Mediterranean farm ponds: trade-offs and synergies between irrigation modernisation and biodiversity conservation. *Freshwater Biology* 58(1): 63-78. (in English) ["(1.) Agricultural intensification has caused dramatic biodiversity loss in many agricultural landscapes over the last century. Here, we investigated whether new types of farm ponds (made of artificial substrata) in intensive systems and natural-substratum ponds in traditional farming systems differ in their value for aquatic biodiversity conservation. (2.) We analysed the main patterns of environmental variation, compared α -, β - and γ -diversity of macroinvertebrates (calculated at the order level and including Odonata) between ponds types and evaluated the role of submerged aquatic vegetation (SAV). Generalised additive models (GAM) were used to analyse the relationships of α - and β -diversity with environmental predictors, and variation partitioning to separate the effect of environmental and spatial characteristics on the variation in macroinvertebrate assemblages. Moran's eigenvector maps (MEMs) were used to define spatial variables. (3.) A principal coordinate analysis (PCoA) detected a primary environmental gradient that separated nutrient-rich ponds from those dominated by SAV; a secondary morphometric gradient distinguished natural-substratum ponds, with large surface area and structural complexity, from artificial-substratum ponds with steeper slopes. Natural-substratum ponds had almost twice the α - and γ -diversity of artificial-substratum ponds, and diversity significantly increased when SAV was present, particularly in artificial-substratum ponds. Total phosphorus (TP) strongly contributed to explain the patterns in diversity, while SAV was a significant predictor of assemblage composition and diversity. GAMs revealed optima of both α -diversity at intermediate SAV covers and β -diversity at intermediate-high TP concentrations. (4.) These findings have im-

portant implications for conservation planning. Adaptation of artificial substratum ponds by adding natural substratum and smoothing the gradient of pond margins would improve their conservation value. Development of SAV with occasional harvests and certain cautionary measures to control nutrient levels may also improve both the agronomical and environmental function of ponds." (2013): Use of historically fishless high-mountain lakes and streams by Nearctic River otters (*Lontra canadensis*) in California. *Northwestern Naturalist* 94(1): 51-66. (in English) ["In California, River Otters are most commonly associated with food-rich lowland aquatic habitats where they forage primarily on fish and crustaceans. Their distribution in high-elevation montane regions of the state, areas in which fish and crayfish were absent historically, is largely unknown. We compiled occurrence records of River Otters in California from elevations >1100 m, and evaluated them using evidentiary standards. Based on 126 records, we report the widespread presence of River Otters in the Klamath, southern Cascades, and Sierra Nevada mountain ranges, including at elevations exceeding 3000 m. Sixty-three percent of the records met our definition as "verified", and the remaining 37% were considered "unverified". The distribution of observations through time and habitats in which observations were made were similar between verified and unverified records. River Otter records spanned the period from 1900 to 2010, with 50% occurring between 1991 and 2010. Ninety-three percent of the water bodies with records of River Otters contained nonnative prey (fish and crayfish). Those lacking nonnative prey all supported native prey, including amphibians and reptiles. Based on records that contained River Otter foraging observations, nonnative fishes and crayfish were represented in 89% of the total accounts, and native frogs and invertebrates were represented in

22%. It remains unclear whether River Otters occurred in California's high-elevation water bodies prior to the introduction of fish and crayfish, and additional research is needed to understand the possible influence of nonnative prey in allowing River Otters to expand their distribution in these habitats. ... Two scats from different lakes contained the remains of large-bodied aquatic insects, including *Aeshna* spp. larvae, adult *Lethocerus* spp. (Hemiptera), and adult *Notonecta* spp. (Hemiptera)." 12729. Geipel, I.; Kalko, E.K.V.; Wallmeyer, K.; Knörnschild, M. (2013): Postweaning maternal food provisioning in a bat with a complex hunting strategy. *Animal Behaviour* 85(6): 1435-1441. (in English) ["Highlights: • We studied postweaning maternal food provisioning in a free-living Neotropical bat. • Mothers provided their pups with prey items for 5 successive months after weaning. • Food provisioning presumably provides pups with two informational benefits. • Provisioned pups may acquire prey-handling skills and learn acoustic images of prey. • Social learning can facilitate the acquisition of the bats' complex hunting strategy. Adult animals of many taxa exhibit extended parental care by transferring food to inexperienced offspring, thus allocating nutritional and sometimes even informational benefits such as the acquisition of adult dietary preferences and foraging skills. In bats, postweaning food provisioning is severely understudied, despite the taxon's diverse and complex foraging strategies. The Neotropical common

big-eared bat, *Micronycteris microtis*, preys on relatively large insects gleaned from vegetation, finding its silent and motionless prey by echolocation. The demands of this cognitively challenging hunting strategy make *M. microtis* a likely candidate for maternal postweaning food provisioning. We studied five free-living mother–pup pairs in their night roost using infrared video recordings. Each mother exclusively fed her own pup and mother–pup recognition was mutual. Provisioned pups were volant and had started their own hunting attempts. Weaned pups were provisioned for 5 subsequent months with a variety of insects, reflecting the adult diet. Mothers transferred over 50% of their prey to pups. Maternal prey transfers declined as pups matured, whereas the pups' own prey captures increased. During prey transfers, aggressive behaviour between mothers and pups was rare. We argue that postweaning maternal food provisioning might yield two informational benefits for *M. microtis* pups. First, learning how to handle large and well-defended prey is mandatory for inexperienced pups and could be practised with prey items provided by their mothers. Second, acoustically characteristic echo images of prey items could be gained during mother–pup prey transfers, probably facilitating the successful acquisition of *M. microtis*'s complex hunting strategy." (Authors) The illustration shows the transfer of a large libellulid from mother to her pup.] Address: Geipel, Inga, Institute of Experimental Ecology, Faculty of Natural Sciences, University of Ulm, Ulm, Germany. 12730. Gibbons, M.E.; George, M.P. (2013): Clutch identity and predator-induced hatching affect behavior and development in a leaf-breeding treefrog. *Oecologia* 171(4): 831-843. (in English) ["For species with complex life cycles, transitions between life stages result in niche shifts that are often associated with evolutionary trade-offs. When conditions across life stages are unpredictable, plasticity in niche shift timing may be adaptive; however, factors associated with clutch identity (e.g., genetic or maternal) may influence the effects of such plasticity. The red-eyed treefrog (*Agalychnis callidryas*) is an ideal organism for investigating the effects of genetics and life stage switch point timing because embryos exhibit adaptive phenotypic plasticity in hatching time. In this study, we evaluated the effects of experimentally manipulated hatching time and clutch identity on antipredator behaviour of tadpoles and on developmental traits of metamorphs, including larval period, mass, SVL, and jumping ability. We found that in the presence of dragonfly nymph predator cues at 21 days post-oviposition, tadpoles reduced both their activity level and height in the water column. Furthermore, early-hatched tadpoles were less active than late-hatched tadpoles of the same age. This difference in behaviour patterns of early- and late-hatched tadpoles may represent an adaptive response due to a longer period of susceptibility to odonate predators for early-hatched tadpoles, or it may be a carry-over effect mediated by

early exposure to an environmental stressor (i.e., induction of early hatching). We also found that hatching time affected both behavioural traits and developmental traits, but its effect on developmental traits varied significantly among clutches. This study shows that a single early-life event may influence a suite of factors during subsequent life stages and that some of these effects appear to be dependent on clutch identity. This interaction may represent an evolutionary response to a complex life cycle and unpredictable environments, regardless of whether the clutch differences are due to additive genetic variance or maternal effects." 12731. Gobbi, M.; Riservato, E.; Bragalanti, N.; Lencioni, V. (2013): Dalle collezioni museali alla prima lista di specie prioritarie di invertebrati per il Trentino. *Museologia scientifica memorie* 9: 157-161. (in Italian, with English summary) ["From the museum collections to the first list of priority invertebrate species of Trentino: In this paper the first list of priority invertebrate species for the Trentino Province is presented. The list was drawn up starting from a list of 229 species in collaboration with a local network of entomologists and by using the expert based approach. Seventy species of conservation interest (including *Leucorrhinia pectoralis*, *Ophiogomphus cecilia*, *Sympecma paedisca*) were selected according to 10 objective criteria, and a database with 771 geo-referenced records was created. The database was integrated with spatial data from the Italian CKmap and from museums and private collections not included in the CKmap. For 42 species was possible to link the habitat typology (nat2000 and not), therefore to create a database specie-site and specie-habitat, and realize maps on the actual and potential distribution. Such list of species is an helpful tool to support stakeholder decisions regarding the designation of new protected areas or the extension of those already existing." 12733. González-Tokman, D.; González-Santoyo, I.; Córdoba-Aguilar, A. (2013): Mating success and energetic condition effects driven by terminal investment in territorial males of a short-lived invertebrate. *Functional Ecology* 27(3): 739-747. (in English) ["The terminal investment hypothesis has two predictions: in the face of an infection (i) mature males will increase investment to traits that increase mating success, while such investments will occur to a less extent in young males; and (ii) physiological costs of resource reallocation will be more severe for infected mature males than for infected young males. Although these predictions have been tested in long-lived vertebrates, prior studies have not examined actual resource allocation conflicts. Here, we have tested the above predictions and have investigated the energetic costs of increased mating by old males, using a short-lived invertebrate, the damselfly *Hetaerina americana*. Males of this species defend territories as the main way to obtain access to females. Using groups of infected vs. noninfected males of two different ages, we found that compared to young infected males, mature infected males defended territories for longer, had higher mating success and directed agonistic behaviour to conspecific males more frequently. Despite similar immune responses by mature and young males, infected mature males ended up with less fat reserves compared to infected young males. This suggests that resource allocation conflicts are more severe for mature than for young males. In general, these results suggest that the terminal investment hypothesis applies in males of short-lived invertebrates and that a cause of increased mating success for males of advanced ages is reduced energetic stores." 12734. Grewe, Y.; Hof, C.; Dehling, M.; Brandl, R.; Brändle, M. (2013): Recent range shifts of European dragonflies provide support for an inverse relationship between habitat predictability and dispersal. *Global Eco-*

logy and Biogeography 22(4): 403-409. (in English) ["Aim: We compared the effects of recent shifts of northern range boundaries of odonates adapted to either lentic (standing water) or lotic (running water) habitats in Europe. Lentic species are thought to have a higher dispersal propensity than lotic species because of the lower spatial and temporal persistence of lentic habitats on average. Hence, we expected shifts in the range boundaries particularly of lentic species. Location: Europe. Methods: Our analyses are based on odonate distribution maps from two field guides that present the European ranges of dragonflies and damselflies in 1988 and 2006. We categorized species according to their preference for lentic or lotic habitats, and then assigned each species to a southern or a northern group according to the centre of its distribution. Shifts in northern range boundaries were calculated as the average distance between the 10 northernmost grid cells in 1988 and 2006. Range boundary shifts were also analysed with regard to prevalence, phenology, body size and wing size. Results: Lentic species of the southern group expanded their range boundaries on average 115 km northwards per decade, whereas lotic species of the southern group on average did not change their range boundaries. Northern lentic and lotic species showed no consistent trends in their changes in range boundaries. These results did not qualitatively change when we considered the effects of phylogeny, phenology, body size and wing size. Main conclusions: Our results support the hypothesis that species adapted to lentic habitats, which are assumed to be less persistent in time and space, disperse better than lotic species." 12737. Guillermo-Ferreira, R.; Del-Claro, K. (2013): Mate recognition in *Acanthagrion truncatum* (Odonata: Coenagrionidae). *Acta Scientiarum. Biological Sciences* Maringá 35(3): 451-453. (in English, with Spanish summary) ["Sexual and species recognition, along with sexual colour dimorphism, play an important role in the reproduction of many animal species. In this article, it was investigated if males of the dimorphic Neotropical damselfly *Acanthagrion truncatum* are able to recognize mates and differentiate them between co-specific males and hetero-specific females of sympatric species. The results showed misguided mating attempts from males towards other males and *Homeoura chelifera* females. They also seem able to recognize *A. lancea* and *Telebasis carmesina* females as hetero-specifics. This study support the hypothesis that male-male interactions are misdirected sexual behaviour and that sympatric morphologically similar species may represent visual interference for mate searching males." 12739. Gvoždík, L.; Černická, E.; Van Damme, R. (2013): Predator-prey interactions shape thermal patch use in a newt larvae-dragonfly nymph model. *PLoS ONE* 8(6): e65079. doi:10.1371/journal.pone.0065079: 6 pp. (in English) ["Thermal quality and predation risk are considered important factors influencing habitat patch use in ectothermic prey. However, how the predator's food requirement and the prey's necessity to avoid predation interact with their respective thermoregulatory strategies remains poorly understood. The recently developed 'thermal game model' predicts that in the face of imminent predation, prey should divide their time equally among a range of thermal patches. In contrast, predators should concentrate their hunting activities towards warmer patches. In this study, we test these predictions in a laboratory setup and an artificial environment that mimics more natural conditions. In both cases, we scored thermal patch use of newt larvae (prey)

and free-ranging dragonfly nymphs (predators; *Aeshna cyanea*). Similar effects were seen in both settings. The newt larvae spent less time in the warm patch if dragonfly nymphs were present. The patch use of the dragonfly nymphs did not change as a function of prey availability, even when the nymphs were starved prior to the experiment. Our behavioural observations partially corroborate predictions of the thermal game model. In line with asymmetric fitness pay-offs in predator-prey interactions (the 'life-dinner' principle), the prey's thermal strategy is more sensitive to the presence of predators than vice versa." 12743. Hassall, C. (2013): Time stress and temperature explain continental variation in damselfly body size. *Ecography* 36(8): 894-903. (in English) ["Body size is among the most important biological variables but despite much measurement of this trait, the factors driving its variation are not fully understood. Here, I describe variation in body size in *Calopteryx maculata* to estab-

lish whether variations in growth and development observed in response to experimental manipulation of temperature and time stress in the laboratory can be scaled-up to variation among natural populations. Nine hundred and seven specimens of *C. maculata* males were collected from 34 sites across the species' entire range in North America during the summer of 2010. A general measure of body size was derived from a series of wing and leg measurements. I compare the fit of models based on latitude (Bergmann's rule), temperature (the temperature–size rule) and seasonal effects (a combination of temperature and time stress) using Akaike's information criterion (AIC). The U-shaped relationship between size and latitude was best explained by a seasonality model containing both photoperiod and temperature. The presence of both these terms suggests that time stress dominates in the southern part of the range, reducing body size by accelerating development. However, the temperature–size rule dominates in the northern part of the range, increasing body size closer to the northern range margin. The best-fit model of geographic variation in size is in accordance with previous laboratory studies of temperature and photoperiod in damselflies and theoretical work, indicating that the findings from such studies can be applied to natural populations. These findings are likely applicable to any species with complex life histories inhabiting seasonal environments." 12745. Heino, J. (2013): Does dispersal ability affect the relative importance of environmental control and spatial structuring of littoral macroinvertebrate communities? *Oecologia* 171(4): 971-980. (in English) ["Both spatial processes and environmental control may structure metacommunities, but their relative importance may be contingent on the dispersal ability of organisms. I examined the roles of spatial and environmental factors for the structuring of littoral macroinvertebrate communities

across a set of lakes in a boreal drainage basin. I hypothesized that dispersal ability would affect the relative importance of spatial processes and environmental control, and thus the biological data were divided into four groups of species differing in dispersal ability. In general, the group of the strongest aerial dispersers showed greatest relative pure environmental control and least pure spatial structuring of community structure and species richness, while spatial processes seemed to be more important for the other three dispersal ability groups. However, these results were contingent on the indirect measure of spatial processes, with the spatial variables and connectivity variables providing slightly different insights into the spatial processes and environmental control of metacommunity structuring. It appears, however, that dispersal ability has effects on the spatial processes and environmental control important in metacommunity organization, with strong dispersers being more under environmental control and less affected by spatial processes compared to weak dispersers." 12746. Hilfert-Rüppell, D.; Rüppell, G. (2013): Do coloured-winged damselflies and dragonflies have flight kinematics different from those with clear wings? *International Journal of Odonatology* 16(2): 119-134. (in English) ["The flights of male odonates encountering conspecifics at their reproduction sites were investigated by means of slow-motion films. We recorded large and generally consistent differences between species with clear wings (SCLW) and species with coloured wings (SCOW). SCLW mostly fought having physical contact and moved their wings without pauses in wing beats (hereafter designated wing pauses), attacking the other males. During encounters, SCOW males showed pauses of all wings or of the fore or the hind wings only. The wing beat frequencies of SCOW therefore showed much greater variation than in SCLW. In Zygoptera SCOW, parallel flapping of both wing pairs was frequent. The two investigated species of Calopterygidae showed several special flight patterns when encountering other males. Male Anisoptera with coloured wings also used wing pauses, and often displayed their wing patterns by gliding and banking to the other male or by flying in an upright posture. Thus, we found that most odonate males with coloured wings, in the presence of rivals, exhibited special flight styles, implying signalling functions. We interpret wing pauses as an adaptive characteristic that allows rival males to evaluate the quality of their opponent by assessment of the coloured wings. Sexual selection is suggested as a possible cause for the evolution of these flights." 12749. Iserbyt, A.; Bots, J.; van Gossum, H.; Sherratt, T.N. (2013): Negative frequency-dependent selection or alternative reproductive tactics: maintenance of female polymorphism in natural populations. *BMC Evolutionary Biology* 2013, 13:139: 10 pp. (in English) ["Background: Sex-limited polymorphisms have long intrigued evolutionary biologists and have been the subject of long-standing debates. The coexistence of multiple male and /or female morphs is widely believed to be maintained through negative frequency-dependent selection imposed by social interactions. However, remarkably few empirical studies have evaluated how social interactions, morph frequencies and fitness parameters relate to one another under natural conditions. Here, we test two hypotheses proposed to explain the maintenance of a female polymorphism in a species with extreme geographical variation in morph frequencies (*Nehalennia irene*). We first elucidate how fecundity traits of the morphs vary in relation to the frequencies and densities of males and female morphs in multiple sites over multiple years. Second, we evaluate whether the two female morphs differ in resource allocation among fecundity traits, indicating alternative tactics to maximize reproductive output. Results: We present some of the first empirical evidence collected under natural conditions that egg number and clutch mass was higher in the rarer female morph. This morph-specific fecundity advantage gradually switched with the population morph frequency. Our results further indicate that all investigated fecundity traits are negatively affected by relative male density (i.e. operational sex ratio), which confirms male harassment as selective agent. Finally, we show a clear trade-off between qualitative (egg mass) and quantitative (egg number) fecundity traits. This trade-off, however, is not morph-specific. Conclusion: Our reported frequency- and density-dependent fecundity patterns are consistent with the hypothesis that the polymorphism is driven by a conflict between sexes over optimal mating rate, with costly male sexual harassment driving negative frequency-dependent selection on morph fecundity." 12750. Johansson, H.; Stoks, R.; Nilsson-Örtman, V.; Ingvarsson, P.K.; Johansson, F. (2013): Large-scale patterns in genetic variation, gene flow and differentiation in five species of European Coenagrionid damselfly

provide mixed support for the central-marginal hypothesis. *Ecography* 36(6): 744-755. (in English) ["Recently, an increased effort has been directed towards understanding the distribution of genetic variation within and between populations, particularly at central and marginal areas of a species' distribution. Much of this research is centred on the central-marginal hypothesis, which posits that populations at range margins are sparse, small and genetically diminished compared to those at the centre of a species' distribution range. We tested predictions derived from the central-marginal hypothesis for the distribution of genetic variation and population differentiation in five European Coenagrionid damselfly species (*Coenagrion armatum*, *C. johanssoni*, *C. puella*, *C. pulchellum*, *C. mercuriale*). We screened genetic variation (microsatellites) in populations sampled in the centre and margins of the species' latitudinal ranges, assessed genetic diversity (HS) in the populations and the distribution of this genetic diversity between populations (FST). We further assessed genetic substructure and migration with Bayesian assignment methods, and tested for significant associations between genetic substructure and bioclimatic and spatial (altitude and latitude) variables, using general linearized models. We found no general adherence to the central-marginal hypothesis; instead we found that other factors such as historical or current ecological factors often better explain the patterns uncovered. This was illustrated in *C. mercuriale* whose colonisation history and behaviour most likely led to the observation of a high genetic diversity in the south and lower genetic diversity with increasing latitude, and in *C. armatum* and *C. pulchellum* whose patterns of low genetic diversity coupled with the weakest genetic differentiation at one of their range margins suggested, respectively, possible range shifts and recent, strong selection pressure." 12751. Johnston, P.R.; Rolff, J. (2013): Immune- and wound-dependent differential gene expression in an ancient insect. *Developmental & Comparative Immunology* 40(3-4): 320-324. (in English) ["Two of the main functions of the immune system are to control infections and to contribute to wound closure. Here we present the results of an RNAseq study of immune- and wound-response gene expression in *Coenagrion puella*, a representative of the odonates, the oldest taxon of winged insects. De novo assembly of RNAseq data revealed a rich repertoire of canonical immune pathways, as known from model insects, including recognition, transduction and effector gene expression. A shared set of immune and wound repair genes were differentially expressed in both wounded and immune-challenged larvae. Moreover three-fold more immune genes were overexpressed only in the immune-challenged treatment. This is consistent with the notion that the immune-system reads a balance

of signals related to wounding and infection and that the response is tailored accordingly. Highlights: *Infection transcriptome of an odonate, oldest group of pterygote insects. *Wounding and immune challenge lead to over-expression of immune genes. *More genes are overexpressed in immune-challenged vs. wounded individuals. *Odonates have a repertoire of immune transcripts comparable to more derived taxa." 12752. Kalkman, V.J.; Orr, A.G. (2013): Field Guide to the damselflies of New Guinea. *Brachytron* 16, Suppl.: 3-120. (in English, with Bahasa Indonesian) ["With this book in hand the reader can identify all genera and most species of damselflies occurring in New Guinea. It will doubtless stimulate people to explore their local streams and standing waters of New Guinea and to appreciate the wonderful diversity of damselflies and dragonflies to be found there. Over 500 copies are being donated to universities throughout New Guinea. As well as introducing students and researchers to the beauty of damselflies, the guide provides a basis to study them and use them in biodiversity studies supporting the conservation of freshwater habitats. The guide contains nearly 300 colour drawings and over 250 line drawings by Albert Orr and twenty-two colour photographs taken in the field by Stephen Richards. Many genera and most species included have never been depicted in colour before."] Approximately 60% of the known zygopteran taxa is figured and described. [Vincent Kalkman has had an interest in the damselflies and dragonflies of New Guinea since 2005. In 2006 and 2008 he conducted fieldwork with the Kelempok Entomologi Papua in the Indonesian part of the island and in 2009 he joined the expedition by Conservation International to Muller Range in Papua New Guinea. Albert Orr's interest in the insect fauna of New Guinea dates back to undergraduate days when he made two lengthy excursions in 1971 and 1973/4, collecting butterflies and dragonflies. He has authored and illustrated several identification guides to Asian dragonflies and damselflies [2003, 2005 and 2007), and the butterflies of Australia (2010). ... This field guide was made possible by grants from: Van Tienhoven Foundation, Van der Hucht De Beukelaar Stichting, the International Dragonfly Fund, Nederlandse Vereniging voor Libellenstudie, Theo Benken, Klaus-Jürgen Conze, Andre Günther, Holger Hunger, Dietmar Ikemeyer, Lutz & Ursel Koch, Martin Lemke, Ludwig Quandt, Richard Seidenbusch, Klaus-Peter & Mechtild Seiler, Wolfgang Schneider, Anke & Michael Tydecks-Jürging and Isolde Wiesmath." 12753. Katayama, M. (2013): Differential survival rates of damselfly larvae in the presence of newt and dragon-

fly predators. *International Journal of Odonatology* 16(2): 177-182. (in English) ["The damselfly species *Paracercion melanotum* has been found to be the most abundant species in damselfly larval communities on Okinawa-zima Island in southwest Japan. To clarify differential susceptibility to predation, a possible factor affecting relative population densities in larval communities, between *Paracercion melanotum* and a less common damselfly species, *Ischnura senegalensis*, laboratory experiments were conducted using three abundant predator species: the sword-tailed newt (*Cynops ensicauda popei*), anisopteran larvae (*Crocothemis servilia servilia*), and a planktivorous fish (*Poecilia reticulata*). *Paracercion melanotum* survived predation by the newt and the dragonfly well compared to *I. senegalensis*. Fishes consumed approximately equal numbers of the two damselfly species. From these results, the newt and the dragonfly were suggested as the most probable predators regulating damselfly larval communities on Okinawa-zima Island. Predators could be a crucial factor determining relative abundance in damselfly larval communities." 12754. Kaunisto, K.M.; Suhonen, J. (2013): Parasite burden and the insect immune response: interpopulation comparison. *Parasitology* 140(1): 87-94. (in English) ["The immune response affects host's survival and reproductive success. Insurmountable immune function has not evolved because it is costly and there is a trade-off between other life-history traits. In previous studies several factors such as diet and temperature have been proposed to cause interpopulation differences in immune response. Moreover, the insect immune system may be functionally more protective upon secondary exposure, thus infection history may associate with the immune response. Here we measured how geographical location and parasite burden is related to variation in immune response between populations. We included 13 populations of *Coenagrion hastulatum* in Finland over a latitudinal range of 880 km to this study. We found that water mites associated strongly with the immune response at interpopulation level: the more the mites, the higher the immune response. Also, in an alternative model based on AIC, latitude and individual size associated with the immune response. In turn, endoparasitic gregarines did not affect the immune response. To conclude, a positive interpopulation association between the immune response and the rate of water mite infection may indicate (i) local adaptation to chronic parasite stress, (ii) effective 'induced' immune response against parasites, or (iii) a combined effect of both of these." agrion mercuriale (Odonata: Coenagrionidae) am Beispiel des Smaragd-Gebiets Oberaargau. Entomo Helvetica 6: 87-99. (in German, with English and French summaries) ["C. mercuriale is a critically endangered damselfly in Switzerland and is also a target species in the Emerald and Natura 2000 network of European protected areas. One of the most important sites of C. mercuriale in Switzerland is located in the Emerald area Oberaargau. Here, this damselfly species inhabits streams and ditches flowing through agricultural meadows. Within a larger research project, several studies have been performed on C. mercuriale in the Oberaargau region. (1) Conservation measures and their costs were assessed, (2) the effectiveness of the Emerald information campaigns were surveyed and analysed with a questionnaire, and (3) the connectivity of annually monitored populations was studied in a mark-recapture study and genetic analyses. Overall, these studies showed positive results. The calculations of conservation costs revealed a moderate amount of expenses for conservation measures of C. mercuriale. The survey indicated that local people were well informed about the protection of C. mercuriale because of the information campaigns. Furthermore, population monitoring indicated a positive development of local damselfly populations. Connectivity between populations located within the same stream system was ensured by frequent dispersal along the water courses across distances up to 0.5 km. However, dispersal across distances larger than 0.5 km occurred less often, but across open agricultural land. Such long-distance dispersal events are important for the interconnectivity of distant populations." (2013): Trophic relationships between macroinvertebrates and fish in a pampean lowland stream (Argentina). Iheringia 103(1): 57-65. (in English, with Spanish summary) ["The diet and trophic relationships between the macroinvertebrates Phyllogomphoides joaquina Rodrigues Capitulo, 1992 and Coenagrionidae, Chironomidae (Diptera), *Diplodon delodontus* (Lamarck, 1919) (Bivalvia: Hyriidae), and *Pomacea canaliculata* (Lamarck, 1822) (Gastropoda: Ampulariidae) and the fishes *Pimelodella laticeps* Eigenmann, 1917 (Hepptapteridae) and *Bryconamericus iheringii* (Boulenger, 1887) (Characidae) in a temperate lowland lotic system in Argentina were assessed on the basis of gut contents and stable-isotope analyses. The feeding strategies were analyzed by the Amundsen method. Relative food items contribution for the taxa studied indicated a generalist-type trophic strategy. In macroinvertebrates, in general, the values of stable isotope confirmed the result of the analysis of gut contents. With the fish, stable-isotope analysis demonstrated that both species are predators, although *B. iheringii* exhibited a more omnivorous behaviour. These feeding studies allowed us to determine the trophic relationships among taxa studied. Detritus and diatoms were a principal source of food for all the macroinvertebrates studied. In La Chozza stream the particulate organic matter is a major no limited food resource, has a significant influence upon the community." (2013): Species diversity of adult Odonata in selected areas from Misamis Occidental Province, Philippines. *AAFL Bioflux* 6(4): 421-432. (in English) ["Odonata is considered an environmental indicator group of freshwater habitats. Thus there is a need to have a good baseline data to use it for monitoring fluvial habitats. However, species composition of Odonata in Misamis Occidental is poorly known. This study was conducted to determine the species diversity of Odonata in the municipality of Sinacaban and in the cities of Oroquieta and Ozamiz, Misamis Occidental, Philippines. Opportunistic sampling method using sweep nets was employed. There were 266 Odonata individuals collected comprising 22 species. Seven species (31.82%) are Philippine endemic. Low species diversity was recorded in all the sampling sites with more or less even distribution of species. Results indicate that the sampled areas are already disturbed." 12763. Marinov, M.; Richards, S.; Theuerkauf, J. (2013): Damselflies and Dragonflies (Insecta: Odonata) of the Mt. Panié and Roches de la Ouaième region, New Caledonia. *A Rapid Biological Assessment of the Mt. Panié and Roches de la Ouaième region, province Nord, New Caledonia*: 113-130. (in English, with French summary) ["We surveyed odonates at 46 sites in north-eastern New Caledonia, including 38 primary sites in three catchments on and around Mt. Panié. A total of 23 species were recorded during this survey, which comprises 41% of the 56 species known for the country. The lowest number of species was documented within the La

Guen river catchment, where less species were found than in the Dané Yém river catchment despite only limited sampling (half a day) at this latter site. Localities within the La Guen catchment also appeared to suffer from higher disturbance compared to those in the We-wec river catchment where species richness was high. They had lower water pH, higher amounts of filamentous algae and an apparently low abundance of primary consumers (macroinvertebrates). Anthropogenic impacts, including bushfires and introduced mammals, may these differences. Our results suggest that odonates are useful bioindicators within the Mt. Panié area. This survey has provided baseline data on species occurrence and abundance at a range of sites, and identified several questions regarding disturbance to aquatic ecosystems that require further investigation." 12765. McGoff, E.; Solimini, A.G.; Pusch, M.T.; Jurca, T.; Sandin, L. (2013): Does lake habitat alteration and land-use pressure homogenize European littoral macroinvertebrate communities? *Journal of Applied Ecology* 50(4): 1010-1018. (in English) ["Beta diversity is the compositional heterogeneity of biotic assemblages among sites, and biotic homogenization is the decrease in beta diversity, facilitated by an increase in similarity of biotic communities over time. Environmental harshness decreases the importance of stochastic processes in structuring assemblages, resulting in a homogenization of the biota. We investigated if increasing nutrient enrichment, land-use pressure, and within-lake habitat alteration would decrease the beta diversity of macroinvertebrates in 46 lakes across Europe. Beta diversity was calculated using global multivariate dispersion. We utilized a structural equation modelling approach to account for hierarchical interdependence between potential impacts, that is the direct effects and correlations among the different impacts. We found clear indications that European macroinvertebrate communities are being homogenized by ongoing lake shore development. Increasing land-use pressure in the form of residential and commercial development had a direct negative effect on beta diversity (standardized coefficient = -0.40), as did roadways, albeit indirectly through an increase in engineering structures (standardized coefficient = -0.31). Increasing within-lake silt levels also homogenized macroinvertebrate communities (standardized coefficient = -0.18), independent of near shore land use. Our results indicate the negative effect of both the near shore land-use pressure and the within-lake habitat alteration on macroinvertebrate beta diversity, with significant inter-

actions between these pressures. Habitat protection should take a more holistic approach to assessing lake development pressure, over a range of scales, as a solely site specific approach is not always biologically meaningful. Thus, future management plans should carefully control and mitigate ongoing development pressure if lake ecosystem health and resilience is to be maintained. Synthesis and applications. This study is the first of its kind to demonstrate European-wide homogenization of littoral macroinvertebrate lake communities with increasing habitat alteration and land-use pressure. Significant interactions occur between different habitat scales, with no one scale entirely accounting for the homogenization effect. To avoid further biotic homogenization, development pressure must be carefully managed at multiple scales, and where possible, minimized. This presents a challenge, as globally there is an increasing expansion of the human population and a consequent increase in anthropogenic pressure across all habitats." Grey-headed Sparrow *Passer griseus* and adult Southern Red Bishop *Euplectes orix* in Burundi. *Malimbus* 35: 1-10. (in English, with French summary) ["We studied the diet composition of Northern Grey-headed Sparrow and Southern Red Bishop in four localities of the Rusizi Plain, northwest Burundi. We analyzed crop contents of 100 adults from each of the two species and the composition of food brought by parents to nestlings of the sparrow at ten nests. In all four sites, the sparrow's diet consisted primarily of rice. The bishop also fed mostly on rice grains but also ate Lepidoptera caterpillars, some other insects and wild grass seeds such as *Panicum* sp. and *Brachiaria* sp. For adults of both bird species, there was no significant variation in diet throughout the year. However, the diet of young sparrows was much more diverse and changed from the day of hatching until fledging. On the day of hatching, chicks ate mainly caterpillars but by the tenth day, food items comprised one third caterpillars, one third Orthoptera and the rest of other insects including Odonata, Dictyoptera, Isoptera and adult Lepidoptera. After this and until fledging, the chicks were fed increasingly on rice seeds. Simultaneously, the proportion of caterpillars taken gradually decreased until none was fed to the nestlings at the end of the nestling period. The items brought by parents also varied with time of day, with caterpillars and grasshoppers in higher proportions in the morning, decreasing around mid-day and then increasing in the evening." (in Japanese, with English summary) ["A few mature males of *Zygomma petiolatum* were observed to fly over the surface of a metallic dark-green coloured car at Deep Water Bay in Hong Kong on July 11, 1993. Another observation was made at Kutchan town in Hokkaido, Japan, on August 8, 1998. A male *Aeshna juncea juncea* flew over a black vehicle for several minutes. In both cases their behaviours looked like patrol flight of territorial males at the water. The causes of these behaviours are briefly discussed." (Author)] Address: E-mail: romluna@y4.dion.ne.jp

12770. Natuhara, Y. (2013): Ecosystem services by paddy fields as substitutes of natural wetlands in Japan. *Ecological Engineering* 56: 97-106. (in English) ["This paper reviews research on the ecosystem services or multifunctionality of paddy rice cultivation in Japan, focusing on biodiversity as a basis for ecosystem services, with the aim of describing the current status and impact of the subject and exploring options for sustainable practices. Ecosystem services provided by paddy fields include; groundwater recharge, production of non-rice foods, flood control, soil erosion and landslide prevention, climate-change mitigation, water purification, culture and

landscape, and support of ecosystems and biodiversity. Among these services, the value of services that regulate ecosystem functions was estimated to be US\$ 72.8 billion in Japan. More than 5000 species have been recorded in paddy fields and the surrounding environment. Because paddy fields are artificially disturbed by water level management, plowing, and harvest, most species move between paddy fields and the surrounding environment. The linkage between paddy fields and the associated environment plays an important role in biodiversity. Two changes that have affected the ecosystem of paddy fields are modernization and abandonment of farming. Satoyama, a traditional socio-ecological production landscape, which provided a functional linkage between paddy fields and the associated environment has lost its functions. Biodiversity-conscious rice farming has been promoted by collaborations among farmers, consumers and governments. Biodiversity certification programs are successful examples of biodiversity-conscious framing. In these programs incentives include direct payments and/or premium prices paid by consumers, as well as farmers willingness to improve the safety of food and environment." (2013): Dual role of outer epicuticular lipids in determining the wettability of dragonfly wings. *Colloids and Surfaces B: Biointerfaces* 106: 126-134. (in English) ["Numerous natural surfaces possess superhydrophobicity and self-cleaning properties that would be extremely beneficial when applied in industry. Dragonfly wings are one example of such surfaces, and while their general surface structure is known, their precise chemical composition is not. Here, the epicuticular lipids of dragonfly wing membranes were characterized to investigate their significance in contributing to self-cleaning and superhydrophobic properties. After just 10 seconds of lipid extraction using chloroform, the water contact angles exhibited by the wings decreased below the accepted threshold for superhydrophobicity (150°). Infrared spectra collected at the Australian Synchrotron contained characteristic absorption bands of amide, ester and aliphatic hydrocarbons moieties on the wing surfaces, the latter of which was decreased post-extraction with chloroform. GCMS data analysis revealed that the epicuticular wax components were dominated by n-alkanes with even-numbered carbons, especially n-hexacosane, and palmitic acid. SEM and AFM data analysis conducted on the untreated and chloroform-extracted wing surfaces demonstrated that surface topography changed after extraction; the surface nanostructure was progressively lost with extended extraction times. The data presented here indicate that epicuticular lipids contribute not only to self-cleaning and superhydrophobic properties through

their inherent hydrophobic nature, but also by forming the physical structure of the wing surface. This knowledge will be extremely valuable for reconstruction of dragonfly wing structures as a biomimetic template." (2013): The evolution of species recognition in competitive and mating contexts: the relative efficacy of alternative mechanisms of character displacement. *Ecology Letters* 16(5): 670-678. (in English) ["Sympatric divergence in traits affecting species recognition can result from selection against cross-species mating (reproductive character displacement, RCD) or interspecific aggression (agonistic character displacement, ACD). When the same traits are used for species recognition in both contexts, empirically disentangling the relative contributions of RCD and ACD to observed character shifts may be impossible. Here, we develop a theoretical framework for partitioning the effects of these processes. We show that when both mate and competitor recognition depend on the same trait, RCD sets the pace of character shifts. Moreover, RCD can cause divergence in competitor recognition, but ACD cannot cause divergence in mate recognition. This asymmetry arises because males with divergent recognition traits may avoid needless interspecific conflicts, but suffer reduced attractiveness to conspecific

ic females. Therefore, the key empirical issue is whether the same or different traits are used for mate recognition and competitor recognition." 12775. Okuyama, H.; Samejima, Y.; Tsubaki, Y. (2013): Habitat segregation of sympatric *Mnais* damselflies (Odonata: Calopterygidae): microhabitat insolation preferences and competition for territorial space. *International Journal of Odonatology* 16(2): 109-117. (in English) ["Distribution and abundance of sympatric *Mnais costalis* and *M. pruinosa* damselflies were studied in a low mountain stream in Shiga, Japan, from 2008 through 2012. The reproductive seasons of the two species overlapped almost entirely: both species emerged in early May and disappeared in late June each year. Males of both species hold territories within the same stretch of the river; however, *M. costalis* was more abundant on the lower stream, while *M. pruinosa* was more abundant on the upper stream. Canopy openness varied at territorial sites. Results of these observations suggest that habitat segregation of the two species is due to different preference for light/shade conditions. Morisita's R_d index suggests that interspecific exclusion (or avoidance) contributes to the habitat segregation of the two species." 12776. Onishi, Y.; Genkai-Kato, M. (2013): Benthic invertebrates and attached algae in the upstream region of the Kagami River, Kochi Prefecture. *Kuroshio Science* 6(2): 208-216. (in Japanese, with English summary) ["In lotic ecosystems, the downstream environments are affected by the upstream environments. Surveys were conducted for water chemistry, attached algae and benthic invertebrates in five headwater streams of the Kagami River, Kochi Prefecture, western Japan. The discharge rate among the streams ranged between 0.24 and 2.46 m³/s, but there was no correlation between the discharge rate and attached algae or benthic invertebrates. Attached algae were dominated by diatoms, and the density of chlorophyll *a* varied between 4.8 and 30.5 mg/m² depending on the streams. The invertebrate communities in the streams were dominated by mayflies, caddisflies and freshwater crabs. Streams with abundant freshwater crabs tended to have fewer aquatic insects and lower biodiversity, and vice versa. This indicates that the invertebrate community structure in the upstream region of the Kagami River is strongly affected by the abundance of freshwater crabs." (Authors) The list of taxa includes Odonata *Calopteryx cornelia* and 'Gomphidae'.] Address: Onishi, Yukiko, Department of Biology, Faculty of Science, Kochi University, 2-5-1 Akebono-cho, Kochi 780-8520, Japan

12777. Outomuro, D.; Adams, D.C.; Johansson, F. (2013): The evolution of wing shape in ornamented-winged damselflies (Calopterygidae, Odonata). *Evolutionary Biology* 40(2): 300-309. (in English) ["Flight has conferred an extraordinary advantage to some groups of animals. Wing shape is directly related to flight performance and evolves in response to multiple selective pressures. In some species, wings have ornaments such as pigmented patches that are sexually selected. Since organisms with pigmented wings need to display the ornament while flying in an optimal way, we might expect a correlative evolution between the wing ornament and wing shape. We examined males from 36 taxa of calopterygid damselflies that differ in wing pigmentation, which is used in sexual displays. We used geometric morphometrics and phylogenetic comparative approaches to analyse whether wing shape and wing pigmentation show correlated evolution. We found that wing pigmentation is associated with certain wing shapes that probably increase the quality of the signal: wings being broader where the pigmentation is located. Our results also showed correlated evolution between wing pigmentation and wing shape in hind wings, but not in front wings, probably because hind wings are more involved in signalling than front wings. The results imply that the evolution of diversity in wing pigmentations and behavioural sexual displays might be an important driver of speciation due to important pre-copulatory selective pressures." 12779. Outomuro, D.; Adams, D.C.; Johansson, F. (2013): Wing shape allometry and aerodynamics in ca-

lopterygid damselflies: a comparative approach. *BMC Evolutionary Biology* 2013, 13:118 doi:10.1186/1471-2148-13-118: 11 pp. (in English) ["Background: Wing size and shape have important aerodynamic implications on flight performance. We explored how wing size was related to wing shape in territorial males of 37 taxa of the damselfly family Calopterygidae. Wing coloration was also included in the analyses because it is sexually and naturally selected and has been shown to be related to wing shape. We studied wing shape using both the non-dimensional radius of the second moment of wing area (RSM) and geometric morphometrics. Lower values of the RSM result in less energetically demanding flight and wider ranges of flight speed. We also re-analyzed previously published data on other damselflies and dragonflies. Results: The RSM showed a hump-shaped relationship with wing size. However, after correcting for phylogeny using independent contrast, this pattern changed to a negative linear relationship. The basal genus of the study family, Hetaerina, was mainly driving that change. The obtained patterns were specific for the study family and differed from other damselflies and dragonflies. The relationship between the RSM and wing shape measured by geometric morphometrics was linear, but relatively small changes along the RSM axis can result in large changes in wing shape. Our results also showed that wing coloration may have some effect on RSM. Conclusions: We found that RSM showed a complex relationship with size in calopterygid damselflies, probably as a result of other selection pressures besides wing size per se. Wing coloration and specific behaviour (e.g. courtship) are potential candidates for explaining the complexity. Univariate measures of wing shape such as RSM are more intuitive but lack the high resolution of other multivariate techniques such as geometric morphometrics. We suggest that the relationship between wing shape and size are taxa-specific and differ among closely related insect groups." España) mediante el uso de macroinvertebrados acuáticos. *Nova Acta Científica Compostelana (Biología)* 20: 1-9. (in Spanish, with English summary) ["In this work, the results of the study of the water quality of the Furnia River (Pon-tevedra, NW Spain) using the aquatic macroinvertebrate (including Odonata) assemblages are presented. Semi-quantitative surveys were carried out in autumn of 2007 and spring of 2008, and different indices based on these assemblages (abundance, richness, EPT, IASPT, Shannon-Wiener, IBMWP and % of feeding groups) were calculated. Several environmental variables that complemented the biological data were also measured. Although the indices decreased slightly along the water course, the results indicate a very good water quality of the Furnia River and a very diverse community of aquatic macroinvertebrates that must be conserved." 12785. Petrulevicius, J.F. (2013): Palaeoenvironmental and palaeoecological implications from body fossils and ovipositions of Odonata from the Eocene of Patagonia, Argentina. *Terrestrial Arthropod Reviews* 6(1-2): 53-60. (in English) ["Odonata are beginning to be well recorded in the Eocene of Patagonia, Argentina. They are represented by body fossils and traces in three localities. Oviposition scars are recorded in Río Pichileufú (Lutetian: 47.7 Ma; Río Negro province) and Laguna del Hunco (Ypresian: 52.2 Ma; Chubut province), nymphs in Confluencia (Ypresian; Río Negro), and adults (wings) in Laguna del Hunco. The absence of different stages in given localities could depend on different factors, such as as environmental, taphonomical and/or sampling bias. Laguna del Hunco is well sampled and the absence of nymphs seems to depend on taphonomical factors since there are other preimaginal aquatic inhabitants of the lake, such as Trichoptera nymph cases. Confluencia has not been well sampled and adults could be absent due to a sampling bias. The nymphs of Confluencia indicate a water body with low energy flux. Ovipositions in Laguna del Hunco and Río Pichileufú are made on terrestrial leaves of bushes and trees and have three different morphologies. Leaves are interpreted to be alive when oviposition was done as they show tissue reactions associated to the injuries. Wrinkled wings at Laguna del Hunco are interpreted to be signals of predation probably by birds or mammals." (2013): Trophic structure and mercury biomagnification in tropical fish assemblages, Iténez River, Bolivia. *PLoS ONE* 8(5): e65054. doi:10.1371/journal.pone.0065054: 9 pp. (in English) ["We examined mercury concentrations in three fish assemblages to estimate biomagnification rates in the Iténez main river, affected by anthropogenic activities, and two unperturbed rivers from the Iténez

basin, Bolivian Amazon. Rivers presented low to moderate water mercury concentrations (from 1.25 ng L⁻¹ to 2.96 ng L⁻¹) and natural differences in terms of sediment load. Mercury biomagnification rates were confronted to trophic structure depicted by carbon and nitrogen stable isotopes composition ($\delta^{15}\text{N}$; $\delta^{13}\text{C}$) of primary trophic sources, invertebrates and fishes. Results showed a slight fish contamination in the Iténez River compared to the unperturbed rivers, with higher mercury concentrations in piscivore species (0.15 $\mu\text{g g}^{-1}$ vs. 0.11 $\mu\text{g g}^{-1}$ in the unperturbed rivers) and a higher biomagnification rate. Trophic structure analysis showed that the higher biomagnification rate in the Iténez River could not be attributed to a longer food chain. Nevertheless, it revealed for the Iténez River a higher contribution of periphyton to the diet of the primary consumers fish species; and more negative $\delta^{13}\text{C}$ values for primary trophic sources, invertebrates and fishes that could indicate a higher contribution of methanotrophic bacteria. These two factors may enhance methylation and methyl mercury transfer in the food web and thus, alternatively or complementarily to the impact of the anthropogenic activities, may explain mercury differences observed in fishes from the Iténez River in comparison to the two other rivers." 12787. Preston, D.L.; Orlofske, S.A.; Lambden, J.P.; Johnson, P.T.J. (2013): Biomass and productivity of trematode parasites in pond ecosystems. *Journal of Animal Ecology* 82(3): 509-517. (in English) ["Ecologists often measure the biomass and productivity of organisms to understand the importance of populations and communities in the flow of energy through ecosystems. Despite the central role of such studies in the advancement of freshwater ecology, there has been little effort to incorporate parasites into studies of freshwater energy flow. This omission is particularly important considering the roles that parasites sometimes play in shaping community structure and ecosystem processes. Using quantitative surveys and dissections of over 1600 aquatic invertebrate and amphibian hosts, we calculated the ecosystem-level biomass and productivity of trematode parasites alongside the biomass of free-living aquatic organisms in three freshwater ponds in California, USA. Snails and amphibian larvae, which are both important intermediate trematode hosts, dominated the dry biomass of free-living organisms across ponds (snails = 3.2 g m⁻²; amphibians = 3.1 g m⁻²). An average of 33.5% of mature snails were infected with one of six trematode taxa, amounting to a density of 13 infected snails m⁻² of pond substrate. Between 18% and 33% of the combined host and parasite biomass within each infected snail consisted of larval trematode tissue, which collectively accounted for 87% of the total trematode biomass within the three ponds. Mid-summer

trematode dry biomass averaged 0.10 g m², which was equal to or greater than that of the most abundant insect orders (Coleoptera = 0.10 g m², Odonata = 0.08 g m², Hemiptera = 0.07 g m² and Ephemeroptera = 0.03 g m²). On average, each trematode taxon produced between 14 and 1660 free-swimming larvae (cercariae) infected snail-1 24 h⁻¹ in mid-summer. Given that infected snails release cercariae for 3–4 months a year, the pond trematode communities produced an average of 153 mg m² yr⁻¹ of dry cercarial biomass (range = 70–220 mg m² yr⁻¹). Our results suggest that a significant amount of energy moves through trematode parasites in freshwater pond ecosystems, and that their contributions to ecosystem energetics may exceed those of many free-living taxa known to play key roles in structuring aquatic communities." 12789. Qin, C.; Zhang, Y.; Yu, H.; Wang, B. (2013): Concordance among different aquatic insect assemblages and the relative role of spatial and environmental variables. *Biodiversity Science* 21(3): 326-333. (in Chinese, with English summary) ["Indicator groups are often used for biodiversity monitoring and conservation, however, the effectiveness of these groups in representing biodiversity is rarely tested. To explore community congruence among different aquatic insect groups and how this may be affected by spatial factors and environmental variables, we carried out an investigation on aquatic insects in April 2010 in 21 headwater streams within the Dongtiaoxi Basin, China. In total, we recorded 130 species from 92 genera, 44 families and 7 orders. We divided the stream insects into three groups, Coleoptera (C), Ephemeroptera + Plecoptera + Trichoptera (EPT), and Diptera + Megaloptera + Odonata (DMO). In Mantel tests, three aquatic insect groups showed significant cross-taxon concordance, C versus EPT ($r = 0.65$, $P < 0.001$), C versus DMO ($r = 0.67$, $P < 0.001$) and EPT versus DMO ($r = 0.82$, $P < 0.001$). According to variance partitioning procedures, environmental variables were the major determinants of aquatic insect community structures, while spatial factors were less important. Species composition in different taxon groups exhibited similar relationships to environmental gradients. Altitude, pH, mean velocity and concentration of oxygen were the most important drivers of aquatic insect assemblage patterns. Overall, our results indicated that, at least in the studied region, community

congruence among different aquatic insect groups was strong. We propose that one group, such as the EPT group, may be used as a biodiversity indicator in future cost-effective surveys." 12790. Ragaie, M.; Sabry, A.H. (2013): Insect wings as a solar cell system. *International Journal of Open Scientific Research* 1(3): 10-26. (in English) ["This work demonstrated that most flying insect species use their wings pigment to absorb light and reemits this light as fluorescence. *Orthetrum brunneum* [the species figured in the paper is *Anax ephippiger*]; seven-spotted lady beetle, *Coccinella septempunctata*; *Pentodon bispinosus* (Coleoptera) and sphingid moth, *Acherontia styx* were studied. The results showed that the yellow and black pigments which in the lady beetle adults wings have many elements such as carbon, nitrogen, oxygen, potassium, phosphor, sulphur, chloride and calcium. Magnesium, phosphor, sulphur and calcium not found in the posterior wings (which known that a membrane). The dragon fly adult also has a yellow pigment in all anterior and posterior wings. The results showed that the yellow pigment has silicon in yellow pigment except in central veins of wings. Carbon, nitrogen, oxygen, potassium, sodium and chloride were found in white grub adult wings. The adult of sphingid moth (which have yellow and black pigment in anterior and posterior wings) has silicon, aluminum and chloride which known as the main component in solar cell system. These elements were found in the yellow pigment in the anterior wings. Silicon and chloride not found in the black pigment in the adult wings. Data cleared that the flying insects use the colour in their wings as a solar system to generate the power. This mechanism can be used as an alternative source of energy in nature." 12791. Rajabi, H.; Darvizeh, A. (2013): Experimental investigations of dragonfly wings functional morphology. *Chinese Phys. B* 22(8) 088702: 8 pp. (in English) ["Nowadays, the importance of identifying the dragonfly flight mechanism, as an inspiration for designing flapping wing vehicles, is well known. Experimental approach to understanding the complexities of the insect wings, as organs of flight, could provide significant outcomes for designing purposes. In this paper, a comprehensive investigation is carried out on the morphological and microstructural features of dragonfly wings. Scanning electron microscopy (SEM) and tensile testing are used to experimentally verify the functional roles of different parts of the wings. A number of SEM images of the wing elements such as nodus, leading edge, trailing edge, and vein sections, which play dominant roles in strengthening the whole structure, are presented. The

results from the tensile tests indicate that the nodus might be the critical region of the wings subjected to high tensile stresses. Considering the patterns of the longitudinal corrugations of the wings obtained in this paper, it can be supposed that they increase the load-bearing capacity, giving the wings an ability to tolerate dynamic loading conditions. In addition, it may be suggested that the longitudinal veins, leading, and trailing edges are structural mechanisms to further improve fatigue resistance by providing higher fracture toughness, preventing crack propagation, and allowing the wings to sustain a significant amount of damage without loss of strength." 12792. Rákósy, L.; Heiser, M.; Mancu, C.-O.; Schmitt, T. (2013): Strong divergences in regional distributions in Romania: recent ecological constraints in dragonflies (Odonata) versus ancient biogeographical patterns in butterflies (Lepidoptera: Rhopalocera). *Insect Conservation and Diversity* 6(2): 145-154. (in English) ["(1.) While the biogeographical structuring of Europe as a whole is already relatively well understood, patterns at the more regional scale are still poorly explored. Especially the influence of differing ecological demands among species groups on regional distribution patterns is mostly unresolved. Therefore, we compare the distributions of strictly terrestrial butterflies with those of semi-aquatic dragonflies. (2.) We analysed a regionalised distribution of the 196 butterfly and 68 dragonfly taxa of Romania with cluster analyses and principal component analyses, and worked out the different faunal regions and faunal elements for this country. (3.) We obtained a clear regional structuring for the butterflies (e.g. Transylvanian Basin, Carpathians, SE Romania, W/SW Romania), but only a vertical structuring in the dragonflies from the Danube lowlands to the elevations of the Carpathians. (4.) This structure implies a recent distribution trigger based on ecological and climatic constraints in dragonflies with water and energy availability being of high importance. (5.) The more ancient biogeographical pattern in butterflies reflects the different biogeographical elements of Europe and the connections of the Carpathian regions to the Balkan Peninsula and the Eastern European steppes, with energy being of considerably higher importance for butterfly occurrences than water availability." 12793. Riva-Murray, K.; Bradley, P.M.; Chasar, L.C.; Button, D.T.; Brigham, M.E.; Scudder Eikenberry, B.C.; Journey, C.A.; Lutz, M.A. (2013): Influence of dietary carbon on mercury bioaccumulation in streams of the Adirondack Mountains of New York and the Coastal Plain of South Carolina, USA. *Ecotoxicology* 22: 60-71. (in English) ["We studied lower food webs in streams of

two mercury-sensitive regions to determine whether variations in consumer foraging strategy and resultant dietary carbon signatures accounted for observed within-site and amongsite variations in consumer mercury concentration. We collected macroinvertebrates (primary consumers and predators [including Aeshnidae and Libellulidae]) and selected forage fishes from three sites in the Adirondack Mountains of New York, and three sites in the Coastal Plain of South Carolina, for analysis of mercury (Hg) and stable isotopes of carbon ($\delta^{13}\text{C}$) and nitrogen ($\delta^{15}\text{N}$). Among primary consumers, scrapers and filterers had higher MeHg and more depleted $\delta^{13}\text{C}$ than shredders from the same site. Variation in $\delta^{13}\text{C}$ accounted for up to 34 % of within-site variation in MeHg among primary consumers, beyond that explained by $\delta^{15}\text{N}$, an indicator of trophic position. Consumer $\delta^{13}\text{C}$ accounted for 10 % of the variation in Hg among predatory macroinvertebrates and forage fishes across these six sites, after accounting for environmental aqueous methylmercury (MeHg, 5 % of variation) and base-N adjusted consumer trophic position ($D\delta^{15}\text{N}$, 22 % of variation). The $\delta^{13}\text{C}$ spatial pattern within consumer taxa groups corresponded to differences in benthic habitat shading among sites. Consumers from relatively more-shaded sites had more enriched $\delta^{13}\text{C}$ that was more similar to typical detrital $\delta^{13}\text{C}$, while those from the relatively more-open sites had more depleted $\delta^{13}\text{C}$. Although we could not clearly attribute these differences strictly to differences in assimilation of carbon from terrestrial or inchannel sources, greater potential for benthic primary production at more open sites might play a role. We found significant variation among consumers within and among sites in carbon source; this may be related to within-site differences in diet and foraging habitat, and to among-site differences in environmental conditions that influence primary production. These observations suggest that different foraging strategies and habitats influence MeHg bioaccumulation in streams, even at relatively small spatial scales. Such influence must be considered when selecting lower trophic level consumers as sentinels of MeHg bioaccumulation for comparison within and among sites." 12796. Rudolf, V.H.W.; Rasmussen, N.L. (2013): Ontogenetic functional diversity: Size-structure of a keystone predator drives functioning of a complex ecosystem. Ecology 94(5): 1046-1056. (in English) ["A central challenge in community ecology is to understand the connection between biodiversity and the functioning of ecosystems. While traditional approaches have largely focused on species-level diversity, increasing evidence indicates that there exists substantial ecological diversity among individuals within species. By far, the largest source of this intraspecific diversity stems from variation among individuals in ontogenetic stage and size. Although such ontogenetic shifts are ubiquitous in natural communities, whether and how they scale up to influence the structure and functioning of complex ecosystems is largely unknown. Here we take an experimental approach to examine the consequences of ontogenetic niche shifts for the structure of communities and ecosystem processes. In particular we experimentally manipulated the stage-structure in a keystone predator, larvae of the dragonfly *Anax junius*, in complex experimental pond communities to test whether changes in the population stage/size-structure of a keystone species scale up to alter community structure and ecosystem processes, and how functional differences scale with relative differences in size among stages. We found that the functional role of *A. junius* was stage specific. Altering what stages were present in a pond lead to concurrent changes in community structure, primary producer biomass (periphyton and phytoplankton), and ultimately altered ecosystem processes (respiration and net primary productivity), indicating a strong, but stage-specific trophic cascade. Interestingly the stage-specific effects did not simply scale with size or biomass of the predator, but instead indicated clear ontogenetic niche shifts in ecological interactions. Thus, functional differences among stages within a keystone species scaled up to alter the functioning of entire ecosystems. Therefore, our results indicate that the classical approach of assuming an average functional role of

a species can be misleading because functional roles are dynamic and will change with shifts in the stage-structure of the species. In general this emphasizes the importance of accounting for functional diversity below the species level to predict how natural and anthropogenic changes alter the functioning of natural ecosystems." (2013): Ontogenetic shifts in male mating preference and morph-specific polyandry in a female colour polymorphic insect. BMC Evolutionary Biology 2013, 13:116 doi:10.1186/1471-2148-13-116: 11 pp. (in English) ["Background: Sexual conflict over mating rates may favour the origin and maintenance of phenotypes with contrasting reproductive strategies. The damselfly *Ischnura elegans* is characterised by a female colour polymorphism that consists of one androchrome and two gynochrome female morphs. Previous studies have shown that the polymorphism is genetic and to a high extent maintained by negative frequency-dependent mating success that varies temporally and spatially. However, the role of learning in male mating preferences has received little attention. We used molecular markers to investigate differences in polyandry between female morphs. In addition, we experimentally investigated innate male mating preferences and experience-dependent shifts in male mating preferences for female morphs. Results: Field and molecular data show that androchrome females were less polyandrous than gynochrome females. Interestingly, we found that naïve males showed significantly higher sexual preferences to androchrome than to gynochrome females in experimental trials. In contrast, experienced males showed no preference for androchrome females. Conclusions: The ontogenetic change in male mate preferences occurs most likely because of learned mate recognition after experience with females, which in this case does not result in a preference for one of the morphs, but rather in the loss of an innate preference for androchrome females." 12799. Sanford, M.R.; Ramsay, S.; Cornel, A.J.; Marsden, C.D.; Norris, L.C.; Patchoke, S.; Fondjo, E.; Lanzaro, G.C.; Lee, Y. (2013): A preliminary investigation of

the relationship between water quality and *Anopheles gambiae* larval habitats in western Cameroon. *Malaria Journal* 2013, 12:225: 8 pp. (in English) ["Background: Water quality and anopheline habitat have received increasing attention due to the possibility that challenges during larval life may translate into adult susceptibility to malaria parasite infection and/or insecticide resistance. Methods: A preliminary study of *Anopheles gambiae* s.s. larval habitats in the north-west and south-west regions of Cameroon was conducted in order to detect associations between *An. gambiae* s.s. molecular form and 2La inversion distributions with basic water quality parameters. Water quality was measured by temperature, pH, conductivity, total dissolved solids (TDS) at seven sites in Cameroon and one site in Selinkenyi, Mali. Results: Principal components and correlation analyses indicated a complex relationship between 2La polymorphism, temperature, conductivity and TDS. Cooler water sites at more inland locations yielded more S form larvae with higher 2La inversion polymorphism while warmer water sites yielded more M form larvae with rare observations of the 2La inversion. Discussion: More detailed studies that take into account the population genetics but also multiple life stages, environmental data relative to these life stages and interactions with both humans and the malaria parasite may help us to understand more about how and why this successful mosquito is able to adapt and diverge, and how it can be successfully managed. ... There were no known predatory insects observed in the pools the mosquitoes were collected from at the time of collections. No beetles, dragonfly nymphs or aquatic hemipterans were observed. However, it is possible that predatory mosquito larvae may have been present as they would have been impossible to differentiate by sight. However, no predatory mosquito larvae were collected in the reared and preserved samples. The correlation between the larval sex ratio and temperature was not statistically significant ($\chi^2 = 11.433$, d.f. = 6, $P = 0.076$)."] (Authors)] Address: Lee, Y., Vector Genetics Laboratory, School of Veterinary Medicine, Univ. of California, Davis, CA, USA. 12804. Schulte, L.M.; Schulte, R.; Lötters, S. (2013): Avoiding predation: The importance of chemical and visual cues in poison frog reproductive behaviour. *Chemical Signals in Vertebrates* 12: 309-321. (in English) ["The detection of biological signals is especially important in predator-prey systems. Anuran amphibians have evolved a remarkable diversity of defense strategies against predators, but the most risk-free is the prevention of a possible danger. This is valid for the protection of offspring as well. The Neotropical poison frog *Ranitomeya variabilis* deposits both eggs and tadpoles in phytotelmata. The exploitation of these small pools is advantageous as it lowers the risk of offspring predation compared to larger water bodies. Nonetheless, there are potential predators in these pools as well. We analysed how the parent frogs avoid conspecific cannibalistic tadpoles and damselfly larvae of the species *Microstigma rotundatum*. We compared the use of chemical and visual cues and show that *R. variabilis* avoids conspecific tadpoles for the deposition of its offspring using chemical cues, while visual tadpole models alone were not avoided by the frogs. Damselfly larvae in contrast were avoided when present, but could not be detected by chemical cues alone. We suggest that the invertebrate predators mask their chemical cues, forcing the frogs to use other senses to detect them." 12807. Seymour, R.S.; Matthews, P.G.D. (2013): Physical gills in diving insects and spiders: theory and experiment. *J. Exp. Biol.* 216: 164-170. (in English) ["Insects and spiders rely on gas-filled airways for respiration in air. However, some diving species take a tiny air-store bubble from the surface that acts as a primary O₂ source and also as a physical gill to obtain dissolved O₂ from the water. After a long history of modelling, recent work with O₂-

sensitive optodes has tested the models and extended our understanding of physical gill function. Models predict that compressible gas gills can extend dives up to more than eightfold, but this is never reached, because the animals surface long before the bubble is exhausted. Incompressible gas gills are theoretically permanent. However, neither compressible nor incompressible gas gills can support even resting metabolic rate unless the animal is very small, has a low metabolic rate or ventilates the bubble's surface, because the volume of gas required to produce an adequate surface area is too large to permit diving. Diving-bell spiders appear to be the only large aquatic arthropods that can have gas gill surface areas large enough to supply resting metabolic demands in stagnant, oxygenated water, because they suspend a large bubble in a submerged web." 12808. Shanku, A.G.; McPeck, M.A.; Kern, A.D. (2013): Functional annotation and comparative analysis of a zygopteran transcriptome. *G3 - Genes, Genomes, Genetics* 3: 763-770. (in English) ["In this paper we present a de novo assembly of the transcriptome of the damselfly, *Enallagma hageni*, through the use of 454 pyrosequencing. *E. hageni* is a member of the suborder Zygoptera within the order Odonata, and the Odonata are the basal lineage of the winged insects (Pterygota). To date, sequence data used in phylogenetic analysis of *Enallagma* species have been derived from either mtDNA or ribosomal nuclear DNA. This transcriptome contained 31,661 contigs that were assembled and translated into 14,813 individual open reading frames. Using these data, we constructed an extensive dataset of 634 orthologous nuclear protein-coding genes across 11 species of Arthropoda, and used Bayesian techniques to elucidate *Enallagma*'s place in the Arthropod phylogenetic tree. Additionally, we demonstrate that the *Enallagma* transcriptome contains 169 genes that are evolving at rates that differ relative to the rest of the transcriptome (29 accelerated and 140 decreased), and through multiple Gene Ontology searches and clustering methods, we present the first functional-annotation of any palaeopteran's transcriptome in the literature." (Authors)] Address: Shanku, A.G., Rutgers, The State University of New Jersey, Department of Genetics, Nelson Bio Labs-B416, 604 Allison Road, Piscataway, NJ 08854-8082. 12810. Sidagyte, E.; Višinskiene, G.; Arbaciauskas, K. (2013): Macroinvertebrate metrics and their integration for assessing the ecological status and biocontamination of Lithuanian lakes. *Limnologica - Ecology and Management of Inland Waters* 43(4): 308-318. (in English) ["We present an assessment system for determining the ecological status (eutrophication and land use pressures) and non-indigenous macroinvertebrate species (NIMS) specific deviation from naturalness of Lithuanian lakes, using semi-quantitative sampling of littoral macroinvertebrates. This system includes two integrated indices, the multimetric Lithuanian Lake Macroinvertebrate Index (LLMI) and the Fauna Autochthony Index (FAI). The LLMI, developed for the assessment of ecological status, averages four metrics: the conventional Average Score Per Taxon (ASPT) and the first Hill's number (H1), as well as the newly validated number of Coleoptera, Ephemeroptera and Plecoptera taxa (#CEP) and the proportion of Coleoptera, Odonata and Plecoptera individuals (COP). Furthermore, the metrics of biocontamination were transformed into the WFD-compliant FAI for the NIMS-specific naturalness evaluation. The LLMI had significant correlations with total phosphorus, total nitrogen, chlorophyll a, biochemical oxygen demand, water transparency, the morphoindex and the combined trophomorphoindex. Relationships between the LLMI or its core metrics and biocontamination were not found; thus the LLMI and the FAI are not interdependent and have the advantage of separately accounting for pressures requiring different management techniques. Variation of the LLMI and the FAI did not differ between stony/pebbly and vegetated littoral mesohabitats suggesting that any of the mesohabitats or a multihabitat sampling technique can be suitable for a reliable evaluation of lake status. Aquatic beetles revealed themselves as good indicators of the trophic status, while caddisflies and conventional macroinvertebrate metrics ETO and EPT proved unworkable. The ineffectiveness of the latter metrics may be due to the relatively low trophic level in most of the studied lakes which resulted in an increment of caddisfly metrics with an increase of nutrient loads, as well as due to the susceptibility of caddisflies to the invasive species, the zebra mussel *Dreissena polymorpha* and amphipod *Pontogammarus robustoides*." 12814. Smolinský, R.; Gvoždík, L. (2013): Does developmental acclimatization reduce the susceptibility to predation in newt larvae? *Biological Journal of the Linnean Society* 108(1): 109-115. (in English) ["Many organisms respond to the heterogeneity of abiotic environmental conditions by plastic modifications of their phenotypes (acclimation or acclimatization). Despite considerable research efforts in this area, the beneficial (adaptive) effect of acclimation or acclimatization is still debated. We examined whether the development of newt larvae (*Ichthyosaura alpestris*) under different natural light and thermal conditions subsequently altered their susceptibility to predation in sun-exposed versus shaded tanks in nature. During predation trials in various light and temperature conditions, newt larvae that developed in sun-exposed warmer tanks consistently suffered from higher predation by dragonfly nymphs (*Aeshna cyanea*) compared to larvae from shaded or colder tanks. We conclude that higher sun exposure during embryonic and larval development negatively affects antipredator performance even in sun-exposed tanks: this result is inconsistent with the beneficial acclimation hypothesis." 12817. Subrero, E.; Poma, S.; Cucco, M. (2013): Gli Odonati come indicatori delle condizioni ambientali in aree di riqualificazione ambientale del Parco fluviale del Po. *Rivista piemontese di Storia naturale* 34: 127-146. (in Italian, with English summary) ["Odonata as bioindicators of restoration in the Po River Park.: Recently there has been an increase in environmental restoration activity aimed at restoring natural habitats in agricultural and/or degraded areas. Among the most threatened habitats the lowland wetlands show a particularly critical condition, due to human activities. In this study we used the Odonata (sampling the exuviae) as indicators of the effectiveness of environmental restoration. Our aim was to collect information about ecological succession of species in areas subject to management, and to assess the time necessary to reach the characteristics of natural wetlands. To this end, in the territory of the Po river Park (Piedmont, Italy), we compared 6 sites resulting from environmental remediation and 5 of natural origin. For each site, in May-September 2011, we collected quantitative sampling of Odonata exuviae (28 species found), qualitative surveys of prevalent aquatic plants (presence/absence), environmental physical-chemical parameters (pH, temperature, conductivity, dissolved oxygen), and we measured the cover of 16 land use categories near the sampling sites. The multivariate statistical analysis (Correspondence Analysis) showed that the Odonata population is related to the environmental condition in terms of land use and aquatic vegetation, while physical-chemical parameters were less important. The dragonfly species composition differed among sites resulting from environmental restoration, where the exuviae of *Ischnura elegans* and *Crocothemis erythraea* (pioneer species) were very abundant, and sites of natural origin, where the *C. erythraea* was absent and *I. elegans* was present in significantly small-

ler numbers, replaced by other more sensitive species. The site of Canale di Brema, characterized by lotic waters, is particularly relevant because exuviae belonging to the species *Gomphus flavipes* and *Ophiogomphus cecilia*, both included in the Habitats Directive 92/43/EEC lists, were found." (Authors)] Address: Subrero, Eerica, Università del Piemonte Orientale, DISIT, via T. Michel, 11 - 15121 Alessandria, Italy.

12818. Takahashi, Y.; Kawata, M. (2013): Alternative trait combinations and secondary resource partitioning in sexually selected color polymorphism. *Ecology and Evolution* 3(7): 2038-2046. (in English) ["Resource partitioning within a species, trophic polymorphism is hypothesized to evolve by disruptive selection when intra-specific competition for certain resources is severe. However, in this study, we reported the secondary partitioning of oviposition resources without resource competition in the damselfly *Ischnura senegalensis*. In this species, females show colour polymorphism that has been evolved as counteradaptation against sexual conflict. One of the female morphs is a blue-green (andromorph, male-like morph), whereas the other morph is brown (gynomorph). These female morphs showed alternative preferences for oviposition resources (plant tissues); andromorphs used fresh (greenish) plant tissues, whereas gynomorphs used decaying (brownish) plants tissues, suggesting that they chose oviposition resources on which they are more cryptic. In addition, the two-colour morphs had different egg morphologies. Andromorphs have smaller and more elongated eggs, which seemed to adapt to hard substrates compared with those of gynomorphs. The resource partitioning in this species is achieved by morphological and behavioural differences between the colour morphs that allow them to effectively exploit different resources. Resource partitioning in this system may be a by-product of phenotypic integration with body colour that has been sexually selected, suggesting an overlooked mechanism of the evolution of resource partitioning. Finally, we discuss the evolutionary and ecological consequences of such resource partitioning." 12819. Takahashi, Y.; Kawata, M. (2013): A comprehensive test for negative frequency-dependent selection. *Population Ecology* 55(3): 499-509. (in English) ["Understanding the mechanisms that maintain genetic diversity within a population remains a primary challenge for evolutionary biology. Of the processes capable of maintaining variation, negative frequency-dependent selection (NFDS), under which rare phenotypes (or alleles) enjoy a high fitness advantage, is suggested to be the most powerful. However, few experimental studies have confirmed that this process operates in nature. Although a lot of suggestive evidence

has separately been provided in various polymorphic systems, these are not enough to prove the existence of NFDS in each system. Here we present a general review of NFDS and point out some problems with previous works to develop reasonable alternative research strategies for testing NFDS. In the second half of this paper, we focused on NFDS in *Ischnura senegalensis*, that shows female-limited genetic polymorphism. We show (1) the proximate causal mechanisms of the frequency-dependent process, (2) frequency-dependent inter-morph interaction, (3) rare morph advantage and (4) morph frequency oscillations in a natural population. These results provide unequivocal empirical support for NFDS in a natural system." (Authors)] Address: Takahashi, Y., Division of Ecology and Evolutionary Biology, Graduate School of Life Sciences, Tohoku University, 6-3 Aoba, Aramaki, Aoba, Sendai, Miyagi, 890-8578, Japan. 12820. Talucdher, R.; Shivakumar, K. (2013): Tensile properties of veins of damselfly wing. *Journal of Biomaterials and Nanobiotechnology* 4: 247-255. (in English) ["Microtension test of Costa and Radius veins of damselfly (*Lestes* sp.) wing was conducted to measure tensile strength and modulus. The specimens were classified into fresh and dry depending on when the samples were prepared and tested. Fresh samples tested immediately after extracting from the fly while the dry samples were tested one year after extraction and stored in a desiccator. Measured load-displacement response and fracture load were used to calculate modulus and strength. Field Emission Scanning Electron Microscope was used to measure the fracture morphology and cross-section of the vein. The results showed that the veins are brittle and fracture surface is flat. The average strength (232 - 285 MPa) and modulus (14 - 17 GPa) of the Costa and Radius veins were nearly same for both fresh and dry samples. The tensile modulus of the veins was 8% - 10% higher than the indentation (compressive) modulus and was nearly the same as that of human bones." 12828. Van, K.D.; Janssens, L.; Debecker, S.; De Jong, M.; Lambret, P.; Nilsson-Örtman, V.; Bervoets, L.; Stoks, R. (2013): Susceptibility to a metal under global warming is shaped by thermal adaptation along a latitudinal gradient. *Global Change Biology* 19(9): 2625-2633. (in English) ["Global warming and contamination represent two major threats to biodiversity that have the potential to interact synergistically. There is the potential for gradual local thermal adaptation and dispersal to higher latitudes to mitigate the susceptibility of organisms to contaminants and global warming at high latitudes. Here, we applied a space-for-time substitution approach to study the thermal dependence of the susceptibility of *Ischnura elegans* damselfly larvae to zinc in a common garden warming experiment (20°C and 24°C) with replicated

populations from three latitudes spanning >1500 km in Europe. We observed a striking latitude-specific effect of temperature on the zinc-induced mortality pattern; local thermal adaptation along the latitudinal gradient made Swedish, but not French, damselfly larvae more susceptible to zinc at 24°C. Latitude- and temperature-specific differences in zinc susceptibility may be related to the amount of energy available to defend against and repair damage since Swedish larvae showed a much stronger zinc-induced reduction of food intake at 24°C. The pattern of local thermal adaptation indicates that the predicted temperature increase of 4°C by 2100 will strongly magnify the impact of a contaminant such as zinc at higher latitudes unless there is thermal evolution and/or migration of lower-latitude genotypes. Our results underscore the critical importance of studying the susceptibility to contaminants under realistic warming scenarios taking into account local thermal adaptation across natural temperature gradients." (in English) ["The Odonata fauna of Balabac Island, Philippines was studied in March 2013. A total of 41 species under 33 genera were recorded. 28 species were recorded for the first time in the island. One genus - *Mortonagrion* was recorded for the first time in the Philippines. *Mortonagrion astamii* spec. nov. and *Prodasineura poncei* spec. nov. are new to science and are described. Three previously recorded species remained elusive and not seen during the survey." (Au-

thors)] Address: Villanueva, R.J.T., D3C Gahol Apartment, Lopez Jaena St., PH-8000 Davao, Philippines. E-mail: rjtvillanueva@gmail.com

12831. Wagler, R.; Wagler, A. (2013): Knowledge of arthropod carnivory and herbivory: Factors influencing preservice elementary teacher's attitudes and beliefs toward arthropods. *International Journal of Environmental & Science Education* 8(2): 303-318. (in English) ["Human negativity toward arthropods has been well documented but the factors that contribute to this negativity have been elusive. This study explored knowledge of arthropod carnivory (including *Hagenius brevistylus*) and herbivory as possible casual factors that contribute to the negative tendencies preservice elementary teachers have toward most arthropods. Specifically, this study investigated the effect knowledge of arthropod carnivory and herbivory had on United States kindergarten through sixth grade preservice elementary teacher attitude toward that arthropod and belief concerning the likelihood of incorporating information about that specific arthropod into their future science classroom. A cluster randomized design with a control group was used for the study. The treatment group consisted of 147 preservice elementary teachers and the control group consisted of 151. Unique to this study is the finding that arthropod carnivory and herbivory are causal factors that strongly affect preservice elementary teacher attitude and belief toward arthropods. When the participants of the study were made aware that an arthropod they thought was a herbivore was actually a carnivore, their attitude and likelihood of incorporation significantly declined. When the participants of the study were made aware that an arthropod they thought was a carnivore was actually a herbivore, their attitude and likelihood of incorporation significantly increased. Implications and future research are discussed." (Authors)] Address: Wagler, R., The University of Texas at El Paso, Department of Teacher Education, 500 West University Avenue, Education Building 601, El Paso, TX 79968, USA. 12832. Walker, P.D.; Wijnhoven, S.; van der Velde, G. (2013): Macrophyte presence and growth form influence macroinvertebrate community structure. *Aquatic Botany* 104: 80-87. (in English) ["Multivariate analysis demonstrated that macroinvertebrate assemblages of macrophyte-dominated sub-habitats within a small eutrophic pond differed markedly from those of Bottom substrate and Open water habitats. Certain habitats (e.g. *Nymphaea* and *Phragmites*) appeared to be quite similar in their macroinvertebrate communities, whereas others appeared to be very distinct in terms of the species composition (e.g. Open water habitat). Analysis of functional feeding groups also revealed differences between habitats in terms of the community structure. Again, the Open water habitat exhibiting the most marked difference. Macrophyte growth form does not cause significant differences in macroinvertebrate species richness

and diversity but it has a significant effect on macroinvertebrate abundance. Habitats consisting of highly branched and dissected macrophyte growth forms provide more food resources and microhabitats supporting larger numbers of macroinvertebrates than macrophytes with firm undissected stalks and leaves. This study highlights the importance of maintaining the ecological quality of small freshwater habitats in order to promote macrophyte growth and thus maintain a high level of species richness within such ecosystems. Highlights: *We investigated how macrophytes influence macroinvertebrate communities, which is useful for predicting overall biodiversity. *The data presented show interesting results with respect to presence and growth form of the macrophytes within a single aquatic system. *Previous studies often used artificial structures/plants in waters with different physico-chemical conditions making comparisons difficult. *This study employed an alternative approach to minimise variation due to season, physico-chemical conditions and spatial variation." (Authors) The list of taxa includes *Ischnura elegans*, *Enallagma cyathigerum* and *Aeshna grandis*.] Address: Walker, P.D., Dept of Animal Ecology & Ecophysiology, Inst. for Water and Wetland Research, Faculty of Science, Radboud Univ. (2013): Description of *Rhinocypha taiwana* sp. nov. from Taiwan, with a preliminary molecular phylogenetic analysis of the *Rhinocypha drusilla*-group (Odonata: Chlorocyphidae). *International Journal of Odonatology* 16(1): 93-107. (in English) ["*Rhinocypha taiwana* Wang & Chang, sp. nov. is described and illustrated for both sexes. The genetic distance of the cytochrome c oxidase I (COI) gene in *R. taiwana* and related species ranges from 4.2% to 10.4%. *R. taiwana* is shown to be a good species based on morphological and genetic criteria. It also is clearly retrieved as a distinct species based on COI phylogenetic analysis. The *R. drusilla* group is proposed and defined by a combination of characteristics which distinguish them from all other *Rhinocypha* species: male abdomen with reddish orange markings and S2 with a unique dorsal spade-shaped or similar marking. A key to the males of the six species of the *R. drusilla* group is provided. Two morphologically distinct continental species, *R. drusilla* and *R. arguta*, are shown to have a rather small genetic distance, only 1.2–1.7%. More material from the continental populations of this group is needed for further morphological and molecular studies." 12835. Waters, R.M.; Burghardt, G.M. (2013): Prey availability influences the ontogeny and timing of chemoreception-based prey shifting in the Striped Crayfish Snake, *Regina alleni*. *Journal of Comparative Psychology* 127(1): 49-55. (in English) ["Striped crayfish snakes (*Regina alleni*) undergo a dietary shift from dragonfly larvae to crayfish during ontogeny. Godley (1980) suggested that this shift is attributable to crayfish availability rather than an initial preference for dragonfly larvae. We experimentally tested this hypothesis by measuring the chemosensory response of newborn snakes to prey odors at 2 ages and also after they were fed on either dragonfly larvae or crayfish. The results show that *R. alleni* respond equally to dragonfly larvae, hard crayfish, and soft crayfish before feeding experience. We also show that the maintenance of this preference over fish and control stimuli is subsequently determined by the prey type encountered, through an unusual interaction. Snakes fed dragonfly larvae increased their chemosensory response to both dragonfly larvae and crayfish, whereas snakes fed crayfish increased their response only to crayfish. Our study demonstrates that innate chemosensory responses to prey can be modified by prey availability and that they do not necessarily result from maturation alone. Such plasticity has adaptive value to newborn animals that must fend for themselves from birth and respond to changing environmental conditions." 12838. Wiederman, S.D.; Shoemaker, P.A.; O'Carroll, D.C. (2013): Correlation between OFF and ON channels underlies dark target selectivity in an insect visual

system. *The Journal of Neuroscience* 33(32): 13225-13232. (in English) ["In both vertebrates and invertebrates, evidence supports separation of luminance increments and decrements (ON and OFF channels) in early stages of visual processing (Hartline, 1938; Joesch et al., 2010); however, less is known about how these parallel pathways are recombined to encode form and motion. In *Drosophila*, genetic knockdown of inputs to putative ON and OFF pathways and direct recording from downstream neurons in the wide-field motion pathway reveal that local elementary motion detectors exist in pairs that separately correlate contrast polarity channels, ON with ON and OFF with OFF (Joesch et al., 2013). However, behavioural responses to reverse-phi motion of discrete features reveal additional correlations of the opposite signs (Clark et al., 2011). We here present intracellular recordings from feature detecting neurons in the dragonfly that provide direct physiological evidence for the correlation of OFF and ON pathways. These neurons show clear polarity selectivity for feature contrast, responding strongly to targets that are darker than the background and only weakly to dark contrasting edges. These dark target responses are much stronger than the linear combination of responses to ON and OFF edges. We compare these data with output from elementary motion detector-based models (Eichner et al., 2011; Clark et al., 2011), with and without stages of strong center-surround antagonism. Our data support an alternative elementary small target motion detector model, which derives dark target selectivity from the correlation of a delayed OFF with an undelayed ON signal at each individual visual processing unit (Wiederman et al., 2008, 2009)." 12839. Wiederman, S.D.; Shoemaker, P.A.; O'Carroll, D.C. (2013): Modeling selective attention in an insect visual neuron. 6th Australian Workshop on Computational Neuroscience The University of Melbourne 30-31 January 2013: 68. (in English) [Verbatim: Whether considering a lion focused on a single zebra within a panicked herd, or a dragonfly capturing flies amidst swarms of prey and conspecifics, each animal selects a single object amongst distracting stimuli. Little is known about the neuronal mechanisms that allow animals to accomplish this 'attentional' task. Diverse evidence from functional imaging and physiology to psychophysics, highlights the importance of 'competitive selection' in attention for vertebrates, artificial intelligence and even in fruitflies. Although direct neural correlates for such attention are scarce, we have recently demonstrated responses from an identified dragonfly visual neuron, the 'centrifugal small target motion detector' (CSTMD1), that perfectly match a model for competitive selection within the limits of neuronal variability ($r^2=0.83$). Responses of CSTMD1 to individual moving targets differ in both magnitude and time course depending on loca-

tion of the target within the cell's receptive field. However, responses to two simultaneous targets almost always match those elicited by one of the two targets acting alone. Successive repetition of stimulus pairs over variable sizes, separation and contrasts all elicit responses equivalent to single targets, regardless of whether the 'winner' is the stronger stimulus if presented by itself. Here we examine winner-takes-all networks as putative components of the small target detection system, considering biologically plausible implementations and how they might contribute to the physiological responses of CSTMD1. By examining such competitive selection models we gain insight into how the pre-synaptic elements to CSTMD1 could be arranged to permit the 'absolute' encoding of a single target in a multiple target environment.] Address: Wiederman, S.D., Adelaide Centre for Neuroscience Research, School of Medical Sciences, The University of Adelaide, Adelaide, SA 5005, Australia

12840. Wiesenborn, W.D. (2013): Phosphorus contents in desert riparian spiders and insects vary among taxa and between flight capabilities. *Florida Entomologist* 96(2): 424-432. (in English) ["Phosphorus occurs in a variety of biological molecules including DNA and RNA, ATP and other adenine nucleotides, phosphorylated metabolites, and phospholipids. Variation in phosphorus content among spiders and insects would influence the element's uptake by insectivorous birds. I measured amounts of phosphorus in 3 families of spiders and 7 orders and 24 families of insects collected in riparian habitat next to the Colorado River in western Arizona. Relation between phosphorus mass and body dry-mass, $P \mu\text{g} = 9.6$ (body mg), in spiders and insects was not allometric. Phosphorus concentration, as a mean percentage of body dry-mass, was higher in spiders (1.33%) than in insects (0.96%). Phosphorus contents varied most among families but also among orders and genera. Insect predators contained higher phosphorus concentrations (1.01%) than insect herbivores (0.90%). Strong-flying insects, Odonata, Neuroptera, Diptera, and Hymenoptera except Formicidae, also contained higher phosphorus concentrations (1.04%) than weak flying or wingless insects (0.89%), Orthoptera, Hemiptera, Coleoptera, and Formicidae. Larger flight-muscles with higher concentrations of phosphorylated metabolites likely increase phosphorus contents in strong-flying insects. Birds that eat aerial insects may benefit from higher phosphorus contents in their prey." (Author)] Address: Wiesenborn, W.D., U.S. Bureau of Reclamation, Lower Colorado Regional Office, P.O. Box 61470, Boulder City, Nevada 89006, USA. E-mail: wwiesenborn@fastmail.fm

12841. Wildermuth, H. (2013): Entwicklung der Libellenfauna (Odonata) am Husemersee (Kanton Zürich) im Verlauf der letzten 130 Jahre. *Entomo Helvetica* 6: 7-21. (in German, with English and French summaries) ["Between 1885 and 2012 a total of 55 dragonfly species have been recorded in the Husemersee region.

While 14 of them have definitely disappeared, 31 species are still present and 10 are new to the locality. The locally extinct species are typical moorland species that have lost their habitats by intense peat exploitation during World War I and II. It is assumed that many of the newcomers have profited from the climate change. The extant dragonfly fauna is discussed in the context of the current habitat supply and measures for habitat management to promote the odonate populations are suggested." 12846. Zhang, H.-C.; Zheng, D.-R.; Wang, B.; Fang, Y.; Jarzembowski, E.A. (2013): The largest known odonate in China: *Hsiufua chaoi* Zhang et Wang, gen. et sp. nov. from the Middle Jurassic of Inner Mongolia. *Chinese Science Bulletin* 58(13): 1579-1584. (in English) ["A new genus and species, *Hsiufua chaoi* Zhang et Wang, is established based on a forewing from the Middle Jurassic Haifanggou Formation in Inner Mongolia, China and attributed to *Campteropteroidea*, *Isophlebioidea*, Odonata. It is the largest odonate known in China and the fourth in the world in terms of forewing length. The maximum size (based on forewing length) of Odonata is smaller in the Permian than in the Mesozoic which is probably due to competition for prey between Odonata and Protodonata in the Permian. The reason that the maximum size of Jurassic odonates is larger than that of their extant relatives is most probably less competition and lower predation pressure from contemporary aerial vertebrates." 12853. Miyashita, M. (1999): Studies on conservation and restoration of the habitat of the damselfly *Mortonagrion hirosei*. *Proc. Envir. Syst. Res.* 27: 293-304. (in Japanese, with English summary) [Japan; "M. hirosei, was designated as an endangered species by the Environment Agency in 1991, because its habitat is vulnerable to the effects of land reclamation and river improvement. The low-flying insect lives in reed plains and measures about three centimeters long when fully grown. Relationships between the habitat of the damselfly, salinity, topography and vegetation were studied at 9 tidal rivers from Hinuma marsh in Ibaraki Prefecture to the Nagaitaura Bay in the Tsushima Islands. The larvae of the damselfly were collected only from the pool in a sunken place covered with dead leaves on the riverside. Salinity and the time required for the completion of the habitat of the damselfly were above 0.50.PERMIL. and about 4 years, respectively. The damselfly which lived on the riverside at Suigo-ohashi bridge across the Tonegawa River died out in 1998, because of reduced salinity of its habitat. It is supposed that the salinity of the habitat was the most important environmental element required for holding communities of the damselfly." (Author)]

12854. Orr, R. (1999): The dragonflies and damselflies of the Cove Point LNG Site, Calvert county, Maryland. <http://www.covepoint-trust.org/reports/orr-001.pdf>: 31 pp. (in English) ["The Cove Point Liquid Natural Gas Site (Cove Point Site) consists of 900 acres of undeveloped property in Calvert County, Maryland. The property is owned by the Cove Point LNG Limited Partnership and approximately 600 acres are subject to a conservation easement that was granted to the Maryland Environmental Trust and The Nature Conservancy to oversee. The Cove Point Site borders the western shore of the Chesapeake Bay, just south of Calvert Cliffs. A wide variety of pristine and managed aquatic water habitats oc-

cur at the Site including marshes, ponds, streams, and seeps. A survey was conducted for the Odonata of the Cove Point Site during 1998 and 1999 under a Cove Point Natural Heritage Trust Research Contract. Field data were collected on June 5, July 7, July 29, August 22, September 11, September 30, October 14 and December 2 in 1998. In 1999 field data were collected on January 3, March 31, April 23, April 30, May 21, June 6, July 8, September 3, and October 7. The survey was based mostly on adult odonates, but limited cast skins and larvae were also sampled. The species, date and habitat (along with any note-worthy behaviour or life-history observations) were recorded for 10,916 individual dragonflies and damselflies over the course of the survey. 53 species of Odonata were recorded at the Cove Point Site during the 1988-1999 season. 24 species were first records for Calvert County. *Gomphus rogersi*, is ranked as S1 in Maryland. *Cordulegaster bilineata* and *Somatochlora filosa* have tentative ranks of S2, *Archilestes grandis*, *Amphiagrion saucium*, *Anax longipes*, *Gomphaeschna furcillata*, *Celithemis fasciata*, and *Libellula axilena* have tentative ranks of S3. 34. *Erythemis simplicicollis* -- Eastern Pondhawk: *E. simplicicollis* hunts by staying on the ground and flying up to capture prey in the air. An interesting behavioural observation was noticed between the Eastern Pondhawk and one of its prey animals the tiger beetle *Cicindela hirticollis*, on the beach at Cove Point. The dragonfly would only take the tiger beetle when it was in flight which would occasionally happen when I disturbed the beetles while walking on the beach. If the beetle managed to land before being captured, the dragonfly would land next to it, often just a couple of inches away. I got the impression (but it does need to be further observed or tested) that the tiger beetle was behaviourally programmed to run and not fly away from the dragonfly -- thus avoiding capture. When I approached the tiger beetles they appeared to more readily take to the air than they did when a dragonfly was next to them. As a side note -- I have watched the Eastern Pondhawk hunt *Cicindela dorsalis* at Flag Ponds in the early 1990s but did not see any captured (only attempts). However, the Flag Ponds rangers informed me that they had seen them being taken. One thing that is for sure, is that at the beach at Cove Point, during the heat of the day, *E. simplicicollis* are an active predator of tiger beetles." 12857. Roy, A.H.; Rosemond, A.D.; Leigh, D.S.; Paul, M.J.; Wallace, J.B. (2003): Habitat-specific responses of stream insects to land cover disturbance: biological consequences and monitoring implications. *J. N. Am. Benthol. Soc.* 22(2): 292-307. (in English) ["Changes in catchment land cover can impact stream ecosystems through altered hydrology and subsequent increases in sedimentation and nonpoint-source pollutants. These stressors can affect habitat suitability and water quality for aquatic invertebrates. We studied the impact of a range of physical and chemical stressors on aquatic insects, and tested whether the effects of these stressors differed in 3 habitat types: riffles, pools, and banks. Our study was conducted in Piedmont streams in Georgia (USA) where catchment development pressure and the potential for aquatic biodiversity loss are high. We sampled 3 replicates of riffle, pool, and bank habitats within a 100-m reach of 29 streams (11-126 km²) that varied in catchment land cover. Correlations between environmental variables and aquatic insects (both richness and density) within habitat types indicated that riffle habitats (vs pool and bank habitats) exhibited the strongest relations with environmental variables. Riffle assemblages were negatively affected by both physical (e.g., bed mobility) and chemical (e.g., specific conductance, nutrient concentrations) variables. The density of aquatic insects in pools was also correlated to physical and chemical variables, but there were few relationships with pool or bank richness or bank density. Because of greater relative impacts of disturbance in riffles versus

banks, we found greater differences between riffle and bank richness in streams with greater sediment disturbance. The proportion of bank richness (bank richness / bank + riffle richness) increased with finer bed sediment ($r^2 = 0.43$) and increased bed mobility ($r^2 = 0.35$). We compared richness of facultative taxa (found in multiple habitats) between sites we characterized as minimally impacted and sediment-impacted. In riffles, richness of facultative taxa was lower in sediment-impacted vs minimally impacted sites (11.0 vs 20.2, $p = 0.002$, t-test), but was similar for both disturbance groups in banks (20.1 vs 22.7, $p > 0.05$, t-test). Our results suggest that taxa richness may be retained in bank habitats when riffle quality is poor and banks may serve as a refuge in highly disturbed systems. Such shifts in the distribution of benthos may be an early warning indicator of biotic impairment and have implications for biomonitoring and maintenance of habitat." (Authors) Taxa included Odonata and were treated at genus level.] Address: Roy, A.H., Institute of Ecology, The University of Georgia, Athens, Georgia 30602 USA. E-mail: aroy@uga.edu

12858. Zhu, C.-j.; Muraoka, J.; Mizuno, H. (2003): CG simulation of dragonflies based on aerodynamics. Information Processing Society of Japan SIG Notes 2003(15): 31-36. (in Japanese, with English summary) ["A dragonfly is a kind of familiar insect by which the sense of season can be shown. The expression of a dragonfly by CG can be expected as an element which will improve the sense of season in landscape simulation, virtual reality, etc. In this paper, the flight model of a dragonfly, based on aerodynamics, is proposed. In this model, a dragonfly can be made to fly in real time considering the force caused by the flapping of the wings. Steep rise, sudden stop, hover and rapid turn, which are the flight characteristics of a dragonfly, can be performed. Furthermore, depending on the control-points placed in the space, the flight route of a dragonfly can be established easily." (Authors)] Address: Zhu, C.-j., Tohoku Institute of Technology, Japan

12859. Bunnell, F.L.; Campbell, R.W.; Squires, K.A. (2004): Allocating scarce resources for conservation in a species-rich environment: Guidelines from history and science. In: T.D. Hooper, editor. Proceedings of the Species at Risk 2004 Pathways to Recovery Conference. March 2-6, 2004, Victoria, B.C. Species at Risk 2004 Pathways to Recovery Conference Organizing Committee, Victoria, B.C.: 1-20. (in English) ["British Columbia is one of the most species-rich areas in north temperate regions. Its size, location, and topography encourage small incursions of species that are more abundant elsewhere. Given this richness, the province faces formidable challenges in the allocation of limited resources to conservation. The importance of making wise decisions is revealed by recent reviews of North American recovery expenditures that suggest that about 50% of

efforts have failed. Fortunately, lessons from history and science can help formulate guidelines. Part of history's lesson is that we begin too late, and that more resources should be allocated to preemptive measures. We consider criteria to prioritize species and four classes of action appropriate to conditions in British Columbia that can be used to guide the allocation of resources in a cost-effective fashion. For example, about 93% of global bird extinctions since the 1600s have been island endemics. British Columbia hosts at least 90 endemic taxa, of which about 66% are island dwelling. Because centres of endemism are concentrated, preemptive monitoring plans based on a frequency that reflects natural history characteristics and known threats are possible. From a review of natural history characteristics, we have collated lists of species that are appropriate to specific conservation actions (summarized here) and provide a checklist that should precede development of a recovery plan for any specific taxon." (Authors) The paper included several references to Odonata.] Address: Bunnell, F.L., Forest Sciences Dept, University of British Columbia, 270 - 2357 Main Mall, Vancouver, BC, V6T 1Z4, Canada. 12860. Jiang, Y. (2004): *Sympetrum infuscatum* as a medicinal dragonfly species in Heilongjiang. Quarterly of Forest By-product and Speciality in China 4(GSNO. 71): 29-30. (in Chinese, with English summary) [China; *S. infuscatum* was analysed for nutrient contents (protein and fat content resulted in 56.22% and 22.93% resp.) and medical/pharmacological purposes in traditional Chinese medicine.] Address: Jiang, Yuxia, Dept of Biology, Mudangjiang Teachers College, Mudangjiang 157012, China

12861. Morrison, F.; McLain, D.; Sanders, L. (2004): Dragonfly abundance and emergence behavior before and after bank stabilization on the Connecticut River in Gill, Massachusetts. <http://www.odes.millersriver.net/Speakers/fredmorrison.htm>: (in English) [Verbatim: While stabilization has become an important tool for reducing excessive riverbank erosion, the impacts on emerging dragonflies are unknown. To investigate the effects of bank stabilization, we surveyed a 1200-ft. stretch of eroding bank on the Connecticut River in Gill, Massachusetts for emerging dragonfly species before (2001) and after (2002-2003) bank stabilization. The site was stabilized in fall 2001 by grading the slope, planting with native vegetation, and adding a rock footing at the average water line. We collected exuviae from the entire site at least weekly from early June to late July each year. We also observed the behaviour of nymphs in the process of emerging from the river. In 2003, we added 4 reference sites for comparison between stabilized and natural habitat. Several of the 15 species showed marked increases in abundance following stabilization. The most dramatic change was with *Gomphus vastus*, which increased from 357 in 2001 to 12,270 in 2003. *Gomphus abbreviatus*, *Stylurus spiniceps*, *S. amnicola*

and *Dromogomphus spinosus* were more abundant after stabilization, but declined in the third year of the study. *Neurocordulia yamaskanensis* and *Macromia illinoisensis* declined in the second year and were most abundant in the third year. *Gomphus ventricosus* was only common in the third year, while *G. fraternus* was absent following stabilization. The changes in abundance between years could not be differentiated between cause-and-effect and natural fluctuations. However, notable changes occurred in the behaviour of emerging nymphs. After stabilization, *G. abbreviatus*, *S. spiniceps*, *S. amnicola*, and *D. spinosus* eclosed close to the water line when the river level was low on the riprap. This behaviour made them susceptible to being splashed by boat waves and submerged by rapidly rising water level. These species were much more abundant at the natural reference sites than at the stabilized sites. Nymphs of *S. spiniceps* crawled a significantly ($\alpha = 0.05$) shorter distance on the riprap (0.9 ft.) than on natural banks (11.2 ft.). Mortality of *G. abbreviatus* from boat waves and rising water was as high as 33% in 2002. While the impact of riprap on dragonfly populations is unknown, the observed mortality indicates that standard-sized riprap does not provide a favourable substrate for dragonfly emergence. Alternative stabilization methods should be explored that incorporate dragonfly conservation.] Address: Morrison, F., A Natural Focus, Montague Rd, Westhampton, MA 01027, USA. 12865. Fenoglio, S.; Bo, T.; Agosta, P.; Cucco, M. (2005): Mass loss and macroinvertebrate colonisation of fish carcasses in riffles and pools of a NW Italian stream. *Hydrobiologia* 532: 111-122. (in English) ["In this study, we analysed the decomposition of trout carcasses in a low-order Apennine stream, with the aim to investigate the mass loss rate in a Mediterranean lotic system, and to examine the influence of microhabitats on the invertebrates colonising fish carcasses. In May 2003, we put 56 dead rainbow trout (*Oncorhynchus mykiss*) in the stream, placing seven sets (four trout each) in both riffle and pool habitats. At four dates, we removed one trout per set to measure its dry mass and determine the associated macroinvertebrate assemblage. Fifty-eight macroinvertebrate taxa colonised the carcasses, with significant differences between the erosive and depositional microhabitats. Riffle trouts hosted richer and denser colonist communities than pool trouts. Chironomidae, *Serratella ignita*, *Habrophlebia* sp., *Dugesia* sp. and *Protonemura* sp. were the five most abundant taxa. Decomposition was initially very rapid in both environments and then tapered off over time. The mass loss rate was higher ($k = 0.057 \text{ day}^{-1}$) than that found in other studies. Higher Mediterranean temperatures probably increase the process. Although we found no significant difference between riffles and pools, mass loss was more regular in erosive habitats, underlining the importance of local, small-scale conditions. In small, low-order, heterotrophic streams, fish carcasses represent an important resource and shelter for rich and diversified invertebrate assemblages." (Authors) *Calopteryx virgo*, *Onychogomphus* sp., *Boyeria irene*, and *Chalcolestes viridis* were found to have settled on the carcasses.] Address: Fenoglio, S., University of Eastern Piedmont, Di.S.A.V., Via Cavour 84, I-15100 Alessandria, Italy. 12867. Subramanian, K.A.; Sivaramakrishnan, K.G.; Gadgil, M. (2005): Impact of riparian land use on stream insects of Kudremukh National Park, Karnataka state, India. *Journal of Insect Science* 5:49: 10pp. (in English) ["The impact of riparian land use on the stream insect communities was studied at Kudremukh National Park located within Western Ghats, a tropical biodiversity hotspot in India. The diversity and community composition of stream insects varied across streams with different riparian land use types. The rarefied family and generic richness was highest in streams with natural semi evergreen forests as riparian vegetation. However, when the streams had human habitations and areca nut plantations as riparian land use type, the rarefied richness was higher than that of streams with natural evergreen forests and grasslands. The streams with scrub lands and iron ore mining as the riparian land use had the lowest rarefied richness. Within a landscape, the streams with the natural riparian vegetation had similar community composition. However, streams with natural grasslands as the riparian vegetation, had low diversity and the community composition was similar to those of paddy fields. We discuss how stream insect assemblages differ due to varied riparian land use patterns, reflecting fundamental alterations in the functioning of stream ecosystems. This understanding is vital to conserve, manage and restore tropical riverine ecosystems." (Authors) (Odonata) taxa were treated at the genus level.] Address: Subramanian, K.A., Centre for Ecological Sciences, Indian Institute of Science, Bangalore-560012, India. 12869. Karlsson, M. (2006): Relationship between mate-guarding strategies and the number of ovarioles in Libellulidae (Odonata). Master's thesis in Applied Ecol-

ogy at Halmstad University: 11 pp. ["In Libellulidae there are two types of egg-laying behaviour, non-contact guarding where the male accompany the female during oviposition and tandem guarding where the male is physically coupled with the female. These egg laying strategies also shows differences in egg size distribution and egg size. In species which perform non-contact guarding the egg size is inversely proportionate to the order of laying. In tandem species on the other hand, the egg size is more randomly distributed and the eggs are slightly larger than in non-contact species. To see if there is a difference in the female internal reproductive organs between the two guarding types, the ovariole number was counted. The result shows that in species which perform tandem guarding during oviposition have a fewer number of ovarioles compared to the non-contact species. This difference in ovariole number was also species specific. The impact on ecosystems is increasing and the survival of dragonflies or any other insects can no longer be taken for granted. Therefore this information can be valuable in conservation biology when new habitats are created for preservation of species." (Author) The following species were studied: (a) Non-contact guarders: *Trithemis kirbyi*, *Crocothemis erythraea*, *Leucorrhinia dubia*, *Libellula depressa* (b) Tandem guarders: *Sympetrum fonscolombii*, *Pantala flavescens*, *Philonomon luminans*, *Tramea basilare*, *Urothemis edwardsii*, *Diplacodes lefebvrii*, *S. vulgatum*, *S. danae*, *S. frequens*, *S. infuscatum*.] Address: not stated.

2007

12870. Campbell, W.B.; Novelo-Gutiérrez, R. (2007): Reduction in odonate phylogenetic diversity associated with dam impoundment is revealed using taxonomic distinctness. *Arch. Hydrobiol.* 168(1): 83-92. (in English) ["Taxonomic distinctness is a highly useful index combining species richness and taxonomic (phylogenetic) diversity to detect changes in the taxonomic structure of communities and assemblages. While analysis of an odonate assemblage before and after construction of a hydroelectric impoundment in the state of Hidalgo, Mexico, revealed no significant increase in average monthly species richness (although annual counts were slightly higher for the latter survey), taxonomic distinctness and its variation were reduced. The impoundment converted natural lotic conditions into lentic habitat with more littoral vegetation. Such conditions favoured plant-dependent species (mostly in the Zygoptera) with more species per genus and genera per family relative to those not dependent (mostly in the Anisoptera). High ratios reduce the average risk of losing higher taxonomic structure with loss of a species. Reduced taxonomic distinctness and its variation occurred at the expense of the Gomphidae and Corduliidae, and several genera in the Libellulidae having non-plant dependent species that favour inorganic substrate in flowing waters. The results contrast with the common assumption that higher odonate diversity occurs in lentic habitats. Seasonal pat-

terns of taxonomic distinctness appeared similar between surveys and may reflect reproductive and emergence cycles. The results support the use of taxonomic distinctness and its variation over species richness in ecological assessments and its application in further freshwater research. We encourage its use with aquatic insects, but recommend frequent sampling intervals to account for effects from emergence and reproductive behaviours. These results suggest new and added breadth to the value of taxonomic distinctness in ecological research regarding habitat change." (Authors)] Address: Novelo-Gutiérrez, R., Depto de Entomología, Instituto de Ecología A.C., Km 2.5. antigua carretera a Coatepec, Aparatdo Postal 63, 91000 Xalapa, Veracruz, Mexico. 12884. Dziock, F.; Wacowska, K.; Siegl, S.; Briesenick, T.; Ernst, R. (2009): Erfassung und Bewertung der Vorkommen der Asiatischen Keiljungfer und Grünen Flussjungfer an der Elbe bei Roßlau. *Naturschutz im Land Sachsen-Anhalt* 46 (Sonderheft): 169-175. (in German) [Exuviae of *Stylurus flavipes* and *Ophiogomphus cecilia* were quantitatively sampled in groynes along a stretch of river Elbe, Sachsen-Anhalt, Germany. The conservation status of the local populations was assessed and causes of threats (gravelling of the sandy habitats between goynes) were briefly discussed.] Address: not stated

12885. Landmann, A. (2009): Die Höhenverbreitung als Indikator der Gefährdung von Insekten im Alpenraum. *Contributions to Natural History* 12: 829-856. (in German, with English summary) ["Altitudinal distribution as an indicator of threat in insects: an analysis of red data books from the Alps and adjoining regions. — The Alps represent one of the most important biodiversity hot spots in Europe but at the same time are the most developed mountain system in the world. However, human impact is very uneven within alpine landscapes. Topographical conditions restrict the space available for agriculture, settlements, traffic systems and industrial development. Human activities therefore have a focus at valley bottoms and other suitable lowland areas. While large nearly pristine areas still can be found at higher elevations, high local population densities together with intensive tourism have led to an over-exploitation and strong fragmentation of natural habitats at lower altitudes. Specialised lowland species can thus be expected to be under disproportionately strong pressure and should show an unfavourable conservation status. By contrast, species (groups) with broader altitudinal distribution or with preferences for higher elevations should experience less threat and this pattern should be expressed in the red data books as well (percentage of endangered species, distribution over threat-

categories). This hypothesis was tested using data concerning altitudinal distribution and national as well as regional red data books from different areas within the Alps (Switzerland, Austria, Tyrol, Carinthia) and at its northern border (Lower Austria, Bavaria). Dragonflies and grasshoppers were used for analysis because good and recent data are available for both groups and most regions. Species were first grouped into two (Odonata) to three (Saltatoria) main classes regarding their regional altitudinal distribution patterns: "valley (lowland) species", "midmountain species", and "mountain species", and their threat status was compared (separately per region) thereafter. For Tyrol and Switzerland more detailed data about vertical distribution (e.g. the absolute stretch of vertical distribution; the number of altitudinal zones used) exist and were directly correlated with threat status (red data categories). Overall the percentage of species regarded as "safe" (LC = least concern species) in recent red data books was significantly higher in species (species groups) belonging to the "midmountain" and especially the "mountain" groups than in species of the "valley group". The groups (esp. "valley" vs. "mountain") also strongly differed in the overall patterns (dimensions) of threat, valley species exhibiting a much higher proportion of species within the highest categories (CR = critically endangered, EN = endangered). Differences between "valley" and "mountain" species were higher in central parts of the Alps but comparatively low at the northern edge of the Alps, in Lower Austria and Bavaria. This fits to differences in overall landscape settings because both latter regions offer more area and more suitable habitats for sensitive lowland species. Moreover, for dragonflies as well as for grasshoppers, there was a clear trend of decreasing threat with increasing number of altitudinal zones inhabited in the Tyrol and Switzerland. Altitudinal distribution patterns might therefore be a useful indirect indicator of conservation problems (threat status) for animal groups in the Alps and adjoining regions, especially when more direct measures (e.g. data about population trends) are not available. However, further analysis for more and different animal groups are needed and called for to test this hypothesis." Additional species of regional interest were *Orthetrum albistylum*, *Sympetrum pedemontanum*, *S. depressiusculum*, and *S. meridionale*.] Address: Aguzzi, S. c/o Dipto Biol. Anim., Univ. Pavia, Pavia, Italy

12889. Archer, M.W. (2010): Retention, movement, and the biotic response to large woody debris in the channelized Missouri River. M.Sc. Thesis, Graduate College at the University of Nebraska, Lincoln, Nebraska: X + 116 pp. (in English) ["Large woody debris (LWD) is an important component of a healthy aquatic ecosystem. However, little is known about the dynamics of LWD in a large, channelized river such as the Missouri River. My objectives were to first, assess the abundance of LWD found along the channelized portion of the Missouri River. Second, I documented movement of LWD that entered the river. Lastly, using PRIMER software I ana-

lyzed what effect, if any, river segments, bend types, and LWD had on the community composition of the macroinvertebrate and fish that inhabit the river. Abundance of LWD was greater along bends that have flow diverted away from the bank compared to bends that had recent modifications to divert flow to the shore (major modification bends) and areas with little bank armouring, such as, side channel chutes ($P < 0.05$). Recruitment of LWD into the river that could become available as aquatic habitat occurred mostly within 5 m of the bankfull width (BFW). Telemetry analysis of LWD showed that LWD located within the BFW of the river was often (63% of LWD) displaced downstream. Minimum distance of displaced LWD was 0.02 rkm, median distance was 146.50 rkm, and maximum distance was 1454.69 rkm. No differences were found in the community composition of macroinvertebrates between segments ($P = 0.43$) or between bend types (0.074). Community composition did differ between LWD and non-LWD sites ($P = 0.016$). Fish communities differed between the segments ($P = 0.043$) therefore further analyses were split between the segments. Segment 8 fish communities did not differ between bend types ($P = 0.35$) or between LWD and non-LWD sites ($P = 0.55$). Results were similar in Segment 9 (bend types ($P = 0.20$), LWD and non-LWD sites ($P = 0.19$)). Combining the macroinvertebrate communities and fish communities to test for differences in the combined biota community composition showed that differences did not exist between the segments ($P = 0.59$) or bend types ($p = 0.29$). However, the composition of the composite community was different between LWD and non-LWD sites ($P = 0.011$). My results suggest that while retention of LWD is low it still has an effect on the composition of the composite communities that inhabit the Missouri River." (Author Taxa including Odonata are treated at the order level.] Address: Archer, M.W., University of Nebraska at Lincoln, USA. E-mail: michael.archer@huskers.unl.edu

12890. Cobb, M. (2010): The damselfly enigma: better bigger or smaller? Outside JEB doi: 10.1242/?jeb.036665 September 1, 2010 J. Exp. Biol. 213: VI. (in English) [Verbatim: "Damselflies show abrupt, darting flight, which is the envy of aero-engineers. This amazing ability is used both to capture prey and, by males, to establish territories that can attract females. Insects are ectothermic, so maintaining this flying ability in the face of fluctuating environmental changes is a major challenge. Furthermore, body size has both a direct effect on manoeuvrability and an indirect effect, through its impact on heat retention. Two Japanese researchers from Kyoto University, Yuka Samejima and Yoshitaka Tsubaki, have studied how body size and temperature affect flight ability in this stunning insect. The damselfly they chose to study – *Mnais costalis* – lives by fast-flowing mountain streams and shows male polymorphism: orange-winged larger males tend to have territories while clear-winged smaller males do not. These morphs reflect different mating strategies, with smaller males

'sneaking' mating opportunities. The authors used an infrared thermographic camera to measure the surface temperature of males, which they manipulated in the laboratory by using a halogen lamp, and studied the flight performance of each male. They estimated maximum lifting force and size-corrected lifting force, which they measured by attaching weights to the insects' wings with fishing line. Size-corrected lifting force is an index of acceleration that is linked to the damselfly's superb aerial acrobatics. The authors found that both measures of flight performance were positively correlated with body temperature. This is not particularly surprising, as it is well known that insect flight muscle activity increases with temperature. However, although body size led to higher maximum lifting force, it was negatively correlated with size-corrected lifting force. Simply put, larger males were less agile. When the authors took their thermographic camera into the field, they discovered that the story was even more complex: larger, territorial, males showed substantial variation in body temperature, as their territory showed varying patches of light and shade. Smaller, non-territorial males, however, generally had higher body temperatures, as they tended to bask in sunlit areas, as part of their 'sneaky' mating strategy. This combination of behavioural ecology and physiology enriches our understanding of the maintenance of polymorphic mating strategies in this species. Due to their smaller body size and their more constant, higher body temperature, smaller males are apparently more agile, and therefore gain an advantage in terms of 'sneaky' mating and avoiding predation. However, their smaller size means that they are less able to lift females – essential during mating – or to combat larger males. The best strategy, it would appear, would be to be a large male with a perpetually sunlit territory. Indeed, the authors' unpublished data suggest that such males have higher reproductive success. However, such territories are rare and may be temporally or physically fragile; natural selection has led to the current polymorphism of alternative male strategies, with underlying alternative physiologies. Who would have thought that the beautiful flight of the damselfly concealed such complexity?" For the full paper see: Samejima, Y. and Tsubaki, Y. (2010). Body temperature and body size affect flight performance in a damselfly. *Behav. Ecol. Sociobiol.* 64, 685-692.] Address: Cobb, M., University of Manchester, UK. E-mail: cobb@manchester.ac.uk

12891. Cordero Rivera, A.; Córdoba-Aguilar, A. (2010): 15. Selective forces propelling genitalic evolution in Odonata. In: Edited by Janet Leonard and Alex Córdoba-Aguilar (eds.): *The Evolution of Primary Sexual Characters in Animals*. ISBN13: 9780195325553. 552 pp: 332-352. (in English) ["Conclusions and suggestions for future research: Although it seems that sexual selection, particularly sperm competition, is an important force shaping genital morphology and function, other selective forces cannot be disregarded. Other sexual selec-

tion forces are cryptic female choice and sexual conflict. A similar argument can be made for natural selection hypotheses, especially the lock and key hypothesis. Further investigations should test hypotheses from both sexual and natural selection. Our knowledge of genital functional morphology is still rather poor for many families of Anisoptera (but see Pfau 2005; for a comprehensive work see Siva-Jothy 1997), and this is especially true for females. Another research priority is tropical families, and also species-poor and primitive taxa, like the Hemiphysbiidae or Petaluridae. Furthermore, study of the genital morphology of highly diverse and localized taxa, like *Megalagrion* in Hawaii (Polhemus & Asquith 1996) or *Nesobasis* in Fiji (Donnelly 1990), both with more than 20 species, would be appropriate tests of hypotheses of genital evolution and speciation on islands. As we have mentioned above, there is limited evidence for mating frequency having negative effects on females, and we lack direct evidence for genital damage, two predictions derived from sexual conflict hypotheses, and therefore open to future studies. Finally, the lock-and-key and pleiotropy hypotheses are still not formally tested with odonates, a group that offers high rewards for future studies of genital diversity." 12901. Ott, J. (2010): Résumé de la communication orale: Alien Invasive Species (AIS) - a threat for European dragonflies? *Martinia* 26(3-4): 167. (in English) [Verbatim: After the negative effects of climatic changes presently a new threat becomes more and more important for European dragonflies: Alien Invasive Species (AIS). As a consequence of the globalisation, introductions by aquarists and fishermen many new species can be found in the waters. Some of them also do reproduce and are increasing their ranges, out of these species some are having negative - some even dramatic - effects on the biocoenosis. In particular some fish (e.g. *Ctenopharyngodon idella*) and crayfish species (e.g. *Orconectes limosus*, *Procambarus* sp., *P. clarkii*) could be identified as dangerous for the native dragonfly fauna, as they are altering the biotic conditions or the food chain (e.g. reduction of water plants - lack of substrate for oviposition) or as they are strong direct predators for the larvae. As these AIS often are favoured by higher temperatures, climatic changes and AIS now may have synergistic and cumulative effects. After a short review on recent developments and trends of the distribution and ecology of Odonata in Europe the possible consequences for nature conservation and the future for native dragonfly populations are outlined. In this context also the results of a current research on the effects of crayfish on dragonfly larvae and other water organisms will be presented.] Address: Ott, J., Friedhofstr. 28, 67705 Trippstadt, Germany. 12907. Ayme-Southgate, A.; Philipp, R.A.; Southgate, R.J. (2011): Projectin PEVK domain, splicing variants and domain structure in basal and derived insects. *Insect Molecular Biology* 20(3): 347-356. (in English) ["The third elastic filament of striated muscles consists of giant proteins: titin (in vertebrates) and kettin/projectin (in insects). In all three proteins, elasticity is at least partly associated with the so-called PEVK domain. The projectin PEVK domains of diverse insects are highly divergent compared with an otherwise conserved protein organization. We present the characterization of the PEVK domain in two dragonflies (*Pachydiplax longipennis*, *Libellula pulchella*) and in human lice. A conserved segment at the end of the PEVK, the NH(2)-terminal conserved segment-1 (NTCS-1), may serve as an anchor point for projectin to either myosin or actin, providing a mechanical link. The analysis of alternative splicing variants identifies the shortest PEVK isoform as the predominant form in the flight muscles of several insects, possibly contributing to myofibrillar stiffness."] (Authors)] Address: Ayme-Southgate A., Department of Biology, College of Charleston, Charleston, SC, USA. 12908. Barnard, P. (2011): Royal Entomological Society Book of British Insects. John Wiley & Sons: 368 pp. (in English) ["This book is the only modern systematic account of all 558 families of British insects, covering not just the large and familiar groups that are included in popular books, but even the smallest and least known. It is beautifully illustrated throughout in full colour with photographs by experienced wildlife photographers to show the range of diversity, both morphological and behavioural, among the 24,000 species. All of the 6,000 genera of British insects are listed and indexed, along with all the family names and higher groups. There is a summary of the classification, biology and economic importance of each family together with further references for detailed identification. All species currently subject to legal protection in the United Kingdom are also listed. The Royal Entomological Society (RES) ... began its famous Handbooks for the Identification of British Insects in 1949, and new works in that series continue to be published. The RES Book of British Insects has been produced to demonstrate the on-going commitment of the RES to educate and encourage each generation to study these fascinating creatures. This is a key reference work for serious students of entomology and amateur entomologists, as well as for professionals who need a comprehensive source of information about the insect groups of the British Isles they may be less familiar with."] (Publisher) Chap. 8 treats Odonata.] Address: Royal Entomological Society, The Mansion House, Chiswell Green Lane, St Albans AL2 3NS, UK

12909. Blanchon, V.; Durand, E.; Lambret, P. (2011): Redécouverte de *Gomphus flavipes* (Charpentier, 1825) en Provence-Alpes-Côte d'Azur (Odonata, Anisoptera: Gomphidae). *Martinia* 27(2): 121-122. (in French) [In June and July 2011, exuviae of *Stylurus flavipes* were found at the shore of the Isle of Saxy, Rhône, north of Arles (43,70972° N / 4,618611° E), France.] Address: Blanchon, V., Chemin de la Mourgatte, F-26200 Montélimar, France. 12910. Bogan, M.T.; Lytle, D.A. (2011): Severe drought drives novel community trajectories in desert stream pools. *Freshwater Biology* 56: 2070-2081. (in English) [Arizona, USA; "(1.) Ecological communities can be relatively stable for long periods of time, and then, often as a result of disturbance, transition rapidly to a novel state. When communities fail to recover to pre-disturbance configurations, they are said to have experienced a regime shift or to be in an alternative stable state. (2.) In this 8-year study, we quantified the effects of complete water loss and subsequent altered disturbance regime on aquatic insect communities inhabiting a formerly perennial desert stream. We monitored two study pools seasonally for 4 years before and 4 years after the transition from perennial to intermittent flow to evaluate pre-drying community dynamics and post-drying recovery trajectories. (3.) Mean species richness

was not affected by the transition to intermittent flow, though seasonal patterns of richness did change. Sample densities were much higher in postdrying samples. (4.) The stream pool communities underwent a catastrophic regime shift after transition to intermittent flow, moving to an alternative stable state with novel seasonal trajectories, and did not recover to pre-drying configurations after 4 years. Six invertebrate species were extirpated by the initial drying event, while other species were as much as 40 times more abundant in post-drying samples. In general, large-bodied top predators were extirpated from the system and replaced with high abundances of smaller-bodied mesopredators. (5.) Our results suggest that the loss of perennial flow caused by intensified droughts and water withdrawals could lead to significant changes in community structure and species composition at local and regional scales." (Authors) *Libellula saturata* was a significant pre-drying indicator.] Address: Bogan, M.T., Department of Zoology, Oregon State University, Corvallis, OR, USA. (2011): Écologie et gestion des populations de *Leucorrhinia albifrons* (Burmeister, 1839) et *L. caudalis* (Charpentier, 1840) (Odonata, Anisoptera: Libellulidae) sur un étang du Saumurois (département du Maine-et-Loire). *Martinia* 27(2): 81-94. (in French, with English summary) ["*Leucorrhinia albifrons* and *L. caudalis* were discovered at a forest pool in Gennes (Maine-et-Loire) during summer 2009, several hundred miles away from their nearest breeding sites. The first is a new species to the Pays de la Loire, whereas the second was regularly observed at a site more and more altered since 2006. Following this discovery, a survey is carried out to study both the ecology of these *Leucorrhinia* species and the crucial habitat parameters for their survival. The research based on both exuviae' and adults' surveys brought us phenological and ecological data on these species, and emphasized the role of dense aquatic vegetation which allows the survival of larvae over their entire development period. Water quality and structure of vegetation also play a vital role for *L. caudalis* and *L. albifrons* during reproduction. The management plan based on these data provides suitable suggestions to ensure the optimal conditions for these Whitefaces." In: Duda, J.J., Warrick, J.A., and Magirl, C.S., eds., 2011, Coastal habitats of the Elwha River, Washington - Biological and physical patterns and processes prior to dam removal: U.S. Geological Survey Scientific Investigations Report 2011-5120, 264 pp: 175-223. (in English) ["The removal of two long-standing dams on the Elwha River in Washington State will initiate a suite of biological and physical changes to the estuary at the river mouth. Estuaries represent a transition between freshwater and saltwater, have unique assemblages of plants and animals, and are a critical habitat for some salmon species as they migrate to the ocean. This chapter summarizes a number of studies in the Elwha River estuary, and focuses on physical and biological aspects of the ecosystem that are expected to change following dam removal. Included are data sets that summarize (1) water chemistry samples collected over a 16 month period; (2) beach seining activities targeted toward describing the fish assemblage of the estuary and migratory patterns of juvenile salmon; (3) descriptions of the aquatic and terrestrial invertebrate communities in the estuary, which represent an important food source for juvenile fish and are important water quality indicators; and (4) the diet and growth patterns of juvenile Chinook salmon in the lower Elwha River and estuary. These data represent baseline conditions of the ecosystem after nearly a century of changes due to the dams and will be useful in monitoring the changes to the river and estuary following dam removal." (Authors) Taxa (including Odonata) were treated at order level.] Address: not available

12914. Fiorenza, T.; Del Bianco, C.; Chiandetti, I.; Uboni, C.; Zandigiacomo, P. (2011): Gli Odonati del Friuli Venezia Giulia: risultati di uno studio triennale. *Bollettino Soc. Naturalisti "Silvia Zenari", Pordenone* 35: 109-122. (in Italian with English summary) ["During the period 2009-2011, a survey was carried out on the occurrence and distribution of Odonata in the Friuli Venezia Giulia region (north-eastern Italy). The aim of this study is to provide a regional Atlas of the Odonata at the end of 2013. Fifty-one species of Odonata have been found. This number agrees with the previous checklists of Kiauta (1969; 52 species) and Pecile (1984; 55 species). The occurrence of the Zygopteran *Nehalennia speciosa*, a threatened species, and of the Anisopteran *Cordulegaster heros*, a species widespread in the Balkan area and included in the Annexes II and IV of the Habitat Directive (Dir. 92/43/CEE) is extremely important from a naturalistic point of view. Both species are present in Italy only in Friuli Venezia Giulia. Further survey is expected to be planned in the next years, that will lead to the detection in the region of

about ten new species." (Authors)] Address: Fiorenza, T., Via Morosina 17/c, 33100 Udine, Italy. E-mail: E-mail: tizianofiorenza@libero.it

12916. Gu, W.; Ma, L.; Ding, X.H.; Zhang, J.; Han, Z.W. (2011): Insect diversity of different habitat types in Zhalong Wetland, northeast China. *Chinese Journal of Applied Ecology* 22(9): 2405-2412. (in Chinese) ["In order to approach the effects of different habitat types in wetland on insect diversity, an investigation was conducted on the insects in eight types of habitats in Zhalong Wetland. A total of 5822 insects were collected, belonging to 143 species, 58 families, and 11 orders, among which, Orthoptera, Diptera and Odonata ("Libellulidae, Platycnemididae") were the dominant taxa. The species diversity was the highest in grassland meadow, and the Shannon diversity index and evenness index were higher in lakeside but the lowest in wet meadow. Cluster analysis and principal component analysis showed that the similarity of the insect community in the habitats was related to the water source status and vegetation type, and the species and individual number of predatory taxa had important regulation effects on the insect community stability. Lakeside had the strongest insect community stability, while wet meadow had the weakest one, indicating that habitat water source status could affect insect survival, and further, affect the species composition and distribution pattern of insect community." 12928. Mitra, A.; Dow, R.; Subramanian, K.A.; Sharma, G. (2011): Chapter 5. The status and distribution of dragonflies and damselflies (Odonata) of the Eastern Himalaya. The status and distribution of freshwater biodiversity in the Eastern Himalaya: 54-66. (in English) ["5.5 Conclusions and conservation recommendations: Of the 367 species of Odonata considered present within the Eastern Himalayan assessment region, more than one third (135) are Data Deficient. This shows that there is lack of good quality research and recent data from the region. Lahiri (1989) has published a list of 78 Odonata species and subspecies that have not been reported from India since 1948 and 49 of these are part of present assessment. Thirty-eight of these 49 species are in the Data Deficient list of the present assessment. A further 13 of these 49 species were recorded from Nepal from the mid-1960s to late 1980s (Vick 1989), making the records around 30 years old, and records for many other species are of a similar age. Only 50 species of dragonflies have been reported from parts of eastern and southern Bhutan (Mitra 2008), much of Bhutan is still unexplored, a situation that is repeated across much of the assessment region, for example in Arunachal Pradesh in India, and in Myanmar. There is an urgent need for extensive, expert survey across the region. However fresh survey efforts are hampered by existing legislation in some regional countries which make it difficult to obtain permits for collection and loan of invertebrate specimens for scientific research; this is entirely counter productive for conservation efforts. Additional serious constraints include a lack of funding for fieldwork, and the need to train experts in taxonomy and field research methodologies. Moreover, large parts of the assessment region are affected by insurgency and political instability which has discouraged extensive

fieldwork in these areas; the mountainous and forested terrain in many parts of the region itself makes access difficult. Most species considered endemic to the region have been assessed as Data Deficient which raises doubts over their status as endemic to the region. Fieldwork in the unexplored areas within and outside the assessment region, and fresh fieldwork even in the relatively well known areas, might reveal that of some of these species are not actually endemic to the project region, but have wider ranges. Similarly, fieldwork is needed to determine the habitat requirements etc. for the Data Deficient species. Without extensive fieldwork the status of the Data Deficient species cannot change. Indeed, the lack of data can be considered to be a major threat to the Odonata of the region, as until this lack is remedied, proper conservation planning is not possible. The fundamental need is for extensive, good quality, fieldwork over the entire region. There is also a pressing need for high quality taxonomic work on the Odonata of the region. Revisions in many groups would likely result in the discovery that many of the currently Data Deficient species are in fact junior synonyms of better known species on the one hand, and in the discovery of new species in the region on the other. However such taxonomic work is made almost impossible by the lack of material for those groups where the taxonomical problems are most severe, by legislation that hampers international scientific collaboration in some countries, and by difficulties in locating and gaining access to type material for a number of species, as well as by poor maintenance of insect collections in many regional institutions. As far as the conservation of the Odonata fauna of the region is concerned, the only measures that are effective in protecting invertebrate populations are habitat protection measures, which need to be planned using the kind of data that we mostly lack for the region. Lahiri (1989) pointed out that most of the type localities of rare and endemic Odonata of eastern India concentrate in and around northern Bengal and Sikkim and Khasi Hills; however there has been insufficient sampling in other eastern Indian states such as Manipur, Arunachal Pradesh, and Nagaland. With their diverse ecosystems, these areas also sustain the majority of known Indian species. Identifying such pockets in other countries within the assessment region and giving at least parts of such pockets protected status would safeguard a high percentage of species and their habitats. For Odonata, if areas to be protected are chosen carefully, they do not have to be large, in practice more good might be done by protecting many small areas including examples of all habitat types in a particular region, than by protecting one or two large, but homogenous in terms of habitat, areas. To summarize, the following actions are recommended: (1). Funding should be made available for extensive expert sampling of Odonata across the project region, and for relevant training. (2). Priority should be given to taxonomic research. (3). Regional governments should review their existing legislation that affects scientific collection of in-

vertebrates, and loan and exchange of material with researchers in other countries, and remove or revise the ill-advised barriers to these activities that are currently in place. (4). When fresh data becomes available, and any taxonomic studies that are needed become available, Odonata experts should reassess the Odonata of the region currently placed in any category other than Least Concern, and, where necessary make recommendations on the protection of suitable habitat. 5. Standards of curation and storage of regional insect collections should be raised to prevent loss of type and other scientifically valuable material. The actions recommended above are mostly concerned with research, but until this research has taken place, actual conservation measures cannot be planned affectively." 12929. Nelson, S.J.; Chen, C.; Roebuck, H.; Zoellick, B. (2011): Sensible sentinels: preliminary mercury data for dragonfly nymphs (Odonata: Anisoptera) across northern New England corroborate expected spatial pattern. Poster presentation. The 10th International Conference on Mercury as a Global Pollutant (ICMGP), 24–29 Jul 2011; Halifax, Canada: (in English) [Verbatim: Mercury (Hg) is a potent neurotoxin that is delivered to ecosystems via deposition from a global atmospheric pool, and ultimately bioaccumulates in aquatic and terrestrial foodwebs. Around the Gulf of Maine, research sites in 'pristine' areas have fish and other biota that exceed thresholds considered safe for human consumption or wildlife protection. All Maine, Vermont, and New Hampshire surface waters are under fish consumption advisory and are considered impaired with respect to Hg because of these patterns and the difficulty in predicting which systems are most affected. Together with a team of citizen scientists, we are evaluating the utility of dragonfly nymphs (Odonata: Anisoptera) as indicators of Hg status in the Gulf of Maine region. We propose that dragonfly nymphs will be good sentinels because they are: (1) widespread and found in most surface waters in the region, (2) long-lived in aquatic systems (1-5 yr as nymphs), (3) exhibit site philopatry, (4) important prey species for fish that are consumed by humans, and (5) simple to capture, process, and analyze at meaningful Hg concentrations. Specifically, because dragonfly nymphs are themselves predators, Hg concentrations are high enough for laboratory and statistical analyses to be meaningful. The average Hg concentration in dragonfly nymphs sampled across Maine was 0.097 ppm (wet weight basis), greater than the proposed wildlife safety criterion (0.077 ppm). At sites across the region (ME, NH, VT, and MA), we used our data to address hypotheses regarding whether Hg varied with body size or by family; these characteristics were less important than a field site's landscape setting. Data from a survey of a variety of surface water sites in or near four National Park areas in ME (Acadia), MA (Boston Harbor Island and Saugus Ironworks), and VT

(Marsh Billings Rockefeller) confirmed that Hg in dragonfly nymphs was more variable among sites than within a site, suggesting that they are useful indicators for Hg. Further, three years of research by citizen scientists has confirmed correlation between Hg in dragonfly nymphs and DOC in five streams within Sunhaze National Wildlife Refuge. Hg in dragonfly nymphs were related to concentrations in other media at three long term monitoring sites within Acadia National Park where Hg in mature forests has been shown to be greater than early successional forests. More research on dragonfly larval life history will help to develop a mechanistic understanding of this spatial variability in Hg bioaccumulation.] Address: Nelson, Sarah, Senator George J Mitchell Center for Environmental and Watershed Research and Department of Plant, Soil, and Environmental Sciences, University of Maine, Orono, ME, USA. Emerging larvae were found up to 50 m from shore line and up to a height of 5 m.] Address: Schmid, F, Graben 23, 7225 Münsingen, Germany. E-mail: fcschmid@t-online.de

12933. Shah, D.N.; Tachamo Shah, R.D.; Pradhan, B.K. (2011): Diversity and community assemblage of littoral zone benthic macroinvertebrates in Jagadishpur

Reservoir. *Nepal Journal of Science and Technology* 12: 211-219. (in English) ["Littoral benthic macroinvertebrates diversity and community assemblage of Jagadishpur Reservoir were studied during post-monsoon (2008) and pre-monsoon (2009) seasons. Altogether twelve sites in the littoral zone of the reservoir were sampled for benthic macroinvertebrates (including Odonata) ... At each site, benthic macroinvertebrate samples were taken from different possible substrate types. The environmental variables of each site were collected based on Lentic Ecosystem Field Protocol during sampling. Biological metrics were used to describe the diversity and composition of benthic macroinvertebrates. The relationship between benthic macroinvertebrates assemblage and substrate types were examined by using principal component analysis. Cluster analyses were performed to describe the similarity among samples. In total, 50 taxa, belonging to 15 orders were recorded for littoral zone of the reservoir. The recorded higher number of taxa (family level) belonged to order Heteroptera and Diptera, and class Mollusca. Mollusca for post-monsoon and Diptera (particularly Chironomidae) for pre-monsoon shared the highest proportion in the total density. Shannon diversity index (H') for post-monsoon was 1.82 ± 0.46 and for pre-monsoon was 1.38 ± 0.53 and was significantly different between seasons ($p=0.01$). Principal component analysis revealed that increase in taxa numbers were positively correlated to soft substrates while negatively correlated to non-soft substrates in littoral zone of the reservoir. Cluster analyses discriminated the sites into two main groups for both seasons. The study concludes that benthic macroinvertebrates diversity is highly influenced by substrate types, water level fluctuation, and human accessibility to the reservoir. Therefore, in order to stabilize benthic macroinvertebrates diversity and their abundance, it is essential to maintain surface water level, stabilize bank substrate and minimize human pressure." 12934. Stryjecki, R. (2011): Invertebrate fauna of the Minina River, taking into account environmental factors. *Acta Biologica* 18: 37-48. (in English) [Poland; "A total of 5,613 macroinvertebrate specimens, belonging to 43 taxa (including "Anisoptera, Calopteryx sp., Zygoptera non det.") of varying systematic positions, were collected at four study sites in the Minina River. Dominant in the material collected were Gammarus sp. (33.9%), Chironomidae larvae (30.4%) and Ephemera sp. larvae (7.0%). More individuals (3,551) and taxa (39) were caught in the lentic zone than in the lotic zone (2,062 specimens and 30 taxa). The biological diversity index ranged from 1.57 to 3.14 within the sites and from 1.04 to 3.77 within habitats (zones of the river). The taxonomic composition and the abundance of the fauna were mainly influenced by biotic factors (e.g. amount of aquatic vegetation) and abiotic factors (e.g. water cur-

rent and type of bottom sediment), while human impact (presence of hydraulic structures, straightening of the river bed) did not significantly affect the fauna." 12938. Baeta, R.; Sansault, E.; Présent, J. (2012): Repartition et premiere estimation quantitative des populations de *Leucorrhinia caudalis* (Charpentier, 1840) en Indre-et-Loire (37), region Centre (Odonata, Anisoptera: Libellulidae). *Martinia* 28(2): 109-119. (in French, with English summary) ["Considered as threatened in France, *L. caudalis* is concerned by a National Action Plan. Following the discovery of a small population in 2008 in the Savigne basin (Indre-et-Loire - France), researches have been set up in 2011 and 2012 around the department of Indre-et-Loire. They led to the observation of 124 males, eight females, one larva and 30 exuviae in 10 localities, among which nine were unknown. The population size could therefore be estimated at several hundreds individuals in Indre-et-Loire. Three main areas have been identified: the Savigne basin (seven localities), the south Touraine (two localities) and the Champagne area (one locality). In France and Europe, several populations have been recently discovered, yet the only long term dataset available in Centre region (Brenne)

suggests a relatively negative trend. The Indre-et-Loire populations discovered recently are probably linked to the recent intensification of sampling efforts occurring in this department. In order to get a better understanding of the populations' distribution and functionality, useful field and genetic studies are proposed and detailed." (in Korean, with English summary) ["This study was conducted to understand landscape ecological characteristics on habitats of *N. pygmaea*, an endangered species in South Korea. The ecological characteristics of the habitats were investigated in abandoned paddy fields where *N. pygmaea* populations have been found in Chungcheongnam-do Kongju, Gyeonggi-do Kwangju and Gyeongsangbuk-do Mungyeong from 2009 to 2010. We surveyed the dominant vegetation, areas, water depth and temperature, and plant height and coverage to compare the wetlands living *N. pygmaea* and not living *N. pygmaea*. As a result, habitats of *N. pygmaea* in all regions were dominated by *Salix koreensis* community. There is no significant difference in the water temperature, plant height and coverage among wetlands of the three different sites, but depth was varied within 2.5~9.5cm. The water depth of habitat was deeper in Gongju than the others. Percentage of open water was 1.7~6% in the wetlands living *N. pygmaea*. but it did not appear in the wetlands not living *N. pygmaea*. Therefore, the ecological characteristics of wetlands as abandoned paddy fields should be taken into account for *N. pygmaea* habitat conservation and restoration." (Authors)] Address: not available

12951. Crabtree, A.G. (2012): Modeling a small pond odonate population: Exploring the complex life history dynamics of *Pachydiplax longipennis* (Odonata: Libellulidae). Thesis, Northern Illinois University. Biological Sciences. Proquest, Umi Dissertation Publishing: 152 pp. (in English) ["Members of the insect order Odonata are excellent examples of organisms that demonstrate complex life histories. Both the larval and adult stages must be studied to understand the dynamics of such species, A population of *P. longipennis* was studied at a small fishless pond in north central Illinois in 2008 and 2009. Additionally, a dynamic population model of the species was developed using the graphical modelling software, STELLA, to further understand the life history dynamics of *P. longipennis*. The larval dragonfly community in the pond was composed of nine species, all of which were also present as adults. The adult dragonfly community contained an additional four species, for a total of 13. Although, the maximum larval density of *P. longipennis*, which occurred in the middle of the summer, was ~15 m² in 2008 and 2009, mean density was higher in 2009. Based on this maximum density, it was estimated the maximum larval population size for the pond was ~170,000. Head capsule width and total length of larvae were used to identify 14 larval instar classes for the species. Changes in head capsule width between adjacent instar classes generally conformed to Dyar's Ratio, with the exception of the changes between the first and last two instars. Skipping of instar classes was common among larvae reared in the lab. Mean maximum *P. longipennis* adult abundance occurred in July in both 2008 and 2009. It was higher in 2008 than that observed in 2009, ~12 per 10 m sector versus 8 per 10 m sector. The

estimated adult population size in 2009 based on mark-recapture data using Craig's estimation method was 2,000. Average clutch size, determined from six captured, mated females, was 1,238+/-431 eggs per clutch. Average clutch survivorship was 27.51%+/-16.38. A density-ceiling model generated a stable population of *P. longipennis* larvae and adults that cycled in 54 week intervals. Short term (2 years) results predicted an early instar larval population of ~175,000 individuals, a late instar larval population of ~40,000, and an adult population of ~4,000. Long term (20 years) results predict early instar larval population of ~300,000 individuals, a late instar larval population of ~75,000, and an adult population of ~6,000. Long term estimates were comparable to those predicted by larval and adult sampling. Sensitivity analysis of varying mortality rates found that changing early instar larval mortality rate had a significant impact on observed abundances in all modelled life stages, while changes in breeding adult mortality had little effect. Simulations of ten different survivorship scenarios of larval and adult mortality resulted in three specific categories of response in terms of larval and adult abundances: one or both reached carrying capacity, both went extinct, or either or both stabilized at an intermediate abundance. Scenario results also suggested a greater importance of larval stage mortality rates, similar to the results of the sensitivity analysis. A density-dependent model generated unrealistic results in both short term and long term simulations." (Author)] Address: not stated

12961. Fulan, J.A.; Henry, R.; Davanso, R. (2012): Os efeitos da ação antrópica sobre a distribuição de macroinvertebrados no Rio Guareí, São Paulo - Anthropogenic action influence on macroinvertebrates distribution in Guareí River, São Paulo State - Brazil. *Estud Biol.* 34 (82): 51-56. (in Portuguese, with English summary) ["In this study, it was examined, during the period from March to December 2006, the effects of human disturbance on the macroinvertebrates that live near macrophytes in Guareí River, São Paulo State - Brazil. It was questioned if the high conductivity recorded in Guareí River affected the distribution of the macroinvertebrates and what were the most important variables that affect macroinvertebrates in a river with a strong nutrient concentration. The objective of this study was to investigate the effects of environmental variables on densities and composition of the macroinvertebrates. Three stands of aquatic plants were sampled with with 0.25 mm mesh net on a 0.07m² square metal frame. Air and water temperature, depth, pH, electrical conductivity, suspended solids, dissolved oxygen and macrophyte biomass were measured. A canonical correspondence analysis (CCA) was performed using the density of the macroinvertebrates and environmental variables. Chironomidae, Culicidae, Acanthagrion, *Coryphaeschna*, *Erythrodiplax*, *Miathyria marcella*, *Micrathyria*, *Gastropoda*, *Ostracoda* and *Hemiptera* were the only taxa that showed significant correlation with the axes. From the results, we can conclude that the high conductivity recorded in Guareí River due to the high amount of organic matter released during its course did not significantly affected the distri-

bution of the macroinvertebrates during the studied period. However, the ACC recorded that oxygen was the most significant environmental factor for the density variance of the macroinvertebrates, especially larval Odonata." 12962. Gabel, F.; Garcia, X.F.; Schnauder, I.; Püsch, M.T. (2012): Effects of ship-induced waves on littoral benthic invertebrates. *Freshwater Biology* 57: 2425-2435. (in English) ["(1.) Ship-induced waves can affect the physical characteristics of lake and river shorelines, and laboratory studies have shown effects on littoral invertebrates. Here, we explored whether these effects could be observed under field conditions along a natural lake shore affected by wave sequences (trains) produced by boats. (2.) Individuals of five invertebrate species (*Bithynia tentaculata*, *Calopteryx splendens*, *Dikergammarus villosus*, *Gammarus roeselii*, *Laccophilus hyalinus*) were exposed to waves with increasing shear stress in five habitats differing in structural complexity. (3.) Detachment of invertebrates increased with increasing shear stress and was best modelled using sigmoid response curves. Habitat structural complexity mitigated the effects of shear stress, and detachment rate was influenced more by habitat type than by species. A threshold (90% of the individual invertebrates unaffected) stress level of 0.64 N m² was found for a structurally complex reed habitat, compared to 0.37 N m² for a simple sand habitat. (4.) Shear stress associated with wave trains created by recreational boating at a distance of 35 m from the shore and at a speed of 11 km h⁻¹ resulted in 45% detachment of littoral invertebrates. Decreasing the boat-to-shore distance to 20 m increased wave shear stress by 30% and invertebrate detachments up to 75%. (5.) Disturbance of littoral habitats and invertebrate assemblages are widespread in inland waters used for recreational and/or commercial navigation. Our findings show that the integrity of littoral zones of navigable surface waters could be much improved by implementing management measures such as physically protecting complex habitats with dense reed belts and tree roots, and reducing boat speeds and increasing their minimum shoreline distance." (Authors)] Address: Gabel, Fredericke, Dept of Limnology of Shallow Lakes & Lowland Rivers, Leibniz-Institute of Freshwater Ecology & Inland Fisheries, Berlin, Germany

12963. Gabel, F. (2012): Impacts of ship-induced waves on benthic macroinvertebrates. Dissertation, Landwirtschaftlich-Gärtnerischen Fakultät, der Humboldt-Universität zu Berlin: 124 pp. (in English) ["Inland navigation constitutes a major human use of major rivers and lakes worldwide which is expected to increase in the future. Navigation does not only lead to river training and inputs of toxic compounds, but also significantly affects shore habitats by the ship-induced waves. In contrast to

the importance of such pressures, the effects of these hydrodynamic disturbances on benthic invertebrates in the littoral zones are poorly understood, even that invertebrates constitute a central element of littoral food webs. Hence, in this thesis I investigated i) the direct and immediate effects of ship-induced waves on benthic invertebrates (including *Calopteryx splendens*) in the littoral zone, ii) their subsequent effects on trophic interactions and iii) on the growth and fitness of invertebrates, and finally iv) the long-term effects on the community composition of benthic invertebrates in littoral zones. Both laboratory and field experiments showed increasing detachment of invertebrates with higher wave-induced shear stress, following a sigmoid response curve. Detachment was significantly mitigated by higher structural complexity of some habitats, as complex habitats dissipate wave energy and provide better fixing possibilities for invertebrates. Moreover dislodgement of invertebrates resulted in an elevated risk of being preyed upon by fusiform fish. In contrast, deep bodied fish reduced feeding under wave disturbance. Waves also reduced the growth and energy storage of native invertebrates via reduced feeding rate or increased energy expenditure, while non-native invertebrates were not affected. The cumulative impact of the demonstrated various mechanistic effects of ship-induced waves alters the community composition of benthic invertebrates. The abundance of native invertebrates and total species richness was shown to be lower at sites exposed to ship-waves, while non-native invertebrates increased in abundance. Thus, ship-induced waves affect benthic invertebrates on the individual, species, and community levels, as well as the interaction of trophic levels, and hence will alter the ecological structure and function of whole littoral zones. This knowledge on the pathways how ship-induced waves affect littoral zones may be also used to develop scientifically based and target-oriented management plans for surface waters used as inland waterways. Adverse effects of ship-induced waves may be mitigated by specifically protecting structural complex habitats such as tree roots and dense reed belts, and by minimizing wave generation by increasing minimum sailing distance to shore or by adjusting vessel speed." 12964. Gäde, G.; Marco, H.G. (2012): The adipokinetic hormone (AKH) of one of the most basal orders of Pterygota: structure and function of Ephemeroptera AKH. *Journal of Insect Physiology* 58(11): 1390-1396. (in English) ["This is the first reported primary sequence of a bioactive peptide isolated from three Ephemeroptera families. Peptides of the adipokinetic hormone (AKH) family from the corpora cardiaca of nymphs of *Afronurus* spp. (Heptageniidae), *Siphonurus lacustris* (Siphonuridae) and *Ephemerella danica* (Ephemeridae) were investigated functionally in homologous (hypertrehalosaemic activity

demonstrated in *E. danica* nymphs) and heterologous (active in cockroach and locust) bioassays, and structurally by liquid-chromatography coupled with ion trap electrospray ionisation mass spectrometry. All species investigated synthesise the octapeptide code-named Anaim-AKH (pGlu-Val-Asn-Phe-Ser-Pro-Ser-Trp amide). Confirmation of this peptide being present in corpora cardiaca of *E. danica* nymphs was obtained via reverse phase-high pressure liquid chromatography. Phylogenetically, the presence of only one AKH peptide may constitute a basal condition; all other lower insect orders, e.g. Odonata, Blattodea, Orthoptera, amongst others, have more than one AKH analogue. We propose that Anaim-AKH is the ancestral peptide which may support the Palaeoptera hypothesis that mayflies (Ephemeroptera) and dragonflies (Odonata) form the Palaeoptera clade, the sister group of Neoptera. The structural data cannot, however, shed any light on the phylogenetic scenarios within Ephemeroptera itself. Finally, this study demonstrates the successful use of larvae as an alternative biological source to study neuropeptides in ephemeral, elusive or difficult to obtain adult insects." 12974. Jung, K.S. (2012): Odonatological research society of Korea (Osok). *Notul. odonatol.* 7(9): 87-88. (in English) [Verbatim: The Society was founded on 13 May 2006. By September 2011, it had 36 members; the current President is the author of this note. The objective of the Society is the study of odonate systematics, faunistics and distribution in the Korean peninsula. The results are published in the biennial OSOK-Report, the 3rd volume of which is in preparation now. So far 123 species are known to occur in Korea; 102 of these were recorded from South Korea, including 29 Zygoptera (4 families, 13 genera) and 73 Anisoptera (6 families, 39 genera). Since the establishment of the Society, its members brought on record *Paracercion sieboldii*, *Sympetrum fonscolombii* (both in 2007) and *Brachidiplax chalybea flavovittata* (in 2010) for the first time from South Korea. In 2011, an undescribed *Boyeria* species was discovered. The response of the odonates to the recent climate change is receiving particular attention by the Society. As climate-sensitive biological indicator species in Korea were selected *Ceriagrion nipponicum*, *Ischnura elegans*, *Sympetrum speciosum* and *S. striolatum*. Since 2009, the status and habitats of these species are regularly monitored. So far, Nannophya

pygmaea has been the sole species on the Odonata Red List of Korea. Following the suggestion by the Society, *Macromia daimoji* and *Libellula angelina* were added in 2011. The publication of the monographic works, *Dragonflies and damselflies of Korea* (2012, Ill-gongyuska, Seoul) and *Odonata larvae of Korea* (2011, Nature & Ecology Academic Series, Seoul), both by the author of this note, facilitates the work on the Korean odonates.] Address: Jung, K.S., 6F, IBS Building, 1572-18 Seocho-Dong, Seocho-ku, Seoul 137-070, Korea

12975. Kadye, W.T.; Booth, A.J. (2012): Detecting impacts of invasive non-native sharptooth catfish, *Clarias gariepinus*, within invaded and non-invaded rivers. *Biology and Conservation* 21(8): 1997-2012. (in English) ["In aquatic ecosystems, impacts by invasive introduced fish can be likened to press disturbances that persistently influence communities. This study examined invasion disturbances by determining the relationship between non-native sharptooth catfish *Clarias gariepinus* and aquatic macroinvertebrates in the Eastern Cape, South Africa. A Multiple Before-After Control-Impact (MBACI) experimental design was used to examine macroinvertebrate communities within two rivers: one with catfish and another one without catfish. Within the invaded river, macroinvertebrates showed little response to catfish presence, whereas predator exclusion appeared to benefit community structure. This suggests that the macroinvertebrate community within the invaded river was adapted to predation impact because of the dominance of resilient taxa, such as Hirudinea, Oligochaeta and Chironomidae that were abundant in the Impact treatment relative to the Control treatment. High macroinvertebrate diversity and richness that was observed in the Control treatment, which excluded the predator, relative to the Impact treatment suggests predator avoidance behaviour within the invaded river. By comparison, within the uninvaded river, catfish introduction into the Impact treatment plots indicated negative effects on macroinvertebrate community that was reflected by decrease in diversity, richness and biomass. A community-level impact was also reflected in the multivariate analysis that indicated more variation in macroinvertebrate composition within the Impact treatment relative to the Control in the uninvaded river. Catfish impact within the uninvaded river suggests the dominance of vulnerable taxa, such as odonates that were less abundant in the Impact treatment plots after catfish introduction. From a disturbance perspective, this study revealed different macroinvertebrate responses to catfish impact, and suggests that within invaded habitats, macroinvertebrates were less responsive to catfish presence, whereas catfish introduction within uninvaded habitats demonstrated invasion impact that was shown by a decrease in the abundance of vulnerable taxa. The occurrence of non-native sharptooth catfish within many Eastern Cape rivers is a concern because of its predation impact and potential to influence trophic interrelationships, and efforts should be

taken to protect uninvaded rivers, and, where possible, eradicate the invader." (Authors) Taxa including Odonata were treated at family level.] Address: Booth, A.J., Dept Ichthyology & Fishery Science, Rhodes University, P.O. Box 94, Grahamstown, 6140 South Africa. E-mail: t.booth@ru.ac.za

12977. Khelifa, R. (2012): Flight period, apparent sex ratio and habitat preferences of the Maghribian endemic *Calopteryx exul* Selys, 1853 (Odonata: Zygoptera). *Revue d'écologie* 68(1): 37-45. (in French, with English summary) [*Calopteryx exul* is an endangered endemic Odonata species restricted to the Maghreb that shows an increasing concern about its conservation status, due to substantial habitat loss. A study dealing with its flight period, the apparent sex-ratio of imagoes and adult habitat preferences was carried out in the Seybouse basin, northeastern Algeria, during two years. The flight period of the species begun on early May and ended on late July, showing a peak around late May / early June. Either a small second generation or delayed emergences was responsible of the record of scarce tenerals and immatures in early September. Additional larval investigations are needed to elucidate the origin of such late emergences. The maturation period was estimated to extend over 11-12 days. The apparent daily sex-ratio in the adult population present on site was mostly biased with 65 to 67% of females. Additional work addressing sex-ratio at emergence is needed to understand this disequilibrium. Multivariate analysis showed that adults of *C. exul* prefer relatively fast flowing shallow water when compared to its congeneric *C. haemorrhoidalis*, which was mainly observed at deeper, slower and very shaded running waters with dense banks vegetation. The population of *C. exul* dealt with in this study is currently the largest one reported so far in the Maghreb. Data on adult phenology and habitat preferences will allow future investigations about the present distribution of the species in Algeria and the whole Maghreb." (Author)] Address: Khelifa, R., Département d'écologie et du génie de l'environnement, Faculté des Sciences de la Nature et de la Vie et des Sciences de la Terre et de l'Univers, Université 08 Mai 1945, Guelma 24000, Algeria

12980. Li, H.-x.; Zhang, R.-q.; Wu, F.-c.; Guo, G.-h.; Feng, C.-l. (2012): Comparison of mercury species sensitivity distributions of freshwater biota in China and the United States. *Acta Scientiae Circumstantiae* 32(5): 1183-1191. (in Chinese, with English summary) ["Based on single-species freshwater acute toxicity data in China and the United States, species sensitivity distributions (SSDs) of vertebrates (including fish) and invertebrates (including arthropods and non-arthropod invertebrates) to mercury were constructed, and species sensitivity to mercury in these two countries were compared. The results of this study indicated that there was no significant difference between sensitivity distributions of the Chinese and American taxa. However, the hazardous concentration for 5% of the species (HC5) range of Chinese species to short-term mercury exposure was lower than that of the American species, especially for non-arthropod invertebrates. HC5 for American non-arthropod invertebrates to mercury was 7D times larger than that for the corresponding Chinese species. Under the 95% protection level and including all the species, the tested invertebrates were more sensitive to mercury than the vertebrates in both China and the United States. However, in the lower taxonomic classification level, the sensitivity decreased in the order of arthropod > non-arthropod invertebrates > fish in China, but the order was arthropods > fish > non-arthropod invertebrates in the United States. Therefore, in determining the water quality criteria based on the sensitivity of all the species, we should also consider the influence of SSD of individual groups. The water quality

criteria derived from the species sensitivity distribution of American species may make the aquatic species in China out of protection." (Authors) The paper includes a reference to Odonata.] Address: Wu, F.-c., State Key Laboratory of Environmental Criteria and Risk Assessment, Chinese Research Academy of Environment Sciences, Beijing 100012, China. (2012): Yellow-spotted Whiteface *Leucorrhinia pectoralis* (Charpentier, 1825) (Odonata: Libellulidae) in the Silesian Province in the years 2002–2012. *Odonatrix* 8(2): 33-42. (in Polish, with English summary) [*L. pectoralis* was studied at 244 sites in the Silesian Province in 2002–2012, and was recorded at 34 sites. "The comparison of the present with historical data from the years 1958–1965 showed that *L. pectoralis* vanishes from peat bogs in this region. The reason for this situation is deteriorating condition of these habitats, mainly because of their desiccation and industrial pollution. It was noted however, that the species is present in a relatively high number on forest sinkhole ponds emerging over coal exploitation areas in the central, industrialized part of the province. Approximately 20% of investigated sinkholes presented conditions favourable for the reproduction and development of *L. pectoralis*. However, these habitats are unstable and do not sustain permanent presence of the species." (Authors)] Address: Miszta, Alicja, Centrum Dziedzictwa Przyrody Górnego Śląska, ul. Św. Huberta 35, 40–543 Katowice, Poland. E-mail: a.miszta@cdpgs.katowice.pl

12985. Norval, G.; Huang, S.-C.; Mao, J.-J.; Goldberg, S.R.; Slater, K. (2012): Additional notes on the diet of *Japalura swinhonis* (Agamidae) from southwestern Taiwan, with comments about its dietary overlap with the sympatric *Anolis sagrei* (Polychrotidae). *Basic and Applied Herpetology* 26: 87-97. (in English) ["*Japalura swinhonis* is an endemic agamid lizard in Taiwan, and although its diet has been examined in northern Taiwan and Orchid Island, it has not been investigated in other parts of its range. Investigating the diet of a species from different parts of its range is crucial due to temporal and spatial variations in it. This study examined the dietary items of 47 *J. swinhonis* from Santzepu and Yunlin, southwestern Taiwan. We also reviewed the diet of *J. swinhonis* and compared it with that of *A. sagrei* from Santzepu, where these species are sympatric in anthropogenically created habitats such as *Areca* catechu plantations and fruit orchards. The diet of *J. swinhonis* from Santzepu was dominated by hymenopterans, followed by coleopterans, lepidopterans and trichopterans, while that of the *J. swinhonis* from Yunlin was dominated by isopterans, followed by hymenopterans, lepidopterans and coleopterans. The diet of *A. sagrei* from Santzepu was mainly dominated by hymenopterans, lepidopterans, araneids, hemipterans, coleopterans, dipterans, isopterans and orthopterans, in that order of frequency. From the results of this study it is evident that in areas where *J. swinhonis* and *A. sagrei* are sympatric there is a substantial dietary niche overlap, and competition for prey is very likely." (Authors) The paper includes a few references to Odonata as prey of *Anolis sagrei*.] Address: Norval, G., Applied Behavioural Ecology & Ecosystem Research

12988. Orr, R. (2012): 2011-2012 Survey of the dragonflies and damselflies (Odonata) of the Cove Point LNG property (Calvert county, Maryland). <http://www.covepoint-trust.org/studies.html>: 20 pp. (in English) [USA; "Full property surveys for Odonata were completed in 1998-1999 and again in 2011-2012. In addition, a limited survey was completed along the LNG pipeline right-of-way in 2005. To date, 62 Odonata species have been recorded from the Cove Point LNG property. Seven of the sixty-two species were added since the end of the 1998-1999 survey. Two State-listed Maryland Endangered dragonflies (*Gomphus rogersi* and *Somatochlora filosa*) complete their life cycle on the property. The known larval site of *G. rogersi* is a small stream along the pipeline right-of-way while the larval site of *S. filosa* is Cove Point Marsh. Between the times of the two full property surveys, the larval site of *S. filosa* (Cove Point Marsh) was impacted by storm breaches resulting in saltwater from the Chesapeake Bay mixing with the freshwater of the marsh. In addition, the larval site of *G. rogersi* (along the LNG pipeline right-of-way) had been intersected by the placement of an additional underground pipeline. Both sites have undergone extensive environmental restoration in the hopes of returning these wetlands to their original condition. Before the 2011-2012 survey the fate of the two State-listed species that were first reported during the 1998-1999 survey were unknown. *S. filosa* and *G. rogersi* were relocated during the 2011-2012 survey. Both species were found in reduced numbers in comparison with the 1998-1999 survey. The reduction in the number of individual *S. filosa* is likely due to a decrease in the size of the larval habitat that is now restricted just to the northern section of Cove Point Marsh. The reduction in the number of individual *G. rogersi* is the result of a beaver dam that flooded the small stream where the larvae previously existed. Human intervention has returned the *G. rogersi* habitat to its 1999 condition by removing the dam plus restoring the surrounding environment from the burying of the new pipeline. The restoration of Cove

Point Marsh is currently in progress and it is reasonable to assume that when (or if) the southern section of Cove Point Marsh returns to a healthy freshwater habitat that *S. filosa* will recover to its earlier numbers." 12990. Pepa, B.; Papparisto, A.; Keçi, E. (2012): Preliminary data of water quality of Osumi, Devolli and Shkumbini River based on benthic macro invertebrates during summer of year 2011. *BALWOIS 2012 - Ohrid, Republic of Macedonia - 28 May, 2 June 2012*: 1-12. (in English) ["Recently, monitoring of water quality of Albanian River has a high interest. Based on instructions of Water Frame Directive (WFD) for the water body study an efficient element in monitoring and assessment of water quality are benthic macro-invertebrates. Our study was focused on Osumi, Devolli and Shkumbini River during summer 2011, and the purpose is to show relations between benthic macro-invertebrates and water quality. For each River was monitored respectively three stations. Where Osumi River show that, the total number of organisms is 509 that are related to 18 taxons, and in Devolli River are found 389 organisms that are related to 17 taxons. While in Shkumbini River are found 809 organisms which are related to 25 taxons. The result has shown that: EPT-Biotic Index represent different values in different stations. Osumi River: St 1 =4.32, St 2=3.99, St 3 =5.1; Devoll River: St 1 =3.90, St 2=3.93, St 3 =3.76; Shkumbini River: St 1 =3.86, St 2=4.37, St 3 =3.96. Based to these data the water quality of each river is Good (bioclassification 3.75-6.5). Also two others parameters (SWRC-Biotic Index, Family- Biotic Index) are in accordance with EPT- Biotic. Three Rivers have a good water quality with a slight impact." (Authors) Taxa including Odonata were treated at the family or suborder level.] Address: Pepa, B., Faculty of Natural Sciences, Tirana University, Albania. E-mail: bledpepa@hotmail.com

12991. Pessacq, P.; Santos, T.C.; Costa, J.M. (2012): Checklist and updated distribution of Protoneuridae from Brazil. *International Journal of Odonatology* 15(2): 59-73. (in English) ["Protoneuridae are represented in

the Neotropics by 16 genera and 117 species, of which 64 species in 12 genera are known to occur in Brazil. Most of them are known only from the original descriptions or isolated records. During 2009 the Protoneuridae collection of MNRJ was revised; 2800 specimens were studied, belonging to 40 species in nine genera. As a result, the distribution of 25 species is extended, including 50 new records for several states and three new records for the country: *Epipleoneura lamina* Williamson, *Protoneura woytkowskii* Gloyd, and *Psaironeura remissa* (Calvert). The widest distributions are shown by *Neoneura sylvatica* Hagen in Selys, *Epipleoneura venezuelensis* Rácenis, and *Epipleoneura metallica* Rácenis, which are also recorded from the highest number of states: 11 and eight respectively. Additionally, the distribution of most species within previously recorded states is extended." (Authors)] Address: Pessacq, P., CONICET - Facultad de Ciencias Naturales, (LIESA), Universidad Nacional de la Patagonia San Juan Bosco, Sarmiento 849, 9200, Esquel, Chubut, Argentina. 12992. Phiri, C.; Chakona, A.; Day, J.A. (2012): Body-size distribution, biomass estimates and life histories of common insect taxa associated with a submerged macrophyte *Lagarosiphon ilicifolius* in the Sanyati Basin, Lake Kariba, Zimbabwe. *African Journal of Aquatic Science* 37(3): 289-299. (in English) ["The body-size distributions and biomass estimates of *Caenis* (Ephemeroptera: Caenidae), *Cloeon* (Eph.: Baetidae), *Coenagrionidae* (Odonata), *Micronecta* (Hemiptera: Corixidae), *Chironominae* (Diptera: Chironomidae) and *Orthocladiinae* (Chironomidae), the most common and abundant insect taxa associated with a submerged macrophyte *Lagarosiphon ilicifolius* in Lake Kariba, are presented. *Caenis* has a univoltine life cycle, whilst *Cloeon*, *Coenagrionidae*, *Chironominae* and *Orthocladiinae* have multivoltine life cycles. Growth and reproduction of *Micronecta* occurred all year round. The *Coenagrionidae* had the highest mean biomass, which was significantly greater than those of the other taxa. *Caenis* and *Orthocladiinae* were sensitive to variations in water temperature and dissolved oxygen (DO) concentration, their highest biomasses occurring when temperatures were low and DO concentrations high. The biomasses of *Chironominae* and *Orthocladiinae* increased with rising water levels, but that of *Caenis* decreased. Total insect biomass was minimally affected by variations in water physico-chemical variables. The study suggests that water temperature, water level and DO concentration do have an effect on the biomasses of some insect taxa associated with *Lagarosiphon* in Lake Kariba. Mixing processes during de-stratification also affect the abundance and biomass of the insect taxa." (Authors)] Address: Phiri, C., University of Zimbabwe Lake Kariba Research Station, PO Box 48, Kariba, Zimbabwe

12996. Schiel, F.-J.; Hunger, H. (2012): Vermehrtes Auftreten der Großen Moosjungfer (*Leucorrhinia pectoralis*) in der badischen Oberrheinebene 2012 (Odonata: Libellulidae). *Mercuriale* 12: 37-44. (in German, with English summary) ["In the German Federal State of Baden-Württemberg, the distribution of *L. pectoralis* is mainly

restricted to the southeastern prealpine region. In the Upper Rhine Valley, the species had so far only been recorded at 13 sites between 1959 and 2011; this included one site where the species has reproduced since 2008. In 2012, the species was surprisingly observed 13 times at eleven sites in the Upper Rhine Valley of Baden-Württemberg. Northernmost and southernmost site are about 135 km apart. In only one case a female was observed. All other observations referred to single or few males. The observations in the Upper Rhine Valley corresponded with an increased occurrence in large parts of central and western Europe. Therefore we conclude that there has been long distance dispersal from the northern parts of central Europe which has been favoured by northeasterly winds. It is very probable that this type of dispersal has also occurred to a extent in the past." (Authors)] Address: Schiel, F.-J., Inst. Naturschutz und Landschaftsanalyse, Turenweg 9, 77880 Sasbach, Germany. E-mail: Franz-Josef.Schiel@INULA.de

12997. Schiel, F.-J. (2012): Nachtrag zur Verbreitung von Kleiner und Glänzender Binsenjungfer (*Lestes virens*, *L. dryas*) am Oberrhein (Odonata: Lestidae). *Mercuriale* 12: 23-26. (in German, with English summary) ["Three records of *L. virens* and one of *L. dryas*, documented by E. & K. Westermann from 1977 to 1981 and additionally recent findings of both species in 2012 are supplemented to the synopsis of Schiel (2011). Especially the records of E. & K. Westermann are important for our understanding of the distribution of these two species in the upper Rhine valley. In all *Lestes virens* was recorded at 26 sites in the upper Rhine valley of the German Land of Baden-Württemberg and *L. dryas* at 11 sites. Between 1958 and 1999 *L. virens* was recorded at 11 sites and between 2000 and 2012 at 18 sites. From 1922 to 1999 *L. dryas* was found at four sites in this part of the upper Rhine valley and from 2000 to 2012 at seven sites. New distribution maps are presented and the records are shortly discussed." (Author)] Address: Schiel, F.-J., Inst. Naturschutz und Landschaftsanalyse, Turenweg 9, D-77880 Sasbach, Germany. 13003. Shi, X.; Yu, H. (2012): Finite element analysis of dragonfly wing structural stiffness. *Nongye Jixie Xuebao* (Transactions of the Chinese Society of Agricultural Machinery) 43(1): 224-229. (in English) ["The dragonfly wings were taken as the study objects, CAD and finite element analysis software ANSYS were applied to establish the finite element model of dragonfly wings. Through static analysis, the main vein structure was determined as load-bearing structure in dragonfly wings, the main vein and secondary veins coordinating so as to make the overall structure more reasonable. According to the characteristics of dragonfly wings wrinkled structure, the mesh model of rectangular and staggered quadrilateral fold structure was established, different mechanical properties under load were analysed. The results showed that under the same uniform load, the greater the height of wrinkling was, the smaller structural deformation, and the greater structural stiffness would be. The analysis of quadrilateral mesh (no membrane) model in a different uniform deformation under load of the trend can be seen in the same wrinkle height, as the load increased, the deformation also increased, but as the wrinkle height increased, and with the smaller amount of deformation of the load increased, the quadrilateral mesh stiffness of the structure became slightly larger than staggered quadrilateral

mesh structure. Under the same load, the deformation of a membrane mesh structure was always less than no membrane mesh structure." (Authors)] Address: not stated

13008. Stephan, U. (2012): Einfluss der Untersuchungsmethode auf die Erfassung von Cordulegaster Larven. *Mercuriale* 12: 45-52. (in German, with English summary) ["Two methods of sampling larval Cordulegaster were compared according to their efficiency: the "cullender method": the investigator use a sieve, e.g. a cullender, to remove substrate from the bottom of little streams or seepages and to sort out the larvae being contained in the substrate; the "tremor method": the investigator causes tremors by jumping up and down at the stream margin; some larvae react to the tremors by performing movements, e.g. rising their heads out of the substrate, and therefore reveal their positions. The tremor method was more efficient in collecting larvae, especially the larger ones (body length > 15 mm). However, small larvae (body length < 15 mm) could be more efficiently recorded by the cullender method. In addition, the suitability of the methods was affected by habitat structures: at dark, shady stretches and habitats with lots of leaf litter the cullender method should be used, whereas in stony reaches the tremor method is more suitable." 13011. Sullivan, S.M.P.; Rodewald, A.D. (2012): In a state of flux: The energetic pathways that move contaminants from aquatic to terrestrial environments. *Environmental Toxicology and Chemistry* 31(6): 1175-1183.

(in English) ["In this Focus article, we address ecological and societal issues related to the aquatic-to-terrestrial transport of aquatic contaminants, with the spotlight falling on flowing water ecosystems. We highlight the ways in which a new understanding of the aquatic-terrestrial interface has prompted an integrated view of cross-boundary contaminant flows within complex ecological networks. We pay particular attention to aquatic insects (including Odonata), which as an important source of energy for riparian consumers such as arthropods, birds, mammals, and reptiles, are especially likely to move contaminants into terrestrial ecosystems 4–6. The linkages among aquatic and terrestrial systems represent an emerging ecological and environmental issue. We believe that contextualizing contaminant fluxes within this framework will yield significant short- and long-term benefits to ecological health and human well-being." 13014. Tunmore, M. (2012): Reports from coastal stations - 2011: Lizard Peninsula, Cornwall. *Atropos* 45: 47-49. (in English) [Verbatim: It was a notable year for Odonata, which began early with a male *Anax ephippiger* ... at Kennack Sands on 19 February. This was the prelude to further occurrences during a period of exceptionally warm weather in April. Unidentified dragonflies seen near Goonhilly on 6 April and at Kynance on 19 April were almost certainly this species. More definite was a male present at Windmill Farm NR on 24 April, with two present on a different part of the reserve the next day and one present on 26th; two males were seen near Mullion on 24 April and an ovipositing pair was observed at a site near Predannack on 26th with at least one still present on 28th. A small arrival of *Sympetrum fonscolombii* also occurred at the same time with six present at Windmill Farm on 25 April and three near Mullion the same day. With exceptionally early emergences of resident Odonata also noted, some local observers were able to see nine species in the month of April. The summer brought a lull in Odonata immigration but small numbers of *S. fonscolombii* continued to be reported from Windmill Farm in early June and again in late July/August. An *Anax imperator* was present there between 28 July and 4 August, which was only the second record for the site. Signs of autumn migration included a *Sympetrum striolatum* in the moth-trap at Church Cove on 2 September and an *Aeshna mixta* in the trap at Cury Cross Lanes on 12 September. Two *S. fonscolombii* were at Cury Cross Lanes on 10 September, followed by one at Windmill Farm on 25 October, whilst a pair of *A. ephippiger* were seen ovipositing near Predannack on 28 October.] Address: Tunmore, M., 36 Tinker Lane, Meltham, Huddersfield, West Yorkshire HD7 3ES, UK. 13028. Afzal, G.; Mushtaq, S.; Rana, S.A.; Sheikh, M.A. (2013): Trophic niche breadth and niche overlap among different guilds of spider species in wheat agroecosystem. Pakistan Journal of Life and Social Sciences 11(2): 107-111. (in English) ["Trophic niche breadth and niche overlap of nine spiders including Pardosa timidula (Roewer, 1951), Hippasa olivacea (Thorell, 1887), Plexippus paykulli (Audouin, 1826), Oxyopes javanus (Thorell, 1887) (hunters), Leucauge decorata (Blackwall, 1864), Tetragnatha javana (Thorell, 1890), Neoscona mokerji (Tikader, 1980), Argiope aemula (Walckenaer, 1841) and Cyclosa spirefera (Simon, 1889) (web builders) inhabited in wheat fields of University of Agriculture, Faisalabad, Pakistan were verified. Study was planned to know how the most abundant spiders of wheat are coexisted in terms of habitat and food resources. Evidences of predation in fields were used to compute the coefficients of niche breadth and niche overlap. Diet breadth values were approximately 1 to 2 times greater than the minimum, which specifies substantial differing degree of feeding specialization. All overlap values were <1.00 (range, 0.05-0.92), which indicated that each species had its own feeding niche in the wheat ecosystem. It was concluded that separation of guild members in microhabitat, high plasticity in their foraging patterns may results in reduced competition and coexistence. Thus, such abundantly found spiders are highly responsible to enhance their biological control potential in wheat agroecosystems." (Authors) Odonata had been preyed by all spider species studied, but in most cases were rarely encountered in the spiders diet.] Address: Afzal, G., Department of Zoology & Fisheries, University of Agriculture, Faisalabad-38040, Pakistan

13029. Albrecht, M.P.; Reis, V.C.S.; Caramaschi, E.P. (2013): Resource use by the facultative lepidophage Roeboides affinis (Günther, 1868): a comparison of size classes, seasons and environment types related to impoundment. Neotropical Ichthyology 11(2): 387-394. (in English, with Portuguese summary) ["We report the consumption of scales and other food resources by the facultative lepidophage Roeboides affinis in the upper

Tocantins River where it was impounded by the Serra da Mesa Hydroelectric Dam. We compared the diet among size classes, between dry and wet seasons, and between sites with distinct water flow characteristics (lotic vs. lentic) related to the distance from the dam and phase of reservoir development. As transparency and fish abundance increased after impoundment, we expected a higher consumption of scales in lentic sites. Likewise, habitat contraction, higher transparency and decrease in terrestrial resources availability, would promote a higher consumption of scales. Scales were consumed by 92% of individuals and represented 26% of the total volume of resources ingested by *R. affinis*. Diet composition varied significantly among size classes, with larger individuals consuming more scales and larger items, especially odonates and ephemeropterans. Scale consumption was not significantly different between dry and wet seasons. *Roeboides affinis* incorporated some food items into the diet as a response to the impoundment, like other species. Scale consumption was higher in lotic sites, refuting our initial hypothesis, what suggests that the lepidophagous habit is related the rheophilic nature of *R. affinis*." (Authors)] Address: Albrecht, Miriam, Universidade Federal do Rio de Janeiro, Departamento de Ecologia, Av. Carlos Chagas Filho, 373, Cidade Universitária, 21941-902 Rio de Janeiro, RJ, Brazil. 13030. Andrew, R.J. (2013): Odonates of Zilpi Lake of Nagpur (India) with a note on the emergence of the libellulid dragonfly, *Trithemis pallidinervis*. *Journal on New Biological Reports* 2(2): 177-187. (in English) ["Zilpi lake is a small water-body, formed by the construction of an earth fill dam in 1974 under the irrigation project of the Govt. of Maharashtra. The maximum live storage capacity of the dam is 1.51 MCM. It lies 25 km west of Nagpur city and is today a well known spot for scenic beauty and aquatic birds. A survey of dragonfly fauna of this lake was undertaken during the post monsoon period of 2012. A total of 34 odonate species belonging to the family- Coenagrionidae (7), Lestidae (1), Aeshnidae (3), Gomphidae (1) and Libellulidae (22) were found breeding in this lake. Except the *Diplacodes nebulosa* and *Rhodothemis rufa*, all other species are commonly found in the water bodies of central India. *Trithemis pallidinervis* abundantly breeds in this lake. Study of the emergence pattern of *T. pallidinervis* demonstrates that there is a direct correlation between choice of direction of the larva for emergence and the presence of emergent support and geographic condition of the water edge. 94% of the larvae of *T. pallidinervis* prefer the erect dried twigs of *Cassia tora* (Caesalpinaceae) to emerge. Maximum larvae (61%) preferred the west side of the lake for emergence because of the gradual sloping edge and large cluster of emergent support. The sex ratio is male biased (53.5% male, 46.5% female) and there was no correlation between the sex of the emerging larva and choice of direction." (Author)] Address: Andrew, R.J., Post Graduate Dept of Zoology,

Hislop College, Nagpur-440001, India. E-mail: rajuan-drew@yahoo.com

13035. Bajwa, Y.; Williams, V.; Ren, Y.; Dong, H. (2013): Investigation into the role of dragonfly wing flexibility during passive wing pitch reversal. *Bulletin of the American Physical Society* 58(18): o.p. (in English) ["Wing deformation is a characteristic part of flapping wing flight. In dragonflies, a torsion wave can be observed propagating from the tip to the root during stroke reversal. In this paper, we utilize high-speed photogrammetry and 3d surface reconstruction techniques to quantify wing deformation and kinematics of a dragonfly. We then use finite elements in the absolute nodal coordinate formulation to estimate strain energy in the wing during wing pitch reversal. We use this data to analyse the role of wing structure in facilitating wing rotation and bringing about the characteristic torsion wave. The influence of the elastic force in facilitating wing rotation is then compared with inertial and aerodynamic forces as well. A quantitative look into the variation of strain energy within the insect wing during wing rotation could lead to more efficient design of dynamic wing pitching mechanisms." 13036. Barry, M.J. (2013): Effects of fluoxetine on the swimming and behavioural responses of the Arabian killifish. *Ecotoxicology* 22(2): 425-432. (in English) ["The selective serotonin reuptake inhibitor fluoxetine has frequently been detected in surface waters around the world. Fluoxetine modulates levels of serotonin, a neurotransmitter that regulates several important physiological and behavioural processes including fear and anxiety, aggression, locomotion and feeding. In this study, groups of sub-adult Arabian killifish (*Aphanius dispar*) were exposed to either 0, 0.03, 0.3 or 3 µg/L fluoxetine hydrochloride for 7 days and their swimming behaviour and social interactions videotaped in a circular arena. The fish were subsequently exposed to a predator alarm chemical (from dragonfly larvae fed with *A. dispar*) and their short-term responses recorded. The video was analysed using the open-sourced software program Ctrax which objectively quantified swimming and social behaviours. Aggression (chasing behaviour was significantly reduced at 3.0 µg/L fluoxetine. After the addition of the predator alarm chemicals fish responded quickly, increasing the percentage of time spent drifting or motionless and reducing average swimming velocity. Controls and fish exposed to 0.03 or 3 µg/L fluoxetine reduced swimming speed by 20-30 % but returned to pre-exposure velocities within 6 min. Fish exposed to 0.3 µg/L fluoxetine reduced swimming speed by 38 % after addition of the predator alarm and did not return to

pre-exposure speeds during the recording period (19 min). Schooling behaviour was also affected by fluoxetine and predator alarm with fish exposed to 0.3 µg/L fluoxetine significantly reducing nearest neighbour distance and swimming speed relative to nearest neighbour the following addition of the predator alarm." (Author)] Address: Barry, M.J., Biology Department, Sultan Qaboos University, PO Box 36, Al Khoud, Muscat, 123, Sultanate of Oman. E-mail: mjbarry@squ.edu.om

13037. Barth, G.; Nel, A.; Franz, M. (2013): Two new odonate-like insect wings from the latest Norian of northern Germany. *Polish Journal of Entomology* 82(3): 127-142. (in English) ["Two new well preserved odonate (damselfly-dragonflies) insect wings from the latest Norian (Upper Triassic) of two different localities are described. Although the rather long distance of more than 250 km separates the localities, the holotypes occur in comparable lithologies and are thus described together. We describe an odonate forewing, *Italophlebia baueri* sp. n., from an abandoned quarry at Langenberg near Seinstedt north of the Harz Mountains (Lower Saxony), which is the first occurrence of this genus outside Italy. The second wing, *Triassothemis gartzii* sp. n., was found in the cored well Gartz 1 (NE Germany). In both occurrences the insect wings were associated with abundant autochthonous as well as allochthonous faunal and floral remnants of shallow subaquatic environments." 13040. Benoit, J.M.; Cato, D.A.; Denison, K.C.; Moreira, A.E. (2013): Seasonal mercury dynamics in a New England vernal pool. *Wetlands* 33(5): 887-894. (in English) ["Mercury fluxes into and transformations within a small vernal pool in Massachusetts were investigated over a wet-dry-wet cycle. We measured the deposition of total mercury (HgT) and methyl mercury (MeHg) via litterfall between October 6 and December 2, 2010. Litterfall fluxes were 10 $\mu\text{g m}^{-2}$ and 80 ng m^{-2} , respectively, over that time period. Average HgT concentration in litterfall was 33 ± 2 ng gdw^{-1} ; 0.9 % was present as MeHg. The HgT content of the litter layer increased slightly throughout the year, reaching 55 ± 20 ng gdw^{-1} inside and 42 ± 7 ng gdw^{-1} outside the pool. Litter %MeHg increased only to 1.5 % on the forest floor, while it increased dramatically in the vernal pool after inundation in late November, reaching 9 % by early spring. Measurements in pool benthic invertebrates show that two types of shredders bioaccumulated MeHg 4–9-fold relative to the leaf litter substrate. Overall, our results indicate significant production and bioaccumulation of MeHg in this vernal pool. This de novo MeHg could impact resident amphibians or be exported to the surrounding forest." (Authors) The focus was set on Trichoptera, Diptera, Amphipoda, and Isopoda with only one passing reference to Odonata.] Address: Benoit, Janina, Chemistry Dept, Wheaton College, Norton, MA, 02766, USA. E-mail: jbenoit@wheatonma.edu

13045. Blanckaert, K.; Garcia, X.-F.; Ricardo, A.-M.; Chen, Q.; Pusch, M.T. (2013): The role of turbulence in the hydraulic environment of benthic invertebrates. *Ecology* 6(4): 700-712. (in English) ["The role of turbulence in the dislodgment of benthic stream invertebrates from the riverbed was investigated experimentally in a laboratory flume. For the first time, technological advances allowed measuring the spatio-temporal patterns of turbulent flow around two free-moving invertebrates (*Aeshna cyanea* and *Somatochlora flavomaculata*). A specific methodology was developed for the analysis of turbulence around benthic invertebrates. The results confirmed two hypotheses: (i) on the contrary to sediment particles, invertebrates are not only sensitive to the peak values of the turbulent flow forcing but also to the temporal fluctuations in this flow forcing; and (ii)

the dominant temporal fluctuations are not due to local turbulent structures of the size of the invertebrate, but to turbulent structures that scale with the flow depth and are inherited from upstream. In 15 of the 17 conducted tests, important turbulent events that scale with the flow depth accompanied by rapid temporal flow fluctuations occurred at the moment of dislodgement. The dominant forcing was consistently a threefold increase in shear stress, and was related to a sweep event in 12 of the 17 tests. Thereby, the increase in longitudinal velocity was typically about 40%, which led to a 100% increase in drag force in comparison with the time-averaged drag force. These results enable a new understanding of the detailed hydraulic conditions leading to passive drift of stream invertebrates. In addition, they open new perspectives to improve models predicting the distribution of benthic invertebrates based on hydrodynamics by accounting for turbulence." 13047. Bogan, M.T.; Boersma, K.S.; Lytle, D.A. (2013): Flow intermittency alters longitudinal patterns of invertebrate diversity and assemblage composition in an arid-land stream network. *Freshwater Biology* 58(5): 1016-1028. (in English) [Arizona, USA; "(1.) Temporary streams comprise a large proportion of the total length of most stream networks, and the great majority of arid-land stream networks, so it is important to understand their contribution to biotic diversity at both local and landscape scales. (2.) In late winter 2010, we sampled invertebrate assemblages in 12 reaches of a large arid-land stream network (including perennial and intermittent headwaters, intermittent middle reaches and perennial rivers) in south-east Arizona, U.S.A. Intermittent reaches had then been flowing for c. 60 days, following a dry period of more than 450 days. We sampled a subset of the perennial study reaches three more times between 2009 and 2011. Since intermittent reaches were dry during these additional sampling periods, we used assemblage data from two other intermittent streams in the study network (sampled in 2004–05 and 2010) to explore interannual variability in intermittent stream assemblage composition. (3.) Invertebrate richness was lowest in intermittent reaches, despite their often being connected to species-rich perennial reaches. The assemblages of these intermittent reaches were not simply a subset of the species in perennial

streams, but rather were dominated by a suite of stoneflies, blackflies and midges with adaptations to intermittency (e.g. egg and/or larval diapause). On average, 86% of individuals in these samples were specialists or exclusive to intermittent streams. Predators were 7–14 times more abundant in perennial than in intermittent reaches. (4.) Despite being separated by long distances (12–25 km) and having very different physical characteristics, the assemblages of perennial headwaters and rivers were more similar to one another than to intervening intermittent reaches, emphasising the prime importance of local hydrology in this system. (5.) The duration and recurrence intervals of dry periods, and the relative importance of dispersal from perennial refuges, probably influence the magnitude of biological differences between neighbouring perennial and temporary streams. Although perennial headwaters supported the highest diversity of invertebrates, intermittent reaches supported a number of unique or locally rare species and as such contribute to regional species diversity and should be included in conservation planning... We found invertebrate predators to be 7–14 times more abundant in perennial headwater and river reaches than in intervening intermittent reaches. While we did not estimate predator biomass, the dominant predators in intermittent reaches (Dytiscidae) were of a similar size to those in perennial reaches (Odonata and Dytiscidae). This suggests that intermittent reaches of arid-land streams may provide a significant refuge from invertebrate predation pressure." (Authors)] Address: Bogan, M.T., Department of Zoology, Oregon State University, 3029 Cordley Hall, Corvallis, OR 97331, USA. E-mail: boganmi@science.oregonstate.edu

13048. Bosch, J.G. van't (2013): Rare dragonflies In the Netherlands in 2006-2009, CWNO-reports 5. *Brachytron* 15(2): 112-122. (in Dutch, with English summary) ["This is the fifth report of the Dutch Committee for records of rare odonates (CWNO). In this report, records from the period 2006-2009 are reviewed. Acceptability is judged independently by each of the committee members, based on the documentation available (e.g. descriptions, drawings, pictures or collected material). Only accepted records are reviewed. Of each accepted record the Province, nearby city and/or municipality, location, date, number, gender and names of the observers are given. If photographs are available, this is also mentioned. In most cases only the first record is given. Subsequent records of the same individual or population are accepted on the basis of the first record and are not reviewed. For these first observation the locations are marked with an asterisk *. These locations are regarded as a 'known location'. New records from a known location will not be reviewed in the future. 2006 - A male and a female *Leucorrhinia caudalis* were observed near Maastricht (Limburg). This was the first record of this species since 1970. Unfortunately the species was not found there in subsequent years. Reproduction of *Anax parthenope* was proven for the first time, at one

location in Gelderland and one location in Limburg. In 2006, a very large influx of *Sympetrum meridionale* took place with observations of at least 30 individuals accepted. There were only four previous records of this species. 2007 - The first population of *Coenagrion scitulum* was discovered at Cadzand-Bad (Zeeuws-Vlaanderen). The fifth ever observation of *Anax ephippiger* was near Zeist (Utrecht). The first known reproduction of *Sympetrum meridionale* took place at Westvoorne (Zuid-Holland). A maximum of 15 individuals was seen. Numbers of this species in other parts of the country were also high. At least three males of *Somatochlora flavomaculata* were found near Wassenaar (Zuid-Holland). 2008 - A male *Leucorrhinio caudalis* was seen at Ottema Wiersma reserve (Friesland). Two new populations of *Somatochlora arctica* were discovered in Overijssel. A female *Sympetrum depressiusculum* was found at Hoge Veluwe (Gelderland), far from the few known reproduction locations. Exceptional wanderers of *Somatochlora flavomaculata* were found at Eemshaven (Groningen) and on the Wadden Sea island Schiermonnikoog (Friesland). 2009 - A male *Leucorrhinia caudalis* was photographed in De Weerribben (Overijssel) by a group of Belgian observers. A male *Ophiogomphus cecilia* was photographed at Groote Peel (Limburg), away from the two rivers where populations are known. One of the highlights of 2009 was the observation of at least six males and one female *Onychogomphus forcipatus* along the river Grensmaas near Meers (Limburg). *Coenagrion scitulum* was found at four new locations in Zeeuws-Vlaanderen." 13052. Brossman, K. (2013): Tails and toxins: Exploring life history traits and predator-induced defenses in Eastern Red-spotted newts (*Notophthalmus viridescens viridescens*). M.Sc. thesis, The Graduate School, The Huck Institute of Life Sciences, The Pennsylvania State University: 68 pp. (in English) [Pennsylvania, USA; Chapter 2. *N. v. viridescens* larvae alter morphological but not chemical defences in response to predator cues focus on tadpole-dragonfly (*Anax junius*, *Aeschna sitchensis*, *Gomphaeschna antilope*, and *Aeschna juncea*) interactions: "Prey traits are often modified in response to exposure to predators, a phenomenon known as predator-induced phenotypic plasticity. Morphological plasticity in response to predator cues is well documented in amphibians; however, predator-induced chemical defences have received relatively little attention. *N. v. viridescens*, which possesses tetrodotoxin – a toxin for chemical defence, is most vulnerable to predation during its larval stage. I assessed whether exposing Eastern Red-spotted Newt larvae to predator scent cues (from dragonfly larvae) would elicit change in their morphological and chemical defences. Newt larvae exposed to scent cues of predatory dragonfly larvae exhibited significantly deeper tail depths, which should enhance predator escape ability by allowing them to swim faster, but did not differ in mass, snout-vent length or tail length. Newt larvae toxin concentrations were not significantly affected by exposure to these predator cues. Larval toxicity may be maternally-derived and in-

flexible, or induced toxicity may only be detectable later in development. Predator-induced phenotypic plasticity, especially of chemical defences, warrants greater attention, as potentially important outcomes of species interactions remain unclear." (Author)] Address: Brossman, Kelly, The Pennsylvania State University, The Graduate School, The Huck Institute of Life Sciences

13053. Buczyński, P.; Zawal, A.; Dąbkowski, P.; Szlauer-Lukaszewska, A. (2013): Dragonflies (Odonata) of the nature reserve "Świdwie". *Parki Narodowe i Rezerваты Przyrody* 32(2): 3-13. (in Polish, with English summary) ["32 odonate species were recorded in the year 2010 in the nature reserve "Świdwie" (NW Poland). Ecological, zoogeographical and conservation aspects of the fauna were analysed." 13055. Buczyński, P.; Tończyk, G. (2013): Dragonflies (Odonata) of Tuchola forests (northern Poland). 1. *Wdzydzki Landscape Park. Annales UMCS, Biologia* 68(1): 75-103. (in English, with Polish summary) ["The Wdzydzki Landscape Park lies in the Tuchola Forests which are among the areas of key importance for conservation of dragonflies in Poland. In the years 2002-2009, 55 dragonfly species were recorded in the park and its buffer zone. Lakes and Sphagnum bogs housed the highest species richness. Among the recorded species, one is included in the IUCN Red List of Threatened Species, two in the European Red List, two in the Polish Red List, ten species legally protected in Poland and ten "umbrella species". Peatbog lakes and Sphagnum bogs were most important for conservational issues. Dragonfly fauna of the studied area is among the species-richest in Poland. Its conservation value is high due to occurrence of stenotopic species, its importance for the conservation of rare and endangered species as well as for maintenance of odonatocoenoses typical of a range of natural waters. It results mostly from the forest coverage and high richness, variety and good ecological state of the surface waters. Interesting from the zoogeographical point of view was development of some thermophilic species in the lake littoral. It may be an indication of changes in thermal regime of surface waters, related to climate warming." (Authors)] Address:

13056. Büsse, S.; Hörschemeyer, T. (2013): The thorax musculature of Anisoptera (Insecta: Odonata) nymphs and its evolutionary relevance. *BMC Evolutionary Biology* 2013, 13:237 doi:10.1186/1471-2148-13-237: 13 pp. (in English) ["Background: Among the winged insects (Pterygota) the Odonata (dragon- and damselflies) are special for several reasons. They are strictly aerial predators showing remarkable flight abilities and their thorax morphology differs significantly from that of other Pterygota in terms of the arrangement and number of muscles. Even within one individual the musculature is significantly different between the nymphal and adult stage. Results: Here we present a comparative morphological investigation of the thoracic musculature of dragonfly (Anisoptera) nymphs. We investigated representatives of the Libellulidae, Aeshnidae and Cordulegasteridae and found 71 muscles: 19 muscles in the prothorax, 26 in the mesothorax and 27 in the metathorax. Nine of these muscles were previously unknown in Odonata, and for seven muscles no homologous muscles could be identified in the neopteran thorax. Conclusion: Our results support and extend the homology hypotheses for the thoracic musculatures of Odonata and Neoptera, thus supplementing our understanding of the evolution of Pterygota and providing additional characters for phylogenetic analyses comprising all subgroups of Pterygota." (Authors)] Address: Büsse, S., Abteilung Morphologie, Systematik & Evolutionsbiologie, JFB-Institut für Zoologie & Anthropologie der Georg-August-Universität Göttingen, Germany. 13057. Büsse, S.; Hörschemeyer, T. (2013): The thorax musculature of Anisoptera nymphs (Odonata). 6th Dresden Meeting on Insect Phylogeny, Dresden, September 27–29, 2013. Abstracts — Poster Presentations: 40-41. (in English) [Verbatim: Among the winged insects (Pterygota) the Odonata are special for several reasons. Their thorax morphology differs significantly from that of other Pterygota by a reduced number of muscles (e.g. Asahina 1954; Maloeuf 1935). Even within one individual, between the nymph and adult stage, the musculature is significantly different (e.g. Maloeuf 1935). Here we present a comparative morphological investigation of the thoracic musculature of Anisoptera nymphs. For representatives of the Libellulidae, Aeshnidae and Cordulegasteridae we describe 71 muscles, 19 muscles of the prothorax, 26 muscles of the mesothorax and 27 muscles of the metathorax. This includes nine muscles that were so far unknown in Odonata, as well as seven muscles for which no homologous muscles could be identified in the neopteran thorax. Our results support and extend the homology hypotheses for the thoracic musculature of Odonata and Neoptera (Büsse et al. 2013) thus supplementing our understand-

ing of the evolution of Pterygota and providing additional characters for phylogenetic analyses comprising all subgroups of Pterygota. 13058. Büsse, S. (2013): The Thorax of Odonata (Insecta) including remarks on evolution and phylogeny. Dissertation. Georg-August-Universität Göttingen: 211 pp., app.-I. ["The aim of my dissertation was to study the morphology and evolution of the thorax of damselflies and dragonflies (Odonata). One focus was the morphology of the thorax musculature and the homology between Odonata and a generalized Neoptera thorax as well as ground pattern of Pterygota (all winged insects). Furthermore, wing base skeletal element morphology was studied to extend and underscore the recent homology hypotheses. Beyond that, I examined the morphology, genetics and biogeography, and relating phylogeny of a very rare and enigmatic group of Odonata, *Epiophlebia*. *Epiophlebia* present a unique position within the Odonata. The group of *Epiophlebia* is closely related to all dragonflies but represents the only group of Odonata not belonging to dragonflies (Anisoptera) or damselflies (Zygoptera). The four known species of *Epiophlebia* are adapted to an extreme habitat in Asian mountain regions. They prefer cold and swiftflowing mountain streams at an altitude ranging from 1000 to 3500 meters above sea level (stenoecious lifestyle). The habitats of the *Epiophlebia* species are highly separated from each other on the Asian continent. Their respective range shows no overlap areas today, which typifies speciation via spatial isolation (separation). Results of genetic investigation of three of the four species' DNA segments (sequences) show surprising, extreme homogeneity. These results lead to a biogeographical scenario, which assumes a shared habitat of *Epiophlebia* during the Würm ice age (approximately 20,000 years ago). When the warming phase started, *Epiophlebia*-populations were separated into distinct populations each located in a different glacial refuge (simplified, cold withdraw areas). This short time frame could explain the genetic homogeneity observed. Nevertheless, the question of the species status of *Epiophlebia* remains: Is there only one species – *Epiophlebia superstes* – in four different populations or are there four different species? During a subsequent morphological study the species status at least of *Epiophlebia*

laidlawi Tillyard, 1921 could also be confirmed. Another study that draws directly on the genetic investigation of *Epiophlebia*, comprises a genetic sequence (S4-region of the 28s rRNA gene), which is suitable as a universal species identification tool for insects. Most insect specimens from all insect groups were successfully identified to species level with this tool. The investigation comprised 85 samples of 65 insect species, with at least one species per major clade of which the former represented a genus. We were able to demonstrate that our analysis system – which provides universal applicability and extended functionality – has advantages over the existing one (e.g. COI). The S4-method is applicable for degraded DNA that has, for example, been caused by aging, weathering or chemical influences. Investigation of the Odonata thorax comprised three studies. Two of the musculature and sclerites of adult Zygoptera flight apparatus and one of the entire nymphal Anisoptera thorax musculature. The aim was to understand and highlight peculiarities of the odonatan thorax. To obtain the data and reach the best overall result possible, traditional morphological methods – such as dissecting and hand drawing – were combined with one of the latest morphological methods, which included computer tomography (SR!CT) aided by 3D reconstruction. By doing this, we discovered a total of 11 new, previously unknown muscles for Odonata. These morphological data were used to present the first complete homologization scheme of Odonata and neopterous insect thorax musculature. Furthermore, the homologies of the skeletal elements of the flight apparatus were confirmed and distinctly enhanced. This study also mark the first time muscle attachment points were discussed as important homology criteria. As a whole, these homology assessments allow unprecedented direct comparison between Odonata, which have a highly derived flight apparatus, and all other insects. Insights into the evolution and ground pattern of Odonata, even of all winged insects (Pterygota), were consequently gained. The homologies enable comparison and provide a complete new set of characters for subsequent analysis of the relationship (phylogenetic analysis) of Pterygota. A key, wing base sclerites' characteristic – the subalare –, points to the phylogenetic hypothesis of Paleoptera [Odonata+Ephemeroptera (mayflies)]. A generalized Odonata thorax that includes all recently known muscles will allow simplified work and access to the complex structure for future studies and will aid in furthering knowledge. This generalized thorax might be the initial point for a hypothetical ground pattern of pterygote insects and will allow insights into the development and evolution of the insect flight apparatus." (Author)] Address: Büsse, S., Abteilung Morphologie, Systematik & Evolutionsbiologie, JFB-Institut für Zoologie & Anthropologie der Georg-August Universität Göttingen, Germany

13059. Büsse, S. (2013): Generalized Odonata thorax. 6th Dresden Meeting on Insect Phylogeny, Dresden,

September 27–29, 2013. Abstracts — Poster Presentations: 41. (in English) [Verbatim: The odonatan thorax is a highly specialized and therefore a highly derived character system (e.g. Asahina 1954; Büsse et al. 2013). The generalized odonatan thorax shows all the muscles that have been found in Odonata to date. It compiles all the results of Büsse et al. (2013) and Büsse & Hörnschemeyer (subm.) and is completed by four muscles located independently by both Asahina (1954) and Maloeuf (1935), only. For simplicity's sake, for comparison to Neoptera in particular, the generalized odonatan thorax is shaped like a nymphal thorax, which resembles the neopteran thorax. In order to present an overview, all structures, attachment points and directions have been simplified. It includes all muscles found homologous to Neoptera (Büsse et al. 2013; Büsse & Hörnschemeyer subm.) and the newly described Odonata muscles with no homologies to neopteran thorax (Büsse & Hörnschemeyer subm.). The aim of the generalized odonatan thorax is to gain clear understanding of Odonata's muscle setup. It also represents an initial attempt to develop a hypothetical odonatan ground pattern of a stem-group representative. 13060. Butler, S.G.; Orr, A.G. (2013): The larva of *Heliaeschna simplicia* Karsch, 1891 (Anisoptera: Aeshnidae). *Odonatologica* 42(2): 151-156. (in English) ["The female larva is figured and described for the first time, based on exuviae from a reared specimen and an F larva collected from runnels in peat swamp forest in Sarawak, Malaysia. The larva is compared with those of *Heliaeschna filostyla* Martin, 1906 and *H. uninervulata* Martin, 1909, the only other species of the genus so far described, as well as certain other aeshnid genera. Notes on habitat and behaviour are included." (Author)] Address: Butler S.G., Red Willow, All Stretton, Shropshire SY6 GHN, UK. E-mail: sgbutler15@btopenworld.com

13061. Carle, F.L.; May, M.L.; Kjer, K.M. (2013): A supermatrix approach to the phylogeny of Odonata. 6th Dresden Meeting on Insect Phylogeny, Dresden, September 27–29, 2013. Abstracts — Oral Presentations: 21. (in

English) [Verbatim: Over the past decade, a number of research teams have explored the phylogeny of Odonata with molecular data. Each has targeted their own set of genes, and their own taxa, and little effort has been made to coordinate efforts, or consolidate data from multiple sources. Here we construct a supermatrix from 4 independent genes (28S, 18S; 12S, 16S, COI, COII; EF1a and H3) and over 500 species, representing all families of Odonata. Our phylogenetic results are largely congruent with those we reported in Carle et al. 2008, with monophyletic suborders (Anisoptera and Zygoptera). We find coenagrionoids and calopterygoids together with lepidoptera relatively basal. We find *Epiophlebia* as sister to Anisoptera, with aeshnoids at the base of the Anisoptera. We discuss our strategies for alignment, data exclusion, combining taxa, discovering contaminants and reducing missing data. References: Carle F.L., Kjer K.M., May M.L. 2008: Evolution of Odonata, with special reference to Zygoptera. *Arthropod Systematics & Phylogeny* 66: 37–44.] Address: Frank L. Carle (Rutgers University, Dept of Entomology, 93 Lipman Dr., New Brunswick, NJ 08901, USA

13062. Carvalho, F.G.; Pinto, N.S.; Oliveira Júnior, J.M.B.; Juen, L. (2013): Effects of marginal vegetation removal on Odonata communities. *Acta Limnologica Brasiliensia* 25(1): 10-18. (in English, with Portuguese summary) ["Aim: Here we assess the effects of habitat degradation on individuals of the two suborders of Odonata community of Borecaia river sub-basin. More specifically, we tested the hypothesis that Anisoptera richness would be positively affected by removal of vegetation; on the other hand, Zygoptera richness would be adversely affected by virtue of their ecophysiological requirements; Methods: We selected 10 streams of similar orders, six preserved and four degraded. Streams characterized as preserved had values of Index of Habitat Integrity (IHI) above 0.70 (0.77 ± 0.07 , mean \pm SD) and continuous forest on both sides with a minimum width of 70 meters. Each site was sampled three times on different days. The effect of vegetation removal on richness was assessed using richness estimated by first order Jackknife; Results: Decreased physical integrity (measured with IHI) of streams had no significant effect on the estimated richness to Odonata in general. However, the estimated richness of Anisoptera showed an inverse relationship with the integrity ($r^2 = 0.485$, $P = 0.025$), i.e., there was a reduction in their species richness with increasing integrity; Discussion: As a general pattern, Anisoptera presents higher richness in an altered site; on the other hand, Zygoptera presents higher richness in a preserved one. This pattern suggests that Odonata needs to be considered at the sub-order level to access the effects of habitat degradation on these insects. Because of its restrictions ecophysiological Odonata varied widely in their composition and species richness between the two types of environments, it reinforces the potential of the order of studies and environmental monitoring also shows that Zygoptera be more affected by changes in

habitat. However, further studies including more samples and different streams are need to confirm this pattern, being an interesting line of research for future works." 13064. Chandler, D.; Cham, S. (2013): Dragonfly. New Holland's Natural History Monographs 4. 128 pp (in English). ["Supremely colourful, among the most voracious predators of the insect world and on the wing for more than 300 million years, dragonflies and damselflies capture the imagination in so many ways. Yet many aspects of their fascinating lives are little-known to humans. Dragonfly provides an insight into a hidden world through engaging text and stunning close-up photography. Dragonfly combines insightful writing with rarely seen images of the life and behaviour of the

world's dragonfly and damselfly species. There are chapters on subjects such as hunting, courtship and the emergence of the nymphs and their subsequent transformation into adult dragonflies. These insects are further brought to life through the personal experiences of the author and photographers, and these are woven into the text." (Publishers)]

13065. Chen, J.; Yu, X. (2013): Odonata diversity of the middle and lower reaches of the Red River basin, Yunnan, China. Journal of Insect Biodiversity 1(9): 1-11. (in English) ["Eighty six species of Odonata are recorded from the middle and lower reaches of the Red River basin. Archineura hetaerinoidea is recorded from China for the first time. Five genera and five species are new to Yunnan Province. Among the six types of odonate habitats, forest streams have the highest species diversity whereas ponds have the most species shared with other habitats. Both of these two habitats are important in biodiversity conservation and need urgent protection." 13066. Chen, Y.H.; Skote, M.; Zhao, Y.; Huang, W.M. (2013): Dragonfly (Sympetrum flaveolum) flight: kinematic measurement and modelling. Journal of Fluids and Structures 40: 115-126. (in English) ["Highlights: • The kinematics of the wing is studied thoroughly using high-speed videography. • The costa is shown to be two parts hinged with physical constraint of forty degrees. • Two flapping patterns are revealed: simple figure-eight and a double figure-eight. • Kinematic modelling is established. • Previous misunderstandings regarding the wing rotation during pronation are clarified. The kinematics of the flapping hindwing of S. flaveolum is investigated. Several tracking points along the leading edge and trailing edge of the hindwing are recorded and studied using high-speed videography. By applying more tracking points along the leading edge around the nodus, it is shown that the leading edge is not one rigid piece, but two pieces hinged at the nodus with physical constraint of forty degrees. Such arrangement also eases the difficulties in rotating the wing during pronation by bending the leading edge forward and flattening the wing. From the kinematic experiments, two flapping patterns of the dragonfly wing are revealed as a simple figure-eight and a double figure-eight flapping pattern. Kinematic modelling of the two flapping patterns is then established by transforming the flapping motions into angular rotations about the pivoting wing root in a local body-fixed spherical coordinate system." 13071. Dayaram, A.; Potter, K.A.; Moline, A.B.; Rosenstein, D.D.; Marinov, M.; Thomas, J.E.; Breitbart, M.; Rosario, K.; Argüllo-Astorga, G.R.; Varsani, A. (2013): High global diversity of cycloviruses amongst dragonflies. Journal of General Virology 94: 1827-1840 (in English) ["Members of the family Circoviridae, specifically the genus Circovirus, were thought to infect only vertebrates; however, members of a sister group under the same family, the proposed genus Cyclovirus, have been detected recently in insects. In an effort to explore the diversity of cycloviruses and better understand the evolution of these novel ssDNA viruses, here we present five cycloviruses isolated from three dragonfly species (Orthemum sabina, Xanthocnemis zealandica and Rhionaeschna multicolor) collected in Australia, New Zealand and the USA, respectively. The genomes of these five viruses share similar genome structure to other cycloviruses, with a circular ~1.7 kb genome and two major bidirectionally transcribed ORFs. The genomic sequence data gathered during this study were combined with all cyclovirus genomes available in public databases to identify conserved motifs and regulatory elements in the intergenic regions, as well as determine diversity and recombinant regions within their genomes. The genomes reported here represent four different cyclovirus species, three of which are novel. Our results confirm that cycloviruses circulate widely in winged-insect populations; in eight different cyclovirus species identified in dragonflies to date, some of these exhibit a broad geographical distribution. Recombination analysis revealed both intra- and inter-species recombination events amongst cycloviruses, including genomes recovered from disparate sources (e.g. goat meat and human faeces). Similar to other well-characterized circular ssDNA viruses, recombination may play an important role in cyclovirus evolution." 13072. Davenport, J.M.; Chalcraft, D.R. (2013): Non-consumptive effects in a multiple predator system reduce the foraging efficiency of a keystone predator. Ecology and Evolution 3(9): 3063-3072. (in English) [

"Many studies have demonstrated that the nonconsumptive effect (NCE) of predators (*Anax* sp.) on prey traits can alter prey demographics in ways that are just as strong as the consumptive effect (CE) of predators. Less well studied, however, is how the CE and NCE of multiple predator species can interact to influence the combined effect of multiple predators on prey mortality. We examined the extent to which the NCE of one predator altered the CE of another predator on a shared prey and evaluated whether we can better predict the combined impact of multiple predators on prey when accounting for this influence. We conducted a set of experiments with larval dragonflies, adult newts (a known keystone predator), and their tadpole prey. We quantified the CE and NCE of each predator, the extent to which NCEs from one predator alters the CE of the second predator, and the combined effect of both predators on prey mortality. We then compared the combined effect of both predators on prey mortality to four predictive models. Dragonflies caused more tadpoles to hide under leaf litter (a NCE), where newts spend less time foraging, which reduced the foraging success (CE) of newts. Newts altered tadpole behaviour but not in a way that altered the foraging success of dragonflies. Our study suggests that we can better predict the combined effect of multiple predators on prey when we incorporate the influence of interactions between the CE and NCE of multiple predators into a predictive model. In our case, the threat of predation to prey by one predator reduced the foraging efficiency of a keystone predator. Consequently, the ability of a predator to fill a keystone role could be compromised by the presence of other predators." (Authors)] Address: Davenport, J.M., Divi. Biol. 13073. De Knijf, G.; Adriaens, D.; Van Elegem, B.; Paelinckx, D. (2013): Natura 2000 habitats – more than floral Criteria and use of typical fauna species when assessing the conservation status of a Natura 2000 habitat. *Natuur.focus* 11(3): 109-120. (in Dutch, with English summary) ["The European Habitats Directive dictates that the assessment of the conservation status of a habitat type takes, amongst others, into account the conservation status of its typical fauna species. Therefore, a list of typical species for each habitat type is required, together with a description of the method used to assess their conservation status. When choosing typical fauna species the following considerations should be taken into account: 1) typical species should be good indicators for a favourable habitat quality, 2) it should be possible to detect typical species by non-destructive and inexpensive means and 3) the list of typical species should ideally remain stable over the mid- to long-term. Here we present a list of 153 typical fauna species for the different habitat types present in Flanders. Only species reproducing in a specific habitat type were selected. Distinction is made between species exclusively (type E) present in the habitat type, characteristic species (type K) having half of their popula-

tion reproducing in it, and species which are consistently present (type Ca and Cab), but not restricted to it. Assessment of the status of typical species can be based on best expert opinion, general national surveys, site-based sampling or Red List information. A typical species which is likely to become extinct within the next ten years will automatically lead to an overall unfavourable conservation status of that habitat type. Otherwise assessment will be based on the expected decline of a certain percentage of all typical species for a certain habitat type." (Authors) Odonata were prominently represented as indicator species for freshwater habitats: *Aeshna isocetes*, *A. juncea*, *Brachytron pratense*, *Calopteryx splendens*, *Coenagrion hastulatum*, *C. lunulatum*, *C. pulchellum*, *Cordulegaster boltonii*, *Gomphus vulgatissimus*, *Leucorhinia dubia*, *L. pectoralis*, *L. rubicunda*, *Libellula fulva*, *Somatochlora arctica*, *S. flavomaculata*, and *Sympetrum depressiusculum*.] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. 13082. Dunbier, J.R.; Wiederman, S.D.; O'Carroll, D.C. (2013): Mapping predictive facilitation in a dragonfly target neuron. *Front. Physiol. Conference Abstract: International Conference on Invertebrate Vision*. doi: 10.3389/conf.fphys.2013.25.00002: n.p. (in English) [Verbatim: Dragonflies are masters of aerial pursuit, executing prey capture flights with a 97% success rate. In perching Libellulids, such flights are brief (average 184ms, [1]), although target motion is also tracked from the perch prior to take-off. However many dragonflies also engage in longer duration territorial and courtship pursuits of conspecifics, that can last tens of seconds. These chase sequences include changes in velocity and direction, as well as the possibility of target occlusion by matched background texture. Recent work shows that responses of dragonfly small target motion detector (STMD) neurons may be facilitated over prolonged time courses (up to 500ms) of continuous motion [2,3]. We hypothesize that such facilitation may play a role in increasing robustness by predictively increasing the gain of detectors in the direction of future travel. We tested this in CSTMD1, a dragonfly neuron recently shown to express a form of selective attention for one target in the presence of a distractor [4]. We presented single target stimuli that moved along an initial 'priming' path for 500ms before undergoing spatial, temporal or combined discontinuities in their trajectories. We quantified the facilitation state by comparing the neuronal response (spike rate) in a 200ms window following the discontinuity with that for a naive control, tested at the same receptive field location. We found that facilitation is initially spatially localized: only the smallest spatial displacement tested in the direction of target travel (4°) gives significantly stronger responses than control. When larger spatial displacements were combined with a delay in reappearance, however, responses were significantly elevated, even for a 20° displacement with a 500ms delay in reappearance. Backward displacements (i.e. across previously traversed location) yield strongly inhibited responses. This suggests that facilitation is mediated by a process of local gain modulation that actively spreads from the last seen location of a stimulus and in the approximate direction of travel. Such predictive modulation of local target salience may be a key mechanism for selective attention during target tracking. Acknowledgements: We thank the manager of the Botanic Gardens of Adelaide for allowing insect collection. 13083. Dunbier, J.R., Wiederman, S.D.; Shoemaker, P.A.; O'Carroll, D.C. (2013): Facilitation of dragonfly target-detecting neurons by slow moving features on continuous paths. *Frontiers in Neural Circuits* 6(79): 11 pp. (in English) ["Dragonflies detect and pursue targets such as other insects for feeding and conspecific interaction. They have a class of neurons highly specialized for this task in their lobula, the "small target motion detecting" (STMD) neurons. One such neuron, CSTMD1, reaches maximum response slowly over hundreds of milliseconds of target motion. Recording the intracellular response from CSTMD1 and a second neuron in this system, BSTMD1, we determined that for the neurons to reach maximum response levels, target motion must produce sequential local activation of elementary motion detecting elements. This facilitation effect is most pronounced when targets move at velocities slower than what was previously thought to be optimal. It is completely disrupted if targets are instantaneously displaced a few degrees from their current location. Additionally, we utilize a simple computational model to discount the parsimonious hypothesis that CSTMD1's slow build-up to maximum response is due to it incorporating a sluggish neural delay filter. Whilst the observed facilitation may be too slow to play a role in prey pursuit flights, which are typically rapidly resolved, we hypothesize that it helps maintain elevated sensitivity during prolonged, aerobically intricate conspecific pursuits. Since the effect seems to be localized, it most likely enhances the relative salience of the most recently "seen" locations during such pursuit flights." 13087. Frackiel, K.; Henel, A.; Taylor, J.R.E. (2013): Distribution and habitat selection of *Nehalennia speciosa* (Charpentier, 1840) (Odonata: Coenagrionidae) in Biebrza valley. *Odonatrix* 9(2): 55-64. (in Polish, with English summary) ["Eight new localities of *N. speciosa* were found in the Biebrza river valley, NE Poland, six of them in the Biebrza National Park (Figs 1, 2). The Biebrza river valley is famous as the largest complex of marshes in Poland and in Central Europe. *N. speciosa* has never been recorded there before. Six out of eight localities were found in the southern basin of the river that is best preserved, with vast areas of fen mires. The locality "Osowiec-Twierdza" (Fig. 1) represents small dystrophic water bodies with the *Sphagnum* moss mat; *N. speciosa* is present in the nearby *Carex rostrata* swamp. Habitats of the other seven localities (fen mires) are different from those most typical of the species in Poland as they do not contain *Sphagnum*. Additionally, these fen mires are floristically rich in comparison with many other habitats of *N. speciosa* in Poland. Locality "Bagno Ławki" is especially untypical as the plant community there is dominated by *Equisetum fluviatile* that is known from only very few other localities of *N. speciosa* in Poland. Special feature of five out of six localities in the lower basin of the Biebrza valley is the dominance of *Carex rostrata* that is a common characteristic of the localities in eastern Poland. The presence of *N. speciosa*, recorded in vast are-

as of fen mires of the Biebrza valley may suggest that other localities of the species are to be discovered there." (Authors)] Address: Frackiel, K., Biebrzański Park Narodowy, Osowiec-Twierdza 8, 19-110 Goniądz, Poland. E-mail: kfrackiel@biebrza.org.pl

(2013): Energy flow and the trophic basis of macroinvertebrate and amphibian production in a neotropical stream food web. *Freshwater Biology* 58(7): 1340-1352. (in English) ["Despite the typically high taxonomic and functional diversity of tropical habitats, little is known about the roles of individual consumers in their ecosystem structure and function. We studied the trophic basis of production in a tropical headwater stream by identifying major sources of energy, measuring energy flow through consumers and characterising interactions among trophic levels and functional groups. We examined gut contents of 18 dominant macroinvertebrate (including *Heteragrion* and *Neurocordulia*) and two tadpole taxa and used these data, along with previously published estimates of secondary production, to quantify food-web structure and energy flow pathways. We also examined the prevalence of omnivory and patterns of resource consumption across seasons and habitats. Non-algal biofilm, a heterogeneous polysaccharidic matrix, was the most utilised food resource in the stream. Contrary to some studies of Old World tropical stream food webs, detrital energy sources were consumed at relatively high rates and contributed significantly to overall energy flow, although much of this was attributable to a single shredder taxon. Algal consumption rates were similar to values reported for temperate streams and were highest during the dry season. Omnivory was prevalent across all functional groups, particularly predators, suggesting traditional functional and trophic assignments based on temperate regions may not be appropriate for tropical systems. Seasonal patterns of resource consumption appeared linked to hydrological disturbance. This is the first study to provide quantitative estimates of energy flow through a neotropical stream food web. Extirpation and extinction rates in tropical freshwater habitats are high; our study provides baseline information for conservation and management of remaining systems, and for quantifying the consequences of further losses of biodiversity such as ongoing amphibian declines." 13089. Fulan, J.A.; Davanso, R.C.S.; Henry, R. (2013): A profundidade como fator determinante na variação anual da densidade dos macroinvertebrados associados à *Salvinia auriculata* Aublet. *Revista Brasileira de Biociências* 9(2): 214-219. (in Portuguese, with English summary) ["The depth as a factor in determining annual change density of macroinvertebrates associated with *Salvinia auriculata*: The aim of this work was to study

the effects of water annual variation of Paranapanema River and others variables on macroinvertebrates that lives in macrophytes roots, from March 2006 to February 2007. The sampled was realized with a hand-net ... We measured air and water temperature, depth, dissolved oxygen, pH, K25 and suspended matter. The normality was tested and a Canonical Correspondence Analysis (CCA) was realized. Telebasis showed high density in period studied. There was a high variation in depth: 6.07 m in April 2006 to 1.83 m in November 2007. The CCA showed that Culicidae, Ephemeroptera, Ostracoda, Calopterygidae, Coryphaeschna and Cyanallagma were significative correlated with the depth. We concluded that the effect of the depth on larvae Odonata can not have been direct, but indirect by the effect in substrates as aquatic plants." (Authors)] Address: Fulan, J.A., Univ. Fed. Amazonas (UFAM). CEP: 69800-000, Humaitá, AM, Brasil. E-mail: joaofulan@ig.com.br

13090. Garcia-Trejo, F.; Hurtado-Gonzalez, S.L.; Soto-Zarazúa, G.; Alatorre-Jacome, O.; Gutiérrez-Yurrita, E. R.P.J. (2013): Ecophysiological responses to the effect of annual management on an endemic viviparous fish in central plateau of México. *Neotropical Ichthyology* 11(1): 117-123. (in English, with Spanish summary) ["Studies on the biological aspects of fish typically focus on species that currently have commercial value, causing species that lack such market value to be ignored. This is the case of several freshwater fish, specifically of several members of the Goodeidae family. In the State of Querétaro there are several species of this family characterized for being viviparous and having distinctive sexual dimorphism that may have commercial potential. The subject of this study is *Girardinichthys multiradiatus*, a viviparous fish endemic to the upper-half of the Lerma River basin. The lack of knowledge regarding its biology and ecology has prevented the development of guidelines to manage its habitat and to preserve its population. The objective was to determine the ecophysiological responses of *G. multiradiatus* to its environmental management. From the sampling (24 hours every two months) population structure and dynamics were analyzed throughout a hydrological cycle using meristic data (standard length). Trophic and ecophysiological responses to fluctuations in environmental factors were also identified. Although the mexcalpique is a polytrophic species, results show that it prefers feeding on Diptera or Cladocera, while detritus is the third substance frequently found in their stomachs. Environmentally, the water regime is responsible for fluctuations in the population dynamics of the species, while temperature changes are the most influence its energy balance. These results can guide efforts to conserve this species and its habitat." 13094. Gerlach, J. (ed.) (2013): Odonata, Hemiptera, Hymenoptera and other insects of the Seychelles islands. *Siri Scientific Press*: 400 pp. (in English) ["The Seychelles islands are biogeographically interesting, with ancient affinities to Africa and Asia, recent colonizing species from the Indo-Pacific and modern introductions. Until recently, relatively little was known about the biodiversity of the islands. This has changed through the publication of a series of monographs on the Seychelles fauna, presenting the latest information on all the terrestrial and freshwater animals of the is-

lands. In this current volume on the Odonata, Hemiptera, Hymenoptera and other insects of the Seychelles islands, 15 expert scientists from nine different countries have provided contributions that cover all 954 species of these insect orders and other orders not covered in previous volumes (e.g. Protura, Collembola, Diplura, Microcoryphia, Zygentoma, Thysanoptera, Psocodea, Neuroptera, Siphonaptera and Trichoptera) recorded from the islands. The volume includes taxonomic keys, diagnostic illustrations and descriptions for many species, in addition to distribution records and assessments of species conservation status as defined by the International Union for the Conservation of Nature (IUCN)."(Publisher)]

13095. Gliwa, B. (2013): Die Libellen der Moorgebiete "Praviršulio tyrelis" und "Didysis Tyrulis" in Litauen. Build and Conserve a Livable Environment in the Countryside. ISBN 978-609-95323-1-8: 164-198. (in German, with English and Lithuanian summary) ["Odonata of two nature reserve boglands in Lithuania: Praviršulis and Didysis Tyrulis. While Didysis Tyrulis has been largely destroyed due to peat cutting, Praviršulis remained healthy, however, with disorders of natural hydrological conditions in a large part. As a result Praviršulis contains still two natural lakes and plenty of raised bog and fen. By contrast, at Didysis Tyrulis one finds no natural water bodies at all but lots of secondary „lakes“ in the digged pools together with a dense set of ditches. Praviršulis is well researched in terms of dragonflies, 45 species have been recorded. Among them some species strongly specialized in bogland, e.g. Nehalennia speciosa, Somatochlora arctica. Due to still started research, only 27 species have been recorded at Didysis Tyrulis, among them rare species as Coenagrion armatum and Coenagrion lunulatum. As a surprise, a large of population of N. speciosa could be observed as well. This is the first report of this species in a renaturating habitat. Really large populations were recorded for Leucorrhinia rubicunda and L. pectoralis in 2012." (Author)] Address: Gliwa, B., Sargeliu bendruomenes centras, Sargeliai, Raseiniu r., LT-60443, Lithuania. 13096. Gonzalez-Bellido, P.T.; Peng, H.; Yang, J.; Georgopoulos, A.P.; Olberg, R.M. (2013): In dragonflies, descending visual neurons code prey direction in population vector form. Front. Physiol. Conference Abstract: International Conference on Invertebrate Vision. doi: 10.3389/conf.fphys.2013.25.00058: n.p. (in English) [Verbatim: The population vector is the weighted vectorial sum activity of an ensemble of neurons and it was first shown to predict the direction of an upcoming arm movement in monkeys (Georgopoulos et al. 1983, 1986). In this study we show that in the dragonfly Libellula luctuosa, the population vector algorithm also decodes the target direction information relayed from the brain to the wing motor centers by a group of 16 neurons. Moreover, these 16 neurons (named Target Selective De-

scending Neurons or TSDNs; Olberg 1986), perform such directional information coding with high accuracy across 360°. This is significant because the monkey motor cortex requires upwards of 200 neurons to achieve the same performance (Georgopoulos et al. 1988). To obtain the TSDNs directional tuning curves, we impaled a total of 51 TSDNs from 38 animals with sharp electrodes and recorded their responses to a battery of 3497 target trajectories. The target had a constant speed and size, but random location and direction. To confirm cell ID, Lucifer yellow was injected into 32 of the recorded cells. Although the preferred direction, receptive field and morphological traits (3D tracings) for each TSDN type were consistent among animals, spike rates were not. Importantly, the TSDN spatial (receptive field) and temporal (latency) properties matched the area of the retina where the prey is focused and the reaction time, respectively, during predatory flights. The findings of this study are published in Gonzalez-Bellido et al. 2013. References: Georgopoulos AP, Caminiti R, Kalaska JF, Massey JT. 1983. 13099. Halupka, K.J.; Wiederman, S.D.; Cazzolato, B.S.; O'Carroll, D.C. (2013): Local facilitation improves success in closed loop simulations of insect small target pursuit. Front. Physiol. Conference Abstract: International Conference on Invertebrate Vision. doi: 10.3389/conf.fphys.2013.25.00001: (in English) ["Detecting and intercepting a small target is a computationally challenging task, but one solved elegantly by the small brain of flying insects, which have evolved several strategies for pursuit of either prey or conspecifics [1, 2]. Male houseflies track other flies, constantly updating their heading towards the target, based on an error angle between target and pursuer [3, 4], thus mimicking movements of the target on a spiralling flight path that ends in capture. By contrast, predatory dragonflies use an interception strategy, steering to minimise movement of the prey's image on the retina, resulting in a collision course [5]. To evaluate these two strategies for target pursuit against visual clutter, we developed a closed-loop model inspired by insect STMD (Small Target Motion Detector) neurons and pursuit behaviour, set in natural scenery. This allows quantification of the merits of alternative pursuit strategies and of key stages of visual processing that cannot yet be obtained from in-vivo analysis. We found that the velocity tuning of STMD neurons [6, 7] imposed a lower bound on the discriminable velocity of targets. However the intercept method enabled successful pursuits even when the target was moving significantly faster than pursuer. The preliminary stage of the detection algorithm is readily distracted by false positives generated by complex backgrounds. However, addition of a facilitation mecha-

nism, inspired directly by recent physiological analysis of dragonfly STMD neurons [8, 9] prevents such breakthrough responses by amplifying the weak signal of tiny targets moving on long trajectories. With this additional 2nd order salience-enhancing algorithm, we saw a significant improvement in successful target interception, from just over 50% to almost 80% (Chi square=5.87, p=0.015, n=44, Fig. 1). 13100. Hamamoto, M.; Ohta, Y.; Hara, K.; Hisada, T. (2013): Three-dimensional free-flight analysis of the rapid turning of a dragonfly using fluid-structure interaction analysis. *Journal of Computational Science and Technology* 7(1): 75-88. (in English) ["Recent studies of the flapping flight of insects have succeeded in solving the unsteady aerodynamics of hovering and contributed to realizing bio-inspired micro aerial vehicles (MAVs). However, the effect of wing deformation on the aerodynamics has not been investigated because of a lack of appropriate analysis methods. As an initial step to creating a "total" simulator for flapping flight, we developed a free-flight simulator by combining fluid-structure interaction finite element analysis based on the arbitrary Lagrangian-Eulerian method, which can quantitatively treat the strong interaction between the wing deformation and its surrounding airflow, and a rigid body dynamics analytical solver. With biologically-inspired flapping motion, which mimicked the changes in the stroke motion of the wing, the numerical model of the dragonfly per-

formed rapid turning over 1200°/s of yaw angular velocity. Although the flapping motion for the left wing on the trigger flapping and the right wing on the resumed flapping (or its inversed combination) are identical, a considerable difference in the deformation of the wing during this identical flapping between the former and latter halves of the turn was observed. Thus, while these actuations were identical, the directions of the aerodynamic forces were largely controlled by passive deformations of the wings. These results meant that the effect of wing deformation on its aerodynamics should be taken into account and thus fluid-structure interaction analysis is required to effectively design the actuation of the wing on an artificial MAV." (2013): Food web consequences of long-term invasive crayfish control. *Canadian Journal of Fisheries and Aquatic Sciences* 70(7): 1109-1122. (in English) ["Controlling invasive species can restore ecosystems while also quantifying species interaction strengths. We experimentally removed invasive rusty crayfish (*Orconectes rusticus*) from a Wisconsin lake. Rusty crayfish abundance declined by 99% in eight years, did not significantly increase four years post-harvest, and no compensatory recruitment response was observed. Native crayfish (*O. virilis*) and sunfish (*Lepomis* spp.) abundances increased by two orders of magnitude as rusty crayfish abundance declined, and macrophyte cover increased significantly in 2-4 m waters. We expected benthic macroinvertebrate densities to increase as rusty crayfish were removed; however, fish consumption of invertebrates increased as rusty crayfish density declined, and macroinvertebrate responses varied among families and habitats. Total Gastropoda density increased 300-fold in cobble, while the density of one gastropod family declined in macrophytes. Ephemeroptera, Odonata, and Amphipoda densities also declined in certain habitats as rusty crayfish were removed, suggesting that they are indirectly facilitated by rusty crayfish. This study highlights the importance of considering indirect effects when assessing the impacts of invasive species, and demonstrates that these impacts may be reversed over relatively short timescales" (Authors)] Address: Hansen, Gretchen, Center for Limnology, University of Wisconsin-Madison, 680 N. 13103. Heckmann, S.; Hörschemeyer, T.; Büsse, S. (2013): The thorax musculature of Zygoptera nymphs (Odonata). 6th Dresden Meeting on Insect Phylogeny, Dresden, September 27–29, 2013. Abstracts — Poster Presentations: 39. (in English) [Verbatim: Odonata are arguably the insect group with the most impressive flight skills (e.g. Corbet 1999). Each wing pair can be controlled independently and some species are even able to fly backwards (Hatch 1966). The muscles responsible for the wing movement are connected directly to the wings (Tannert 1958). This exclusively direct mechanism of wing movement distinctly sets Odonata apart from all other winged insects; where the wing beat is done mainly through a system of indirect muscles, many of which are highly reduced or missing in the Odonata (e.g. Snodgrass 1935). Here we present a comparative morphological investigation of the thoracic flight musculature of Zygoptera. The results for *Nealennia speciosa* and *Ischnura elegans* allow first insights into our comprehensive study. Nymphs are aquatic predators, which feed on other Arthropods, whereas adults are arial predators (e.g. Corbet 1999). The amount and kind of muscles therefore significantly differ between nymphal and adult Odonata, which are adapted to their respective habitat (e.g. Asahina 1954; Maloeuf 1935). We used synchrotron radiation micro computed tomography (S μ CT), aided by 3-D reconstruction to study the thorax of Zygoptera. The muscles were identified following the nomenclature introduced by Friedrich and Beutel (2008) as well as the homology hypothesis of Büsse et al. (2013) and Büsse & Hörschemeyer (subm.). 13104. Heger, P.; George, R.; Wiehe, T. (2013): Successive gain of insulator proteins in arthropod evolution. *Evolution* 67(10): 2945-2956. (in English) ["Alteration of regulatory DNA elements or their binding proteins may have drastic consequences for morphological evolution. Chromatin insulators are one example of such proteins and play a fundamental role in organizing gene expression. While a single insulator protein, CTCF (CCCTC-binding factor), is known in vertebrates, *Drosophila melanogaster* utilizes six additional factors. We studied the evolution of these proteins and show here that—in contrast to the bilaterian-wide distribution of CTCF—all other *D. melanogaster* insulators are restricted to arthropods. The full set is present exclusively in the genus *Drosophila* whereas only two insulators, Su(Hw) and CTCF, existed at the base of the arthropod clade and all additional factors have been acquired successively at later stages. Secondary loss of factors in some lineages further led to the presence of different insulator subsets in arthropods. Thus, the evolution of insulator proteins within arthropods is an ongoing and dynamic process that reshapes and supplements the ancient CTCF-based system common to bilaterians. Expansion of insulator systems may therefore be a general strategy to increase an organism's gene regulatory repertoire and its potential for morphological plasticity." (Authors) Several clades/orders were omitted for clarity. Ephemeroptera and Odonata are combined in Palaeoptera.] Address: Heger, P., Cologne Biocenter, Institute for Genetics, University of Cologne, Zùlpicher Str. 47a, 50674 Köln, Germany. 13105. Heintzman, L. (2013): Examination of Polycyclic Aromatic Hydrocarbons in an urban stormwater system and bioaccumulation in Odonata. M.Sc. thesis, Biology, Texas Tech University: 94 pp. (in English) ["Polycyclic aromatic hydrocarbons (PAHs) are toxic organic pollutants produced from combustion processes. Associated with urban runoff they have been detected worldwide in urban wetlands. PAH contaminations in wetlands are known to be influenced by hydrology and environmental factors. Because PAHs and their associated metabolites are carcinogenic, mutagenic, and teratogenic, they pose significant risks to wetland-dependent organisms. Provided meager scientific data on PAHs in playa wetlands, I investigated the occurrence of 16 PAHs within playa surface water samples and tissues of amphibious organisms (Odonata, a flagship group of predatory wetland insects) from seven urban playas along a runoff gradient in Lubbock, Texas. PAH detections from surface water samples were highly variable across sites and dates, with naphthalene and pyrene occurring most often in water samples. Adult Odonata PAH detections were also variable but significantly different from corre-

sponding surface water samples (suggesting bioaccumulation rather than passive chemical exposure), with naphthalene and fluoranthene occurring most often. The number of specific PAH compound detections was significantly associated with percent impervious surface within 300 m of a playa, but not with gradient position or number of inflows. Therefore, results indicate that for urban playas of Lubbock, land-use factors are more important in determining PAH contamination than hydrologic factors." (Author)] Address: not stated

13106. Heiser, M.; Schmitt, T. (2013): Tracking the boundary between the Palaeartic and the Oriental region: new insights from dragonflies and damselflies (Odonata). *Journal of Biogeography* 40(11): 2047-2058. (in English) ["Aim: We aim to define the hotspots, faunal regions and faunal elements of Odonata in Eurasia. We describe the location and the extent of the transition zone between the Palaeartic and Oriental realms. Location: Eurasia. Methods: Odonata are suitable for this study because the number of species in the group is sufficient for the required analyses, their distributions are mostly known, and they are split into the highly dispersive Anisoptera and the weakly dispersive Zygoptera. For our analyses, Eurasia was classified into 63 regions, within which we determined the presence or absence of each of the 1765 Odonata species. We calculated species richness maps and performed cluster analysis and principal components analysis to extract faunal regions and elements. Results: Occurrence records of Eurasian Odonata were partitioned among three major biogeographical entities: (1) Europe, North Africa and North Asia; (2) India, Indochina and southern China; and (3) northern China, Korea and Japan. Each of these entities has further notable substructures and faunal elements, especially in Southeast Asia. The tropical rain forest region of Southeast Asia is the species diversity hotspot of odonates and has the highest number of (often localized) faunal elements. The northern border of the Oriental region reaches southernmost China and the southern slopes of the Himalayas, but the transitional zone between the Oriental and the Palaeartic region extends much farther north, and includes northern China, Japan and Manchuria. The lower dispersal ability of Zygoptera compared with that of Anisoptera is mirrored in various biogeographical patterns: (1) the Western Palaeartic influence on the Eastern Palaeartic is stronger in Anisoptera than in Zygoptera; (2) Zygoptera have more faunal elements on islands than do Anisoptera; and (3) Zygoptera are isolated by the Strait of Gibraltar, but do not show a finer-grained structure of their faunal elements on the mainland. Main conclusions: The less severe impact of the ice ages in Southeast Asia resulted in the evolution and survival of Odonata species in many regional refugia. These faunal elements have had a greater impact on the post-glacial colonization than previously thought and strongly influence the composition of Odonata in East Asia." 13107. Helmker, B.; Hörnschemeyer, T.; Büsse, S. (2013): The thorax musculature of *Epiophlebia* nymphs (Odonata). 6th Dresden Meeting on Insect Phylogeny, Dresden, September 27–29, 2013. Abstracts — Poster Presentations: 39–40. (in English) [Verbatim: *Epiophlebia* is the single taxon inside the recent Odonata, which combines characters of the Anisoptera and the Zygoptera. The four known species of *Epiophlebia* differ in only a few morphological features (e.g. Asahina 1961; Li et al.2011; Carle 2012). Recent publications (Büsse et al. 2012) show that the genetics of three of these species varies very little. This study investigates the thoracic musculature of different nymphal instars of *Epiophlebia laidlawi* and *E. superstes* in order to further reveal the relationship of the two species. Based on Maloeuf's (1935) nomenclature for the thoracic musculature of the Odonata and Asahina's (1954) studies on *E. superstes*, the nymphs were examined via Synchrotron radiation micro computer tomography (S μ CT). Furthermore the identified muscles were homologized with the ones found in the Zygoptera (Büsse et al. 2013) and Anisoptera (Büsse & Hörnschemeyer subm.), based on the nomenclature established by Friedrich & Beutel (2008). The thoracic musculature of *E. laidlawi* and *E. superstes* is highly similar. Every muscle described by Maloeuf (1935) and Asahina (1954) could be confirmed in both species. Five muscles differ from the description of both authors. In addition, thirteen new muscles could be identified, of which one might be unique to the Eiprocta. 13112. Johansson, N. (2013): The genetic effects (mtDNA COI) of the invasive *Anax imperator* on the native *Aeshna grandis* from populations in southern Sweden. B.Sc. thesis. Halmstad University: (in English) ["Climate change will increase the range of some species, including *A. imperator* which first was observed in Sweden in the year 2000 and are now observed annually in the region of Scania (Skåne) and other parts of southern Sweden. *A. grandis* is a common dragonfly from south to north of Sweden and at some places they now share the habitat with *A. imperator*. The changing climate will benefit *A. imperator* and the species will spread north in Sweden. How this will affect the native *A. grandis* is not yet known however this study may reveal some light on the subject. By extracting mtDNA from larvae of *A. grandis* from 16 different sites; 8 sites with observations of *A. imperator* and 8 without, it is possible to reveal if there is a genetic difference between locals within the invasive species range and outside it. This study have used the COI region in mtDNA in *A. grandis* larvae to reveal if the haplotypes in populations that inhabits same habitats as *A. imperator* are negatively affected or, contrary to different sources, they are able to co-exist. The mtDNA were sequenced, MEGA version 5 was used to construct phylogenetic trees and the program TCS was used to estimate the gene genealogies. In this study there was no correlation between habitats within *A. imperator* range and outside of its range, however it is interesting that the tree constructed in MEGA divides the larvae in two groups and the graph in TCS also divides the larvae into two groups. This could still be an effect of climate change; it could be the result of *A. grandis* from Europe immigrating to Sweden. Another hypothesis is two kinds of larvae: one fast-growing larvae which has already adapted to the rising temperatures and have a shorter larva-stage and one slower growing, not yet adapted to temperatures. It could also be a result of an ongoing sympatric speciation however further studies are required to investigate the two types and more importantly, the cause of the two types of larvae." 13113. Jolley, J.C.; Albin, E.S.; Kaemingk, M.A.; Willis, D.W. (2013): A survey of aquatic invertebrate communities in Nebraska Sandhill lakes reveals potential alternative ecosystem states. *Journal of Fish and Wildlife Management* 4(1): 151-162. (in English) ["Aquatic invertebrate communities are important to shallow lake ecosystem form and function, providing vital components to the food web that link primary producers to consumers and thereby important to lake management goals of maximizing food resources for birds, fish and mammals. We characterized lake invertebrate communities and physicochemical variables in six Nebraska Sandhill lakes and examined these characteristics within an alternative stable state framework. Surveys were conducted during 2005 within each of these six Nebraska Sandhill lakes by sampling aquatic macroinvertebrate abundance, zooplankton abundance and biomass, phytoplankton biomass, and physicochemical variables. When placed within an alternative stable state framework, the response variables exhibited a gradient of different ecosystem states. Two lakes appeared congruent with the clear water state (dense submergent vegetation, high invertebrate abundance and diversity, and low phytoplankton), two were congruent with the turbid water state (high phytoplankton, low vegetation coverage, low invertebrate abundance and diversity), while two lakes were intermediate, likely in a state of hysteresis. Principal component groupings further supported these findings by following similar lake-specific patterns with attributes of a clear water state (high secchi depth, abundant benthic macroinvertebrates) or turbid water state (total dissolved solids, biomass of small-bodied zooplankters) grouping meaningfully according to multiple lake states. . The lakes studied contained varied fish communities, which may have influenced the diversity, density, and biomass of invertebrate and zooplankton communities. Generally lakes dominated by piscivorous fish displayed the clear water state while those with abundant planktivores displayed the turbid water state. Shallow lakes containing dense invertebrate communities likely provide a rich food base to important fauna (migratory waterfowl) that aid in reaching desired management objectives for these systems. Multiple small lakes, in close proximity, displaying divergent ecosystem states invites the opportunity for more in-depth analyses of driving mechanisms that will undoubtedly add to our ability to effectively manage these systems in the future." ing world: Biodiversity and management of the Madrean Archipelago III and 7th Conference on Research and Resource Management in the Southwestern Deserts; 2012 May 1-5; Tucson, AZ. Proceedings. RMRS-P-67. Fort Collins, CO: U.S. Department of Agriculture, Forest Service, Rocky Mountain Research Station: 133-137. (in English) ["The biogeographic affinities of butterflies (Lepidoptera: Papilionoidea and Hesperidae), Odonata, and ants (Hymenoptera: Formicidae) reported from the State of Sonora, Mexico were analysed using published species lists. The combined distribution of these taxa was proportionally greater (47.4%) for those species within the Mega-Mexico3 biogeographic category (Southwestern United States south to northern Central America). Formicidae was the most highly restricted taxon with greater proportions of Sonoran desert endemics. Butterflies had a greater proportion of tropical species (82.8%), whereas Odonata from Sonora were most widely distributed either north or south of Mega-Mexico. Differences in the biogeographic affinities of the three insect taxa are attributed to specificity of immature host plants and the distribution and persistence of species habitats." (Authors)] Address: Jones, R.W., Facultad de Ciencias Naturales, Universidad Autónoma de Querétaro, Querétaro, Qro., México

13115. Juslen, A.; Hyvärinen, E.; Virtanen, L.K. (2013): Application of the Red-List Index at a national level for multiple species groups. *Conservation Biology* 27(2): 398-406. (in English) ["The International Union for Conservation of Nature (IUCN) Red List Index (RLI) is recognized as one of the key indicators of trends in the status of species. The red-list assessment done by Finnish authorities of species in Finland is taxonomically one of the most extensive national assessments. We used the Finnish Red Lists from 2000 and 2010 to calculate for the first time the national RLIs for 11 taxonomic groups (including Odonata) at different trophic levels and with different life cycles. The red-list index is calculated on the basis of changes in red-list categories and indicates trends in the status of biological diversity of sets of species. The RLI value ranges from 0 to 1. The lower the value the faster the set of species is heading toward extinction. If the value is 1, all species in the set are least concern and if the value is 0, all species are (regionally) extinct. The overall RLI of Finnish species decreased. This means that, in Finland, these taxonomic groups were heading toward extinction faster in 2010 than in 2000. Of the analysed groups of organisms, RLIs of 5 decreased and RLIs of 6 increased. At the national level, the RLIs and status trends varied markedly between species groups. Thus, we concluded that generalizations on the basis of RLIs of a few taxa only may yield a biased view of ongoing trends in the status of biological diversity at the species level. In addition, one overall RLI that includes many different species groups may also be misleading if variation in RLI among species groups is not considered and if RLI values are not presented separately for each

group." (Authors)] Address: Juslén, A., Finnish Museum of Natural History, Zoology, FI-00014 University of Helsinki, Finland. E-mail: aino.juslen@helsinki.fi

13116. Karle-Fendt, A.; Stadelmann, H. (2013): Entwicklung der Libellenfauna eines regenerierenden Hochmoores nach Renaturierungsmaßnahmen (Odonata). *Libellula* 32(1/2): 1-30. (in German, with English summary) ["The Bavarian Felmer Moos (47°33'N, 10°15'E), a highly fragmented and disturbed bog, was regenerated stepwise since 1986. Starting in 2000, intensive monitoring of the odonate fauna was carried out in order to investigate possible relationships between the technical measures and the dynamics of the dragonfly species typical for moorland habitats and their populations. In total, 47 species of Odonata were recorded as imagines. By quantitative sampling of Anisoptera exuviae between 2001 and 2012 we tried to find a relation between selected species and different types of water bodies and their succession stages respectively. The results showed that the populations were strongly augmented by the increase of the number and size of water bodies as well as by the rising number of various succession stages. In years with unusually warm springs we observed conspicuous decline of the populations. From the results conclusions were drawn for the regeneration concept." (Authors)] Address: Karle-Fendt, A., Hofenerstr. 49, 87527 Sonthofen, Germany. E-mail: karle-fendt@t-online.de

13117. Kaunisto, K.M.; Viitaniemi, H.M.; Leder, E.H.; Suhonen, J. (2013): Association between host's genetic diversity and parasite burden in damselflies. *Journal of Evolutionary Biology* 26(8): 1784-1789. (in English) ["Recent research indicates that low genetic variation in individuals can increase susceptibility to parasite infection, yet evidence from natural invertebrate populations remains scarce. Here, we studied the relationship between genetic heterozygosity, measured as AFLP-based inbreeding coefficient f_{AFLP} , and gregarine parasite burden from eleven *Calopteryx splendens* populations. We found that in the studied populations, 5–92% of males were parasitized by endoparasitic gregarines (Apicomplexa: Actinocephalidae). Number of parasites ranged from none to 47 parasites per male, and parasites were highly aggregated in a few hosts. Mean individual f_{AFLP} did not differ between populations. Moreover, we found a positive association between individual's inbreeding coefficient and parasite burden. In other words, the more homozygous the individual, the more parasites it harbours. Thus, parasites are likely to pose strong selection pressure against inbreeding and homozygosity. Our results support the heterozygosity-fitness correlation hypothesis, which suggests the importance of heterozygosity for an individual's pathogen resistance." (Authors)] Address: Kaunisto, K.M., Section of Ecology, Department of Biology, University of Turku, FI-20014 Turku, Finland. E-mail: kkauni@utu.fi

13118. Kempster, C. (2013): The Abundance and biodiversity of arthropods in biofuel crops: Insects and arachnids in corn, switchgrass and native mixed grass prairie fields. M.Sc. thesis, Environmental Science at Rochester Institute of Technology, Rochester, New York 14623-5603: V + 80 pp. (in English) [Michigan, USA. "Concerns about fossil fuel prices and harmful effects have prompted research and investment in biofuel development. Biofuels have the potential to provide a stable fuel source that reduces carbon emissions. However, the ecological impacts of different crop choices should be examined. Arthropod communities in corn and switchgrass monocultures and mixed grass prairie polycultures were examined to determine the impact of the crop choice on the arthropod communities. Results show that, when compared to corn and switchgrass fields, mixed grass prairie fields had higher values for arthropod biomass, number, size, the number of orders present, the number of individuals in each order, and the overall arthropod diversity. Corn fields were dominated by Diptera (61.83%) and contained very low abundance of the other orders found in this study. Mixed grass prairie fields also showed Diptera as the most prevalent order (43.47%), followed by Hemiptera (17.89%) and Homoptera (13.65%), Hymenoptera (6.12%), Coleoptera (5.61%), with the others each less than 2.5%, Thysanoptera, Acari, Araneae, Lepidoptera, Orthoptera and Odonata. Switchgrass fields showed arthropod communities with diversity levels between that of corn and mixed grass prairies, with Diptera (39.33%), Coleoptera (17.91%) and Hemiptera (16.33%) dominating the community. Hymenoptera 5.53% and Lepidoptera, Odonata, Orthoptera, Thysanoptera, Acari and Araneae total 17%. Average arthropod abundance was 49.33 individuals and 98 milligrams in mixed grass prairie fields, 35.59 individuals and 49 milligrams in switchgrass fields, and only 23.93 individuals and 23 milligrams in corn fields. The average number of orders found was also correlated to field type, with 4.17 in corn fields, 5.53 in switchgrass fields, and 7.08 in mixed grass prairie fields. It is concluded that transitioning from planting fields with corn to growing mixed grass prairie, or switchgrass, for cellulosic ethanol and biodiesel production would increase the overall abundance and biodiversity of the arthropod community." 13119. Kerry, L. (2013): On the relationship between the Small Red Damselfly *Ceriatagrion tenellum* and the terrestrial mite *Leptus killingtoni*. J. Br. Dragonfly Society 29(2): 69-83. (in English) ["Larvae of the terrestrial mite, *Leptus killingtoni* were identified on a population of *Ceriatagrion tenellum* on the East Devon Pebblebed Heaths in 2011. An investigation was undertaken on the interaction between these species during the flight period in 2012. In total 567 individuals (382 males and 185 females) were caught and marked and the location of a total of 808 mites were noted (498 on first capture and a further 310 on recaptures). The highest numbers of *L.*

killingtoni were seen in the middle and driest period at the end of July. Only 19% of immature *C. tenellum* were found to have mites, whereas 36% of male and 49% of female mature damselflies had mites. Paired females were more likely to be infested than unpaired females and males (whether paired or not). Mites were recorded most often from areas more difficult to groom, with 26.6% recorded on the ventral surface of the thorax (and especially between the legs), 20.9% on the abdomen and 17.3% on the femur. Female melanogastrum were recaptured nearly twice as often as *typica*, despite similar numbers being marked." 13124. Kim, Y.H.; Kwona, D.H.; Lee, S.H. (2013): Biochemical characterization of two distinct acetylcholinesterases possessing almost identical catalytic activity in the damselfly *Vestalis gracilis*. *Journal of Asia-Pacific Entomology* 16(4): 465-471. (in English) ["Highlights: • Two acetylcholinesterases were identified in *Vestalis gracilis*. • Both VgAChE1 and VgAChE2 were almost equally active in *V. gracilis*. • Both VgAChE1 and VgAChE2 probably have similar neuronal functions. • VgAChEs were primarily associated with the membrane via the GPI anchor. • VgAChEs exhibited different sensitivities to insecticides. Most insects possess two different acetylcholinesterases (AChEs) (i.e., AChE1 and AChE2). It has been recently reported that only one AChE (either AChE1 or AChE2) has been selected for as the main synaptic enzyme and it varies with different insect lineages (Kim et al., 2012 and Kim and Lee, 2013). Interestingly, however, both AChE1 and AChE2 are almost equally active in a damselfly species, providing a unique example of the incomplete specialization of one AChE function after duplication, where, consequently, both AChE1 and AChE2 likely play a similar role in synaptic transmission. In this study, therefore, we investigated the tissue distribution patterns and the molecular and inhibitory properties of two AChEs (i.e., VgAChE1 and VgAChE2) from *V. gracilis* as a model species possessing two AChEs that are equally active. VgAChEs exhibited almost identical catalytic activity and were expressed in the central nervous system (CNS). The most predominant molecular form of both VgAChEs was a disulfide-bridged dimer, which is associated with the cell membrane via a glycosylphosphatidylinositol anchor. In an inhibition assay, however, VgAChE1 and VgAChE2 exhibited different sensitivities to organophosphate and carbamate insecticides de-

pending on the structure of the inhibitors. These findings suggest that both VgAChEs have neuronal functions. In addition, soluble monomeric and cleaved molecular forms were detected in both the CNS and peripheral nervous system tissues by an AChE2-specific antibody, implying that VgAChE2 probably shares both neuronal and non-neuronal physiological functions in *V. gracilis*. Our results support the notion that both VgAChEs, paralogous of each other, are involved in synaptic transmission, with VgAChE2 being in the early stage of acquiring non-neuronal functions." (2013): Ein Vergleich zweier Großlibellenpopulationen (Odonata: Anisoptera) in Mainz. *Mainzer naturwissenschaftliches Archiv* 50: 321-331. (in German, with English summary) ["Over a period of two months we compared two populations of Anisoptera in the city of Mainz (Rhineland-Palatinate, Germany) by applying three methods: exuviae sampling, adult screening and mark-recapture. The areas under investigation comprised parts of the nature reserve Laubenheimer-Bodenheimer Ried as well as an assemblage of artificial ponds on the campus of the University of Mainz. The two habitats differed in size and structure. Nevertheless, partly the differences between the two populations in number of species and number of specimen, in sex ration, recapture rate, species diversity and the evenness were smaller than expected or even contrary to our expectations (species diversity of the exuviae). The cause of this observation might be that we worked less intensively on the larger area of Laubenheimer. However, we interpret our observation as a hint that even small artificial ponds can offer an adequate habitat for various Anisoptera." (Authors)] Address: Koch, Kamilla, Abteilung Ökologie, Institut für Zoologie, Johannes-Gutenberg-Universität Mainz, Johann-Joachim-Becherweg 13, 55128 Mainz, Germany. E-Mail: kochka@uni-mainz.de

13129. Lambret, P.; Boudot, J.-P. (2013): *Hemianax ephippiger* (Burmeister, 1839) (Odonata, Anisoptera: Aeshnidae): présentation générale. *Martinia* Hors-série, *Hemianax ephippiger* - migration 2011, mai 2013: 13-27. (in French, with English summary) ["The life history and behaviour of *H. ephippiger* are summarized in order to better understand the recent migratory activity of the species observed in Europe. The key criteria for a fast identification of the adults are given. *H. ephippiger* ranges from the South of Africa to the North of Europe and to India. It is autochthonous in the tropical zone and the Mediterranean where the larvae grow rapidly and preferentially in shallow waters, either permanent or temporary. The species is an obligate migrant which leaves early its native habitat, at the post-teneral stage. Following mass emergences, mass migrations bring the species to the north and the west and the latter has been observed as far as Iceland, Central Asia, French Guyana and the West-Indies. Such long-distance migrations are accompanied by successful local breeding and appear to be mostly passive, being allowed for by strong winds blowing into the same direction for several days. In Africa, migrations are initiated mostly from September to November, taking advantage of the mass

emergences launched by the rainfalls of the summer monsoon. Migrations occur first during the winter along the Atlantic African coast and are accompanied by local breeding and production of a new generation. They continue in Western Europe until the spring. More to the east, inland swarms fail to cross the Atlas range during the winter and accumulate in the Sahara before being able to start again northwards in spring. These two Coastal and inland migration pathways are accompanied by successful breeding in suitable habitats in the north of Africa, Mediterranean Europe and sometimes Central Europe. Similar migrations with successful local breeding are also known from the Arabian Peninsula, both along the coasts and inland. They seem to reach Anatolia and Central and Eastern Europe. Central Asian records could result from Indo-Iranian migrations. The secondary generations appearing north of the Saharan/Arabian belt may lead to new mass migrations in summer and autumn in Southern Europe. Due to the obligate migratory behaviour of the species, the European individuals leave their native habitats for unknown destinations; a return to Africa can be advocated but remains highly hypothetical. Egg laying in Europe in autumn is therefore very rare and in this case the European winter conditions make a larval development highly improbable, except in its southernmost parts of the continent. Other noteworthy behaviours of the species are reminded." (Authors)] Address: Lambret, P., Le Trident B2 n°55, rue de la Sansouïre, F-13310 St-Martin-de-Crau, France. E-mail: philambret@hotmail.com

13130. Lambret, P. (2013): De l'émergence et de la coloration chez *Lestes macrostigma* (Eversmann, 1836) (Odonata, Anisoptera: Lestidae). *Martinia* 29(1): 53-64. (in French, with English summary) ["Both the emergence and the colour pattern all along the imaginal life of *L. macrostigma* were studied from 2009 to 2013 in the national natural reserve of the Marais du Vigueirat. Between the break of the larval skin and the moment when the abdomen reaches its final length, the emergence lasted about two hours. Emergences mainly took place in early morning and the exuviae were found around 30 cm above the water table. The sex-ratio at emergence was close to 1 and both sexes emerged synchronously. The coloration of the imagines changed rapidly during the first days. That of the day of the emergence and/or the day after was unique, depending both on the time of emergence as well as the weather, so that it is possible to know if an individual has emerged the day or the day before its observation. The pruinosity seems to cover a maximal surface during the mating period and then decreases, whereas the abdominal tergites darken. The record of tenerals appears to be sufficient to show the autochthony of a population. Coloration patterns can help to identify local populations and their breeding localities." 13132. Lambret, P.; Deschamps, C. (2013): Bilan de la migration d'*Hemianax ephippiger* (Burmeister, 1839) en France en 2011 (Odonata, Anisoptera: Aeshnidae). *Martinia* Hors-série, *Hemianax ephippiger* - migration 2011, mai 2013: 29-46-appendix: 76-96. (in French, with English summary) ["The migration waves of *H. ephippiger* observed in Western Europe in 2011 was so huge that it remains unparalleled in human mind in the region. Basing on a large network of 177 volunteers, we gathered 560 data in France, distributed in 57 departments and covering 18 regions. Most of data were recorded from April to June, corresponding to a first immigration wave. A second wave ranged from July to November, with locally swarms of thousands individuals coming from the south. Immature imagoes were encountered throughout the presence of the species in the country, but some individuals were already very old during the spring immigration. Given the general lack of known significant winter larval development in Europe, spring adults originated most likely from Africa. They bred in France in various standing waters (ponds, gravel pits with well-developed vegetation, lakes...). Imagoes recorded in summer and autumn were in part the offspring of the spring breeders and in part new southern incomers. A wide coastal Atlantic pathway was especially used for this 2011 migration, although the Rhône river axis was more usual in previous migrations. For this reason, and because of its dramatic abundance, *H. ephippiger* is new to 31 French departments. The affinity of *H. ephippiger* for lowlands is obvious: 83.6 % of the observations referred to localities ranging from 0 to 200 m a.s.l. However, *H. ephippiger* was seen at 1428 m a.s.l and bred successfully still at 640 m a.s.l, the latter elevation being to our knowledge the highest known for the species in Europe. Few other noteworthy records about the behaviour of the individuals observed are given." (Authors)] Address: Lambret, P., Cabane de Ligagneau, Route de l'Etoumeau 13104 Mas-Thibert, France. (2013): Distinct genetic clades of Malaysian Copera damselflies and the phylogeny of platycnemine subfamilies. *Scientific Reports* 3, Article number: 2977: 7 pp. (in English) ["The phylogenetic relationships of some taxa in the Platycnemidinae at the species and generic levels have been investigated. Phylogenetic trees were generated from both individual mitochondrial encoded COI, COII, 16S rDNA and nuclear encoded 28S rDNA and also combined sequences; these data indicate that the component taxa of the genus *Copera* belong to two distinct genetic clades – the marginipes group and the annulata group. There was no distinct genetic difference between the red-legged and yellow-legged morphs of *C. vittata*. Molecular data showed that the annulata group is considered a member of the genus *Platycnemis*, as originally proposed. The genus *Coeliccia*, a member of the subfamily Calicnemiinae (Platycnemididae), is not grouped with the Platycnemidinae. The Disparoneurinae of the 'Protoneturidae' showed a closer relationship to the Platycnemidinae than the Calicnemiinae. The dataset supports the placement of the Disparoneurinae as a subfamily of the Platycnemididae. This resolves the monophyly of Platycnemididae." 13135. Liu, G.; Li, C.; Dong, H. (2013): Does dragonfly's abdomen flexion help with fast turning maneuvers? *Bulletin of the American Physical Society* 58(18): o.p. (in English) ["Dragonflies are able to achieve fast turning maneuvers during take-off flights. Both asymmetric wing flapping and abdomen flexion have been observed during the fast turning. It's widely thought that the asymmetric wing beats are responsible of producing the aerodynamic moment needed for the body rotation. However, the dynamic effect of the abdomen flexion is not clear yet. In this study, an integrated experimental and computational approach is used to study the underlying dynamic effect of dragonfly abdomen flexion. It's found that dragonfly abdomen tended to bend towards the same side as the body reorienting to. Quantitative analysis have shown that during take-off turning maneuver the abdomen flexion can modulate the arm of force by changing the position of the centre of mass relative to the thorax. As a result, roll and yaw moments produced by the wing flapping can be enhanced." (Au-

thors)] Address: Liu, G., Dept. of Mechanical and Aerospace Engineering, University of Virginia, USA

13140. Maxwell, J. (2013): Parametric investigations into fluid-structure interactions in hovering flapping flight. M.Sc. Thesis, Department of Mechanical Engineering, University of Maryland, College Park: XI + 128 pp. (in English) ["A parametric investigation into flapping flight is presented. For a Reynolds number of 75, harmonically forced flapping dynamics is studied. A wing section is modelled as two rigid links connected by a hinge with a torsion spring-damper combination. This section is wrapped in a smooth aerodynamic surface for immersion in the fluid domain. An immersed boundary method is employed on a two-dimensional structured Cartesian grid to solve the incompressible form of the Navier-Stokes equations for low Reynolds numbers by using a finite difference method. Fully coupled fluidstructure interactions are considered. Performance metrics, which include cycle-averaged lift, drag, power, and their ratios, are used to characterize the effects of different parameters and kinematics. Principal components of flow-field structures are quantified, and the system's response is correlated to performance. The thesis findings can serve as a basis to understand and identify flapping frequencies that provide high performance." (Author) Figure 3.3 presents a Principal component analysis of a dragonfly picture (*Anax junius*).] Address: not stated

13141. McLamb, S. (2013): Shropshire (VC40) Dragonfly Newsletter. Shropshire (VC40) Dragonfly Newsletter. Spring 2013: 7 pp. (in English) [Content: Flight Season 2012; First and Last Recorded Sightings 2012; Species: A total of 27 species were recorded in 2012 comprising 16 dragonfly and 11 damselfly species; New / Rediscovered Populations: *Sympetrum fonscolombii*, *Ischnura pumilio*; Missing In Action...: The most notable 'missing species' of 2012 was the Keeled Skimmer (*Orthetrum coerulescens*); Coming Soon to a Pond Near You?: *Erythromma viridulum*; BDS National Atlas; Shropshire Dragonflies- the next project!] Address: McLamb, Sue, mclamb1@btinternet.com.

13142. Medvedev, A.F.; Kosterin, O.E.; Malikova, E.I.; Schneider, W. (2013): Descriptions of *Somatochlora exuberata* Bartenev, *Leucorrhinia intermedia* Bartenev and *Sympetrum vulgatum grandis* Bartenev, the fate of A.N. Bartenev's type specimens and designation of the lectotype of *L. intermedia* (Anisoptera: Corduliidae, Libellulidae). *Odonatologica* 42(3): 211-228. (in English) ["Descriptions of *S. exuberata*, *L. intermedia* and *S. vulgatum grandis* were published simultaneously but 4 times in 2 languages and in 3 years, 1910, 1911 and 1912. One of the 1910 publications was fragmented and published in 4 subsequent journal issues, involving confusion with the order of parts and the paper title, but it is this publication which has priority. The date of publication of the above mentioned names is Oct. 1, 1910. Hence *Somatochlora exuberata* Bartenev, 1910 has priority over *Somatochlora japonica* Matsumura, 1911. Syntypes in Bartenev's own collections were most probably lost, as were most of his types, but some may remain in European collections as received by foreign odonatologists from Bartenev in exchange. A male syntype of *L. intermedia* from Ris' collection, kept in Forschungsinstitut und Naturmuseum Senckenberg, Frankfurt/Main, Germany (FMS), is designated as the lectotype of this taxon." 13143. Mikolajewski, D.J.; Wohlfahrt, B.; Joop, G.; Beckerman, A.P. (2013): Sexual size dimorphism and the integration of phenotypically plastic traits. *Ecological Entomology* 38(4): 418-428. (in English) ["Sexual size dimorphism (SSD) reflects adaptive differences in male and female reproductive roles. Understanding the mechanisms generating SSD is of broad ecological and evolutionary interest, because body size is closely linked to fitness. Sex-specific phenotypic plasticity in growth as a response to environmental conditions represents one of the major sources mediating variation in SSD. We investigated phenotypic plasticity associated with predation and seasonal time constraints in development as a source of SSD in *Coenagrion puella*. We complemented this with an analysis of trait correlations (integration) of body size with behavioural, physiological

and life-history traits to investigate how dimorphism manifests. Our results reveal that: (i) plasticity in SSD is mediated by environmental variation; and (ii) environment-dependent, sex-specific changes in the association of body size with growth rate and fat storage mediated changes in the offset of SSD. Our results highlight sex-specific trait responses to the environment channel manifestation of SSD. These findings may be crucial to understanding large parts of the widely documented intraspecific variation of SSD." - 13153.** Nordström, K. (2013): Robust prey detection in a small nervous system. *PNAS* 110(2): 389-390. (in English) ["Vision plays a huge role for us humans, as well as for many other animals. If you have ever tried to walk in a straight line with your eyes closed, you know how important self-generated optic flow is for maintaining a straight trajectory. Besides such widefield optic flow cues, we can also visualize the motion of objects that move independently of the remaining visual surround. Such targets may represent the motion of a ball during a game of cricket, tennis, or baseball (take your pick, depending on your cultural heritage and location in the world). Despite the fact that you are moving, and thereby generating optic flow across your visual field, you can still visualize and identify the independent trajectory of the ball. Motion vision is not only important for human sports stars (1), but also for insects who use these cues for tasks such as maintaining a straight flight trajectory (2), avoiding colliding with approaching tree trunks, and, importantly, identifying targets such as potential prey (3), the subject of a paper published in PNAS (4). Studying the neurophysiology underlying target detection in human subjects, and other vertebrates, quickly becomes quite complicated. Besides the relative inaccessibility of the vertebrate visual cortex, there is the additional inconvenient complication of the eyes being able to move independently of the head (5). In insects, however, the eyes are fixed to the head's exoskeleton, which means we know what the insect looks at if we know what direction the head is facing. Intriguingly, however, despite vertebrates and insects being separated by huge evolutionary distances (6), and being equipped with completely different eyes (7), mo-

tion vision is coded in remarkably similar ways in the vertebrate visual cortex and the insect brain (8). We can therefore, somewhat surprisingly, use the insect visual system to understand ... Dragonflies have compound eyes, which limit the spatial resolution severely compared with the single lens eyes of vertebrates (7). In a compound eye, the maximum resolution is given by the spacing of the individual lenses. Dragonflies, and many other insects that depend on successful target detection, have therefore evolved areas in the compound eye with increased spatial resolution, called acute zones (16). The dragonfly's acute zone is located in the dorso-frontal visual field, in the same area as Gonzalez-Bellido et al. describe the peak TSDN sensitivity (4). This is also the part of the visual field where STMD receptive fields tend to cluster (17), and where dragonflies position their prey during target pursuit (3, 9). Taken together, this highlights the coevolution of optics, neural machinery and behaviour for optimizing successful target pursuit despite the limited hardware—in the form of poor and a small brain—provided." 13154. Noskovič, J.; Rakovská, A.; Porhajašová, J.; Babošová, M.; Čeryová, T. (2013): Biological evaluation of the water quality in the water flow in the southwestern part of the Slovak Republic. *Research Journal of Agricultural Science* 45(2): 171-181. (in English) ["Assessment of the surface water quality in the whole Europe affected the Directive 2000/60/EC of the waters, according to which is the evaluation method of surface waters based on the the evaluation of the ecological and chemical status of the surface water bodies. For environmental assessment are key information on the qualitative and quantitative composition of communities aquatic organisms. On this basis, we collected 28 samples of water flow at 7 sites Caradice brook during year 2009, in the southwestern part of the Slovak Republic. In the water flow Ěaradice stream, which spring in the mountain of Pohronský Inovec and is righthand tributary of the Hron River, thus we obtained 30 776 individuals macrozoobenthos. By determining the mentioned number of the individuals, we found the presence of 146 kinds that were included into 16 systematic groups: Turbellaria, Oligochaeta, Hirudinea, Gastropoda, Bivalvia, Isopoda, Amphipoda, Ephemeroptera, Plecoptera, Odonata, Heteroptera, Megaloptera, Coleoptera, Trichoptera, Diptera, Chironomidae. From these systematic groups the largest number of representatives of the systematic group Amphipoda had regularly occurred at all sampling sites. Most widespread type of this systematic group and also the most numerous of all species of macroinvertebrate found in the waters of the Caradice stream was *Gammarus fossarum*, which we regard to its mass occurrence (28%) identified as eu-dominant species. The smallest numerous individuals were represented systematic group Megaloptera that

monitored the water flow occurred infrequently, so we included them to subprecedent species. The greatest constancy, i.e. stability of in the community had species *Eiseniella tetraedra*, *Gammarus fossarum*, *Pisidium obtusale*, which we evaluated as the species always present. The species of *Cloeon dipterum*, *Erpobdella octocolata*, *Hydropsyche angustipennis* was species the almost always present. The greatest frequency had family Chironomidae (100%). The Saprobic indices in the reporting period ranged from 1.7151 to 2.2399 on the basis of what we categorized the water from Caradice stream to the level of beta - mesosaprobity. The average annual value of the saprobic index of benthic invertebrates of Caradice brook (SAS=2,00) does not meet the requirements of the indicator of water quality - Part E "biological and microbiological parameters, which are set out in Government Regulation No. 269/2010 Coll. (SAS = 1,3)." (Authors)] Address: Noskovič, J., Dept of Environmental Sciences and Zoology, Slovak University of Agriculture in Nitra, Tr. A. Hlinku 2, 949 76 Nitra – Slovakia. tebrates of selected ponds in Agbede flood plain, southern Nigeria. *Journal of Biology, Agriculture and Healthcare* 3(1): 23-29. (in English) ["Ecological study on three selected ponds of Agbede flood plain was fortnightly carried out between January and June, 2007 to assess and document the macrobenthic fauna composition, abundance and distribution, as well as the physicochemical status of some parameters in water which were collected and analyzed monthly. Benthos was sampled for using the Ekman Grab operated by hand in shallow waters together with the Kick sampling method. Among the eight physicochemical characteristics investigated, pH fluctuated from slightly acidic to slightly alkaline with range of values (5.90 – 7.35) at the studied stations. Significant difference ($P < 0.05$) was observed for biological oxygen demand (BOD5) and dissolved oxygen (DO). A total of ten (10) groups comprising macroinvertebrates taxa with one thousand and thirty one (1,031) individuals were recorded in this study. Most dominant groups were represented by Coleopterans (35.79% and 374 individuals), Hemiptera (20.19% and 211 individuals) and Dipterans (18.47% and 193 individuals). Evenness was highest in pond 1 (0.4973). The highest number of macroinvertebrates were collected from pond 2 (416) where no human activities occurred and however implied that human activities can rapidly alter any previously stable communities of aquatic environments." (Authors) Identification of taxa is obscure because the checklist includes Palaearctic and Nearctic taxa.] Address: Olumukoro, J.O., Department Of Animal And Environmental Biology, Faculty Of Life Sciences, University Of Benin, Benin City, P.M.B. 1154, Nigeria. 13158. Orwa, P.O.; Raburu, P.O.; Kipkemboi, J.; Rongoei, P.; Owuor, O. (2013): Use of macroinvertebrate assemblage to assess the ecological integrity of Nyando Wetlands, Kenya. *Journal of Ecology and the Natural Environment* 587: 152-164. (in English) ["This study aimed to investigate changes in macroinvertebrate assemblage within Nyando wetlands and developed an index of biotic integrity for monitoring human disturbances. Triplicate macroinvertebrate samples were collected monthly for seven months using a scoop net. They were sorted live, counted and identified to genus level. Water samples for nutrients were collected and analyzed using standard methods. Physico-chemical parameters were taken in situ using electronic meters. Macroinvertebrates were analyzed for richness, diversity, dominance and abundance. Abundance was correlated with physico-chemical parameters. Kruskal-Wallis test was used to test spatial differences in macroinvertebrate community. Metrics for index of biotic integrity were chosen, tested, and a 5, 3, 1 scoring criteria was used. A total of 45 genera (including four Odonata genera) were identified and Kruskal-Wallis test analysis revealed significant spatial differences in macroinvertebrate abundance. Repeated measures ANOVA showed significant spatio-temporal differences. Tolerant ma-

croinvertebrates were abundant at the disturbed sites whereas intolerant taxa showed a strong negative correlation with nutrient levels. Sites with higher disturbance recorded a total index score far below the reference site score. The results indicated that macroinvertebrates in Nyando wetlands can be used to monitor its ecological integrity. The IBI developed should be used to protect the lake from eutrophication." 13159. Outomuro, D.; Dijkstra, K.-D.B.; Johansson, F. (2013): Habitat variation and wing coloration affects wing shape evolution in dragonflies. *Journal of Evolutionary Biology* 26(9): 1866-1874. (in English) ["Habitats are spatially and temporally variable, and organisms must be able to track these changes. One potential mechanism for this is dispersal by flight. Therefore, we would expect flying animals to show adaptations in wing shape related to habitat variation. In this work, we explored variation in wing shape in relation to preferred water body (flowing water or standing water with tolerance for temporary conditions) and landscape (forested to open) using 32 species of dragonflies of the genus *Trithemis* (80% of the known species) (*Trithemis aconita*, *T. adelpha*, *T. aenea*, *T. aequalis*, *T. africana*, *T. annulata*, *T. arteriosa*, *T. aurora*, *T. basitincta*, *T. bifida*, *T. bredoi*, *T. dejouxi*, *T. dichroa*, *T. donaldsoni*, *T. dorsalis*, *T. ellenbeckii*, *T. festiva*, *T. furva*, *T. grouti*, *T. hartwigi*, *T. hecate*, *T. imitata*, *T. kalula*, *T. kirbyi*, *T. monardi*, *T. nuptialis*, *T. pluvialis*, *T. pruinata*, *T. selika*, *T. stictica*, *T. tropicana*, *T. wernerii*). We included a potential source of variation linked to sexual selection: the extent of wing coloration on hindwings. We used geometric morphometric methods for studying wing shape. We also explored the phenotypic correlation of wing shape between the sexes. We found that wing shape showed a phylogenetic structure and therefore also ran phylogenetic independent contrasts. After correcting for the phylogenetic effects, we found (i) no significant effect of water body on wing shape; (ii) male forewings and female hindwings differed with regard to landscape, being progressively broader from forested to open habitats; (iii) hindwings showed a wider base in wings with more coloration, especially in males; and (iv) evidence for phenotypic correlation of wing shape between the sexes across species. Hence, our results suggest that natural and sexual selection are acting partially independently on fore- and hindwings and with differences between the sexes, despite evidence for phenotypic correlation of wing shape between males and females." 13160. Pacini, N.; Donabaum, K.; De Villeneuve, P.H.; Konecny, R.; Pineschi, G.; Pochon, Y.; Salerno, F.;

Schwaiger, K.; Tartari, G.; Wolfram, G.; Zieritz, I. (2013): Water quality management in a vulnerable large river: the Nile in Egypt 11(2). *International Journal of River Basin Management*: 205-219. (in English) ["We review the severe water management problems of the Nile Basin, where physical water scarcity is associated with high demographic growth, leading to a sharply-rising demand for competing water uses such as hydropower and large-scale irrigation. Rapid economic growth is perceived as the means to emerge from the poverty trap that afflicts livelihoods in the Upper Basin and vital wetland ecosystem services such as fish biomass, freshwater biodiversity, groundwater recharge, flow regulation and local climate moderation are threatened by the water development schemes and pollution that follow from this policy. Their cumulative impacts remain unaddressed. The High Aswan Dam's impacts on freshwater biodiversity are incompletely understood; a significant number of species may have become threatened as a result of its construction. Today the reservoir water quality is high, it is thought to support 47 fish species, its local human activities are restricted by central government regulations and recent estimates indicate that eutrophication threats are unlikely. Sediment and nutrient inputs coming into it from upstream will, however, continue to decrease in the near future as a result of newly built and planned dams in the upper basin. The dams will also reduce discharge and cause further loss of connectivity between the river and its floodplain; exacerbated by the possible completion of the Jonglei Canal bypassing the Sudd swamps. These impacts will affect the Nile's vulnerable aquatic biodiversity and regulatory services that are likely to affect local climate conditions. Under the current geopolitical scenario, management decisions that could favour participatory and sustainable options are over-ruled by high-level political trade-offs between the numerous riparian states. The financing of major hydropower developments by vested interests creates a scenario that is unlikely to favour sustainable resource management and conflict resolution.... Below Aswan, the whole river can be described as a potamon dominated by Odonata, Coleoptera, Corixidae and Chironomidae." 13162. Panov, E.N.; Opaev, A.S. (2013): Behavior of males in a reproductive aggregation of the banded damselfly *Calopteryx splendens* (Insecta, Odonata). *Entomological Review* 93(7): 805-813. (in English) ["The view according to which damselfly males practice two alternative reproductive tactics of access to females is critically discussed. It is widely accepted that some males ("territorial" ones) have priority as potential female partners, while others ("sneakers" or "wanderers") are incapable of retaining an individual territory. They have a chance of mating only by intruding briefly into the area defended by a "territorial" male when a female is present there. Thus, the tactics of a "territorial" male consists in waiting for a female in its territory and copulating with it "by agreement," whereas non-territorial males resort to forced copulations. By observation of individually marked males (48 out of 118) it was shown that every male could be regarded as "territorial" during a certain period and as a "wanderer" before and after it. Thus, no correlation between the modes of space use by a male (residence/mobility) and the characters of its external morphology and/or signal behaviour appears to be possible in principle. According to the data obtained, a more plausible explanation is that the female chooses not the male but the best area for oviposition. In addition, it was ascertained that adherence to forced copulations cannot constitute successful "tactics" since they rarely result in insemination, neither by "territorial" nor "non-territorial" males. In other words, we are dealing not with certain alternative tactics (i.e., specialized adaptive mechanisms that have evolved in the species) but simply with the results of different sets of circumstances at a given moment." 13163. Payton, G. (2013): The effects of predator chemical cues on the behavior of spotted salamander larvae (*Ambystoma maculatum*). *BIOS 35502: Practicum in Field Biology, Advisor: Shayna Sura*: 15 pp. (in English) [Wisconsin, Michigan, USA "The detection of kair-

omones, or chemical cues released by hunting predators, is an important ability of prey that allows them to exhibit anti-predator behaviour, thus increasing their chance of survival and fitness. This study aims to elucidate the effect of the kairomones of two native predators, diving water beetle larvae and dragonfly larvae (Libellulidae), on the behaviour of spotted salamander larvae. Observational laboratory trials were conducted to determine the effect that the addition of kairomone-containing water had on the larvae's preference for depth and cover in their environment. I predicted that the larvae would prefer to live in a shallow environment when treated with dragonfly larvae chemical cues, a deep environment if exposed to diving water beetle chemical cues, and an even split between the two depths when exposed to the kairomones of both predators, based on the predators' different hunting methods. I also hypothesized that the salamander larvae would prefer to inhabit areas with foliage to areas with no foliage when treated with the kairomones of dragonfly larvae and/or diving water beetles. However, it was found that there was no significant difference in mean time spent in each quadrant between each of the treatments. Perhaps the effect of chemical cues is a learned trait for the salamander larvae, and thus the predator naïve larvae used in this experiment had no knowledge of the predators' effects or hunting techniques." 13169. Quina, C.L.; Pelli, A.; Costa Martins, A.G. (2013): Succession of benthic macroinvertebrates on rat carcasses in Uberaba river - MG. *SaBios-Revista de Saúde e Biologia* 8(2): 73-80. (in Portuguese, with English summary) ["There are patterns of ecological succession in different stages of decomposition in the rat carcasses. According to the stages of decomposition, the succession happens in stages characterized by defined groups and species. The aim of this research was to evaluate the ecological succession in animal carcasses in lotic environments. Five neonates rats previously sacrificed in cold anesthesia were evaluated. Within a bag of shade, the material was deposited in lotic environments and re-

moved in intervals of 1 to 4 days. The analysis was performed in the laboratory after sieving the sample solution and preserved in alcohol 75%. The material was sorted and identified under a stereoscopic microscope. Insecta was the dominant group. Trichoptera and Diptera were dominant with three families, followed by two Ephemeroptera families and one family of Coleoptera and Odonata ("Libellulidae") orders. Two orders of Crustacea, the phyla Annelida and Sarcodina were also observed. There was a succession of organisms related to functional or morphological behaviour. There was a tendency of increase in density and species richness and that the pattern of succession in artificial substrate - carcasses - reflects the environmental conditions." 13171. Rebora, M.; Piersanti, S.; Gaino, E. (2013): The mechanoreceptors on the endophytic ovipositor of the dragonfly *Aeshna cyanea* (Odonata, Aeshnidae). *Arthropod Structure & Development* 42(5): 369-378. (in English) ["This study investigates the mechanoreceptors located on the cutting valvulae of the ovipositor of *A. cyanea*, using both SEM and TEM, with the aim of providing an overview of the sensory equipment of an odonatan endophytic ovipositor. Four kinds of sensilla have been described. Notwithstanding their different external and internal morphology, they show features typical of mechanoreceptors. Three of them are evident along the external surface of the two cutting valvulae in the form of sub-spherical pegs, pit organs type 1 (holes) and pit organs type 2 (depressions), these last similar to amphinematic scolopidia, while the fourth type is represented by subintegumental mononematic scolopidia having no direct relationship with the cuticle. In spite of their structural differences, the morphology of the described mechanoreceptors is consistent with performing a main role in allowing the perception of compression/ stretching of the thick cuticle of the valvulae and their bending due to the pressure acting on the distal end of the ovipositor during substrate penetration. Such an organization is coherent with the need of endophytic Odonata to be able to evaluate the stiffness of the plant where to lay eggs." (Authors)]

13172. Reeve, B.C.; Crespi, E.J.; Whipps, C.M.; Brunner, J.L. (2013): Natural stressors and ranavirus susceptibility in larval Wood Frogs (*Rana sylvatica*). *EcoHealth* 10(2): 190-200. (in English) ["Chronic exposure to stressors has been shown to suppress immune function in vertebrates, making them more susceptible to pathogens. It is less clear, however, whether many natural stressors are immunosuppressive. Moreover, whether stressors make disease more likely or more severe in populations is unclear because animals respond to stressors both behaviourally and physiologically. We tested whether chronic exposure to three natural stressors of wood frog tadpoles—high-densities, predator-cues, and low-food conditions—influence their susceptibility to a lethal ranavirus both individually in laboratory experiments, and collectively in outdoor mesocosms. Prior to virus exposure, we observed elevated corticosterone only in low-food treatments, although other treatments altered rates of growth and development as well as tadpole behaviour. None of the treatments, however, increased susceptibility to ranavirus as measured by the proportion of tadpoles that became infected or died, or the time to death compared to controls. In fact, mortality in the mesocosms was actually lower in the high-density treatment even though most individuals became infected, largely because of increased rates of metamorphosis. Overall we find no support for the hypothesis that chronic exposure to common, ecologically relevant challenges necessarily elevates corticosterone levels in a population or leads to more severe ranaviral disease or epidemics. Conditions may, however, conspire to make ranavirus infection more common in metamorphosing amphibians ... Predator cues were generated by feeding wood frog tadpoles to a dytiscid beetle larvae (Dytiscidae) or dragonfly larvae (families Libellulidae, Aeshnidae, and Corduliidae), each in 400 mL of water." 13175. Roh, C.; Saxton-Fox, T.; Gharib, M. (2013): Characterization of ventilatory modes in dragonfly nymph. *Bulletin of the American Physical Society* 58(18): n.p. (in English) ["A dragonfly nymph's highly modified hindgut has multiple ventilatory modes: hyperventilation (i.e. jet propulsion), gulping ventilation (extended expiratory phase) and normal ventilation. Each mode involves dynamic manipulation of the exit diameter and pressure. To study the different fluid dynamics associated with the three modes, Anisopteran larvae of the family Aeshnidae were tethered onto a rod for flow visualization. The result showed distinct flow structures. The hyperventilation showed a highly turbulent and powerful jet that occurred at high frequency. The gulping ventilation produced a single vortex at a moderate frequency. The normal ventilation showed two distinct vortices, a low-Reynolds number vortex, followed by a high-Reynolds number vortex. Furthermore, a correlation of the formation of the vortices with the movement of the sternum showed that the dragonfly is actively controlling the timing and the speed of the vortices to have them at equal distance from the jet exit at the onset of inspiration. This behaviour prevents inspiration of the oxygen deficient expired water, resulting in the maximization of the oxygen intake." (Authors)] Address: not stated

13176. Ronne, C.; Blanchon, Y. (2013): Redécouverte de *Brachytron pratense* (Müller, 1764) dans le département du Var (Odonata, Anisoptera: Aeshnidae). *Martinia* 29(1): 43-45. 13185. Sharkey, C.R.; Roberts, N.W.; Partridge, J.C. (2013): Dragonfly larval polarization sensitivity as a contrast enhancer in turbid water. *Front. Physiol. Conference Abstract: International Conference on Invertebrate Vision.* doi: 10.3389/conf.fphys.2013.25.00078: n.p. (in English) [Verbatim: A challenge faced by visual systems underwater is the presence of scattered light haze, or 'veiling light', that reduces the contrast of the scene. Light scattered underwater by sub-wavelength particles is polarized, forming a light field that is maximally polarized in a band orthogonal to the direction of the sun (Waterman, 2006). An animal able to filter out this scattered, polarized light would benefit from a greater perceived contrast, enhancing the detection of objects in an underwater scene (Rowe et al., 1995; Schechner et al., 2003). If this mechanism were present, it could potentially benefit an aquatic predator by enhancing prey detection. We compared the responses of three larval instars of dragonfly, *Anax imperator*, to moving gratings with a range of spatial frequencies, seen by the insects through turbid water under different illumination conditions. Animals were placed in an optomotor drum, with a surrounding circular tank filled with diluted milk; the grating to be tested being placed on the outside of the drum. The milky solution was illuminated from above through linear Polaroid filters with transmission axes aligned either radially or tangentially with respect to the drum, thereby creating either a weakly (10%) vertically polarized or a more strongly (30%) horizontally polarized light field, respectively. The head angles of animals, during the experiment, were measured and 'gain', the rotational velocity (degrees per second) of the animal's head was expressed as a fraction of that of the drum, used as a measure of their response. Data were

log transformed and analysed by fitting Linear Mixed Models. For all three larval instars, responses to the moving gratings were significantly stronger overall when the light field was polarized horizontally (?deviance=5.945, d.f.=1, p=0.015; Fig.1, bars represent SE) particularly at 0.09 cycles/degree. Animals responded differently to different spatial frequencies, exhibiting reduced responses at the highest and lowest frequencies tested. Responses to different spatial frequencies were dependent on instar, with response peaking at a lower frequency for earlier instars (?deviance=13.56, d.f.=6, p=0.035). The increase in response, observed when animals are in a horizontally polarized light field, may be due to a contrast-enhancing effect of polarization sensitivity, a suggestion supported by preliminary data, derived from on-going behavioural experiments. This contrast enhancing effect could increase the chance of a successful strike during hunting and increase the distance at which both predators and prey can be detected. References: Rowe, M. 13189. Simon, S.; Brugler, M.R.; DeSalle, R.; Hadrys, H. (2013): First insights in the embryonic development of the damselfly *Ischnura elegans*. 6th Dresden Meeting on Insect Phylogeny, Dresden, September 27–29, 2013. Abstracts — Oral Presentations: 21-22. (in English) [Verbatim: The new sequencing technologies have massively increased the amount of data available for comparative transcriptomics which can be used to infer insect relationships but also to study the transcriptional

signatures and dynamics of developmental processes. In addition, for *Drosophila* species it has been shown that expression divergence correlate with sequence divergence among putative orthologous genes, making comparative gene expression analyses to a useful tool in molecular phylogenetics (Zhang et al. 2007; Kalinka et al. 2010). However, transcriptomic data across developmental stages are mainly available for derived holometabolous insects, especially drosophilid dipteran species. Here, we fill in an important gap for future comparative gene expression analyses by analyzing and comparing transcriptomic data across the embryonic development of *I. elegans*. Roche 454-multiplexed transcriptomic data was generated for four time-periods (day 1–3, 4–5, 6–7, 8–9) spanning the entire embryonic lifespan. The assembled 454 reads and comparative analyses between the different embryonic stages will provide the first insights in the temporal gene expression changes during early damselfly development. In addition, highquality ds cDNA libraries for each embryonic developmental stage (day) were generated for further in-depth gene expression analyses using quantitative RT-PCR. The long-term goal of this ongoing research project is to systematically search for expression divergence between distantly related insect species, their correlation to sequence divergence (known phylogenetic relationships) and to study their role in morphological changes. 13190. Singh, K.M.; Singh, M.P.; Kumawat, M.M.; Riba, T. (2013): Entomophagy by the tribal communities of North East India. *Indian Journal of Entomology* 75(2): 132-136. (in English) ["A survey was conducted to document the edible insects available at East Siang District, Arunachal Pradesh and Bishnupur District, Manipur, northeast India. East Siang district is predominated by the Adi tribe and Bishnupur district by the Meitei community. The two ethnic groups, viz. Adi and Meitei accept insects as their food. Most of the edible insects belong to the order Hymenoptera, Hemiptera, Orthoptera, Odonata and Coleoptera. *Philosamia ricini* is a commercialized insect species as food in Arunachal Pradesh. Based on their resources, Adis of East Siang accepted more terrestrial insects compared to Meiteis of Bishnupur. Meitei community of Bishnupur consumed more aquatic insects. One or the other species of insects are available in all the seasons, however, more species are available in the warm season. Most of the insects are consumed after processing. Some points to

be considered for encouraging these edible insects as human food are also discussed." (Authors)] Address: Singh, K.M., College of Horticulture and Forestry, Central Agricultural University, Pasighat, Arunachal Pradesh, India. E-mail: mamoento@gmail.com

(2013): Proper orthogonal decomposition of flexible clap and fling elastic motions via high-speed deformation measurements. *Experimental Mechanics* 53(7): 1127-1141. (in English) ["Many complex unsteady mechanisms are thought to facilitate the high efficiency and agility commonly observed in small biological flyers. One of these, the flexible clap and fling maneuver, has not been extensively studied; an experimental characterization is the focus of this work. The clap-fling mechanism is approximated with a single flexible membrane flapping wing, replacing the symmetry plane between two wings with a splitter plate simulating the pair wing. This produces a complex vibro-impact aeroelastic problem, the deformation resulting from which is measured with a high-speed visual image correlation system. A low-dimensional representation of the ensuing large data set is obtained with proper orthogonal decomposition. The POD modes, and the relative importance of each, can help elucidate crucial mechanisms and relationships within the flapping system, and are computed for various membrane wing structures and flapping frequencies, with or without the presence of the splitter plate." 13200. Thuyet, D.Q.; Watanabe, H.; Motobayashi, T.; Ok, J. (2013): Behavior of nursery-box-applied fipronil and its sulfone metabolite in rice paddy fields. *Agriculture, Ecosystems & Environment* 179(1): 69-77. (in English) ["Highlights: • Behaviour of insecticide fipronil in paddy environment was examined. • Fipronil concentrations in paddy water were different depending on the treatment. • Fipronil indicated half-lives less than 3.1 days in water and 26.4 days in soil. • Concentrations in root zone were about 10 times higher than in the inter-row zone. • Toxic metabolite fipronil sulfone was found in every water and soil samples. The granular insecticide fipronil has been widely applied in rice nursery boxes, both before transplanting (BT) and during at-sowing (AS) treatments to control insect pests at the early stages of rice cultivation in Japan. Although a potential effect of fipronil on paddy ecosystems and downstream aquatic environments has been observed, the environmental effect of this substance in paddy fields remains unsought. Here we investigate the environmental behaviour of nursery-box-applied granular fipronil and its sulfone metabolite in paddy water and paddy soils during BT and AS treatments performed in a paddy field in Japan. Although the fipronil concentrations in the paddy water in the AS treatment were significantly lower than those measured in the BT treatment, no significant differences were observed in the paddy soil between the two treatments. Fipronil was mainly found in the 0- to 5-cm surface soil layer of the rice-root zone, where its concentrations were approximately ten times higher than those in the soil of the inter-row zone. The insecticide concentration in the 0- to 1-cm layer of the inter-row zone in the surface soil was approximately 2.5 times higher than that in the 0- to 5-cm layer. The maximum concentrations of fipronil in the 0- to 1-cm surface soil layer ranged from 65.8 to 92.1 $\mu\text{g}/\text{kg}$ on the first day after rice transplanting (DAT), and the corresponding values in the paddy water ranged from 0.9 to 2.5 $\mu\text{g}/\text{L}$. The dissipation of fipronil from the paddy water and paddy soil was described by first-order kinetics. The compound's half-life (DT_{50}) was 0.9–3.1 days in paddy water and 12.3–26.4 days in paddy soil. Compared to the BT treatment, the AS treatment may pose a smaller risk to the paddy water and the adjacent environment. Fipronil sulfone was found in every water and soil sample, with the maximum concentrations ranging from 0.4 to 0.9 $\mu\text{g}/\text{L}$ in the paddy water and from 9.7 to

59.2 $\mu\text{g}/\text{kg}$ in the paddy soil on the third DAT. These values gradually decreased over time. Ecotoxicological risk assessments of fipronil products in rice paddies should not only consider the toxicity of fipronil itself but also that of fipronil sulfone because of its relatively high concentrations in paddy water and paddy soil. ...The studies of the environmental impact of fipronil on paddy fields suggest that the dragonfly (*Sympetrum* species) population has rapidly decreased since 1989, and that the observed reduction was positively correlated with the increased use of nursery-box-applied fipronil ..."] (Authors)] Address: Motobayashi, T., Tokyo University of Agriculture and Technology, 3-5-8, Saiwaicho, Fuchu, Tokyo 183-8509, Japan. 13201. Touron-Poncet, H.; Bernadet, C.; Compin, A.; Bargier, N.; Céréghino, R. (2013): River classification as the basis for freshwater biological assessment in overseas Europe: Issues raised from Guadeloupe (French Lesser Antilles). *International Review of Hydrobiology* 98: 34-43. (in English) ["Over the past decade, Europe's Water Framework Directive (WFD) has prompted a large amount of ecological research aiming at establishing river typologies and ecological indicators in member States. Yet, the lack of robust bioindicators in Europe's overseas regions arguably reflects minimal knowledge of the distribution patterns of aquatic species in the Community's outermost areas. Specifically, there has been no published classification of rivers for any European overseas region. 51 sites were sampled for benthic invertebrates and environmental variables (land-cover, physical habitat, and water chemistry) in Guadeloupe, French Lesser Antilles. Redundancy analysis and k-means clustering were used to bring out spatial patterns in species composition in relation to environmental conditions. Our results highlighted the importance of land cover and geomorphology in delineating three ecological sub-regions (clusters) for freshwater invertebrates. Deviation from predictable community structure only occurred when river sites were subjected to harsh water chemistry alterations (urban runoff, wastewaters). Changes in species richness did not detect environmental stress efficiently within a given sub-region, probably because most sites are naturally species-poor due to the insular context and/or because disturbance is often weak. However, differences existed between clusters in terms of species identity and numerical dominance. Our a posteriori typology of sites was compared to local a priori expert opinion of river health, in an attempt to better characterize the network of survey sites, and to target sites for reference conditions." (Authors) Odonata in this study were represented by *Argia concinna*, *Enallagma coecum*, *Ischnura ramburii*, *Libellulidae* *Brechmorhoga*, *Macrothemis celeno*, and unidentified taxa.] Address: Céréghino, R., UPS EcoLab Univ. 13202. Tummylovich, O.A. (2013): Interannual dynamics of the species composition and relative abundance of dra-

gonflies in one of the ponds of Kaliningrad. Materials of the Fifth All-Russia Symposium on Amphibiotic and Aquatic Insects / Papanin Institute for Biology of Inland Waters, Russian Academy of Sciences. – Yaroslavl: Filigran, 2013. – 254 pp: 214-218. (in Russian, with English summary) ["Dragonfly larvae and changes in anthropogenic pressure on the ecosystem were monitored for 4 years (2005–2007) in one of the ponds of Kaliningrad. In 2004, the pond had virtually no anthropogenic pressure, and it was inhabited by seven species of dragonflies (*Libellula quadrimaculata*, *L. depressa* Enallagma cyathigerum, *Coenagrion hastulatum*, *C. pulchellum*, *Ischnura elegans*, and *Aeshna grandis*). Anthropogenic influence increased during the period of study, leading to degradation of aquatic vegetation, soil pollution, and disruption of the shoreline due to the increased recreational pressure. This was accompanied by a decrease in the occurrence frequency of all dragonfly species and average number of larvae per sample (from 2.71 to 0.31 individuals), and the gradual disappearance of six species. In 2007, only *L. quadrimaculata* remained in the pond, the most widespread and abundant species, not only in Kaliningrad Oblast, but throughout Russia and Europe." (Author)] Address: Tummylovich, O.A., Kaliningrad State Technical University Sovetsky prosp. 2, Kaliningrad, 236000, Russia. E-mail: levente@rambler.ru

13203. Valk, van der, R. (2013): Calculation of the maturation period of the Black Darter (*Sympetrum danae*). *Brachytron* 15(2): 128-132. (in Dutch, with English summary) ["The maturation period of *S. danae* was studied over a period of three years and calculated using the statistical model that Underhill & Zuchinni (1986) used to describe primary moult in birds. The development of the pterostigma colour was used as a measure for maturation. During the maturation period the pterostigma colour changes from white to intense black. To visualize this process the stages of the maturation were estimated in the field as follows: • stage "fresh": the colour of the pterostigma is practically white and the body is more or less pale; • stage "immature": the colour of the pterostigma is not white anymore but also not completely dark; • stage "mature": the colour of the pterostigma is black. In this manner the number of dragonflies in each stage is counted. As a result of this model the duration t in days of the maturation period (stage "immature") can be calculated. In addition two other parameters are calculated i.e. the mean starting date μ and the standard deviation σ of the starting dates. In this model it is assumed that the starting dates have a Gaussian distribution $N[\mu, \sigma]$. These parameters were calculated using a computer programme. The duration of the maturation period in the year 2007 stands out with respect to the year 2006. 2005 appeared to be a more average year. The duration of the maturation period of *S. danae* appears to depend strongly on weather conditions (Table 2). In 2005 the duration of the maturation period was seventeen days, which is in ac-

cordance with the duration mentioned in Nederlandse Vereniging voor Libellenstudie (2002). In years with more extreme weather conditions the duration of the maturation period may differ by as much as a factor three." (Author)] Address: Valk, van der, R., J. Buiskoolweg 10A, 9695 TT Bellingwolde, The Netherlands. E-mail: valk0078@kpnmail.nl

13204. Vassilenko, D.V. (2013): Dragonflies of the family Kennedyidae Tillyard, 1925 (Insecta: Odonata) in Permian odonatofaunas. Materials of the Fifth All-Russia Symposium on Amphibiotic and Aquatic Insects / Papanin Institute for Biology of Inland Waters, Russian Academy of Sciences. – Yaroslavl: Filigran, 2013. – 254 pp: 32-35. (in Russian, with English summary) ["Kennedyid dragonflies are a group of protozopterans specialized on living among dense vegetation. The fossil record of Kennedyidae is extremely incomplete. Members of this family are invariably scant and rather uniform in Permian deposits, which is explained by their mode of life and low probability of their fossilization under typical sedimentation conditions. Owing to the fossil site Isady, which gives an idea of the fauna of a small waterbody and its environs, it has been shown that kennedyids played a very important role in such biotopes. The actual taxonomic diversity of the family was considerably higher than documented, not only because of the incompleteness of the fossil record, but also because of wing venation reduction, which results in low variation of venation even at the level of genera, and thus in underestimations of the number of identifiable species." (Author)] Address: Vassilenko, D.V., Borisiak Palaeontological Institute. Russian Academy of Sciences ul. Profsoyuznaya 123, Moscow, 117997, Russia. E-mail: lab@palaeoentomolog.ru

13205. Venkatesh, A.; Tyagi, B.K. (2013): Predatory potential of *Bradinopyga geminata* and *Ceriagrion coromandelianum* larvae on dengue vector *Aedes aegypti* under controlled conditions (Anisoptera: Libellulidae; Zygoptera: Coenagrionidae; Diptera: Culicidae). *Odonatologica* 42(2): 139-149. (in English) ["The predatory potential of *B. geminata* and *C. coromandelianum* larvae on *Aedes aegypti* larvae was investigated under laboratory condition with a view to screening these predators for use in the control of *Ae. aegypti* breeding in dengue prone areas. The feeding rate of 8th instar *B. geminata* on *Ae. aegypti* showed maximum predation on 1st instar larvae (86%), followed by 2nd, 3rd and 4th instars (72%, 66% and 48%), respectively. In the first hour, the consumption rate was maximal for all instars and a low intake (about 5%) was observed in subsequent hours. In 12th instar *B. geminata* larvae maximum predation was observed for the 1st and 2nd instar larvae (98%) of *Ae. aegypti*, followed by 3rd and 4th instars (92% and 78%), respectively. The feeding rate of 12th instar *C. coromandelianum* larvae on *Ae. aegypti* larvae showed that the maximum predation was of the 1st instar larvae (82%), followed by 2nd, 3rd and 4th in-

stars (51%, 35% and 24%) respectively. The first hour consumption rate was maximum for all instars and no significant intake was seen in the following hours. The predation of *Aedes* larvae by the 2 spp. of odonate larvae was compared for the 4 mosquito larval instars by using one way ANOVA. No significant difference was found between them for 1st instar larvae of *Ae. aegypti* but there was a significant difference ($P < 0.05$) in predation on the other 3 instars, with *B. geminata* consuming more mosquito larvae. A single anisopteran larva is sufficient for eliminating the huge mass of larval mosquitoes breeding in a cement tank or a cement cistern. Therefore, this biological control agent could be released to control *Aedes* larval production in areas of dengue epidemics." 13206. Walker, B. (2013): Some observations on the effect of temperature on dragonfly recording. *J. Br. Dragonfly Society* 29(2): 84-96. (in English) ["The British Trust for Ornithology added odonates to the species that contributors are asked to record from 2011. Records for the first two years of dragonfly records from this scheme have been analysed and indicate a marked difference in observations in the spring between 2011 and 2012. Spring 2011 was warmer than the recent average and noticeably warmer than in 2012 and dragonflies were recorded earlier in numbers in 2011 than in 2012. Based on a comparison of the records and the average weekly temperatures a correction factor is proposed to account for reduced dragonfly activity when temperatures are lower and it is suggested that this can explain some fluctuations in the raw data. It is also noted that the reduction in records from their peak can be described by a daily survival rate approach." (Author)] Address: Walker, B., 49 Roman Way, Wantage, Oxon OX12 9YF, UK

(2013): Study on fauna and diversity of Odonata in Yuntai mountain, Jiangsu Province. *Hubei Agricultural Sciences* 52(8): 1821-1832. (in Chinese, with English summary) [41 species were recorded between 2000 and 2010. The records were analysed according biogeographical regions.] Address: Wang, C.-x., Biochemical and Environmental Engineering college, Nanjing Xiaozhuang University, Nanjing 211171, China

13208. Warren, J.M.B. (2013): An assessment of benthic macroinvertebrate communities from three wadeable streams in central Texas. *Water Quality Technical Series Publication WQTS-2013-01. PWD PWD RP V3400-1784.* Texas Parks and Wildlife Department, Austin, TX: V + 16 pp. (in English) ["Benthic macroinvertebrates were collected and identified from three streams in the middle Brazos River Basin as a vehicle

for a biologist to gain experience in study design and working with an unfamiliar taxonomic group. The three streams selected for the study were among the few streams that continued to flow in the middle Brazos River Basin during an extreme drought in 2011. The sample sites were the Leon River at FM 1829, Salado Creek at Pace Park in Salado and Tehuacana Creek upstream of FM 2491. All three streams shared similar substrate and cover at the sample sites. Benthic macroinvertebrates were collected from riffles dominated by cobble, algae and leaf debris. Flow varied among the three streams, ranging from 1.0 ft³/s at Tehuacana Creek to 6.6 ft³/s at Salado Creek. Instantaneous physicochemical data varied among the three streams as well. Benthic macroinvertebrate taxa were most numerous at Salado Creek with 29 collected. Tehuacana Creek and Leon River taxa were 19 and 15, respectively. Numbers and types of individuals collected from each creek translated into an aquatic life use (ALU) scores that are the sum of 12 individual metrics. Salado Creek's ALU ranked high (score = 37), the Leon River scored intermediate (26), and Tehuacana Creek scored intermediate (28). Data results agreed with field observations and instantaneous physico-chemical data, and the study challenged the novice benthic macroinvertebrate taxonomist." (Authors) The list of taxa includes *Argia*, *Enallagma*, *Erpetogomphus*, and *Libellula*.] Address: Bronson Warren, Jennifer M., Water Resources Branch, Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas 78744, USA

13209. Wasserberg, G.; White, L.; Bullard, A.; King, J.; Maxwell, R. (2013): Oviposition site selection in *Aedes albopictus* (Diptera: Culicidae): Are the effects of predation risk and food level independent? *Journal of Medical Entomology* 50(5): 1159-1164. (in English) ["For organisms lacking parental care and where larval dispersal is limited, oviposition site selection decisions are critical fitness-enhancing choices. However, studies usually do not consider the interdependence of the two. In this study, we evaluated the effect of food level on the oviposition behaviour of *Aedes albopictus* (Skuse) in the presence or the absence of a nonlethal predator (caged dragonfly nymph). We also attempted to quantify the perceived cost of predation to ovipositioning mosquitoes. Mosquitoes were presented with oviposition cups containing four levels of larval food (fermented leaf infusion) with or without a caged libellulid nymph. By titrating larval food, we estimated the amount of food needed to attract the female mosquito to oviposit in the riskier habitat. As expected, oviposition rate increased with food level and decreased in the presence of a predator. However, the effect of food level did not differ between predator treatments. By calculating the difference in the amount of food for points of equal oviposition rate in the predator-present and predator-absent regression lines, we estimated the cost of predation risk to be 1950 colony-forming-units per millilitre. Our study demonstrated the importance of considering the possi-

ble interdependence of predation risk and food abundance for oviposition-site-seeking insects. This study also quantified the perceived cost of predation and found it to be relatively low, a fact with positive implications for biological control." (Authors)] Address: not available

13210. Weihrauch, F.; Erfurth, L. (2013): He who is too slow is punished by life: *Calopteryx virgo* (L.) entangled by the tendril of a vetch during emergence (Zygoptera: Calopterygidae). *Odonatologica* 42(3): 253-256. (in English) ["At a rivulet in the western fringe area of Munich, Germany, an immature male was photographed with its right forewing tightly entwined around by the tendril of a vetch. Obviously the tendril had entangled the not yet unfolded wing briefly after emergence. The living insect was unable to escape from its bonds. This is only the third published case of a biotic interaction of this type." (Authors)] Address: Weihrauch, F., Jägerstr. 21A, 85283 Wolnzach, Germany. E-mail: Florian.Weihrauch@t-online.de

13211. Więcek, M.; Martin, P.; Gąbka, M. (2013): Distribution patterns and environmental correlates of water mites (Hydrachnidia, Acari) in peatland microhabitats. *Exp. Appl. Acarol.* 61: 147-160. (in English) ["In Europe peatlands are wetlands of postglacial origin. Because of climatic changes and agricultural activities (i.e. drainage and peat extraction), they are one of the most endangered ecosystems worldwide. Water mites are well known as indicators of changing environments in other ecosystems such as springs and lakes. For our study we selected seven peatlands located in North-Western Poland and focused on water mite distribution and associated habitat and water quality variables. We described water mite fauna in various microhabitats (aquatic and semiaquatic) along the mineral-richness gradient to test whether this gradient is reflected in the composition of water mite assemblages. We selected conductivity, pH and vegetation as variables reflecting the poor-rich gradient. Additionally, we measured water depth, temperature and dissolved oxygen, which are often important parameters for water mites. We also noted presence of prey and host taxa of particular water mite species. Based on physicochemical parameters we identified three types of habitats harbouring three distinctive species groups of water mites. We were able to distinguish species that appear to be typical of spring fens (e.g. *Hygrobates norvegicus*, *Lebertia separata*), connected with acidic, nutrient poor pools (e.g. *Arrenurus neumani*, *A. pustulator*) and species seemingly typical of temporary habitats dominated by *Sphagnum* mosses (e.g. *Piersigia intermedia*, *Zschokkea oblonga*, *A. stecki*). The poor-rich gradient is strongly reflected in the composition of water mite assemblages. We also found strong correlations between the water mite fauna and both conductivity and pH gradient. Our results show that water conductivity is the most important of the examined factors, driving mite-species distribution in peat-

lands." (Authors) The paper includes many references to Odonata.] Address: Więcek, M., Dept of Animal Morphology, Faculty of Biology, Adam Mickiewicz University, Umultowska 89, 61-614 Poznań, Poland. E-mail: roztoc@wp.pl

13215. Wu, X.; Li, F.; Cong, R.; Chu, B. (2013): Preliminary Analysis on Feeding Habits of *Megalurus pryeri* in Nanji Wetland, Jiangxi. *Sichuan Journal of Zoology*: 438-441. (in Chinese, with English summary) ["The feeding habits and food composition of marsh grassbird *Megalurus pryeri* in Nanji Wetland National Nature Reserve (Jiangxi province) were investigated during breeding season (April, 2011) and non-breeding season (November, 2011). The brood behaviour of parent birds was observed by using binoculars and cameras in breeding season, and the stomach contents of 7 dead individuals collected from bird banding in non-breeding season were examined also. The results showed that the marsh grassbird mainly eat arthropods including dragonfly insects, spiders, imago or larva of *Grillotapidae* (mole crickets) and *Lepidoptera* insects in breeding season. While the diet was made up of both arthropods (70.24%) and vegetation (29.76%) such as *Orthoptera*, *Coleoptera*, *Odonata*, *Lepidoptera* insects, spiders and seeds, foliage in non-breeding season. In conclusion, the feeding habits of mash grassbird are different in breeding and non-breeding season, and this difference is due to seasonal changing of food composition in the

habitats and that the nestlings need higher protein nutrition food." (Authors) Odonata contributed with 8.36% to the diet.] Address: Li, F., College of Wildlife Resources, Northeast Forestry University, Harbin 150040, China. E-mail: lifeng604@163.com

(in English) ["The final stadium larva of *C. mingxiensis* is described and illustrated. The female adult is also described for the first time. The larva can be easily separated from all known *Coeliccia* larvae by the following distinct morphological characters: (1) prementum longest in all known *Coeliccia* larvae; median lobe with 4 pairs of premental setae and palpal lobe with 6 palpal setae; (2) caudal gills shortest of all known *Coeliccia* larvae when compared with body length; median gill rounded at apex and lateral gill with a small median projection at apex. The female is similar to the male in many respects, differing chiefly in several respects as follows: the transverse yellow band on vertex of head broader and straighter than in male; antehumeral stripe on mesepisternum somewhat incurved basally, not forming a strong hook, which is present in male; distal abdomen with obviously different colour pattern; anal appendages brownish-black, shorter than S10; vulvar scales robust, brownish-yellow, projecting well beyond end of abdomen." 13217. Yapo, L.M.; Atsé, C.B.; Kouassi, P. (2013): Composition, abundance and diversity of aquatic insects in fishponds of southern Ivory Coast, West Africa. *Entomologie Faunistique – Faunistic Entomology* 66: 123-133. (in English, with French summary) ["Abundance, density, biomass, and diversity of aquatic insects collected in water column from fishponds in southern Ivory Coast were studied. Monthly samplings have been conducted from December 2007 to November 2008. A total of 27,381 individuals belonging to 64 taxa, 25 families and 6 orders (Ephemeroptera, Odonata, Hemiptera, Lepidoptera, Coleoptera, and Diptera) were collected. Among these six orders, Hemipterans dominated quantitatively and qualitatively aquatic insect's community structure. The most abundant species were *Anisops sardea* Kirkaldy 1904 (64.17%), *Plea pullula* Stål 1855 (5.87%), *Eurymetra* sp. (3.87%), *Amphiops* sp. (3.79%), *Mesovelgia* sp. (3.41%) and *Cloeon bellum* Navas 1931 (2.21%). A spatiotemporal variation was observed for the different recorded parameters (density, biomass, and diversity). The maximum abundance, density, and biomass were recorded during the rainy season in the station of Layo. The Shannon-Weaver index indicated that the highest diversity of aquatic insects was obtained during the rainy season in the stations of Banco, Anyama I and Anyama II. In contrast, evenness reached

maximum values during the dry season in the stations of Layo, and Banco. Local environmental conditions (i.e. temperature, dissolved oxygen, pH, transparency, conductivity, ammonium, nitrite and phosphorus) accounted for 91.70% of variation in aquatic insect assemblages using canonical correspondence analysis (CCA). Seasonal trends in aquatic insect community composition were also related to changes in environmental characteristics of the fishponds." 13220. Zhu, R.; Ayodeji Bode-Oke, A.; Yan Ren, Y.; Dong, H. (2013): Analysis of dragonfly take-off mechanism: Initial impulse generated by aerodynamic forces. *Bulletin of the American Physical Society* 58(18): o.p. ["Take-off is a critical part of insect flight due to not only that every single flight initiates from take-off, but also that the take-off period, despite its short duration, ac-

counts for a relatively large fraction of the total energy consumption. Thus, studying the mechanism of insect take-off will help to improve the design of Micro Air Vehicles (MAVs) in two major properties, the success rate and the energy efficiency of take-off. In this work, we study 20 cases in which dragonflies (species including *Pachydiplax longipennis*, *Epitheca cynosura*, *E. princeps* etc.) take off from designed platform. By high-speed photogrammetry, 3-d reconstruction and numerical simulation, we explore how dragonflies coordinate different body parts to help take-off. We evaluate how aerodynamic forces generated by wing flapping create the initial impulse, and how these forces help save energy consumption." (Authors)] Address: not stated

13221. Živić, I.; Živić, M.; Milošević, D.; Bjelanović, K.; Stanojlović, S.; Daljević, R.; Marković, Z. (2013): The effects of geothermal water inflow on longitudinal changes in benthic macroinvertebrate community composition of a temperate stream. *Journal of Thermal Biology* 38(5): 255-263. (in English) ["Highlights: • We monitored effects of water temperature increase on macrozoobenthos communities. • Water temperature increase severely decreased macrozoobenthos diversity. • Warm waters were dominated (98.9%) by Chironomidae, Mollusca and Oligochaeta. • Plecoptera, Coleoptera, Gammaridae, and Odonata completely disappeared in warm waters. • Significant warm waters annual temperature variations had profound influence too. Studies of macroinvertebrate communities in thermal streams are highly geographically localized and mostly faunistical, making the efforts to understand in situ water thermal regime effects on those biocoenoses barely achievable. We examined the effects of geothermal water inflow on benthic macroinvertebrate community composition in a temperate stream. Environmental data analysis has shown that water temperature is a major factor determining the faunistical composition, especially downstream of the geothermal water inflow situated some 20 m upstream of locality V3. The increase in mean annual water temperature from 11.5 ± 4.1 °C at locality V2 to 22.0 ± 5.0 °C at locality V3 induced an enormous shift in community composition from a diverse one, composed mainly of Gammaridae, Simuliidae, Chironomidae, Trichoptera and Ephemeroptera, and to a lesser extent of Plecoptera, Coleoptera, other Diptera, Hirudinea, Odonata, Mollusca and Oligochaeta, to a uniform one strongly dominated by Chironomidae, Mollusca and Oligochaeta, comprising $98.9 \pm 0.5\%$ of collected individuals. While the disappearance of Plecoptera and Ephemeroptera and the increase in representation of Mollusca and Oligochaeta at locality V3 might be solely explained by water temperature increase, in the case of Chironomidae the increase in water discharge and relatively high annual water temperature variation at locality V3 had additional positive effects. However, the latter factor induced disappearance of Gammaridae at locality V3. In addition to the increase in water temperature, increase of water velocity significantly determined the

longitudinal dynamics of Coleoptera." (Authors)] Address: Živić, Ivana, University of Belgrade, Faculty of Biology, Studentski trg 16, 11000 Belgrade, Serbia

(in English) ["The goal of this research project is to investigate the neuronal control of flying prey interception in dragonflies by designing, constructing, and testing an apparatus to simulate the complex motions of a flying insect. Our three-dimensional motion device is capable of mimicking a flying insect by moving a small bead accurately up to speeds of 1 m/s in any direction. Dragonflies are efficient aerial predators that can intercept and capture small insects in flight. Our stimulus device will be used to determine the way in which dragonfly neurons encode information about object movement in three dimensions. Sinusoidal position tracking experiments using multiple input frequencies were conducted using the apparatus. The results indicate that the machine operates with good repeatability with little variability between trials. Preliminary dragonfly testing with the apparatus showed favourable results, indicating proof of concept." Additionally, autumnal records of all central European species are compiled from the literature and unpublished sources, and compared with the Lower Rhine situation. The results are discussed in terms of individual age, reproductive ability, and causes of mortality." (Author)] Address: Jödicke, R., Großenging 14, D-49699 Lindern, Germany

13227. Thorp, J.H.; DeLong, M.D.; Greenwood, K.S.; Casper, A.F. (1998): Isotopic analysis of three food web theories in constricted. *Oecologia* 117(4): 551-563. (in English) ["Analyses of stable isotope ($\delta^{13}\text{C}$ and $\delta^{15}\text{N}$) and C:N ratios of food webs within a floodplain and a constricted-channel region of the Ohio River during October 1993 and July 1994 indicate that the increasingly influential flood pulse concept (FPC) does not, for either location, adequately address food web structure for this very large river. Furthermore, results of this study suggest that the riverine productivity model (RPM) is more appropriate than the widely known river continuum concept (RCC) for the constricted region of this river. These conclusions are based on stable isotope analyses of potential sources of organic matter (riparian C3 trees, riparian C4 grasses and agricultural crops, submerged macrophytes, benthic filamentous algae, benthic particulate organic matter, and transported organic matter containing detritus and phytoplankton) and various functional feeding groups of invertebrate and fish consumers. The FPC, which stresses the key contribution of organic matter,

particularly terrestrial organic matter, originating from the floodplain to riverine food webs, was judged inappropriate for the floodplain region of the Ohio River for hydrodynamic and biotic reasons. The rising limb and peak period of discharge typically occur in November through March when temperatures are low (generally much less than 10°C) and greater than bank-full conditions are relatively unpredictable and short-lived. The major food potentially available to riverine organisms migrating into the floodplain would be decaying vegetation because autotrophic production is temperature and light limited and terrestrial insect production is minimal at that time. It is clear from our data that terrestrial C4 plants contribute little, if anything, to the consumer food web (based on $\delta^{13}\text{C}$ values), and $\delta^{15}\text{N}$ values for C3 plants, coarse benthic organic matter, and fine benthic organic matter were too depleted ($\sim 7\text{--}12\%$ lower than most invertebrate consumer values) for this organic matter to be supporting the food web. The RPM, which emphasizes the primary role of autotrophic production in large rivers, is the most viable of the remaining two ecosystem models for the constricted-channel region of the Ohio based on stable isotope linkage between sources and consumers of organic matter in the food web. The most important form of food web organic matter is apparently transported (suspended) fine (FTOM) and ultra-fine particulate organic matter. We propose that phytoplankton and detritus of an autochthonous origin in the seston would represent a more usable energy source for benthic (bivalve molluscs, hydropterygids, caddisflies) and planktonic (microcrustaceans) suspension feeders than the more refractory allochthonous materials derived from upstream processing of terrestrial organic matter. Benthic grazers depend heavily on nonfilamentous benthic algae (based on gut analysis from a separate study), but filamentous benthic algae have no apparent connection to invertebrate consumers (based on $\delta^{13}\text{C}$ values). Amphipod and crayfish show a strong relationship to aquatic macrophytes (possibly through detrital organic matter rather than living plant tissue). These observations contrast with the prediction of the RCC that food webs in large rivers are based principally on refractory FTOM and dissolved organic matter from upstream inefficiencies in organic-matter processing and the bacteria growing upon these suspended or dissolved detrital compounds. The conclusions drawn here for the Ohio River cannot yet be extended to other floodplain and constricted-channel rivers in temperate and tropical latitudes until more comparable data are available on relatively pristine and moderately regulated rivers." 2003

13234. Beatty, C.D. (2003): Habitat associations and life histories of Odonata in riverine wetlands of the Willamette Valley, Oregon. M.Sc. thesis, Oregon State University: 92 pp. (in English) ["This thesis explored the distributions and life histories of Odonata of the riverine wetlands of the Willamette Valley in western Oregon, USA. Odonate species distributions were characterized over two seasons in the autumn of 2000 and the spring of 2001-at twenty-seven wetlands located throughout the valley. Distributions of nymphs and adults were compared with wetland habitat conditions that may affect odonate diversity. Odonate nymph and adult distributions were analyzed through Hierarchical Agglomerative cluster analysis (HA). HA identified discrete clusters of sites based on the distributions of species in the genera *Aeshna*, *Erythemis*, *Lestes*, *Libellula*, *Pachydiplax*, *Sympetrum* and *Tamea*. To identify habitat associations with odonate species, nymph and adult data were analyzed by Non-metric Multidimensional Scaling (NMS). NMS revealed that odonate distributions are associated with site hydrology, water depth and temperature, the presence of large emergent plants (e.g. *Typha latifolia*), the presence of fish, and surrounding landcover. These data will provide guidance for wetland managers in the use of odonates as indicators of wetland health. To further examine the relationship between odonate species and their wetland habitats, quantitative life history data for the 27 odonate species were analyzed to determine functional associations between species attributes and the environments in which they are found. Oviposition location, presence of a resting egg, over-wintering life stage, nymphal foraging strategy and adult flight season were subjected to NMS, to determine biological similarities between species occupying particular locations. Life history patterns correlated strongly with hydrology. Analysis of sites by odonate species richness

found a relationship between richness and site hydrology, but failed to explain the distribution of several species associated with wetlands that dry during part of the year. We conclude from our results that species-level life history data are essential for explaining odonate distributions. We determined that the presence of odonate species in a wetland is indicative of habitat condition, that analysis of odonate distributions at the species level is necessary to understand habitat associations, and that analysis of life-history attributes provides a functional understanding of odonate distributions that measurements of species richness or the distributions of genera or families alone cannot explain." (Author)] Address: Beatty, C., Dept Biology, Santa Clara Univ., 500 El Camino Real, Santa Clara, California 95053-0268, USA. E-mail: cbeatty@scu.edu

13235. Englund, R.A.; Arakaki, K.; Preston, D.J.; Evenhuis, N.L.; McShane, M.K.K. (2003): Systematic inventory of rare and alien aquatic species in selected O'ahu, Maui, and Hawai'i Island streams. Contribution No. 2003-017 to the Hawaii Biological Survey: II + 14 pp. (in English) ["The Hawaii Biological Survey (HBS) of the Bishop Museum collected and identified aquatic insects and other stream invertebrates in selected Hawaiian streams as part of an inventory of rare native and new alien aquatic species. Three remote streams on each island (O'ahu, Maui, Hawai'i) were assessed during this study. The purpose of these surveys was to provide a systematic inventory in selected streams of rare native aquatic species and invasive alien species in remote and difficult to access portions of the Hawaiian archipelago. The results of this study also provided an indication of aquatic ecosystem health and native biodiversity in areas not normally accessible because of geographic constraints such as steep waterfalls and dense vegetation. These surveys provided a baseline inventory of aquatic insect species present in each stream assessed and also ensured museum specimens and related databases will be available for future researchers. Stream reaches examined during this study had little to no impacts from urbanization or irrigation diversions, with the Maui and Hawai'i Island streams found to be particularly pristine. A representative cross-section of pristine stream reaches was examined on each island surveyed. The aquatic insect fauna found during these surveys contained a remarkably high percentage of native species in streams surveyed among O'ahu, Maui, and Hawai'i Islands. Only the lowest surveyed elevations of Punalu'u Stream, O'ahu at 100-200 ft elevation (50-56%) and Kawainui Stream, O'ahu (57%) contained lower proportions of native aquatic insect species than the other streams assessed during these surveys. Punalu'u Stream was the only stream where a longitudinal transect was conducted from a low to high elevation (100- 900 ft), and the percent native species increased greatly as elevation increased. Hawai'i Island streams surveyed during this study yielded several range extensions and a rich assortment of aquatic insects that are either indicators of high water quality, or also can be considered uncommon. East Maui streams such as West

Wailua Iki and Kopiliula were also found to contain aquatic insects that are now extremely rare and sensitive to disturbance. The most significant finding of this study was the discovery of eight previously uncollected species of endemic Hawaiian aquatic insects; six new species were found on Maui and one each from O'ahu and Hawai'i Islands. All eight new species are Diptera that are the most diverse group of native aquatic insects in the Hawaiian archipelago. Aquatic Diptera are important in the diet of native Hawaiian stream fish; healthy and diverse populations will ensure an abundant year-round food supply for native fish such as *Lentipes concolor*. Additionally, at least five undescribed species of the aquatic moth *Hypomocoma* were collected during these surveys. Additionally, efforts at aquatic insect collections have been high between 1990-2003, and the collection of eight new species during this study greatly exceeds the rate found in the previous 13 years of intensive collections. This also illustrates how little basic information is known on the numbers and types of aquatic insects for Hawaiian inland waters, let alone their basic ecological, evolutionary, and life history parameters." (Authors) The following species had been found: *Anax junius*, *A. strenuus*, *Crocothemis servilia*, *Orthemis ferruginea*, *Pantala flavescens*, *Tramea abdominalis*, *Enallagma civile*, *Ischnura ramburii*, *I. posita*, *Megalagrion blackburni*, *M. calliphya*, *M. hawaiiense*, *M. n. nigrohamatum*, and *M. n. nigrolineatum*.] Address: Hawaii Dept of Land & Natural Resources, 1151 Punchbowl Street, Room 330, Honolulu, Hawai'i 96813, USA

13237. De Knijf, G.; Taily, M. (2004): Oviposition from *Aeshna cyanea*: some remarkable observations. *Gom-*

phus 20(1): 21-26. (in Dutch, with English summary) ["Three remarkable observations of oviposition by *Aeshna cyanea* are described. 1) on rocks forming a dam in full sunshine, at an at the time of observation dry pond, 2) in dead wood and bark of an elder (*Sambucus nigra*) at more than 4 m from the waterside and 3) in moss (*Amblystegium varium*) at 0,20 m above the water in mosses at 0,30 m above and 0,40 m from the waterside. Thus *A. cyanea* seems not to be linked strictly to water for its oviposition, but shows a predilection for moist, shadowed substrats like mosses, dead plants, branches, wood, mud and soil. The water level at the moment of hatching (shortly after the winter) is generally higher, so the prolarvae are at that time already in the water or have only a short distance to go; probably they are capable of jumping or creeping some meters to reach the water if necessary." (Authors)] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, 1070 Brussel, Belgium. E-mail: geert.deknijf@inbo.be

13238. Hillwalker, W.E. (2005): Selenium and trace metal accumulation in detrital-benthic food webs of lotic and lentic wetlands, Utah, USA. Ph.D. thesis, Oregon State University: 105 pp. (in English) ["Concentrations of selenium (Se), manganese (Mn), zinc (Zn), cadmium (Cd), lead (Pb) and arsenic (As) were measured in the water column, sediment and biota, in conjunction with selected physicochemical data, from representative wetland types at a mining site within Salt Lake County, Utah, USA. The selected field sites included Oolitic Pond (lentic) and Lee Creek (lotic), which are moderately contaminated brackish, alkaline aquatic wetlands managed by a copper mining industry. These fishless wetlands are located in a geographic region that poses risk to migratory shorebird populations from dietary Se. A spatial sampling study demonstrated the extent of variation in total Se concentration within the wetlands. With the exception of the sediment compartment, Se concentration did not differ significantly along the 2-mile length of Lee Creek or within the Pond. The differences in sediment total Se concentrations between the Creek East and West segments characterize lower Lee Creek as having two segments distinguished by unique processes that influence the sediment Se accumulation profiles. Se accumulation trends were observed temporally over 3-years (2000 to 2002) and over two seasons (spring and autumn). Total Se body burden in benthic invertebrates was more clearly associated with sediment/detritus Se concentrations than with surface water concentrations. Three invertebrate groups dominated the aquatic invertebrates assemblage in the lotic and lentic benthos; primary consumers (Chironomidae, Diptera), generalist feeders (Hemiptera) and predators (Odonata). The chironomid larvae accumulated 1.3 to 39 times the trace metal concentrations of the Hemiptera or odonate taxa, independent of trace metal type (essential or non-essential) or wetland occupation. Organism-specific factors, such as habitat selection and

preferential feeding habits, were proposed to influence benthic invertebrate accumulation profiles by modifying trace metal exposure. Mixed diets, trophic omnivory and the complexity of wetland biogeochemistry limit the power of stable nitrogen fractionation signatures to define benthic food web relationships. Wetland site-specific processes impacted Se accumulating efficiency, with trace metal concentrations from 4 to 7 times greater within the lentic benthic system than the lotic. The fractionation of the natural abundant stable carbon isotopes revealed the importance of sedimentary and detrital organic carbon as dietary sources for the benthic food web. Sediment organic content was not significantly associated with sediment, or invertebrate, Se accumulation profiles. Ecological risk assessments based on sound understanding of metal chemistry and the interactions between the sediment matrix and benthic organisms are necessary to provide tools for environmental management." 13241. Bo, T.; Cucco, M.; Fenoglio, S.; Malacarne, G. (2006): Colonisation patterns and vertical movements of stream invertebrates in the interstitial zone: a case study in the Apennines, NW Italy. *Hydrobiologia* 568: 67-78. (in English) ["We examined vertical migration and colonisation patterns of stream macroinvertebrates within the substratum of an Apennine creek in NW Italy. Macroinvertebrates was sampled at three depths in the streambed (0-5, 5-10, 10-15 cm) by means of artificial baskets filled with natural substratum. We placed 42 traps (5 x 5 x 15 cm), i.e. 21 top-opened (T-traps) and 21 bottom-opened (B-traps), each composed of three overlapping baskets (high-H, medium-M and low-L), to evaluate differences in the vertical movements. We also collected Surber samples to compare interstitial assemblages with streambed communities. The multilevel traps yielded 42 taxa, compared

with 60 taxa in the natural riverbed. Interstitial traps were rapidly colonised; both taxa richness and organism number increased during the 42-day study period. We found active migration in both vertical directions, but there were more invertebrates in the top-opened traps than in the bottom-opened traps. In the T-traps the most colonised baskets were those placed at the H level, while in the B-traps the L level baskets were more rapidly colonised. The interstitial assemblages differed markedly from the streambed communities in both composition and functional organisation, with more collector-gatherers and predators in the interstitial zone and more filterers and scrapers in the natural riverbed. In Apennine lotic systems, the interstitial zone is an important habitat for stream macroinvertebrates, although it may not be used by all species." 13242. Fenoglio, S.; Bo, T.; Cucco, M.; Malacarne, G. (2006): Leaf breakdown patterns in a NW Italian stream: Effect of leaf type, environmental conditions and patch size. *Biologia*, Bratislava 61/5: 555-563. (in English) ["We studied the decomposition process and macroinvertebrate colonisation of leaf packs to determine to what extent leaf consumption and invertebrate abundance depend on the pollution level, season, leaf type and patch size. We exposed 400 leaf packs made of two leaf types, alder and chestnut, at two sites of the Erro River (NW Italy) with different environmental alteration levels. Leaf packs were set out as three patch sizes (alone, or in groups of 6 or 12). A first experiment was carried out in winter and a second in summer. Leaf packs were retrieved after 15, 30, 45 and 60 days of submersion to determine the leaf mass loss and to quantify the associated macroinvertebrates. Natural riverbed invertebrates were collected in the same areas. Patch size, season, leaf type and pollution level significantly affected mass loss. The breakdown process was faster for alder leaves, during summer, at the unpolluted site, and in smaller patches. Leaf type and patch size did not affect macroinvertebrate density and richness, but the highest taxon richness was found in winter and at the unpolluted site. There were more shredders and predators than in the natural riverbed. Our study supports two recent ideas regarding leaf processing in streams: that patch size influences the leaf breakdown rate and that the breakdown rate can be used to evaluate water quality and environmental health." (Authors) The data set includes Odonata.] Address: Fenoglio, S., University of Piemonte Orientale, Di.S.A.V., Via Bellini 25, I-15100 Alessandria, Italy. E-mail: fenoglio@unipmn.it

(in English) ["The influence of streambed sediment clogging on macroinvertebrate communities was investigated in the Lemme creek (NW Italy). To assess how fine sediment accumulation can influence the colonisation process and community composition of macroinvertebrates, we placed 48 traps in the riverbed. The traps consisted of boxes built with metal net (mesh 1 cm, height 15 cm, sides 5 cm) covered with nylon net except for the apex, allowing access exclusively from the top. We created four trap types filled with 100% gravel, 30% sand and 70% gravel, 70% sand and 30% gravel and 100% sand. After 20 and 40 days, we removed 6 traps / type. Macroinvertebrates rapidly colonised the traps, as we found no significant community differences between the two removal dates. Among the four trap types, we found significant differences in taxa number and abundance, which both decreased with increasing clogging. Thus, our study supports the hypothesis that clogging and the accumulation of fine substratum elements strongly affects benthic stream communities." 13250. Quiroz-Martinez, H.; Rodriguez-Castro, V.A. (2007): Aquatic insects as predators of mosquito larvae. *Journal of the American Mosquito Control Association* 23(sp2): 110-117. (in English) ["Mosquitoes are serious biting pests and obligate vectors of many vertebrate pathogens. Their immature larval and pupal life stages are a common feature in most tropical and many temperate water bodies and often form a significant proportion of the biomass. Control strategies rely primarily on the use of larvicides and environmental modification to

reduce recruitment and adulticides during periods of disease transmission. Larvicides are usually chemical but can involve biological toxins, agents or organisms. The use of insect predators in mosquito control has been exploited in a limited fashion and there is much room for further investigation and implementation. Insects that are recognized as having predatorial capacity with regard to mosquito prey have been identified in the Orders Odonata, Coleoptera, Diptera (primarily aquatic predators), and Hemiptera (primarily surface predators). Although their capacity is affected by certain biological and physical factors, they could play a major role in mosquito control. Furthermore, better understanding for the mosquitoes-predators relationship(s) could probably lead to satisfactory reduction of mosquito-borne diseases by utilizing either these predators in control programs, for instance biological and/or integrated control, or their kairomones as mosquitoes' oviposition repellents. This review covers the predation of different insect species on mosquito larvae, predator-prey-habitat relationships, co-habitation developmental issues, survival and abundance, oviposition avoidance, predatorial capacity and integrated vector control." 13255. Chan, T.-W.; Wong, K.-C. (2008): Taxonomic study of the larval stage of Aeshnidae (Odonata) in Taiwan. The 29 Annual Meeting of Taiwan Entomological Society - Abstract Booklet: 37. (in Chinese and English) [Verbatim: The Aeshnidae is the second largest family of Odonata in Taiwan, with some 23 species now assigned to 9 genera. Seventeen species of larval aeshnids from 8 genera collected in Taiwan were taxonomically studied. Based on literature records and examination of an extensive collection, a redescription of the larva of *Periaeschna magdalena* Martin, 1909, *Planaeschna risi risi* Asahina, 1964, *Planaeschna taiwana* Asahina, 1951, *Aeshna petalura taiyal* Asahina, 1938, *Polycanthagyna erythromelas* (McLachlan, 1896), *P. melanictera* (Selys, 1883), *Anaciaeschna jaspidea* (Burmeister, 1839), *A. martini* Selys, 1897, *Anax nigrofasciatus nigrofasciatus* Oguma, 1915, *A. panybeus* Hagen, 1867, *A. parthenope julius* Brauer, 1865, *Gynacantha japonica* Barteneff, 1909, *G. ryukyuensis* Asahina, 1962 is provided. Morphological characteristics of the larva of *Sarasaeschna pyanan* (Asahina, 1951), *Sarasaeschna lienii* (Yeh & Chen, 2000), *Planaeschna ishigakiana flavostria* Yeh, 1996, *Polycanthagyna ornithocephala* (McLachlan, 1896) is described and illustrated for the first time. In addition, all 17 larval aeshnids are keyed for reference in future research. For some more details see: <http://ndltd.ncl.edu.tw/cgi-bin/gs32/gsweb.cgi/login?o=dnclcdr&s=id=%22097NHLT5404004%22.&searchmode=basic>] Address: Chan, T.-W., Graduate institute of biological resources and technology, National Dong Hwa University, Taiwan

13256. Chang, C.-T.; Tsai, F.-Y.; Shih, M.-C.; Chi, K.-J. (2008): The role of pterostigma in wing mechanics of

dragonflies (Odonata, Libellulidae). The 29 Annual Meeting of Taiwan Entomological Society - Abstract Booklet: 72. (in Chinese and English) [Verbatim: Pterostigma is a thickened and darkened region on an insect wing, located distally from the wing base and near the leading edge. Because of interspecific variation in its size, morphology, and related position, pterostigma is often used as a trait for classification. To date, the only study that examined its mechanical function indicates that, in dragonflies, the pterostigma changes the distribution of wing mass, which may change the vibration characteristics of wings and consequently the flight performance. However, no direct empirical evidence has been reported to explain how it works. In this study, we aimed to examine how pterostigma affects the dynamic characteristics of wings in *Pantala flavescens*, a species commonly found in Taiwan. Scanning electron micrographs were taken in order to compare the thickness of pterostigma and wing cell. Direct measurements of pterostigma showed that it accounted for only 0.5% of the wing area, yet more than 2.5% of the wing mass. That is, the pterostigma is five times heavier than the rest of the wing. To examine the effects of pterostigma, we compared the vibration characteristics of complete wings with those without this structure. To this end, each wing sample was cut off from the thorax and glued onto an oscillator that provided different frequencies to vibrate the wing. High-speed videocamera was used to record the behaviour of the vibrating wing, from which we could quantify its deformation. Preliminary results reveal that the existence of pterostigma changes the wave amplitudes and shapes of a flapping wing, which implies a functional consequence in dragonfly flight.] Address: Chang, C.-T., Institute of Biophysics, National Chung Hsing University, Taiwan

13257. Fogarty, F.A.; Bybee, S.M.; Ingley, S.J.; Branham, M.A. (2008): Phylogenies of the Flatwing Damselflies: Molecular and morphological evidence (Odonata: Megapodagrionidae). <http://esa.confex.com/esa/2008/webprogram/Paper37035.html>. (in English) ["A phylogenetic analysis was carried out on the Neotropical flatwing damselflies (Odonata: Megapodagrionidae), using both morphological and molecular data. Megapodagrionidae has a worldwide distribution, yet its monophyly is questionable, as are the major groupings within the family (Bybee et al., 2008). Neotropical lineages were shown to be especially problematic. All 13 Neotropical genera were examined; in addition to 20 outgroup taxa (e.g., old world megapodagrionids: *Austroargiolestes*, *Caledopteryx*, *Pseudolestes* and *Rhipidolestes*; coenagrionoids; calopterygoids and *Thaumatoneura*. Analyses were rooted to *Lestes disjunctus*. 52 Morphological characters were coded for each taxon in the analysis. Molecular data was analyzed for six genes: 12s, 16s, 28s, COii, ND1 and h3 (~4800bp). Molecular data was combined with morphological data under Bayesian (MrBayes) and Parsimony (TNT) methods for tree reconstruction. Megapodagrionidae is not supported as monophyletic but the taxon sampling for old world groups is not exhaustive. Trees do not

reconstruct the Neotropical Megapodagrionidae as a monophyletic clade. Neotropical genera are distributed across several clades that include old world megapodagrionids (e.g., *Teinopodagrion* and *Allopodagrion*). Interestingly, *Thaumatoneura* (Central American) appears to be sister to *Paraphlebia* supporting this monospecific genus as a megapodagrionid, a relationship suggested by Calvert in 1902, but currently not supported by other phylogenetic studies. Though Megapodagrionidae is not monophyletic the most primitive lineage representing the group has its origins in the Neotropics. The larger monophyletic clade representing "Megapodagrionidae" has no clear pattern of distribution or correlation with geography among genera." (Authors)] Address: Bybee, S., Graduate Research Assistant: Branham Laboratory, Dept Entomology & Nematology, University of Florida. Natural Area Drive, P.O. Box 110620, Gainesville, FL 32611-0620, USA. E-mail: seth.bybee@gmail.com

13258. Lin, S.-C.; Chen, Y.-F.; Yang, P.-S. (2008): Taxonomy of the Sauter's clubtail (*Leptogomphus sauteri*) (Odonata: Gomphidae). The 29 Annual Meeting of Taiwan Entomological Society - Abstract Booklet: 34. (in Chinese and English) [Verbatim: *L. sauteri* is endemic to Taiwan and it includes two geographical subspecies (*L. s. sauteri* Ris and *L. s. formosanus* Matsumura). In order to compare both morphological and molecular difference between two subspecies, we collected the specimens around the Taiwan Island. The preliminary results indicate that there were relatively morphological variations in the body color and male genitalia. The diagnostic characters of these two subspecies can not easily be defined. Furthermore, the mitochondrial cytochrome oxidase I gene (mtCOI) was amplified using universal primers for these two subspecies. The other clubtail species from Taiwan and the Himaehosoi clubtail (*L. yayeyamensis* Matsumura) from Yaeyama Islands, Japan, were also amplified. Then, these molecular data were combined for analysis. The phylogenetic trees among mtDNA sequences were constructed using neighbour-joining methods and maximum parsimony methods. The results suggest that Sauter's clubtail would be divided into the Southern Taiwan group and the Central-Northern-Eastern Taiwan group. The geographical distributional limit of these two groups is relatively fit for the previous specimen records, but we still need more specimens to assess the diagnostic characters.] Address: Lin, Sue-Cheng, Dept of Entomology, National Taiwan Univ., Taiwan

13259. Mäkinen, J. (2008): Idänkirsikorento *Sympecma paedisca* Lappeenrannassa [*Sympecma paedisca* recorded in Lappeenranta, SE Finland]. *Crenata* 1: 38-39. (in Finnish) [Just emerged specimens of *S. paedisca* were found in Lappeenranta on 10-13 August 2007 by Jouko and Jere Rantanen. This is the first confirmed case of this species breeding in Finland. Earlier only migrant specimens were known from the coastal areas of the Gulf of Finland. A few other records of this species are listed. (Matti Hämäläinen / Asmus Schröter)] Address:

13260. Subramanian, K.A.; Ali, S.; Ramachandra, T.V. (2008): Odonata as indicators of riparian ecosystem health a case study from south western Karnataka, India. *Fraseria* (N.S.) 7: 83-95. (in English) ["The influence of riparian land use on the diversity and distribution were investigated by sampling 113 localities covering 4 districts in south-western Karnataka. A total of 55 species in 12 families were recorded. Streams, rivers and lakes had higher diversity than marshes and sea coast. However, lakes had low endemism than streams and rivers. Streams flowing through evergreen forests had higher diversity and endemism. Human impacted riparian zones such as paddy fields had relatively lower species richness. However, streams flowing through forestry plantations had higher diversity than other natural riparian zones such as dry deciduous, moist deciduous and semi evergreen forests. Myristica swamps - a relict evergreen forest marsh had low diversity and high endemism. Odonate communities of lentic ecosystems, and human impacted streams and rivers were characterized by widespread generalist species. Endemics and habitat specialists were. restricted to streams and rivers with undisturbed riparian zone. The study documents possible odonate community change due to human impact: The influence of riparian landuse change on odonate community is also discussed." 13262. Bouchard, R. W. (2009): Chapter 5. Odonata (Dragonflies & Damselflies). *Guide to Aquatic Invertebrate Families of Mongolia* | 2009: 63-74. (in English) ["The guide to Mongolian aquatic invertebrate families is modified from a guide developed for the Upper Midwest of North America. Most of the illustrations in both guides are from species that occur in North America and in many cases are not known from Mongolia. In addition, the keys were also originally developed with North American taxa in mind. Despite this, many of the families and even genera occur in both North America and Mongolia and most illustrations and characters used in keys should be appropriate. I have added families known from Mongolia that were not included in the guide to invertebrates in the

Upper Midwest of North America. However, corrections and additions may still be needed to make the guide complete and accurate for use in Mongolia." 13263. Cupsa, D.; Birkas, M.; Telcean, I. (2009): Studies upon the structure and dynamics of the benthic macroinvertebrate communities from two habitats of The Ier River's Channel (Bihor county, Romania). *Bihorean Biologist* 3(1): 59-70. (in English) ["The aim of the present study was to describe the structure and dynamics of the macrozoobenthic communities on a sandy and muddy substrate from Ier Channel, in order to show the importance of the composition of the substratum in the macrozoobenthic community settlement. During the study period (May-October 2006) we identified 43 species and 884 individuals of benthic organisms, especially Gastropoda and insect larvae. The number of species and individuals exhibited high variability on the sandy substrate. Groups with high density were Gastropoda, Trichoptera and Chironomidae larvae. The most frequent groups were Hirudinea, Gastropoda, Bivalvia and Chironomidae larvae. The most abundant species were found to be tolerant to water pollution and the sensitive groups were missing. The diversity indices showed a more diverse community on the muddy substrate and the value of the IBGN index revealed a poor water quality. ...The Odonata species have low densities and excepting *Ischnura elegans* they were found accidentally." (Authors) Additional species recorded are *Coenagrion pulchellum*, *Lestes sponsa*, *Libellula quadrimaculata*, *L. depressa*, and *Sympetrum sanguineum*.] Address: Cupsa, Diana, Univ. of Oradea, Faculty of Sciences, Dept of Biology, 1 Universitatii str., 410087, Oradea, Romania. 13268. Rahman, M.H.; Miah, M.J.U.; Ali, H.; Alam, M.S.; Islam, M.A. (2009): Effect of fertilizer on the qualitative and quantitative abundance of benthic fauna in ponds. *J. Agrofor. Environ.* 3(1): 25-28. (in English) ["The present research was conducted to assess the effects of added fertilizers on the qualitative and quantitative abundance of benthic fauna in ponds for a period of six months from August, 2008 to January, 2009 in the Bangladesh Agricultural University, Mymensingh, Bangladesh. All the experimental ponds were rectangular in shape, each with surface area of 44 m² and the average depth of water was 1m. Three treatments such as GM [Goat manure + Urea: 3000+50 kg/ha], SM (Sheep manure + Urea: 3000+50 kg/ha) and C (control) were run in duplicates. Fertilizers were used fortnightly and benthos samples were collected randomly from the ponds at monthly intervals. Seven groups of benthic fauna viz. Oligochaeta, Chironomidae, Ceratopogonidae, Mollusca, Ephemeroptera, Odonata and Hirudinea were recorded throughout

the experimental period. The total average number in the abundance of benthic fauna was recorded as (2196.09 ± 216.35/m², 2108.49 ± 211.50/m² and 1397.36 ± 233.04/m²) in the treatments GM, SM and C respectively. The abundance of Oligochaeta and Chironomidae were found dominant with the treatments GM and SM in all the months during the whole study period. The maximum numbers of benthic fauna (2743.90 ± 457.32/m², 2515.24 ± 228.66/m² and 1905.50 ± 228.66/m²) were found with the treatments GM, SM, and C respectively in August, 2008 and minimum (1676.84 ± 304.88/m², 1600.62 ± 228.66/m² and 1219.52 ± 152.44/m²) were found with the treatments GM, SM and C respectively in January, 2009. The mean values of temperature (°C) [23.52 ± 1.78, 23.48 ± 1.82 and 23.70 ± 1.81], transparency (cm) [33.53 ± 0.90, 33.02 ± 0.89 and 33.08 ± 1.09], pH (8.03 ± 0.20, 8.18 ± 0.18 and 8.20 ± 0.19) and dissolved Oxygen (mg/l) [5.37 ± 0.35, 5.37 ± 0.37 and 5.67 ± 0.33] were found in the treatments GM, SM and C respectively. The fluctuations in abundance of benthic fauna were found to be more or less related with the pH, temperature, dissolved oxygen as well as transparency." 13270. Bellingan, T.A. (2010): The diversity of aquatic insects in the Tsitsikamma region, with implications for aquatic ecosystem conservation. MSc. thesis, Rhodes University, Grahamstown: XVI + 187 pp. (in English) ["As a result of research carried out within the last decade to assess the diversity of macroinvertebrates of the Salt River in the Western Cape Province, South Africa, surveys of macroinvertebrates of 20 sites on 11 selected rivers from the same mountain range source were undertaken. This was done to make a preliminary assessment of the conservation status of the rivers of this region. Aquatic insects from the orders Ephemeroptera, Odonata, Plecoptera, Megaloptera, Trichoptera and the dipteran family Simuliidae were collected using techniques to

maximize the number of taxa found. The insects collected were identified to species level where possible. Water physicochemical parameters were recorded at all sites for each sampling trip to characterize these rivers and to establish a set of baseline data for future comparisons. These parameters included measurements made on site and analysis of the concentrations of all the major ions in water samples in the laboratory. .. A total of 31 species were collected from 20 genera, from nine families. The most common species collected were *Orthetrum julia capicola* and *Allocnemis leucosticta*, both occurring at 17 sites, followed by *Pseudagrion furcigerum*, occurring at 14 sites. Three species of Synlestidae were the next most common species, *Chlorolestes conspicuus*, *Chlorolestes umbratus* and *Ecchlorolestes nylephtha* occurred at 12 sites each. Unique or uncommon species are difficult to distinguish as 14 of the species were collected at two sites or fewer, making nearly half of the total number of species collected "rare" with respect to this study. "] Address: Bellingan, T.A., Rhodes University, P.O. Box 94, Grahamstown 6140, South Africa

13271. Boudot, J.-P. (2010): Spécificités du peuplement en Odonates du nord de l'Afrique et observations récentes d'espèces remarquables (Insecta: Odonata). *Martinia* 26(3-4): 109-122. (in French, with English summary) ["The author summarizes the main distinctive features of the Odonata fauna in Africa North of the 17th parallel and comments the most noteworthy recent discoveries. An overall predominance of European and European-derived species is recognized, except in Egypt where the Palearctic component is strongly depressed and the Afro-tropical component enhanced thanks to the so-called "Nile corridor effect". Among the recently discovered or confirmed species, *Orthetrum machadoi* is new for the whole Palearctic realm, *O. ransonnetii* is new to the Northern Maghreb, *Sympetrum sinaiticum* is new to Morocco and the African part of Egypt, *Selysiotthemis nigra* is new to Morocco, and *Agriocnemis sania* is new to the African part of Egypt." 13272. Briggs, N.; Schneider, E.G.; Sones, J.; Puryear, K. (2010): Inventory of Odonata (Dragonflies and Damselflies) at Fire Island National Seashore. Natural Resources Technical Report NPS/NCBN/NRTR—2010/295. National Park Service. Fort Collins, CO: 78 pp. (in English) ["In order to expand knowledge of odonate biodiversity and to make recommendations for management, we conducted a comprehensive baseline inventory of Odonata at Fire Island National Seashore (FIIS), Suffolk County, New York. During 2004 and 2005 we conducted a checklist inventory at sites where odonates could potentially breed, as well as at potential migratory and foraging. Checklist walks are unrestricted, complete searches that provide an efficient means for initial determination of

species presence. During the combined 2004 and 2005 field seasons, 27 species of odonates were documented across 18 of the 34 sites surveyed. Two New York state listed species were observed, *Ischnura ramburii* and *Libellula needhamii*. Of the 847 individuals sighted during 2004 and 2005, 92 were collected as voucher specimens, representing 25 of the 27 species recorded. The most widely distributed species included *Anax junius*, *Erythrodiplax berenice*, *Libellula semifasciata*, and *Pantala hymenaea*. Of all sites surveyed during 2004 and 2005, Kismet Pond showed the greatest abundance (n = 481 individuals) and species richness (0.85) of odonates. Migration events were not observed during odonate surveys; however, a migration event was documented by one researcher at Bellport Beach at the Otis Pike Wilderness Area during 2004. Overall, FIIS contains few habitats that are appropriate for odonate reproduction; however, several sites offer good foraging and migration habitat." (Authors)] Address: Briggs, Nina, Rhode Island Natural History Survey, P.O. Box 1858, Kingston, RI 02881, USA

13273. Buczyński, P.; Cichocki, W.; Rozwałka, R. (2010): Rediscovery of *Somatochlora alpestris* (Selys, 1840) and new locality of *S. arctica* (Zetterstedt, 1840) in the Orawa - Nowy Targ Basin (Odonata: Corduliidae). *Odonatrix* 6(2): 42-46. (in Polish, with English summary) ["During studies on spiders of high peat bogs in Orawa - Nowy Targ Basin (southern Poland), a few larvae of two *Somatochlora* species were caught in Barber's traps. Larvae were found in traps situated by the edges of peat bogs, in places without isolated water bodies, in patches of damp Sphagnum. *Somatochlora alpestris* was caught in Puścizna Wielka (49°27'N, 19°46'E, UTM: DV17) and Baligówka (49°28'N, 19°50'E, DV18) peat bogs. Both localities are situated at the height of ca. 650 m a.s.l. New data confirm the occurrence of the species in peat bogs in the Orawa - Nowy Targ Basin: the last record from 78 years ago was given by Fudakowski (1932). Taking into consideration small effectiveness of Barber's traps in collecting dragonflies, even so scarce material shows that *S. alpestris* can be present in the area numerously and in many sites, however, this needs to be verified on the field. This species does not react on climatic changes as *Aeshna caerulea* whose range of occurrence moved from 840 to ca. 1400 m a.s.l. Together with data about good condition of mountain populations of this species it proves the validity of shifting *S. alpestris* in the Red list of Dragonflies of Poland from EN category to NT. New locality of *Somatochlora arctica* is a nature reserve „Bór na Czerwonem" (49°27'N, 20°02'E, DV37). This site is important for the protection of this species for its acreage has become even more fragmented in Poland." (Authors)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

13276. Dejean, A.; Leroy, C.; Corbara, B.; Roux, O.; Céréghino, R.; Orivel, J.; Boulay, R. (2010): Arboreal ants use the "Velcro® principle" to capture very large prey. *PLoS ONE* 5 (6): 7 pp. (in English) ["Plant-ants live in a mutualistic association with host plants known as "myrmecophytes" that provide them with a nesting place and sometimes with extra-floral nectar (EFN) and/or food bodies (FBs); the ants can also attend sap-sucking Hemiptera for their honeydew. In return, plant-ants, like most other arboreal ants, protect their host plants from defoliators. To satisfy their nitrogen requirements, however, some have optimized their ability to capture prey in the restricted environment represented by the crowns of trees by using elaborate hunting techniques. In this study, we investigated the predatory behaviour of the ant *Azteca andreae* which is associated with the myrmecophyte *Cecropia obtusa*. We noted that up to 8350 ant workers per tree hide side-by-side beneath the leaf margins of their host plant with their mandibles open, waiting for insects to alight. The latter are immediately seized by their extremities, and then spread-eagled; nestmates are recruited to help stretch, carve up and transport prey. This group ambush hunting technique is particularly effective when the underside of the leaves is downy, as is the case for *C. obtusa*. In this case, the hook-shaped claws of the *A. andreae* workers and the velvet-like structure of the underside of the leaves combine to act like natural Velcro® that is reinforced by the group ambush strategy of the workers, allowing them to capture prey of up to 13,350 times the mean weight of a single worker." (Authors) The prey also includes a 10 cm large unidentified dragonfly.] Address: Dejean, A., Centre National de la Recherche Scientifique, Écologie des Forêts de Guyane (UMR-CNRS 8172), Campus Agronomique, Kourou, France, E-mail: alain.dejean@wanadoo.fr

13280. Lohr, M. (2010): Libellen zweier europäischer Flusslandschaften. Besiedlungsdynamik und Habitatnutzung von Libellengemeinschaften am Unteren Allier (Frankreich) und an der Oberweser (Deutschland). *Arbeiten aus dem Institut für Landschaftsökologie Münster* 17: 183 pp. (in German, with French and English summaries) ["The odonates of two European fluvial landscapes - dynamics of colonisation and habitat selection by dragonfly assemblages in the alluvial floodplains of the Lower Allier (France) and the Upper Weser (Germany). The main aim of the present thesis is the description of the colonisation by dragonflies in alluvial floodplains of semi-natural and regulated rivers by the examples of the lower course of the place Allier (placecountry-region France) and the upper course of the place Weser (placecountry-region Germany). Therefore, spatio-temporal dynamics of the dragonfly assemblages is analysed. From the results recommendations for measures to regenerate alluvial floodplains are derived. The place Allier, where the study area is situated on its lower course («UR Allier»), is regarded as one of the last natural-like rivers of Central and place Western Europe due to a nearly unchanged morphological and hydrological dynamics. In

contrast, the place Upper Weser, where the study area «UR Weser» is situated, has been subject to deep anthropogenic changes since the Middle Ages. Beside river engineering measures, these changes also include water pollution by salts. Descriptions of the place Upper Weser from the 19th century permit the conclusion that the place Weser possessed comparable structures and was subject to a similar morphological dynamics as actually shown in the place Lower Allier. A total of 56 odonate species was recorded, 50 of them having been observed in the UR Allier and 43 in the UR Weser. Although the study areas show some climatic differences and the distance between them amounts to approximately 700 km, the proportion of species being present in both areas is high and currently comes up to 37 species. Three species found in the UR Allier appear in the appendix 2 of the FFH directive - *Coenagrion mercuriale*, *Oxygastra curtisii* and *Ophiogomphus cecilia*. The populations of *O. cecilia* observed in the UR Allier are probably the largest ones in Central and place Western Europe. In 1997, for the first time the species has been found in the UR Weser in the lower course of the river Diemel. Now it is probably autochthonous there. For 32 species the seasonal dynamics of emergence and flight periods in the UR Weser are characterised by phenograms. Therefore, the species are classified into six groups according to different types of life cycles. For *Ischnura elegans* and *Crocothemis erythraea*, evidences for a bivoltine development in at least some years were found. Observations of exceptionally early emergence of *Cordulegaster bidentata* point at a regulation of the emergence date by day length. Based on more than 10 000 data sets from the period of 1989-2005 the trends in occurrence of Odonata species are calculated and analysed for the UR Weser. A significant increase of occurrence can be stated for nine species, five species show a significant decline. A strong expansion of *Crocothemis erythraea* between 2000 and 2005 in the floodplain of the place Upper Weser is evident. This trend is part of an expansion of its distribution area in many parts of place Central Europe whereas the increase in occurrence of *Erythromma viridulum*, *Aeshna affinis* and *Gomphus pulchellus* is due to a regional outspread of these species. These positive trends must be regarded in context with the observed climate change, but should also have been advanced by an anthropogenic increase of habitat availability. Due to meteorological conditions *Sympetrum flaveolum* shows strong fluctuations. The negative trend in occurrence of *Lestes dryas* is a result of drought-effects on reproduction habitats due to lack of precipitation in some years. Founding on indicator and differential species eight different Odonata coenoses are described for the UR Allier on the basis of 61 sampling sites. The Odonata assemblages of 152 sampling sites in the UR Weser are classified to 16 coenoses. The coenosis of the main course of the place Allier is remarkable. Due to quasi-natural morphodynamical conditions it shows an exceptionally high species diversity of 19 species. Among others, six species of gomphids (*Gomphidae*) live in these habitats.

Considered as specialists of various sediments they can often be found side by side, although each species prefer habitats of different grain sizes. This is a consequence of the micro-spatial distribution of different sediments, which is typical of natural rivers. In contrast, the coenosis of the main course of the place Upper Weser has a very low diversity. Many species were probably only able to reproduce here since salt pollution had been reduced in the 1990s. For some species of gomphids settling in the place Allier, actually a positive trend in occurrence even in strongly regulated rivers in place Central Europe is observed where current velocity is secondarily reduced between groynes. In the future, some of them could also appear in the place Upper Weser if salt pollution will decrease. Permanent waters of former secondary channels have a high species diversity in both study areas. In the UR Allier the coenosis of these waters can be differentiated according to the influence of cattle grazing. Alluvial ponds situated in pasture areas are colonized by thermophilous species like *Orthetrum albistylum* and *Coenagrion scitulum* due to a poor shading of their habitats. Besides, species preferring ponds with a low cover of vegetation like *Orthetrum brunneum* and *Ischnura pumilio* are found here. Ponds lacking influence of cattle grazing show both higher vegetation density and shading. Here, *Aeshna affinis*, *Lestes dryas* and *L. barbarus* are breeding. In the UR Weser, alluvial ponds of former secondary channels are subject to strong water level fluctuations. Permanent waters as well as shallow zones drying up temporarily are present. According to these conditions the coenosis has a high species diversity including 31 species. Here, species of permanent waters live beside several species with tolerance of habitat drying like *Aeshna affinis*, *Lestes dryas* and *Sympetrum flaveolum*. In these waters species with different habitat preferences can be found jointly due to high hydrological dynamics being typical of alluvial ponds. Exclusively in the UR Weser gravel pits were studied. Their coenoses can be differentiated by vegetation development and shading. Only waters with intermediate stages of succession show a high species richness due to vegetation diversity. In the UR Weser, *Crocothemis erythraea* and *Gomphus pulchellus* are exclusively found here. Because of very important water depths and steep banks, these features not being typical for alluvial water bodies, gravel pits are only exceptionally colonized by species characterising alluvial floodplains. The development of dragonfly assemblages in three re-deepened ponds in a former secondary channel of the UR Weser shows that even in regulated alluvial landscapes dynamic processes can 'be reactivated with low expenditure. Only a few years later structure diversity had been promoted by these restoration measures, the ponds were colonized by diverse dragonfly assemblages being typical of alluvial waters. The proximity of different waters is very important. Hereby, the species can select those ponds offering their preferred habitat conditions according to the actual meteorological situation. Recommendations for the development and the restoration of alluvial floodplains

can be derived from the results of the study and the analysis. The main aim of floodplain restoration is the re-activation of hydrological and morphological processes. Therefore, regeneration measures are proposed, these having to be adjusted to the individual conditions of the alluvial landscape." 13281. Lorenzo-Carballa, M.O.; Beatty, C.D.; Cordero-Rivera, A. (2010): Parthenogenesis in islands insects: The case study of *Ischnura hastata* Say (Odonata, Coenagrionidae) in the Azores. In: Artur R. M. Serrano, Paulo A. V. Borges, Mário Boeiro and Pedro Oromí (eds.): Terrestrial arthropods of Macaronesia - Biodiversity, ecology and evolution. Sociedade Portuguesa de Entomologia: 199-230. (in English) ["Conclusions: Despite the a priori advantages that islands represent for parthenogenetic reproduction, such as isolation from sexual competitors and lower "biological accommodation", the evidence of parthenogenetic forms of otherwise sexually reproducing species found inhabiting islands is still anecdotal (but see Aguin-Pombo et al., 2006). The case of *I. hastata* however, represents a clear classical example of geographic parthenogenesis, with sexual populations widely distributed in the continent and all-female populations found at the Azores islands. Cuellar (1994) has pointed out the importance of differences in vagility between sexual and asexual forms as a possible reason why asexuals can establish. In his review, the evolution of flightlessness in sexuals is offered as an example of a way that parthenogens could outcompete sexual populations through rapid colonisation of an area that sexuals, while reproductively more competitive, cannot invade as quickly. Odonates are extremely vagile animals and some species, such as *Pantala flavescens*, are almost cosmopolitan. In the American continent. *I. hastata* acts as a colonizer and shows a widespread distribution. Genetic data support these observations and indicate that populations probably interchange migrants. These features could have prevented purely parthenogenetic populations for becoming established in the original species' distribution area. Furthermore. *I. hastata* has been found in the Galápagos Islands, where both males and females have been reported (Peck, 1992). Thus the Azorean *I. hastata* is the first and unique case where parthenogenetic forms of this species have established. The great distance between the Azores archipelago and the American continent may have prevented sexual *I. hastata* to arrive and outcompete parthenogenetic populations. Also, the habitat of the Azores islands contains few competitors and predation rates are low, as is the incidence of parasitism by water mites (Lorenzo-Carballa et al., 2011), which would benefit parthenogenetic populations in the long term. Parthenogenesis in *I. hastata* has probably evolved spontaneously from sexual reproduction, which raises the possibility of finding spontaneous/facultative parthenogenesis in sexual populations in other locations. An important goal

for future work is to study and quantify the tytoparthenogenetic capacities of otherwise sexual *I. hastata* females; which will permit us to determine the biotic and abiotic conditions under which parthenogenesis will prevail over sexual reproduction. Finally, it is important to note that chance has probably played a major role in the establishment of the parthenogenetic *I. hastata* populations in the Azores, which makes them a unique case within the order Odonata and stresses the importance of conserving these populations." 13282. Mazzoni, R.; Nery, L.L.; Iglesias-Rios, R. (2010): Ecologia e ontogenia da alimentação de *Astyanax janeiroensis* (Osteichthyes, Characidae) de um riacho costeiro do Sudeste do Brasil. *Biota Neotrop.* 10(3): 53-60. (in English, with Portuguese summary) ["In the present work we aimed to describe the spatio-temporal and ontogenetic variations of *Astyanax janeiroensis* diet in Ubatiba stream, a coastal fluvial system from Serra do Mar. We analyzed 540 specimens collected monthly during twelve months in six sites differing in the degree of vegetal cover (opened and closed sites). We verified that *A. janeiroensis* is an omnivorous species whose diet is largely based on autochthonous items. The estimated intestinal coefficient was 0.74 (+ 1.2), being compatible with an omnivorous behaviour. We did not register differences in the diet from dry and rainy seasons. Nonetheless, we found differences in the diet from opened and closed sites. We registered quite absolute predominance of autochthonous items in the diet from the closed sites, whereas, in the opened ones we found similar ingestion of allo- and autochthonous items. Concerning juveniles and adult specimens, we found differences in the consumption of animal and vegetal items with a relative reduction of animal ingestion among adult specimens. The intestinal coefficient of adult specimens was higher than that of juveniles, corroborating the diet results." (Authors) Diet includes regularly Odonata.] Address: Mazzoni, Rosana, Dept de Ecologia, Instituto de Biologia, Universidade Federal do Rio de Janeiro – UFRJ, CP 68020, Rio de Janeiro, RJ, Brasil. 13283. Santi, E.; Mari, E.; Piazzini, S.; Renzi, M.; Bacaro, G.; Maccherini, S. (2010): Dependence of animal diversity on plant diversity and environmental factors in farmland ponds. *Community Ecology* 11(2): 232-241. (in English) ["Farmland ponds represent habitats with a high conservation value that make a significant contribution to regional biodiversity. Understanding the influence of plant species composition and environmental variables in driving variations in animal species composition in ponds is an important issue in the fields of ecological research and conservation biology. Using variance partitioning techniques to quantify independent effects, we examined

how plant species composition, local-landscape configuration and physicochemical variables interact in influencing aquatic insect and amphibian community composition. The ponds investigated in this study were located in the Site of Community Importance — Special Protected Area (Natura 2000 Network) "Monte Labbro — Alta Valle dell'Albegna" (Tuscany, central Italy). Our results showed that: (i) plant community composition (such as *Carex hirta*, *Glyceria fluitans*, *Potamogeton natans*, *Typha latifolia*) is a good predictor for amphibian but not for aquatic insect species composition; (ii) aquatic insect species composition was more strongly affected by the landscape context, whereas for amphibians the local characteristics of the ponds were determining; (iii) the physicochemical context is a poor predictor for these animal taxa; (iv) lastly, and notably, the explanatory variables explained a high proportion of the total variation in amphibian and aquatic insect species composition. Our results have important implications with respect to the creation of new ponds, which should preferentially take place close to semi-natural grasslands and other wetlands, in order to maintain greater connectivity, and away from urban areas. Moreover, larger ponds are preferable for the preservation of pond biodiversity. The management and conservation of ponds is necessary to ensure the protection of habitats, the survival of individual species and overall pond biodiversity.... *Pyrrhosoma nymphula* and *Anax imperator* were positively correlated with the pond area, whereas *Orthetrum brunneum* and *Notonecta glauca* were negatively correlated with this factor. ...In contrast, *Ilyocoris cimicoides*, *Libellula depressa*, *Anax parthenope* and *Hyphydrus aubei* mainly occurred on sites situated at lower altitudes with a low cover of pastures. Ponds with higher frequencies of *Cloeon dipterum*, *Acilius sulcatus* and *Libellula quadrimaculata* were positively correlated with the presence of torrents (refuges). Finally, most of the aquatic insect species appear to be negatively correlated with high trampling intensity and high altitude." 13293. Dow, R.A.; Reels, G.T. (2011): Odonata from a remnant patch of disturbed peat swamp forest on the outskirts of Kuching, west Sarawak. *Agrion* 15(2): 50-51. (in English) [Verbatim: Before large-scale human alterations began, much of the surroundings of what is now Kuching, the state capital of Sarawak, consisted of various types of swamp forest, including much peat swamp forest. Later, rubber was planted in parts of this swamp forest. MA Lieftinck (1953: 236), under the description of *Podolestes harrissoni*, gave an incomplete list of species collected in "an old rubber garden" on the Matang Road outside of Kuching, on September 22, 1950. This list included a number of apparently very scarce species (eg *Amphicnemis madelenae*, *Nannophyopsis chalcosoma* and *Pseudagrion optera diotoma*). Since Lieftinck's day Kuching has expanded considerably and there has been extensive development along the Matang Road, so that most of the peat swamp/old rubber habitat has gone. However, one patch remains, although probably not for much longer. Indeed, it may already have been bulldozed; we last passed the site in July 2010, when building work was occurring immediately adjacent to it. We first visited this site in January 2006, and made return visits in 2008 and 2010. The site is small, consisting of disturbed peat swamp with many old rubber trees that are still being tapped (on his last visit, RAD was ordered out of the site by machete-wielding rubber tappers). This site is at least near to Lieftinck's site, but remarkably we have collected a number of species not found by Lieftinck, illustrating the biodiversity of this kind of habitat in west Sarawak, and the extreme localisation of some species. Most notable of our discoveries at the Matang road was *Pachycypha* sp. cf. *aurea*. *P. aurea*, a tiny chlorocyphid, was described from the south of Kalimantan, and remains the only named species in the genus, which has not been recorded outside of Kalimantan until now. Despite the small size of the Matang Road site, it was not until May 2010 that we found this minute taxon, along one short section of a tiny stream. Both sexes descended from the canopy only in full sunlight, typically perching high. They were at low densities, and no interactions were observed between the sexes. They typically returned to the canopy almost immediately after the sun became obscured by clouds. A full list of the 26 species we have collected at the site is given below. Most of them were not listed by Lieftinck, but probably a number of these were actually collected by him; six species (at least) collected by Lieftinck were not collected by us. At least two of the species listed here are as yet unnamed; descriptions of both are being prepared by RAD.] Address: Dow, R.A., 6 Bramley Avenue, Coulsdon, Surrey, CR5 2DP, UK. E-mail: rory.dow@virgin.net

13294. Englund, R.A. (2011): Guam and Palau aquatic insect surveys. Contribution No. 2011-007 to the Pacific Biological Survey. Final Report. Prepared for: Southeast-

ern Ecological Science Center, U.S. Geological Survey, Gainesville, Florida: 21pp. (in English) ["From 15 to 26 March, 2010, collections of aquatic insects were made from freshwater habitats on the island Guam and the Republic of Palau. These surveys were part of a developing a regional biosecurity plan, and personnel from the Pacific Biological Survey of the Bishop Museum assisted scientists from the United States Geological Survey Southeast Ecological Science Center (USGS–SESC) based in Gainesville, Florida in obtaining data required for this plan. The results from these surveys will be used in conjunction with the USGS–SESC project entitled "Risk Analysis of Freshwater Nuisance Species Associated with Department of Defense Operations in Micronesia" that obtained critical baseline information regarding native and non–native freshwater invertebrates. The objective of these aquatic insect surveys was to provide a systematic inventory in selected streams on the islands Guam and in the Republic of Palau. Streams on both Guam and Palau were sampled for one week each. A total of 35 aquatic insect species were collected during surveys on Guam from 15–19 March, and 28 species were found on Palau from 21–26 March, 2010 (Tables 3–5). In the Republic of Palau, the vast majority of freshwater habitats are located on Babeldaob Island, so efforts were concentrated here. These results should be considered preliminary as this was a biological reconnaissance due to limited sampling time and effort for each site. However, this study does provide baseline information regarding particularly rich areas of biodiversity. Although reservoir habitats were assessed on Guam and Palau, lotic habitats were by far the most species-rich habitats. These surveys provided a baseline inventory of aquatic insect species present in each stream assessed and also ensured museum specimens will be available for future researchers. During the course of this study no obvious invasive aquatic invertebrates were observed in the streams sampled on Guam and Palau. All taxa identified to the species level were ascertained to be native species, and at least three species of aquatic Heteroptera on Guam were island endemics (*Limnogonus lundbladi*, *Microvelia mariannarum*, and *Saldula guamensis*). For Palau, a conservative estimate of finding at least 4 island endemics was made, including the three endemic damselflies (*Drepanosticta palauensis*, *Pseudagrion palauense*, and *Teinobasis palauensis*) and the gyrrinid (whirlygig) beetle. The identity of an *Ischnura* found in lentic habitats on Palau remains a mystery, but as it is not a widespread species such as *Ischnura aurora* or *Agriocnemis femina femina* it is likely that it at least is indigenous if not possibly endemic to Palau. The majority of endemism found during the present study was in relatively undisturbed forested watersheds that appeared to have little to no water diversions. Sampling areas around rifles/cascade areas were found to be particularly species rich. Streams above Fena Reservoir in the Naval Magazine such as the diverse Maulap River are currently strictly protected from development and human impacts, but uncontrolled feral animals such as water buffalo and

pigs could disturb the watershed to such an extent to impede water quality. Although feral animals did not appear to be a problem on Babeldaob, logging, increased agricultural development and water withdrawals are all potential future threats to maintaining a highly diverse and unique freshwater aquatic ecosystem on Palau." (Author) March 2010 Guam surveys: *Anax guttatus*, *Hemicordulia mindana*, *Diplacodes bipunctata*, *Orthetrum sabina*, *Pantala flavescens*, *Rhyothemis phyllis*, *Tholymis tillarga*, *Tramea transmarina*, *Agriocnemis* sp. undet., *Agriocnemis femina femina*, *Ischnura aurora*. Aquatic insect taxa observed and collected on Babeldaob Island during March 2010 Palau surveys: *Agriocnemis femina femina*, *Drepanosticta palauensis*, *Ischnura* sp. 1 undet., *Pseudagrion palauense*, *Teinobasis palauensis*, *Anax guttatus*, *Hemicordulia lulico*, *Diplacodes bipunctata*, *Neurothemis terminata*, *Orthetrum sabina*, *Pantala flavescens*, *Rhyothemis phyllis*, *Tholymis tillarga*, *Tramea transmarina*. 13295. Futahashi, R. (2011): A revisional study of Japanese dragonflies based on DNA analysis (1). *Tombo* 53: 67-74. (in Japanese, with English summary) ["Phylogenetic analyses using DNA sequences of dragonflies have been increasing recently. Here I review the recent findings of phylogenetic relationships between each family of Odonata based on DNA analyses by foreign research groups, and introduce the classification of Japanese dragonflies based on my ongoing DNA analyses. Several studies reported that Zygoptera and Anisoptera (including Epiophlebiidae) are monophyletic, and Chlorogomphidae and Macromiidae are accepted at the family level. Corduliidae is confirmed as non-monophyletic clade, and among Japanese Corduliidae species, *Macromidia ishidaei* Asahina, 1964 belongs to a different family. Coenagrionidae is divided into two well-supported subdivisions. The first includes a group of coenagrionids mostly characterized by having an angulate frons (including *Ceriagrion* and *Nehalennia*), and the second division includes typical Coenagrionidae. From my nuclear DNA analysis of all Japanese species, *Rhipidolestes aculeatus* Ris 1912 and *Anotogaster sieboldii* (Selys 1854) were recovered as strongly diphyletic, suggesting that *R. a. yakusimensis* Asahina, 1951 should be accepted at species level, and the Yaeyama group of *A. sieboldii* should be regarded as the distinct species *A. flaveola* Lohmann, 1997. Within subspecies, *Orthetrum japonicum japonicum* (Uhler, 1858) and *O. j. internum* McLachlan, 1894 were recovered as deeply separated lineages. Together with differences in their larval characteristics, these two subspecies are better recog-

nized as distinct species as in Ishida (1996). In contrast, only a few differences were found between the following two combinations of allopatric species; *Planaeschna milnei* (Selys, 1883) and *Planaeschna naica* Ishida, 1994, *Somatochlora japonica* Matsumura, 1911 and *Somatochlora exuberata* Bartenev, 1912, and no differences were found between the allopatric species *Aeshna nigroflava* Martin, 1908 and *Aeshna crenata* Hagen, 1856, suggesting that the two species of each combination should be recognized as the same species. The advantage, points of caution, and usage of DNA analysis are also discussed." (Author)] Address: Futahashi, R., Fujiwara Lab., Univ. Tokyo, Biosci. Bldg 501, Kashiwa, Chiba, 377-8562, Japan

13296. Gathman, J.P.; Burton, T.M. (2011): A Great Lakes coastal wetland invertebrate community gradient: Relative influence of flooding regime and vegetation zonation. *Wetlands* 31(2): 329-341. (in English) ["Wetland invertebrate community composition is affected by habitat conditions associated with flooding regimes and vegetation characteristics, yet distinguishing among these influential factors is difficult because they tend to co-vary spatially. We studied a Great Lakes coastal wetland invertebrate community along an elevation gradient as Lake Huron water level rose and fell over a three-year period. This hydrologic variation caused changes in the gradient of flooding conditions, while plant zonation remained relatively unchanged. Multivariate analysis indicated that the invertebrate community varied continuously along the elevation gradient, and that it changed substantially within vegetation zones as water level changed. Variation across the gradient decreased because the high-elevation wet meadow community became more similar to lower-elevation communities as a result of upslope expansion in distributions of many taxa, and substantial increases in dominance of a subset of taxa. Invertebrate density increased dramatically with high-water conditions, and diversity decreased in general. Results suggested that invertebrate community composition was influenced by flooding conditions more than vegetation. These results may have important implications for conservation of high-elevation wetland zones as high-water refuges for wet-meadow invertebrates, and for coastal wetland monitoring schemes based on vegetation zones as habitat for particular invertebrate assemblages. ... Libellulidae (and, to a lesser extent, Aeshnidae) dragonfly nymphs became conspicuously abundant in the Year 3 wet meadow (and June hummock zone; see Table 3), even though water levels were dropping (Gathman 2000). Many of these nymphs were found dead in shallow, warm pools of water in depressions on the recently exposed wet meadow substrate. Stranded aquatic invertebrates are easy prey for birds and terrestrial animals, and may nutritionally supplement terrestrial communities" (Authors)] Address: Gathman, J.P., Dept of Biology, University of Wisconsin River Falls, River Falls, WI 54022, USA. (in English) ["Insects are small relative to vertebrates, possibly owing to limitations or costs associated with their blind-ended tracheal respiratory system. The giant insects of the late Palaeozoic occurred when atmospheric PO₂ (aPO₂) was hyperoxic, supporting a role for oxygen in the evolution of insect body size. The paucity of the insect fossil record and the complex interactions between atmospheric oxygen level, organisms and their communities makes it impossible to definitively accept or reject the historical oxygen-size link, and multiple alternative hypotheses exist. However, a variety of recent empirical findings support a link between oxygen and insect size, including: (i) most insects develop smaller body sizes in hypoxia, and some develop and evolve larger sizes in hyperoxia; (ii) insects developmentally and evolutionarily reduce their proportional investment in the tracheal system when living in higher aPO₂, suggesting that there are significant costs associated with tracheal system structure and function; and (iii) larger insects invest more of their body in the tracheal system, potentially leading to greater effects of aPO₂ on larger insects. Together, these provide a wealth of plausible mechanisms by which tracheal oxygen delivery may be centrally involved in setting the relatively small size of insects and for hyperoxia-enabled Palaeozoic gigantism." 13300. Hugo, C.D. (2011): The influence of fire and plantation management on wetlands on the Tsitsikamma plateau. MSc thesis, Nelson Mandela Metropolitan University: X + 81 pp + 2 app. (in English) [South Africa; "Conclusion: Dragonfly abundance of wetlands on the Tsitsikamma Plateau was low but considering the absence of surface water, species richness was still fairly high. Dragonfly abundance is expected to increase when the drought ends, but the pattern of the results are expected to remain the same in wetter conditions. Fire indirectly influences dragonfly species composition and abundance

by altering vegetation structure. Generally, in this study dragonfly abundance and species richness was higher in palustrine wetlands with old vegetation, which had not burnt for at least nine years. Thus, it is important that structural vegetation succession of wetlands can take place. This study found female dragonflies frequented the palustrine wetlands more than males, which suggests the importance of palustrine wetlands as a refuge habitat for female dragonflies, and thus highlights the need for their conservation and further research. The wetland habitats on the plateau likely play a vital role as refuge habitats for female dragonflies, aiding in population dynamics by serving as geneflow corridors and dispersal grounds." 13304. Rannap, R.; Kaart, T.; Briggs, L.; de Vries, W. (2011): Habitat requirements of *Pelobates fuscus* and *Leucorrhinia pectoralis*. Project report "Securing *Leucorrhinia pectoralis* and *Pelobates fuscus* in the northern distribution area in Estonia and Denmark" LIFE08NAT/EE/000257. Tallinn 2011: 23 pp. (in English) ["Discussion and conclusions - *Leucorrhinia pectoralis*: To determine habitat requirements of *L. pectoralis* only data from Estonia was used, because in Denmark just three sites with *L. pectoralis*' larvae were found during the inventory in 2010. This dragonfly species has declined sharply in the westernmost parts of its range and its present distribution is very patchy (Sahlén et al., 2004). Thus, knowledge on habitat demands of *L. pectoralis*, gained from Estonia, would be very useful for active habitat management planning in Denmark and in other Western and Central European countries (e.g. Germany, France, the Netherlands, Belgium, etc.) as well. In Estonia *L. pectoralis* preferred larger natural lakes with extensive shallow littoral zones and large swampy edges of moor vegetation for breeding. At the same time artificial man made ponds with generally small size and steep banks were avoided as reproduction sites for *L. pectoralis*. In many areas in Europe natural lakes surrounded by bogs and swamps have completely vanished or their number has decreased rapidly. If such sites still exist, it would be important to preserve those in a state as close to natural as possible. In the other hand, while planning actions of habitat management for *L. pectoralis* creation of large wetlands and restoration of large permanent depressions with depth variation and extensive littoral zones should be considered. In addition, tense network of natural water bodies (lakes, bogs, beaver floods, river flood plains etc) is essential to harbour a vital population of *L. pectoralis*. Therefore aquatic habitats should be created and restored in clusters. *Leucorrhinia pectoralis* favoured to reproduce in water bodies with peaty sediment and avoided water bodies with mud. The sediment type turned out essential for the species probably due to its influence to the water chemistry and macrophytes' community. Sediment type also indicates the species' preference to natural clean water bodies and avoidance of eutrophicated waters. Thus, when restoring or creating breeding sites for this species, sediment type should be taken into account and agricultural pollution as well as nutrient influx should be prevented. In accordance to earlier studies, breeding site selection of *L. pectoralis* was strongly associated with presence of macrophytes in the water body (Schindler et al. 2003, Sahlén et al., 2004). Less than 1

m tall vegetation cover, as well as presence of 20 Sphagnopsida and Bryopsida mosses associated positively with larval abundance of *L. pectoralis*. Water vegetation has various important functions for adults and larvae, which include concealment from predators (Askew 1982), substrate for egg deposition, larval habitat, as well as for mating and feeding perches (Buchwald 1992, Schindler et al. 2003). Presence of forest and bogs in the close vicinity of breeding site was essential for *L. pectoralis* and the shorter distance to the forest was favoured. Forest provides shelter for the adults. At the same time open areas and buildings had significantly negative influence on breeding site selection. As demonstrated by Chin and Taylor (2009) the dispersal ability in the genus *Leucorrhinia* was limited by open areas, particularly in short distances, whereas forest shelters acted as dispersal routes for the adults. Thus, breeding sites should be created near the woodlands and large open areas as well as urban areas should be avoided." 13305. Rochlin, I.; Dempsey, M.E.; Iwanejko, T.; Ninivaggi, D.V. (2011): Aquatic insects of New York salt marsh associated with mosquito larval habitat and their potential utility as bioindicators. *Journal of Insect Science* 11(172): 1-17. (in English) ["The aquatic insect fauna of salt marshes is poorly characterized, with the possible exception of biting Diptera. Aquatic insects play a vital role in salt marsh ecology, and have great potential importance as biological indicators for assessing marsh health. In addition, they may be impacted by measures to control mosquitoes such as changes to the marsh habitat, altered hydrology, or the application of pesticides. Given these concerns, the goals of this study were to conduct the first taxonomic survey of salt marsh aquatic insects on Long Island, New York, USA and to evaluate their utility for non-target pesticide impacts and environmental biomonitoring. A total of 18 species from 11 families and five orders were collected repeatedly during the five month study period. Diptera was the most diverse order with nine species from four families, followed by Coleoptera with four species from two families, Heteroptera with three species from three families, then Odonata and the hexapod Collembola with one species each. Water boatmen, *Trichocorixa verticalis* Fieber (Heteroptera: Corixidae) and a shore fly, *Ephydra subopaca* Loew (Diptera: Ephydriidae), were the two most commonly encountered species. An additional six species; *Anurida maritime* Guérin-Méneville (Collembola: Neanuridae), *Mesovelina mulsanti* White (Heteroptera: Mesovelidae), *Enochrus hamiltoni* Horn (Coleoptera: Hydrophilidae), *Tropisternus quadristriatus* Horn (Coleoptera: Hydrophilidae), *Dasyhelea pseudocincta* Waugh & Wirth (Diptera: Ceratopogonidae), and *Brachydeutera argentata* Walker (Diptera: Ephydriidae), were found regularly. Together with the less common *Erythrodiplax berenice* Drury (Odonata: Libellulidae), these nine species were identified as the most

suitable candidates for pesticide and environmental impact monitoring due to abundance, position in the food chain, and extended seasonal occurrence. This study represents a first step towards developing an insect-based index of biological integrity for salt marsh health assessment." 13311. Belmar, O.; Velasco, J.; Gutiérrez-Cánovas, C.; Mellado-Díaz, A.; Millán, A.; Wood, P.J. (2012): The influence of natural flow regimes on macroinvertebrate assemblages in a semiarid Mediterranean basin. *Ecology* 6(3): 363-379. (in English) ["The investigation of flow-ecology relationships constitutes the basis for the development of environmental flow criteria. The need to understand hydrology-ecology linkages in natural systems has increased owing to the prospect of climate change and flow regime management, especially in water-scarce areas such as Mediterranean basins. Our research quantified the macroinvertebrate community response at family, genus and species level to natural flow regime dynamics in freshwater streams of a Mediterranean semiarid basin (Segura River, SE Spain) and identified the flow components that influence the composition and richness of biotic assemblages. Flow stability and minimum flows were the principal hydrological drivers of macroinvertebrate assemblages, whereas the magnitude of average and maximum flows had a limited effect. Perennial stable streams were characterized by flow sensitive lotic taxa (Ephemeroptera, Plecoptera and Trichoptera) and intermittent streams by predominately lentic

taxa (Odonata, Coleoptera, Heteroptera and Diptera). Relatively minor biological changes were recorded for intermediate flow regime classes along a gradient of flow stability. Seasonal variation and minimum flows are key hydrological components that need to be considered for river management and environmental flows in the Segura River basin and other Mediterranean basins. The anthropogenic modification of these parameters, due to both human activities and climate change, would probably lead to significant changes in the structure and composition of communities in perennial stable streams. This would be characterized by a reduction of flow sensitive Ephemeroptera, Plecoptera and Trichoptera taxa and an increase in more resilient Odonata, Coleoptera, Heteroptera and Diptera taxa." (Authors) Odonata are treated at genus level: *Anax*, *Boyeria*, *Calopteryx*, *Cercion*, *Ischnura*, *Pyrrhosoma*, *Cordulegaster*, *Gomphus*, *Onychogomphus*, *Libellula*, *Orthetrum*, *Sympetrum*, *Platycnemis*.] Address: Belmar, O., Department of Ecology and Hydrology, University of Murcia, Espinardo Campus, 30100 Murcia, Spain. 13314. Bruno, C.G.G. (2012): Assessment of heavy metal contamination in Brazilian savanna's streams using Odonata larvae as bioindicators. MSc. thesis. Federal University of Uberlandia. Uberlandia-MG. 92 pp. (in Portuguese, with English summary) ["The aquatic ecosystems are the main receptors of pollutants and contaminants from industrial and agricultural activities and of the discharge of sewage. Among the various substances potentially harmful, heavy metals are a threat to the aquatic ecosystems and the biota. This research aimed to evaluate the contamination of Cerrado's streams by heavy metals using Odonata's larvae as bioindicators, by analyzing biological parameters and evaluating the concentration of metals in the sediments and in the larvae. Samples were collected between October 2010 and August 2011. For the fauna, the abundance of individuals, richness of taxa and the diversity index of Shannon-Wiener (H') and Pielou's equity index (J) were calculated. The presence of metals in the sediment and in the larvae was measured by atomic absorption spectrometry and atomic emission spectrometry with inductively coupled plasma, respectively. Cluster analysis was performed for the set of streams for the concentrations of Cu, Zn, Ni, Fe and Mn in sediments, and concentrations of Cu, Zn and Ni in the sediment were compared with a table of guide values. Canonical Redundancy Analysis (RDA) was performed to discriminate metals that contributed most to the variance of the biological parameters. Significance of heavy metals on the fauna of Odonata was evaluated by Canonical Correspondence Analysis (CCA). A Principal Component Analysis (PCA) was performed to determine the most important patterns in the concentrations of Cu, Zn, Fe and Mn in the larvae and in the sediments and the bioaccumulation factor (BAF) was calculated to assess the potential for bioaccumulation of metals by the larvae. The Cluster analysis promoted the formation of groups of streams due to the greater or lesser concentration of heavy metals in the sediment which may have been influenced by the presence or absence of riparian vegetation and agricultural activities in the surrounding areas of the streams. The comparison with the table of guide values indicated that the streams which showed the highest concentrations of metals in the sediment were also those who had values above the limits given for at least one of the metals evaluated. The CCA indicated that most taxa of Odonata presented opposite distribution in relation to the vectors of heavy metals, while the family Libellulidae

was abundant in streams subject to greater anthropogenic influence. There was low similarity between the distribution patterns of the PCA diagrams for the sediment and larvae, which indicates the importance of assessments not only in the sediment, but also in the organisms for the achievement of results more efficient about heavy metal contamination. The BAF showed a tendency to bioaccumulation of Zn and Mn by the Gomphidae larvae, indicating that these metals are able to concentrate on its bodies, reflecting the environmental conditions where these organisms live and thus serving as important tools in biomonitoring studies. The results of this study emphasize the potential of the order Odonata for environmental studies, because they demonstrated to be able to reflect the conditions of their environment with respect to the concentration of heavy metals." 13315. Das, H.; Dutta, A. (2012): Effects of industrial effluents on ecology of a wetland of Nalbari district, Assam with special reference to ichthyofauna. The Ecoscan, Special issue 1: 147-153. (in English) ["Industrial effluents discharge into the water bodies is a major threat to the aquatic life. The wetland near District Industries and Commerce Centre (DIC) of Nalbari district provides a typical example of aquatic pollution due to industrial discharge. A study was undertaken during 2010-2011 to examine selected physico-chemical parameters of this wetland that receives effluents from different categories of small scale industries like aluminum utensil manufacturing industry, flour industry and mustered oil industry located at DIC. The water quality parameters that observed to estimate pollution level were temperature (18-25°C), colour (dark brown to blackish), odour (H₂S like), DO (3.9-4.7 mg/L), FCO₂ (3.6-5.1 mg/L), pH (8.5-9.2), alkalinity (349-410 mg/L), total hardness (69-147 mg/L), chloride (58-67 mg/L). Among these water quality parameters certain parameters like temperature and total hardness were within the acceptable limit. However, others exceeded the acceptable range of sustainable fish growth. Effects of pollutants were studied on certain hardy fishes like *Channa gachua*, *Clarias batrachus* and *Anabas testudineus*. Industrial effluents affect the integument, gills and several organs of such fishes especially liver. Plankton and aquatic insects were also studied to throw some light on the indicator species." 13317. Del Arco, A.I.; Ferreira, V.; Graça, M.A.S. (2012): The performance of biological indicators in assessing the ecological state of streams with varying catchment urbanisation levels in Coimbra, Portugal. *Limnetica* 31(1): 141-154. (in English) ["The performance of biological indicators in assessing the ecological state of streams with varying catchment urbanisation levels in Coimbra, Portugal The growth of human populations has resulted in the expansion of metropolitan areas and changes in land use, both of which affect watersheds and streams. The ecological integrity of streams is likely to be negatively affected by urbanisation, compromising freshwater ecosystem services. The aim of this study was to assess how efficient structural and functional indicators are in evaluating the ecological conditions of water in urban stream ecosystems. Two urban streams crossing the city and one stream crossing a suburban area of Coimbra, Portugal were selected. Total impervious area (TIA) was used as an indicator of urbanisation. Physical and chemical parameters of water were measured and analysed within the Water Framework Directive (WFD/2000/60/EC). Benthic macroinvertebrates were used as structural indicators, and the IBMWP biotic index (modified) and the Portuguese IPTIS index were calculated. The decomposition rates of oak (*Quercus robur*) and alder (*Alnus glutinosa*) leaves were used as indicators of functional quality. Biotic indices and litter decomposition rates indicated poor ecological conditions in the urban streams compared to the suburban stream, consistent with the degree of urbanisation. The decrease in ecological quality in urban streams most likely reflected decreases in dissolved oxygen and increases in water temperature and conductivity. We emphasise (a) the need to combine physical and chemical data with biological data and (b) the high performance of a novel functional indicator based on litter breakdown rate as an accurate, efficient and integrative measure of ecological integrity in urban streams." (Authors) The analysis also considers 'Cordulegaster' and 'Onychogomphus'.] Address: Del Arco, Ana Isabel, IMAR-CMA, Dept of Life Sciences, University of Coimbra, P.O. 13318. Dunbier, J.R.; Wiederman, S.D.; O'Carroll, D.C. (2012): Predictive response facilitation to moving targets in an insect neuron. *Front. Behav. Neurosci.* Conference Abstract: Tenth International Congress of Neuroethology, College Park. Maryland USA, USA, 5 Aug - 10 Aug, 2012. doi: 10.3389/conf.fnbeh.2012.27.00234: (in English) ["Hemicordulia tau, is an efficient aerial insect predator. Much of their airborne behaviour is related to the pursuit of other flying insects, both conspecifics and prey. The dragonflies identify these target animals at distance against visually cluttered, dynamic backgrounds. Additionally this must all be separated from the motion signals generated by the dragonflies' movement through the world. The visual system of the dragonflies possesses numerous specialisations to facilitate these essential behaviors. Small target motion detecting (STMD) neurons have been identified in the lobula of several insect spe-

cies that engage in visual chase behaviors. This class of neurons respond robustly to small, discrete targets moving within a region of the visual field even in the presence of other non-target based motion [Nordström and O'Carroll 2009]. How do STMDs generate robust responses to target motion despite motion of other background features? Previous work from our lab shows that despite STMDs having a short absolute latency of response, response to the continuous motion of a discrete target increases to its maximum over several hundreds of milliseconds [Nordstrom et al 2011]. The dragonfly centrifugal small target motion detector, CSTMD1 is ideal for investigating the mechanisms underlying this response facilitation. We recently showed that disruption of the path into discontinuous paths abolishes facilitation in a manner predicted poorly by parsimonious physiological explanations for such a slow response, leading to the conclusion that facilitation must involve a higher order mechanism that is locally circumscribed [Dunbier et al 2011]. To test this hypothesis we presented CSTMD1 with controlled spatial, temporal and spatio-temporal discontinuities in target trajectories. Spatial displacements reveal the instantaneous extent of facilitatory spread to be limited to less than 21 degrees from the current target location. Temporal discontinuities revealed that the local response remains primed in that region for at least 500msec, longer in some cases. Most interesting of all we found that for a velocity matched spatio-temporal discontinuity (the equivalent of a target disappearing behind an obstruction), facilitation spreads away from the disappearance location to a greater degree than in the purely spatial discontinuities. i.e. responses at more distant locations that were not initially facilitated, become more so after a delay matching the predicted target speed. While our experiments reveal a fascinating, predictive mechanism for boosting the target response at expected future locations, it is not yet clear whether this subserves a boost in local target detectability amidst complex clutter, or a higher order mechanism of attention to a feature of interest (or both). ... 13319. Falico, D.A.; Lopez, J.A.; Antoniazzi, C.E. (2012): Opportunistic predation upon dragonflies by *Pseudis limellum* and *Pseudis paradoxa* (Anura: Hylidae) in the Gran

Chaco region, Argentina. *Herpetology Notes* 5: 215-217. (in English) ["On January the 7th, 2010 we manually captured 19 postmetamorphic *P. paradoxa* individuals (mean snout-vent length= 46.12 ± 2.46 mm) and 14 *P. limellum* individuals (mean snout-vent length = 18.06 ± 1.54 mm). All individuals were euthanized in situ and subsequently deposited in the herpetological reference collection of the National Institute of Limnology (INALI: CONICET-UNL). After dissection, the entire content of the gastrointestinal tract of each individual was analyzed under a microscope. To describe the diet, we calculated the hierarchic index of relative prey importance (IRI%), that combines prey numerosity (N), volume (V) and frequency of occurrence (FO) to obtain a general expression of the importance of each prey item (George and Hadley, 1979): Eighty-nine percent of the *P. paradoxa* (hereafter Pp) individuals and 79% of the *P. limellum* (hereafter Pl) individuals contained dietary remains. We identified 78 prey items (Pp = 41, Pl = 37) classified in 17 categories (Table 1). Odonata was the most important prey in both species. Diet similarity between species was high (Pjk=75.98%). However, post-hoc analysis revealed that odonates consumed by *P. paradoxa* were significantly larger than those consumed by *P. limellum* (Odonata length: unpaired t test, t13 = 5.12, p = 0.0002; Odonata width: unpaired t test, t13 = 10.284, p < 0.0001; Odonata volume: unpaired t test with Welch correction, Welch's approximate t7 = 7.471, p = 0.0001). The high dietary overlap found in our study could potentially be attributed to a high temporary abundance of odonates during the sampling date (authors pers. obs.). Odonates are vulnerable to predation by anurans during oviposition, when reproducing individuals are in direct contact with the water surface, and during emergence, when larvae shed their skin (exuvia) as part of their metamorphosis to the adult stage (Rehfeldt, 1992; Worthen, 2010). The possibility of *P. limellum* and *P. paradoxa* to co-occur with an elevated diet overlap could therefore be facilitated by the temporary abundance of this food resource (i.e. summer dragonfly oviposition and emergence), variation in mean prey item size (larger frogs consumed larger dragonflies, probably a larger proportion of Anisoptera versus Zygoptera), and the high productivity of these wetlands (Seib and Lajmanovich, 2003-2004). For this reason, we proposed that, as *P. paradoxa* and *P. limellum* are generalist predators, they tend to opportunistically exploit temporary abundant prey - such as dragonflies during oviposition or emergence - which causes a temporary rise in 'taxonomic' diet overlap but likely results in minor food competition." 13320. Ferreira, R.B.; Schineider, J.A.P.; Teixeira, R.L. (2012): Diet, fecundity, and use of bromeliads by *Phyllodytes luteolus* (Anura: Hylidae) in southeastern Brazil. *Jour. Herpetology* 46(1): 19-24. (in English) ["This study explores the feeding ecology, habitat use, and fecundity of *Phyllodytes luteolus* inside bromeliads in the restinga

of Regência (sandy coastal plain), Espírito Santo state, southeastern Brazil. Because bromeliads are harvested for commercial use, and frogs may be collected accidentally, the ecology of this frog is of particular interest. We collected 363 individuals of *P. luteolus* (103 tadpoles, 74 juveniles, 64 males, and 122 females) from three species of bromeliads in a 4-km² area bimonthly from February to December of 1998. Ants and termites were the dominant food items in terms of number and mass over time. The percentage of prey items and the size of prey eaten by juveniles differed significantly from those of adults. Dominant prey items were relatively similar across the sampled bromeliad species and locations. *Phyllodytes luteolus* preferred *Vriesea procera*, the most-complex bromeliad in our study site. Half of the individuals were found in bromeliads located in transitional zones. Female *P. luteolus* were slightly larger than the males, which may have determined the strong sex ratio bias toward females. We found females with developed oocytes (range 11–15) in every sampled month, indicating a protracted spawning period. This frog can be considered an active forager and specialist, feeding preferentially on colonial insects. *Phyllodytes luteolus* uses several species of harvested bromeliads and possesses several attributes that could facilitate its success as an invasive species." (Authors) Odonata larvae were found in low numbers.] Address: Ferreira, R.B., Dept Wildland Res.s & Ecol. Center, Utah State Univ., Logan, Utah 84322–5230, USA. E-mail: rodrigoecologia@yahoo.com.br

(2012): Gli Odonati del Friuli Venezia Giulia: aggiornamento della checklist. *Bollettino Soc. Naturalisti "Silvia Zenari"*, Pordenone 36: 117-131. (in Italian, with English summary) ["The Odonata of the Friuli Venezia Giulia region: an updated checklist. During surveys carried out in 2012 in the context of the Project "Atlas of the Odonata of Friuli Venezia Giulia" (north-eastern Italy) the regional Odonatofauna list has been enriched with seven new species mainly found in mountain and hilly areas. Up to now, the new checklist includes 57 species. The new observed species are *Coenagrion hastulatum* and *Somatochlora arctica*, *S. meridionalis*, *Sympetrum meridionale*, *S. vulgatum*, *S. danae* and *Leucorrhinia dubia*. Notably, no specimens of *Nehalennia speciosa* were found in the Palude di Cima Corso biotope, therefore this species is present in the region (and in Italy) only in the Torbiera di Lazzacco biotope. All collected data will be useful in the development of projects in order to protect important biotopes for the conservation of threatened species." 13322. Gurumayum Shantabala, D.; Goswami, U.C. (2012): Spatial and seasonal distribution of macrobenthic fauna of three rivers of Manipur. *Indian journal of fisheries* 59(1): 37-42. (in English) ["Benthic fauna of three important rivers of Manipur state viz., Khuga, Thoubal and

Imphal were studied during 1999 - 2000. Macroinvertebrate zoobenthos population was low in all the rivers and was found between 85-1,255 μm^{-2} . In Khuga (129-1,255 μm^{-2}) and Thoubal (173-1,100 μm^{-2}) rivers macroinvertebrate benthos population were poor to medium where as in the Imphal River all the three stretches studied showed lowered macroinvertebrate population (85-390 μm^{-2}). During pre-monsoon period there was maximum benthos density in both the stretches in Thoubal, Khuga and Imphal rivers, whereas in the middle stretches of Imphal River, maximum population was observed in post-monsoon. Upper stretch showed richer benthos population both in terms of density and species composition in Khuga and Thoubal rivers. In the Imphal River distinct spatial variation of macroinvertebrate benthos population was lacking, but species composition was richer in lower stretch. Altogether nine macrozoobenthic groups (including Odonata, without any details) were observed during the study and the details are presented in this paper." 13326. Horvath, J.; Ferenczi, M.; Móra, A.; Vad, C.F.; Ambrus, A.; Forró, L.; Szövényi, G.; Andrikovics, S. (2012): Invertebrate food sources for waterbirds provided by the reconstructed wetland of Nyirkai-Hany, northwestern Hungary. *Hydrobiologia* 697: 59-72. (in English) ["The Nyirkai-Hany wetland reconstruction area in northwestern Hungary is now designated as a Ramsar and a Natura 2000 site. It was created in 2001–2002 by the Fertő-Hanság National Park Directorate to restore a part of the formerly drained large wetland called Hanság and to offer waterbirds a suitable habitat for feeding and breeding. We focused on this aim of the restoration project and studied the temporal and spatial variation in abundance of birds and their invertebrate prey in this newly created wetland. From April 2007 until May 2008, we sampled plankton, nekton and benthos of different habitats monthly and monitored waterbirds weekly on the three different areas of the Nyirkai-Hany. During our investigations, 135 invertebrate and 53 waterbird species were recorded. Benthos and macrophyte decomposition accelerating guilds were the most abundant waterbird guilds—besides the dominant grazing importer material transporter guild, represented primarily by geese—in the Nyirkai-Hany. Zooplankton assemblages primarily consisted of small species not easily used as a food by planktivorous waterbirds. The low density of zoobenthic biomass and the small extent of shallow water mudflats probably accounted for the scarcity of the bioturbating guild group of birds. Nektonic biomass varied greatly among locations having different vegetation types, was greatest in the shallow water areas dominated by *Typha*, *Carex* and *Phragmites* species and lowest at offshore vegetation-free sites. Chironomids, mayflies and odonates were especially abundant and their biomass significantly correlated with several waterbird species, mainly belonging to the macrophyte decomposition accelerating guild (e.g. *Anas platyrhynchos*, *Fulica atra*). This guild itself, which has increa-

sed in abundance in recent years, showed an exceptionally strong correlation with odonate abundance. These results indicate the growing importance of the Nyirkai-Hany wetland area as a foraging site for waterbirds." (Authors) Odonata listed are: *Aeshna mixta*, *Anax* sp., *Brachytron pratense*, *Coenagrion puella*, *C. pulchellum*, *Ischnura elegans*, *Lestidae* sp., *Sympecma fusca*, and *Sympetrum vulgatum*.] Address: Horváth, Z., Department of Systematic Zoology and Ecology, Eötvös Loránd University, Pázmány Péter sétány 1/C, 1117 Budapest, Hungary. 13327. Jones, O.M. (2012): The effects of SPINOSAD on *Culex quinquefasciatus* (Diptera: Culicidae) and non-target insect species. MSc thesis. Agricultural and Mechanical College, Department of Entomology, Graduate Faculty of the Louisiana State University: VI + 36. (in English) [USA "Spinosaad is a relatively new insecticide with a unique mode of action that is being valued for control of larval mosquitoes. Whereas a number of toxicological studies have measured effects of spinosaad on various mammals, fish, birds, and terrestrial arthropods, fewer studies have been conducted on the effects of spinosaad on non-target aquatic insect species. Such studies are important as these species might be found in the same environments as mosquito larvae targeted for control. A neighbourhood pond was surveyed to find a representative species of mosquito as well as other common aquatic insects with which to examine susceptibility to spinosaad and non-target effects. The mosquito species chosen was *Culex quinquefasciatus* and the most common non-target taxa were immature stages of a mayfly (*Caenis* spp., Ephemeroptera: Caenidae), a damselfly (*Ischnura* spp., Odonata: Coenagrionidae) and a dragonfly (*Pachydiplax longipennis*, Odonata: Libellulidae). Bioassays of mosquitoes from a reference susceptible strain (Sebring-S) and field-collections of *C. quinquefasciatus* were used to determine susceptibility to spinosaad. In addition, susceptibility was examined in nontarget taxa using spinosaad concentrations corresponding to the LC50 of a field-collected mosquitoes (0.031 ppm) and the labeled rate (1.6 ppm) of Natular®, an EC formulation of spinosaad. Susceptibility to spinosaad did not differ between Sebring-S and field-collected mosquitoes. However, there was a marked difference in susceptibility among non-target taxa. Susceptibility was greatest in *Caenis* spp., followed by *Ischnura* spp., then *P. longipennis*. Results from this study will allow better future management strategies for the use of spinosaad as a mosquito larvicidal agent." (Author)] Address: James Ottea, J., Dept of Entomology, Louisiana State University Agricultural Center, Baton Rouge, LA 70803, USA

13328. Kalninš, M. (2012): The dragonflies (Odonata) species composition changes, spatial distribution and their determining factors in Latvia. PhD thesis. Larvijas Universitate, Riga: 84 pp. (in bilingual in Latvian and English) ["Conclusions: (1.) In line with the latest investigations, there are 59 dragonfly species in Latvia. The

changes in Latvian dragonfly fauna in the last 20 years are related to the extension of southern species areas in the northern direction. In future 5 new dragonfly species may be identified in Latvia – *Lestes viridis*, *Erythromma viridulum*, *Aeshna affinis*, *Orthetrum coerulescens* and *Sympecma fusca*, while the total number of new species in a larger period of time might reach 12 species. The foreseen changes in the dragonfly fauna are related to the distribution of southern species in the northern direction. (2.) The distribution of separate dragonfly species in Latvia is very irregular, as Latvia lays in the periphery of the species' area (*Coenagrion johanssoni*) and due to disjunctive distribution of species habitat (*Gomphus flavipes*, *Aeshna subarctica*) and climate changes (*Anax parthenope*, *Sympetrum fonscolombii*, *Sympetrum pedemontanum*). (3.) The variety of dragonfly species found in raised bogs is increased by the presence of water pools in open landscape (less common are pools in pine groves). Low variety of species is found in wooded mire (wooded [pine groves] mire landscape with mounds and depressions) and open mire (open mire landscape with mounds and depressions, but with no water bodies or woods) habitats. For dragonflies, the most important structures are open water and *Ledum palustre*, *Vaccinium uliginosum*, *Calluna vulgaris* and *Andromeda polifolia* vegetation structures. (4.) In the research of river dragonflies Gomphidae it was found that *Gomphus vulgatissimus* is an ecologically flexible species and the highest density of population can be found in micro habitats with sand and mud (and lower speed of the stream). *Onychogomphus forcipatus*, on the other hand, is less flexible and the highest density of larvae population is found in micro habitats with gravel, pebbles and cobbles (and higher speed of the stream). For *Ophiogomphus cecilia* the density of larvae population is relatively low, but no specific micro habitats were identified in Latvia. (5.) In Latvia, contrary to other European countries, *Nehalennia speciosa* may populate both small and large water bodies, if the vegetation is appropriate for the species. The distribution of the species in Latvia is most likely determined by the climate – the level of moisture and continentality of the climate. Fundamental differences regarding the vegetation populated by the species and the size of populations were not established. (6.) *Aeshna subarctica* in Latvia populates raised bogs with water pools and lakes and lakes with fen and poor fen banks, but, unlike in other European countries, it is not found in peat quarries. The distribution of the species in Latvia is most likely determined by the climate – the level of moisture and continentality of the climate. Fundamental differences regarding the size of the populated water bodies and populations were not established. (7.) *Ophiogomphus cecilia* in Latvia populates similar river habitats as in other places in the species area. Unlike in case of the part of the species area on the south from Latvia, in Latvia the distribution of the species is more determined by the climate – the level of moisture and continentality of the climate. (8.) The population of *Leucorrhinia* family dragonflies in Latvia, in comparison with the population of this species

in other places in Europe, is quite small. *L. albifrons* are more often found in dystrophic (acidic) lakes and also habitats of anthropogenic origin; *L. caudalis* comparatively often can be found in oxbow lakes, which is more characteristic to the periphery of the species area; the number of new localities of *L. pectoralis* has grown considerably, despite the downward tendency in Europe. The habitats suitable for these species are characterized more by the vegetation of the habitat rather than its origin (naturalism)." 13329. Kalninš, M. (2012): The ecology and conservation of the Bog Hawker *Aeshna subarctica* Walker, 1908 (Odonata: Aeshnidae) in Latvia. *Latvijas Entomologs* 51: 40-57. (in English) ["*A. subarctica* is a declining and already regionally extinct species in some areas in Europe. Published and all known unpublished data have been used to present and analyse its distribution, population size, habitat selection, and conservation status. The distribution of *A. subarctica* has been mapped using a basic grid of 5x5 km squares in the Baltic grid system. In total, *A. subarctica* has been recorded from 21 squares and 21 localities occurring sparsely or in small concentrations over a large part of the country apart from its western territories. The majority of the recent localities are situated in northern and southern Latvia. The known pattern of the species' distribution partly results from the abundance and density of appropriate habitats and possibly a climatic influence. However, this also may be a consequence of an insufficient and uneven odonatological exploration of the country. *A. subarctica* has mostly been recorded in primary habitats in Latvia, such as raised bogs with bog pools, lakes and lakes within fens and bogs. The flight season of the *A. subarctica* in Latvia ranges mainly from August to September. The conservation measures are suggested." 13331. Kuc, R.; Kuc, V. (2012): Bat wing air pressures may deflect prey structures to provide echo cues for detecting prey in clutter. *J. Acoust. Soc. Am.* 132(3): 1776-1779. (in English) ["Bats have remarkable echolocation capabilities to detect prey in darkness. While it is clear how bats do this for prey that is isolated, moving, or noisy, their ability to find still and quiet prey within clutter has remained a mystery. A video published by the ChiRoPing group shows the gleaning bat *Micronycteris microtis* capturing a still dragonfly specimen sitting on a leaf surface. While hovering over the dragonfly, the bat's wings exert air forces that cause the dragonfly wings to deflect in synchrony with the bat's wing beats. This paper illustrates that echoes from such deflecting wings vary in both amplitude and time-of-flight, producing robust echo cues that permit prey detection, even when the prey is embedded within clutter. Experiments with a dragonfly specimen mounted on a leaf driven by periodic air puffs produced wing deflections that were sensed with sonar pulses. Results demonstrate that echo variations synchronized with periodic air puffs are easily distinguishable from surrounding clutter, even when clutter produces the first echoes. These results suggest a strategy that bats can employ to detect still and silent prey embedded within cluttered environments." (2012): Effects of the fungicide metiram in outdoor freshwater microcosms: responses of invertebrates, primary producers and microbes. *Ecotoxicology* 21: 1550-1569. (in English) ["The ecological impact of the dithiocarbamate fungicide metiram was studied in outdoor freshwater microcosms, consisting of 14 enclosures placed in an experimental ditch. The microcosms were treated three times (interval 7 days) with the formulated product BAS 222 28F (Poliram). Intended metiram concentrations in the overlying water were 0, 4, 12, 36, 108 and 324 lg a.i./L. Responses of zooplankton, macroinvertebrates, phytoplankton, macrophytes, microbes and community metabolism endpoints were investigated. Dissipation half-life (DT50) of metiram was approximately 1–6 h in the water column of

the microcosm test system and the metabolites formed were not persistent. Multivariate analysis indicated treatment-related effects on the zooplankton (NOECcommunity = 36 lg a.i./L). Consistent treatment-related effects on the phytoplankton and macroinvertebrate communities and on the sediment microbial community could not be demonstrated or were minor. There was no evidence that metiram affected the biomass, abundance or functioning of aquatic hyphomycetes on decomposing alder leaves. The most sensitive populations in the microcosms comprised representatives of Rotifera with a NOEC of 12 lg a.i./L on isolated sampling days and a NOEC of 36 lg a.i./L on consecutive samplings. At the highest treatment-level populations of Copepoda (zooplankton) and the blue-green alga *Anabaena* (phytoplankton) also showed a short-term decline on consecutive sampling days (NOEC = 108 lg a.i./L). Indirect effects in the form of short-term increases in the abundance of a few macroinvertebrate and several phytoplankton taxa were also observed. The overall community and population level no-observed-effect concentration (NOECmicrocosm) was 12–36 lg a.i./L. At higher treatment levels, including the test systems that received the highest dose, ecological recovery of affected measurement endpoints was fast (effect period 8 weeks)." 13333. Lobón-Cerviá, J.; Rezende, C.F.; Castellanos, C. (2012): High species diversity and low density typify drift and benthos composition in Neotropical streams. *Fundamental and Applied Limnology* 181(2): 129-142. (in English) [oas 40;" We hypothesized that Neotropical streams might exhibit higher drift and benthos densities than their Palearctic counterparts in order to sustain the high diversity of drift-and benthos-feeding fish species that typify this vast region. We assessed drift and benthos composition in two pristine streams deemed to represent the two less documented Neotropical regions: Rio Amazonas (i.e., Yahuaraca) and Coastal Serra do Mar (i.e., Mato Grosso). Four monthly benthos and drift samples were collected over diel cycles in the rainy and dry seasons. Although the two streams showed remarkably low drift and benthos densities, in Mato Grosso benthos density was markedly higher. The same aquatic families predominate in the drift and benthos of the two streams. High taxonomic richness, low drift density, consistent diel cycles with a peak just after dusk, higher density during the night and temporal changes unrelated to seasonality typify drift composition of the two streams. Although drift densities were lower in Yahuaraca, the dominant families did exhibit drift behaviour, with two drift peaks at night. In Mato Grosso only Baetidae showed such behavioural drift with density peaks at night; other families demonstrated passive drift. Overall, these results refute our hypothesis that Neotropical streams should exhibit higher drift and benthos densities. Actually these pristine streams show among the lowest drift and benthos densi-

ty values worldwide." (Authors) Drifted specimens also contained a few Odonata specimens from several different families.] Address: Lobón-Cerviá, J., Museo Nac. de Ciencias Naturales (CSIC), C/ José Gutiérrez Abascal, 2. Madrid 28006 Spain. E-mail: MCNL178@mncn.csic.es

13334. Maradova, M.; Soldán, T. (2012): Effect of meander restoration on macroinvertebrate biodiversity: the case of the Borová stream (Blanský Les, Czech Republic). *Silva Gabreta* 18(1): 1-21. (in English) ["This study brings a view on the effects of restoration of a formerly channelized small submontane stream situated in the Blanský Les Protected Landscape Area (South Bohemia, Czech Republic) on macroinvertebrate assemblages as an indicator group. The restoration project was carried out during two stages (1998 and 2000). It consisted of excavating a new channel to restore the historic meandering pattern. The evaluation of this project is primarily based on the comparison of composition between pre-restoration (1995) and post-restoration (2000–2003) macroinvertebrate samples focusing on species richness, species composition, and representation of rare Ephemeroptera and Plecoptera species. The analyses showed a substantial increase in species richness that was especially prominent shortly after the restoration intervention. This increase was not only due to the creation of lentic habitats, but was even observed at every single sampling site of the stream. The DCA ordination of species composition of the pre- and post-restoration sites indicated a considerable increase in the between-site diversity. This was apparently caused mainly by the establishing of lentic habitats, whereas diversity of lotic sites showed only a slight increase, which was most prominent during the last year of the sampling period. The shift in the species composition was profound for lotic sites as well. Although the restoration intervention considerably increased species richness and markedly changed species composition, there was no detectable increase of rare or vulnerable Ephemeroptera and Plecoptera species." (Authors) The restoration resulted in a complete loss of all dragonfly species.] Address: Maradova, Monika, Anglo-Czech High School, Trebízského 1010, 37006 České Budejovice, Czech Republic. centrals). *Arxiu - Butlletí de la Institució Catalana d'Història Natural* 76: 105-121. (in Catalanian, with Spanish and English summaries) [Spain; "The basin of the Flamisell river, a tributary of the Noguera Pallaresa river, was surveyed and a preliminary list of the dragonfly species present and of the main types of habitats where they reproduce was obtained. In this study, a total of 37 species were recorded. In the alpine and subalpine glacial lakes area no dragonflies were detected except in some small shallow lakes and ponds, where holarctic species *Enallagma cyathigerum* and *Aeshna juncea* were found. In the lotic habitats, the species related with high fluvial ecological status *Calopteryx virgo meridionalis*, *Boyeria irene*, *Onychogomphus uncatulus* and *Cordulegaster boltonii* were found to be widely distributed. The marginal marshy habitats of the Montcortès carstic lake were identified as a biodiversity hotspot for dragonflies in Catalonia since they support a rich assembly of 25 species. Finally, a monitoring scheme of the dragonfly communities in their characteristic habitats is proposed in order to detect possible impacts of the growing resort and real state development in the Flamisell river basin." 13338. Morante, T.; Garcia-Arberas, L.; Anton, A.; Rallo, A. (2012): Macroinvertebrate biomass estimates in Cantabrian streams and relationship with brown trout (*Salmo trutta*) populations. *Limnetica* 31(1): 85-94. (in English) ["Macroinvertebrate biomass estimates in Cantabrian streams and relationship with brown trout (*Salmo trutta*) populations In this work, the average biomass of 80 relatively common families of benthic macroinvertebrates in the streams of the Biscay region (Basque Country, northern Iberian Peninsula) was estimated. The macroinvertebrates were collected using a kick net and preserved alive in cool aerated stream water. The fresh weight, dry weight, and ash-free dry weight (AFDW) were obtained for each family. The biomass values obtained were applied to more than a hundred macroinvertebrate samples collected from 1997 to 2006 in 17 stretches of 14 rivers inhabited by brown trout. The total and partial biomass of each sample was estimated. Significant differences in the density ($F = 2.91$; $df = 16, 100$; $P < 0.001$) and biomass ($F = 6.52$; $df = 16, 100$; $P < 0.001$) of the macroinvertebrates occurred among the stations, with up to a 11-fold and 17-fold range, respectively. The brown trout population size was positively correlated to both the macroinvertebrate abundance and biomass. By age classes, this relationship was significant for only the 1+ and 2+ trout.

The AFDW metric is recommended because it represents the real organic biomass value that joins the trophic food chain, avoiding an overestimation of the energy contribution of taxa with shells or cases. The Gammaridae had higher values of AFDW than expected, due to their high content of organic matter. A positive selection of gammarids by the trout was also observed in some cases." (Authors) The analysis includes Odonata without further details.] Address: Morante, T., Dept Zoology and Animal Cell Biology. Faculty of Science and Technology. University of the Basque Country. P.O. 13342. Richman, D.B.; O'Keefe, W. (2012): Life on a high isolated mountain: the arthropod fauna of Mt. Taylor, Cibola county, New Mexico. *Zoological Studies* 51(6): 793-803. (in English) ["The arthropod fauna of Mt. Taylor, New Mexico at 2874-3445 m (9424-11,300 ft) was examined by pitfall trapping, and to a lesser extent by pan trapping and hand collection between 1997 and 2008, with continuous pitfall trapping in 1997-2000. This fauna was characteristically Canadian in nature (as might be

expected as the area covers Canadian and Hudsonian life zones with a tiny area of Arctic-Alpine at the top of the peak's north face; see Price 1997), but also contained unique elements such as a then-undescribed species of trapdoor spider (Araneae: Cyrtacheniidae) from the pitfall traps (described as *Neoapachella rothi* Bond and Opell in 2002) and a still-undescribed jumping spider of the genus *Habronattus* (Araneae: Salticidae). At least 237 species in a minimum of 75 families were collected over the course of the study. As our methods were somewhat limited, we expect many more species to be found in the area covered. Pitfall traps were maintained near the summit until 2000. Dominant arthropods included *Carabus* (*Oreocarabus*) *taedatus agassii* LeConte (Coleoptera: Carabidae), *Anystis* sp. (Acari: Anystidae), and *Pardosa concinna* (Thorell) (Araneae: Lycosidae), among others. The Canadian and Rocky Mountain tiger beetle *Cicindela longilabris* Say (Coleoptera: Carabidae), the alpine dragonfly *Oplonaeschna armata* (Hagen) (Odonata: Aeshnidae), and the short-winged grasshoppers *Chorthippus curtipennis* (Harris) and *Melanoplus magdalenae* Hebard were examples of less-common hand-collected or pan-trapped high-elevation species." 13343. Rolls, R.J.; Boulton, A.J.; Gowns, I.O.; Maxwell, S.E.; Ryder, D.S.; Westhorpe, D.P. (2012): Effects of an experimental environmental flow release on the diet of fish in a regulated coastal Australian river. *Hydrobiologia* 686: 195-212. (in English) ["Environmental flow rules are developed to provide a flow regime necessary to maintain healthy river and floodplain ecosystems in rivers regulated for human uses. However, few studies have experimentally assessed potential ecological mechanisms causing declines in the health and productivity of freshwater fish assemblages in regulated rivers to inform the development of appropriate environmental flows. We tested whether an experimental flow release in a regulated tributary of the Hunter River, Australia, altered the diet of two widely distributed fish species (Australian smelt *Retropinna semoni* and Cox's gudgeon *Gobiomorphus coxii*) compared with data from unregulated reference and regulated control tributaries. Neither species had significant differences in the number of prey taxa ingested, gut fullness or composition of gut contents due to the environmental flow release (EFR). The diet of *R. semoni* did not differ significantly between regulated and unregulated tributaries in either catchment. However, the diet of *G. coxii* differed in only one of the two pairs of rivers consistently across all sample times. Assuming the EFR was sufficient to alter the composition of prey available for consumption by the fish species studied, our findings imply that functional indicators, such as the diet of generalist higher-order consumers, may be more suitable indicators of long-term flow regime change rather than short-term flow events." (Authors) The diet includes specimens

of *Nannophlebia*.] Address: Rolls, R.J., Australian Rivers Institute, Griffith University, Nathan, QLD, 4111, Australia. E-mail: r.rolls@griffith.edu.au

13344. Rybak, J.; Niedzielska, K. (2012): The biological water quality assessment of the Rudna River situated near the post-flotation tailing pond "Żelazny Most" on the basis of communities of benthic invertebrates. *Inżynieria Ekologiczna* 29: 119-129. (in Polish, with English summary) ["As a result of copper ore extraction lots of fine-grained mineral waste, constituting over 90% of extracted ore, appear. It contains traces of heavy metals, biosurfactants and foams applied in the process of extraction and copper enrichment. Waste rock with technological water is delivered and deposited in post-flotation tailing ponds. Such sites are harmful to the environment as dust containing toxic heavy metals is blown away causing water and soil contamination. The influence of such sediments on macroinvertebrates inhabiting the neighbouring river Rudna seems significant, since they are regarded as almost perfect bioindicators and constitute the majority of systems of water quality control. A four study sites of different distance from "Żelazny Most" tailing pond have been selected in order to assess a water quality. A set of different biotic indices based on zoobenthos was applied for the assessment. The water quality was evaluated with following indices: BMWP-PL, ASPT-PL, FBI, EPT, BBI, TBI and CBS which were compared with each other in order to check their usefulness. The water biodiversity was also assessed in the studied area. We calculated a dominance and frequency of families, as well as Hurlbert and Margalef indices. The obtained results suggest the significant influence of the tailing pond on river biocoenosis in the closest areas to "Żelazny Most".(Authors) The analysis includes 'Calopterygidae' and 'Gomphidae'.] Address: Rybak, Justyna, Zakład Biologii i Ekologii, Wydział Inżynierii i Ochrony Środowiska, Politechnika Wroclawska, ul. 13345. Samways, M.J.; Hamer, M.; Veldtman, R. (2012): Development and Future of Insect Conservation in South Africa. In New, T.R. (Ed.): *Insect Conservation: Past, Present and Prospects*, Part 3. Springer Netherlands: 245-278. (in English) ["When considering the history of insect conservation activities in South Africa, it is important to consider its biodiversity value in a global context. The country has been rated as the third most biologically diverse in the world after Indonesia and Brazil. It also has within its borders three or the world's 34 biodiversity hotspots (Mittermeier et al. 2004). In discussions of South Africa's biodiversity, it is mostly the country's flora that is recognized as being of enormous conservation value, followed by the variety of large mammals and rich bird fauna that form the basis of a large ecotourism industry. The contribution of the insect fauna to the country's biodiversity, in terms of both richness and functioning, is less well known among the public, decision makers and even some conservation scientists. Insect con-

ervation can be considered a relatively new and possibly also a neglected discipline in South Africa, but there has certainly been some progress through various activities, at both landscape and species levels. The future of insect conservation in South Africa faces both challenges and opportunities, most of which are shared with other parts of the world with high and irreplaceable biodiversity." (Authors) The paper includes references to Odonata.] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

13346. Silver, C.A.; Vamosi, S.M. (2012): Macroinvertebrate community composition of temporary Prairie wetlands: A preliminary test of the effect of rotational grazing. *Wetlands* 32: 185-197. (in English) ["Over half the temporary wetlands in the prairie pothole region of North America (PPR) have been drained for agricultural purposes and nearly all those remaining have agriculturally impacted margins. Cattle grazing is a common practice in the PPR. Rotational grazing utilizes several pastures, with cattle grazing one pasture while the others are rested. The success of this practice in increasing the suitability of rested wetlands for macroinvertebrates has not been evaluated for temporary wetlands. We repeatedly sampled macroinvertebrate communities in 13 rotationally grazed temporary wetlands. Seven wetlands were in an early grazed pasture (i.e., grazed when wetlands were wet), and six wetlands were in an adjacent late grazed pasture (i.e., grazed when wetlands were dry). The communities were examined from two perspectives, traditional taxonomy and an emerging functional traits perspective. Late grazed wetlands contained more abundant and diverse macroinvertebrate communities than early grazed wetlands. Chironomidae were significantly more abundant in late grazed wetlands. Scrapers were more common in the early grazed wetlands, whereas late grazed wetlands contained more gatherers. Our results suggest that rotational grazing may have a positive influence on macroinvertebrate diversity by allowing some wetlands to escape grazing pressure during the wet season. ... Chironominae dominated late grazed wetlands, whereas early grazed wetlands contained more other dipterans and predaceous Odonata larvae." (Authors)] Address: Silver, Carly, Dept Biol. Sci., Univ. Calgary, T2N 1N4, Calgary, Alberta, Canada. E-mail: carlysilver8@gmail.com

13348. Smolinský, R.; Gvoždík, L. (2012): Interactive influence of biotic and abiotic cues on the plasticity of preferred body temperatures in a predator-prey system. *Oecologia* 170(1): 47-55. (in English) ["The ability to modify phenotypes in response to heterogeneity of the thermal environment represents an important component of an ectotherm's non-genetic adaptive capacity. Despite considerable attention being dedicated to the study of thermally-induced developmental plasticity, whether or not interspecific interactions shape the plastic response in both a predator and its prey remains unknown. We tested several predictions about the joint influence of predator/prey scents and thermal conditions on the plasticity of preferred body temperatures (T_p) in both actors of this interaction, using a dragonfly nymphs-newt larvae system. Dragonfly nymphs (*Aeshna cyanea*) and newt eggs (*Ichthyosaura alpestris*) were subjected to fluctuating cold and warm thermal regimes (7–12 and 12–22°C, respectively) and the presence/absence of a predator or prey chemical cues. Preferred body temperatures were measured in an aquatic thermal gradient (5–33°C) over a 24-h period. Newt T_p increased with developmental temperature irrespective of the presence/absence of predator cues. In dragonflies, thermal reaction norms for T_p were affected by the interaction between temperature and prey cues. Specifically, the presence of newt scents in cold regime lowered dragonfly T_p . We concluded that predator-prey interactions influenced thermally-induced plasticity of T_p but not in a reciprocal fashion. The occurrence of frequency-dependent thermal plasticity may have broad implications for predator-prey population dynamics, the evolution of thermal biology traits, and the consequences of sustaining climate change within ecological communities." 13354. Tyrrell, M. (2012): The Impact of spring temperature on emergence patterns in five 'spring' species. *J. Br. Dragonfly Society* 28(2): 102-107. (in English) ["The first emergence dates for five 'spring' species were monitored at a single site over a seven season period. During this time, average spring temperature was also monitored and the two related to determine the impact of average air temperature on the first emergence of each species. It was noted that during warm springs, for example 2007

and 2011, the five species emerged significantly earlier than in an average spring, for example 2010. During a cold spring, for example 2012, first emergence coincided with the dates for average springs. This implies that, for these species, spring air temperature is only a critical factor determining emergence if it is high, in which case day length is not a trigger but sun intensity may be. Cooler temperatures in spring have little or no impact on first emergence compared to an average spring, in which case day length may then be the critical factor determining emergence." 13355. Van den Broeck, M. (2012): De Interactie tussen Predator en Prooi in een Opwarmend Klimaat: een Ongelijke Strijd? Proefschrift, Master in de Biologie Faculteit Wetenschappen, Departement Biologie, Laboratorium voor Aquatische Ecologie en Evolutiebiologie, K.U.Leuven: 43 pp. (in Dutch, with English summary) ["The effects of global change and consequently changes in temperature, have different impacts on ecosystems around the world, mainly in and between aquatic systems. These consequences are diverse, ranging from changes in life-history traits of populations, to species migrations, including effects in Odonata. This order of insects functions as intermediate predator in aquatic systems where they can reduce the number of zooplankton populations. Both can affect the primary producers (phytoplankton) and consumers in the trophic cascade, whereby influences of global change on these species and their interactions can cause large effects in such aquatic systems, with drastic effects on humans, nature and environment. Using a predator-prey model (the damselfly *Ischnura elegans* as predator and *Daphnia magna* as prey), possible scenarios resulting from climate change were simulated whereat animals from three latitudes, under two temperature conditions were confronted with their predator or prey. Depending on the relative effect of temperature and/or latitude on predator and prey, the ability to find, capture and digest a prey by a predator decreases, increases or remains stable. Also the efficiency of a prey can vary depending on these factors. The predation experiments were always performed with two damselflies and 60 *Daphnia*, 20 individuals of each latitude. The surviving *Daphnia* were screened with allozymes to perform a percentage comparison between the different conditions." (Author)] Address: not stated

13357. Xin, Y.; Bu, W.j.; Zhu, L. (2012): Research advances in eco-environment assessment using dragonfly as a bioindicator. *Chinese Journal of Ecology* 31(6): 1585-1590. (in Chinese, with English summary) ["Dragonfly, due to its wide distribution, indepth research and easy to sample, is an ideal bioindicator for eco-environment assessment. In recent decades, more and more related researches are using dragonfly to assess eco-environment. In this review, the related researches were generalized into five types, i. e., general environmental assessment, environment pollution degree assessment, environmental improvement assessment, climate change assessment, and large-scale environmental assessment, and a brief introduction for each type of the researches was given. The current status and deficiency of the researches in China were discussed, and the broad prospects of using dragonfly as a bioindicator for eco-environment assessment were analyzed through the comparison of the superiority of this bioindicator than the others. It was point out that to build up a thoroughly sourced database of dragonfly diversity in China and to develop specific assessment methods could be the most important things to make progress. Using dragonfly as a bioindicator to assess ecological environment would be low-cost, high-efficient, and environmentally friendly, not only important but also necessary to the needs of China today's economic development." 13359. Ábelová, M.; David, S. (2013): The morphometry of male adults of Southern Hawker (*Aeshna cyanea*) (Müller, 1764) Odonata: Aeshnidae) from the Slovak Republic. *MENDELNET 2013* (Proceedings of International PhD Students Conference Mendel University in Brno, Czech Republic, November 20th and 21st, 2013): 686-690. (in English) ["The study elaborates the morphometric analysis of 112 male imago specimens of *A. cyanea* from 8 localities of Slovakia. 12 morphometric signs for imago specimens of Southern Hawker are measured by calliper. The research has confirmed several distortions of normality of data, partly caused by measurement error, e. g. in mm wingspan ($WS = \text{average} \pm SE: 96.66 \pm 3.93$), body length ($BL = \text{average} \pm SE: 64.86 \pm 2.18$). This

morphometric structure is the most problematic to measure, because of curvature caused by placement in test-tubes with alcohol (97%). We researched there exist correlation between morphometric signs wingspan and the length of body. In addition it has been proved that the correlation of signs is not often linearly correlated. The results are also important, because morphometric signs are used in many determination keys of Odonates. In fact Odonata species are bioindicators of pollution and global warming; measured morphometric structures could be used such as means for monitoring of changing environmental variables in future. We have processed so far the largest data set of morphometric data for Slovakia." 13360. Akira, T. (2013): Records of aquatic insects Kahokugata, Ishikawa Prefecture in 2012. *Kahokugata Lake Scienc* 16: 1-6. (in Japanese, with English translation of title) [11 common Odonata species are documented.] Address: Akira, T., 923-0911 Ishikawa Komatsu Okawacho 3-71, Japan

13361. Álvarez, M.; Nova, N. (2013): Detección de potenciales poblaciones de *Sympetrum meridionale* (Selys, 1841) en Asturias (norte de la Península Ibérica) (Odonata: Libellulidae). *Fotografía y Biodiversidad*. *BVnews* 31: 100-105. (in Spanish, with English summary) [Records from two localities in Asturias, Spain are presented: (1) 22-IX-2013, in the dunes of Playa de Xagó (Gozón, Asturias, [Latitud: 43.599; Longitud: -5.922]); (2) 29-IX-2013, Cabo de Peñas ([Latitud: 43.653; Longitud: -5.852]) Address: Álvarez, Marián, Experto del Grupo de Odonata de Biodiversidad Virtual – Oviedo (Asturias, España), E-mail: madamcoolpix@gmail.com

13362. Amr, Z.S.; Al Azzam, L.S.; Katbeh-Bader, A.; Eid, E.K. (2013): Odonata of Wadi Al Mujib catchment with notes on the impact of Wadi Al Mujib dam, Jordan (Insecta: Odonata). *Jordan Journal of Biological Sciences* 6(4): 292-299. (in English) ["A total of 14 species pertaining to five families (Platycnemididae, Coenagrionidae, Gomphidae, Aeshnidae and Libellulidae) were identified along eight sites in the Wadi Al Mujib catchment. Collected species varied along the eight sampling sites, ranging from a single species from Al Mujib dam to a maximum of seven species in the waterfalls to the bridge site. In the present study, eight species are considered as new records to the Odonata of the Wadi Al Mujib catchment (*Ischnura elegans*, *I. evansi*, *I. fontaineae*, *I. senegalensis*, *Anax parthenope*, *Orthetrum sabina*, *Sympetrum fonscolombii* and *Zygonyx torridus*). Such changes over the past 35 years reflect the dynamics of dragonflies' spatial movement within their distribution range. Results shown in this study strongly indicates the negative impact of the Wadi Al Mujib dam on the dragonfly fauna, as a single species was recovered from the dam proper. This is mainly due

to the sharp cliffs and water level fluctuation and the limited breeding areas. Few flat areas with scarce vegetation were identified around the dam. Water level fluctuation does not allow steady vegetation growth around the edges of the dam, yet, the abrupt water depth is not suitable for development of the larval stages of dragonflies. Sharp edges are not suitable for breeding and perching of these insects." (Authors)] Address: Amr, Z.S., Dept Biology, Jordan University of Science and Technology, P. O. Box 3030, Irbid, Jordan. E-mail: amrz@just.edu.jo

13363. Anjos-Santos, D.; Pessacq, P. (2013): *Peristicta guarellae* sp. nov. from Brazil (Odonata: Protoneuridae). *International Journal of Odonatology* 16(4): 293-299. (in English, with Spanish summary) ["*Peristicta guarellae* sp. nov. (holotype: Brazil, Paraná State, Exc. 399/col. 3, stream in km 50 of Curitiba-Ponta Grossa route [BR 376], about 25°20'08" S, 49°51'15" W, 21-XI-1971, N. D. Santos leg., deposited in the Collection of "Museu Nacional, Universidade Federal do Rio de Janeiro", Rio de Janeiro, Brazil) is described and illustrated. An identification key for males of *Peristicta* (excluding *P. lizeria* Navás), comparisons and comments on other species of the genus are presented." (Authors)] Address: Anjos-Santos, Danielle, Lab. 13364. Anwer, S.F.; Ashraf, I.; Mehdi, H.; Ahmad, A.; Grafi, H. (2013): On the aerodynamic performance of dragonfly wing section in gliding mode. *Advances in Aerospace Science and Applications* 3(3): 227-234. (in English) ["A comprehensive numerical of fluid dynamic study of a pleated wing section based on the wing of *Aeshna cyanea* has been performed at ultra low Reynolds numbers (RN) corresponding to the gliding flight of these dragonflies. The simulations employ an unstructured triangular mesh based on finite volume discretization. A critical assessment of the computed results was performed. In this work, we investigate the aerodynamic characteristics and spatio-temporal dynamics of a cut section of *Aeshna cyanea*'s wing. Numerical simulations were performed at ultra low RN (100 to 1000) at different angle of attacks ranging from 0° to 15°. The results give a satisfactory measure of confidence in the fidelity of the simulation. The effect of the RN on the gliding ratio is that at Re 1000 and at angle of attack (here after, AOA) 15°. The largest gliding ratios are obtained. Flow invariably for all RN, minimum Drag coefficient is obtained at AOA 15°." (Authors)] Address: Grafi, H., Dept Mechanical Engg, Taibah Univ., P.O. Box. 344, Al Madina Al Munawara, Kingdom of Saudi Arabia

13365. Aristova, D.S.; Bashkuev, A.S.; Golubev, V.K.; Gorochov, A.V.; Karasev, E.V.; Kopylov, D.S.; Ponomarenko, A.G.; Rasnitsyn, A.P.; Rasnitsyn, D.A.; Sinitshenkova, N.D.; Sukatsheva, I.D.; Vassilenko, D.V. (2013): Fossil Insects of the Middle and Upper Permian of European Russia. *Paleontological Journal* 47(7): 641-832.

["Fossil insects (including Odonata) of European Russia from the Urzhumian to Vyatkian stages are reviewed, new taxa are described, and dynamics of insect taxonomic diversity around the Permian–Triassic boundary in light of the Paleozoic–Mesozoic boundary global extinction problem is analyzed. Traces of interactions between arthropods and plants are analyzed. Insectbearing deposits of the Late Paleozoic found in the northern and eastern areas of the East European Platform are unique on the global scale in their completeness and continuity, allowing us to trace especially comprehensively the biotic processes that occurred around the boundary described as the time of the greatest biotic catastrophe of the Phanerozoic. A total of 28 genera and 111 species are newly described. Within the range from the Urzhumian to the Permo–Triassic boundary, 15 representative successive assemblages, including 112 families, are recognized (seven in the area in question and eight in other regions of Asia, Australia, and Africa). New tools are developed for the analysis of the dynamics of diversity. These tools show an approximately equilibrium (slightly positive) dynamics in the Urzhumian and Severodvinian and a drop in diversity during the Vyatkian Age. It is shown that Permian insect assemblages acquired a substantially postPaleozoic pattern much earlier than the end of the Paleozoic. The character of changes that took place in the Induan and Olenekian remains uncertain, but a largescale extinction event did not occur here: most families that have not been recorded at the beginning of the Triassic are recorded again in the Middle and Upper Triassic. Nevertheless, a biotic crisis probably actually took place, but was reduced to reorganization of the biota's structure, which provided enormous growth of biodiversity over subsequent hundreds of millions of years, rather than resulted in catastrophic extinction. This study is intended for entomologists, stratigraphers, and all readers interested in the biotic events that took place around the Permian–Triassic boundary." (in Spanish, with English summary) [*T. kirbyi* was recorded for the first time in the Cádiz province (Spain) at 7-VI-2009: river of Hozgarganta near Jimena de la frontera (UTM 30S 278931 4035716, 74 m a.s.l.).] Address: Arturo Bernal, C/Juan Ramón Jiménez 28. 11160 - Barbate (Cádiz)

13372. Bárta, D.; Dolný, A. (2013): Dragonflies of Sungai Wain. *Ecological Field Guide to the Odonata of Lowland*

Mixed Dipterocarp Forest of Southeastern Kalimantan. Taita Publishers. 168pp. (In English, Czech and Indonesian) ["Dragonflies of Sungai Wain is clearly a labour of love by the authors, and a successful labour: it is a beautiful book that represents a valuable contribution to our knowledge of the dragonflies of Borneo. Not much is known about the dragonfly fauna of south-eastern Kalimantan and this book will help both visitors to Borneo and local researchers and enthusiasts to identify many of the species that can be found in the lowlands. The reader is given not only information and images of the species themselves, but an insight into how dragonflies are entwined with the habitat in which they are found, and how changes to that habitat affect them, and how they in turn reflect those changes. It is to be hoped that the book will encourage people to visit Sungai Wain, and other locations in Kalimantan, to look for dragonflies, and, most importantly, that it will stimulate local interest in these insects and their role as bio-indicators. 223 colour scans of 82 species, 24 habitat photos, 46 photos of living species." (Publisher)] Address: <http://www.taitapublishers.cz/dragonflies-of-sungai-wain/?id=25>

13373. Böhm, K.; Raab, B.; Grimmer, F.; Müller, K.; Albrecht, H. (2013): Habitatansprüche der Imagines von *Ophiogomphus cecilia* an mittelfränkischen Gewässern (Odonata: Gomphidae). *Libellula* 32(3/4): 97-114. (in German, with English summary) ["Habitat preferences of

perching males of *O. cecilia* in Middle Franconia (Odonata: Gomphidae) – *O. cecilia* is considered to be threatened throughout Europe. Therefore, the species is listed in Annex II and IV of the Habitats Directive of the EU. The objective of this study was to identify the environmental factors which primarily determine the suitability of different river sections as habitats for perching males of *O. cecilia*. The study was carried out at 68 sections of the three rivers Aurach, Bibert and Zenn on a total length of 12 km, which all cross the sandstone basin of Middle Franconia from west to east. Sixty variables, which also include attributes used to monitor *O. cecilia* for Habitats Directive reporting, were sampled and correlated to the abundance of perching imagines. The numbers of males showed significant correlations to shading, structure and dynamics of the water surface and to the land use in the surrounding area. Recommendations for the habitat management of *O. cecilia* are given." (2013): Description of a new species of the genus *Sarasaeschna* Karube & Yeh, with a key to the species of Taiwan (Odonata: Anisoptera: Aeshnidae). *Zootaxa* 3764(1): 92-100. (in English) ["*Sarasaeschna Chiangchilii* sp. nov. collected from Daxi, Taoyuan County in northern Taiwan is described and diagnosed. Judging from male penile structure, this species is considered to belong to the *pryeri*-group of its genus. It is easily distinguished from all known congeners in having peculiar sickle-shaped cerci in male. The habitats of *S. Chiangchilii* are mainly shaded brooks in lowland areas, which are exceptional for its Taiwanese relatives.

Distributional maps and a key are also provided for the four species of Taiwanese *Sarasaeschna*." (Authors)] Address: Yeh, W.-C., Conservation and Research Center, Taipei Zoo, Taipei, Taiwan. E-mail: dwx24@zoo.gov.tw

13385. Córdoba-Aguilar, A.; Munguía-Steyer, R. (2013): The sicker sex: Understanding male biases in parasitic infection, resource allocation and fitness. *PLoS ONE* 8(10): e76246. doi:10.1371/journal.pone.0076246: 15 pp. (in English) ["The "sicker sex" idea summarizes our knowledge of sex biases in parasite burden and immune ability whereby males fare worse than females. The theoretical basis of this is that because males invest more on mating effort than females, the former pay the costs by having a weaker immune system and thus being more susceptible to parasites. Females, conversely, have a greater parental investment. Here we tested the following: a) whether both sexes differ in their ability to defend against parasites using a natural host-parasite system; b) the differences in resource allocation conflict between mating effort and parental investment traits between sexes; and, c) effect of parasitism on survival for both sexes. We used a number of insect damselfly species as study subjects. For (a), we quantified gregarine and mite parasites, and experimentally manipulated gregarine levels in both sexes during adult ontogeny. For (b), first, we manipulated food during adult ontogeny and recorded thoracic fat gain (a proxy of mating effort) and abdominal weight (a proxy of parental investment) in both sexes. Secondly for (b), we manipulated food and gregarine levels in both sexes when adults were about to become sexually mature, and recorded gregarine number. For (c), we infected male and female adults of different ages and measured their survival. Males consistently showed more parasites than females apparently due to an increased resource allocation to fat production in males. Conversely, females invested more on abdominal weight. These differences were independent of how much food/infecting parasites were provided. The cost of this was that males had more parasites and reduced survival than females. Our results provide a resource allocation mechanism for understanding sexual differences in parasite defense as well as survival consequences for each sex." (Authors)] Address: Córdoba-Aguilar, A., Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo, Apdo. P. 69-1, Plaza Juárez, Pachuca, Hidalgo 42001, Mexico E-mail: acordoba@uaeh.reduaeh.mx

13386. Costa, Z.J.; Vonesh, J.R. (2013): Prey subsidy or predator cue? Direct and indirect effects of caged predators on aquatic consumers and resources. *Oecologia* 173(4): 1481-1490. (in English) ["The non-consumptive effects of predators on prey can affect prey phenotypes, potentially having important consequences for communities due to trait-mediated indirect interactions. Predicting non-consumptive effects and their impacts on communities can be difficult because predators can affect resources directly through nutrient cycling and indirectly by altering prey resource use, which can lead to complex in-

teractions among resources and consumers. In this study we examined the effects of caged dragonfly predators on aquatic resources in the presence and absence of two focal herbivores, the tadpoles of Neotropical tree frogs *Agalychnis callidryas* and *Dendropsophus ebraccatus*. We crossed the presence/absence of caged dragonflies with four tadpole treatments: no tadpoles, each tadpole species alone, and both species together to examine interactions among tadpole composition, predator presence, and time on tadpole growth, resources, and zooplankton abundances. Predator effects on growth changed through ontogeny and was species-dependent. Predators initially reduced then dramatically increased *A. callidryas* growth, but had no effect on *D. ebraccatus*. Predators also increased the abundances of both periphyton and phytoplankton. However, there was no evidence of a trait-mediated trophic cascade (i.e., tadpole by predator interaction). Instead, nutrients from prey carcass subsidies likely played an increasingly important role in facilitating resources, and shaping tadpole growth, competitive interactions, and zooplankton abundances through time. In nutrient-poor aquatic systems the release of nutrients via the consumption of terrestrially derived prey items by aquatic predators may have important impacts on food webs by facilitating resources independent of the role of trait-mediated trophic cascades." (2013): Range extension and larval habitat of *Lyriothemis tricolor* Ris, 1919 (Odonata: Anisoptera: Libellulidae) from southern Western Ghats, India. *Journal of Threatened Taxa* 5(17): 5237-5246. (in English) ["Worldwide many species of odonates are known to use phytotelmata as a breeding habitat. Hitherto, no species are known to breed in phytotelmata in India. However, field studies conducted in the southern Western Ghats revealed that *L. tricolor* uses tree holes as a larval habitat. Here we report the range extension of *L. tricolor* to southern Western Ghats and describe morphology of the larva, exuvia, and adult female. Based on the present study, we describe the larval habitat of *L. tricolor* in the southern Western Ghats. Our findings reveal that *L. tricolor* breeds in the tree holes of evergreen and semi-evergreen forests in the southern Western Ghats." (Authors)] Address: Das, K.S, Centre for Conserv. (in English) ["A survey of odonatofauna was carried out in Mata do Baú, a predominantly forested area in Barroso, Minas Gerais, regarded as a priority area for conservation and scientific investigation, as published by Biodiversitas, a Brazilian nongovernmental institution. Sample collection was conducted over twenty-six days from November 2009 to February 2011. Fifty-seven species of Odonata were collected and grouped into 30 genera and nine families. The dominant families were Libellulidae (46.5%), Coenagrionidae (20.6%), and Megapodagrionidae (10.3%). A specimen of *Heteragrion obsoletum* (Selys, 1886) was collected, which to-date is known by a single specimen collected in 1880 and red-listed as endangered. Special attention was given to the presence of five species of the genus *Heteragrion*, strictly limited to lotic forest streams, with two new species'. This genus is especially sensitive to environmental deterioration, indicating that the forest stream's environmental conditions are beneficial to the area and create a baseline for future monitoring of similar environments." 13392. Dijkstra, K.-D.B.; Kalkman, V.J.; Dow, R.A.; Stokvis, F.R.; van Tol, J. (2013): Redefining the damselfly families: a comprehensive molecular phylogeny of Zygoptera (Odonata). *Systematic Entomology* 39: 68-96. (in English)

["An extensive molecular phylogenetic reconstruction of the suborder Zygoptera of the Odonata is presented, based on mitochondrial (16S, COI) and nuclear (28S) data of 59% of the 310 genera recognized and all (suspected) families except the monotypic Hemiphlebiidae. A partial reclassification is proposed, incorporating morphological characters. Many traditional families are recovered as monophyletic, but reorganization of the superfamily Coenagrionoidea into three families is proposed: Isostictidae, Platycnemididae and Coenagrionidae. Archboldargia Lieftinck, Hylaeargia Lieftinck, Palaiargia Förster, Papuargia Lieftinck and Onychargia Selys are transferred from Coenagrionidae to Platycnemididae, and Leptocnemis Selys, Oreocnemis Pinhey and Thaumagrion Lieftinck from Platycnemididae to Coenagrionidae. Each geographically well-defined clade of Platycnemididae is recognized as a subfamily, and thus Disparoneurinae (i.e. Old World 'Protoneuridae') is incorporated, Calicnemiinae is restricted, and Allocnemidinae (type genus: Allocnemis Selys) subfam. n., Idiocnemidinae (type genus: Idiocnemis Selys) subfam. n. and Onychargiinae (type genus: Onychargia Selys) subfam. n. and Coperini trib. n. (type genus: Copera Kirby) are described. Half of Coenagrionidae belongs to a well-supported clade incorporating Coenagrion Kirby and the potential subfamilies Agriocnemidinae, Ischnurinae and Pseudagrioninae. The remainder is less well defined, but includes the Pseudostigmatidae and New World Protoneuridae that, with Argiinae and Teinobasinae, may prove valid subfamilies with further evidence. Ninety-two per cent of the genera formerly included in the polyphyletic Amphipterygidae and Megapodagrionidae were studied. Pentaplebiidae, Rimanellidae and Devadattidae fam. n. (type genus: Devadatta Kirby) are separated from Amphipterygidae, and Argiolestidae, Heteragrionidae, Hypolestidae, Philogeniidae, Philosinidae and Thaumtoneuridae from Megapodagrionidae. Eight further groups formerly placed in the latter are identified, but are retained as incertae sedis; the validity of Lestoideidae, Philogangidae and Pseudolestidae is confirmed. For some families (e.g. Calopterygidae, Chlorocyphidae) a further subdivision is possible; Protostictinae subfam. n. (type genus: Protosticta Selys) is introduced in Platystictidae. Numerous new combinations are proposed in the Supporting Information. Many long-established families lack strong morphological apomorphies. In particular, venation is incongruent with molecular results, stressing the need to review fossil Odonata taxonomy: once defined by the reduction of the anal vein, Protoneuridae dissolves completely into six clades from five families." (Authors)] Address: Dijkstra, K.D., Netherlands Centre for Biodiversity Naturalis, P.O. Box 9517, NL-2300 RA, Leiden, The Netherlands. E-mail: dijkstra@nrm.nl

13393. Division of Wildlife (2013): Dragonflies and damselflies of Ohio - Field guide. Division of Wildlife Publication 5320 (R812): 76 pp. (in English) ["Ohio is a great state for dragonfly and damselfly diversity. To date, 164 species have been recorded, and like vagrant birds, out-of-range dragonflies can appear far from their normal

haunts. The newest addition to Ohio's Odonata (the order of insects that includes dragonflies and damselflies) were several striped saddlebags, *Tramea calverti*, which were found in late summer of 2006 at Magee Marsh Wildlife Area on western Lake Erie – far from their normal range in the extreme southern U.S. With 7,000 miles of streams and scores of lakes, ponds, and wetlands, Ohio has plenty of good places to look for dragonflies and damselflies. Some of the best spots are listed beginning on page 9. Until recently, learning about dragonflies and damselflies has been difficult for the casual naturalist. The only books available were out-of-date technical manuals. This booklet is one of several new publications that provide an introduction to dragonflies and damselflies. There has been an enormous increase in interest in the Odonata; not surprising, given their beautiful appearance and incredible flying abilities. The Odonata are also excellent indicators of water quality and thus serve as barometers of the health of our streams, lakes, and wetlands." 13394. Dolný, A. (2013): Population size estimation of *Aeshna caerulea* (Odonata: Aeshnidae) in the Czech part of Úpské rašeliniště bog (Giant Mountains). *Casopis Slezského Zemského Muzea - serie A - vedy prirodni* 62(1): 83-89. (in English) ["*A. caerulea* is present as a post-glacial relict in central European mountains. This species is listed as critically endangered in the Czech Republic (very restricted distribution occurring in two isolated populations) and the European population trend of this species is decreasing. The main objective of the study was to estimate the population size of *A. caerulea* in the Úpa bog National Nature Reserve (Czech Republic) using capture-mark-recapture data. Population estimates of adults using the Schnabel method was 425 (the 95% confidence limits: 248.1 / 992.3), and using the Schumacher-Eschmeyer method was 416 (the 95% confidence limits: 326.8 / 570.4). Imago activity became apparent at the beginning of July. This study has suggested that the possible future threats for the *A. caerulea* in the Czech Republic are drying up, air nitrogen depositions, eutrophication, pollution of water by external sources, and terrestriation, mainly as a result of global warming." (Author)] Address: Dolný, A., Dept of Biology and Ecology/Institute of Environmental Technologies, Faculty of Science, University of Ostrava, Chittussiho 10, CZ-710 00 Ostrava, Czech Republic. 13395. Edwards, P.G.; Gaines, K.F.; Bryan, A.L.; Novak, J.M.; Blas, S.A. (2013): Trophic dynamics of U, Ni, Hg and other contaminants of potential concern on the Department of Energy's Savannah River Site. *Environmental Monitoring and Assessment* 186: 481-500. (in English) ["The Department of Energy's Savannah River Site is a former nuclear weapon material production and current research facility located in South Carolina, USA. Wastewater discharges from a fuel and nuclear reactor target manufacturing facility released depleted and natural U,

as well as other metals into the Tims Branch-Steed Pond water system. We investigated the current dynamics of this system for the purposes of environmental monitoring and assessment by examining metal concentrations, bioavailability, and trophic transfer of contaminants in seven ponds. Biofilm, detritus, and Anuran and Anisopteran larvae were collected and analyzed for stable isotopes ($\delta^{15}\text{N}$, $\delta^{13}\text{C}$) and contaminants of potential concern (COPC) with a focus on Ni, U, and Hg, to examine metal mobility. Highest levels of Ni and U were found in biofilms U (147 and 332 mg kg⁻¹ DW, respectively), while highest Hg levels were found in tadpoles (1.1 mg kg⁻¹ DW). We found intraspecific biomagnification of COPCs as expressed through stable isotope analysis. Biofilms were the best indicators for contamination and Anuran larvae with the digestive tract removed were the best indicators of the specific bioavailability of the focal metals. Monitoring data showed that baseline $\delta^{15}\text{N}$ values differed between ponds, but within a pond, values were stable throughout tadpole Gosner stage, strengthening the case to use this species for monitoring purposes. It is likely that there still is risk to ecosystem integrity as COPC metals are being assimilated into lower trophic organisms and even low levels of this mixture has shown to produce deleterious effects to some wildlife species." (Authors)] Address: Gaines, Karen, Department of Biological Sciences, Eastern Illinois University, 600 Lincoln Ave, Charleston, IL, 61920, USA. E-mail: kfgaines@eiu.edu

13396. Ellenrieder, N. von (2013): A revision of *Metaleptobasis* Calvert (Odonata: Coenagrionidae) with seven synonymies and the description of eighteen new species from South America. *Zootaxa* 3738(1): 1-155. (in English, with Spanish summary) ["Examination of over 1,400 specimens of the neotropical genus *Metaleptobasis* Calvert, 1907, including primary types or paratypes of 18 of the 20 currently available species names and large series of specimens including pairs in tandem and copula, allowed me to unequivocally associate older names with species, distinguish between specific and intraspecific variability, associate both sexes for each species, and recognize the existence of female polymorphism. As a result, seven names are found to be junior synonyms: *Metaleptobasis mauritia* Williamson, 1915 junior synonym of *M. bicornis* (Selys, 1877), *M. manicaria* Williamson, 1915 and *M. fernandezi* Rácenis, 1955 junior synonyms of *M. diceras* (Selys, 1877), *M. westfalli* Cumming, 1954 junior synonym of *M. foreli* Ris, 1915, and *M. tetragena* Calvert, 1947, *M. weibezahni* Rácenis, 1955, and *M. incisula* De Marmels, 1989 junior synonyms of *M. brysonima* Williamson, 1915. Lectotypes are designated for *M. amazonica* and *Leptobasis diceras*. Eighteen new species of *Metaleptobasis* are described: *M. brevicauda* (Holotype male, Peru, Huánuco Dep., Shapajilla, jungle, 11 v 1939, F. Woytkowski leg., in UMMZ); *M. falcifera* (Holotype male, Peru, Madre De Dios Dep., Pakitza, Reserved Zone, Manu National Park, T2 to R2 to T1 to base camp, 11°55'48"S, 71°15'18"W, 250 m, 17 ix 1989, J.A. Louton leg., in USNM); *M. furcifera* (Holotype male, Peru, Loreto Dep.,

Iquitos, iii 1936, G.G. Klug leg., in BMNH); *M. gabrielae* (Holotype male, Peru, Loreto Dep., Tamshiyacu-Tahuayo Reserve, forest interior (4°23'40"S, 73°14'56"W), 27 vii 2009, T. Faasen leg., in RMNH); *M. guillermoi* (Holotype male, Peru, Loreto Dep., Yarinacocha, temporary forest stream (8°17'S, 74°37'W, 145 m), 2 vi 1972, D.L. Pearson leg., in FSCA); *M. inermis* (Holotype male, Brazil, Pará State, Jacareacanga, vii 1969, F.R. Barbosa leg., in UMMZ); *M. leniloba* (Holotype male, Peru, Loreto Dep., Pacaya-Samiria National Reserve, Santa Luisa trail (5°15'S, 74°40'W), 10 vi 2008, C. Beatty, A. Cordero & J. Hoffmann leg., in FSCA); *M. longicauda* (Holotype male, Brazil, Mato Grosso State, C. Teles Pires, Alto Tapajos, 1-31 viii 1956, Sick leg., in MNRJ); *M. orthogonia* (Holotype male, Peru, Loreto Dep., San Juan, Río Amazonas, near Iquitos, viii 1939, J. Schunke leg., in FSCA); *M. paludicola* (Holotype male, Peru, Loreto Dep., Tamshiyacu-Tahuayo Reserve, swamp, 4°23'49"S, 73°14'57"W, 27 ii 2009, T. Faasen leg., in RMNH); *M. panguanae* (Holotype male, Peru, Huánuco Dep., Biological Station Panguana, E side Río Yuyapichis, 9°37'S, 74°57'W, 6-17 iv 2003, H.J. & E.-G. Burmeister leg., in ZSM); *M. peltata* (Holotype male, Peru Loreto Dep., Tamshiyacu-Tahuayo Reserve, 4°21'22"S, 73°11'0"W, 19 ii 2010, T. Faasen leg., in RMNH); *M. prostrata* (Holotype male, Peru, Junín Dep., Satipo, v 1945, P. Paprzycki leg., in UMMZ); *M. silvicola* (Holotype male, Peru, Madre de Dios Dep., Explorer's Inn on Río Tambopata, 30 km SW Puerto Maldonado, main trail, 1 viii 1979, M. Perkins & P. Donahue leg., in FSCA); *M. spatulata* (Holotype male, Peru, Huánuco Dep., 10 km N of Cucharas, confluence of Huallaga and Pacay rivers, viii 1954, F. Woytkowski leg., in UMMZ); *M. tridentigera* (Holotype male, Brazil, Rondônia State, Porto Velho, Area Abunan, T11 Aleatorio, 8°46'S, 63°54'W, 86 m, 16 v 2010, Nogueira & Mendes leg., in MZUSP); *M. truncata* (Holotype male, Brazil, Pará State, Jacareacanga, xi 1969, F.R. Barbosa leg., in UMMZ); and *M. turbinata* (Holotype male, Peru, Loreto Dep., Tamshiyacu-Tahuayo Reserve, forest swamp (4°24'18"S, 73°14'38"W), 25 ii 2010, T. Fassen leg., in RMNH). Illustrations, keys, diagnoses, and distribution maps for all 31 currently known species are provided. Phylogenetic relationships within the genus *Metaleptobasis* are analyzed based on 33 adult morphological characters, including the 31 currently described species of *Metaleptobasis* and eleven outgroup taxa of other Coenagrionidae of the subfamily Teinobasinae. The cladistic analysis recovered *Metaleptobasis* as monophyletic, and as sister group of *Aceratobasis* Kennedy, a teinobasine genus some of the species of which possess an articulated spur on base of male cercus. Hypothesized relationships among its species are discussed." 13400. Farkas, A.; Jakab, T.; Müller, O.; Móra, A.; Lajter, I.; Dévai, G. (2013): Sex ratio in Gomphidae (Odonata) at emergence: is there a relationship with water temperature? *International Journal of Odonatology* 16(4): 279-287. (in English) ["Although the sex ratio of Odonata at emergence has received much attention, we are still far from understanding the exact causes of its variability and imbalance. In this paper we studied the sex ratios at emergence in natural populations of two Gomphus species based on samples of exuviae taken from two European lowland rivers. We hypothesized a possible relationship between the water temperature during larval development and the sex ratio at emergence. Sex ratio records exhibited no consistent bias towards one sex but varied between habitats and years in both species. We found correlations between sex ratio and water temperature in the year preceding emergence. Furthermore, the

correlation between sex ratios and water temperature was in opposite directions in the two congeneric species, which may be attributed to differences in their voltinisms. We conclude that the effect of water temperature can be mediated through cohort-splitting; temperature-dependent development of minor cohorts, including unequal proportions of males and females due to the faster development of male larvae, affects the sex ratio at emergence. The supposed effect does not cause a long-term consistent bias, but may explain the year-to-year variations."] (Authors)] Address: Farkas, Anna, Dept Hydrobiology, Centre of Arts, Humanities & Sciences, Fac. (2013): Diversidade de larvas de Odonata (Insecta) da Bacia do Rio Ibicuí, Rio Grande do Sul, Brasil. *Ciência e Natura* 35(2): 84-94. (in Portuguese, with English summary) ["An inventory of larval odonates in lotic systems from two courses (slope and lowland) in the Ibicuí River basin, Rio Grande do Sul, Brazil, was carried out in 2009 and 2010. In total, 964 specimens were sampled and classified in 34 genera and seven families. Libellulidae was the richest family with 14 genera and Gomphidae was the most abundant. Three new genera (*Agriogomphus*, *Cacoides* and *Mnesarete*) are new records for Rio Grande do Sul State. The dominant and more

frequent genera were *Progomphus*, *Hetaerina* and *Argia*. There was no significant difference in genus richness between the two courses, but a difference in frequency of occurrence of some genera was recorded. This difference is due to the distinguishing characteristics of the substrate between sections, which promoted a predominance of the genera of the gomphid family, especially in the sandy stretch from the lowland course." (Authors)] Address: Figueiredo, N., Universidade Federal de Santa Maria, UFSM, Santa Maria, RS, Brazil

13404. Fitzgerald, T. (2013): Nonlinear fluid-structure interactions in flapping wing systems. PhD thesis, Faculty of the Graduate School of the University of Maryland, College Park: X + 178 pp. (in English) ["This work relates to fluid-structure interactions in the context of flapping wing systems. System models of flapping flight are explored by using a coupling scheme to provide communication between a fluid model and a structural model describing a flexible wing. The constructed computational models serve as a tool for investigating complex fluid-structure interactions and characterizing them. Primary goals of this work are construction of models to understand nonlinear phenomena associated with the flexible flapping wing systems, and explore means and methods to enhance their performance characteristics. Several system analysis tools are employed to characterize the coupled fluid-structure system dynamics, including proper orthogonal decomposition, dimension calculations, time histories, and frequency spectra. Results obtained from two-dimensional simulations conducted for a combination of a two-link structural system and a fluid system are presented and discussed. Comparisons are made between the use of direct numerical simulation and the unsteady vortex lattice method as the fluid model in this coupled dynamical system. To enable three-dimensional studies, a novel solid model is formulated from continuum mechanics for geometrically exact finite elements. A new partitioned fluid-structure interaction algorithm based on the Generalized- method is formulated and implemented in a large scale fluids solver inside the FLASH framework. Consistent boundary conditions are also formulated by using Lagrangian particles. Several examples demonstrating the effectiveness of the methods and implementation are shown, in particular, for flapping flight at low Reynolds numbers. Unique experiments have also been undertaken to determine the first few natural frequencies and mode shapes associated with hawkmoth wings. The computational framework developed in this dissertation and the research findings can be used as a basis to understand the role of flexibility in flapping wing systems, further explore the complex dynamics of flapping wing systems, and also develop design schemes that might make use of nonlinear phenomena for performance enhancement."(Author)] Address: not stated

13405. Fleck, G.; Legrand, J. (2013): Notes on the genus *Libellulosoma* Martin, 1906, and related genera (Odonata: Anisoptera: Corduliidae). *Zootaxa* 3745(5): 579-586. (in English) ["The holotype of *Libellulosoma minuta*, until

now regarded as the unique specimen of this monotypic genus and considered lost for half a century, was found again in the dragonfly collection of the Muséum National d'Histoire Naturelle in Paris. A second specimen, also from Madagascar (probably East Madagascar) was found in the collection René Martin together with the holotype. A redescription, including the structure of the secondary copulatory apparatus, is provided. The genus *Libellulosoma* is closely related to the genera *Pentathemis* and *Aeschnosoma*, and its membership in the clade *Aeschnosomata* is well supported. Evidence from biogeography, the fossil record, and phylogeny indicates that this group, possible sister group of remaining *Corduliidae* s.s., was probably already present in the Early Cretaceous." 13407. Fulan, J.A.; Henry, R. (2013): A comparative study of Odonata (Insecta) in aquatic ecosystems with distinct characteristics. *Ambiência Guarapuava* (PR) 9(3): 589-604. (in English with Portuguese summary) ["The objective of this study was to compare the richness and density of Odonata larvae in four distinct environments: lotic with large pollutant loads, lotic with small pollutant loads, lentic disconnected from a river and lentic connected to a river, as well as to record the physical and chemical parameters of the water in the four environments. We identified (with one exception at the genus level) a total of 1,302 Odonata larvae in the four habitats. The environmental variables measured were: dissolved oxygen, pH, conductivity, suspended matter, air and water temperature, precipitation, depth, and the biomass of the macrophytes. The lentic habitats exhibited a greater Odonata larvae density in relation to the lotic habitats, except during April and December of 2006. The Guareí River, however, presented an elevated conductivity, possibly because of a greater quantity of pollutants it received during the period between June and September of 2006, and it

showed a higher density of Odonata larvae in comparison to the Paranapanema River. The temperature and the dissolved oxygen on the water surface were, respectively, greater and smaller in the lakes in comparison to the rivers. In spite of the Odonata density being higher in the lentic ecosystems in comparison to the lotic, the richness was not altered during the period studied. Nevertheless, the genera composition was distinct, showing that some taxa show a certain preference for certain types of ecosystems like Calopterygidae and Neogomphus, which were shown exclusively in the Paranapanema River." 13410. Gołąb, M.J.; Śniegula, S.; Drobnik, S.M.; Zajac, T. Serrano-Meneses, M.A. (2013): Where do floaters settle? An experimental approach in odonates. Animal Behaviour 86: 1069-1075. (in English) ["Highlights: •We investigated the effect of habitat quality on the settlement of floaters. •Habitat disturbances affect mostly the nonterritorial part of a population. •Vacated high-quality territories are always taken over by new residents. •Nearly half of vacated low-quality territories are not taken over. •Floaters settle in the vicinity of high-quality sites. According to classic ecological models, nonterritorial males should settle in low-quality habitats as a result of losing competition over reproductive sites ('defeated male' hypothesis). Alternatively, according to evolutionary game theory models, nonterritorial males should settle in the vicinity of high-quality sites and 'choose' to delay breeding until these habitats are vacant for them ('male player' hypothesis). However, nonterritorial male spatial distribu-

tion has not been experimentally tested. If the defeated male hypothesis is true (1) deterioration of high-quality sites should increase the number of nonterritorial males in a population and (2) vacated low-quality territories should be taken over by new territorial males. If the male player hypothesis is true, a similar manipulation should (1) decrease the number of nonterritorial males and (2) vacated low-quality territories should not be taken over. We performed two types of field experiment to test these hypotheses: male removal and patch quality manipulation. Our study species was the territorial damselfly Calopteryx splendens; males of this species exhibit both territorial and nonterritorial behaviour. Our results suggest that deterioration of high-quality habitats significantly reduced the number of nonterritorial males. The proportion of take-overs of the high-quality territories was significantly higher than that of low-quality territories. Our study supports the assumptions of the male player hypothesis and indicates that nonterritorial damselflies are more sensitive to habitat quality changes than territorial ones. Because nonterritorial individuals exist in most populations of territorial taxa, a better understanding of their settlement rules may be relevant for population dynamics and modelling." 13411. Gomez-Anaya, J.A.; Novelo-Gutierrez, R.; Ramirez, A. (2013): Temporal variation in Odonata larval assemblage diversity in a lowland stream in western Mexico. Odonatologica 42(4): 309-323. (in English) ["There is limited information on the structure and seasonality of Mexican Odon., in particular for lowland regions. Here, the structure and seasonal changes in the diversity of larval Odon. at El Ticuiz stream (10m asl) are described by conducting seven surveys over the yr. The study reach was impacted by dredging that resulted in the occurrence of lotic and lentic-like environments that promoted the abundant growth of aquatic macrophytes. Overall, Odonata diversity was high and a total of 13 species of Zygoptera and 23 of Anisoptera were recorded. The dominant species were Argia pulla and Telebasis salva, both dominating assemblages during the entire period of study. Two peaks in species richness, spring and autumn, were found suggesting that most spp. have at least 2 generations per year. Potential causes for the high diversity found include the low elevation, low flow, the effects of dredging in habitat availability, and the presence of water hyacinths and Potamogeton sp. Changes in species richness and composition appear to be mostly related to seasonality." 13412. Gonzalez-Tokman, D.M.; Gonzalez-Santoyo, I.; Munguía-Steyer, R.; Cordoba-Aguilar, A. (2013): Effect of juvenile hormone on senescence in males with terminal investment. J. Evol. Biol. 26: 2458-2466. (in English) ["Senescence, a decline in survival and reproductive prospects

with age, iscontrolled by hormones. In insects, juvenile hormone (JH) is involved in senescence with captive individuals, but its effect under natural conditions is unknown. We have addressed this gap by increasing JH levels in young and old wild males of the damselfly *Hetaerina americana*. We assessed survival in males that were treated with a JH analogue (methoprene), which is known to promote sexual activity, and an immune challenge, which is known to promote terminal investment in reproduction in the studied species. We replicated the same procedure in captivity (to control for environmental variation), where males were deprived of any activity or food. We expected old males to show the lowest survival after being treated with JH and immune-challenged, because the effect of terminal investment on senescence would be exacerbated by JH. However, this should be the case for wild animals, but not for captive animals, as the effects of JH and immune challenge should lead to an increase in high energetic-demanding activities only occurring in the wild. Old animals died sooner compared with young animals in both the wild and captivity, confirming that males are subject to senescence. In wild but not captive animals, JH decreased survival in young males and increased it in old males, confirming that JH is sensitive to the environment when shaping animal senescence. Immune challenge had no effect on survival, suggesting no effect of terminal investment on senescence. Additionally, contrary to the expected effects of terminal investment, with an immune challenge, recapture rates increased in young males and decreased in old males. Our results show that male senescence in the wild is mediated by JH and that terminal investment does not cause senescence. One explanation is that animals undergoing senescence and terminal investment modify their feeding behaviour to compensate for their physiological state." 13416. Gustafsson, S.; Österling, M.; Skurdal, J.; Schneider, L.D.; Calles, O. (2013): Macroinvertebrate colonization of a nature-like fishway: The effects of adding habitat heterogeneity. *Ecological Engineering* 61, Part A: 345-353. (in English) ["Nature-like fishways are designed to imitate the characteristics of natural streams, thereby providing both fish passage and habitat for a variety of aquatic organisms. To date, however, the potential for habitat rehabilitation of nature-like fishways has not been fully realized. To develop the concept of how to design a nature-like fishway, a 500-m long nature-like fishway, termed the biocanal, was constructed at the Eldforsen hydroelectric facility, Sweden. It included four habitat types: riffle, pool, floodplain and braided (i.e. with islands), each replicated three times. The riffle sections were considered controls for typical Swedish nature-like fishways. Thus the biocanal had a more varied in-stream environment than those of conventional fishways. To test the prediction that the biocanal had a positive effect on biodiversity, we compared the physical habitat and benthic fauna composition of the more diverse habitat types in the biocanal to the riffle habitats. We also made comparisons between the biocanal and six natural reference streams in the area. After two years, 63% of the benthic fauna families found in the reference streams had colonized the biocanal. Families present in the reference streams, but not in the biocanal, were predominantly slow colonizers or taxa linked to riparian vegetation, which was scarce and in an early successional stage along the biocanal. In the biocanal, pool and floodplain habitats contained the highest number of families, the highest family diversity (Shannon–Weaver) and the highest densities of Ephemeroptera, Plecoptera and Trichoptera. Since these habitats contained more families and had higher diversities than the riffle habitats which are typical of conventional nature-like fishways, we suggest that the construction of bio-

canals indeed possesses the potential for high biodiversity... The Odonata were among the slowest colonizers, and only one out of the seven Odonata families found in the reference streams was found in the biocanal at the end of the study. (Aeshnidae, Calopterygidae, Cordulegastridae, Corduliidae, Gomphidae, Platycnemididae)". (Authors)] Address: Gustafsson, Stina, Department of Biology, Karlstad University, S-651 88 Karlstad, Sweden. 13417. Ha, N.S.; Goo, N.S. (2013): Flapping frequency and resonant frequency of insect wings. 10th International Conference on Ubiquitous Robots and Ambient Intelligence (URAI), Oct. 30 2013-Nov. 2 2013: 29-31. (in English) ["In this study, we experimentally studied the relationship between wingbeat frequency and resonant frequency of 30 individuals of eight insect species from five families: Odonata (*Sympetrum flaveolum*), Lepidoptera (*Pieris rapae*, *Plusia gamma* and *Ochlodes*), Hymenoptera (*Xylocopa pubescens* and *Bombus rupestris*), Hemiptera (*Tibicen linnei*) and Coleoptera (*Allomyrina dichotoma*). We found that wingbeat frequency does not have a strong relation with resonance frequency: in other words, insects have not been evolved sufficiently to flap at their wings' structural resonant frequency. This contradicts the general conclusion of other reports—that insects flap at their wings' resonant frequency to take advantage of passive deformation to save energy." 13421. Haro, R.J.; Bailey, S.W.; Northwick, R.M.; Rolfhus, K.R.; Sandheinrich, M.; Weiner, J. (2013): Burrowing dragonfly larvae as biosentinels of Methylmercury in freshwater food webs. *Environmental Science & Technology* 47(15): 8148-8156. (in English) ["We assessed the utility of larval burrowing dragonflies (*Arigomphus cornutus*, *Dromogomphus spinosus*, *Gomphus adelphus*, *Gomphus exilis*, *Gomphus graslinellus*, *Gomphus lividus*, *Gomphus spicatus*, *Hagenius brevistylus*, *Ophiogomphus colubrinus*, *Progomphus obscurus*) as biosentinels of methylmercury (MeHg) contamination. Gomphids were the most abundant family of dragonflies sampled during 2008-2010 from 17 lakes in four national parks of the northwestern Laurentian Great Lakes region. Ten species of burrowing gomphids were sampled; 13 lakes contained 3 or more species, and 2 species of *Gomphus* co-occurred in 12 lakes. Most of the total Hg (THg) in whole, late-instar larvae was MeHg, with mean percent MeHg exceeding 60% in 16 lakes. Mean MeHg in larvae of a given species varied greatly among lakes, ranging from 4 to 109 ng g⁻¹ dry weight. Methylmercury levels in larvae, however, were much less variable within a given lake and species. The mean concentration of MeHg in burrowing gomphids was positively correlated with mean MeHg concentration in unfiltered lake water. Mean concentrations of THg and MeHg in multispecies assemblages of *Gomphus* were also positively correlated with mean THg in coexisting prey fish and game fishes. We recommend—and provide guidance on—the application of burrowing gomphids as biosentinels of MeHg contamination, which can extend the bioassessment of MeHg to fishless fresh waters." (2013): Bactericidal activity of black silicon. *Nature Communications* 4:2838. DOI: 10.1038/ncomms3838: 7 pp. (in English) ["Black silicon is a synthetic nanomaterial that contains high aspect ratio nanoprotusions on its surface, produced through a simple reactive ion etching technique for use in photovoltaic applications. Surfaces with high aspect-ratio nanostructures are also common in the natural world, for example, the wings of the dragonfly *Diplacodes bipunctata*. Here we show that the nanoprotusions on the surfaces of both black silicon and *D. bipunctata* wings form hierarchical structures through the formation of clusters of adjacent nanoprotusions. These structures generate a mechanical bactericidal effect, independent of chemical composition. Both surfaces are highly bactericidal against all tested Gram-negative and Gram-positive bacteria, and endospores, and exhibit estimated average killing rates of up to 4.5×10^5 cells $\text{min}^{-1} \text{cm}^{-2}$. This represents the first reported physical bactericidal activity of black silicon or indeed for any hydrophilic surface. This biomimetic analogue represents an excellent prospect for the development of a new generation of mechano-responsive, antibacterial nanomaterials." 13427. Jaeschke, A.; Bittner, T.; Reineking, B.; Beierkuhnlein, C. (2013): Can they keep up with climate change? – Integrating specific dispersal abilities of protected Odonata in species distribution modelling. *Insect Conservation and Diversity* 6: 93-103. (in English) ["(1.) The effects of climate change on the distribution of species are typically inferred using bioclimatic envelope models, assuming either no or unrestricted dispersal abilities. Information on species-specific dispersal abilities, especially of animals, is rarely incorporated. (2.) We analysed European records of two damselflies and four dragonflies protected by the Habitats Directive of the European Union. In addition to no or unrestricted dispersal scenarios, we considered species-specific dispersal distances based on literature information to improve realism in assessing conservation implications of climate change. The climate model HadCM3 and the emission scenario A2 were applied to project potential changes in occurrence probabilities up to 2035. As modelling algorithms, generalised linear models (GLM) and boosted regression trees (BRT) were used. (3.) The species *Coenagrion ornatum*, *Coenagrion mercuriale* and *Ophiogomphus cecilia* are projected to lose range (up to -68%) when incorporating specific dispersal distances, while they are projected to extend their range (up to +23%) in the unre-

stricted dispersal scenario. Furthermore, suitable climatic conditions tend to decline for *Leucorrhinia albifrons* and *Leucorrhinia caudalis* (up to -73%), whereas *Leucorrhinia pectoralis* is projected to gain distribution area (up to +37%) assuming either species-specific or unrestricted dispersal and subsequently successful breeding. Cross-validated model performance (AUC values) ranges between 0.77 and 0.92. (4.) 4. The integration of species-specific knowledge about dispersal distances in species distribution models promises to improve estimates of potential range changes and their implications for conservation management. Contrasting model results under different dispersal scenarios highlight the importance of research on species' ecology including dispersal distances." (Authors)] Address: Jaeschke, Anja, University of Bayreuth, Universitätsstr. 30, D-95447 Bayreuth, Germany. E-mail: anja.jaeschke@uni-bayreuth.de

13428. Jimenez-Cortes, J.G.; Cordoba-Aguilar, A. (2013): Condition dependence and trade-offs of sexual versus non-sexual traits in an insect. *Journal of ethology* 31(83): 275-284. (in English) ["Sexual traits often communicate male condition and so are known to be highly condition-dependent. Thus, it is expected that, under restricted environments, sexual traits will be more heavily impacted than non-sexual traits, and so a negative covariation will be expected between sexual traits and non-sexual traits as only high-quality males will sustain the costs of producing both trait types. Such covariation will not necessarily appear in non-restricted environments. We tested these predictions using males of the American rubyspot, *Hetaerina americana*. First, fully mature males from different seasons were collected and their sexual [a wing red spot and body size (this corrected for body mass using residuals)], and condition-indicating, non-sexual (phenoloxidase and protein concentration) traits were measured. Second, larvae were reared under different food quantities and the same traits plus another non-sexual trait [pro-phenoloxidase (proPO)], were measured in recently emerged males. Contrary to expected, non-sexual traits showed larger expression variance than sexual traits. We found a significant covariation between body size and proPO for experimental males. Both rich and poor diet groups showed a negative slope for body size and proPO. This supposes a resource allocation trade-off between these two traits for recently emerged animals. On the other hand, the presumed signaling function between sexual traits, such as spot size, and physiological indicators of condition in this species, is not supported." (Authors)] Address: Jimenez-Cortes, J.G., Departamento de Ecología Evolutiva, Instituto de Ecología, Univ. Nacional Autónoma de México, Apdo. Postal 70-275, Ciudad Universitaria, 04510 México, D. F., Mexico

13429. Jones, N.E. (2013): Patterns of benthic invertebrate richness and diversity in the regulated Magpie River and neighbouring natural rivers. *River Research and Applications* 29(9): 1090-1099. (in English) ["Fluctuating flows common in hydropeaking operations present biota with contrasting and challenging environments. Taxa that

require a narrow range of water velocity or are not adapted to withstand sudden changes in discharge will likely be eliminated or competitively disadvantaged under such circumstances, perhaps leading to reduced biodiversity. I investigated the whole river, longitudinal and lateral patterns of benthic invertebrate abundance, Shannon–Wiener diversity, and rarefied taxa density and richness in the hydropeaking Magpie River and 16 neighbouring natural rivers. The Magpie River had greater abundances of benthic invertebrates than natural rivers, particularly near the dam. General differences in benthic community characteristics were largely based on the near absence of Odonata and Plecoptera and an abundance of snails and worms in the Magpie River. Family density, richness and diversity were greater in the regulated Magpie River and unregulated upper Magpie River than found in natural rivers. Longitudinally, family density, diversity and particularly richness increased downstream in the Magpie River. Laterally, diversity did not show any trends with increasing depth along transects, except at near the dam where it decreased sharply with depth, velocity, and an abundance of filter feeding invertebrates. Taxa density did not show any lateral trends in natural rivers, whereas in the Magpie River, it increased with water velocity and depth. The results of this study are contradictory to the general findings of others implying reduced biodiversity below hydropower facilities. Possible explanations are examined and contrasted with other examinations of benthic invertebrate response below hydropeaking dams. General differences in benthic community characteristics were largely based on the near absence of Odonata and Plecoptera and an abundance of snails and worms in the Magpie River. ... Axis 2 eigenvalues were heavily weighted by Odonata, worms and snails. ..." 13430. Jones, O.M.; Ottea, J. (2013): The effects of Spinosad on *Culex quinquefasciatus* and three nontarget insect species. *Journal of the American Mosquito Control Association* 29(4): 346-351. (in English) ["Spinosad is a relatively new insecticide with a unique mode of action that is being evaluated for control of larval mosquitoes. Whereas a number of toxicological studies have measured effects of spinosad on various animals, few have been conducted on the effects of spinosad on nontarget, aquatic insect species. Such studies are important as these species might be found in the same environments as mosquito larvae targeted for control. A neighborhood pond was surveyed to find a representative species of mosquito as well as other common aquatic insects with which to examine susceptibility to spinosad and nontarget effects. The mosquito species chosen was *Culex quinquefasciatus* and the most common nontarget taxa were immature stages of a mayfly (*Caenis* sp., Ephemeroptera: Caenidae), a damselfly (*Ischnura* sp., Odonata: Coenagrionidae), and a dragonfly (*Pachydiplax longipennis*).

nis, Odonata: Libellulidae). Bioassays of mosquitoes from a reference susceptible strain (Sebring-S) and field collections of *Cx. quinquefasciatus* were used to determine susceptibility to spinosad. In addition, susceptibility was examined in nontarget taxa using spinosad concentrations corresponding to the LC50 of field-collected mosquitoes (0.031 ppm) and the maximum label rate (1.6 ppm) of spinosad (Natular®EC). Susceptibility to spinosad did not differ between Sebring-S and field-collected mosquitoes. However, there was a marked difference in susceptibility among nontarget taxa. Susceptibility was greatest in *Caenis* sp., followed by *Ischnura* sp., and then *P. longipennis*. 13435. Kang, S.R.; King, S.L. (2013): Seasonal comparison of aquatic macroinvertebrate assemblages in a flooded coastal freshwater marsh. *Open Journal of Ecology* 3: 94-101. (in English) [White Lake Wetlands Conservation Area (WLWCA, 29°52'N, 92°31'W) in the Chenier Plain of southwestern Louisiana, USA; "Marsh flooding and drying may be important factors affecting aquatic macroinvertebrate density and distribution in coastal freshwater marshes. Limited availability of water as a result of drying in emergent marsh may decrease density, taxonomic diversity, and taxa richness. The principal objectives of this study are to characterize the seasonal aquatic macroinvertebrate assemblage in a freshwater emergent marsh and compare aquatic macroinvertebrate species composition, density, and taxonomic diversity to that of freshwater marsh ponds. We hypothesize that 1) freshwater emergent marsh has lower seasonal density and taxonomic diversity compared to that of freshwater marsh ponds; and 2) freshwater emergent marsh has lower taxa richness than freshwater marsh ponds. Seasonal aquatic macroinvertebrate density in freshwater emergent marsh ranged from 0 organisms/m² (summer 2009) to 91.1 ± 20.53 organisms/m² (mean ± SE; spring 2009). Density in spring was higher than in all other seasons. Taxonomic diversity did not differ and there were no unique species in the freshwater emergent marsh. Our data only partially support our first hypothesis as aquatic macroinvertebrate density and taxonomic diversity between freshwater emergent marsh and ponds did not differ in spring, fall, and winter but ponds supported higher macroinvertebrate densities than freshwater emergent marsh during summer. However, our data did not support our second

hypothesis as taxa richness between freshwater emergent marsh and ponds did not statistically differ." (Authors) Data on the mean density (ind-m²) in freshwater emergent marsh by season are presented at the genus level for *Coryphaeschna*, *Enallagma*, *Ischnura*, *Erythemis*, and *Pachydiplax*] Address: Kang, S.R., School of Renewable Natural Resources, LSU AgCenter, Baton Rouge, Louisiana 70803-4301, USA. 13436. Karube, H.; Suda, S., Umeda, T.; Hayashi, H. (2013): Odonata fauna of Izu Archipelago, Japan. *Tombo* 55: 99-114. (in Japanese, with English summary) ["Izu archipelago, situated south of Tokyo, consists of 9 main islands. Here we recorded 23 odonate species in total. Some of the species (*Anaciaeschna martini*, *Anax nigrofasciatus nigrofasciatus*, and *Crocothemis servilia marianae*) were recorded for the first time from the archipelago. All the islands are of volcanic origin, thus fresh water bodies are very limited, and the islands have relatively short geological histories. Therefore the archipelago has a poor odonate fauna without endemic species/subspecies. We confirmed many alien species: some of them are invasive and we consider their predation as the main cause of the extinction of *Deielia phaon*." (Authors)] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan. E-mail: paruki@nh-kanagawa-museum.jp

13437. Kawade, S.T. (2013): Diversity and abundance of damselflies of Saikheda Water Reservoir of Yavatmal district, Maharashtra (India). *Science Park Research Journal* 1(20): 1-5. (in English) ["Saikheda water reservoir of Yavatmal district, Maharashtra (India) were studied for rainy season from June 2013 to September 2013 of two station of Saikheda dam. A total of 10 species belonging to three families of zygoptera were identified." (Author)] Address: Kawade, Sarita, Department of Zoology, S. M. College Pandharkawada, Dt., Yavatmal (M.S), India

13438. Keller, D.; Holderegger, R. (2013): Damselflies use different movement strategies for short- and long-distance dispersal. *Insect Conservation and Diversity* 6(5): 590-597. (in English) ["Dispersal is an important process for any organism, but especially for endangered species in fragmented landscapes. To enhance the dispersal of a certain species, connectivity measures are implemented, which require knowledge on the species' dispersal behaviour and habitat. It is often assumed, that the preferred reproductive habitat of a species is also used as the main dispersal habitat. Although this assumption has often been confirmed, there are also cases where it has been disproved. With a combination of a mark-resight study and genetic analysis conducted in a fragmented agricultural landscape in Switzerland, the dispersal habitats of the threatened damselfly *Coenagrion mercuriale* were analysed for different distance classes. In addition, maximum dispersal distances were estimated. The mark-resight study detected movement over short distances (=500 m) mainly within the reproductive habitat of *C.*

mercuriale (i.e. streams). In contrast, the genetic study detected both short- and long-distance dispersal. Short-distance dispersal occurred along streams, and discontinuity of streams hindered dispersal. Long-distance dispersal was suggested to happen along more or less straight lines and crossing agricultural land. Genetic analysis also showed that populations were well connected and that few individuals dispersed over larger distances (=4500 m). Our study showed that connected reproductive habitat enhanced short-distance dispersal in *C. mercuriale*. Although short-distance dispersal occurred frequently, long-distance dispersal was rare, but important to connect more isolated populations. Therefore, it would be relevant to differentiate between these two dispersal types when planning connectivity measures." (2013): Niche partitioning in three sympatric congeneric species of dragonfly, *Orthetrum chrysostigma*, *O. coerulescens anceps*, and *O. nitidinerve*: The importance of microhabitat. *Journal of Insect Science* 13(71): 1-17. (in English) ["Habitat heterogeneity has been shown to promote co-existence of closely related species. Based on this concept, a field study was conducted on the niche partitioning of three territorial congeneric species of skimmers (Anisoptera: Libellulidae) in Northeast Algeria during the breeding season of 2011. According to their size, there is a descending hierarchy between *O. nitidinerve*, *O. chrysostigma*, and *O. coerulescens anceps*. After being marked and surveyed, the two latter species had the same breeding behaviour sequence. Knowing that they had almost the same size, such species could not co-occur in the same habitat according to the competitive exclusion principle. The spatial distribution of the three species was investigated at two different microhabitats, and it was found that these two species were actually isolated at this scale. *O. chrysostigma* and *O. nitidinerve* preferred open areas, while *O. c. anceps* occurred in highly vegetated waters. This study highlights the role of microhabitat in community structure as an important niche axis that maintains closely related species in the same habitat." (2013): Elinympäristön perustaminen täplälampikorennolle (*Leucorrhinia pectoralis*) [Establishing habitats for Yellow-spotted Whiteface (*Leucorrhinia pectoralis*)]. *Crenata* 6: 22-25. (in Finnish, with English summary) ["This article examines the factors that effect the colonisation of Odonata in new habitats, especially newly formed wetland pools. Wetland pools were dug in Lintulahdet Life project to the shore areas to provide a suitable living environment for dragonflies. The special target species was *Leucorrhinia pectoralis*. The persistence of Odonata populations was studied by monitoring of larvae, exuviae and adults. The monitoring showed that *L. pectoralis* and many other dragonfly species inhabited the newly formed pools. By controlling the shadowing reed beds it was possible to increase the breeding success of Odonata populations." (Author)] Address: Korkeamäki, E., Karkunkatu 18 a 4 b, FIN-48600 Karhula, Finland

13443. Korkeamäki, E. (2013): Siberian Hawker (*Aeshna crenata*) in the Salpausselkä Ridge area. *Kymijoen vesi ja ympäristö ry:n tutkimusraportti no 217/2013*: 11 pp, app.. (in Finnish, with English summary) ["*A. crenata*,

is an impressive, but rare, localized and poorly known species in Europe. A total of 44 small ponds and lakes, situated within the Salpausselkä Ridge, north of Kouvola city in south-eastern Finland, were surveyed for populations of *A. crenata* during the summer period 2011-2012. Adults and exuviae were searched for in sunny weather. Altogether, 29 odonate species recorded in these 44 ponds. *Aeshna crenata* was found in 21 ponds and it seems to have rather specialized habitat requirements in the study area. It occurs mainly in small, circular and oligotrophic ponds with slightly swampy shoreline. These ponds – ‘suppa pits’ – are typical glacial age formations in the Salpausselkä Ridge and influenced by clear groundwater. Sex ratio is also checked with *Aeshna* –exuviae and the majority members were females. Potential threats by the human activity to the populations of *A. crenata* is also discussed." (Author)] Address: Korkeamäki, E., Karkunkatu 18 a 4 b, FIN-48600 Karhula, Finland

13444. Korte, T.; Eberhard, T. (2013): Was lebt im Lämpkes Mühlenbach? In spite the fact the renaturation of the book is assessed as successful, even 17 year after the measurements, no rheophilous Odonata have colonised the brook.] Address: Korte, T., Emschergenossenschaft/Lippeverband, Geschäftsbereich Technische Services, Kooperationslabor mit dem Ruhrverband, Kronprinzenstraße 37, 45128 Essen, Germany. E-Mail: korte.thomas@eglv.de

13445. Kosterin, O.E. (2013): *Somatochlora arctica* (Zett.) Seems to migrate to escape from wildfires (Anisoptera: Corduliidae). *Notulae Odonatologicae* 8(2): 35-36. (in English) ["*S. arctica* is known from the Novosibirsk province, Russia, only by scarce records from small forest lakes in the districts of Bolotnoe and Moshkovo, situated N of Novosibirsk (KOSTERIN et al., 2001, *Sympetrum*, Hyogo 7/8: 24-49). In the Bakchar district (Tomsk prov.), some 200 km N of Novosibirsk, it appears as one of the most abundant dragonfly species (BERNARD & KOSTERIN, 2010, *Odonatologica* 39: 1-28): during 12-22 July 2006 the foraging swarms were found above any dry open area, although the abundance of these drastically decreased after the 14th of July. The breeding sites were not found, they are probably located in the inaccessible mesotrophic fens, overgrown with sedge amidst vast *Sphagnum* bogs. In 2012, five dead *S. arctica* specimens were collected in Novosibirsk Academy Town, ca 30 km S of downtown Novosibirsk (and ca 50 km S of the Moshkovo district border), obviously crashed by traffic while foraging along and above the asphalt-paved roads. In four specimens the wings were clear and in one male moderately smoked (they are frequently smoked in specimens from Tomsk province). During some 30 years of more or less regular observations in Academy Town, the

species has never been encountered there. The environmental conditions prevailing at the time the above specimens were found were exceptional: July had been very hot and smog of various intensities occurred in the province of Novosibirsk almost every day, with the hot air poorly transparent, smelling smoke. The sun could be watched by naked eye: as a red spot with sharp margins against a white sky. This was due to the forest fires, occupying vast areas of Siberia, in particular that part of Tomsk province, situated N of Novosibirsk province, which seemed to be a *S. arctica* paradise (see above). "The summer of 2012 has proved to be the most severe wildfire season Russia has faced in a decade. [...] More than 17,000 wildfires had burnt more than 30 million hectares (74 million acres) through August 2012, according to researchers at the Sukachev Institute of Forest in Russian Academy of Sciences." (<http://www.nasa.gov/misionpages/fires/main/world/20120913-siberia.html>). We assume, *S. arctica* escaped the fires in its native area by long migration. An alternative option would be a mass propagation, triggering the individuals to expand by plain diffusion, resulting in their noticeable numbers far from that area. This seems less likely as it would imply two independent anomalies: fires and mass propagation. High temperatures could favour the propagation, but they could have no effect if taking place after the emergence of the adults, as was the case in the summer of 2012." (Author)] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. E-mail: kosterin@bionet.nsc.ru

13447. Kulijer, D.; Topić, G. (2013): First record of a Balkan population of *Ceriatrigon tenellum* outside the influence of the Mediterranean climate (Odonata: Coenagrionidae). *Libellula* 32(3/4): 193-204. (in English, with German summary) ["*C. tenellum* is rare in the Balkan Peninsula and has hitherto been known as restricted only to the areas under the influence of the Mediterranean climate. On 21 July 2011 and on 3 June 2012 the species was found at the small Dol Lake in the valley of Pliva River, central Bosnia and Herzegovina. Altogether 14 dragonfly species could be observed at the site. This is the first finding of a population of *C. tenellum* in the Danube catchment and in the area outside the Mediterranean region of the Balkans. All known records from the eastern Adriatic were gathered and the distribution of the species in the Adriatic region is outlined. In Bosnia and Herzegovina *C. tenellum* is found at seven localities. The species prefers habitats with rich and diverse water

vegetation and the presence of flowing water. This finding is discussed in relation to the distribution and the habitats of the species in the East Adriatic and Europe. A short discussion on the threats and the conservation status in the Balkan region is appended." (Authors)] Address: Kulijer, D., National Museum of Bosnia and Herzegovina, Zmaja od Bosne 3, 71000 Sarajevo, Bosnia and Herzegovina. E-mail: dejan.kulijer@gmail.com

13448. Kumon, Y.; Otsuka, M. (2013): Development of Sirocco fan featuring dragonfly wing. *Transactions of The Japan Institute of Electronics Packaging* 6(1): 24-31. (in English) ["We have developed high-performance electric fans by applying features of the wings of living creatures. This paper proposes an air purifier sirocco fan blade that mimics the wings of a dragonfly. Air quality has increasingly attracted attention in Japanese homes, and one or more air purifiers are installed in almost 40% of all houses in the country. The purpose of an air purifier is to maintain air cleanness, and it is operated overnight. There is, however, the problem of the loud noise created by the fan, which also makes overnight operation inconvenient. To solve this problem, we adopted the shape of the dragonfly wing in the sirocco fan blade of an air purifier. As a result, a maximum reduction of 2.5 dB was achieved." (Authors)] Address: Kumon, Yui, Development Dept., Health & Environmental Systems Group, Sharp Corporation, 3-1-72, Kitakamei-Cho, Yao-Shi, Osaka 581-8585, Japan

13449. Liang, Z. (2013): Computational analysis of vortex structures in flapping flight. PhD thesis, Wright State University: XVIII + 210 pp. ["Vortex structures and vortical formation in flapping flight are directly related to the force production. To analyze the connection between vortex structures and aerodynamic performance of flapping flight, we have developed highly efficient algorithms for large-scale flow simulations with moving and deforming bodies. To further understand the underlying mechanisms of force generation caused by the coherent structures of the vortex formation, a new analysis method has been developed to measure the influence of Proper Orthogonal Decomposition (POD) modes on aerodynamic forces. It is challenging to finish three-dimensional Direct Numerical Simulations (DNS) of insect flight in a limited amount of time. In the current work, the Modified Strongly Implicit Procedure (MSIP) has been implemented into an existing Computational Fluid Dynamics (CFD) solver, as a smoother for the multigrid method to solve the pressure equation and an iterative method to solve the momentum equation. The new solver is capable of performing a 17-million-mesh simulation within 10 days on a single core of an Intel i5-3570 chip at 3.4GHz, nearly 10 times faster than the traditional Line-SOR solver. Based on this numerical tool, the free flight of a dragonfly for eight-and-a-half wing beats is studied in detail. The results show that the dragonfly has experienced two flight stages during the flight. In a maneuver stage, wing-wake interaction generated by the fore- and hindwings attenuates the total force by 8% (peak value). In contrast, in an escape

stage, the fore- and hindwings collaborate to generate force which is 8% larger than when they flap separately. Especially, the peak force on the forewing is significantly increased by 42% in a downstroke and this enhancement is known to associate with a distorted trailing edge vortex, as demonstrated by a theoretical model based on wake survey methods. The movement of the trailing edge vortex is a response to the motion of the hindwing. When the fore- and hindwings flap closely with only a short distance existing between them, the hindwing exerts a wall effect to the trailing edge vortex. Vortex formation of flapping flight and force generation are considered to be closely linked; however, it is difficult to accurately determine the influence of an individual vortex on the overall aerodynamic performance. Here, as an alternative, we examine the influence of coherent structures, which are thought as special types of vortices in terms of kinetic energy. First, wake structures are decomposed by the POD method and the most energetic vortices are extracted. Then, a pressure corrected POD Reduced-Order Models (ROM) method is used to verify that the POD modes can capture the dynamics of the flows. Finally, the force of POD modes is quantified by a new method, termed the POD mode Force Survey Method (POD-FSM). The process is applied to investigate the flow field generated by a two- or three-dimensional plate undergoing a pitching-plunging motion. Superposition of force of the POD modes shows a good agreement with the DNS result. In addition, it is found that some POD modes have zero lift, and some have zero thrust. These force behaviours are related to symmetry of POD mode. According to the symmetry or antisymmetry about the streamwise line (or the crossflow plane in three-dimension), the POD modes can be qualitatively grouped into two sets. Combining POD modes in the same set can help to decompose the flow into thrust- and lift-producing flows. It is found that the force acting on the plate is a linear combination of the force of the thrust- and lift-producing flows and their interactions. Because two flows have different frequency spectrum, it is possible to perform flow control with respect to frequency to achieve the desired aerodynamic performance." (Author)] Address: not stated.

13450. Lingenfelder, U. (2013): Die Libellen der Queichniederung (Insecta: Odonata). Fauna Flora Rheinland-Pfalz 12(3): 921-998. (in German, with English and French summaries) ["The article gives an overview of the dragonfly fauna of Queichniederung and summarizes the results of the mapping of dragonflies in 2006 within the Natura 2000 sites „Bellheimer Wald mit Queichtal“ and „Offenbacher Wald, Bellheimer Wald und Queichwiesen“ including supplementary examinations. In the alluvium of the river Queich, a total of 51 dragonfly species could be detected between the years 1954 to 2012. During the field-mapping in 2006, the occurrence of species was documented in permanently water-bearing streaming waters, temporary water-bearing irrigation ditches, flood meadows and some standing waters. The focus of the investigation was on the systematic mapping of the dis-

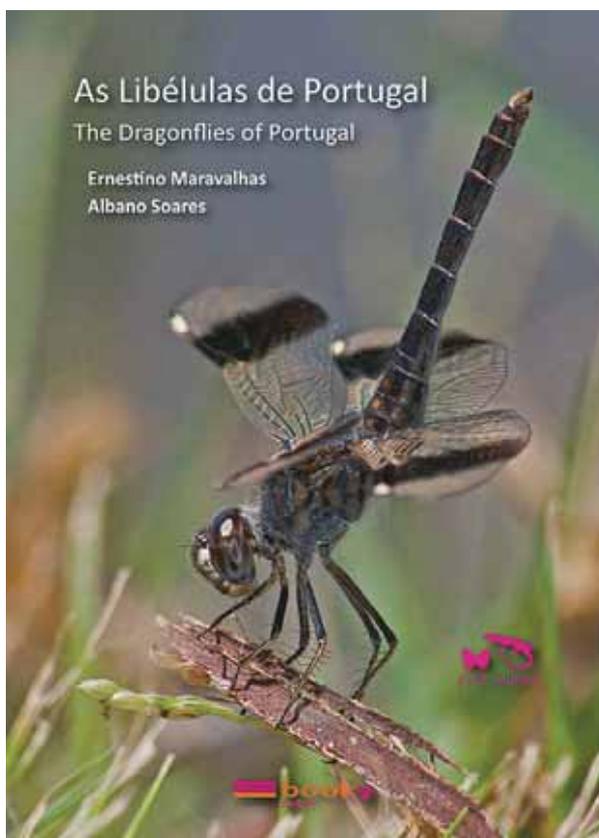

tribution of the Habitats Directive species *Coenagrion mercuriale* and *Ophiogomphus cecilia*. Together with complementary acquisitions from previous years (1999, 2004, 2005) and from the year 2010 there were 33 species detected at 32 studied watersites with a total of 109 sample sites." 13452. Loomis, D. (2013): Reproductive success and foraging ecology of the rusty blackbird on the Copper River Delta, Alaska. M.Sc. thesis, Oregon State University: 84 pp. (in English) ["The Rusty Blackbird (*Euphagus carolinus*) has suffered significant population declines across its entire geographic range and the mechanisms associated with this decline are poorly understood. Although much of the Rusty Blackbird breeding habitat in Alaska has remained relatively unaltered by anthropogenic activities, this species continues to decline by an estimated 5% annually. As part of a collaborative effort to obtain data on the reproductive ecology, breeding success, and habitat requirements of this species throughout their range, a total of 42 nests were found and monitored for two consecutive breeding seasons (2009 – 2010) on the Copper River Delta in south-central Alaska. Nests were monitored every 2-4 days to calculate nest success, survival rates, clutch initiation date, clutch size, egg viability, and fledging rates. In 2010, chick provisioning rates, chick diet, and aquatic invertebrate availability in Rusty Blackbird foraging habitats were also investigated. Mean clutch size ranged from 5 to 7 eggs both years (2009 = 5.41 ± 0.15 , 2010 = 5.67 ± 0.13). Daily nest survival rate averaged over both seasons was high, at 0.9913 ± 0.0043 (95% CI 0.9772-0.9967) and most eggs were viable (N = 31 nests), with 0.8922 ± 0.0275 of eggs over both seasons hatching. Approximately 85% of clutches were initiated within a two week period for both years of the study. Clutch-initiation date (CID) was significantly different between years (p -value < 0.0001), with mean CID of 10 May ($\bar{x} = 10.476 \pm 0.95$) in 2010 and May 18 ($\bar{x} = 18.421 \pm 1.13$) in 2009. The mean provisioning rate was 0.84 (± 0.06 ; 95% CI: 0.72 to 0.95) invertebrate food items per chick per hour. Large odonate nymphs, specifically dragonflies, made up the bulk

(97.2%) of the observed food items provisioned to chicks. Weekly pond sampling revealed four taxonomic groups of invertebrates that were of the size observed provisioned to chicks (Coleoptera, Hirudinea, Zygoptera, Anisoptera) and Anisoptera were among the rarest collected (16.2%) of this size. Although the least common large invertebrate collected, Anisoptera nymphs were present in all weekly samples. The week with the most abundant Anisoptera collection coincided with the week of peak hatching during 2010 of the study. Thus, availability of dragonfly nymphs appear to be important to Rusty Blackbird reproductive success on the Copper River Delta and may have contributed to the high nest success observed in this study." Portugal. It provides a comprehensive identification guide to the 67 recorded species. For each species there is a concise text, a map and photos of living specimens in their natural environment as well as numerous photos of details to aid identification. Illustrated throughout in colour with over 600 high quality photographs. Distribution maps to all species." (Publisher)] Address: not stated

13455. Marinov, M.; Pikacha, P. (2013): On a dragonfly collection from the Solomon Islands with overview of fauna from this Pacific archipelago (Insecta: Odonata). *Faunistic Studies in South-East Asian and Pacific Island Odonata* 4: 1-48. (in English, with Toksave summary) ["Odonata fauna of the Solomon Islands (considered in its political rather than geographical borders) is revised following a recent collecting trip to Guadalcanal Island in April 2012. Some important taxonomic considerations are discussed and a complete literature review is provided for the country with an updated checklist of 64 species that is in accordance with the latest taxonomic studies on the group from that part of the world. The collection reported here was carried out on two and a half effective field days and resulted in a total of 30 taxa. Two of them (*Agyrtacantha browni* and *Gynacantha amphora*) are new to science and already described elsewhere and three others (*Lestes concinnus*, *Lathrecista asiatica festa* and *Rhyothemis resplendens*) are new to the country. A female of *Pseudagrion incisurum* is described for the first time and another female (*Rhinocypha liberata*) will be described later." 13459. Mary, R. (2013): Ecology and predatory efficiency of aquatic (Odonate) insect over the developmental stages of mosquitoes (Diptera: Culicidae). *Journal of Academia and Industrial Research* 2(7): 429-436. (in English) ["Mosquitoes of the genera *Aedes*, *Anopheles* and *Culex* are considered relatively dangerous among the individuals of family Culicidae, because they cause significant public health threat all over the world. Predatory efficiency of the confirmed predators (Odonata: Aeshnidae) by in vitro experiments on the developmental stages of the mosquitoes namely, *Aedes aegypti*, *Anopheles stephensi* and *Culex quinquefasciatus* with reference to the duration of the prey availability, changes in the relative preference or selectivity of predators over the mosquito larvae at different stages (I, II, III and IV instars larvae and pupae) of development, changes in the relative consumption rate of the predators with reference to the species of mosquitoes, attack rate and success rate of the predators on the larval mosquitoes were investigated. Seasonal (month-wise) dynamics of each of the selected predators in some familiar freshwater bodies in Coimbatore, for two consecutive years i.e. from January 2009 to December 2011, relationship (correlation), if any, between physico-chemical parameters of the water and the abundance of the predators in the water bodies and the range of co-efficient of association, between and among the different species of the predators were also investigated. Relative incidence of larval mosquitoes of genera

Aedes, *Anopheles* and *Culex* in the selected water bodies and the range of co-efficient of association between the predator and prey were also investigated. The results of the predatory capacity of *Anax* nymph on the larvae and pupae of the mosquitoes for 24 h and 1 h of dragonfly showed the highest predation rate against I instar larvae of the mosquito compared to that of the capacity of other predators tested in the present study. Total consumption rate of 7 predatory individuals towards I instar of *C. quinquefasciatus* was 50 out of 700 i.e. 72% was fed in 24 h." 13460. McCauley, S.J. (2013): Relationship between morphology, dispersal and habitat distribution in three species of *Libellula* (Odonata: Anisoptera). *Aquatic Insects* 34(3-4): 195-204. (in English) ["Morphology is an important determinant of flight performance and can shape species' dispersal behaviour. This study contrasted the morphology of flight-related structures in dragonfly species with different dispersal behaviours to gain insights into the relationship between morphology and dispersal behaviour. Specifically, wing size, wing shape and thorax size were compared in three co-occurring species from different clades within the genus *Libellula* to assess how these morphological traits are related to differences in dispersal behaviour and to how broadly their larvae occur across a habitat gradient. Two species had broad larval habitat distributions as well as high rates and distances of dispersal. These two species had relatively larger wings and thoraces than the third species, which was found only in permanent lakes and had limited dispersal. The hind-wings of more dispersive species also had lower aspect ratios and a relatively wider basal portion of the wing than the less dispersive species. Broad hind-wings may facilitate the use of gliding flight and reduce the energetic costs of dispersal. Determining the morphological traits associated with alternative dispersal behaviours may be a useful tool to assess the differential dispersal capacities of species or populations."] (Author)] Address: McCauley, S.J., Department of Biology, University of Toronto Mississauga, 3359 Mississauga Rd, Mississauga, ON L5L 1C6, Canada

13461. Mediani, M.; Boudot, J.P.; Benazzouz, B.; El Bella, T. (2013): Two dragonfly species (Insecta: Odonata) migrating at Dakhla (region of Oued Ad-Dahab Lagouira, Morocco). *International Journal of Odonatology* 15(4): 293-298. (in English) ["Large numbers of migrating imagoes of *Anax ephippiger* were observed from the end of January to March 2012 at Dakhla Bay, Southern Morocco, in an area where long-lasting fresh and brackish waters are lacking, and thus which is unfavourable for the reproduction of Odonata. This supports well the classical scheme of northward mass migration of the species along the Atlantic coast of Africa, induced by autumnal mass emergences in the Sahel as a result of the summer African monsoon. Small numbers of *Sympetrum fonsco-*

lombii were previously temporarily recorded from the same area in July 2011. They were probably nomadic individuals of which the origin could not be verified, but which could have been involved in long distance vagrancy, typical of the species, due to the scarcity of fresh and brackish water in the area." 13464. Naraoka, H. (2013): Diurnal activity and reproductive behavior of *Indolestes peregrinus* (Ris, 1916) (Lestidae: Odonata). *Tombo* 55: 91-98. (in Japanese, with English summary) ["The diurnal activity and the reproductive behaviour of *I. peregrinus* are described based on observations at Aomori prefecture, northern Japan, in

2008-2012 and briefly compared with those of other zygopteran species. In their diurnal activity, males were found at a rice field, pond and barrage of the reproductive site between 8:00 am and 5:00 pm above 17-18°C air temperature. They were active in the morning, but in contrast spent most time inactively perched after 11:00 am. They rested on trees at the night. On the other hand, single females, except when in tandem with males, were rarely seen at the reproductive site. Copulation and oviposition were observed between 8:00 am and 6:00 pm on warmer day but was suppressed on cloudy and cooler days. When a pair did not complete oviposition before night fall, they again started to oviposit the next day as the same couple, after resting for the night. The duration of intra-male sperm translocation was significantly and negatively correlated with air temperature. The duration of copulation was significantly and negatively correlated with the time of copulation onset. Copulation was divided into 3 stages. Stage I was characterized by the pumping movement of the male's abdomen with several breaks in copulation. Stage II was, shorter than the other stages, with a few quick pumping. Stage III was divided into two substages III-A and III-B, the former of which are almost inactive, but the latter showed active pumping. The female oviposited on the aerial stems or leaves of emergent plants, but never into the water. She usually did so in tandem linkage with the male, rarely singly." (Author)] Address: Naraoka, H., 36-71 Motoizumi, Fukunoda, Itayanagi-machi, Kita-gun, Aomori, 038-3661, Japan

13465. Neveu, G.; Hubert, A. (2013): Sites d'émergence d'*Oxygastra curtisii* dans le département de la Somme (Odonata: Corduliidae). *Martinia* 29(2): 79-85. (in French, with English summary) ["*O. curtisii* is a species of Western Europe and northern Africa, which is not present in the French departments bordering the northern Channel and the North Sea. In the Somme department, the species was recorded for the first time in 1997 and seems to be permanently established and to extend increasingly in the Somme valley since that time. The first exuviae were observed in 2005 and were discovered around a standing water habitat. Although already known, this is quite atypical but new observations have been made regularly since then. The species does not yet extend to neighbouring departments. However, a first data was reported in the Pas-de-Calais department in 2012." (Author)] Address: Neveu, G., 22 rue de Sailly le sec, F-80800 Sailly Laurette, France. E-mail: gilles.neveu@orange.fr

13466. Ngiam, R.W.N.; Dow, R.A. (2013): The larva of *Leptogomphus risi* Laidlaw from Singapore with a comparison to *Leptogomphus williamsoni* Laidlaw from Sarawak and congeners (Odonata: Anisoptera: Gomphidae). *Nature in Singapore* 6: 307-312. (in English) ["The final instar larva of *Leptogomphus risi* Laidlaw is described and illustrated for the first time based on an exuvia collected from Singapore. A comparison of this larva with known larvae of congeners is discussed, including a first description of the larva of *Leptogomphus williamsoni*

Laidlaw from Sarawak." (Authors)] Address: Ngiam, R.W.N, National Biodiversity Centre, National Parks Board 1 Cluny Road, Singapore 259569, Republic of Singapore. E-mail: ngiamwenjiang@nparks.gov.sg

13467. Novelli, I.A.; Gomides, S.C.; Singer Brugiolo, S.S.; de Sousa, B.A.1 (2013): Alimentary habits of *Hydromedusa maximiliani* (Mikan, 1820) (Testudines, Chelidae) and its relation to prey availability in the environment. *Herpetology Notes* 6: 503-511. (in English) ["*Hydromedusa maximiliani* is endemic to mountainous regions, with distribution in the Atlantic Forest region along mountain ranges in Southeastern and part of northeastern Brazil. This work aimed at studying the feeding habits of a *H. maximiliani* population from Minas Gerais state, Southeastern Brazil. Specimens were captured, marked, measured and submitted to stomach washing. Pitfall traps were used to capture prey in terrestrial environments, and nets were used to collect macroinvertebrates in the aquatic environment. We captured and recaptured a total of 33 individuals. From 16 samples of stomach content, we recorded aquatic insect larvae, crabs, and terrestrial invertebrates. In total, 16 categories of prey items were identified. These belonged to 16 orders and 70 families of Insecta (including Odonata), 3 families of Diplopoda, 2 families of Crustacea, and 13 families of Arachnida. Lepidoptera, Baetidae and Diplopoda reached maximum electivity. The most representative group in the diet was Insecta, especially those with aquatic larval phase. The information obtained in this study about the diet of *H. maximiliani* indicates this vertebrate as a potential predator for regulating the density of benthic macroinvertebrates, and our data corroborate other studies which also showed the importance of *H. maximiliani* as a predator essential to aquatic food web dynamics. These data will be useful in future studies dealing with the bio-monitoring of *H. maximiliani*, and contributing to its preservation as well as to the preservation of habitats where this species lives." 13470. Obolewski, K. (2013): Use of macrozoobenthos for biological assessment of water quality in oxbow lakes of varying hydrological connectivity to the main river channel in the example of Łyna River valley. *Ochrona Środowiska* 35(2): 19-26. (in Polish, with English summary) ["This study presents influence of hydrological connectivity between oxbow lakes and the river on water quality determined based on the structure of aquatic invertebrate communities in oxbow lakes. Five oxbow lakes of the Łyna River were investigated, i.e. two lotic, two semilotic and one lentic ecosystem. It was shown that Chaoboridae (Diptera), Oligochaeta and Hydrobiidae (Gastropoda) were the most abundant groups of invertebrates, often accompanied by Chironomidae larvae (Diptera). Ephemeroptera and Trichoptera were the only invertebrate bioindicators observed in the studied water bodies. The EPT% index, determined based on their abundance, as well as EPT:C, determined based on their proportion to Chironomidae, indicated that groups of these organisms sensitive to environmental conditions occurred at low abundance in all hydrological types of oxbow lakes. Family Biotic Index (FBI), Biological Monitoring Working Party index (BMWP-PL) and Average Score per Taxon (ASPT), both adapted to the Polish conditions, revealed low water quality regardless of the degree of hydrological connectivity. This study shows that the structure of invertebrate communities inhabiting oxbow lakes can be a source of valuable monitoring data. BMWP-PL seems to be the most objective among the biotic indices. Hence, it can be applied in biomonitoring research of many types of aquatic ecosystems." (Authors) The list of taxa includes 'Lestidae' and 'Corduliidae'.] Address: Obolewski, K., Akademia Pomorska w Słupsku, Wydział Matematyczno-Przyrodniczy, Zakład Ekologii, ul. 13471. Orlofske, J.M.; Baird, D.J. (2013): The tiny mayfly in the room: implications of size-dependent invertebrate taxonomic identification for biomonitoring data properties. *Aquatic Ecology* 47(4): 481-494. (in English) ["The appropriate level of taxonomic identification, taxonomic suf-

iciency, for biomonitoring purposes continues to be controversial. Taxonomic sufficiency, however, fails to address the bias created by size-dependent taxonomic identification, which can result in coarse-resolution identification for immature specimens lacking distinguishing characteristics. Our study provides a direct test for this potential systematic bias in biomonitoring data by examining two morphological traits: body size and shape of key organisms (Ephemeroptera, Plecoptera, Trichoptera and Odonata) collected from standard aquatic biomonitoring samples. Direct measurement of body size and a geometric morphometric description of body shape provide consistent, quantitative variables to describe the composition of specimens identified at different levels of taxonomic resolution (genus or family). Corroborating our expectations, we observed evidence of systematic size bias in family-level identifications. Specimens that could only reliably be identified to the family level were significantly smaller than specimens identified to the genus level. Qualitative comparisons of shape variation between specimens demonstrated a high degree of variation in specimens identified only at the family level and support the conclusion that specimens identified at the family level possess multiple constituent taxa (genera or species). Thus, size-dependent taxonomy can have negative consequences for the accurate determination of biodiversity and may invalidate common biomonitoring metrics. Improvements to biomonitoring protocols through technological advances, including DNA-based taxonomy to augment specimen identification, should effectively remove the size-bias problem in the long term. In the short-term, recognizing instances of size bias, the degree to which it may impact bioassessment and exploring methods for remediation, including traits-based assessments, can enhance data quality and inferences derived from biomonitoring studies." (Authors)] Address: Orlofske, Jessica M., Canadian Rivers Institute & Dept of Biology, University of New Brunswick, PO Box 4400, 10 Bailey Drive, Fredericton, NB E3B 5A3, Canada. 13472. Orr, A.G.; Hämäläinen, M. (2013): Two new species of *Pericnemis* from Borneo with comparative notes on related species (Zygoptera: Coenagrionidae). *Odonatologica* 42(4): 335-345. (in English) ["*Pericnemis triangularis* Laidlaw was described on the basis of a single female from Bettotan in NE Borneo. Specimens from Brunei and neighbouring Sarawak previously referred to this species are reappraised with reference to the type and described as *Pericnemis dowi* sp. n. *P. kiautarum* sp. n. from Sabah, N. Borneo is described and figured based on a single male specimen. The new species are also compared and discussed in relation to *P. stictica*, the other Sundaland species of the genus. Both are distinguished by their male caudal appendages and by the form of a well developed horn on the hindlobe of the pronotum. The form of the appendages suggests a closer relationship between *P. dowi* and *P. kiautarum* than *P. stictica*. Both *P. dowi* and *P. stictica* breed in phytotelmata and it is conjectured that *P. kiautarum* probably does likewise. The potential hazards of describing species

from the female sex only are discussed." (Authors)] Address: Orr, A.G., Griffith School of the Environment, Griffith Univ., Nathan, Q-4111, Australia. E-mail: agorr@bigpond.com

13473. Osozawa, S.; Su, Z.-H.; Oba, Y.; Yagi, T.; Watanabe, Y.; Wakabayashi, J. (2013): Vicariant speciation due to 1.55 Ma isolation of the Ryukyu islands, Japan, based on geological and GenBank data. *Entomological Science* 16(3): 267-277. (in English) ["The Ryukyu island arc, originally a continental margin arc, separated from the Chinese continent by the rifting of the Okinawa trough, a process which began at 1.55 million years ago (Ma) and continues to the present. In addition, the Ryukyu arc was simultaneously divided into the northern Amami-Okinawa and southern Yaeyama islands by the Kerama rift valley, and consequently formed two isolated island units. The Kuroshio warm current began to flow into the Okinawa trough from the Yonaguni Strait, and flow out through the Tsushima and Tokara straits also at 1.55 Ma, and these seaways effectively acted as barriers between the Ryukyu islands and Taiwan, China and Japan. Through this geological process, vicariant speciation generated Ryukyu endemic animal species. We support this hypothesis by drawing linearized maximum likelihood (ML) phylogenetic trees of the species in four endemic insect groups (peacock butterfly, Chinese windmill butterfly, golden-ringed dragonfly - *Anotogaster sieboldii*, window firefly) using GenBank sequence data. We determined the precise branching ages for these phylogenetic trees, and show simultaneous speciation at 1.55 Ma for Amami-Okinawa and Yaeyama units. The Taiwan and Tsushima straits, barriers between Taiwan and China, and Japan and Korea, respectively, did not form sufficient barriers to migration during glacial low stands, and species were intermingled. A marine embayment may have posed as a migration barrier between northern and southern China in the Quaternary or a little earlier. From our study we also estimate the precise molecular evolution rate and justify the molecular clock." 13474. Ott, J. (2013): Erstnachweis der Östlichen Moosjungfer – *Leucorrhinia albifrons* (Burmeister, 1839) – in Rheinland-Pfalz (Insecta: Odonata). *Fauna Flora Rheinland-Pfalz* 12(3): 1075-1086. (in German, with English summary) ["*L. albifrons* was discovered for the first time in Rhineland-Palatinate, Germany in the year 2013. A single male was observed over a period of about two hours at an acid water near Kaiserslautern and also pictures for documentation were taken. The total number of dragonfly species for the federal state rises now to 68." (Author)] Address: Ott, J., Friedhofstr. 28, 67705 Trippstadt, Germany. E-mail: L.U.P.O.GmbH@t-online.de

13475. Ott, J. (2013): Erfassung der Gestreiften Quelljungfer (*Cordulegaster bidentata*) Selys, 1843 im Natur-

park und Biosphärenreservat Pfälzerwald (Insecta: Odonata). Fauna Flora Rheinland-Pfalz 12(3): 1039-1074. (in German, with English summary) ["During a field-study in the nature parc and biosphere reserve (BSR) "Pfälzerwald" taking place in fall 2012 *C. bidentata* was researched in 44 springs and spring brooks. This study is part of a monitoring project of the Forstliche Forschungsanstalt für Waldökologie und Forstwirtschaft (FAWF a forestry research institute) of springs and 30 sites were given from this general project, whereas another 14 were added in order to look in particular for the target species. Between the end of October and beginning of November over ten days the study was carried out in good weather conditions and at eight sites larvae *C. bidentata* were found; also at eight sites larvae of the sister species *C. boltonii* were found, whereas in three sites larvae of both species were present. In four more sites out of these 44, which were presently not occupied by *Cordulegaster* spp., in recent years *C. bidentata* was found and during various investigations in the BSR in six other sites larvae of the species were registered, as well as one adult in another locality. Finally 19 springs or spring brooks settled by this typical forest species – until today believed as very rare in the BSR – are now known and it seems to have a much wider distribution, underlining the value of the BSR for biodiversity protection. It was remarkable, that the larvae of *C. bidentata* occurred also in pretty acid conditions, partly also under a pH of 5, where the species, as well as *C. boltonii*, normally should not be present. Some more populations of *C. bidentata* recently were found in areas bordering north and west of the BSR in Rhineland-Palatinate and consequently the species should be taken from the national red list (listed as "endangered") and also the federal red list ("endangered by extinction"). Nevertheless the species, for which Germany and Rhineland-Palatinate have a high responsibility, faces many threats which certainly impact the populations in a negative way. Here in particular the dense conifer plantations neighbouring their habitats endanger their survival, as well as other impacts from intensive forestry management in the vicinity (e.g. deposition of old branches etc. in the springs, new infrastructures near the springs). In addition, the technical extension of the springs and spring brooks has a negative impact on the species, as well as the high density of wild boars, destroying the habitats and feeding on the larvae. In the medium and long term also climatic changes might be of more importance, in particular longer hot and dry periods in the summer, even if the larvae are somewhat tolerant to dry conditions. Several measurements to protect *C. bidentata* can be proposed, which also will improve the habitat conditions of *C. boltonii*: conversion of the coniferous forest into deciduous forests in the neighborhood of the springs, creation of diverse forest glades with flowering plants as maturation and feeding habitats, strict protection of the springs (no obstructions in the water cycle, no trampling damage etc.)." 13479. Pedrono, M.; Smith, I.I. (2013): Overview of the natural history of Madagascar's endemic tortoises and freshwater turtles: Essential components for effective conservation. Chelonian Research Monographs 6: 59-66. ["Madagascar had seven endemic chelonian species, including six tortoises and one aquatic turtle. The now extinct tortoises species, *Aldabrachelys grandidieri* and *Aldabrachelys abrupta*, as well as the extant species, *Astrochelys yniphora*, *Astrochelys radiata*, *Pyxis planicauda*, and *Pyxis arachnoides*, all occurred in the arid bush and in the mosaic of dry forests and wooded savannahs from south to northwestern regions of the island. The aquatic Madagascar Big-headed Turtle, *Erymnochelys madagascariensis*, occurs in rivers and large lakes in western Madagascar. These species all have delayed maturity offset by a prolonged reproductive lifespan. They also have a moderate annual reproductive output that includes multiple small clutches of eggs within a season, thus their intrinsic population growth rates are low. The last two decades have brought an increased understanding of the demographic vulnerability of Madagascan chelonians to overexploitation. Particularly significant are the drivers of population dynamics relating to adult mortality

and fecundity. The maximum level of harvest that their populations can sustain is low and is already greatly exceeded in most locations. This is the point at which the design of sound conservation strategies is crucial; increased integration of the natural history of Madagascan chelonians in conservation strategies could significantly improve their effectiveness. ... Juvenile *Erymnochelys madagascariensis* have a diet of aquatic or terrestrial invertebrates that have fallen into the water (e.g., molluscs, Coleoptera, Trichoptera larvae, Odonata, and Ephemeroptera)." 13480. Petrovičová, K.; David, S. (2013): Ecology and habitat preferences of *Onychogomphus forcipatus* (Linnaeus, 1758) Odonata: Gomphidae) from the Slovak Republic. MENDELNET 2013 (Proceedings of International PhD Students Conference Mendel University in Brno, Czech Republic, November 20th and 21st, 2013): 769-773. (in English) ["*O. forcipatus* is a conspicuous and ecologically interesting dragonfly species with low population density, occurring in lowland and foothill watercourses. In Slovakia, the species is known from 32 localities and 11 orthographic units with a total number of 106 specimens (51 males 3 females 14 Ex 38 L). *O. forcipatus* has a double-peak hyposometric distribution of localities with a height of 100-200 m and 400-500 m.a.s.l.. We assume that the atypical occurrence is linked to the preference of a river bed substrate: lithal (from pebbles to fine gravel) part of the watercourse hyporhithral and psammal/psammopelal (sandy-loamy-alumina substrate) part of the stream epipotamal. *O. forcipatus* occurs in the localities along with 36 dragonfly species with a positive correlation to rheophilous species *Platycnemis pennipes*, *Calopteryx splendens*, *C. virgo*, *Ophiogomphus cecilia* and *Gomphus vulgatissimus*. The significance of substrate, longitudinal zonation of the watercourse, and altitude were tested using Monte Carlo permutation test. After removal of the correlation of factors (inflation factor), the test showed statistically significant correlations for substrate types psammal (positive correlation, $p = 0,002$) and pleisopotamal (negative correlation, $p = 0,001$). Our results are consistent with published data." (Authors)] Address: Petrovičová, Kornelia, Dept of Zoology & Anthropology, Fac. Natural Sciences, Constantine the Philosopher Univ. in Nitra, Tr. A. tum ETRS89, 570 m a.s.l.). At the same locality, also three exuviae of *Macromia splendens* were found.] Address: Pino, P.L., Museu de les Terres de l'Ebre, Gran Capità, 34, 43870 Amposta (Tarragona), Spain. E-mail: odonats@yahoo.es

13482. Pires, M.M.; Kotzian, C.B.; Spies, M.R.; Neri, D.B. (2013): Diversity of Odonata (Insecta) larvae in streams and farm ponds of a montane region in southern Brazil. *Biota Neotropica* 13(3): 259-267. (in English, with Portuguese summary) ["This study presents an inventory of the genera of Odonata found in streams and artificial farm ponds in a montane region, with temperate climate, in southern Brazil. Differences in richness of lotic and lentic environments were also investigated. The diversity of odonate families and genera in southernmost Brazil is lower than in warmer, either tropical or subtropical, regions of the country. Nine genera are new records for the region and six genera had their geographical ranges extended to regions with temperate climate of the Neotropics. The overall richness and especially the overall abundance recorded in the studied area are possibly determined by the occurrence of numerous farm ponds because natural standing waters are scarce in the region. The presence of macrophytes in these artificial ponds allowed the establishment of a diversified odonatofauna, typical of lentic environments." 13486. Rebora, M.; Piersanti, S.; Dell'Otto, A.; Gaino, E. (2013): The gustatory sensilla on the endophytic ovipositor of Odonata. *Arthropod Structure & Development* 42(2): 127-134. (in English) ["The present paper aims at describing the fine structure of coeloconic sensilla located on the cutting valves of the endophytic ovipositor of two Odonata species, *Aeshna cyanea* and *Ischnura elegans*, by carrying out parallel investigations under SEM and TEM. In both species these coeloconic sensilla are innervated by four unbranched neurons forming four outer dendritic segments enveloped by the dendrite sheath. One dendrite terminates at the base of the peg forming a well developed tubular body, while the other three enter the peg after interruption of the dendrite sheath. The cuticle of the peg shows an apical pore and a joint membrane. This last feature, together with the tubular body and the suspension fibers, represent the mechanosensory components of the sensillum while the pore and the dendrites entering the peg allow chemoreception. The ultrastructural organization of these coeloconic sensilla is in agreement with the one reported for insect gustatory sensilla. Our investigation describes for the first time typical insect gustatory sensilla in Odonata. Electrophysiological and behavioral studies are needed to verify the role that these structures can perform in sensing the egg-laying substrata. Highlights: *The presence of chemoreceptors on ovipositor of endophytic Odonata was hypothesized. *No data on these sensilla are available at TEM level. *We investigate coeloconic sensilla on ovipositor of endophytic Odonata under SEM/TEM. *Sensilla show a pore and one of the outer dendritic segments forms a tubular body. *This is the typical morphology of insect gustatory sensilla." 13487. Redin, A.; Sjöberg, G. (2013): Effects of beaver dams on invertebrate drift in forest streams. *Šumarski list*

11–12: 597-607. (in English, with Bosnian summary) ["We aimed to assess the effects of beaver dams on the invertebrate drift fauna in five central Swedish boreal forest streams. Each stream was sampled once during the autumn, with drift traps placed upstream and downstream of the beaver dams. Drift densities (numbers/100 m³ water) were calculated. The invertebrates were determined, dried and weighed. No significant differences were noted in total drift densities or in the drift densities of pelagic species. The drift densities of benthic species were higher upstream of the dam, mainly because Ephemeroptera were more abundant in the upstream part. No significant difference was observed in diversity or dry weight. The functional feeding group ratio: filtering collectors / gathering collectors was significantly higher downstream of the dam." (Authors) Upstream-number of Odonata was very low. No drifting specimens were observed.] Address: Redin, A., Department of Wildlife, Fish, and Environmental Studies, SLU, SE-90183 Umea, Sweden. 13492. Rüppell, G.; Hilfert-Rüppell, D. (2013): Biting in dragonfly fights. *International Journal of Odonatology* 16(3): 229-229. (in English) ["Slow motion films of fight behaviour of five different species of Odonata were analysed. In all cases biting played a major role. The biting duration depended on the duration of a stable connection between the two opponents. Sitting odonates showed much longer biting than those that were flying. In fights of *Anax junius* and *Calopteryx splendens* long biting between males led to serious injuries and death. Two males of *Anax imperator* bit each other by very short strikes during looping flights together, better described as hack-biting. This hack-biting was seen in two other fights: a female of *Libellula quadrimaculata* bit a harassing male on the head, immobilizing him, and during a male–male fight in *C. splendens* flying nearly on the spot. Loops, very brief but relatively stable flight positions, were used for biting in three cases. The significance of biting in inter- and intrasexual competition in Odonata is discussed." 13493. Ruiz-Guzmán, G.; Canales-Lazcano, J.; Jiménez-Cortés, J.G.; Contreras-Garduño, J. (2013): Sexual dimorphism in immune response: Testing the hypothesis in an insect species with two male morphs. *Insect Science* 20(5): 620-628. (in English) ["It has been proposed that given that males should invest in sexual traits at the expense of their investment in immune response, females are better immunocompetent than males. Typically, this idea has been tested in monomorphic species, but rarely has been evaluated in polymorphic male species. We used *Paraphlebia zoe*, a damselfly with two male morphs: the black wing (Black-W) morph develop black spots as sexual traits and the hyaline wing morph (Hyaline-W) resembles a female in size and wings colour. We predicted that Black-W should have a lower immune response than Hyaline-W, but that the latter males should not differ from females in this respect. Nitric oxide (NO)

and phenoloxidase (PO) production, as well as haemolymph protein content, were used as immune markers. Body size (wing length) was used as an indicator of the male condition. The results show that, as we predicted, females and Hyaline-W had higher values of NO than Black-W, corresponding to differences in size. However, the opposite was found in relation to PO production. Females had the highest levels of haemolymph protein content, whereas no differences were found between Black-W and Hyaline-W. These results partially support the sexual selection hypothesis and are discussed in the context of the life history of this species. Black-W, Hyaline-W and females could express the immune markers that are prioritized by their particular condition, and probably neither of them could express all immune markers in an elevated manner, as this would result in an excessive accumulation of free radicals." Climate-induced range shifts and possible hybridisation consequences in insects. *PLoS ONE* 8(11): e80531. doi:10.1371/journal.pone.0080531: 10 pp. (in English) ["Many ectotherms have altered their geographic ranges in response to rising global temperatures. Current range shifts will likely increase the sympatry and hybridisation between recently diverged species. Here we predict future sympatric distributions and risk of hybridisation in seven Mediterranean ischnurid damselfly species (*I. elegans*, *I. fontaineae*, *I. genei*, *I. graellsii*, *I. pumilio*, *I. saharensis* and *I. senegalensis*). We used a maximum entropy modelling technique to predict future potential distribution under four different Global Circulation Models and a realistic emissions scenario of climate change. We carried out a comprehensive data compilation of reproductive isolation (habitat, temporal, sexual, mechanical and gametic) between the seven studied species. Combining the potential distribution and data of reproductive isolation at different instances (habitat, temporal, sexual, mechanical and gametic), we infer the risk of hybridisation in these insects. Our findings showed that all but *I. graellsii* will decrease in distributional extent and all species except *I. senegalensis* are predicted to have northern range shifts. Models of potential distribution predicted an increase of the likely overlapping ranges for 12 species combinations, out of a total of 42 combinations, 10 of which currently overlap. Moreover, the lack of complete reproductive isolation and the patterns of hybridisation detected between closely related ischnurids, could lead to local extinctions of native species if the hybrids or the introgressed colonising species become more successful." 13497. Sasamoto, A.; Futahashi, R. (2013): Taxonomic revision of the status of *Orthetrum triangulare* and *melania* group (Anisoptera: Libellulidae) based on molecular phylogenetic analyses and morphological comparisons, with a description of three new subspecies of *melania*. *Tombo* 55: 57-82. (in English) ["The taxonomic status of the libellulid dragonflies *Orthetrum triangulare* (Selys, 1878) and allied taxon *O. [triangulare] melania* (Selys, 1883) has been inconclusively resolved until present. In addition, the *melania* group has conspicuous geographical variations in morphology, which have not yet been discussed in detail. We present a taxonomic revision based on the molecular phylogenetic analyses using nuclear ITS1, ITS2, and mitochondrial 16SrRNA and COI genes, as well as external morphology. We confirm that *triangulare* and *melania* are well separated by the both nuclear and mitochondrial gene molecular phylogenies. The external morphologies of these two groups are conspicuously different, indicating that *O. melania* should be regarded as a genuine species. Although the genetic differences between *O. triangulare malaccense* and *O. t. triangulare* were subtle, the morphological differences between these two subspecies could be recognized. Furthermore,

based on molecular phylogenetic analyses and external morphological comparisons, *O. melania* could be separated into four subgroups: (1) mainland Japan (Hokkaido to Kyushu) and northern Ryukyu, (2) continental China, Taiwan, Korean Peninsula, (3) middle Ryukyu (from Tokara Islands to Kumejima Island), and (4) southern Ryukyu (Yaeyama Islands). Therefore we recognize the following four subspecies: *nominotypical melania*, m. *continentale* ssp. nov. (holotype female: Linfan, Zhejiang prov., R. P. china), m. *ryukyense* ssp. nov. (holotype female: Mt. Nago, Nago city, Okinawajima Island, Japan), and m. *yaeyamense* ssp. nov. (holotype female: Otomipass, Taketomi-cho, Iriomotejima Island, Yaeyama Isis., Japan)." 13498. Schneider, T. (2013): Frühsommer-Beobachtungen an *Cordulegaster helladica buchholzi* und anderen Libellen auf Naxos, Griechenland (Odonata: Cordulegastriidae). *Libellula* 32(3/4): 151-158. (in German, with English summary) ["Early summer observations of *Cordulegaster helladica buchholzi* and other dragonflies on Naxos (Greece) - In June 2013 during a two day trip 17 dragonfly species were recorded from Naxos. *Cordulegaster helladica buchholzi* was found in great numbers exclusively in the upper part of a single river system. This subspecies might be threatened by further water extraction from the brook and by the cutting of the forests along the water courses. *Aeshna affinis* and *Trithemis annulata* are new for the island, increasing the number of known taxa from 19 to 21. *Sympetma fusca* was rediscovered since the report of K.F. Buchholz more than 50 years ago." (Author)] Address: Schneider, T., Arnold-Knoblach-Ring 76, 14109 Berlin/Wannsee, Germany. E-mail: thomas.rs@gmx.de

13499. Seehausen, M. (2013): Die Libellen (Odonata) der Sammlung Gerning. *Libellula* 32(1/2): 45-58. (in German, with English abstract) ["The Odonata of the collection Gerning – The Gerning collection of the Wiesbaden Museum is partly over 250 years old and one of the most important collections of the 18th century. Beside butterflies, beetles and other insects it contains also Odonata. These were revised and catalogued. Altogether 92 individuals in 44 species could be assigned to the collection. Furthermore, there are 25 specimens in 13 species from Java collected by Ernst Albert Fritze, two *Sympetrum vulgatum* from an unknown collector (abbreviation "K") and one unidentified *Aeshnidae* larvae without label in this collection by mistake. In comparison to the 1830 committed catalogue (Gerning n.y.) there are 41 specimens of the Coll. Gerning missing. Two males of *Uracis imbuta* (Burmeister, 1839) from Buenos Aires were certified according to the citation of Rambur (1842). Problems when dealing with historical references and collections are mentioned." (2013): Research of trematodes digenetics from *Heleobia* spp. (Mollusca: Hydrobiidae) in area of occurrence of equine monocytic ehrlichiosis, in Rio Grande do Sul, Brazil. *Arq. Inst. Biol.*, São Paulo 80(3): 266-272. (in Portuguese, with English summary) ["The equine monocytic ehrlichiosis in the region South of the Rio Grande do Sul has demonstrated to be important in the creations of Crioulo horses. It has been reported as cause of diarrhea in equine not surround and as cause of losses with treatments and death of the animals, being pointed as a limited factor in the range breeding in some regions. The way of transmission for the oral way, intermediated for trematodes in aquatic environments, has been supported. Freshwater snails are involved as intermediate hosts of trematodes and harbor of the *Neorickettsia risticii*. A total of 16,846 *Heleobia* snails had been collected in the cities of Arroio Grande, Rio Grande, Palmares do Sul and Santa Vitoria do Palmar, 92.2% of which had been found in the roots of aquatic plants (*Eichornea* spp.). The frequency of trematodes present in the snails varied of 2.3 to 12.8% in the collected regions. Three types of cercariae were found, morphology type 1, morphology type 2 and morphology type 3, and two morphologic type of metacercariae of the snails. A total of 357 insects of the Odonata order were collected, stages of metacercariae had been found in the tissues of suborder Anisoptera with 5.3% of frequency. More studies are necessary for identification of the joined larval phases, as well as knowing the host definitive and identifying the adult parasite and the relation of its cycle of life with the occurrence of equine monocytic ehrlichiosis." 13506. Stewart, B.A.; Close, P.G.; Cook, P.A.; Davies, P.M. (2013): Upper thermal tolerances of key taxonomic groups of stream invertebrates. *Hydrobiologia* 718: 131-140. (in English) ["Southwestern Australia has already undergone significant climatic warming and drying and water temperatures are increasing particularly in small streams where riparian vegetation has been cleared. The ability to predict how freshwater fauna may respond to these changes requires understanding of their thermal tolerances. A review of relevant literature and laboratory testing of four aquatic species from southwestern Australia were used to compare upper thermal tolerance (UTT) among key taxonomic groups. UTT for selected species determined by LT50 tests were similar to that of species tested elsewhere. Mean UTT, based on relevant literature and LT50 experiments, ranged from 22.3°C for Ephemeroptera to 43.4°C for Coleoptera. Mean UTT for both Coleoptera and Odonata (41.9°C) were significantly higher than those for all the other groups (22.3–31.5°C) with the exception of Planaria. The mean UTT value of 22.3°C for Ephemeroptera was significantly lower than for Decapoda (29.6°C), Trichoptera (30.1°C) and Mollusca (31.5°C). For three insect orders tested, eurytherms had significantly higher UTT values than stenotherms. The variation in UTT among taxa suggests that additional thermal shifts, caused by riparian disturbance and/or climate change, are likely to create novel assemblages due to the replacement of temperature-sensitive taxa by more tolerant taxa. This has im-

plications for the sustainability of regionally important endemic cool water species." (Authors)] Address: Stewart, Barbara, Centre of Excellence in Natural Resource Management, Univ. of Western Australia, Albany, WA 6330, Australia. E-mail: barbara.cook@uwa.edu.au

13508. Svensson, E.I.; Waller, J.T. (2013): Ecology and sexual selection: Evolution of wing pigmentation in calopterygid damselflies in relation to latitude, sexual dimorphism, and speciation. *The American Naturalist* 182(5): E174-E195. (in English) ["Our knowledge about how the environment influences sexual selection regimes and how ecology and sexual selection interact is still limited. We performed an integrative study of wing pigmentation in calopterygid damselflies, combining phylogenetic comparative analyses, field observations and experiments. We investigated the evolutionary consequences of wing pigmentation for sexual dimorphism, speciation, and extinction and addressed the possible thermoregulatory benefits of pigmentation. First, we reconstructed ancestral states of male and female phenotypes and traced the evolutionary change of wing pigmentation. Clear wings are the ancestral state and that pigmentation dimorphism is derived, suggesting that sexual selection results in sexual dimorphism. We further demonstrate that pigmentation elevates speciation and extinction rates. We also document a significant biogeographic association with pigmented species primarily occupying northern temperate regions with cooler climates. Field observations and experiments on two temperate sympatric species suggest a link between pigmentation, thermoregulation, and sexual selection, although body temperature is also affected by other phenotypic traits such as body mass, microhabitat selection, and thermoregulatory behaviors. Taken together, our results suggest an important role for wing pigmentation in sexual selection in males and in speciation. Wing pigmentation might not increase ecological adaptation and species longevity, and its primary function is in sexual signaling and species recognition." (Authors)] Address: Svensson, E.I., Evol. 13509. Swaegers, J.; Mergeay, J.; Therry, L.; Bonte, D.; Larmuseau, M.H.D.; Stoks, R. (2013): Rapid range expansion increases genetic differentiation while causing limited reduction in genetic diversity in a damselfly. *Heredity* 115(4): 422-429. (in English) ["Many ectothermic species are currently expanding their geographic range due to global warming. This can modify the population genetic di-

versity and structure of these species because of genetic drift during the colonization of new areas. Although the genetic signatures of historical range expansions have been investigated in an array of species, the genetic consequences of natural, contemporary range expansions have received little attention, with the only studies available focusing on range expansions along a narrow front. We investigate the genetic consequences of a natural range expansion in the Mediterranean damselfly *Coenagrion scitulum*, which is currently rapidly expanding along a broad front in different directions. We assessed genetic diversity and genetic structure using 12 microsatellite markers in five centrally located populations and five recently established populations at the edge of the geographic distribution. Our results suggest that, although a marginal significant decrease in the allelic richness was found in the edge populations, genetic diversity has been preserved during the range expansion of this species. Nevertheless, edge populations were genetically more differentiated compared with core populations, suggesting genetic drift during the range expansion. The smaller effective population sizes of the edge populations compared with central populations also suggest a contribution of genetic drift after colonization. We argue and document that range expansion along multiple axes of a broad expansion front generates little reduction in genetic diversity, yet stronger differentiation of the edge populations." 13511. Tatarkiewicz, D. (2013): Analysis of the emergence of the Scarce Chaser *Libellula fulva* O.F. Müller, 1764 (Odonata: Libellulidae). *Aquatic Insects* 34(3-4), (2012): 173-193. (in English) ["*L. fulva* is widespread in Europe and in many regions is relatively common. It is also

abundant in the lake districts of western and northern Poland. Although the species frequently occurs in large numbers its biology is poorly known. Emergence of *L. fulva* was investigated in this study as a contribution to the life history of the species. Studies were carried out in the vicinity of Chojno (52°41' N, 16°12' E) on the edge of the Notecka Forest in 2003 and 2004. The stem habitat of the population is a stream with the adjacent swamps. *L. fulva* belongs to the spring species sensu Corbet (1999). The emergence of the studied population lasted 19 days (between 18 May and 5 June) and 31 days (between 13 May and 12 June) in 2003 and 2004, respectively. It was characterized by synchronous and, especially in the first phase, mass emergence. The high synchronisation is reflected in the fact that 50% of the population had emerged by the seventh (in 2003) and the fifth (in 2004) days of the process. This is vital to the imagines, which mature and return to the water body as soon as possible to reproduce. Timing of the end of emergence depends on atmospheric conditions during its duration and the conditions preceding the start of emergence on a given day. In the daily course there is a tendency for emergence to finish as soon as possible. Extension of the emergence is synonymous with increased mortality in the dragonfly population caused by predators." 13516. Tsai, F.-Y.; Chi, K.-j. (2013): Wing deformation of dragonfly: Aerodynamic effects and flapping. MSc.thesis, Faculty of Science> Institute of Biological Physics, Chung Hsing University, Institute of Biophysics: (in Chinese, with English summary) ["Pterostigma is a darken region at the leading edge of the wings of many insects. It is bilayer in structure, and is thicker and heavier than the other cells of the wing. Previous study shows that a dragonfly wing with pterostigma would increase wing's bending deformation at same vibration frequency and amplitude. In this study, I further examined the mechanical characteristics and consequences of pterostigma of dragonfly wings. Firstly, I controlled the vibration amplitudes of the wing base to explore how they affect wing's bending deformation. Secondly, I applied flow visualization technology to examine the effects of pterostigma, and hence difference in bending deformation, on the flow behaviours around the flapping wings. Because of the limits of our experimental setup, I used lower vibration frequency for wings in lower wind speed to meet similarity of Strouhal number. The results show that, whether the wing had pterostigma, the wing's bending deformation was greater when the amplitude increased; however, the effect is more pronounced in wings with pterostigma. Furthermore, the Y-position of pterostigma (i.e. the amplitude of pterostigma) increased with the amplitude of wing base, indirectly implying that a flapping wing with greater bending deformation would also have higher pterostigma position. Results from the wind tunnel experiments show that removal of pterostigma would change the range and angles of wing's angle of attack. However, the effects of pterostigma on the behaviours of vortices are not conclusive." (Authors)] Address: not stated

13517. Ueda, T.; Hiroshi, J. (2013): The ecological impact of the insecticides fipronil and Imidacloprid on Sym-

petrum frequens in Japan. Tombo 55: 1-12. (in Japanese, with English summary) ["Recently the dramatic decline in population numbers of *Sympetrum frequens* has been manifest and was repeatedly reported on by many mass media in Japan. Here we reviewed the studies related to the problem. It appears that the sharp decline began in the late 1990's and numbers dropped to 1 % or less of previous population size, with regional differences. The major factor in the decline would be the application of insecticides fipronil and imidacloprid to seedling in the nursery box, and the subsequent transplanting of these into paddies. Several laboratory tests and field experiments have revealed that these new type insecticides directly and/or indirectly caused extremely high mortality in larvae of the dragonfly. A simple simulation model that reflects larval mortality caused only by these insecticides predicted well the decline pattern in some districts in Japan. The decrease of planted rice acreage since 1970 and agricultural improvement since 1963 may have caused a long-term decline in the population numbers of *S. frequens*." 13518. Vanappelghem, C.; Houard, X.; Jolivet, S. (2013): Observations de *Chalcolestes parvidens* en Corse (Odonata: Lestidae). *Martinia* 29(2): 139-146. (in French, with English summary) ["Two surveys carried out in Corsica in June 2011 and June/July 2013 have revealed two new localities of *C. parvidens*. Localities where the genus *Chalcolestes* was observed are described. Both the criteria to identify of the females and the habitats of *C. parvidens* are discussed." (Authors)] Address: Vanappelghem, C., Conservatoire d'espaces naturels du Nord et du Pas-de-Calais, 152 boulevard de Paris. F-62190 Lillers, France. E-mail: cedric.vanappelghem@espaces-naturels.fr

13519. Vanappelghem, C.; Quevillart, R. (2013): Emergence d'*Epitheca bimaculata* sur les étangs de la Forge à Glageon (Nord) (Odonata: Corduliidae). *Martinia* 29(2): 125-138. (in French, With English summary) ["The ponds « étangs de la Forge » host the most important population of *Epitheca bimaculata* in the Nord-Pas-de-Calais region (Northern France). Some scheduled works on these ponds have led us to study the population, particularly in comparing the two ponds of the site. The emergence pattern and supports were described in 20 plots where 580 exuviae were collected. The emergences began in early May and ended on 20 May. The EM50, the cumulative emergence median, lasted seven days. We estimated that the emerging population size in 2009 was about 3000 individuals, one of the ponds being more favorable for the species. Over 66 % of the 580 collected exuviae were located more than 5 m from the water. Nearly 90 % of exuviae were found below 50 cm high. The results show that *E. bimaculata* emerges preferentially in the herbaceous layer. Finally, proposals for the conservation of the species on the site and in the area are made, including the treatment of the riparian and the

surrounding vegetation." (Authors)] Address: Vanappelghem, C., Conservatoire d'espaces naturels du Nord et du Pas-de-Calais, 152 boulevard de Paris. F-62190 Lillers, France. E-mail: cedric.vanappelghem@espaces-naturels.fr

13520. Wagh, P.; Kurhade, S. (2013): Odonata of Nandur Madhmeshwar wetland, a proposed RAMSAR site in Maharashtra, India. *Notulae Odonatologicae* 8(2): 32-35. (in English) ["In total, 21 common and widespread species are listed and their local status of abundance is marked. The documented odonate diversity is high as compared to the Ujani and Nathsagar wetlands of Maharashtra. Since the wetland fulfills some important IBA criteria, it is a prime candidate for a Ramsar site in Maharashtra." 13523. White, M.R.; Switzer, P.V. (2013): Examining the causes of rarity for the Odonata of Illinois. Transactions of the Illinois State Academy of Science 106: 13-14. (in English) ["Odonata play an important role in habitat management and conservation, but our understanding of the causes of commonness versus rarity in this group is limited. In this study we examined the causes of rarity for the Odonata of Illinois. Using S-ratings for conservation status and published habitat classifications for Illinois odonates, we investigated whether habitat type (lotic versus lentic) or habitat specificity (whether they were limited to a specific type of aquatic habitat) was related to commonness. We found that lotic species and habitat specialists were more likely to be rare than lentic and generalist species. More information, however, is needed on the distributions and natural histories of Illinois odonates if we are to more fully understand the causes of rarity in this important group." 13525. Witt, J.W.; Forkner, R.E.; Kraus, R.T. (2013): Habitat heterogeneity and intraguild interactions modify distribution and injury rates in two coexisting genera of damselflies. Freshwater Biology 58(11): 2380-2388. (in English) ["(1) Sublethal effects of predation can affect both population and community structure. Despite this, little is known about how the frequency of injury varies in relation to habitat, aquatic community characteristics or between trophically similar, coexisting taxa. (2) In a tidal freshwater ecosystem, we first examined injuries (lamellar autotomy) of Enallagma and Ischnura damselfly larvae, which have unique behaviours and susceptibilities to predation, as a function of habitat type, body size and overall odonate density. We also examined relative abundance of these genera and potential anisopteran predators as a function of habitat type. (3) The frequency of injury to Enallagma was high when larvae were small and overall odonate density was high. For Ischnura, however, the frequency of injury depended on habitat and was high for small larvae in less disturbed habitats low on the shore. Ischnura were most frequently found in more disturbed habitats high on the shore, whereas Enallagma were more frequently found in less disturbed habitats low on the shore. (4) The relative importance of factors hypothesised to structure odonate communities varied between coexisting Enallagma and Ischnura. Distinctive distributions and patterns of injury for each genus provided new insights on the potential for intraguild inter-

actions to modify habitat associations in tidal freshwater ecosystems." (Authors)] Address: Witt, J.W., U.S. Environmental Protection Agency, Global Change Research Program, U.S. EPA – ORD, Mail Code: 8601P 1200 Pennsylvania Avenue, NW, Washington, DC 20460, USA. E-mail: witt.jonathan@epa.gov

13526. Wünsch, H.-W.; Gospodinova, H.; Heydrich, W. (2013): Beobachtungen zum Fortpflanzungsverhalten von *Sympecma fusca* (Odonata: Lestidae). Libellula 32(3/4): 187-192. (in German, with English summary) ["In the first days of spring 2012, between 23 March and 27 March, we observed some reproductive behavior of approximately 100 individuals of *Sympecma fusca* at different ponds in North Rhine-Westphalia, Germany. A lot of males competing for females impeded many copulations. An example of female refusal behaviour was documented by photos." 13528. Zawal, A.; Buczyński, P. (2013): Parasitism of Odonata by *Arrenurus* (Acari: Hydrachnidia) larvae in the Lake Świdwie, nature reserve (NW Poland). Acta Parasitologica 58(4): 486-495. (in English) ["Larvae of a vast majority of water mite species are parasites of aquatic insects. Owing to this, they migrate to new localities, and are able to survive unfavourable environmental conditions. This also concerns species from subgenus *Arrenurus* s. str., parasites of dragonflies. The detailed analysis of this phenomenon, however, has only been possible in the last several years, since the key to the identification of larvae from genus *Arrenurus* Dug. was published. In 2010, the parasitism of *Arrenurus* s. str. larvae on dragonflies in the Lake Świdwie reserve (NW Poland) was analysed. Larvae of 9 species of water mites were recorded on 107 imagines of dragonflies from 8 species. The following were identified as hosts of water mites for the first time: *Anax imperator*, *Libellula quadrimaculata*, and *Leucorrhinia caudalis*. The highest prevalence occurred in the case of: *Erythromma najas* and *Lestes dryas* (100%), *Coenagrion pulchellum* (96.5%), and *C. puella* (80.0%). *Coenagrion pulchellum* was in-

fested by 9 species of parasites, *C. puella* by 6, and *Erythromma najas* and *Lestes dryas* by three species. The highest number of host species occurred in the case of *Arrenurus maculator* (5); followed by *A. cuspidator*, *A. batillifer* cf., *A. bicuspidator*, and *A. tetracyphus* (3 each); *A. papillator*, *A. tricuspikator*, and *A. bruzelii* (2 each), and *A. claviger* (1). Differentiation of preferences of particular parasites towards various parts of the host body was observed, probably related to the coevolution of parasites and hosts, and competition between the host species. The body sizes of the parasites suggest that approximately 50% of body size growth of water mites from subgenus *Arrenurus* s. str. occurs at the stage of parasitic larva." (2014): Patterns in the organization of Cerrado pond biodiversity in Brazilian pasture landscapes. *Hydrobiologia* 723: 87-101. (in English) ["There is a worldwide concern on the loss of pond biodiversity in human dominated landscapes. Nevertheless, agricultural activities appear to increase pond number in the Brazilian Cerrado through damming streams for cattle raising. These man-made ponds may represent important landscape features, but their importance to regional biodiversity has not yet been studied. Here, we evaluated differences in alpha and beta diversity under a multi-taxonomic approach, as well as tested pond size as the main driver of local species richness. We also assessed the importance of environmental heterogeneity through the analysis of the regional species accumulation curves (SAC). The overall result suggests that species turnover was the major component of regional biodiversity for all groups. Major physical and chemical water conditions had no effects on algae, macrophytes, water bugs, and birds species richness. Pond size had a significant effect on Odonata and fish species richness, while water beetles and amphibians were influenced by trophic conditions. Results from regional SAC show variations among different taxonomic groups regarding landscape heterogeneity: only algae, fish, and birds do not reached to an asymptote and had higher z-values. Our results highlight the importance of ponds for biodiversity conservation in increasingly agricultural landscapes in central Brazil." 13532. Degabriele, G. (2014): An overview of the dragonflies and damselflies of the Maltese Islands (Central Mediterranean) (Odonata). *Bulletin of the Entomological Society of Malta* 6 (2013): 5-127. (in English) ["17 species of odonates have been recorded on the Maltese Islands of which *Pantala flavescens* represents a new record. Diagnostic features of the adult and larval stages of these species are described in this work. The work also combines findings from previous literature on Maltese Odonata with information gathered from fieldwork data in order to give an insight on the current situation of the Odonata of the Maltese Islands and serves as an identification guide to both adults and larvae of these insects. The anatomy and physiology of the larval and adult forms of these insects, which are discussed in this work, are adapted to the predatory lifestyle which they lead. The fact that odonate larvae frequent different habitats from adults helps to reduce competition for resources. Adult odonates can be found in a number of local habitats, mostly near freshwater but also brackish water bodies since freshwater is a scarce natural resource on the Maltese Islands. Global warming is affecting the distribution range of odonates in the Mediterranean - while some species may be on the decline, others which can thrive in

hot dry environments are progressively being recorded in the Mediterranean and southern Europe, including the Maltese Islands. Relatively little work on the Odonata of the Maltese Islands has been done previous to the present work. Most of this involves listing of locally recorded species; very little research investigates odonate behaviour and distribution. No information exists as to why species such as *Sympetrum striolatum*, and *Orthetrum cancellatum* have become progressively uncommon in recent years, and therefore more research is required on the matter. Because of limiting water resources, freshwater habitats on the Maltese Islands are quickly drained of water, which may be used for agricultural purposes. This may tend to reduce species richness of local odonates. Biologists are now considering dragonflies as biological indicators of a healthy environment and make recommendations in order to preserve the habitats frequented by these insects." 13533. Dijkstra, K.-D.B.; Monaghan, M.T.; Pauls, S.U. (2014): Freshwater biodiversity and aquatic insect diversification. *Annual Review of Entomology* 59: 143-163. (in English) ["Inland waters cover less than 1% of Earth's surface but harbor more than 6% of all insect species: Nearly 100,000 species from 12 orders spend one or more life stages in freshwater. Little is known about how this remarkable diversity arose, although allopatric speciation and ecological adaptation are thought to be primary mechanisms. Freshwater habitats are highly susceptible to environmental change and exhibit marked ecological gradients. Standing waters appear to harbor more dispersive species than running waters, but there is little understanding of how this fundamental ecological difference has affected diversification. In contrast to the lack of evolutionary studies, the ecology and habitat preferences of aquatic insects have been intensively studied, in part because of their widespread use as bioindicators. The combination of phylogenetics with the extensive ecological data provides a promising avenue for future research, making aquatic insects highly suitable models for the study of ecological diversification." (Authors) The study includes data on Odonata.] Address: Dijkstra, K.D., Netherlands Centre for Biodiversity Naturalis, P.O. Box 9517, NL-2300 RA, Leiden, The Netherlands. E-mail: dijkstra@nbn.nl

13534. Dohrmann, M. (2014): The influence of ignoring secondary structure on divergence time estimates from ribosomal RNA genes. *Molecular Phylogenetics and Evolution* 71: 214-223. (in English) ["Highlights: •Model choice can have an influence on molecular divergence time estimates. •For rDNA paired regions this has only been investigated once. •reinvestigate this issue using empirical data. •Ignoring structure biases age estimates but this is negligible in a Bayesian setting. •The bias is not randomly distributed across nodes. Genes coding for ribosomal RNA molecules (rDNA) are among the most popular markers in molecular phylogenetics and evolu-

tion. However, coevolution of sites that code for pairing regions (stems) in the RNA secondary structure can make it challenging to obtain accurate results from such loci. While the influence of ignoring secondary structure on multiple sequence alignment and tree topology has been investigated in numerous studies, its effect on molecular divergence time estimates is still poorly known. Here, I investigate this issue in Bayesian Markov Chain Monte Carlo (BMCMC) and penalized likelihood (PL) frameworks, using empirical datasets from dragonflies (Odonata: Anisoptera) and glass sponges (Porifera: Hexactinellida). My results indicate that highly biased inferences under substitution models that ignore secondary structure only occur if maximum-likelihood estimates of branch lengths are used as input to PL dating, whereas in a BMCMC framework and in PL dating based on Bayesian consensus branch lengths, the effect is far less severe. I conclude that accounting for coevolution of paired sites in molecular dating studies is not as important as previously suggested, as long as the estimates are based on Bayesian consensus branch lengths instead of ML point estimates. This finding is especially relevant for studies where computational limitations do not allow the use of secondary-structure specific substitution models, or where accurate consensus structures cannot be predicted. I also found that the magnitude and direction (over- vs. underestimating node ages) of bias in age estimates when secondary structure is ignored was not distributed randomly across the nodes of the phylogenies, a phenomenon that requires further investigation." 13535. Dow, R.A.; Silviu, M.J. (2014): Results of an Odonata survey carried out in the peatlands of Central Kalimantan, Indonesia, in 2012. *Faunistic Studies in South-East Asian and Pacific Island Odonata* 7: 1-37. (in English) ["The results of a survey of Odonata (dragonflies and damselflies) in the peatlands of Central Kalimantan, Indonesia, in 2012 are presented. Fifty four species of Odonata found in the area in June-July 2012 are listed, along with brief notes and the locations in which they were found. Of the species found, twelve had not been recorded in Central Kalimantan previously, and of these at least four are completely new to science. Six species, originally described from Central Kalimantan and not recorded any-where since 1953, were rediscovered. At least sixteen of the species found during the survey are considered to be of conservation concern. The discovery of at least four new species to science in a relatively short survey indicates a high probability of occurrence of many more species that are awaiting discovery, and that many undiscovered species may be lost or highly threatened because of the rapid demise of peat swamp forest habitats. A checklist of the Odonata known from Central Kalimantan is provided in an appendix." (Authors)] Ad-

dress: Dow, R.A., Naturalis Biodiversity Centre, P.O. Box 9517, 2300 RA Leiden, The Netherlands. E-mail: rory.dow230@yahoo.co.uk

13536. Faithpraise, F.; Chatwin, C.; Obu, J.; Olawale, B.; Young, R.; Birch, P. (2014): Sustainable control of *Anopheles* mosquito population. *Environment, Ecology & Management*, Vol 2014, Article ID 3: 19 pp. (in English) ["Despite the widespread use of insecticides, community engagement programmes and preventive measures mosquito borne diseases are growing and new tools to prevent the spread of disease are urgently needed. An alternative control measure for the eradication of *Anopheles* mosquitoes is suggested by the use of a Sustainable Control Model, which demonstrates the capability of Odonata, a natural beneficial predator, to exercise control over *Anopheles* mosquitoes in less than 140 days." 13538. Grant, M.; Robinson, A.; Fincke, O.M. (2014): Use of stable isotopes to assess the intraspecific foraging niche of males and female colour morphs of the damselfly *Enallagma hageni*. *Ecological Entomology* 39(1): 109-117. (in English) ["(1) For the first time, diet and isotopic niche overlap among males and two female-specific colour

morphs of a damselfly were quantified to test whether sexual conflict could cause intra-sexual diet variation. (2) Relative to the green female morph, blue females, similar in coloration to the blue males, may be more likely overlooked by mate-searching males. If so, blue females should be more likely to forage unmolested at lake shores, where the density of males and prey is high. The blue morph's isotopic niche space should therefore differ from that of green females and be more similar to that of males. (3) Stable isotope analyses of two Michigan populations failed to support these predictions. Despite population differences in $\delta^{13}\text{C}$ and diet, within sites isotopic niches overlapped among males and females, with little difference between the two female colour morphs. (4) Males exhibited the broadest isotopic niche area, which increased across years, whereas that of blue females became more restricted, possibly due to greater sexual harassment in forest feeding sites. (5) There was an unexpectedly high shift in $\delta^{13}\text{C}$ from prey to predator. Future work is merited to determine whether such trophic shifts are characteristic of Odonata, a group of important aquatic and terrestrial predators." 13539. Groner, M.L.; Rollins-Smith, L.A.; Reinert, L.K.; Hempel, J.; Bier, M.E.; Relyea, R.A. (2014): Interactive effects of competition and predator cues on immune responses of leopard frogs at metamorphosis. *The Journal of Experimental Biology* 217: 351-358. (in English) ["Recent hypotheses suggest that immunosuppression, resulting from altered environmental conditions, may contribute to increased incidence of amphibian disease around the world. Antimicrobial peptides (AMPs) in amphibian skin are an important innate immune defense against fungal, viral and bacterial pathogens. Their release is tightly coupled with release of the stress hormone, norepinephrine. During metamorphosis, AMPs may constitute the primary immune response in the skin of some species because acquired immune functions are temporarily suppressed in order to prevent autoimmunity against new adult antigens. Suppression of AMPs during this transitional stage may impact disease rates. We exposed leopard frog tadpoles (*Lithobates pipiens*) to a factorial combination of competitor (including *Anax junius*) and caged-predator environments and measured their development, growth, and production of hydrophobic skin peptides after metamorphosis. In the absence of predator cues, or if the exposure to predator cues was late in ontogeny, competition caused more than a 250% increase in mass-standardized hydrophobic skin peptides. Predator cues caused a decrease in mass-standardized hydrophobic skin peptides when the exposure was late in ontogeny under low competition, but otherwise had no effect. Liquid chromatography mass spectrometry/mass spectrometry of the skin peptides showed that they may include three previously uncharacterized AMPs in the brevinin and temporin families. Both of these peptide

families have previously been shown to inhibit harmful microbes including *Batrachochytrium dendrobatidis*, the fungal pathogen associated with global amphibian declines. Our study shows that amphibians may be able to adjust their skin peptide defenses in response to stressors that are experienced early in ontogeny and that these effects extend through an important life history transition." 13540. Huang, S.c.; Chiou, T.-h.; Marshall, J.; Reinhard, J. (2014): Spectral sensitivities and color signals in a polymorphic damselfly. *PLoS ONE* 9(1): e87972. doi: 10.1371/journal.pone.0087972: 8 pp. (in English) ["Animal communication relies on conspicuous signals and compatible signal perception abilities. Good signal perception abilities are particularly important for polymorphic animals where mate choice can be a challenge. Behavioral studies suggest that polymorphic damselflies use their varying body colorations and/or color patterns as communication signal for mate choice and to control mating frequencies. However, solid evidence for this hypothesis combining physiological with spectral and behavioral data is scarce. We investigated this question in the Australian common blue tail damselfly, *Ischnura heterosticta*, which has pronounced female-limited polymorphism: andromorphs have a male-like blue coloration and gynomorphs display green/grey colors. We measured body color reflectance and investigated the visual capacities of each morph, showing that *I. heterosticta* have at least three types of photoreceptors sensitive to UV, blue, and green wavelength, and that this visual perception ability enables them to detect the spectral properties of the color signals emitted from the various color morphs in both males and females. We further demonstrate that different color morphs can be discriminated against each other and the vegetation based on color contrast. Finally, these findings were supported by field observations of natural mating pairs showing that mating partners are indeed chosen based on their body coloration. Our study provides the first comprehensive evidence for the function of body coloration on mate choice in polymorphic damselflies." (Authors)] Address: Huang, S.c., Queensland Brain Institute, Univ. Queensland, St Lucia, Queensland, Australia. E-mail: shaochang.huang@uqconnect.edu.au

13541. Ilg, C.; Oertli, B. (2014): How can we conserve cold stenotherm communities in warming Alpine ponds?. *Hydrobiologia* 723: 53-62. (in English) ["Freshwater biodiversity has shown to be highly vulnerable to climate warming, alpine cold stenotherm populations being especially at risk of getting extinct. This paper aims at identifying the environmental factors favouring cold stenotherm species in alpine ponds. This information is required to provide management recommendations for habitats restoration or creation, needed for the mitigation of the effects of climate warming on alpine freshwater biodiversity. Cold stenotherm species richness as well as total (i.e. stenotherm and eurytherm) richness were ana-

lyzed for aquatic plants, Coleoptera and Odonata in 26 subalpine and alpine ponds from Switzerland and were related to environmental factors ecologically relevant for pond biodiversity. Our results confirmed that the set of environmental variables governing pond biodiversity in alpine or subalpine ponds is specific to altitude. Altitude and macrophyte presence were important drivers of cold stenotherm and total species richness, whereas connectivity did not show any significant relation. Therefore, the management of pond biodiversity has to be 'altitude-specific'. Nevertheless, cold stenotherm species from the investigated alpine ponds do not show some specific requirements if compared to the other species inhabiting these ponds. Therefore, both total and cold stenotherm species richness could be favoured by the same management measures." (Authors)] Address: Ilg, Christiane, hepia Geneva Technology, Architecture and Landscape, University of Applied Sciences Western Switzerland, 150 route de Presinge, 1254, Jussy, Geneva, Switzerland. E-mail: christiane.ilg@hesge.ch

13542. Iyengar, V.K.; Castle, T.; Mullen, S.P. (2014): Sympatric sexual signal divergence among North American Calopteryx damselflies is correlated with increased intra- and interspecific male-male aggression. *Behavioral Ecology and Sociobiology* 68(2): 275-282. (in English) ["Divergence of sexual signals in sympatry can arise as a consequence of (1) interspecific competition for resources, (2) selection against maladaptive hybridization, or (3) as a result of selection to reduce the cost of interspecific aggression; termed agonistic character displacement (ACD). Calopterygid damselflies have emerged as a model system for studying the evolution of divergent sexual signals due to the repeated evolution of sympatric species pairs with fully and partially melanized wings. Damselfly wing patterns function during both courtship and territory defense. However, the relative contributions of natural and sexual selection to phenotypic divergence and enhanced isolation in sympatry remain unclear in many cases. Here, we investigated the hypothesis that interference competition, in the form of increased interspecific male-male aggression, drives the evolution of character displacement in sympatry between two species of North American damselflies, *Calopteryx aequabilis* and *C. maculata*, that show no evidence of ecological divergence or ongoing hybridization. In paired behavioral trials, we found that interspecific male aggression related to territory defense varied between site, species, and as a function of the relative abundance of con- vs. hetero-specific males. Specifically, we found that large-spotted *C. aequabilis* males received increased intra- and interspecific aggression but that aggression against large-spotted males declined during the middle of the flight season when both species were equally abundant. Based on these results, we suggest that ACD leads to enhanced species recognition, and may be a common outcome of the antagonism between interspecific male-male competition and the countervailing force of intra-specific sexual selection favoring increased wing melani-

zation among territorial damselfly species." (Authors)] Address: Mullen, S.P., Dept of Biology, Boston University, 5 Cummington Mall, Boston, MA, 02215, USA. E-mail: smullen@bu.edu

13543. Janssens, L.; Stoks, R. (2014): Non-pathogenic aquatic bacteria activate the immune system and increase predation risk in damselfly larvae. *Freshwater Biology* 59(2): 417-426. (in English) [(1) Pathogens can increase vulnerability to predation through their harmful effects on hosts. Recently, it was shown that the mere activation of the immune system by pathogens may increase the host's risk of predation. Here, we test whether exposure to non-pathogenic bacteria also activates the immune system and thereby increases vulnerability to predation. (2) We exposed *Enallagma cyathigerum* damselfly larvae to a non-pathogenic strain of the bacterium *Escherichia coli* and measured immune defence, anti-predator behaviour and survival times in the presence of larval dragonfly predators. To evaluate whether non-pathogenic bacteria also generated energy-based trade-offs leading to other fitness costs, we also quantified growth rate and survival in the absence of predators. (3) Exposure to the non-pathogenic bacterium did not affect survival in the absence of the predator but increased growth rate, possibly a response to reduce exposure time to the bacterium. Larvae exposed to the bacterium activated their immune response as shown by an increase in the activity of phenoloxidase and the number of haemocytes. The bacterium affected anti-predator traits involved in avoiding detection by predators as well as traits involved in escape after detection. Pre-exposed larvae showed higher activity levels and further increased the number of feeding strikes in the presence of predation risk, possibly driven by energetic constraints. Pre-exposed larvae swam less often when attacked, but faster. This impaired anti-predator response came at the ecological cost of increased vulnerability to predation. (4) Our study demonstrated that exposure to non-pathogenic bacteria increases vulnerability to predation, which is a novel type of antagonistic interaction. This highlights the unexplored possibility that non-pathogens may play a role in maintaining variation in immune defence through insidious effects on predator-prey interactions. Since non-pathogenic bacteria can be very abundant, this unexplored ecological cost of immune system activation in terms of increased predation may have major consequences in natural systems and may provide an unexplored new force underlying variation in immune defence." 13544. Kalita, G.J.; Boruah, B.; Das, G.N. (2014): An observation on odonata (damselflies and dragonflies) fauna of Manchabandha reserve forest, Baripada, Odisha. *Advances in Applied Science Research* 5(1): 77-83. (in English) [India; the area is located at 21°54'21.23"N &

86°45'10.35" E. 48 Odonata species were recorded between September 2012 and October 2013, covering all 3 seasons viz. summer (March to June), monsoon (July to October) and winter (November to February).] Address: Kalita, G.J., Department of Wildlife & Biodiversity Conservation, North Orissa University, India

13545. Kaur Kohli, M.; Schneider, T.; Müller, O.; Ware, J.L. (2014): Counting the spots: a molecular and morphological phylogeny of the spotted darner *Boyeria* (Odonata: Anisoptera: Aeshnidae) with an emphasis on European taxa. *Systematic Entomology* 39: 190-195. (in English) ["*Boyeria irene* and *B. cretensis* are species of spotted dragonflies belonging to the 'darner' family, Aeshnidae. In 1991, Peters classified *Boyeria* from Crete as *B. cretensis*, based on adult morphological characters. In this study, we used molecular evidence to determine if indeed *B. irene* and *B. cretensis* are different species. DNA was sequenced from samples of *B. irene* (from France, Switzerland, Tunisia, Spain and Italy) and *B. cretensis* (from Crete). These species were recovered as two different clades with strong support. We conclude that *B. irene* and *B. cretensis* are different species, with evidence based on molecular and morphological differences. In addition, we present the first phylogenetic hypothesis for *Boyeria* for which we have sequenced all but three species. Lastly, we discuss different scenarios that may have led to the present-day distribution and speciation patterns of Mediterranean *Boyeria*." 13546. Kissling, W.D.; Pattemore, D.E.; Hagen, M. (2014): Challenges and prospects in the telemetry of insects. *Biological Reviews*: (in English) ["Radio telemetry has been widely used to study the space use and movement behaviour of vertebrates, but transmitter sizes have only recently become small enough to allow tracking of insects under natural field conditions. Here, we review the available literature on insect telemetry using active (battery-powered) radio transmitters and compare this technology to harmonic radar and radio frequency identification (RFID) which use passive tags (i.e. without a battery). The first radio telemetry studies with insects were published in the late 1980s, and subsequent studies have addressed aspects of insect ecology, behaviour and evolution. Most insect telemetry studies have focused on habitat use and movement, including quantification of movement paths, home range sizes, habitat selection, and movement distances. Fewer studies have addressed foraging behaviour, activity patterns, migratory strategies, or evolutionary aspects. The majority of radio telemetry studies have been conducted outside the tropics, usually with beetles (Coleoptera) and crickets (Orthoptera), but bees (Hymenoptera), dobsonflies (Megaloptera), and dragonflies (Odonata) have also been radio-tracked. In contrast to the active transmitters used in radio telemetry, the much lower weight of harmonic radar

and RFID tags allows them to be used with a broader range of insect taxa. However, the fixed detection zone of a stationary radar unit (<1 km diameter) and the restricted detection distance of RFID tags (usually <1–5 m) constitute major constraints of these technologies compared to radio telemetry. Most of the active transmitters in radio telemetry have been applied to insects with a body mass exceeding 1g, but smaller species in the range 0.2–0.5 g (e.g. bumblebees and orchid bees) have now also been tracked. Current challenges of radio-tracking insects in the field are related to the constraints of a small transmitter, including short battery life (7–21 days), limited tracking range on the ground (100–500 m), and a transmitter weight that sometimes approaches the weight of a given insect (the ratio of tag mass to body mass varies from 2 to 100%). The attachment of radio transmitters may constrain insect behaviour and incur significant energetic costs, but few studies have addressed this in detail. Future radio telemetry studies should address (i) a larger number of species from different insect families and functional groups, (ii) a better coverage of tropical regions, (iii) intraspecific variability between sexes, ages, castes, and individuals, and (iv) a larger tracking range via aerial surveys with helicopters and aeroplanes equipped with external antennae. Furthermore, field and laboratory studies, including observational and experimental approaches as well as theoretical modelling, could help to clarify the behavioural and energetic consequences of transmitter attachment. Finally, the development of commercially available systems for automated tracking and potential future options of insect telemetry from space will provide exciting new avenues for quantifying movement and space use of insects from local to global spatial scales." 13547. Koch, K.; Wagner, C.; Sahlén, G. (2014): Farmland versus forest: comparing changes in Odonata species composition in western and eastern Sweden. *Insect Conservation and Diversity* 7(1): 22-31. (in English) ["Despite the loss of natural ecosystems in the developed world during the past millennia, anthropogenic landscapes still sustain much biodiversity. Our question was, whether ten year changes in regional Odonata faunas are comparable between farmland and forested areas, or if the species pool of farmland areas respond in other ways than that of forest. We used data of dragonfly larvae collected from 16 lakes in a farmland area in south-western Sweden in the years 2002 and 2011/12, and compared these to data from 34 lakes in a forest area in south-eastern Sweden in the years 1996 and 2006. The species-richness in the agricultural region increased by 17% but decreased by 13% in the forested region. The changes in occurrence and regional distribution were similar in both areas, affecting 71% and 69% of the species pool. Average extinction rates were comparable between the agricultural and the forested region (38% and

43%) while colonisation rates differed greatly (64% and 114%). The species composition differed between the regions; the forest lakes harboured a 29% larger species pool. It is possible that in the forested region, the regional species pool in areas surrounding the study sites could stabilise the extinction and have a positive effect on changes in species composition. We assume that the different habitat structures of the waters in the agricultural and the forest regions and changes in temperature are the main driving forces behind the shifts. The mean seasonal air temperature has increased by circa 0.5 °C in both regions, when comparing ten-year periods before each sampling year." 13549. Kosterin, O.E. (2014): Odonata of the south-west and north-east of Cambodia as studied in early rainy season of 2013. *International Dragonfly Fund - Report 67*: 1-94. (in English) ["Results of an odonatological survey of the coastal SW regions and continental NE regions of Cambodia in May 22 - June 8, 2013 are presented. All Odonata recorded are listed by localities. Of 107 Odonata species encountered, 104 were identified to species level, of which 15 are reported for the first time for Cambodia, namely *Macromidia genialis shanensis* Fraser, 1927 in Koh Kong Province, *Chalibeothemis fluviatilis* Lieftinck, 1933 in Kampong Saom Province and *Ceriagrion azureum* (Selys, 1891), *Prodasineura coerulea* Fraser, 1932, *Protosticta caroli* van Tol, 2008; *Gomphidia abbotti* Williamson, 1907, *Lamelligomphus castor* (Lieftinck, 1941), *Macrogomphus kerri* Fraser, 1922, *Nychogomphus duaricus* (Fraser, 1924), *Orientogomphus minor* (Laidlaw, 1931), *Macromia aculeata* Fraser, 1927, *Macromia chaiyaphumensis* Hämäläinen, 1985, *Macromia cincta* (Rambur, 1842), *Nesoxenia lineata* (Selys, 1879) and *Palpopleura sexmaculata* (Fabricius, 1787) in Ratanakiri Province. Besides, *Ceriagrion indochinense* Asahina, 1967 is confirmed for Cambodia. Cambodian specimens of *Hemicordulia* sp. are reidentified as *Hemicordulia tenera* ssp. The country list now reaches 152 named species. Of them, most interesting are 5 species with generally Malay ranges: *Archibasis viola*, *Aethriamanta gracilis*, *M. cincta*, *C. fluviatilis* and

Nesoxenia lineata. Characters and/or taxonomy are also discussed of *Vestalis gracilis* (Rambur, 1842), *Euphaea masoni* Selys, 1859, *Rhinagrion viridatum* Fraser, 1938, *Aciagrion* spp., *Archibasis* spp., *P. caroli*, *Gynacantha sub-interrupta* Rambur, 1842, *Idionyx thailandica* Hämäläinen, 1985, *Neurothemis fluctuans* (Fabricius, 1793) and *P. sexmaculata*. Notes on habitats and habits of some species are provided. General notes on the areas and their Odonata as well as field impressions are briefly outlined and illustrated by photos." 13550. Kutcher, T.E.; Bried, J.T. (2014): Adult Odonata conservatism as an indicator of freshwater wetland condition. *Ecological Indicators* 38(1): 31-39. (in English) ["Highlights: • Coefficients of conservatism can be empirically estimated for adult Odonata. • Adult Odonata conservatism can be used to evaluate freshwater wetland condition. • Adult Odonata respond predictably to both in-wetland and buffer disturbances. • Odonata conservatism did not vary with sampling effort, unit size, or wetland class. There is a growing need to identify effective and efficient biological indicators for wetland assessment, and adult Odonata possess several attributes that make them attractive for this application. We introduce a general indicator of freshwater wetland condition based on objectively estimated adult Odonata species conservatism, or sensitivity to human disturbances. We used an extensive opportunistic survey dataset from Rhode Island (USA) to empirically assign a coefficient of conservatism (CoC) to each of 135 Odonata species, based on their exclusivity to categories of degradation among 510 wetlands; the mean CoC of species observed in the adult stage was applied as an index of wetland integrity. An independent sample of 51 wetlands was also drawn from the opportunistic survey to test the performance of the index relative to human disturbance, as measured by multimetric rapid assessment and surrounding impervious surface area. The index was well predicted by both disturbance measures and showed no evidence of dependence on sampling effort, wetland size, or geomorphic class. Our findings suggest that conservatism of adult Odonata averaged across species may provide a robust indicator of freshwater wetland condition. And because adult Odonata are generally easy to identify, especially relative to larval Odonata, the index could be particularly useful for wetland assessment. Our straightforward empirical approach to CoC estimation could be applied to other existing spatially referenced Odonata datasets or to other species assemblages." 13551. Lee, M. (2014): Dragonfly wings: Special structures for aerial acrobatics. In: Lee, M. (ed): Remarkable natural material surfaces and their engineering potential.

Springer: 65-77. (in English) ["Over history, dragonflies have been found across the globe, allowing a rich multitude of culture and symbolism to be developed around these four-winged creatures. For example, in Native American history, dragonflies were symbols of activity and swiftness and were often associated with horses. In Japanese history, these insects were considered to serve as winged mounts for the Hotoke-Sama, or August Spirits of the Ancestors. Among Buddhists, the Hotoke-Sama were thought to return on August 15th, riding dragonflies into their old homes to be reunited with their families (Mitchell and Lasswell, *A dazzle of dragonflies*. Texas A&M University Press, College Station, 2005). Though such folklore may have diffused over time as scientific research dedicated to dragonflies began, fascination with their flying and maneuvering capabilities has not, perhaps even increasing in recent years. One look at the dragonfly's impressive flying abilities can convince that this attention is well afforded: they can fly sideways, forwards and backwards, hover in midair and reverse directions instantaneously, accelerate rapidly, and fly as fast as 50 km/h (Rajabi et al., *J Bionic Eng* 8:165–173, 2011). Although dragonfly wings account for less than 2 % of the total body mass, they are the main enablers of such diverse flight behavior. The membrane of dragonfly wings is thin, transparent, and film-like, supported by a framework of veins (Sun and Bhushan, *CR Mecanique* 340:3–17, 2012). It is also layered and superhydrophobic (Song et al., *Mat Sci Eng A* 457(1–2):254–260, 2007). Wing corrugation increases strength and stiffness and its ability to absorb stress against bending in the spanwise direction (Sun and Bhushan, *CR Mecanique* 340:3–17, 2012). Wing vein structure is hierarchical, consisting of a sandwich structure on the primary level and a multilayered chitinous shell and protein fibril structure on the secondary level (Chen et al., *J Bionic Eng* 9:185–191, 2012). Finally, micro- and nano-scale ripple morphologies reduce pressure drag during flight (Shelton, *Probing question: how do dimples make golf balls travel farther?* <http://news.psu.edu/story/141235/2007/06/18/research/probing-question-how-do-dimples-make-golf-balls-travel-farther>, 2007), while vein-joints contribute to wing flexibility (Donoughe et al., *J Morphol* 272(12):1409–1421, 2011). All of these properties make dragonfly wings an optimal source of bioinspiration for micro-air-vehicles (MAVs) compared to other animals such as hummingbirds and butterflies. Novel designs of MAVs have already been developed based on research of the dragonfly (Ratti & Vachtsevanos, *J Intell Robot Syst* 65:437–455, 2012)." 13557. Martínez-Sanz, C.; Puente-García, S.M.; Rebolledo, E.R.; Jiménez-Prado, P. (2014): Macroinvertebrate richness importance in coastal tropical streams of Esmeraldas (Ecuador) and its use and implications in environmental management procedures. *International Journal of Ecology* Volume 2014, Article ID 253134: 11 pp. (in English) ["This study was aimed at determining the performance of some indices and community attributes frequently used to assess river quality and test the role of macroinvertebrate taxa richness as element of bioindication in several coastal tropical streams of western Esmeraldas (Ecuador). In addition, a macroinvertebrate taxon list of this region was provided for the first time. Thirteen sampled points distributed across nine streams were selected for this study and nineteen parameters and attributes of bioindication were tested. The differences between nonimpact and impact places were evaluated mainly using one-way analysis of variance. Jackknife 2 and Clench were used to estimate the regional richness and the quality of the inventory, respectively. Seventy taxa (principally genus and family) of the main groups of macroinvertebrates were collected. Measured richness and family richness were the best metric followed by BiologicalMonitoringWorking Par-

ty/Colombia (BMWP/Col), Odonata richness, Shannon-Weiner, and EPT richness (Ephemeroptera + Plecoptera + Trichoptera) indices. Only a slight right trend (Ephemeroptera, Trichoptera, and Chironomidae attributes) or incorrect performances (Average Score Per Taxon (ASPT) and % EPT) were showed by frequently used metrics. Finally, several recommendations were made about taxonomic level used, the ranks of quality of taxa richness, and the effort-results relationship in the field of bioindication." 13558. Matlaga, T.H.; Phillips, C.A.; Soucek, D.J. (2014): Insensitivity to road salt: an advantage for the American bullfrog? *Hydrobiologia* 721: 1-8. (in English) ["The health of freshwater ecosystems is negatively affected by a multitude of pollutants. In northern latitudes, road deicing agents enter nearby ponds and waterways elevating chloride concentrations in winter and spring. Few studies have examined how amphibians respond to road salt contamination and no study has focused on the response of an invasive amphibian. We examined the effects of NaCl, the most commonly used deicing agent, on the embryos and tadpoles of the American bullfrog, *Lithobates catesbeianus*, a species that is invasive in many regions around the world. In the first experiment, we exposed *L. catesbeianus* embryos to ecologically relevant levels of chloride for 60 days. The second experiment examined the indirect consequences of chloride contamination by exposing *L. catesbeianus* tadpoles to dragonfly larvae. *Lithobates catesbeianus* did not experience reduced survival, growth, or ability to evade predation in elevated chloride concentrations compared to controls. The lack of a response by *L. catesbeianus* suggests that its population growth will not be negatively impacted by road salt contamination. This result may be good news for *L. catesbeianus*, but raises concern for sympatric amphibians that have to contend with negative impacts of both chloride contamination and non-native *L. catesbeianus*." (Authors)] Address: Matlaga, Tanya, Illinois Natural History Survey, Prairie Res. Inst., Univ. of Illinois, Champaign, IL, 61820, USA. E-mail: matlagat@susqu.edu

13559. Mlynarek, J.J.; Knee, W.; Forbes, M.R. (2014): Explaining susceptibility and resistance to a multi-host parasite. *Evolutionary Biology* 41(1): 115-122. (in English) ["Closely related host species are known to show variation in the level of resistance towards the same or similar parasite species, but this phenomenon is understudied. Such studies are important for understanding the ecological factors that might promote susceptibility or resistance to parasites: in particular, whether one host species is a larger target of selection for the parasite by virtue of being more abundant locally or more regionally widespread than another host species. In this study, we examined the expression of resistance by two closely related species of

damselflies (*Nehalennia irene* and *Nehalennia gracilis*) against an *Arrenurus* water mite species. We show that the host species at each of two isolated sphagnum bogs have statistically indistinguishable levels of prevalence and intensity of infection by mite larvae. Despite having similar measures of parasitism, the regionally less represented species (*N. gracilis*) showed total resistance, whereas the regionally well-represented species (*N. irene*) was completely susceptible. Moreover, the form of resistance expressed by *N. gracilis* was unique, in that the oral glands of the mite were melanised. Also, this mite species was not found outside of isolated bog habitats. These results suggest that there might have been strong historical selection from this mite on the bog specialist, *N. gracilis*, and that this selection may have resulted in resistance evolving to fixation in a series of isolated populations." 13560. Moraes, M.; Ferreira Rezende, C.; Mazzoni, R. (2014): Feeding ecology of stream-dwelling Characidae (Osteichthyes: Characiformes) from the upper Tocantins River, Brazil. *Zoologia* 30(6): 645-651. (in English, with Portuguese summary) ["In this contribution we studied the trophic ecology of four Characidae species from the Cavalo Stream, upper Tocantins River, considering diet overlap and trophic niche breadth. The diet of the four species was composed of adult and immature insects, both autochthonous and allochthonous in origin. Autochthonous items dominated the diet of *Moenkhausia dichroua* (Kner, 1858), *Bryconamericus* sp., and *Creagrutus atrisignum* Myers, 1917. By contrast, allochthonous items were dominant in the diet of *Astyanax bimaculatus* (Linnaeus, 1758). Trophic niche breadth varied among species, with the highest value recorded for *M. dichroua* (0.48), followed by *Bryconamericus* sp. (0.39), *A. bimaculatus* (0.33) and *C. atrisignum* (0.29). Similarity analysis revealed two groups with different patterns of food preference. The first group was composed of insectivorous and the second by omnivorous species. The overlap in food items consumed by the four species studied was high. We suggest that resources are not limited in this stream and that competition might not be regulating these populations. This is one more case corroborating the general pattern registered for Tropical environments, where resource partitioning and specialization are responsible by the organization of fish communities." (Authors) App. 5% of the diet of *Moenkhausia dichroua* are Odonata larvae. In the rest of studied fish species, Odonata play a minor role as prey.] Address: Mazzoni, Rosana, Departamento de Ecologia, Instituto de Biologia Roberto Alcântara Gomes, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, 20550-013 Rio de Janeiro, RJ, Brazil. 13562. Quin, Y.-H.; Wu, H.-Y.; Ji, X.-Y.; Yu, W.-W.; Du, Y.-Z. (2014): Mitochondrial genome of the stonefly *Kamimuria wangi* (Plecoptera: Perlidae) and phylogenetic position of Plecoptera based on mitogenomes. *PLoS ONE* 9(1): e86328. doi:10.1371/journal.pone.0086328: 9 pp. (in English) ["This study determined the mitochondrial genome sequence of the stonefly, *Kamimuria wangi*. In order to investigate the relatedness of stonefly to other members of Neoptera, a phylogenetic analysis was undertaken based on 13 protein-coding genes of mitochondrial genomes in 13 representative insects. The mitochondrial genome of the stonefly is a circular molecule consisting of 16,179 nucleotides and contains the 37 genes typically found in other insects.... Phylogenetic analysis using maximum likelihood and Bayesian inference of 13 protein-coding genes supported a novel relationship between the Plecoptera and Ephemeroptera. The results contradict the existence of a monophyletic Plecoptera and Plecoptera as sister taxa to Embiidina, and thus requires further analyses with additional mitogenome sampling at the base of the Neoptera." 13563. Robin, J.; Wezel, A.; Bornette, G.; Arthaud, F.; Angélibert, S.; Rosset, V.; Oertli, B. (2014): Biodiversity in eutrophicated shallow lakes: determination of tipping points and tools for monitoring. *Hydrobiologia* 723: 63-75. (in English) ["Nutrient-rich freshwater ecosystems are generally considered as having low ecological quality and low associated biodiversity. In such systems we analysed the effects of water quality on biodiversity of several species groups, to determine tipping points and tools for monitoring. We investigated the water quality of 99 eutrophic and hypertrophic shallow lakes with extensive fish culture during a 3-year study, through the measures of physico-chemical parameters, phytoplankton biomass and structure. In a second step, we related the water quality with richness of aquatic plants, macroinvertebrates and dragonflies. With concentrations of chlorophyll-a above 30 or 70 µg l⁻¹, shallow lakes are normally classified, respectively, in a poor or bad ecological state. However, our results show that chlorophyll-a concentra-

tions up to 78 µg l⁻¹ could be found together with relatively high species or family richness of aquatic plants, invertebrates and dragonflies. We identified most tipping points with 50–60 µg l⁻¹ of chlorophyll-a, values above which a significant decrease of species diversity was found. For monitoring of these shallow lakes we propose to use chlorophyll-a concentrations in combination with water transparency during spring. These parameters are easily applicable and cheap and they yield a good forecast of the biodiversity for the species groups studied." (Authors)] Address: Robin, J., Lab. 13564. Sanchez-Guillen, R.A.; Córdoba-Aguilar, A.; Cordero-Rivera, A.; Wellenreuther, M. (2014): Genetic divergence predicts reproductive isolation in damselflies. *Journal of Evolutionary Biology* 27: 76-87. (in English) ["Reproductive isolation is the defining characteristic of a biological species, and a common, but often untested prediction is a positive correlation between reproductive isolation and genetic divergence. Here, we test for this correlation in odonates, an order characterized by strong sexual selection. First, we measure reproductive isolation and genetic divergence in eight damselfly genera (30 species pairs) and test for a positive correlation. Second, we estimate the genetic threshold preventing hybrid formation and empirically test this threshold using wild populations of species within the *Ischnura* genus. Our results indicate a positive and strong correlation between reproductive isolation and genetic distance using both mitochondrial and nuclear genes cytochrome oxidase II (COII: $r = 0.781$ and 18S–28S: $r = 0.658$). Hybridization thresholds range from -0.43 to 1.78% for COII and -0.052–0.71% for 18S–28S, and both F1-hybrids and backcrosses were detected in wild populations of two pairs of *Ischnura* species with overlapping thresholds. Our study suggests that threshold values are suitable to identify species prone to hybridization and that positive isolation–divergence relationships are taxonomically widespread." 13565. Savard, M. (2014): L'anax précoce au Québec: une libellule migratrice. *Le Naturaliste canadien* 138(1): 20-31. (in French, with English summary) ["The northern limits for Québec of the dispersion and breeding ranges of *Anax junius* were updated during work for the Migratory Dragonfly Partnership. The new limits presented are based on scientific literature and previously unpublished data from the Québec Dragonfly Atlas Initiative. Each year, the first adults arriving from the United States of America are reported from the lowlands of the Outaouais and St. Lawrence rivers in May, and exceptionally in late April. The species is also occasionally reported from the Laurentian and Appalachian foothills, and from inhabited

areas along the shores of the Estuary and the Gulf of the St. Lawrence River between the 47th and 50th parallels north. In the extreme southern part of Québec, the emergence of overwintering populations is occasionally observed in June or early July. In the temperate deciduous region of the province, the emergence of summer populations regularly occurs from mid-August to early October. In the temperate mixed region found in the Témiscouata area, emergences may occur and this might also be the case in the Saguenay–Lac-Saint-Jean area. According to the climate model proposed by Gérardin and McKenney (2001), the northern limit of the breeding range of the common green damer could reach the 49th parallel, following the 15.7°C isotherm for the warmest three summer months. Therefore, it seems unlikely that this species is able to complete its life cycle in boreal regions, such as on Anticosti Island. Climate change could be marked by an earlier arrival of immigrant adults in the spring, and by an increase in the frequency of the emergence of overwintering and summer populations of naiads." 13566. Shantibala, T.; Lokeshwari, R.K.; Debaraj, H. (2014): Nutritional and antinutritional composition of the five species of aquatic edible insects consumed in Manipur, India. *Journal of Insect Science* 14(14): 10 pp. (in English) ["The people living in Manipur have a distinct identity, culture, and food habits. They have a prototype culture of eating insects. In our study, the nutritive contents of five potentially-edible aquatic insects, *Lethocerus indicus* (Lepeletier and Serville) (Hemiptera: Belostomatidae), *Laccotrephes maculatus* (F.), *Hydrophilus olivaceus* (F.) (Coleoptera: Dytiscidae), *Cybister tripunctatus* (Olivier), and *Crocothemis servilia* (Drury) (Odonata: Libellulidae), were analyzed to inform consumers about the nutritional quality of the insects and the suggested quantity of their intake. A good amount of protein content and high gross energy was recorded among the insects. The results showed high levels of sodium, calcium, and magnesium present in the insects, indicating that they are a good source of minerals. Antinutritional properties of these insects were below 0.52%, which is a non-toxic level. Aquatic insects, such as *C. tripunctatus*, also possesses strong antioxidant activity (110 ig/mL). Therefore, these insects can play a major role in food security, health, and environment management. It is essential to cultivate edible insects to maintain their population sustainability." 13568. Smolinský, R.; Gvoždík, L. (2014): Effect of temperature extremes on the spatial dynamics of predator-prey interactions: a case study with dragonfly nymphs and newt larvae. *Journal of Thermal Biology* 39(1): 12-16. (in English) ["Highlights: • We examine predator-prey interactions under extreme temperatures. • Predator activity increases with rising temperature, but prey activity does not. • The co-occurrence of predator and prey increases at high temperatures, but the probability of predation does not. • Diel thermal extremes negatively affect predators through the mismatch between space use and prey capture rate. Theory predicts that predators are more vulnerable to increasing temperature than prey. Despite huge variations in the magnitude and duration of thermally-extreme episodes in nature, most empirical studies on predator-prey interactions consider conditions induced by a climatic shift in mean temperature. We asked whether the increased vulnerability of predators holds under daily thermal extremes occurring during heat waves, using dragonfly nymphs and newt larvae as the predator-prey model system. Direct exposure of predator to prey in heated and non-heated aquaria under semi-natural conditions revealed that predator movements increased with rising temperature, whereas prey activity decreased. In contrast to the theory of predator-prey space use, the spatial co-occurrence of predator and prey individuals increased with temperature, while predation rates diminished. We conclude that daily thermal extremes affect trophic interactions in the same way, i.e. through the increased vulnerability of predators, as do long-term shifts in mean environmental temperature. Our results highlight the importance of behavioural studies for understanding mechanisms mediating the effect of extreme thermal events on species interactions." 13569. St. Clair, C.R.; Fuller, C.A. (2014): Atrazine exposure increases time until cannibalistic response in a dragonfly larva. *Canadian Journal of Zoology* 92(2): 113-117. (in English, with French summary) ["Agricultural

runoff containing herbicide is known to have adverse effects on freshwater organisms. Aquatic insects are particularly susceptible, and herbicide runoff has the potential to affect behaviour in this group. Here we examine the effects of short-term exposure to the herbicide atrazine on cannibalistic behaviour in larvae of *Libellula luctuosa*. Large larvae (> 12 mm length) were exposed to concentrations of 0, 1, 10, or 100 µg/L atrazine for 96 hours. A smaller (< 8 mm) conspecific was then placed with the large larva, and the behavior of the large larvae was observed for 30 minutes. Time until initiation of stalking and time until strike were determined. After the initial 30 minutes, each pair was checked at 2, 4, 6, 24 and 48 hours. Time of consumption and amount consumed were determined. The number of larvae that engaged in cannibalistic activity within the initial 30-minute observation period was significantly higher for controls compared to all experimental treatments. When stalking, striking and consumption times were examined together (a measure of overall response time) concentration had a significant effect, with the 10 µg/L group taking significantly longer to cannibalize than the control group. Cannibalism is a particularly important behaviour in dragonfly larvae populations, and this study confirms that this interaction is altered by exposure to atrazine, with the potential to affect ecological relationships." 13570. Stoks, R.; Geerts, A.N.; De Meester, L. (2014): Evolutionary and plastic responses of freshwater invertebrates to climate change: realized patterns and future potential. *Evolutionary Applications* 7(1): 42-55. (in English) ["We integrated the evidence for evolutionary and plastic trait changes in situ in response to climate change in freshwater invertebrates (aquatic insects and zooplankton). The synthesis on the trait changes in response to the expected reductions in hydroperiod and increases in salinity indicated little evidence for adaptive, plastic, and genetic trait changes and for local adaptation. With respect to responses to temperature, there are many studies on temporal trait changes in phenology and body size in the wild that are believed to be driven by temperature increases, but there is a general lack of rigorous demonstration whether these trait changes are genetically based, adaptive, and causally driven by climate change. Current proof for genetic trait changes under climate change in freshwater invertebrates stems from a limited set of common garden experiments replicated in time. Experimental thermal evolution experiments and common garden warming experiments associated with space-for-time substitutions along latitudinal gradients indicate that besides genetic changes, also phenotypic plasticity and evolution of plasticity are likely to contribute to the observed phenotypic changes under climate change in aquatic invertebrates. Apart from plastic and genetic thermal adjustments, also genetic photoperiod adjustments are widespread and may even dominate the

observed phenological shifts." (Authors) The publication includes references to Odonata.] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

13571. Therry, L.; Nilsson-Örtman, V.; Bonte, D.; Stoks, R. (2014): Rapid evolution of larval life history, adult immune function and flight muscles in a poleward-moving damselfly. *Journal of Evolutionary Biology* 27: 141-152. (in English) ["Although a growing number of studies have documented the evolution of adult dispersal-related traits at the range edge of poleward-expanding species, we know little about evolutionary changes in immune function or traits expressed by nondispersing larvae. We investigated differentiation in larval (growth and development) and adult traits (immune function and flight-related traits) between replicated core and edge populations of the poleward-moving damselfly *Coenagrion scitulum*. These traits were measured on individuals reared in a common garden experiment at two different food levels, as allocation trade-offs may be easier to detect under energy shortage. Edge individuals had a faster larval life history (growth and development rates), a higher adult immune function and a nearly significant higher relative flight muscle mass. Most of the differentiation between core and edge populations remained and edge populations had a higher relative flight muscle mass when corrected for latitude-specific thermal regimes, and hence could likely be attributed to the range expansion process per se. We here for the first time document a higher immune function in individuals at the expansion front of a poleward-expanding species and documented the rarely investigated evolution of faster life histories during range expansion. The rapid multivariate evolution in these ecological relevant traits between edge and core populations is expected to translate into changed ecological interactions and therefore has the potential to generate novel eco-evolutionary dynamics at the expansion front." 13572. Van Praeta, N.; De Jonge, M.; Blust, R.; Stoks, R.; Bervoets, L. (2014): Behavioural, physiological and biochemical markers in damselfly larvae (*Ischnura elegans*) to assess effects of accumulated metal mixtures. *Science of The Total Environment* 470-471: 208-215. (in English) ["Highlights: •At which organismal level effects of metal mixtures in nature can best be detected? •Differences in metal accumulation were observed between populations of *Ischnura elegans*. •Relations between the metal load index and both biochemical (GST) and physiological endpoints (energy storage) were observed. •No sublethal endpoint could be used to detect the observed variation among populations. Currently it is not known at which organismal level effects of metal mixtures in nature can best be detected, which is relevant to develop accurate monitoring schemes and quality stand-

ards. The present study investigated relationships between accumulated metals with different levels of biological organisation in the aquatic larval stage of *Ischnura elegans*. Larvae were collected in seven Flemish ponds differing in metal load. In each field-collected larva we quantified concentrations of accumulated metals and a set of biochemical markers (acetylcholinesterase (AChE) and glutathione-S-transferase (GST)), physiological endpoints (energy storage), and behavioural responses (locomotory activity and the feeding rate). Accumulated metal levels and the measured endpoints significantly differed among ponds, however, a large variation in metal load index was observed within individuals of the same population. Only GST and energy availability could be partly predicted by the observed variation in metal load index on individual damselfly level. However, no single endpoint could be used to detect the observed variation in metal load index among populations. In conclusion, the sublethal endpoints cannot be used as reliable biomarkers to monitor the toxicity of accumulated metal mixtures in natural populations of *I. elegans*." 13574. Whatley, M.H.; van Loon, E.E.; van Dam, H.; Vonk, J.A.; van der Geest, H.G.; Admiraal, W. (2014): Macrophyte loss drives decadal change in benthic invertebrates in peatland drainage ditches. *Freshwater Biology* 59(1): 114-126. (in English) ["Agricultural peatlands and their associated drainage systems are often highly managed and exposed to anthropogenic pressures, such as eutrophication and stable water tables, maintained via drainage during periods of high rainfall and inlet of, alkaline-rich, waters during dry periods. These pressures promote peat degradation, resulting in the accumulation of fine-degraded peat particles that dramatically alter aquatic habitats by smothering surfaces and decreasing water quality. Consequential effects on benthic communities are expected but have not been investigated so far. We hypothesised that peat degradation can lead to the decline in submerged macrophytes, which are of critical importance to sustaining biodiversity of benthic invertebrate communities. To investigate this, we analysed de-

cadal (1985–2007) changes in benthic species richness in 29 peat ditches in the Netherlands and, to determine patterns of macroinvertebrate habitat occupancy, carried out a complementary field experiment with submerged artificial macrophytes, natural sediments and emergent bank vegetation. Results from long-term monitoring indicate that chemical conditions in agricultural peat ditches have improved slightly over the last decades; however, there has been a simultaneous decline in benthic invertebrate species richness and densities corresponding to a decline in the numbers of submerged macrophytes. The apparent dependence of macroinvertebrates on macrophytes was reinforced by our field experiment which revealed that invertebrate density was highest in submerged artificial plants, while invertebrate species richness was highest in natural emergent vegetation. Conversely, degraded peat sediments supported extremely few invertebrates. Our results clearly illustrate the strong influence of submerged macrophyte loss on macroinvertebrate assemblages in peatland waters. Furthermore, this suggests that improvements in water quality alone will not benefit invertebrates in the absence of suitable vegetative habitats." (2002): Post-assessment of the habitat of the damselfly, *Mortonagrion Hirosei*, at the site of the Tone Kamome Ohashi Bridge. *Environmental Systems Research* 30: 419-428. (in Japanese, with English summary) ["*M. Hirosei*, was designated as an endangered species by the Environment Agency in 1991, because its habitat is vulnerable to the effects of land reclamation and river improvement. Pre- and post-assessments of the habitat of the damselfly were taken at the site of the Tone Kamome Ohashi Bridge project spanning the Tonegawa River, which marks the border between Hasakimachi, Ibaraki Prefecture, and Choshi, Chiba Prefecture. Before the project, the larvae of the damselfly were found abundantly in the reed-covered area of this bridge on the Ibaraki side of the river in October 1998. However, there were no larvae found on this side after the project in December 2001. Also, the adults of the damselfly were not observed in July 2002. The larvae of the damselfly were collected only from the puddle of the depressed ground covered with dead leaves of reed plants. However, the puddles were filled with the alluvial deposits. The level of the habitats of the damselfly after the project was higher than before the project from 20 to 100mm. Because the water supply from the watercourses and springs was decreased remarkably, the habitats of the damselfly were dried and the salinity of the habitats also became high. It was supported that the extinction of the damselfly on the Ibaraki side of the Tone Kamome Ohashi Bridge was caused by the reconstruction of the watercourse, which was extended and changed into boarded." USGS FS 2005-3129: 2 pp. (in English) [Verbatim: Surveys Detect Endangered Damselflies: Another candidate endangered species found in anchialine pools is the orange-black damselfly (*Megalagrion xanthomelas*) or pinao'ula (Fig. 4). These damselflies feed on both native and exotic flies, including mosquitoes, which breed in the pools. Pinao'ula breed in both fresh and brackish pools along coastal areas, which are commonly threatened by development. Very few of these habitats are protected; in Hawai'i, only three National Historical Parks contain suitable breeding habitat for pinao'ula, and all three parks are located on the west coast of Hawai'i Island.] Address: Email: davidfoote@usgs.gov

2006

13588. Cailles, C.R. (2006): Phenotypic and genetic effects of Chernobyl-derived radionuclide contamination on the red-eyed damselfly *Erythromma najas* (Odonata, Coenagrionidae). Ph.D. thesis, Faculty of Science and Technology, University of Plymouth: 15 + 307 pp. (in English) ["The 1986 Chernobyl accident released large amounts of radioactive contamination into the surrounding environment. As a result, the Chernobyl region provides a suitable site for investigations into the effects of ionising radiation on non-human biota. Studies of this type are important in order to establish whether or not current anthropocentric radiation protection guidelines are appropriate for the protection of the wider environment. Despite the presence of many freshwater habitats in the region, there have been few studies investigating the effects of radiation on aquatic invertebrates. In the present study, the effects of Chernobyl-derived radionuclide contamination on *E. najas* were investigated. This large scale study involved analysis of 720 *E. najas* specimens obtained from eight lakes in the Chernobyl region ranging in ¹³⁷Cs contamination levels from 37000 kBq m² to 100 kBq m². Estimated external dose rates of ionising radiation ranged from 24 µGyhr⁻¹ to 0.066 µGyhr⁻¹. Fitness of *E. najas* populations was assessed both phenotypically (by the use of fluctuating asymmetry (FA) techniques) and genetically (by the use of inter simple sequence repeat (ISSR) markers and mitochondrial (mt) DNA sequencing techniques). FA was assessed by the analysis of eight bilateral traits and no relationship between FA and dose rates of ionising radiation was found. Analysis of 61 ISSR bands revealed no evidence of elevated mutation rates in contaminated lakes. This finding was supported by the results of the mtDNA sequencing study which involved sequencing of the COI and COII regions of 80 *E. najas* specimens. The sequencing study revealed high levels of gene flow between the Chernobyl lakes and no evidence of either an increased mutation rate in contaminated lakes or a population bottleneck. In summary, these studies have revealed no adverse effects of Chernobyl-derived ionising radiation on *E. najas* populations." (Author)] Address: not stated

13589. Fochetti, R.; Argano, R. (2006): Patterns of benthic invertebrate assemblages in rivers of Central Italy. *Italian Journal of Zoology* 73(2): 145-151. (in English)

["The present paper aims to analyse and compare the benthic composition (including Odonata) of several rivers of Northern, Central Apenninic and Southern Italy. We considered faunistic data from seven Italian streams (Adige, Mignone, Arrone, Fiora, Aniene, Amaseno and Simeto rivers). In particular, we wanted to compare how, using detailed taxonomic data, every single river or stretch of river would conform or differentiate from other rivers (or stretches of river) in respect to their faunistic and structural aspects. We used presence-absence data of taxonomic groups, identified mainly at species level. Similarity indexes, Principal Component Analysis and divisive analysis (DIVA) gave almost overlapping results. Aggregative, ordination and divisive algorithms, in fact, group each of the studied rivers as single independent units, isolated and differentiated from the others. We discuss the results with respect to the main longitudinal zonation theories on running waters." (Authors)] Address: Fochetti, R., Dipartimento di Scienze Ambientali, Univ. della Tuscia, Largo dell'Università snc, 01100 Viterbo, Italy. E-mail: fochetti@unitus.it

13595. Fenoglio, S.; Bo, T.; Cucco, M.; Malacarne, G. (2007): Response of benthic invertebrate assemblages to varying drought conditions in the Po river (NW Italy). *Italian Journal of Zoology* 74(2): 191-201. (in English) ["In the rivers of northern Italy, the presence of water is typically continuous all year long, although in the last five decades there has been a conspicuous increase in drought periods, mainly caused by human impacts and climate change. The aim of this study was to assess the impact of the length of the drought periods on macroinvertebrate assemblages. We collected invertebrates in four reaches of the Po river, characterised by different periods of absence of surface water. We found significant differences among the stations in invertebrate abundance and taxa richness, with a decrease in the more drought affected stream reaches. Collector-gatherers significantly increased as the drought period lengthened, while the opposite occurred for scrapers and shredders. The areas with a discontinuous presence of water were mainly colonised by small, fastgrowing, plurivoltine organisms. A main result of our study is that only a few taxa appear to be able to survive in reaches with intermittent flow, underlining the great ecological difference between perennial and naturally intermittent streams. Our results suggest that the recent increase of droughts will likely cause an impoverishment of benthic communities in prealpine rivers." (Authors) The list of taxa includes 'Coenagrionidae' and 'Cordulidae'.] Address: Fenoglio, S., University of Piemonte Orientale, Di.S.A.V., Via Bellini 25, I-15100 Alessandria, Italy. 13603. Scalici, M.; Gibertini, G. (2007): Feeding habits of the crayfish *Austropotamobius pallipes* (Decapoda, Astacidae) in a brook in Latium (central Italy). *Italian Journal of Zoology* 74(2): 157-168. (in English) ["The several studies regarding the feeding habits of freshwater decapods have provided a few detailed descriptions of their natural diets and have seldom analysed variations in their feeding habits due to season, size, age, and changes in their physiological state. This situation led us to analyse the stomach content of different age classes of the crayfish *A. pallipes*, in order to increase the knowledge available on this species' diet. Ingestion index, vacuity frequency, and occurrence frequency were calculated; then, a graphical representation was carried out only for the animal component (mainly insect larvae) observed within the stomach. The results show *A. pallipes* to be an omnivorous and opportunistic

animal. Its diet includes the exploitation of more easily accessible vegetal and detritus resources, which are the main sources of energy and proteins in freshwater ecosystems. Invertebrates are very important for the crayfish diet; in fact, the animal component, and in particular Trichoptera, Diptera, and shellfish, plays a very important role for juveniles and adult females. Feeding strategies might reduce competition between sexes, satisfying their energetic and nutritional needs. The acquired knowledge of the crayfish trophic niche may be used, for example, to improve the diet of animals kept in captivity." (Authors) Odonata were represented in the diet of crayfishes from all sampling sites.] Address: Scalici, M., Dipartimento di Biologia, Università degli Studi "Roma Tre", v.le G. 13632. Gomez Anaya, M. (2008): Ecología de los ensamblajes de larvas de odonatos (insecta) y su uso potencial como indicadores de calidad ecológica en la Sierra de Coalcomán, Michoacán, México. Tesis, Universidad autónoma del estado de Hidalgo, Instituto de ciencias básicas e ingeniería, área académica de biología, doctorado en recursos bióticos: XXV + 306 pp. (in Spanish, with English summary) [Five Odonata larvae assemblages from Coalcomán Range, Michoacán, México were described and compared: Pinolapa (RP), Chichihua (CH), Ticuiz (TZ), Colorín (CL) and Estanzuela (EZ). The objectives of the study were describe and compare the assemblages and to relate them with some environmental variables judging their utility as conservation indicators. Two sampling trips for each year station were carried out, generally to beginning and final of each station. Simultaneously, the physio-

chemical variables pH, temperature, dissolved oxygen and conductivity were measured. Other variables of the streams like width, depth, current speed and gradient were measured in some additional trips. The streams were sampled in longitudinal sections of approximately 500 m using D-net and Hess sampler. We used a stratified sampling design (shores, rapids and eddies) and inside each stratum sampling was aleatory. The fauna was conserved in alcohol 96% with a replacement before 24 hours. All the larvae were identified to the species level regardless of their development stadium. As descriptive of each assemblage (alpha diversity) different diversity indexes were calculated (Shannon-Weaver H', Berger Parker, Williams's alpha), richness (Margalef), dominance (Simpson D), equitativity (Pielou). To compare and order the diversity of the water bodies the Renyi's index was used. The Bray-curtis' similarity index was used to evaluate the replacement rate (beta diversity) space and temporarily. An estimation of the theoretical richness using non parametric methods (presence/absence: Chao2, Jack2, Bootstrap and Mao Tau; abundance: ACE and Chaol) and parametric methods (Clench and von Bertalanffy) was carried out. Abundance of species was adjusted to the four classic models (stick broken, normal log, log series and geometric); additionally, each assemblage was separated in two groups, core and occasional species, according to Magurran & Henderson (2002). We used Canonical Correlation (CC) and Correspondences Analysis (AC) to explore the possible relationship between the physiochemical and environmental variables with species abundance. Discriminante Analysis (AD) was used to corroborate if the assemblages of Zygoptera, Anisoptera and *Argia* was able to segregate well the streams, the year stations and the strata. Among the results, the water bodies showed important physiochemical differences creating a temporal and geographical mosaic of variation. A total of 75 Odonata species (gamma diversity) were registered of a total of 380 samples. Number of species was higher at Ticuiz (36) and smaller at Colorín (18). These water bodies represented the ends in diversity and conservation in Coalcomán Range. Additionally, Ticuiz represents a mixed environment (lotic - lentic) with a moderate degree of stress being this fact the possible reason of its highest diversity and corroborating the intermediate-disturbance hipótesis. On the other hand, Colorín represents the water body more conserved with a characteristic Odonata assemblage of mountain streams of cloudest forest. According to the richness estimators, the five lists of species are still incomplete, being the most complete those of Estanzuela and Colorín. CC showed that some physiochemical variables could be responsible for the abundance of some species, while the AC indicated that a possible association can exist between the species and the strata, being the shores that support the highest diversity and abundance. AD evidenced that the assemblages of Zygoptera, Anisoptera and *Argia* can segregate well among the water bodies, year stations and strata. Final-

ly, we considered convenient to looking for indicator species of conservation among the *Argia* genus." (Author)] Address: Gomez Anaya, J.A., Instituto de Ecología, A.C. Apartado Postal 63, 91000 Xalapa, Veracruz, Mexico. E-mail: antonio.gomez@inecol.edu.mx

(in English) ["Johann H.L. Flögel (1834–1918) was an amateur scientist and self-taught microscopist in Germany who 130 years ago pioneered comparative arthropod neuroanatomy. He was fascinated by innovations in optical instrumentation, and his meticulous studies of the insect supraoesophageal ganglia were the first to use serial sections and photomicrographs to characterize the architecture of circumscribed regions of brain tissue. Flögel recognized the interpretative power resulting from observations across various species, and his comparative study of 1878, in particular, provided a baseline for subsequent workers to evolve a secure nomenclature of insect brain structures. His contributions stand out from contemporary accounts by virtue of their disciplined descriptions and emphasis on identifying comparable elements in different taxa. Here we give a biographical sketch of his life and summarize his remarkable achievements." (Authors) The publication includes a photograph of the brain structure of *Aeshna mixta* from Flögel's original publication from 1878: Flögel, J.H.L., 1878. Ueber den einheitlichen Bau des Gehirns in den verschiedenen Insecten-Ordnungen. *Zeitschrift für wissenschaftliche Zoologie* 30, 556–592.] Address: Strausfeld, N.J., Arizona Research Laboratories, Division of Neurobiology, 611 Gould-Simpson, University of Arizona, Tucson, AZ 85721, USA. 13652. Bend, Y.L.; Cong, Q.; Wang, X.j. (2009): Mechanism of hydrophobicity of dragonfly wing surface. *Transactions of the Chinese Society for Agricultural Machinery* 40(9): 205-208. (in Chinese, with English summary) ["By means of scanning electron microscope (SEM), Fourier transform infrared spectroscopy (FT-IR) and optical contact angle measuring instruments, the microstructure, ingredient and hydrophobicity of dragonfly wing surface was investigated. Results show that dragonfly wing surface is covered with large number of papilla, leading to the composite contact between liquid droplet and dragonfly wing surface, which enhances the hydrophobicity of dragonfly wing surface. The waxy layer increases the hydrophobic capacity of dragonfly wing surface. Moreover, the hydrophobic equation of dragonfly wing surface was established through the Cassie model, and the multivariate coupling mechanism of dragonfly wing surface was analyzed. It is the conclusion that the hydrophobicity ascribes to co-coupling of the microstructure and ingredient of dragonfly wing surface." (2010): The Wagner Parsimony using morphological characters: a new method for palaeosynecological studies. *Ann. soc. entomol. Fr.* (n.s.) 46(1–2): 276-292. (in English, with French summary) ["The limits and difficulties related to the tools currently in use for palaeosynecological comparisons of faunas or floras of different geological periods are discussed. The new method of the Wagner parsimony Applied to Palaeosynecology Using Morphology (WAPUM method), is defined and tested on morphological characters gathered from two insect groups Odonoptera and Thripida. The difficulties related to the monophyly of the taxonomic groups used in the more traditional approaches are no longer a problem when using the WAPUM method. In the WAPUM a character is 'presence versus absence of species bearing a morphological structure'. The results obtained from use of the WAPUM minimize the number of changes among character states. Application of the WAPUM could reveal signals to confirm or object the currently available scenarios for the global changes in the evolution of past diversity and disparity of organisms (major changes or global crises of diversity)." (Authors)] Address: Nel, A., Lab. Ent.. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrs1.mnhn.fr

13656. Poinar, G. (2010): Palaeoecological perspectives in Dominican amber. *Ann. soc. entomol. Fr.* (n.s.) 46(1–2): 23-52. (in English, with French summary) ["Palaeoecological and palaeobiogeographical aspects of Dominican amber are discussed based on the known insect fauna. Topics covered are examples of speciation, extinctions, longevity as well as associations between insects and plants, insects and vertebrates and various arthropod groups. Examples of camouflage, oviposition and predator-prey associations are presented. Ecological and medical implications from recently discovered vector-parasite associations (malaria, trypano-

nosomiasis and leishmaniasis) are discussed. Paleosymbiotic associations, with examples of phoresis, mutualism, parasitism and pathogens, are examined. Insects in Dominican amber, together with their cohabitants, can assist in determining specific habitats and reconstructing ancient landscapes." (Author) Figure 8 demonstrates *Diceratobasis worki* (Zygoptera: Coenagrionidae) probably bred in tank bromeliads.] Address: Poinar, G. Jr., Dept of Zoology, Oregon State Univ., Corvallis, OR 97331, USA: E-mail: poinarg@science.oregonstate.edu

13657. Rowe, R.J. (2010): *Ischnura aurora* (Brauer 1865) (Zygoptera: Coenagrionidae), an Australo-Pacific species. *New Zealand Journal of Zoology* 37(2): 189-192. (in English) ["There is some confusion over the identity of small forms of *Ischnura* occurring in South and East Asia and the Australo-Pacific region. Here, characters are given that separate *Ischnura aurora* (Brauer 1865) of the Australo-Pacific region from animals from the Asian mainland and nearby islands. Difficulties in attaching a name, or names, to Asian forms are considered. ... As work to progress this problem needs to be done with fresh, and possibly with living, material, this is a problem which can only be solved by persons resident in the area. The name, or names, to be associated with these Asian forms will require examination of the types of *rubilio*, *amelia* and *bhimtalensis*, together perhaps with a sensitive choice of a lectotype for *delicata*." 13661. Dow, R.A.; Reels, G.T. (2011): Odonata from a remnant patch of disturbed peat swamp forest on the outskirts of Kuching, west Sarawak. *Agrion* 15(2): 50-51. (in English) ["Before large-scale human alterations began, much of the surroundings of what is now Kuching, the state capital of Sarawak, consisted of various types of swamp forest, including much peat swamp forest. Later, rubber was planted in parts of this swamp forest. M.A. Liefertinck (1953: 236), under the description of *Podolestes harrissoni*, gave an incomplete list of species collected in "an old rubber garden" on the Matang Road outside of Kuching, on September 22, 1950. This list included a number of apparently very scarce species (e.g. *Amphicnemis madelenae*, *Nannophyopsis chalcosoma* and *Pseudagrionoptera diotoma*). Since Liefertinck's day Kuching has expanded considerably and there has been extensive development along the Matang Road, so that most of the peat swamp/old rubber habitat has gone. However, one patch remains, although probably not for much longer. Indeed, it may already have been bulldozed; we last passed the site in July 2010, when building work was occurring immediately adjacent to it. We first visited this site in January 2006, and made return visits in 2008 and 2010. The site is small, consisting of disturbed peat swamp with many old rubber trees that are still being tapped (on his last visit, RAD was ordered out of the site by machete-wielding rubber tappers). This site is at least near to Liefertinck's site, but remarkably we have collected a number of species not found by Liefertinck, illustrating the biodiversity of this kind of habitat in west Sarawak, and the extreme localisation of some species. Most notable of our discoveries at the Matang road was *Pachycypha* sp cf *aurea*. *P. aurea*, a tiny chlorocyphid, was described from the south of Kalimantan, and remains the only named species in the genus, which has not been recorded outside of Kalimantan until now. Despite the small size of the Matang Road site, it was not until May

2010 that we found this minute taxon, along one short section of a tiny stream. Both sexes descended from the canopy only in full sunlight, typically perching high. They were at low densities, and no interactions were observed between the sexes. They typically returned to the canopy almost immediately after the sun became obscured by clouds. A full list of the 26 species we have collected at the site is given below. Most of them were not listed by Liefertinck, but probably a number of these were actually collected by him; six species (at least) collected by Liefertinck were not collected by us. At least two of the species listed here are as yet unnamed; descriptions of both are being prepared by RAD." (Authors)] Address: Dow, R.A., NCB Naturalis, P.O. Box 9517, 2300 RA Leiden, The Netherlands. E-mail: rory.dow230@yahoo.co.uk

13662. Engelmann, A. (2011): Analyse von Exkrementen gefangener Waschbären (*Procyon lotor* L., 1758) aus dem Müritz-Nationalpark (Mecklenburg-Vorpommern) unter Berücksichtigung individueller Parameter. Diplomarbeit. Ernst-Moritz-Arndt-Universität Greifswald: 109 pp. (in German, with English summary) ["In the current study the diet behaviour of the raccoon (*Procyon lotor* L., 1758) has been investigated in a semi-natural habitat of the North-Eastern Lowland (Müritz National Park, Mecklenburg-West Pomerania) by means of 220 faeces samples collected between 2006 and 2009. Each of the samples could be associated to a day with a single individual raccoon. Thus, it was possible to relate the results of the fecal analysis to other known parameters (sex, age, habitat use). The raccoon's diet, being dominated by invertebrates (biomass = 43,7 %) and plants (biomass = 41,3 %), mainly consisted of earthworms, molluscs, insects, fruit, and nuts. Furthermore, the diet depended on the season of the year and the age, sex and habitat use of the individual." (Author) 26 of the faeces included Odonata.] Address: Engelmann, Anett, Projekt Waschbär, Goldenbaum 38, 17237 Carpin, Germany

13663. Fabbri, R. (2011): Two species of Odonata new to Emilia-Romagna Region, and one confirmed. (*Insecta Odonata*). *Quaderno di studi e notizie di storia naturale della Romagna* 34: 47-50. (in Italian, with English summary) ["*Oxygastra curtisii* and *Trithemis annulata* are reported as new for the dragonfly fauna of Emilia-Romagna. *Coenagrion mercuriale castellanii* is confirmed as present in Romagna in four new localities." 13664. Hatami, R.; Soofiani, N.M.; Ebrahimi, E.; Hemami, M.R. (2011): Evaluating the aquaculture effluent impact on macroinvertebrate community and water quality using BMWP index. *Journal of Environmental Studies* 37(3): 13-15. (in Farsi) ["We investigated the environmental impact of trout farm discharge on Za-

yandeh-Rud River. Three farms with different production capacities; 250, 25 and 70 tones were assigned to this study. Five sampling sites were designated to each farm. Benthic macroinvertebrates were collected in autumn, winter, and spring using the quantitative techniques. A total of 11 classes, 16 orders and 53 families' of macroinvertebrates were identified. Information on macroinvertebrates of each site was used to calculate the biological monitoring working party (BMWP). BMWP index was significantly ($p < 0.01$) low at farm effluents especially when the production capacity was high. At these locations, abundance of tolerant taxa (e.g. Chironomidae, Simuliidae, Oligochaeta families) increased, but sensitive taxa (Ephemeroptera and Trichoptera) declined in number. The BMWP index values were closely related to production rate and the lowest values (6.03 ± 1.17) was recorded at the farm with the highest production. Although, BMWP index at site 50 m after the outfall showed low or no recovery of water quality and community structure, however, at site 1 km after the outfall BMWP values exhibited a partial downstream spatial recovery of community structure so that no significant difference with upstream site was observed. We concluded that self-purification capacity and the high water flow of the river dilutes effluents so that biotic index showed no alarming condition at the farthest downstream station." 13666. Hunt, P.D. (2011): Odonata of the Lamprey River, NH. <http://www.lampreyriver.org/UploadedFiles/Files/odonatareport2011.pdf>: 18 pp. (in English) [New Hampshire, USA "Extensive surveys for Odonata were conducted along the Lamprey River from Northwood to Durham in 2011 and supplemented with data collected in previous years. A total of 74 species has been reported along the river, 29 of which can be considered specialists of rivers and streams. Overall, the percentage and total number of such species at a site increased from the headwaters (mean of 6.5 river species) through the lower portions (e.g., Lee and Durham, mean of 23 river species). This increase in species richness likely results from the increased size and habi-

at diversity at downstream sites, since only a few species were restricted to upstream areas. No river species of statewide conservation concern were detected along the Lamprey, probably because these species are more typical of larger rivers like the Connecticut and Merrimack. One common river group – the snaketails in the genus *Ophiogomphus* – seemed relatively rare compared to other rivers in New Hampshire. Given available data, the local rarity of *Ophiogomphus* might be related to in-stream conditions or to a general rarity in coastal plain streams. Issues known to affect the Lamprey, and thus potentially its odonate fauna, include sedimentation, temperature, and extremely high or low flows, but more detailed study would be needed to determine if any of these is affecting local species distributions. Overall, the odonate fauna of the Lamprey appears diverse and healthy and is likely to persist in the absence of large-scale perturbations such as extensive losses of riparian buffers, increased pollution, or excessive alteration of substrate conditions." (Authors)] Address: Hunt, Pamela, NH Audubon, Lamprey River, 203 Wadleigh Falls Road, Lee, NH 03861, USA

13667. Kastner, F.; Mückenwarf, M.; Buchwald, R. (2011): Zum Vorkommen der FFH-Libellenart *Aeshna viridis* Eversmann, 1836 (Odonata: Aeshnidae) in Krebscherengraben der Hunte- und Wesermarsch, Niedersachsen. *Drosera* 2010: 103-108. (in German, with English summary) ["On the occurrence of *A. viridis*, species of the European Habitat Directive, in ditches with Water Soldier in the Hunte and Weser river marshes, Lower Saxony, Germany. *A. viridis* is strongly linked to standing waters with dense stands of the Water Soldier (*Stratiotes aloides*), that serves the dragonfly as the only oviposition plant species for the dragonfly. In north-western Germany, *A. viridis* predominantly occurs in the river plains of Aller, Elbe, Weser, and Ems. For this study, we analysed all available inventories (expert reports, student research projects) on the distribution and present habitats of *Aeshna viridis* in the Hunte and Weser river marshes between Oldenburg and Bremen. In 2010, we recorded the occurrence of the endangered dragonfly species in the following locations with marsh ditches: NSG Bornhorster Huntewiesen, Iprump, Huntebrück, Warfleth, and Sandhausen. We consider its presence in these habitats to be autochthonous." 13676. Beukema, J.J.; Manger, R. (2012): Threats of drought for dragonflies in dune areas. *Levende Nat.* 113(6): 288-291. (in Dutch, with English summary) ["In dune areas, Odonata mostly depend on small and shallow ponds and pools. For over 10 years, numbers of dragonflies were monitored at ponds in the dunes of the northern part of Holland. At all pools, their abundances were strongly reduced at low water levels after periods of drought. Such declines were more substantial at shallow than at deeper ponds. In ponds that had run dry completely, recovery of numbers took 2 or 3 years in Zygoptera, whereas the larger Anisoptera immigrated more rapidly and reached the usual numbers within the first year. Deepening of shallow pools or digging of new pools resulted in higher abundances, again much faster in Anisoptera than in Zygoptera. To keep dune areas well populated by dragonflies, we advise to maintain sufficient pond depths." (Authors)] Address: Beukema, J.J., Linieweg 19, NL-1783BA Den Helder, The Netherlands

13677. Buczyński, P.; Łabędzki, A. (2012): Landscape park of "Janowskie Forests" as a hotspot of dragonfly (Odonata) Species diversity in Poland. In: Dyguś, K.H. (ed.): *The natural human environment. Dangers, protection, management, education.* Wyższa Szkoła Ekologii i Zarządzania, Warszawa: 151-174. (in English, with Polish summary) ["The "Janowskie Forests" Landscape Park protects a major part of the Janowskie Forests – one of the most environmentally valuable, compact forest complexes in Poland. It constitutes a key fragment of one of hotspots of diversity of dragonflies in Poland. The authors discuss results of long-term studies on the area (1988-1990, 1993-1998). In a relatively small area (approximately 40 000 ha) 58 species of dragonflies were recorded here (79.4% of the national fauna). Such rich species diversity results from a fortunate coincidence. In spite of regular conducting of forest economy measures, natural waters were destroyed to little extent. Particularly peatbogs, streams, and rivers survived in a good state. This is why populations of majority of stenotopes were preserved, as reflected by identification of 10 protected species, two species from the Polish red list of dragonflies, and one species from the European red list of dragonflies. Human economy contributed to increased differentiation of the landscape, and development of numerous anthropogenic waters, particularly fish ponds and sand pits, inhabited by rich communities of dragonflies. The character of the catchment, constituting an efficient forest "biological filter", often determines the habitat features of ponds, similar to

those of dystrophic lakes, or at most moderately eutrophic lakes. The study area can be treated as an object of an unintentional experiment which contributed to enriching the dragonfly fauna, and did not lead to loss of majority of the most valuable primary elements. It provides valuable guidelines for management of other protected areas, and particularly for implementation of active protection measures." (in German, with English summary) ["In the frame of the 13th "Geo day of biodiversity" on June 4th 2011 the authors explored the fauna and flora of several areas in the rural district of Birkenfeld (Upper Nahe Mts., Rhineland-Palatinate, Germany). The main focus was on the nature reserve "Clay pits Birkenfeld" west of the city of Birkenfeld, the floodplain of the river Nahe next to the airfield Hoppstädten-Weiersbach and the nature reserve "Alter Nahearm", an oxbow lake of the river Nahe southwest of Hoppstädten-Weiersbach. Altogether the authors detected 1,491 animal and plant species within 24 hours. Among them were 450 plant species, 920 invertebrates and 111 vertebrate species. Some of the species were first records within the investigated areas." (Authors) 21

Odonata species were recorded.] Address: Schlotmann, F., Weserstr. 11, D-55296 Harxheim, Germany. Email: frank.schlotmann@gmx.net

13685. Rennie-Lis, C. (2012): The microhabitat preferences of an isolated colony of *Coenagrion mercuriale* in Oxfordshire. M.Sc., Conservation Ecology, School of Life Sciences. Oxford Brookes University: 85 pp. (in English) ["*C. mercuriale* is a rare Odonata species that is only found in the UK in a selection of specialised habitats in the south. It has a declining population and is listed as endangered on the IUCN red list. It is the only species of Odonata currently given Biodiversity Action Plan (BAP) priority status in the UK, due to its limited distribution, both nationally and on a global scale. This project aimed to investigate the ecological requirements for an isolated colony of *C. mercuriale* that was mysteriously discovered in Oxfordshire in the 1990s, so that suitable habitat management activities could be developed. Mark-release-recapture surveys were conducted to enable an accurate population size to be estimated at 280 adult individuals across two sub-sites. Detailed mobility information was also gathered, which showed that dispersal distances were limited to an average of around 28m for the colony, meaning that range expansion is unlikely. Furthermore, behavioural observations uncovered some unusual breeding activity at one of the sub-sites, where there has also been a population decline trend in recent years. This warrants concerns about the viability of this population into the future. Hence, habitat management modifications have been recommended with the aim of preventing further decline." 13686. Taylor, J. (2012): Bali jewel-damselfly display. *Agrion* 16(2): 47. (in English) [Verbatim: In 2004, I witnessed the display of a male damselfly around a female which was laying eggs. He circled facing her with his white legs outstretched and smoky wings flashing iridescent colours in the sunlight. It was so attractive I thought it would be good if I could capture it on video. On a visit last December I had the opportunity to do just this. The damselfly, *Rhinocypha fenestrata cornellii*, breeds in fast-flowing water and I found a site on an irrigation conduit near Ubud where there were many males and females active. I noticed that some of the females were laying eggs in objects near the flowing water and, seeing this, I moved a chunk of rotten wood to a place suitable for photography. Females soon arrived to lay eggs in it, and a male saw his chance and began defending the wood against other males. He displayed around the females laying eggs or settling nearby and I saw him fly off with one of them to mate on a fern leaf. In the video the display is shown in real time and slow motion. The video can be seen on YouTube (http://www.youtube.com/watch?feature=player_detailpage&v=h18vryX4Jul) or search for key words: *Rhinocypha*, Bali, & Damselflies.] Address: Jan Taylor [jmtay5@bigpond.net.au]

(in English) ["Inspired by the co-coupling of the non-smooth structure and the waxy layer inducing the hydrophobicity of dragonfly wing surface, we developed a simple and versatile method to fabricate a superhydrophobic surface with the dragonfly wing structures. In this work, Ag nanorods grew on highly ordered anodic aluminum oxide (AAO) surface via a galvanic reduction approach. Then the AAO-Ag multilayer was fabricated. Furthermore, the surface free energy of AAO-Ag multilayer was reduced by modifying with perfluorodecanethiol. The modified AAO-Ag multilayer was superhydrophobic and the static contact angle reached as high as 168°. X-ray photoelectron spectra (XPS) were used to characterize the chemical structure of the obtained products. The morphologies of AAO-Ag multilayer was similar to microstructure of dragonfly wing surface and presented hierarchical rough structure. The results showed that the co-coupling of the rough structure and low surface free energy induced the superhydrophobic performance of the AAO-Ag multilayer surface." 13690. Alexander, A.C.; Luis, A.T.; Culp, J.M.; Baird, D.J.; Cessna, A.J. (2013): Can nutrients mask commu-

nity responses to insecticide mixtures?. *Ecotoxicology* 22: 1085-1100. (in English) ["The ecological effect of simultaneous exposure to two nutrient gradients, three insecticides and different predator intensities was investigated over a 3-week period in 80 outdoor, artificial streams using field-collected benthic invertebrates. The experimental design consisted of a 2 × 5 factorial structure with two nutrient levels (oligotrophic or mesotrophic) and five concentrations of the ternary insecticide mixture consisting of the insecticides (chlorpyrifos, dimethoate and imidacloprid). Equivalent toxic unit doses were summed to create a ternary insecticide dose (e.g., 0.1 + 0.1 + 0.1 = 0.3 TU) resulting in a range of ternary insecticide mixture toxicity (i.e., control groundwater, 0.3, 0.6, 0.9 and 1.2 TU). Two genera of insect predators, *Gomphus* spp. (Odonata) and *Agnetina* spp. (Plecoptera) were also added into each replicate stream, at densities and sizes comparable to those found at our collection site, to evaluate how the contribution of predators may change in nutrient limited (oligotrophic) versus amended (mesotrophic) systems. We describe a causal mechanism whereby the combined action of nutrients and insecticides reshaped aquatic community structure by interacting through multiple pathways. Specifically, mesotrophic conditions reduced the toxic effects of ternary insecticide mixtures for aquatic insects which, in some cases, appeared to increase abundance of aquatic insects. However, higher levels of insecticides in mesotrophic streams negated this effect and were even more toxic; for example, to aquatic insect grazers than the same insecticide doses in oligotrophic treatment levels. Effects of predators were only significant in oligotrophic streams. Evidence is provided as to how nutrient and contaminant interactions can greatly complicate the assessment of community level responses to insecticide mixtures due to direct and indirect effects of the resulting changes in the density of different genera and functional feeding groups within a community." (Authors)] Address: Alexander, Alexa, Department of Biology at the University of New Brunswick, #10 Bailey Drive, P.O. Box 4400, Fredericton, NB, E3B 5A3, Canada. E-mail: alexa.alexander@unb.ca

13691. Amhaeva, L.S.; Kozminov, S.G.; Ketenchiev, H.A. (2013): Preimaginal stages of *Coenagrion puella* L. 1758 (Odonata). *Ecology of animals - The South of Russia: ecology, development* 4: 40-45. (in Russian, with English summary) ["Aim. Ages and stages of *C. puella* with a wide area of distribution throughout Russia were determined in the laboratory. Morphological and morphometric characteristics of larvae instars are described. Location. Zoological laboratory of Kabardino-Balkarian State University (Russia). Methods. Common methods of entomological research were used. In experimental conditions, the development stage (F) of 260 ex. of *C. puella* were studied. Eggs of *C. puella* were taken from natural reservoirs and incubated at 22-24 °C. Larvae were fed once a day by Cladocera,

Copepoda, Ostracoda, Chironomidae, Oligochaeta. Results and conclusions. Larvae of *C. puella* are hatched from eggs after 24–26 days at the temperature 22–24 °C. Time diapason between exuviations is increased with age of larvae: 1–5 stages exuviate by 3–4 days, 6–7 stages by 5–6 days, 8–9 by 6–18 days, 10th by 9–12 days. Morphometric parameters of the larvae are changed with each molting. Main morphological changes indicate a stages of development and are due with change of mask (including its distal margin), lateral lobe, external lamellae (gill plates), antennae and tarsi. The results can be used in ecological monitoring, micropopulation studies. These data can help to determine the variability of dragonflies in mountain ecosystems." 13692. Ananian, V.Yu.; Tailly, M. (2013): Additions to the dragonfly (Odonata) fauna of Armenia, with new records of rare or uncommon species. Russian entomological journal 22(4): 249-254. (in Russian, with English summary) ["This review presents the results of the second phase of recent surveys of the dragonfly fauna and its distribution in Armenia, covering the period 2004-2012. Four species *Coenagrion armatum*, *Cordulegaster vanbrinkae*, *Crocothemis servilia* and *Selysiothemis nigra* were recorded for the first time in Armenia. Other annotated records deal with rare or uncommon species with sporadic finds in the country, and with rarities rediscovered since their last accounts half a century ago — *Lestes macrostigma*, *Gomphus schneiderii*, *Onychogomphus assimilis* and *Libellula pontica*. A few scarcely recorded commoner species are discussed as well." (Authors)] Address: Ananian, V.Yu., 179 Bashinjaghian Str., apt. 23, Yerevan 0078, Armenia. E-mail: gomphus@gmx.com

13693. Batty, P. (2013): Site condition monitoring for dragonflies (Odonata) at Claish Moss SSSI. Scottish Natural Heritage Commissioned Report No. 707: IV + 7 pp. (in English) ["Background: Site Condition Monitoring is a six year rolling programme of assessment of the state of notified features on Sites of Special Scientific Interest (SSSI). Two visits were made in 2013 (25 June and 5 August) to assess the condition of dragonflies and damselflies at Claish Moss SSSI, which has a notable assemblage (nine species) of Odonata. Main findings: Ten species of dragonflies were found breeding and a cast skin of the rare *Somatochlora artica* was seen. There was suitable habitat for *Aeshna caerulea*, although this species was not recorded. The site was found to be in favourable condition for Odonata, and the current management should be maintained. It will be helpful to contact surrounding landowners to ensure that some sheltered feeding areas for the northern emerald remain in future management plans for the surrounding forestry plantations." (Author)] Address: Batty, Patricia, Kirnan Farm, Kilmichael Glen, Lochgilphead, Argyll, PA31 8QL, UK

13694. Batzer, D.P.; Ruhí, A. (2013): Is there a core set of organisms that structure macroinvertebrate assemblages in freshwater wetlands? *Freshwater Biology* 58(8): 1647-1659. (in English) ["We analysed taxa lists from 447 individual wetlands from several ecoregions across the world using nestedness and similarity-based multivariate analyses. We examined how similar wetland assemblages are across regions, whether variation in assemblages is ordered (nested) or unpredictable (idiosyncratic), whether individual taxa occur predictably or unpredictably across wetland habitats, and if any of these patterns differed between temporary- and permanent water habitats. We found that macroinvertebrate assemblages were highly nested ($N = 0.947$), but unexpectedly 37 of the 40 most widespread taxa (>10% occurrence) were idiosyncratic. Of the 447 wetlands, we identified 277 that shared more than 40% similarities in assemblages, were mostly nested, and clustered together in ordination space, and thus could be considered a core set of wetlands in terms of assemblage structure. Assemblages in the 170 wetlands outside this core (mostly idiosyncratic) tended to be depauperate sites in arid or high elevation areas, or alternatively taxonomically rich sites supporting numerous lotic or lacustrine organisms. The 'Core' itself split into two main parts, one comprised of wetlands from semi-arid or mild climate areas dominated by strong flying insects, and the second comprised of wetlands from wetter, more northerly areas where non-insects with passive dispersal were very prevalent. Climate and geology appear to be major controls on macroinvertebrate distributions across the set of 447 wetlands. Hydrology (temporary versus permanent) of wetlands was a lesser control on assemblage structure over the set of 447 wetlands. That wetlands are dominated by about 40 widely-occurring macroinvertebrate taxa, and those taxa tend to occur idiosyncratically, suggests that overall assemblages across wetlands may share many similarities, but some of widespread taxa may still be missing from many individual wetlands. Why these otherwise fairly ubiquitous taxa do not occur in specific wetlands may shed important light on how those wetlands are controlled ecologically; in other words, do sites lack specific factors required by these taxa?" (Authors) The analysis of taxa is conducted at family level and includes Libellulidae, Coenagrionidae and Lestidae.] Address: Batzer, D.P., Department of Entomology, University of Georgia, Athens, GA, 30602, USA. 13695. Bennett, A.M.; Pereira, D.; Murray, D.L. (2013): Investment into defensive traits by anuran prey (*Lithobates pipiens*) is mediated by the starvation-predation risk trade-off. *PLoS ONE* 8(12): e82344. doi:10.1371/journal.pone.0082344: 9 pp. (in English) ["Prey can invest in a variety of defensive traits when balancing risk of predation against that of starvation. What remains unknown is the relative costs of different defensive traits and how prey reconcile investment into these traits when energetically limited. We tested the simple alloca-

tion model of prey defense, which predicts an additive effect of increasing predation risk and resource availability, resulting in the full deployment of defensive traits under conditions of high risk and resource saturation. We collected morphometric, developmental, and behavioural data in an experiment using dragonfly larvae (predator, *Aeshna* sp.) and Northern leopard frog tadpoles (prey) subject to variable levels of food availability and predation risk. Larvae exposed to food restriction showed limited response to predation risk; larvae at food saturation altered behaviour, development, and growth in response to predation risk. Responses to risk varied through time, suggesting ontogeny may affect the deployment of particular defensive traits. The observed negative correlation between body size and activity level for food-restricted prey – and the absence of a similar response among adequately-fed prey – suggests that a trade-off exists between behavioural and growth responses when energy budgets are limited. Our research is the first to demonstrate how investment into these defensive traits is mediated along gradients of both predation risk and resource availability over time. The interactions we demonstrate between resource availability and risk level on deployment of inducible defenses provide evidence that both internal condition and extrinsic risk factors play a critical role in the production of inducible defenses over time." 13696. Breithaupt, N. (2013): Zur Häufigkeit der Farbformen von Weibchen der Zarten Rubinjungfer (*Ceragrion tenellum*) im Naturschutzgebiet Mindelsee (Odonata: Coenagrionidae). *Mercuriale* 13: 7-10. (in German, with English summary) [Baden-Württemberg, Germany; "At a calcareous peat bog in the northern borderline of Lake Mindelsee the frequency of the female colour morphs of *C. tenellum* was determined at two dates in August 2011. With a frequency of 64 % *f. typicum* dominated, followed by 34 % of *f. erythrogastrium*. With a frequency of 2 % females of *f. melanogastrium* were rarest at the study site. The results are compared with those in other parts of Germany and shortly discussed." (Author)] Address: Breithaupt, Ninja. E-mail: ninja-b@gmx.de

13697. Brookshire, B.A. (2013): Comparison of Odonata populations in natural and constructed emergent wetlands in the bluegrass region of Kentucky. Eastern Kentucky University Encompass. Honors Theses. Paper 124: III, 33 pp. (in English) ["With the degradation and destruction of many natural wetlands in Kentucky, there are high incentives to look at the remaining natural wetlands and the new artificial wetlands that are beginning to become prevalent among biologists. Wetlands are important to dragonfly populations just as dragonflies are vital to wetland function. In my study I looked at the fluctuation in Odonata populations at ten artificial wet-

lands and ten natural wetlands in the Inner Bluegrass region of Kentucky. In my study the dragonfly populations were monitored based on Shannon and Simpson's diversity, Species richness, and number of individual and species numbers. The wetlands were also compared on a season to season basis and the health of the wetlands were considered using a rapid assessment method. My research found that the artificial wetlands, though they scored low on the rapid assessment method, scored high in all categories except for species richness in the fall season of data collection. This study can be important in discovering the differences between natural and artificial wetlands, since Odonates are such an important biological indicator of wetland health and function. This could be vital in increasing the health of remaining natural wetlands and new artificial wetlands that are being created to supplement the lack of many of Kentucky's natural wetlands." (Author)] Address: Brookshire, Brittany Ann, Eastern Kentucky University, USA. E-mail: BrittanyBrookshi@eku.edu

13698. Bunker, B.; Janovy, J.; Tracey, E.; Barnes, A.; Duba, A.; Shuman, M.; Logan, J.D. (2013): Macroparasite population dynamics among geographical localities and host life cycle stages: Gregarines in *Ischnura verticalis*. *Journal of Parasitology* 99(3): 403-409. (in English) ["Populations of several species of gregarine parasites within a single host species, the damselfly *Ischnura verticalis*, were examined over the course of 1 season at 4 geographic localities separated by a maximum distance of 9.7 km. Gregarines, having a life cycle with both exogenous and endogenous stages, are subject to a wide variety of selective pressures that may drive adaptation. Gregarine species showed some specificity for host life cycle stage; *Steganorhynchus dunwoodyi* and *Hoplorhynchus acanthatholius* were most prevalent in larval hosts, while *Steganorhynchus dunwoodyi*, *Actinocephalus carrillynae* and *Nubenocephalus nebraskensis* were most prevalent in adult hosts. Species prevalence and abundance differed by geographic locality. Gregarine prevalence was significantly higher in adult female damselflies than males at 2 localities; sex differences in prevalence were insignificant for larval damselflies at all 4 localities. In larval hosts, gregarine abundance was independent of age (size). The present study therefore shows that pond characteristics, host life cycle stage, and adult host sex are the main factors that influence the prevalence and abundance of gregarine populations." 13701. Clarke, T. (2013): Mixed pairing between Emerald Damselfly *Lestes sponsa* and Azure Damselfly *Coenagrion puella*. *Atropos* 50: 84-85. (in English) [Verbatim: The image published here was taken on 21 August 2013, just before noon, at Pleasley Pit Nature Reserve, North Derbyshire, during a warm and sunny day. I spotted this mixed pairing between a male *Lestes sponsa* and a male *Coenagrion puella* approximately two metres from the bankside, on dead reed protruding from the water. I have no idea how long the pair had been in tandem and they split up within minutes of my spotting them. Just time for the one photograph!] Address: Clarke, T., 5 Nottingham Drive, Wingerworth, Chesterfield, Derbyshire, S42 6ND, UK

13702. Contreras-Martinez, E. (2013): Diversidad de Entomofauna acuática en tres ríos de la Ecoregión Darién, Choco biogeográfico (Colombia). *Dugesiana* 20(2): 243-250. (in Spanish, with English summary) ["There are few studies on insect diversity from rivers and streams of coastal areas, particularly within the Chocó biogeographic area. In this study we conducted a spatially explicit inventory of insects from three freshwater bodies in the Darien Ecoregion (located in the Colombian Caribbean). To establish the aquatic insect spatial patterns of richness, multiple habitats were sampled at seven stations from three streams located between the flat and mountainous parts. Also some physicochemical parameters were measured and each sampling station was characterized according to the quality of riparian cover and habitat heterogeneity following rapid assessment protocols such as Quality Index of Riparian

forest (QBR) and Fluvial Habitat Index (IHF), respectively. To describe the macroinvertebrate assemblage, Shannon Diversity and Pielou Equity indices, and Jaccard similarity were calculated and a non Parametric Multidimensional Scaling (NMDS) performed; the number of groups used in the clusters and the dendrogram were determined by the k -means partition method (k -Means Partitioning). Clustering patterns were interpreted based on the riparian cover condition and the physicochemical variables. A total of 3399 individuals were collected and identified to family level, most abundant insect families were Leptophlebiidae, Chironomidae and Hydropsychidae. Differences between sampling stations were found where Carolina Middle and High Capurganá sections had the higher richness values with 31 and 30 families respectively. The most diverse station was the medium reach El Regalo and less diverse was the high reach La Carolina, which separated from the other stations by the similarity analysis. The clustering pattern found could partially respond to similarities in riparian coverage, habitat heterogeneity and the particular characteristics provided by these parameters, since they have an indirect effect on other variables such as temperature which has a strong influence on the presence and / or establishment of the insect population. The effect of temperature was related to the function of vegetation cover and the drought period experienced by the region at the time of sampling." (Authors) Taxa are treated at family level and include 'Libellulidae, Megapodagrionidae, Calopterygidae, Coenagrionidae, Gomphidae, and Platystictidae'.] Address: Contreras-Martínez, Eliana, Instituto de Biología; Universidad de Antioquia; Medellín; Colombia. contreras.eliana5@gmail.com

13703. Cook, T.; Smith-Heeron, A.J. (2013): Gregarines infecting *Ischnura* spp. in Texas U.S.A. including description of *Septemlatuspora rasberryi* n. gen. n. sp. (Apicomplexa: Actinocephalidae: Acanthosporinae) and revision of *Steganorhynchus dunwoodyi* (Apicomplexa: Actinocephalidae: Menosporinae). *Journal of Parasitology* 100(1): 99-105. 13704. Copatti, C.E.; Fagundes, L.S.; Quaini, J.B.; Copatti, B.R. (2013): Diversity of aquatic arthropods on *Eichhornia crassipes* (Mart.) Solms roots before and after removal of substrate in a reservoir in southern Brazil. *Pan-American Journal of Aquatic Sciences* 8(4): 265-275. (in English, with Portuguese summary) ["The objective of this study was to determine the influence of substrate removal on the diversity, composition and trophic structure of aquatic arthropods found on *Eichhornia crassipes* roots. Because many arthropods are intimately associated with their substrate, its removal might result in increased richness and diversity for the aquatic arthropods on *E. crassipes* roots. The study

was performed in the Lajeado da Cruz River in Cruz Alta-RS, where the identification of the aquatic arthropods captured during eight samplings between August 2008 and May 2011 was performed. Four samples were collected prior to removal of the substrate and four were collected afterward. A total of 8,894 exemplars and 55 families of aquatic arthropods were sampled. The families Palaemonidae and Chironomidae were the most abundant. The diversity indices indicated increases in both diversity and richness after substrate removal. Values of the water quality parameters of turbidity, colour, iron and aluminum were found to be outside the norms, which indicated a need for caution with regard to water quality. The removal of the substrate triggered changes in the community and its trophic structure as well as an increase in the diversity of arthropods on the water hyacinth roots. ... In this study, Odonata and Ephemeroptera were more abundant than Coleoptera and Hemiptera (Table I), indicating that the study area was not in an early stage of succession and that the patterns found had been influenced by the existence or removal of water hyacinths in the substrate." (Authors)] Address: Copatti, C.E., Universidade Federal da Bahia, Depto de Zoologia, Instituto de Biologia, 40170-290, Salvador, BA, Brasil. E-mail: carloseduardocopatti@yahoo.com.br

13705. Day, R.S. (2013): Odonata survey of various sites of the Missouri Prairie Foundation Barton, Dade, Polk, St. Clair, and Vernon Counties in Missouri. Missouri Prairie Foundation. <http://www.moprairie.org/wp-content/uploads/2014/05/Odonate-Survey-Report.pdf>: 68 pp. (in English) ["I recorded a total of 35 species of dragonflies and damselflies between June 3 and August 12, 2013. A complete checklist can be found on page 9 of this report. A total of 76 specimens were deposited at the Enns Entomology Museum at the University of Missouri. No Missouri Species of Conservation Concern were found during this survey. I conducted surveys on June 2-4, July 8-11, and August 10-12, 2013. I visited all sites (n=7) on the contract three times, with the exception of Marmaton Wet Prairie. I was unable to survey Marmaton on two occasions (June and August) due to flood conditions. The Marmaton site was very difficult to access because there are no paths or fire breaks to access areas, and the grass was so tall and thick that it made navigating the prairie very difficult. I did, however, document 15 species when I was there in July. I'm confident that had I been able to survey Marmaton the other two times that I would have found more species. During the June survey, I observed an abundance of teneral dragonflies (newly emerged) on most sites. In July, I saw more species flying overall than in June. By August, there were still many dragonflies, but I noticed a decline in numbers from July. The Penn-Sylvania site always had the most activity and abundance. When I was there on July 9, I witnessed a large flock of swallows swooping over the pond and feeding on the dragonflies. Most of the species observed throughout the

entire survey were in the Libellulidae family, a very common pond dragonfly family. The greatest abundance and Odonata activity was near water sources such as the ponds located on the sites. I found nothing that could be considered out of the ordinary. The drainages in the prairies produced very little Odonata activity. It is my opinion based on the plant communities and habitat present, that large shallow water wetlands would produce more activity and abundance, but most species would still be in the Libellulidae family." 13710. Environment Canada (2013): Management plan for the Pygmy Snaketail (*Ophiogomphus howei*) in Canada. Species at Risk Act Management Plan Series. Environment Canada, Ottawa: iii + 13 pp. (in English) ["*O. howei* is one of the smallest dragonflies in North America. Adults are black, with brown stripes and yellow markings on their abdomen, green on the thorax, and a transparent yellow-orange tint on the basal side of the wings. Aspects of the Pygmy Snaketail life cycle requirements are poorly understood and habitat requirements for the species are complex. Larvae take up to two years to develop to the adult stage, drifting downstream from where eggs are laid; the majority of their adult life is then spent in the upper canopy of riparian areas. *O. howei*, in Canada, is known from 11 sites in New Brunswick and 1 site in Ontario. Little is known of the species' distribution, abundance, and habitat needs in Canada. There are several knowledge gaps with regards to characterizing threats to this species. Dam construction is a threat of high concern in Ontario. All other threats, in both New Brunswick and Ontario, are either of low concern or the impact is unknown and include; dam construction, pollution, invasive species, residential development, forest harvesting and agriculture land use, wakes from boats, and vehicle traffic on roads. The species was assessed as Special Concern by COSEWIC in 2008, and was listed as Special Concern under Schedule 1 of the Species at Risk Act in 2011. In New Brunswick the species is not listed under provincial legislation. In Ontario it is listed as Endangered under the provincial Endangered Species Act, 2007. The management objective for the Pygmy Snaketail is to maintain the presence of existing populations at all sites where they are currently known to occur and conserve new occurrences that are identified. This will be achieved by implementing conservation measures that are organized under the following three broad strategies: (1.) Population monitoring and surveys of suitable habitat (2.) Maintenance of aquatic habitat quality and quantity (3.) Outreach, education, and stewardship to promote conservation " (Authors)]

13711. Farris, S.M. (2013): Evolution of complex higher brain centers and behaviors: Behavioral correlates of mushroom body elaboration in insects. *Brain, Behavior and Evolution* 82: 9-18. (in English) ["Large, complex higher brain centers have evolved many times independently within the vertebrates, but the selective pressures driving these acquisitions have been difficult to

pinpoint. It is well established that sensory brain centers become larger and more structurally complex to accommodate processing of a particularly important sensory modality. When higher brain centers such as the cerebral cortex become greatly expanded in a particular lineage, it is likely to support the coordination and execution of more complex behaviors, such as those that require flexibility, learning, and social interaction, in response to selective pressures that made these new behaviours advantageous. Vertebrate studies have established a link between complex behaviors, particularly those associated with sociality, and evolutionary expansions of telencephalic higher brain centers. Enlarged higher brain centers have convergently evolved in groups such as the insects, in which multimodal integration and learning and memory centers called the mushroom bodies have become greatly elaborated in at least four independent lineages. Is it possible that similar selective pressures acting on equivalent behavioural outputs drove the evolution of large higher brain centers in all bilaterians? Sociality has greatly impacted brain evolution in vertebrates such as primates, but it has not been a major driver of higher brain center enlargement in insects. However, feeding behaviours requiring flexibility and learning are associated with large higher brain centers in both phyla. Selection for the ability to support behavioral flexibility appears to be a common thread underlying the evolution of large higher brain centers, but the precise nature of these computations and behaviors may vary." (Author) The function of mushroom bodies in Odonata is discussed. Regrettably the studies on sensory systems in Odonata of the Italian working group lead by Elda Gaino and Manuela Rebora are not considered. 13712. Festi, A. (2013): Nuova segnalazione di un sito riproduttivo di *Leucorrhinia pectoralis* Charpentier, 1825 (Odonata: Libellulidae) per l'Alto Adige e l'Italia. *Gredleriana* 13: 129-132. (in Italian) [Documentation of records of *L. pectoralis*: 09.-23.06.2013, Bigleidermoos - Torbiera Bigleider near Aldeno, (Prov. Aut. di Bolzano, Italy; WGS 46,37095511,341261).] Address: Festi, A., Via Penegal 7, I-39100 Bolzano, Italy. E-mail: alex.festi@rolmail.net

13713. Fiebig, I.; Lohr, M. (2013): Libellengemeinschaften oligotroph-saurer Sekundärgewässer im Solling, Süd-Niedersachsen (Odonata). *Libellula* 32(3/4): 115-139. (in German, with English summary) ["Odonata communities of oligotrophic-acidic pools in the Solling, Southern Lower Saxony, Germany (Odonata) – In 2011 the Odonata communities of 15 oligotrophic-acidic and two meso- to eutrophic water bodies in the Rutenbruch, Solling, southern part of Lower Saxony were studied by collecting exuviae and recording imagines. The investigated pools were created between 1982 and 2008 in

windthrow areas of spruce forests on former fens. These areas were partly cattle-grazed by Exmoor Ponies since 2010. In total 28 odonate species were found, for 21 of them breeding was confirmed. Many species are characteristic of oligotrophic-acidic waters of moors and bogs or possess their main habitat in these pools within the region, among them *Coenagrion hastulatum*, *Aeshna juncea*, *Leucorrhinia dubia* and *L. rubicunda*. The occurrence of these and further species like *Leucorrhinia pectoralis* is discussed regarding ecological and conservational aspects. Some of the pools were already colonized by typical species of moors and bogs like *Leucorrhinia dubia* and *L. rubicunda* only a few years after their creation. The effects of cattle-grazing on the Odonata must be regarded differently for different life cycle stages. Whereas the habitats of the adults were more suitable, the impact of trampling on the larval habitat of some typical species of bogs and mosses and their populations was adverse. Recommendations on the future grazing-management are given. The pools with the largest populations of species important for conservation should not be grazed simultaneously, but rotational grazing of pastures with intervals of three to five years is suggested." 13715. Funk, A.; Gschöpf, C.; Blaschke, A.P.; Weigelhofer, G.; Reckendorfer, W. (2013): Ecological niche models for the evaluation of management options in an urban floodplain—conservation vs. restoration purposes. *Environmental Science & Policy* 34: 79-91. (in English) ["Highlights: *We analysed potential management options for a floodplain of the Danube. *The aim was to integrate restoration and conservation objectives into management. *Therefore the habitat availability for endangered and flagship species was calculated. *The results represent the actual and potential future community of the system. The Lobau, a former dynamic floodplain area of the Danube River situated close to Vienna (Austria), was strongly affected by the river regulation in 1875. The reduced hydrological connectivity changed the conditions in the system which is nowadays groundwater-fed, back-flooded, and characterized by sedimentation and terrestrialisation processes. On one hand, the artificially created habitat types have a high conservation potential; they harbour a rich community whose habitat range has been reduced due to degradation in the cultural landscape. On the other hand, resto-

ration efforts aim to reverse the anthropogenic impact due to damming and to restore the natural status of the wetland with its dynamic hydrological regime and its associated rheophilic community as far as possible. The challenge for floodplain managers is now to develop a compromise solution that integrates restoration and conservation efforts. The potential options range from the conservation of the present status to the restoration of the floodplain towards pristine conditions. We used a logistic regression approach to predict the potential habitat availability for indicator species including highly endangered and flagship species which are used for attracting public support for the conservation/restoration measures. The results represent the actual and potential future community of the system for the management options. Based on the results we make recommendations for the selection of a best compromise for the management of the floodplain with special regard to the legal objectives." (Authors) *Leucorrhinia pectoralis* is assessed as "common" in the Lobau.] Address: Funk, Andrea, WasserCluster Lunz, Dr Carl Kupelwieser Promenade 5, A-3293 Lunz/See, Austria

13716. Gai, K. (2013): Wing damage effect on dragonfly's aerodynamic performance during takeoff. Master of Science in Engineering (MSEgr), Wright State University, Mechanical Engineering: VIII + 56 pp. (in English) ["Insect wing damage resulted from living environment or predation commonly happens in nature. This usually results in deterioration of insect's flight performance and as a consequence, the insect needs adjustment of flapping wings to compensate the effect from the wing loss. In this study, *Erythemis simpliciolis* with and without wing loss is chosen to study the change of aerodynamic performance of flapping wings. Three cases including flight with intact wings (IW), flight with one-sided forewing damage (OFD), and flight with double-side forewing damage (DFD) are determined. An integrated study using high-speed photogrammetry, three-dimensional surface reconstruction, and direct numerical simulation (DNS) are used to quantify wing kinematics and aerodynamics performance. Results have shown that in general, during downstroke of forewings, forewing area loss could reduce insect's lift production; The lift force generated by the outer wings is larger than or equal to that produced by the inner wings during downstroke, but the outer wings' lift production becomes smaller than the inner wings' during upstroke; Span-wise forewing area removal reduces forewing tip vorticity, and it leads to the detachment of the tip vortex ring during upstroke." 13717. Girod, T.E. (2013): Bullfrog (*Lithobates catesbeianus*) diet composition, life history, and time period for larval development in California's north coast. M.Sc. thesis, Biology, Humboldt State University : XI + 94pp. (in English) ["*Lithobates catesbeianus* (American bull-

frogs) are not native to states west of the Rocky Mountains. Since their introduction to California, they have been implicated in the decline of amphibian species. On California's north coast, bullfrogs may be causing local declines of native amphibians through predation, competition, or disease. Knowledge of the diet of introduced bullfrogs can help determine if bullfrogs are directly preying on these amphibians and therefore directly causing decline. Moreover, Humboldt County's coastal areas have a climate that is cooler on average than the American bullfrogs' native climate. Cool, yet stable year-round temperatures may affect larval phenology, knowledge of which is important for timing the larval culling used to manage the species. Bullfrogs and their larvae were captured from five coastal sites in Humboldt County, CA. Sites varied from 2 m to 1400 m in elevation, and from 0.18 km to 27.25 km in straight-line distance from the coast. Frogs were measured for snout-vent length, gender was determined and stomach contents were categorized. For larvae, total length and stage of development (Gosner stage) were recorded. Results showed diet was greatly affected by body size and site location. Native herpetiles made up a very small percentage (7%) of overall bullfrog diet by count, but a larger percentage (32% in adult females to 65% in juveniles) of diet by volume. Most larvae that were captured were large and young tadpoles (i.e., low Gosner stage) were rare. A late stage larva was captured in early spring, suggesting a multi-year development period. This study provides evidence that bullfrogs are directly preying on native herpetiles, and suggests that larval management efforts would best be carried out in late summer, prior to tadpoles metamorphosing or overwintering." (Author) Diet includes Odonata.] Address: not stated

13718. Grönroos, M.; Heino, J.; Siqueira, T.; Landeiro, V.L.; Kotanen, J.; Bini, L.M. (2013): Metacommunity structuring in stream networks: roles of dispersal mode, distance type, and regional environmental context. *Ecology and Evolution* 3(13): 4473-4487. (in English) ["Within a metacommunity, both environmental and spatial processes regulate variation in local community structure. The strength of these processes may vary depending on species traits (e.g., dispersal mode) or the characteristics of the regions studied (e.g., spatial extent, environmental heterogeneity). We studied the metacommunity structuring of three groups of stream macroinvertebrates differing in their overland dispersal mode (passive dispersers with aquatic adults; passive dispersers with terrestrial adults; active dispersers with terrestrial adults). We predicted that environmental structuring should be more important for active dispersers, because of their better ability to track environmental variability, and that spatial structuring should be more important for species with aquatic adults, because of stronger dispersal limitation. We sampled a total of 70 stream riffle sites in three drainage basins. Environmental heterogeneity was unrelated to spatial extent among our study regions, allowing us to examine the effects of these two factors on meta-

community structuring. We used partial redundancy analysis and Moran's eigenvector maps based on overland and watercourse distances to study the relative importance of environmental control and spatial structuring. We found that, compared with environmental control, spatial structuring was generally negligible, and it did not vary according to our predictions. In general, active dispersers with terrestrial adults showed stronger environmental control than the two passively dispersing groups, suggesting that the species dispersing actively are better able to track environmental variability. There were no clear differences in the results based on watercourse and overland distances. The variability in metacommunity structuring among basins was not related to the differences in the environmental heterogeneity and spatial extent. Our study emphasized that (1) environmental control is prevailing in stream metacommunities, (2) dispersal mode may have an important effect on metacommunity structuring, and (3) some factors other than spatial extent or environmental heterogeneity contributed to the differences among the basins." (Authors) The list of taxa only includes a single Odonata species, *Somatochlora metallica*.] Address: Grönroos, Mira, Ecosystem Change Unit, Finnish Environment Institute, Oulu, Finland. 13719. Gutiérrez-Fonseca, P.E.; Rosas, K.G.; Ramírez, A. (2013): Aquatic insects of Puerto Rico: a list of families. *Dugesiana* 20(2): 215-219. (in English, with Spanish summary) ["Studies on aquatic insects in Puerto Rico began early last century. Most taxa have been well documented; however, we lack information on some taxa and there is no single document containing all the scattered information. These are major obstacles for the study of insects on the island. Here we reviewed data collected in published articles, graduate theses, university courses, environmental impact studies and reviewed material deposited in the Museum of Zoology at the University of Puerto Rico. The objective was to compile the first list of aquatic insect families of Puerto Rico. Overall, 61 families belonging to seven insect orders were found. The best known orders were Ephemeroptera, Trichoptera and Odonata. The most diverse orders were Diptera, followed by Coleoptera and Hemiptera. Despite its small size, Puerto Rico is a diverse island compared to the remaining Greater Antilles. This study is the first attempt to develop a list with all information available and contribute to advance our knowledge of aquatic insects. In addition, we hope to aid decision makers and encourage ecological and biogeographical studies on aquatic ecosystems in Puerto Rico." 13720. Hamerlík, L.; Svitok, M.; Novikmec, M.; Očadlík, M.; Bitušík, P. (2013): Local, among-site, and regional diversity patterns of benthic macroinvertebrates in high altitude waterbodies: do ponds differ from lakes?. *Hy-*

drobiologia 723: 41-52. (in English) ["In this study we aimed at comparing invertebrate diversity of high altitude lakes and ponds along hierarchical spatial scales. We compared local, among-site, and regional diversity of benthic macroinvertebrates in 25 ponds and 34 lakes in the Tatra Mountains, central Europe. The ponds showed significantly lower local diversity, higher among-site diversity and similar regional diversity than the lakes. The species–area relationships (SAR), habitat heterogeneity, and environmental harshness are assumed as drivers for the local diversity patterns. An ecological threshold separating pond and lake systems emerged at an area of 2 ha, where the SAR pattern changed significantly. Differences in species turnover between these systems were likely driven by greater environmental variability and isolation of the ponds. High altitude ponds neither significantly support greater regional diversity nor higher number of unique taxa than lakes. The higher among-site diversity of ponds relative to lakes highlights the relevance of ponds for regional diversity in mountain areas. ... Except for Plecoptera (7 taxa) and Odonata (*Aeshna cyanea*, *Aeshna juncea*, *Somatochlora* sp.), the rest of higher taxonomic groups recorded were represented by 1–2 species/taxa. Odonata and Chaoboridae (Diptera) only occurred in ponds ..."] (Authors)] Address: Hamerlík, L., Faculty of Science, Matthias Belius University, Tajovského 40, SK–97 401 Banská Bystrica, Slovakia. 13721. Hanlon, S.H.; Re Iyea, R. (2013): Sublethal effects of pesticides on predator–prey interactions in amphibians. *Copeia* 2013(4): 691-698. (in English) ["Increasing evidence suggests that contaminants in the environment can have important consequences on organismal interactions. While we have a good understanding of the lethal effects of contaminants on organisms, we have a weak understanding of how contaminants can affect organisms by altering the interactions that they have with other species in the community. Using tadpoles of two anuran species (Bullfrogs, *Lithobates* [*Rana*] *catesbeianus*; Green Frogs, *L. clamitans*), we investigated the effects of low nominal concentrations (1 and 10 ppb) of two pesticides (malathion and endosulfan) on tadpole activity and survival when exposed to four predator treatments (no predators; water bugs, *Belostoma flumineum*; newts, *Notophthalmus viridescens*; and dragonfly larvae, *Anax junius*). In both anuran species, adding predators reduced tadpole activity and survival, with increasing rates of mortality occurring with water bugs, newts, and dragonflies, respectively. Additionally, the highest concentration of endosulfan caused tadpole mortality after 48 hrs. Most significant, tadpole species also experienced interactive effects of predators and pesticides on survival after 48 hrs. In Bullfrog treatments, all predators reduced the amount of tadpole mortality when exposed to endosulfan. In Green Frogs, additive negative effects occurred, except that newts increased the tadpole mortality when

exposed to endosulfan. Our findings illustrate that pesticide effects on predator–prey interactions are often complex and have the potential to alter aquatic community composition." 13722. Harabiš, F.; Šigut, M.; Dolný, A. (2013): Density-distribution patterns of egg parasitoids in freshwater habitats. *Časopis Slezského zemského muzea - serie A - vědy přírodní* 62(1): 65-72. (in Harabiš, F., Department of Ecology, Faculty of Environmental Sciences, Czech University of Life Sciences Prague, CZ-165 21 Prague 6, Czech Republic. E-mail: harabis.f@gmail.com) ["Similar in effect to predators, egg parasitoids could have a significant effect on the distribution of host and its' population dynamics. However, knowledge about the biology and ecology of aquatic parasitoids and their effects on the host are very limited. The aim of this study was to determine whether the density of parasitoids is affected by several environmental determinants and if there is a temporal change of density during the season, particularly in relation to the host population dynamics (from order Odonata in this study). In total, 266 individuals of parasitoid wasps (from four families utilizing damselflies as hosts) were identified. The density of parasitoids did not change significantly during the season regardless of the population dynamics of model host *L. sponsa* and other odonates, while there was a significant effect of habitat type on the density of parasitoids. This indicates that eggs of Odonata represent only one of several host taxa. This indicates that egg parasitoids of aquatic invertebrates are host generalists preferring open over afforested habitats." 13723. Hassall, C.; Keat, S.; Thompson, D.J.; Watts, P.C. (2013): Bergmann's rule is maintained during range expansion in a damselfly. *Global Change Biology* 20(2): 475-482. (in English) ["Climate-induced range shifts result in the movement of a sample of genotypes from source populations to new regions. The phenotypic consequences of those shifts depend upon the sample characteristics of the dispersive genotypes, which may act to either constrain or promote phenotypic divergence, and the degree to which plasticity influences the genotype-environment interaction. We sampled populations of *Erythromma viridulum* from Northern Europe to quantify the phenotypic (latitude-body size relationship based on seven morphological traits) and genetic (variation at microsatellite loci) patterns that occur during a range expansion itself. We find a weak spatial genetic structure that is indicative of high gene flow during a rapid range expansion. Despite the potentially homogenising effect of high gene flow, however, there is extensive phenotypic variation among samples along the invasion route that manifests as a strong, positive

correlation between latitude and body size consistent with Bergmann's rule. This positive correlation cannot be explained by variation in the length of larval development (voltinism). While the adaptive significance of latitudinal variation in body size remains obscure, geographical patterns in body size in odonates are apparently underpinned by phenotypic plasticity and this permits a response to one or more environmental correlates of latitude during a range expansion." 13724. Hayasaka, D.; Suzuki, K.; Korenaga, T.; Saito-Morooka, F.; Nomura, T.; Fukasawa, K.; Sánchez-Bayo, F.; Goka, K. (2013): Effects of two successive annual treatments of two systemic insecticides, imidacloprid and fipronil, on dragonfly nymph communities in experimental paddies. *Journal of the Pesticide Science Society of Japan* 38(2): 101-107. (in Japanese, with English summary) ["The effects of two successive annual treatments of imidacloprid and fipronil on dragonfly nymph communities, which are one of the best-known bioindicators in Japanese agroecosystems, were monitored in experimental paddies. The abundance of dragonfly nymphs was lower in both insecticides-treated fields than it was in the controls, particularly following fipronil treatments. Residues of both insecticides were found in the soil throughout the two years, and imidacloprid persisted in water up to three months following each treatment. A Principal Response Curve analysis (PRC) showed that the second annual treatments caused greater structural changes in dragonfly nymph communities than the initial treatments caused, particularly for fipronil. The community structures continued to change even after the insecticides dissipated from the water. This suggests that ecological impacts, and therefore risks, of imidacloprid and fipronil on dragonfly nymph communities depend more on soil residues than they do on waterborne residues. As expected, susceptibility of dragonfly nymphs to these two insecticides differed among species." 13726. Hinojosa-Garro, D.; Arceo-Gómez, J.; Zambraño, L.; Escalera-Vázquez, L.H. (2013): Fish diet composition in permanent and semi-permanent pools in tropical wetlands of the Yucatan Peninsula. *Neotropical Ichthyology* 11(4): 881-890. (in English, with Spanish summary) [Petenes Biosphere Reserve (PBR), Campeche, southern Mexico; "We compared fish diet composition between permanent (P) and semi-permanent (SP) pools in Petenes Biosphere Reserve (PBR), Campeche. A total of 445 gut contents were examined to determine stomach relative fullness (RF), fish diet as index of niche breadth (INB) and diet overlap. In SP pools, species showed a RF of 1.66 (57.20 % empty stomachs) whereas in P pools, the RF was 2.91 (31.16%). We classified fish diet into six trophic groups: detritivorous, herbivorous-detritivorous, insectivorous, piscivorous, omnivorous and malacophagous. Species in P pools were found to be specialist. Conversely, species present in both habitats shifted to generalist patterns. There was a 54.0% dissimilarity in fish diet composition between pools. From all items identified, detritus (21.33% of the total dissimilarity), aquatic and terrestrial invertebrates (12.31%), fish remains (10.29%), plant remains (7.37%), and crustaceans (2.74%) distinguished diets between pools. Significant diet overlaps (>0.6) and low INB values (<0.3) were observed in P pools, whereas in SP pools, intermediate-low diet overlaps (<0.4) and higher INB values (>0.5) were observed. In SP pools seasonality had a strong effect on fish diet, increasing the frequency of food items such as terrestrial insects, amphipods and arachnids, during the rainy season while P pools showed lower variation. Thus, fish trophic habits appear to be regulated by pools hydrology." (Authors) Odonata had significant higher frequencies in fish of P pools compared to SP pools.] Address: Hinojosa-Garro, D., Laboratorio en Manejo de Vida Silvestre y Colecciones Científicas, Área de Ecología Acuática, CEDESU, Universidad Autónoma de Campeche, San Francisco de Campeche, Campeche, México. 13729. Kadye, W.T.; Chakona, A.; Marufu, L.T.; Samukange, T. (2013): The impact of non-native rainbow trout within Afro-montane streams in eastern Zimbabwe. *Hydrobiologia* 720: 75-88. (in English) ["Non-native trout species have been associated with many negative effects in receiving ecosystems. The first aim of this study was to determine the impact of non-native rainbow trout *Oncorhynchus mykiss* on distribution and abundance of native mountain catfish *Amphilius uranoscopus* within Afro-montane streams in Nyanga Mountains, eastern Zimbabwe. The second aim was to compare macroinvertebrate community responses to the presence of the trout and the catfish. We examined trout impact on catfish's habitat associations, whereas macro-invertebrate composition was compared using open fish and fish enclosure experiments in habitats with and without trout. Trout influenced both the distribution and abundance of the catfish that occupied shallow reaches possibly to avoid predation from trout that occurred in the deeper habitats. Within trout invaded reaches, most macro-invertebrate taxa were more abundant in enclosure than open treatments. By contrast, within trout-free reaches, most macro-invertebrates either did not differ between treatments or were generally more abundant in open than enclosure treat-

ments. This suggests that the macro-invertebrate communities responded differently within invaded and non-invaded reaches. By influencing distribution and abundance of native biota, non-native rainbow trout may have wider ecological effects, such as influencing trophic interrelationships within invaded habitats. ... In general, large-bodied Odonate taxa *Atoconeura* sp. and *Aeshna* sp. were more abundant in Mare River that had no trout compared to Pungwe River that had trout." 13735. Khelifa, R.; Mahdjoub, H.; Zebba, R.; Kahalerras, A.; Guebailia, A.; Amari, H.; Houhamdi, M. (2013): Aspects of reproductive biology and behaviour of the regional critically endangered *Urothemis edwardsii* (Odonata: Libellulidae) on Lake Bleu (Algeria). *Zoology and Ecology* 23(4): 282-285. (in English, with Lithuanian summary) ["A study on the reproductive biology and behaviour of the regional critically endangered *Urothemis edwardsii* Selys was conducted in the relict sub-population of Lake Bleu (North-east Algeria) during the reproductive season of 2012. The reproductive behaviour was described from the pair formation to the end of oviposition. Copulation duration was 98.55 ± 16.48 s, and the whole oviposition episode lasted 220.89 ± 32.08 s with usually three bouts interrupted by three rest periods. The species displayed a particular oviposition behaviour characterized by an alternation of contact (during the first bout) and non-contact guarding. The induced clutch size was 646.33 ± 173.10 eggs. In the laboratory, eggs showed direct embryonic development and synchronous egg hatching within the modal period of 10 days ranging between nine and 24 days. The overall hatching success was 85.39%, the main

causes of mortality being infertility and unhatchability." (Authors)] Address: Khelifa, R., Faculty of Biological and Agricultural Sciences, Biology Department, University of Tizi Ouzou, Tizi Ouzou 15000, Algeria. E-mail: rassimkhelifa@gmail.com

13736. Knight, K. (2013): Damselfly larvae select quick release lamellae for survival. *J. Exp. Biol.* 217: 159. (in English) ["Adult damselflies are a spectacular vision of summer, streaking through the air above pond surfaces. Yet survival through their earlier aquatic life stages is extremely precarious. Equipped with leaf-like lamellae hinged at the end of the abdomen for propulsion, the structures provide the perfect appendages for passing predators to grab onto. But the larval insects have a self-preservation mechanism that helps them to escape hungry predators: they self amputate – autotomize – trapped lamellae. Jennifer Gleason, Douglas Fudge and Beren Robinson from the University of Guelph, Canada, explain that the ability of a larva to shed its lamellae with ease improves its chances of survival, which might lead larvae that inhabit heavily predated waters to develop relatively fragile lamellar joints to increase their chances of survival (p. 185). To test the theory, the Canadians measured the force required to break damselfly larvae lamellar joints, as well as the size and cuticle thickness of the joint. They discovered that the joints of damselfly larvae from fishless ponds – where carnivorous dragonfly larvae flourish – were much more fragile than the joints of larvae from ponds where there were few dragonfly larvae. 'This suggests that autotomy may evolve in larval damselflies under selection from small grasping predators like larval dragonflies by favouring smaller joint size or reduced cuticle area of lamellae joints', says the team." 13737. Knillmann, S.; Stampfli, N.C.; Noskov, Y.A.; Becketov, M.A.; Liess, M. (2013): Elevated temperature prolongs long-term effects of a pesticide on *Daphnia* spp. due to altered competition in zooplankton communities. *Global Change Biology* 19(5): 1598-1609. (in English) [Fifty-five outdoor microcosms were installed at the UFZ-Helmholtz Centre for Environmental Research, Germany (51°21'13N, 12°25'55E). "Considerable research efforts have been made to predict the influences of climate change on species composition in biological communities. However, little is known about how changing environmental conditions and anthropogenic pollution can affect aquatic communities in combination. We investigated the influence of short warming periods on the response of a zooplankton community to the insecticide esfenvalerate at a range of environmentally realistic concentrations (0.03, 0.3 and 3 µg L⁻¹) in 55 outdoor pond microcosms. Warming periods increased the cumulative water temperature, but did not exceed the maximum temperature measured under ambient conditions. Under warming conditions alone the abundance of some zooplankton taxa increased selectively

compared to ambient conditions. This resulted in a shift in the community composition that had not recovered by the end of the experiment, 8 weeks after the last warming period. Regarding the pesticide exposure, short-term effects of esfenvalerate on the community structure and the sensitive taxa *Daphnia* spp. did not differ between the two temperature regimes. In contrast, long-term effects of esfenvalerate on *Daphnia* spp., a taxon that did not benefit from elevated temperatures, were observed twice as long under warming than under ambient conditions. This resulted in long-term effects on *Daphnia* spp. until 4 months after contamination at 3 µg L⁻¹ esfenvalerate. Under both temperature regimes, we identified strength of interspecific competition as the mechanism determining the time until recovery. However, enhanced interspecific competition under warming conditions was prolonged and explained the delayed recovery of *Daphnia* spp. from esfenvalerate. These results show that, for realistic prediction of the combined effects of changing environmental factors and toxicants on sensitive taxa, the impacts of stressors on the biotic interactions within the community need to be considered." (Authors) Odonata are considered at the order level.] Address: Knillmann, Saskia, Department of System Ecotoxicology, UFZ - Helmholtz Centre for Environmental Research, Permoserstr. 15, 04318 Leipzig, Germany. 13738. Knorp, N. (2013): Limitations on macroinvertebrate populations in South Florida wetlands. MSc. thesis, Florida Atlantic university: 69 pp. (in English) ["It can be difficult to disentangle the factors that determine population success in freshwater systems, particularly for organisms with disturbance-resistant life stages like aquatic invertebrates. Nevertheless, the effects of environmental variation and habitat structure on animal population success in wetlands are important for understanding both trophic interactions and biodiversity. I performed two experiments to determine the factors limiting crayfish (*Procambarus fallax*) and dragonfly (Family: Libellulidae) populations in wetland environments. A simulation of a dry-disturbance and subsequent sunfish (Family: Centrarchidae) re-colonization revealed that crayfish populations are sensitive to sunfish, while dragonfly naiads seemed to be limited by other drying-related factors. A second manipulation revealed that small-bodied fishes and habitat structure (submerged vegetation) shaped dragonfly communities primarily through postcolonization processes." (Author)] Address: Knorp, Natalie. not available

13739. Kovacs, T.; Muranyi, D. (2013): Larval data of *Caliaeschna microstigma* (Schneider, 1845) from the Balkan Peninsula, with contributions to its biology (Odonata: Aeshnidae). *Folia historico naturalia musei Matraensis* 37: 21-28. (in English) ["Based on larvae or exuviae, we present 59 new localities of *C. microstigma* from Albania (17), Bulgaria (6), Croatia (1), Greece (18), Macedonia (2), Montenegro (11), and from the Eu-

ropean part of Turkey (4). Collecting sites are depicted on a map. Summary on the habitat and biology of the species is given, and morphological characters of the larvae are shown on several figures. Due to the different larval cohorts collected, we conclude that the species has semivoltine life cycle." 13742. Kumar, M. (2013): Image performance characteristics of bio-inspired image sensor. MSc. thesis, The Graduate Faculty of The University of Akron: XIII + 111 pp. (in English) ["Bio-Inspired imaging has the prospective to enhance machine vision and image performance characteristics. The rationale of this study is to explore the image formation by different insect eyes that will benefit the digital imaging with high resolution while maintaining wide field-of-view, for defense and military applications. In this study, three architectures of different compound eyes, namely, the apposition, the superposition and the neural superposition, were studied. Human eye is polarization insensitive and without usage of an artificial polarization filter, it cannot employ the polarization of light. In contrast, insect vision holds numerous advantages, as their compound eyes provides wide viewing angle, good tracking abilities due to large amount of photoreceptor units and foremost im-

portant can detect the polarized light. It is well known, that polarization of light provides enhanced structural and geometrical information, such as high contrast visualization of the surface contours, curvature of objects, surface structures, and locations of different materials. The five insect species that were considered for this study are *Hemicordulia tau*, *Anoplognathus pallidicollis*, *Heteronympha merope*, *Melanitis leda* and *Phalacrocorax aristoteles*. In this study, several insect eyes architecture, were studied. Then, the imaging design parameters by varying the physical, geometrical, optical parameters of the eye architectures were simulated. Specifically, several physical, optical, geometrical, and imaging design parameters considered for this study, namely, the angular spacing of receptors, the diameter of the photoreceptors, the optical field-of-view, flying speed; the modulation transfer function (MTF), optical-blur filters, image contrast, angular sensitivity, spatial and angular resolution, degree of blurring, signal-to-noise ratio, and motion artifacts, were simulated at varying of those parameters. The outcome of this study is to explore the phenomenology of the image formation by diverse insect eye architectures which may benefit the areas of defense and security, surveillance and navigation, healthcare, and others." 13748. Massaro, F.C.; Negreiros, N.F.; Rocha, O. (2013): A search for predators and food selectivity of two native species of *Hydra* (Cnidaria: Hydrozoa) from

Brazil. *Biota Neotropica* 13(2): 35-40. (in English, with Portuguese summary) ["The Hydra is the most common representative of freshwater cnidarians. In general, it is found in freshwaters on every continent, with the exception of Antarctica. The aim of the present study is to gather biological and ecological data on aspects of two species of Hydra native to Brazil: *Hydra viridissima* and *Hydra salmacidis*. Predation and food selectivity experiments were performed to assess the possible predators and the prey preferences, respectively, of the two species. The results indicate that the two species of Hydra were not consumed by any of the predators that were tested, which are typical predators of invertebrates in freshwater: nymphs of Odonata Anisoptera and the phantom midge larvae of *Chaoborus* sp. (Insecta), adults of Copepoda Cyclopoida (Crustacea) and the small fish *Poecilia reticulata*. It was observed that the smaller Hydra, *H. viridissima*, positively selected the nauplii and copepodites of calanoid copepods and small cladocerans and rejected large prey, such as the adults of calanoid copepods and ostracods. The larger *H. salmacidis*, besides the nauplii and copepodites of the calanoid copepods and small cladocerans, also positively selected the large adults of the calanoid copepods. It can be concluded that both *H. viridissima* and *H. salmacidis* are most likely preyed on little or not preyed on at all in many freshwater bodies, as they are top predators in the food chain. At the same time, they are efficient predators, and a positive relationship was observed between the prey size and the Hydra species size. Food selectivity was related to prey size as well as other prey characteristics, such as carapace thickness and swimming efficiency. ... Thus, it can be concluded that Odonata Anisoptera, the phantom midge *Chaoborus* sp., the adults of Copepoda Cyclopoida and the fish *P. reticulata*, which were tested as predators in the present study, do not consume hydras in freshwater." (Authors)] Address: Massaro, Fernanda Cristina, Post Graduate Program in Environmental Engineering Science, São Carlos School of Engineering, University of São Paulo – USP, Av. 13755. Nattress, B. (2013): Mixed pairing by Emerald Damselfly *Lestes sponsa*. *Atropos* 50: 83. (in English) [Verbatim: I was interested to read the note in *Atropos* 47 (Pickess, 2012) about pairing by a male Emerald Damselfly *Lestes sponsa* with a female Large Red Damselfly *Pyrrosoma nymphula*. This observation reminded me of a similar incident that I had witnessed back in 2011. On the afternoon of 27 July 2011, whilst on holiday in Dumfries and Galloway, I visited Balloch Wood Ponds, near Creetown. I was strolling around watching the dragonflies and damselflies, when I noticed a male Emerald Damselfly paired with a female Large Red Damselfly. I took a quick photograph for the record. I watched the pair for not much more than a minute before they moved away.] Address: Nattress, B., 25 West Lea Dive, Tingley, Wakefield, West Yorkshire, WF3 1DH, UK

13756. Nava-Bolaños, A.; Sánchez-Guillén, R.A.; Munguía-Steyer, R.; Córdoba-Aguilar, A. (2013): Isometric patterns for male genital allometry in four damselfly species. *Acta ethologica* 17(1): 47-52. (in English) ["Recent studies have found that insect genitalic traits show negative allometry, i.e., are relatively small in relation to body size. One interpretation of this is that males use their genitalia to stimulate females. Thus, given the nature of damselfly copulation in which males physically reach the rival sperm that females have stored from previous matings, male genitalic traits are not expected to show negative allometry. To test this idea, we assessed (a) the rival sperm displacement function by the mating male and (b) allometry of aedeagal length of four damselfly species (*Argia anceps*, *Argia tezpi*, *Argia extranea*, and *Enallagma praevarum*). Sperm displacement was assessed by inspecting whether the aedeagus reached the rival sperm during copulation in mating pairs for the four species. To have a standard for comparing allometric patterns, allometry of aedeagal was compared to that of two non-genital traits, tibial,

and fourth abdominal segment length. In all cases, the aedeagus was found to reach the rival sperm which supports the idea that stimulation is not the mechanism for sperm displacement but physical displacement. Aedeagal length was isometric, and its slope was lower in general compared to that of tibial length and fourth abdominal segment. Given that this isometric pattern is not common for other odonate species, our interpretation of these varying aedeagal scaling patterns in this insect order is that males' and females' sexual interests are in conflict (males are evolving an elongated aedeagus to reach rival sperm while females are evolving unreachable sperm storage organs to prevent displacement of stored sperm). This sexual conflict scenario would favor varying scaling patterns for aedeagal length in odonates. A final interpretation is that the risk of interspecific matings in damselflies, may also explain different species-specific, aedeagal allometries." 13757. Nelson, S. (2013): Sampling guide for the collection of dragonfly larvae and water samples from National Parks for mercury analysis. University of Maine (UMaine)/Mitchell Center & School of Forest Resources Acadia Learning/Schoodic Education Research Center (SERC) Institute National Park Service (NPS) – Air Resources Division (ARD): 16 pp. (in English) ["Scope and Application: Mercury threatens natural resources the National Park Service is charged with protecting. This citizen science project encourages students and visitors in national parks to collect dragonfly larvae for mercury analyses. The study connects people to parks, advances the educational mission, fosters biodiversity discovery opportunities, and provides baseline data to better understand the spatial distribution of mercury contamination in national parks. Mercury (Hg) is a globally distributed contaminant that can harm human and wildlife health. In its toxic methylated form, mercury bioaccumulates (builds-up) in aquatic and terrestrial foodwebs. Effects include reproductive and neurological impairment. Due in part to emissions from coal-burning power plants, even remote national park environments receive mercury deposition from the atmosphere. (See <http://www.nature.nps.gov/air/AQBasics/mercury.cfm> for background on mercury in national parks.) Dragonfly larvae (Odonata: Anisoptera) could serve as indicators of ecosystem health by characterizing the risk and potential toxic effects of mercury. These aquatic macroinvertebrates are long-lived (up to 5 year as larvae) before emerging as adult dragonflies, widespread across the U.S., predatory (i.e., prone to higher concentrations of mercury), important prey for fish species, and they reflect the mercury sensitivity of a specific watershed. Moreover, they are relatively easy to collect! This citizen science project (<http://www.nature.nps.gov/air/Studies/>

airtoxics/dragonfly/index.cfm) expands the geographic scope of research previously conducted by scientists and citizen scientists, and provides data that can be compared across parks. Early data are being used to develop hypotheses regarding whether mercury varies with odonate larval body size or by family; or whether a site's landscape setting drives variability in mercury in odonate larvae. Educational content and lesson plans for use by interpreters, resource managers, or research learning center staff are also available. Ultimately, this project also helps raise awareness about mercury impacts. The citizen science effort to collect dragonfly larvae from national parks for mercury analysis expanded in 2012 to include a total of approximately 14 parks across the following NPS regions: Northeast, Southeast, Midwest, Intermountain, Pacific West, and Alaska. Citizen scientists involved include students ranging from elementary-aged to college, park visitors, and BioBlitz participants. In addition to collecting dragonfly larvae, all parks are collecting a water sample for mercury-relevant water chemistry (i.e., dissolved organic carbon (DOC), pH, sulfate) and a water sample for total mercury. Most parks will sample once per year but a few parks will sample twice per year to help determine if there is seasonal variability. Data results will be available in 2013/2014. The optimal study design is 2.3 sites per park that represent a gradient in mercury-relevant chemistry (as defined above); or a gradient in landscape condition, such as a high and low elevation, amount of wetlands adjacent to or upstream from the site, or forested versus urban landcover. Consider scoping the sampling locations in advance of collecting samples. Does the proposed sampling location retain a healthy population of dragonflies? (A sample size of 15 dragonfly larvae per site is preferred.) Will nearby riparian flora and fauna get trampled? Is the site spacious enough for a group? Safety of the participants involved is extremely important. Riparian edges can be very slippery, as are stream and lake bottoms. High water levels and turbulent flows may cause an individual to lose balance in the water. Be attentive of the possible risks. A park research permit will be needed to conduct this project; the dragonfly and water samples collected for this project will be destroyed through analysis, or discarded after analysis. In addition, in some cases, a state permit may be needed to collect dragonfly larvae. Example text for the permit application can be found in Appendix A of this sampling protocol. The project's fact sheet and other materials will provide further assistance. (See NPS Dragonfly Larvae web page as above and additional documents on Sharepoint <http://sharenr/ard/DragonflyMercuryProject/Forms/AllItems.aspx>.)" (in German, with English summary) ["A systematic hunt of one male of *A. cyanea* after tandems of *Lestes viridis* was observed five times at 18.10.2013 in southwest

Germany. Two of five observed attacks during 30 minutes were successful, but at the end in all cases the prey escaped." (Author)] Address: Nowak, M., Fuchseckstr. 16/1, 73114 Schlat, Germany. E-mail: Nowak-Schlat@t-online.de

13759. Nowack, M. (2013): Kleine Einblicke zum Verhalten der Großen Moosjungfer *Leucorrhinia pectoralis*. *Mercuriale* 13: 37-40. (in German, with English summary) ["In 2012 the behaviour of *L. pectoralis* was studied during 22 visits at one waterbody in the eastern part of the German Land of Baden-Württemberg. One male was observed 11 times in a time span of three weeks. The activity patterns of two males being present simultaneously at the study site differed significantly. One male showed rhythmic movements with its abdomen, which was in a concave position similar to that of some damselflies. When the sun was hidden behind clouds the observed specimens perched at light stems and open soil, where they sometimes got in touch with their wings to the ground. The only female observed, was ovipositing unguarded by a male over the open water surface in a two minutes timespan. All specimens, which were observed reaching or leaving the breeding water, either came from neighbouring trees or left the water towards the trees. The results are shortly discussed." (2013): A description of the larva of *Heliaeschna idae* Brauer from Borneo, with a supplementary note on the larva of *H. univervulata* Martin (Odonata: Aeshnidae). *International Journal of Odonatology* 16(3): 231-238. (in English) ["The final instar larva of *H. idae* is described and figured for the first time based on the exuvia from an advanced female larva collected in Sarawak, Borneo (East Malaysia). It is compared with the known larvae of the genus and is concluded to be most closely allied to *H. simplicia* Karsch, with which it shares a unique structure on the anterior margin of the prementum of the labium, along with several other distinctive characters.

The dorsal structure of the head of *H. uninervulata* is re-examined and illustrated. It is shown to bear a prominent convexity and tuft of long setae on the vertex which is similar to a structure previously recorded only in *H. simplicia*, and which is only weakly developed in *H. idae*. The taxonomic implications of these partly conflicting observations are discussed and it is concluded the Oriental members of the genus *Heliaeschna* might be separated into two or three separate genera, which are as yet unnamed." Panomwan, Y.; Thanawan, P.-P.; Promm, T.-o, (2013): Aquatic insect communities and water quality in wetland, northern Thailand. *Journal of Applied Sciences in Environmental Sanitation* 8(3): 161-169. (in English) ["Nong Leng Sai wetland is located in Phayao Province, northern Thailand. Agriculture in contiguous lands has caused sedimentation and eutrophication, affecting not only its hydrology but its capacity to sustain a high diversity of aquatic life. The aims of this study were to assess the physicochemical (pH: air and water temperature, dissolved oxygen, conductivity and total dissolved solids) and biological characteristics (aquatic insects) of five sampling sites in the wetland during January to August 2009. Three replicates of samplings by aquatic D-net were used at the sampling sites. A total of 3,724 individuals belonging to seven orders and 26 families were recorded in this study. The hemipterans were the most abundant groups in wetland (8 families) followed by the coleopterans (6 families), the dipterans (3 families), the odonates (3 families), ephemeropterans (3 families), the trichopterans (2 families) and the lepidopteran was least abundant (1 family). The results from CCA indicated that low diversity was probably due to higher conductivity in the month of the dry season." rial de *Perithemis mooma* (Kirby) (Anisoptera: Libellulidae). *EntomoBrasilis* 6(2): 104-107. (in Portuguese, with English summary) ["Effect of the presence of neighbours on the behaviour of territorial *Perithemis mooma*: Some territorial species present less aggressive responses in relation to the entering of neighbours than non-neighbours in their territory. This differentiation in responses is known as "Dear Enemy Effect". The objective of this study was evaluate the interaction of *P. mooma* with its neighbours and invaders, testing the occurrence of the "Dear Enemy Effect". This study was conducted in the Campus Samambaia of the Universidade Federal de Goiás (UFG). The intraspecific agonistic interactions of *P. mooma* were observed in 30 individuals, totalling 300 minutes of observation. We verified that the individuals spend more time in fights with invaders. This information corroborates the hypothesis that individuals recognize the neighbours; consequently spend less time the agonistic interactions with them. For the analysis about time and proportion of fight with neighbours more or less distant, we verified that the individuals spend more time in interactions with closer neighbour than further neighbours. Occurred more proportion of fight with invaders from the side of the lesser distant than from the centre (Tukey test; $p = 0.034$). We observed that in *P. mooma* there is a significant effect indicating that males who recognizes themselves as neighbours interact with lesser aggressively than when interact with invaders. Thus, it is possible suggest that there is an effect dear enemy in males *P. mooma*, since there was a significant difference in time, as well as in the intensity of the interaction with neighbours and with invaders." 13766. Popova, O.N.; Kharitonov, A.Yu. (2013): [Mass reproductive migrations of dragonflies genus *Sympetrum* (Odonata, Libellulidae)]. *Zoologicheskii zhurnal* 92: 893-900. ["The results of observing mass flights of some dragonflies of the genus *Sympetrum* forming tandems are presented. These tandems always fly against the wind, some of them landing for oviposition and then joining the flight again. This variant of migration behaviour has been unexplained until now. A hypothesis is proposed according to which synchronous mass flights of dragonfly tandems facilitate the most uniform oviposition in all the suitable biotopes. The general direction of the flight depends on the wind. As the wind direction changes, the flight course of the tandems changes ac-

cordingly, so that the dragonflies cross the same territory several times, which leads to a denser and more uniform distribution of eggs. It is proposed to refer to this variant of flight as reproductive wanderings. Such a dispersal strategy can maintain the most uniform population density and a more stable abundance of some dragonfly species in the territories with unstable humidity." 13768. Rebor, M.; Dell'Otto, A.; Rybak, J.; Piersanti, S.; Gaino, E.; Hansson, B. (2013): The antennal lobe of *Libellula depressa* (Odonata, Libellulidae). *Zoology* 116 (4): 205-214. (in English) ["Here we describe the antennal lobe of *L. depressa*, identified on the basis of the projections of the afferent sensory neurons stemming from the antennal flagellum sensilla. Immunohistochemical neuropil staining as well as antennal backfills revealed sensory neuron terminal arborizations covering a large portion of the antennal lobe. No clear glomerular structure was identified, thus suggesting an agglomerular antennal lobe condition as previously reported in Palaeoptera. The terminal arbors of backfilled sensory neurons do, however, form spherical knots, probably representing the connections between the few afferent neurons and the antennal lobe interneurons. The reconstruction revealed that the proximal part of the antennal nerve is divided into two branches that innervate two spatially separated areas of the antennal lobe, an anterioventral lobe and a larger posteriodorsal lobe. Our data are consistent with the hypothesis that one tract of the antennal nerve of *L. depressa* contains olfactory sensory neurons projecting into one of the sublobes, while the other tract contains thermo-hygroreceptive neurons projecting into the other sublobe." 13769. Roa-Fuentes, C.A.; Prada-Pedrer, S.; Álvarez-Zamora, R.; Rivera Rondón, C.A.; Maldonado-Ocampo, J.A. (2013): Abundancia relativa y dieta de *Grundulus bogotensis* (Characiformes: Characidae) en

el altiplano Cundiboyacense, Colombia. *Universitas Scientiarum* 18(1): 73-82. (in Spanish, with English and Portuguese summaries) ["Relative abundance and diet of *G. bogotensis* in the Cundiboyacense plateau, Colombia. Abstract. To compare the relative abundance of *G. bogotensis* in two river basins and the diet of the populations of three basins in the Cundiboyacense plateau, we sampled 10 localities using electrofishing equipment between March and June 2006. The relative abundance in each locality was expressed as the number of fish caught per hour on a 100m stretch; any significant differences in relative abundance among basins were identified via a Kruskal-Wallis test. To quantify the diet, we used the volumetric method. Similarities between the basins were determined using three multivariate analyzes: nonmetric multidimensional scaling, analysis of similarity and similarity percentages. In the end, we collected a total of 675 individuals during 600 minutes of capture effort. The abundance of this species in the Bogotá river basin was significantly lower compared to that of the Suárez basin. The dietary composition, of autochthonous origin, primarily immature insects (including 'Aeshnidae') and microcrustaceans and the volume of items proved similar between the basins. In conclusion, the dietary analysis indicated a similarity exceeding 60% in the feed resource use for the three basins. The relative abundance of populations of *G. bogotensis* in the Bogotá river basin was lower than in the Suárez river basin, the latter having, possibly, the greatest abundance of this species throughout its range. The data suggests the most favourable conditions for the survival of the species in Lake Tota." 13770. Robinson, J. (2013): Observations on the predation of *Gyrinus* by *Aeshna grandis* (Odonata: Aeshnidae) and *Triturus cristatus* (Amphibia: Salamandriidae). *Latissimus* 34: 20-21. (in English) [Verbatim: Whilst collecting invertebrate samples from a pond and ditch complex in Lancashire (UK) this summer (12 July 2013) I observed some invertebrate and vertebrate behaviour which I had never seen before. I was taking a break and when I heard distinctly audible splashes in the ditch adjacent to my resting spot. Peeking over the bridge parapet I watched a large brown dragonfly repeatedly diving onto the surface of the ditch causing audible and visible splashes. The action was far too violent to be ovipositing, so I grabbed a pair of binoculars and watched. The dragonfly turned out to be a male *Aeshna grandis* (instantly discounting the ovipositing idea). The dragonfly was actively hunting gyrenids. I watched for a good half hour and the dragonfly took six gyrenids in that time period and "missed" a similar number. It deliberately took individuals that were separate from the main raft. All the texts I've read have suggested that the

volatile chemicals produced by the pygidial glands rendered gyrinids either unpalatable or toxic to predators, however, the *Aeshna* had not apparently read this. It was definitely eating them, not just catching and dropping, if they are that unpalatable and/or toxic, it would have stopped after the first one surely? There were plenty of other prey types available for the *Aeshna* (ciclicids and tabanids were very abundant and not perturbed by any insect repellent my assistant and I cared to apply) I wonder if, on the day in question air temp was ca 30°C, that the volatiles were simply evaporating before they became "effective"? The same ditch had a significant population of Great Crested Newts and later that day I observed an individual taking gyrinids from below, it would rest on a piece of submerged masonry (approx. 200mm) below the surface) until the raft of gyrinids was directly overhead then shoot up, grab one and sink slowly back onto the masonry. The newt showed no sign that the Gyrinids were either unpalatable or toxic as it caught at least nine in the time period that I watched. The only gyrinids I recorded from that ditch were *G. substriatus* Stephens and I have to admit that both the *Aeshna* and GCN caught more than I did! Address: not stated

13771. Rudolf, V.H.W.; Rasmussen, N.L. (2013): Population structure determines functional differences among species and ecosystem processes. *Nature Communications* 4, Article number: 2318 doi:10.1038/ncomms3318: 7 pp. (in English) ["Linking the structure of communities to ecosystem functioning has been a perennial challenge in ecology. Studies on ecosystem function are traditionally focused on changes in species composition. However, this species-centric approach neglects the often dramatic changes in the ecology of organisms during their development, thereby limiting our ability to link the structure of populations and communities to the functioning of natural ecosystems. Here we experimentally demonstrate that the impact of organisms on community structure and ecosystem processes often differ more among developmental stages within a species than between species, contrary to current assumptions. Importantly, we show that functional differences between species vary depending on the specific demographic structure of predators. One important implication is that changes in the demography of populations can strongly alter the functional composition of communities and change ecosystem processes long before any species are extirpated from communities." 13773. Sánchez-Guillén, R.A.; Córdoba-Aguilar, A.; Cordero-Rivera, A. (2013): An examination of competitive gametic isolation mechanisms between the damselflies *Ischnura graellsii* and *I. elegans*. *International Journal of Odonatology* 16(3): 259-267. (in English) ["Recent findings suggest that postmating prezygotic isolation (i.e. gametic barriers) could be an important factor preventing hybrid formation. Competitive gametic barriers emerge when a female is inseminated by a conspecific and a heterospecific male. We examined whether sperm proportions after double matings and copulation duration impede hybrid formation. For this, we used females of *Ischnura graellsii* that mated with one conspecific and one heterospecific (*I. elegans*) male and vice versa, and calculated paternity of the second male by using RFLPs. Values of paternity (although preliminary because of a small sample size) suggest no bias in paternity towards conspecific males. However, proportion of sperm stored in the bursa and spermatheca of the female was biased towards the conspecific male when the heterospecific male was the first male, while copulation duration did not differ between conspecific and heterospecific males. Our results suggest that the relative sperm volumes may play a role as a gametic barrier in this species. However, cryptic female choice mediated by the preferential use of the conspecific sperm, although not detected, could not be discarded owing to small sample sizes in some cases." 13775. Schilthuizen, M. (2013): Something gone awry: unsolved mysteries in the evolution of asymmetric animal genitalia. *Animal Biology* 63: 1-20. (in English) ["The great diversity in genital shape and function across and within the animal phyla hamper the identification of specific evolutionary trends that stretch beyond the limits of the group under study. Asymmetry might be a trait in genital morphology that could play a unifying role in the evolutionary biology of genitalia. Here, I review the current knowledge on the taxonomic distribution, phylogenetic patterns, genetics, development, and ecology of asymmetric (chiral) genitalia. Asymmetric genitalia (male as well as female) have evolved from bilaterally symmetric ones (and sometimes vice versa), innumerable times in most animal taxa with internal fertilisation, and especially in Platyhelminthes, Arthropoda, Nematoda, and Chordata. In groups with asymmetric genitalia, chiral reversal (where species carry genitalia that are the mirror image of those in other, congeneric, species) is common, but antisymmetry (both mirror images present within a species) is rare. Although indications exist that, at least in insects, asymmetry evolves as a compensatory response to the evolution of male-dominant mating positions, many mysteries remain. Main questions are: (i) is genital asymmetry developmentally linked with other (visceral, external) asymmetries? (ii) is genital asymmetry usually correlated with a change in mating position? (iii) is asymmetry more likely to evolve in response to cryptic female choice or sexually-antagonistic coevolution? (iv) why is antisymmetry so rare and how does chiral reversal evolve? Based on an overview of the taxonomic patterns, I advocate a research program that makes use of the simple, binary nature of left-right asymmetry to test hypotheses for its evolution with experimental and comparative methods. I also provide tables with full or summarised data on (a) genital asymmetry across all animal phyla with internal fertilisation; (b) genera with dextral as well as sinistral species; (c) species with dextral as well as sinistral individuals; (d) genera with symmetric as well as asymmetric species; (e) species with symmetric as well as asymmetric individuals." 13776. Schultz, T.D.; Fincke, O.M. (2013): Lost in the crowd or hidden in the grass: signal apparency of female polymorphic damselflies in alternative habitats. *Animal Behaviour* 86(5): 923-931. (in English) ["Highlights: • We quantified apparency of polymorphic female damselflies as mates and prey. • Females matched either the colour of conspecific males or the colour of the visual background. • Cryptic heteromorphs were nearly undetectable to conspecific males or predators in vegetation. • Male-mimicking andromorphs were highly detectable to conspecific males and predators on shore. • We propose that disruptive selection on female colour is driven by sexual conflict and predation. Animals must locate prey and mates in noisy sensory environments. Species that rely on visual cues, and which are prey of visual predators, consequently face trade-offs. Additionally, within species, sexual conflict over mating may impose pressures to avoid both predators and mates. Many studies have attempted to explain female-specific polymorphisms in damselflies, but without considering their actual conspicuousness under natural conditions. Using models of colour perception for damselflies and birds, we assessed the detectability of female coloration to conspecific males and potential predators. Alternative colour morphs reduce female apparency either through signal similarity with conspecific males (i.e. mimicry) or by matching the noise of the visual background. The colours of male-mimicking andromorphs that reduce their apparency among groups of males at breeding sites render them highly detectable to males as well as visual predators in offshore vegetation, where females occur when not reproducing. By presenting tethered female damselflies to free-flying males amidst vegetation, we demonstrated that, among flying females, males were able to detect andromorphs more easily than the more cryptic heteromorphs. Thus, when male density is low, cryptic heteromorphs may experience less harassment than andromorphs, suggesting a scenario of disruptive selection on female coloration driven by males as well as predators. Greater attention is warranted not only to the predation risks of female signals, but also to the effect of variation in the visual environments on encounters between males and unreceptive females." Published by Department of Forestry and Environmental Science, University of Sri Jayewardenepura 18: 143. (in English) [Verbatim: A preliminary study on the diversity of Odonata was carried out for the first time to assess the diversity of Odonata in the Peak Wilderness Sanctuary (PWS), Sri Lanka. It is a biologically rich area surrounding the Adam's Peak which is located at 6° 48' 33.357" N and 80° 29'58.3182" E. Total area of the sanctuary is about 24,000 ha and the altitude ranges from 50 m to 2238 m. The study was conducted from August 2012 to August 2013. Visual encounter survey method was used for the sampling and it was carried out along the existing paths and streams in the sanctuary covering many different habitats types. Sampling was done in the day time from 0800 h to 1700 h as odonates are most active during the day. 34 species of odonates representing 11 families were recorded during the study while 30 of them were identified to the species level. This represents 28.1% (from 121 species) of the Sri Lankan odonate fauna. 19 of the recorded species (55.9%) belong to Suborder Zygoptera while there remaining 15 (44.1%) belongs to the Suborder Anisoptera. Seven of the identified species are endemic to the country while 13 species are considered to be threatened with extinction at the national level. 10 of the threatened species are known to be Vulnerable while three species are endangered. The

nationally data deficient and globally critically endangered damselfly *Sinhalestes orientalis* (Hagen in Selys, 1862) which has not been recorded for 154 years was also observed during this study. The high species richness of Odonata and the presence of many threatened species and data deficient species indicate that the PWS is an important area for the Odonata thus more comprehensive studies and suitable conservation actions should be made.] Address: Sumanapala, A.P., Young Biologists' Association, Institute of Biology, 120/10, Vidya Mawatha, Colombo 7, Sri Lanka. 13783. Tajima, Y.; Watanabe, M. (2013): Male secondary genitalia mimic the female egg during oviposition for sperm displacement in the non-territorial damselfly *Ischnura asiatica* (Brauer) (Zygoptera: Coenagrionidae). *Odonatologica* 42(3): 229-236. (in English) ["The male sperm storage organs of *I. asiatica* include the bursa copulatrix and the spermatheca. The spermatheca is joined to the base of the bursa copulatrix by a spermathecal duct. At the tip of the male's secondary genitalia, there is a pair of horns which might be used to remove sperm from the female sperm storage organs. Since each horn of the male genitalia is shorter than the spermathecal duct, the spermatheca might be inaccessible to males. However, sperm reduction occurs both in the bursa copulatrix and in the spermatheca during copulation. This suggests an alternative mechanism by which the 8 can cause a decline in the spermathecal sperm. In order to investigate the mechanism of sperm reduction, an interrupted copulation experiment was conducted in the field. The extent of sperm reduction in the spermatheca was related to the width of the head of the secondary genitalia of the mated male. Females have mechano-receptive sensilla which communicate the presence of an egg to the muscles surrounding the sperm storage organs for fertilization. Therefore, the head of the secondary genitalia might mimic the movement of the egg that stimulates the sensilla to induce spermathecal sperm ejection by the female." 13784. Taylor, M. (2013): *Dragonflight: In Search of Britain's Dragonflies and Damselflies*. A&C Black Publishers: 256 pp. (in English) ["This book is an account of two years spent getting to know Britain's most dazzling and enigmatic insects - the dragonflies and damselflies. The quest to find, photograph, watch and learn about dragons and damsels took the author on a tour of diverse and lovely wetlands up and down Britain, from the rugged wild peat bogs of north-west Scotland to the languid meanders of the Oxfordshire Thames. The account describes close encounters with the dragons and damsels themselves, set against backdrops of rich and vital habitats teeming with a range of other wildlife. It is

also packed with background detail on dragonfly and damselfly natural history, and wetland ecology in general. The text is enlivened with line drawings and a section of colour photographs." (Publisher)] Address: not stated

13785. Tennesen, K. (2013): *Utterly Bugged*. Red Dragonfly Press. ISBN: 978-1-937693-31-2; 180 pp. (in English) ["Unaware that he has been transported back in time, retired entomologist Amos Garruty lands in a biological world unknown to him. Early on he sees peculiar dragonflies cure an injured snake, a superstition long debunked. Things soon take a turn for the worse when he sees a large bony-toothed bird streak through a clearing in the rainforest. He is aware that these flightless giants went extinct millions of years ago. He soon realizes he is alone. During his frantic struggle to return to the present, he is bitten by mosquitoes and unknowingly contracts a bygone virus. His ensuing travels in the United States unleash a hellish trail of infection. As people along his route get sick, it dawns on him that he might be a carrier. He tries to avoid contact, but is unsure what is really happening. Suspecting that authorities are hunting him, he flees to South America. His obsession with the enigmatic origins of insects continues to escalate, leading to a supernatural encounter that shakes him to his core."] Publisher.

13786. Tiple, A.D.; Andrew, R.J.; Subramanian, K.A.; Talmale, S.S. (2013): Odonata of Vidarbha region, Maharashtra state, Central India. *Odonatologica* 42(3): 237-245. (in English) ["A survey of water bodies of the Vidarbha region of central India was conducted during 2006-2012. A total of 82 species were recorded. The study adds 13 new species for the Vidarbha region and 6 species for Maharashtra state. Of the total, 23 species were abundant or very common, 26 were common, 24 rare and 9 very rare. The study shows that ecological disturbances in Vidarbha due to industrial and human activities are a threat to the odonate fauna. *Mortonagrion varralli* and *Copera ciliata*, which were recorded by earlier workers in this region, were not found during this survey. However, protected small and big water bodies used for agriculture and domestic usage provide valuable habitat for Odonata." 13792. Verberk, W.C.E.P.; Bilton, D.T. (2013): Respiratory control in aquatic insects dictates their vulnerability to global warming. *Biol. Lett.* 9(5): 5 pp. (in English) ["Forecasting species responses to climatic warming requires knowledge of how temperature impacts may be exacerbated by other environmental stressors, hypoxia being a principal example in aquatic systems. Both stressors could interact directly as temperature affects both oxygen bioavailability and ectotherm oxygen demand. Insufficient oxygen has been shown to limit thermal tolerance in several aquatic ectotherms, although, the generality of this mechanism has been challenged for tracheated arthropods. Comparing species pairs spanning four different insect orders, we demonstrate that oxygen can indeed limit thermal tolerance in tracheates. Species that were poor at regulating oxygen uptake were consistently more vulnerable to the synergistic effects of warming and hypoxia, demonstrating the importance of respiratory control in setting thermal tolerance limits." (Authors) The study includes *Cordulegaster boltonii* and *Calopteryx virgo*.] Address: Verberk, W.C.E.P., Dept of Animal Ecology and Ecophysiology, Institute for Water and Wetland Research, Radboud University, Toernooiveld 1, 6525 ED Nijmegen, The Netherlands. 13793. Walker, B. (2013): Some observations on the effect of temperature on dragonfly recording. *J. Br. Dragonfly Society* 29(2): 84-96. (in English) ["The British Trust for Ornithology added odonates to the species that contributors are asked to record from 2011. Rec-

ords for the first two years of dragonfly records from this scheme have been analysed and indicate a marked difference in observations in the spring between 2011 and 2012. Spring 2011 was warmer than the recent average and noticeably warmer than in 2012 and dragonflies were recorded earlier in numbers in 2011 than in 2012. Based on a comparison of the records and the average weekly temperatures a correction factor is proposed to account for reduced dragonfly activity when temperatures are lower and it is suggested that this can explain some fluctuations in the raw data. It is also noted that the reduction in records from their peak can be described by a daily survival rate approach." 13794. Wiederman, S.D.; Dunbier, J.R.; O'Carroll, D.C. (2013): Selective attention in the dragonfly. *Front. Physiol. Conference Abstract: International Conference on Invertebrate Vision.* doi: 10.3389/conf.fphys.2013.25.00003: (in English) [Verbatim: A dragonfly that captures flies amidst swarms of prey and conspecifics must competitively select a single object amongst distracting stimuli. Even though many animals can accomplish this 'attentional' task, little is known about the neuronal mechanisms that permit the selection of one moving feature from competing alternatives [1], which are often moving against complex, textured backgrounds. We recently demonstrated that responses from an identified dragonfly visual neuron, the 'centrifugal small target motion detector' (CSTMD1), perfectly match a model for competitive selection within the limits of neuronal variability ($r^2=0.83$) [2]. Responses to individual targets presented at different locations of the receptive field differ in both magnitude and time course. However, responses to two simultaneous targets exclusively track those for one target alone. In response to a single target, CSTMD1 activity builds slowly over several hundred milliseconds [3,4]. This facilitation could represent a state of 'arousal' (enhanced responses) or the development of a locus of attention in a defined region of space and time (with suppression outside of this locus). In order to test this, we mapped a receptive field by presenting short (100ms) target trajectories on a stimulus monitor. Randomly interspersed with this stimulus, we mapped a 'primed' receptive field, with the same short trajectories following a longer duration priming target. We show that that there is a difference between the control and the primed version, with enhanced activity in an area in front of the current target trajectory. Thus the receptive field is not stationary and must be considered within the context of past stimulation.] Address: Wiederman, S.D., The University of Adelaide, Adelaide Centre for Neuroscience Research, Adelaide, SA, 5005, Australia, steven.wiederman@adelaide.edu.au

13795. Winter, P. (2013): A mixed pairing between Emerald Damselfly *Lestes sponsa* and Large Red Damselfly *Pyrrhosoma nymphula*. *Atropos* 50: 85. (in English)

[Verbatim: On 8 July 2013 I visited the pond on Furzley Common, Hampshire. Along the southern edge of the pond the central, well vegetated, bog island is only two to three metres away. As I scanned through the damselflies along the vegetation edge I came across an unusual tripling where a male *Lestes sponsa* had attached itself to the male of a coupled pair of *Pyrrhosoma nymphula*. I watched them for a couple of minutes and managed to obtain a few record shots. While I was trying to get in a more parallel plane to photograph the insects the male *L. sponsa* detached itself. I noticed that the posterior abdominal segments were 'kinked', presumably arising from the coupling.] Address: Winter, P., 4 Rosebank Close, Rownhams, Southampton, S016 8AU, UK

13799. Zuniga, M.; Chara, J.; Giraldo, L.P.; Chara-Serna, A.-M.; Pedraza, G.X. (2013): Composición de la comunidad de macroinvertebrados acuáticos en pequeñas quebradas de la región andina colombiana, con énfasis en la entomofauna. *Dugesiana* 20(2): 263-277. (in Spanish, with English summary) ["The Colombian Andes are irrigated by an extensive network of small streams that originate the most important rivers of the country and contribute fundamental ecosystem services to local rural communities. Despite the importance of these stream ecosystems, little is known about their biological diversity and function. This work evaluated benthic macroinvertebrate composition in 28 first and second order streams located in La Vieja River Basin (Colombia's central Andes). Results evidenced the high abundance and diversity of the regional macroinvertebrate community. A total of 32,319 individuals, distributed in four phyla, eight classes, 18 orders, 73 families and 91 genera, were collected. Arthropoda and Mollusca were the best represented phyla, whereas Insecta, Gastropoda and Bivalvia, were the most important classes. Chironomidae was the dominant taxa in the studied streams. Odonata was also abundant, contrasting with the typical low abundance of this group in higher order systems. The most common genera were Smicridea, Heterelmis, Atrichopogon, Farrodes, Argia and Limnocois, which also presented distribution patterns different than those found in larger streams. Within the Ephemeroptera, the genus *Zelus* (Baetidae) is highlighted as a new distribution record for the Andean region of the Valle del Cauca. Results demonstrate that even though the studied systems are small and immersed in agricultural landscapes, they harbour an important component of the regional and local diversity." (Authors) *Aeshnidae*, *Gomphidae* (*Progomphus*), *Libellulidae* (*Brechmorhoga*, *Cannaphila*, *Dythemis*, *Libellula*, *Macrothemis*, *Micrathyria*, *Orthemis*, *Perithemis*), *Calopterygidae* (*Hetaerina*), *Coenagrionidae* (*Argia*, *Nehalennia*), *Megapodagrionidae*, *Polythoridae*] Address: Zúñiga, María del Carmen, Centro para la Investigación en Sistemas Sostenibles de Producción Agropecuaria – CIPAV, Carrera 25 No. 6-62, Cali, Colombia. 13800. Adu, B.W.; Ogunjobi, J. A. (2014): Assessment of dragonflies and damselflies of Owena Forest south-western Nigeria. *International Journal of AgriScience* 4(3): 153-159. (in English) ["The odonate species of Owena forest was surveyed once a month for a period of two years (May, 2008 to April, 2010). Six hours were spent at the forest on every fieldwork. Three study sites were identified at the forest: River Owena at the Dam (ROD), River Owena in Forest (ROF), and Cocoa Research Institute of Nigeria (CRIN) substation along Ondo-Akure road Owena. Only adult dragonflies and damselflies specimens were collected at the study sites. A total of 2016 specimens of Odonata were collected at the forest. *Ceriatagrion glabrum* was found to be widespread at the three study sites. *Palpopleura portia* and *P. lucia* were found to be abundant at ROD and CRIN, while *Mesocnemis singularis* and *Congothemis dubia* were dominant species at ROD and ROF. Data collected from the study sites were subjected to Descriptive statistics, Soerensen's Quotient index (SQ) and Diversity indices (Margalef index, Simpson's dominance index, Shannon Wiener index and Evenness). Based on the diversity indices used, ROF was the richest study site (H': 4.48, Simpson dominance (c): 0.99 and Manglef index (d) 13.53). In terms of species distribution, the study revealed that species of Odonata was well distributed at ROF and ROD. ROF and CRIN are the most similar study sites with SQ of 0.75 followed by ROD and CRIN (SQ: 0.60) while the least similar paired sites are ROF and ROD. All the diversity indices used established that ROF was the richest study site. The results also revealed that Owena forest was rich in Odonata fauna; despite the fact that it is a secondary re-growth forest undergoing some anthropogenic activities." (Authors)] Address: Adu, B.W., Biological Science Department, Ondo State University of Science and Technology, Okitipupa, Nigeria. E-mail: williamsadubabs@yahoo.com

13801. Akhtar, N. (2014): Dragonflies of Manglawar Swat Khyber Pakhtoonkhwa Pakistan. *European Academic Research* 2(1): 172-178. (in English) ["Current study was conducted to explore the dragonflies of Manglawar Swat. This study was conducted in the period from August to December 2013. The collection was made in the timing of 10 AM to 4 PM. In current study 11 species in 5 genera were identified belonging to family libellulidae. These species were *Crocothemis erythraea*, *C. servilia*, *Libellula fulva*, *Trithemis aurora*, *T. festiva*, *T. kirbyi*, *T. pallidinervis*, *Acisoma panorpoides*, *Orthetrum chrysis*, *O. sabina* and *O. taeniolatum*." 13802. Allen, K.A.; Thompson, D.J. (2014): Population size and survival estimates for the rare damselflies, *Coenagrion mercuriale* and *Ischnura pumilio*. *Insect*

Conservation and Diversity 7(3): 241-251. (in English) ["(1) *C. mercuriale* is rare in the UK and is threatened across Europe. *I. pumilio* is also threatened in the UK. Both species have suffered population declines in recent years and are vulnerable to habitat fragmentation and loss. Yet, reliable population size and survival estimates are scarce in odonate species. This study provides mark-release-recapture estimates of these parameters for UK stronghold populations of both species. (2) Surveys were performed at four locations in southern England between 2001 and 2006. A total of 12 071 adult individuals were marked across nine populations. Mark-release-recapture modelling techniques were used to provide survival and recapture probabilities and population size estimates. (3) This study presents the first Horvitz-Thompson estimates of population size in odonates, which are among the highest reported for damselflies. Maximum estimates for a single site were $63\ 662 \pm 4997$ for *C. mercuriale* and 7453 ± 382 for *I. pumilio*. More males than females were captured at all sites, but calculated estimates indicated a female-biased sex ratio in adult *I. pumilio* at one location. (4) Daily survival probability is among the highest published for damselflies. Male and female survival was equal or very similar in all populations. Further effects of maturity, age, site, and time on survival were identified. (5) Estimated population sizes are much greater than previously thought, suggesting that where habitat is maintained, populations of threatened odonates can be very large. Furthermore, greater proportions of females have been estimated where wider searching techniques were employed. This has implications for future study design if estimates are to be reliably used for conservation management." (Authors)] Address: Allen, Katherine, School of Environmental Sciences, University of Liverpool, Liverpool L69 3GP, UK. E-mail: kaallen@liv.ac.uk

13803. Almeida, M.V.O.; Pinto, A.P.; Carvalho, A.; Takiya, D.M. (2014): When rare is just a matter of sampling: Unexpected dominance of clubtail dragonflies (Odonata, Gomphidae) through different collecting methods at Parque Nacional da Serra do Cipó, Minas Gerais State, Brazil. *Revista Brasileira de Entomologia* 57(4): 417-423. (in English) ["Capture of dragonfly adults during two short expeditions to Parque Nacional da Serra do Cipó, Minas Gerais State, using three distinct collecting methods: aerial nets, Malaise and light sheet traps reported. The results are outstanding due the high number of species of Gomphidae (7 out of 26 Odonata species), including a new species of *Cyanogomphus* Selys, 1873, obtained by two non-traditional collecting methods. Because active collecting with aerial nets is the standard approach for dragonfly inventories, we discuss some aspects of the use of traps, comparing our results with those in the literature, suggesting they should be used as complementary methods in faunistic studies. Furthermore, *Zonophora campanulata annulata* Belle, 1983 is recorded for the first time from Minas Gerais State and taxonomic notes

about *Phyllogomphoides regularis* (Selys, 1873) and *Progomphus complicatus* Selys, 1854 are also given." 13804. Bajwa, Y.; Bode-Oke, A.; Williams, V.; Zhu, R. (2014): Phase relationship as a flight control mechanism in dragonflies. *The Spectra* 2014: 32-40. (in English) ["Dragonflies can be observed utilizing a wide variety of wing kinematics to elegantly control their bodies in flight, due to their four-winged nature. Odonata have the ability to manipulate the phase difference between their fore and hind wings. Scientists in the field postulate that the relationship between relatively in-phase flapping flight results in enhanced lift and thrust. Such flight can be observed during power-intensive maneuvers such as high-speed turns and take-off. Observations and data reveal that the preferred flying mode for dragonflies employs out-of-phase flight. Such a phase relationship may improve aerodynamic efficiency through the minimization of wing-wake interaction for the hind wing. In this paper, we utilized high speed photogrammetry and 3D surface reconstruction techniques to both capture and digitize dragonfly free flight. We attempted to explore the relation of phase difference with force production by damaging the dragonfly wings. The procedure was to perform chord-wise cuts on individual wings to limit the ability of the dragonfly to produce lift. Our observations showed that when damaged, Odonata compensated for lost force production by manipulating phase difference in a manner that increased lift production." (Authors)] Address: Bajwa, Y., School of Engineering and Applied Science, Dept of Mechanical and Aerospace Engineering, University of Virginia, USA

13805. Batty, P. (2014): Species Review 8: *Somatochlora arctica* (Zetterstedt, 1840) (The Northern Emerald). *J. Br. Dragonfly Society* 30(1): 32-53. (in English) ["In the British Isles it is only found in Scotland, where it is widely distributed in the west, and in a very small number of localities in the south of Ireland. The species and its life cycle are described and its conservation is discussed in the light of potential threats and the possible effects of climate change." 13807. Blyth, C. (2014): Colonisation of a new pond: new habitat for *Coenagrion hastulatum* (Charpentier) (the Northern Damselfly) and other odonate species at a site in Aberdeenshire. *J. Br. Dragonfly Society* 30(1): 1-8. (in English) ["A new pond was constructed in 2011 for the purpose of providing nearby Odonata populations with a new habitat in which to live. This provided the opportunity to begin a long-term colonisation study, part-funded by a British Dragonfly Society Philip Corbet award. The results of the first survey, in summer 2012, indicate quick colonisation by five of the ten known local species, i.e. *Lestes sponsa*, *Pyrrhosoma nymphula*, *Ischnura elegans*, *Sympetrum danae* and *S. striolatum*. The reasons for this are discussed." (Author)] Address: Blyth, Colette, 17 Sythrum Crescent, Glenrothes, Fife, KY7 5DG, UK

13808. Bomark, E. (2014): The antihistamine hydroxyzine and Odonata. Bioaccumulation and effects on predator-prey interactions between dragonfly and damselfly larvae. B.C. Thesis in Biology 15 ECTS, Dept. of Ecology and Environmental Science (EMG), S-901 87 Umeå, Sweden : 13 pp. (in English) ["Through wastewater entering aquatic environments, aquatic insects are continuously exposed to pharmaceuticals including neurologically active antihistamines. The antihistamine hydroxyzine has previously been found to lower activity in damselflies and to reach 2000 times the concentration of surrounding water in damselfly tissue. The purpose of this short-term exposure study was to investigate if hydroxyzine also bioaccumulates in dragonflies and if dilute hydroxyzine (362 ± 50 , mean ng/l \pm SD) have effects on predator-prey interactions between dragonfly *Aeshna grandis* and damselfly *Coenagrion hastulatum* larvae, i.e. number of attacks and predation success. Predators and prey were captured and exposed during one, three or five days (with controls) before taking part in predation experiments; Dragonflies were put in separate containers with six damselflies, they were video recorded and attacks and predated damselflies noted during four hours. Tissue concentrations of hydroxyzine were analyzed from all dragonflies and a subsample of the damselflies showing a mean bioconcentration factor (BCF) of 27 and 7 respectively, surprisingly much lower than previous research. There was no difference in attack rate or predation efficiency between controls and exposed dragonflies. However, dragonflies exposed for

five days were found to attack more and capture more prey than dragonflies exposed for one day, a change that was not seen in the controls. This confounding factor motivates further studies to clarify if hydroxyzine after a period of exposure can have a sublethal effect altering foraging and/or predator avoidance traits with the net result of increased predation success for dragonflies in the predator-prey interaction between dragonflies and damselflies." 13811. Brekelmans, F. (2014): *Ophiogomphus cecilia* on the river Dommel. *Brachytron* 16(1/2): 18-28. (in Dutch, with English summary) ["Between 27 July and 5 August 2012 *O. cecilia* was observed for the first time at the river Dommel, near Valkenswaard and Waalre, Noord-Brabant. With the exception of an observation in 1935, these were the first observations of *O. cecilia* in Noord-Brabant. At least two males and two females were found. One female was observed during oviposition. Larvae and exuviae have not been found, but larvae of this species are hard to find and a thorough search for exuvia has not been performed. It is not clear if a population exists in the river Dommel. The nearest known populations of *O. cecilia* are in Noord-Limburg,

at the rivers Roer and Swalm. It is likely that one of these populations is the origin of the individuals observed in Noord-Brabant. The river Dommel appears to hold suitable habitat for *O. cecilia*. The same applies to the rivers Keersop and Tongelreep in the same region of Noord-Brabant. Water quality in the river Dommel is poor, but this does not appear to be an obstacle for establishment of the species, as has been shown in other populations." 13814. Brossman, K.; Carlson, B.; Stokes, A.; Langkilde, T.T.L. (2014): Eastern newt (*Notophthalmus viridescens*) larvae alter morphological but not chemical defenses in response to predator cues. *Canadian Journal of Zoology* 92(4): 279-283. (in English) ["Prey traits are often modified in response to exposure to predators, a phenomenon known as predator-induced phenotypic plasticity. Morphological plasticity in response to predator cues is well documented in amphibians; however, predator-induced chemical defenses have received relatively little attention. The Eastern newt, which possesses tetrodotoxin – a toxin for chemical defense, is most vulnerable to predation during its larval stage. We assessed whether exposing Eastern newt larvae to predator scent cues (from dragonfly larvae) would elicit

change in their morphological and chemical defenses. Newt larvae exposed to scent cues of predatory dragonfly larvae exhibited significantly greater tail depths, which should increase survival of attempted predation by allowing them to swim faster, but did not differ in mass, snout-vent length, or tail length. Newt larvae toxin concentrations were not significantly affected by exposure to these predator cues. Larval toxicity may be maternally- or environmentally-derived and inflexible, or induced toxicity may only be detectable later in development. Predator-induced phenotypic plasticity, especially of chemical defenses, warrants greater attention, as potentially important outcomes of species interactions remain unclear." 13815. Brown, D.J.; Nowlin, W.H.; Ozel, E.; Mali, I.; Episcopo, D.; Jones, M.C.; Forstner, M.R.J. (2014): Comparison of short term low, moderate, and high severity fire impacts to aquatic and terrestrial ecosystem components of a southern USA mixed pine/hardwood forest. *Forest Ecology and Management* 312: 179-192. (in English) [Bastrop County, Texas, USA; "Highlights. •Magnitude of fire effects on water quality increased with increasing fire severity. •Most forest structure variables were only significantly impacted by high severity fire. •Terrestrial arthropods were only significantly impacted by high severity fire. Historically fire was an important natural disturbance shaping the structure and composition of pine-dominated forests in the southern United States. Longstanding fire suppression policies have resulted in structural and compositional changes, notably accumulation of heavy fuel loads and reduction in vegetation species diversity. Primary goals of forest management through prescribed burning include fuel load reduction and mimicking ecosystem impacts of historically natural wildfires. In addition to the influences of fire frequency and season, the influence of fire severity on ecosystem responses is currently of interest. In this study we sought to quantify the impacts of low, moderate, and high severity fires, and their interaction with prior forest management practices, to several aquatic and terrestrial ecosystem components of a southern U.S. mixed pine/hardwood forest using a before–after, control-impact (BACI) approach. The ecosystem components we assessed were water quality, community composition of aquatic arthropods (wildfire impacts only), forest structure characteristics, community composition of understory vegetation, and community composition of ground-dwelling arthropods. We found that increasing fire severity increased aquatic nutrient levels and productivity, but the magnitude of effects increased with severity. Low and moderate severity fires had weak effects on forest structure characteristics, community composition of understory vegetation, and community composition of ground-dwelling arthropods in the initial

years following burns. In contrast, high severity fires dramatically reduced fine and large fuel loads, increased diversity of understory vegetation, and influenced community composition of ground-dwelling arthropods. Further, wildfire severity was reduced in areas with a prior moderate severity prescribed burn, but not in areas with a prior low severity prescribed burn. Our results provide quantitative evidence for the role of fire severity as a primary factor influencing responses of ecosystems to fire, and indicate that forest management practices influence the impact of high severity fires on ecosystems. ... Unfortunately, sampling of aquatic arthropods in ponds was initiated after the LOWRX and MODRX fires and most of the sampled ponds were not part of those fire treatments. Thus, we were only able to assess impacts of the HIGHWILD fire on the composition of pond arthropods. We sampled aquatic arthropods seasonally, collecting 7 samples at 8 ponds between August 2010 and January 2013 We identified insects to family, with the exception of Ephemeroptera (mayflies) and Odonata (dragonflies and damselflies), which we identified to order, and we identified other arthropods to class or order ... We did not detect a HIGHWILD fire impact on total number of captured individuals of aquatic arthropods ($F_{1,52} = 0.71$, $P = 0.404$). Likewise, the RDA analysis indicated the HIGHWILD fire had no impact on community composition of aquatic arthropods ($P = 0.949$), with 3.2% of the variation explained by the model. In addition, the RDA biplot confirmed the statistical test, with all aquatic arthropod groups located either near the origin or nearly orthogonal to the treatment burn status predictor." 13816. Bush, A.A.; Nipperess, D.A.; Duursma, D.E.; Theischinger, G.; Turak, E.; Hughes, L. (2014): Continental-scale assessment of risk to the Australian Odonata from climate change. *PLoS ONE* 9(2): e88958. doi:10.1371/journal.pone.0088958: 12 pp. (in English) ["Climate change is expected to have substantial impacts on the composition of freshwater communities, and many species are threatened by the loss of climatically suitable habitat. In this study we identify Australian Odonata vulnerable to the effects of climate change on the basis of exposure, sensitivity and pressure to disperse in the future. We used an ensemble of species distribution models to predict the distribution of 270 (85%) species of Australian Odonata, continent-wide at the subcatchment scale, and for both current and future climates using two emissions scenarios each for 2055 and 2085. Exposure was scored according to the departure of temperature, precipitation and hydrology from current conditions. Sensitivity accounted for change in the area and suitability of projected climatic habitat, and pressure to disperse combined measurements of average habitat shifts and the loss experienced with lower dispersal rates. Streams and rivers

important to future conservation efforts were identified based on the sensitivity-weighted sum of habitat suitability for the most vulnerable species. The overall extent of suitable habitat declined for 56–69% of the species modelled by 2085 depending on emissions scenario. The proportion of species at risk across all components (exposure, sensitivity, pressure to disperse) varied between 7 and 17% from 2055 to 2085 and a further 3–17% of species were also projected to be at high risk due to declines that did not require range shifts. If dispersal to Tasmania was limited, many south-eastern species are at significantly increased risk. Conservation efforts will need to focus on creating and preserving freshwater refugia as part of a broader conservation strategy that improves connectivity and promotes adaptive range shifts. The significant predicted shifts in suitable habitat could potentially exceed the dispersal capacity of Odonata and highlights the challenge faced by other freshwater species." (Authors) Figure 4. Predicted suitable habitat in south-eastern Australia under current climate and 2055 and 2085 using emissions scenario RCP8.5 for *Notoaeschna sagittata*, *Coenagrion lyelli* and *Petalura gigantea*.] Address: Bush, A.A., Dept. (2014): The effect of conspecific density on emergence of *Lestes bipupillatus* Calvert, 1909 (Odonata: Lestidae). *Psyche* Volume 2014, Article ID 650427: 3 pp. (in English) ["Conspecific density may influence on adult recruitment and consequently on population dynamics. Several studies have shown the density dependence of larvae growth rates in Odonata. However, few studies evidenced how conspecific density influence final instar larvae emergence date decisions. Considering that larvae may choose date of emergence, the present study investigated if density affects larvae choice. For this, we reared eight final instar larvae in individual aquaria and other 24 larvae in aquaria with three larvae each. This way, we simulated environments with low and high larval density. We then noted the days that larvae took to emerge and compared between low and high density groups. The results showed that larvae seem to emerge earlier when in high densities (Mann-Whitney, $U=10.000$, $p=0.03$). These results support the hypothesis that damselfly last instar larvae may postpone or hasten emergence in response to the social environment and related constraints." 13818. Chahl, J.; Mizutani, A. (2014): Dragonfly hover is primarily mediated by vision. *Proc. SPIE 9055, Bioinspiration, Biomimetics, and Bioreplication 2014*, 905516 (March 8, 2014), San Diego, California, USA doi:10.1117/12.2045029; <http://dx.doi.org/10.1117/12.2045029>

(in English) ["The sensory means by which hover is achieved could be inertial, visual or an unexplained sensory modality. Dragonflies in their natural habitat were shown not to maintain a stationary position in wind. Their position fluctuated significantly while returning to the original position. The movement of the dragonfly is correlated with the movement of vertically standing vegetation. This response would be non-causal with wind for an inertial or putative pressure based internal sensory system. It is postulated that with a substrate of moving water, sensitivity to movement on the visual horizon for controlling hover is a robust strategy." (Authors)] Address: Mizutani, Akiko, Odonatrix Pty. Ltd., One Tree Hill SA 5114, Australia

13819. Chen, S.-L.; Yeh, W.-C. (2014): Description of a new species of the genus *Sarasaeschna* Karube & Yeh, with a key to the species of Taiwan (Odonata: Anisoptera: Aeshnidae). *Zootaxa* 3764(1): 92-100. (in English) ["*Sarasaeschna Chiangchilii* sp. nov. collected from Daxi, Taoyuan County in northern Taiwan is described and diagnosed. Judging from male penile structure, this species is considered to belong to the pryeri-group of its genus. It is easily distinguished from all known congeners in having peculiar sickle-shaped cerci in male. The habitats of *S. Chiangchilii* are mainly shaded brooks in lowland areas, which are exceptional for its Taiwanese relatives. Distributional maps and a key are also provided for the four species of Taiwanese *Sarasaeschna*." (Authors)] Address: Chen, S.-L., Conservation and Research Center, Taipei Zoo, Taipei, Taiwan. 13820. Clayden, M.G.; Kidd, K.A.; Chételat, J.; Hall, B.D.; Garcia, E. (2014): Environmental, geographic and trophic influences on methylmercury concentrations in macroinvertebrates from lakes and wetlands across Canada. *Ecotoxicology* 23(2): 273-284. (in English) ["Macroinvertebrates are a key vector in the transfer of methylmercury (MeHg) to fish. However, the factors that affect MeHg concentrations and bioaccumulation in these organisms are not as well understood as for fish, and studies on a broad geographic scale are lacking. In this study, we gathered published and unpublished MeHg and carbon ($\delta^{13}C$) and nitrogen ($\delta^{15}N$) stable isotope data for freshwater macroinvertebrates from 119 lakes and wetlands across seven Canadian provinces, along with selected physical, chemical and biological characteristics of these systems. Overall, water pH was the most important determinant of MeHg concentrations in both predatory and non-predatory invertebrates [$R^2_{adj} = 0.32$, $p < 0.001$; multivariate canonical redundancy analysis (RDA)]. The location of lakes explained additional variation in invertebrate MeHg (partial $R^2 = 0.08$ and 0.06 for latitude and longitude, respectively; RDA), with higher concentrations in more easterly and southerly regions. Both invertebrate foraging behaviour and trophic position (indicated by functional feeding groups and $\delta^{15}N$ values, respectively)

also predicted MeHg concentrations in the organisms. Collectively, results indicate that in addition to their feeding ecology, invertebrates accumulate more MeHg in acidic systems where the supply of MeHg to the food web is typically high. MeHg concentrations in macroinvertebrates may also be influenced by larger-scale geographic differences in atmospheric mercury deposition among regions." (Authors) The supplementary material details the taxa, but in Odonata in most cases only at the order level.] Address: Kidd, Karen, Biology Department, Canadian Rivers Institute, University of New Brunswick, 100 Tucker Park Road, Saint John, NB, E2L 4L5, Canada. 13821. Dayaram, A.; Galatowitsch, M.; Harding, J.S.; Argüello-Astorga, G.R.; Varsani, A. (2014): Novel circular DNA viruses identified in *Procordulia grayi* and *Xanthocnemis zealandica* larvae using metagenomic approaches. *Infection, Genetics and Evolution* 22: 134-141. (in English) ["Highlights: •Identification of 13 novel ssDNA viruses in *P. grayi* and *X. zealandica*. •The 13 novel viral genomes (1628 - 2668 nt) have NAG-TATTAC nonanucleotide motif. •The novel ssDNA viruses have 2 ORFs that are bidirectional or unidirectional. •Reps of novel ssDNA viruses have conserved the RCR & helicase motifs. Recent advances in sequencing and metagenomics have enabled the discovery of many novel single stranded DNA (ssDNA) viruses from various environments. We have previously demonstrated that adult dragonflies, as predatory insects, are useful indicators of ssDNA viruses in terrestrial ecosystems. Here we recover and characterise 13 viral genomes which represent 10 novel and diverse circular replication associated protein (Rep) -encoding single stranded (CRESS) DNA viruses (1628 - 2668 nt) from *P. grayi* and *X. zealandica* dragonfly larvae collected from four high-country lakes in the South Island of New Zealand. The dragonfly larvae associated CRESS DNA viruses have different genome architectures, however, they all encode two major open reading frames (ORFs) which either have bidirectional or unidirectional arrangement. The 13 viral genomes have a conserved NAGTATTAC-nonanucleotide motif and in their predicted Rep proteins we identified the rolling circle replication (RCR) motif 1, 2 and 3, as well as superfamily 3 (SF3) helicase motifs. Maximum likelihood phylogenetic and pairwise identity analysis of the Rep amino acid sequences reveal that the dragonfly larvae novel CRESS DNA viruses share <63% pairwise amino acid identity to the Reps of other CRESS DNA viruses whose complete genomes have been determined and available in public databases and that these viruses are novel. CRESS DNA viruses are circulating in larval dragonfly populations; however, we are unable to ascertain whether these viruses are infecting the larvae directly or are transient within dragonflies via their diet." 13822. De Knijf, G.; Adriaens, T.; Vermeylen, R.; Van der Schoot, P. (2014): Discovery of a population of *Gomphus flavipes* on the Albert Canal (Belgium), one of the busiest channels in Europe, with an overview of its status in Western and Central-Europe. *Brachytron* 16(1/2): 3-17.["*Gomphus flavipes*, a typical river species, disappeared in many parts of western and central Europe as a result of deterioration of the water quality. Since the beginning of the 1990s *G. flavipes* has been rediscovered in several rivers, first in the Netherlands and Germany. The first observation of *G. flavipes* from Belgium dates from 2000 and originates from the river Meuse, where it forms the border between Belgium and the Netherlands. Several observations were made there, but exuviae have never been found. Although the species has been observed several times since 2002 in the province of Antwerp, these observations were all considered to refer to vagrant individuals from the river Meuse the Netherlands or the river Rhine in Germany. In July 2012 a population of *G. flavipes* was discovered along the Albert Canal in the province of Antwerp, Flanders, Belgium. A freshly emerged individual was found on 28 July 2012 and the following days along the Albert Canal in Broechem. The first exuvium was found on 6 August. The subsequent search (6-12 August 2012) resulted in the discovery of 70 exuviae, all found along the Albert Canal between the sluices of Wijnegem and the bridge over the canal in Grobbendonk, over a distance of 9.5 km. The average density of exuviae found per trajectory with larval skins present was 1.2 (minimum 0.1, maximum 3.3) per 100 meter. Sex-ratio was 1:0.6 in favour of females, which is reported normal in gomphid populations but can also be explained by the late sampling date, as in dragonflies males are mostly the first to emerge. Emergence substratum was highly artificial. Most exuviae were found on the concrete sheet piling of the bank, to a lesser extent also on poles or vertical walls. Based on long-term research in other parts in Europe, we estimated the population along the Albert canal at a minimum of 200 individuals. This discovery of a population of *G. flavipes* in one of the busiest channels in Europe is unique and sheds new light on the potential range of the species in Flanders and suitable habitat in large parts of Europe. *G. flavipes* is also known to reproduce in small irrigation canals (< 5m wide) between the rice paddies in northern Italy, but although also artificial these cannot be compared with the Albert Canal. This local shift in habitat preference from rivers towards canals with concrete banks, is probably a result of the recent range expansion of *G. flavipes* in western Europe." 13823. Denny, E.G.; Gerst, K.L.; Miller-Rushing, A.J.; Tierney, G.L.; Crimmins, T.M.; Enquist, C.A.F.; Guertin, P.; Rosemartin, A.H.; Schwartz, M.D.; Thomas, K.A.; Weltzin, J.F. (2014): Standardized phenology monitoring methods to track plant and animal activity for science and resource management applications. Interna-

tional Journal of Biometeorology 58: 591-601. (in English) ["Phenology offers critical insights into the responses of species to climate change; shifts in species' phenologies can result in disruptions to the ecosystem processes and services upon which human livelihood depends. To better detect such shifts, scientists need long-term phenological records covering many taxa and across a broad geographic distribution. To date, phenological observation efforts across the USA have been geographically limited and have used different methods, making comparisons across sites and species difficult. To facilitate coordinated cross-site, cross-species, and geographically extensive phenological monitoring across the nation, the USA National Phenology Network has developed in situ monitoring protocols standardized across taxonomic groups and ecosystem types for terrestrial, freshwater, and marine plant and animal taxa. The protocols include elements that allow enhanced detection and description of phenological responses, including assessment of phenological "status", or the ability to track presence-absence of a particular phenophase, as well as standards for documenting the degree to which phenological activity is expressed in terms of intensity or abundance. Data collected by this method can be integrated with historical phenology data sets, enabling the development of databases for spatial and temporal assessment of changes in status and trends of disparate organisms. To build a common, spatially, and temporally extensive multi-taxa phenological data set available for a variety of research and science applications, we encourage scientists, resources managers, and others conducting ecological monitoring or research to consider utilization of these standardized protocols for tracking the seasonal activity of plants and animals." 13825. Emerson, Y.S.; Alaban, J. (2014): *Hemidactylus platyurus* (Flat-tailed House Gecko). Predation. *Herpetological Review* 45(1): 129. (in English) [Verbatim: *Hemidactylus platyurus* is a moderate-sized (43–58 mm SVL) gecko with a widespread distribution in Southeast Asia and in the Philippines (Brown and Alcalá 1978.

Philippine Lizards of the family Gekkonidae. Silliman University Press. Dumaguete, Philippines. 146 pp.). This note reports the observed predation of *H. platyurus* by a dragonfly, *Anax* cf. *panybeus* (Odonata: Aeshnidae). At 1330 h on 8 September 2013, JA observed a female *Anax* cf. *panybeus* (60 mm right hindwing length), clutching a still struggling *Hemidactylus platyurus*, land on a branch of a tamarind tree (*Tamarindus indica*) in Pueblo de Panay, Barangay Dinginan, Roxas City, Capiz Province, Panay Island, Philippines (11.548572°N, 122.727822°E, WGS84; elev. 112 m). The dragonfly utilized its anterior legs to hold on to its prey while simultaneously chewing the left eye of the gecko for ca. four minutes. To our knowledge, this is the first recorded incident of a dragonfly preying on a lizard in the Philippines. Photographic vouchers were deposited at the Raffles Museum of Biodiversity Research, National University of Singapore (ZRC[IMG] 2.183a–c). We thank R. J. Villanueva for identification of the dragonfly, Kelvin K. P. Lim for ZRC voucher numbers, and Cameron Siler for comments on this note.] Address: Emerson, Y.S., Philippine Center for Terrestrial and Aquatic Research, 1198 Benavidez St., Unit 1202, Tondo, Manila, Philippines. 13828. Escoto-Moreno, J.; González-Soriano, E.; Escoto-Rocha, J.; Márquez, J. (2014): Riqueza y distribución de la familia Aeshnidae (Odonata: Anisoptera) en el estado de Aguascalientes, México. *Revista Mexicana de Biodiversidad* 85: 209-217. (in Spanish, with English summary) ["The species richness and geographic distribution of the family Aeshnidae in the state of Aguascalientes is presented. A total of 168 adult individuals from 55 localities were collected during a 12 months period between August 2006 and July 2007. They belong to four genera and seven species (*Aeshna persephone*, *Anax junius*, *Anax walsinghami*, *Remartinia luteipennis*, *Rhionaeschna dugesi*, *Rhionaeschna multicolor*, *Rhionaeschna psilus*). ... Specific richness of the family Aeshnidae in the state of Aguascalientes corresponds to the 11.9% of all Odonata species recorded for the state and 23.3% of the species recorded of this family for México. The species accumulation curve is stabilized, but according to Chao 2, Jackknife 1 and

Jackknife 2 non-parametric estimators, the sampling effort performed estimates between 80.3% and 97.5% of the species of this family that theoretically exist in the state of Aguascalientes. The localities that showed a higher species richness were La Rinconada, stream at Malpaso and Puente La Labor, all belonging to the municipality of Calvillo, and the Estación Biológica Agua Zarca (EBAZ) in the municipality of San José de Gracia. The distribution of the species reflects three regional patterns: Altiplano Mexicano, Sierra Madre Occidental and Neotropical." (2014): Natural control of the mosquito population via Odonata and Toxorhynchites. *International Journal of Innovative Research in Science* 3(5): 12898-12911. (in English) ["The main impact of mosquito pests is the transmission of many dangerous diseases and death. Hence, the reduction of their population by the use of a natural control method is a primary objective of this research. This mosquito reduction method utilises different species of predators (Odonata) and (Toxorhynchites) to substantially improve the environment. The frequency of capturing the pest mosquitoes by the predators is determined using a Pascal distribution, whilst insect mortality is modelled using a Weibull distribution. The results from the model show that by using insect predators, a significant reduction of the mosquito population is possible in less than eighty days." 13830. Feindt, W.; Hadrys, H. (2014): Still a one species genus? Strong genetic diversification in the world's largest living odonate, the Neotropical damselfly *Megaloprepus caerulatus*. *Conserv. Genet.* 15: 469-481. (in English) ["Mesoamerican biodiversity is increasingly threatened by anthropogenic destruction of natural land cover. Habitat degradation and climate change are primary threats to specialized forest odonate species that are important model organisms for forest health and defining conservation units. The extreme niche specialization of *M. caerulatus*, the world's largest extant odonate, makes it well suited as an indicator for changing environmental conditions. *Megaloprepus*, which is considered to be a monospecific genus, is highly dependent on old growth forests whose water filled tree holes are limiting reproductive resources for this species. Here, we focus on the question how historical and recent fragmentation events, strong niche conservatism and ecological conditions have affected population dynamics, viability and the species status in this evolu-

tionarily old genus. Two mitochondrial sequence markers (ND1 and 16S rRNA) and a set of microsatellites were used to analyze population structure and genetic diversity of *M. caerulatus* in the northern part of its distributional range. Results suggested an absence of gene flow and no shared haplotypes among the study populations. Statistical parsimony indicated high substructuring among populations with sequence diversity similar to levels found at the species level compared to other odonates. In sum, the genetic data suggest that *Megaloprepus* may actually consist of more than one species. The taxonomic status of the group should be revised in light of the three distinct genetic clusters found in different forest regions. The results may also allow insights into the impact of recent and historical habitat fragmentation on a strong Neotropical forest restricted insect species." 13831. Forbes, M.R.; Mlynarek, J.J. (2014): A hypothesis to explain host species differences in resistance to multi-host parasites. *Ideas in Ecology and Evolution* 7: 17-24. (in English) ["Here, we offer a novel hypothesis to explain why some host species evolve resistance, whereas other related species remain susceptible to a shared parasite species. We first describe instances of single water mite species that are ectoparasitic on different species of host dragonflies, where the mites are killed by resistance mechanisms and have little to no fitness on some host species. This begs the question of why some host species are susceptible, whereas other host species are (nearly) completely resistant. Earlier logic based on parasites exploiting abundant host species at the cost of exploiting rare host species does not explain such instances well. Rather, a hypothesis based on closed populations of some host species being able to evolve parasite recognition is invoked. Parasite recognition is not expected to evolve in host species from more open populations with considerable gene flow across sites, only some sites of which have the parasite species present. The logic of this hypothesis can be explored with simulation models, whereas empirical tests could involve combined approaches using molecular genetics, population genetics, experimental infections and transplantation experiments." 13832. Gallardo, B.; Dolédec, S.; Paillex, A.; Arscott, D.B.; Sheldon, F.; Zilli, F.; Mérigoux, S.; Castella, E.; Comín, F.A. (2014): Response of benthic macroinvertebrates to gradients in hydrological connectivity: a comparison of temperate, subtropical, Mediterranean and semiarid river floodplains. *Freshwater Biology* 59(3):

630-648. (in English) ["(1) Despite a general recognition that benthic macroinvertebrates respond to changes in hydrological connectivity within floodplain ecosystems, no consensus about patterns in community structure and ecosystem processes across large scales and different climates has yet been established. Such knowledge is necessary since anthropogenic activities continue to alter the natural hydrogeomorphology of large floodplains, with most consequences for aquatic communities remaining unknown. (2) Using information from six large rivers located in four different climate regions (humid subtropical, maritime temperate, Mediterranean and dry semi-arid), we compared benthic macroinvertebrate responses along lateral gradients of hydrological connectivity. We tested hypotheses related to differences among climate regions and to similar hydrological constraints within any one climate. The large geographical scale covered by this study provides the first comprehensive comparison of aquatic community patterns across hydrological gradients under different climatic settings. (3) Multivariate ordinations demonstrated a higher overlap of trait community composition (50% variance explained by the first two axes) than taxonomic composition (15%) among floodplains, displaying high interclimate trait stability. The taxonomy-based ordination separated the subtropical floodplain, with an average 86% of non-insect taxa, from the insect-dominated temperate, Mediterranean and semi-arid floodplains (with >50% insect abundance). In the trait-based ordination, large body size (60% of organisms >4 cm) and long lifespan duration (80% of organisms) discriminated the subtropical from the other five studied floodplains. (4) Across a gradient of lateral connectivity, linear mixed effect (LME) models supported seven of 15 hypotheses, which suggests remarkably consistent macroinvertebrate patterns in floodplains regardless of the climate regime. Taxon and trait richness were positively related and peaked at sites of intermediate hydrological connectivity. Our predictions about the feeding guilds of macroinvertebrates (e.g. that shredders and scrapers would be more abundant in connected channels, and predators and deposit feeders at isolated sites) were more strongly supported by the data than those about life history (e.g. plurivoltinism and short lifespan would be better represented in connected channels). This difference was related to the influence of extended periods of hydrological disconnection as disturbance in addition to flooding. (5) Trait stability across hydrological connectivity provides a meaningful ecological context for the comparison of the macroinvertebrate benthos among climatic zones, where taxonomic composition differs strongly. In addition, trait similarities and dissimilarities found in this study suggest that large-scale biogeographical filters do operate on communities, resulting in different trait combinations in temperate and Mediterranean floodplains when compared to semi-arid and subtropical environments. The extent to which global macroecological factors (i.e. climate, dispersal history) and local biotic and abiotic fac-

tors (i.e. drought frequency, habitat structure, water chemistry) contribute to this difference requires further investigation." 13835. Gleason, J. E.; Fudge, D.S.; Robinson, B.W. (2014): Eco-mechanics of lamellar autotomy in larval damselflies. *J. Exp. Biol.* 217(2): 185-191. (in English) ["In larval damselflies, the self-amputation (autotomy) of the caudal lamellae permits escape from predatory larval dragonflies. Lamellar joint size declines among populations with increasing risk of dragonfly predation,

but the breaking force required for autotomy and the biomechanical factors that influence breaking force are unknown. If autotomy enhances survival in larval damselflies, then predation by larval dragonflies should select for joints that require less force to break. We test this adaptive hypothesis by evaluating whether breaking force is negatively related to local predation risk from larval dragonflies. We also test a cuticle structure hypothesis, which predicts that breaking force is positively related to joint size and to joint cuticle thickness because of a structural support relationship between joint and lamella. The peak force necessary for lamellar autotomy was assessed on individual larval *Enallagma* damselflies collected from populations that varied in risk of predation. Easier lamellar autotomy occurred in larvae from sites with higher predation risk because damselflies from fishless ponds (where predatory larval dragonflies are likely more abundant) had lower breaking forces than those from ponds with fish (where larval dragonfly predation is likely reduced). Furthermore, breaking force was a positive function of joint size and also of total cuticle cross-sectional area after controlling for joint size. This suggests that autotomy may evolve in larval damselflies under selection from small grasping predators such as larval dragonflies by favouring smaller joint size or reduced cuticle area of lamellar joints." 13836. Gómez-Anaya, J.A.; Novelo-Gutiérrez, R.; Ramírez, A.; Arce-Pérez, R. (2014): Using empirical field data of aquatic insects to infer a cut-off slope value in asymptotic models to assess inventories completeness. *Revista Mexicana de Biodiversidad* 85: 218-227. (in English, with Spanish summary) ["The selection of the most appropriate model is essential to predict the potential species richness of a site or landscape. Species accumulation curves have been used as a basic tool for comparing richness when different sampling protocols have been applied. Among the parameters generated by these models the slope has been cited as an indicator of completeness without regard to a defined cut-off value. In this work, we fit 12 field data sets of aquatic Coleoptera (Hidalgo) and Odonata larvae (Michoacán) to 2 asymptotic models (Clench and Linear Dependence) in order to calculate the slopes at the maximum effort and relate them with efficiency. Then, the theoretical effort needed to achieve the 95% of the lists was calculated for each data set in order to get the theoretical slopes. The average slope value found was 0.01 with a variance of <0.001, so we propose this value as indicative of a list reaching 95% of completeness for data obtained from similar sampling protocols. Additionally, we propose the use of number of rare species as an additional criterion to evaluate the inventories completeness. The effect of different sampling intensity on fitted models and estimation of parameters and the importance of a cut-off slope value in asymptotic mod-

els as a criterion to evaluate completeness of biological inventories are discussed." (Authors)] Address: Novelo-Gutiérrez, R., Department of Environmental Sciences, University of Puerto Rico, P.O. Box 190341, 00919 San Juan, Puerto Rico. E-mail: rodolfo.novelo@inecol.mx

13837. Gonzalez-Santoyo, I.; Gonzalez-Tokman, D.M.; Munguia-Steyer, R.E.; Cordoba-Aguilar, A. (2014): A mismatch between the perceived fighting signal and fighting ability reveals survival and physiological costs for bearers. *PLoS ONE* 9(1): e84571. doi:10.1371/journal.pone.0084571: 12 pp. (in English) ["Signals of fighting indicate an animal's intention to attack and so they serve to prevent costly aggressive encounters. However, according to theory, a signal that is different in design (i.e. a novel signal) but that fails to inform fighting intentions will result in negative fitness consequences for the bearer. In the present study we used males of the territorial damselfly *Hetaerina americana*, which have a red wing spot during territory defense that has evolved as a signal of fighting ability. By producing a novel signal (covering the red spot with blue ink) in territory owners, we investigated: a) the behavioral responses by conspecific males; b) survival cost and c) three physiological mediators of impaired survival: muscular fat reserves, muscle mass and immune ability. We predicted that males with the novel signal would be attacked more often by conspecifics as the former would fail to convey fighting ability and intentions adequately. This will result in lower survival and physiological condition for the novel signal bearers. We found that, compared to control males (males whose red spot was not changed), experimental males had reduced survival, were less able to hold a territory, and had a reduced muscle mass. It seems that spot modified males were not able to effectively communicate their territory tenancy, which may explain why they lost their defended sites. Our results provide support for theoretical models that a novel signal that fails to inform fighting ability may lead to a fitness cost for bearers." 13839. Günther, A.; Hilfert-Rüppell, D.; Rüppell, G. (2014): Reproductive behaviour and the system of signalling in *Neurobasis chinensis* (Odonata, Calopterygidae) – a kinematic analysis. *International Journal of Odonatology* 17(1): 31-52. (in English) ["The reproductive behaviour of the damselfly *N. chinensis* was filmed at 300 and 600 frames per second in Thailand in spring 2009. This was subsequently viewed in slow motion for detailed analysis. Altogether we observed 26 matings at two different sites. Besides visual observations of behaviour of male–female encounters at the reproductive sites, we analysed their flight cinematographically by measuring velocity, wing beat frequency, phase relationships of fore- and hind wings, and described the flight paths of different flight manoeuvres. Wing clapping by the perched insects was analysed in detail. Also filmed were alternative reproductive behaviour and avoidance behaviour when attacked by a hunting spider. By analysing the video footage in slow motion, details of male flight with hind wings held motionless, a typical flight-style for this genus, were revealed. The significance of this behaviour in interactions with conspecifics is discussed." 13840. Guillermo-Ferreira, R.; Therézio, E.M.; Gehlen, M.H.; Bispo, P.C.; Marletta, A. (2014): The role of wing pigmentation, UV and fluorescence as signals in a Neotropical damselfly. *Journal of Insect Behavior* 27(1): 67-80. (in English) ["Pigmentation patterns, ultraviolet reflection and fluorescent emission are often involved in mate recognition and mate quality functions in many animal taxa. We investigated the role of wing ultra-violet reflection, fluorescence emission, and pigmentation on age and sexual signals in the damselfly *Mnesarete pudica*. In this species, wings are sexually dimorphic in colour and exhibit age dependency: males and females show a smoky black colouration when young, turning red in mature males while it turns brown in females. First, we investigated wing UV patterns through reflectance and emission spectra. Second, behavioural experiments were undertaken to show male and female responses to manipulated wing pigmentation and experimentally reduced UV (UV-). Reflectance spectra of the wings of juvenile and mature males and females were used to show the differences between controls and individuals with manipulated colouration used in the behavioural experiment. UV-reduced, females with wings painted red, and control males and females were

tethered and presented to conspecific males and females, and their behavioral responses were recorded. The male red wing pigmentation and females with red wings elicited an aggressive response in territorial males and a sexual response in females. Both males and females showed neutral responses towards individuals with reduced UV. Wing signals of juvenile individuals also provoked neutral responses. These results suggest that UV, together with pigmentation, plays a role during mate recognition in males and females. Other than butterflies and spiders, it seems that fluorescence signals and UV reflectance can also be part of communication in odonates." 13845. Hart, L.A.; Bowker M.B.; Tarboton W.; Downs C.T. (2014): Species composition, distribution and habitat types of Odonata in the iSimangaliso Wetland Park, KwaZulu-Natal, South Africa and the associated conservation implications. *PLoS ONE* 9(3): e92588. doi: 10.1371/journal.pone.0092588: 11 pp. (in English) ["Maputaland–Pondoland–Albany, South Africa has been identified as a biodiversity hotspot and centre for endemism. Odonata make good indicators of freshwater ecosystem health. Consequently we compiled a list of Odonata species recorded to date in the iSimangaliso Wetland Park. We then detailed important species in terms of endemism, conservation status, and potential as indicator species. Finally, we compared Odonata assemblages of different sites sampled within the park to

illustrate habitat importance. Species identified during two formal surveys and incidental observations made during the study period were combined with an existing database to compile an accurate and up to date species list for the iSimangaliso Wetland Park. Data from this study were then analyzed to determine which water bodies had the most similar species composition. The Dragonfly Biotic Index (DBI) value of each study area was also determined. We recorded 68 odonate species in the iSimangaliso Wetland Park, adding 13 species to the Ezemvelo KwaZulu-Natal Wildlife database for the area. This brings the total number of Odonata species for the iSimangaliso Wetland Park to 86. Eight species are red-listed, 12 are restricted in South Africa to the coastal plains of northern KwaZulu-Natal, and the remainder occurs widely across the southern African savanna. Analyses indicate that species odonate assemblages were most similar in water bodies with comparable habitats. iSimangaliso Wetland Park is identified as an important area for Odonata diversity and endemism, a trend also reflected by the DBI values. Shifts in the existing species assemblages would indicate changes within the ecosystem and thus this species account provides necessary baseline data for the area. Species Conservation efforts should thus target water bodies of varying habitat types to protect greater species diversity." 13846. Hassall, C. (2014): The ecology and biodiversity of urban ponds. *Wiley Interdisciplinary Reviews: Water* 1(2): 187-206. (in English) ["Recent research has demonstrated that ponds contribute a great deal to biodiversity at a regional level as networks of habitat patches that also act as 'stepping stones' to facilitate the movement of species through the landscape. Similarly, a great deal of biodiversity persists in urban environments where synanthropic communities are supplemented by species that thrive in disturbed environments. Aquatic urban biodiversity appears to persist despite anthropogenic stressors: an array of anthropogenic pollutants (road salt and heavy metals), invasive species, and active mismanagement—particularly the removal of riparian vegetation. Optimizing urban ponds for different ecosystem services results in conflicting priorities over hydrological, geochemical, ecological, aesthetic, and cultural functions. The socio-ecosystem approach to environmental management opens a path to greater incorporation of biodiversity into town planning and sustainability, while accounting for cultural attitudes to urban ecosystems. I identify a range of research needs: (1) the roles of design and location of urban ponds in influencing biodiversity, (2) the function of urban wetlands for stormwater and pollution management, and (3) public perceptions of urban ecosystems and how those perceptions are influenced by interactions with natural systems. Urban wetlands offer an important opportunity to educate the general public on natural systems and science in general using a resource that is lo-

cated on their doorstep. In the face of increasing pressures on natural systems and increasing extent and intensity of urbanization, a more comprehensive appreciation of the challenges and opportunities provided by urban ponds could play a substantial role in driving sustainable urban development." (Author) The paper only includes a few references to Odonata.] Address: Hassall, C., School of Biology, University of Leeds, Leeds, UK. E-mail: c.hassall@leeds.ac.uk

13847. Ihara, S. (2014): Food habits of the adult Japanese newt *Cynops pyrrhogaster* (Amphibia: Salamandridae) in the sub-alpine Yachidaira High Moor, East—Central Honshu, Japan. *Current Herpetology* 33(1): 38-45. (in English) ["The diet of the adult *Cynops pyrrhogaster* was studied at a small pond on the Yachidaira high moor (1500 m asl) from 2002 to 2004. In total, 160 individuals examined by stomach flushing yielded 1518 prey items, of which most (95.7% of the total numerically) were small arthropods inhabiting the pond or surrounding land. Of these, chironomid larvae and Cladocera numerically represented 34.3% and 34.7%, respectively. By mass, *Rhacophorus arboreus* tadpoles, Odonata adults, Brachycera adults, and conspecific newt eggs comprised 13.7%, 11.5%, 10.7%, and 9.8% of all prey, respectively. The composition of prey items varied seasonally and annually. These results suggest that the food habits of adult *C. pyrrhogaster* in the alpine high moor areas are influenced by yearly and seasonal changes in various small animals in and around the ponds." 13848. Janssens, L.; Van, K.D., Debecker, S.; Bervoets, L.; Stoks, R. (2014): Local adaptation and the potential effects of a contaminant on predator avoidance and antipredator responses under global warming: a space-for-time substitution approach. *Evolutionary Applications* 7(3): 421-430. (in English) ["The ability to deal with temperature-induced changes in interactions with contaminants and predators under global warming is one of the outstanding, applied evolutionary questions. For this, it is crucial to understand how contaminants will affect activity levels, predator avoidance and antipredator responses under global warming and to what extent gradual thermal evolution may mitigate these effects. Using a space-for-time substitution approach, we assessed the potential for gradual thermal evolution shaping activity (mobility and foraging), predator avoidance and antipredator responses when *Ischnura elegans* damselfly larvae were exposed to zinc in a common-garden warming experiment at the mean summer water temperatures of shallow water bodies at southern and northern latitudes (24 and 20°C, respectively). Zinc reduced mobility and foraging, predator avoidance and escape swimming speed. Importantly, high-latitude populations showed stronger zinc-induced reductions in escape swimming speed at both temperatures, and in

activity levels at the high temperature. The latter indicates that local thermal adaptation may strongly change the ecological impact of contaminants under global warming. Our study underscores the critical importance of considering local adaptation along natural gradients when integrating biotic interactions in ecological risk assessment, and the potential of gradual thermal evolution mitigating the effects of warming on the vulnerability to contaminants." 13849. Janssens, L.; Van, K.D.; Stoks, R. (2014): Extreme temperatures in the adult stage shape delayed effects of larval pesticide stress: a comparison between latitudes. *Aquatic Toxicology* 148: 74-82. (in English) ["Highlights: •Global warming and pesticides are major threats to aquatic biodiversity. •Larval pesticide and adult heat stress reduced fitness traits in a damselfly. •High-latitude damselflies were more sensitive to the pesticide and heat stress. •Both stressors interacted across metamorphosis; similarly across latitudes. •Risk assessment should consider temperature extremes shaping pesticide effects. Global warming and pesticide pollution are major threats for aquatic biodiversity. Yet, how pesticide effects are influenced by the increased frequency of extreme temperatures under global warming and how local thermal adaptation may mitigate these effects is unknown. We therefore investigated the combined impact of larval chlorpyrifos exposure, larval food stress and adult heat exposure on a set of fitness-related traits in replicated low- and high-latitude populations of the damselfly *Ischnura elegans*. Larval pesticide exposure resulted in lighter adults with a higher water content, lower fat content, higher Hsp70 levels and a lower immune function (PO activity). Heat exposure reduced water content, mass, fat content and flying ability. Importantly, both stressors interacted across metamorphosis: adult heat exposure lowered the reduction of fat content, and generated a stronger decrease in PO activity in pesticide-exposed animals. Larval pesticide exposure and larval food stress also reduced the defense response to the adult heat stress in terms of increased Hsp70 levels. In line with strong life history differences in the unstressed control situation, high-latitude animals were less sensitive to food stress (body mass and water content), but more sensitive to pesticide stress (development time and PO activity) and heat exposure (PO activity and Hsp70 levels). While low-latitude adults could better withstand the extreme temperature as suggested by the weaker increase in Hsp70, heat exposure similarly affected the delayed effects of larval pesticide exposure at both latitudes. Our study highlighted two key findings relevant for ecological risk assessment under global warming. Firstly, the delayed effects of larval pesticide exposure on adult damselflies depended upon subsequent adult heat exposure, indicating that larval pesticide stress and adult heat stress interacted across metamorphosis. Secondly,

low- and high-latitude animals responded differently to the imposed stressors, highlighting that intraspecific evolution along natural thermal gradients may shape sensitivity to pesticides." 13850. Juen, L.; Oliveira-Junior, M.B.; Shimano, Y.; Mendes, T.P.; Cabette, H.S.R. (2014): Composition and richness of Odonata (Insecta) in streams with different levels of conservation in a Cerrado-Amazonian Forest ecotone. *Acta Amazonica* 44(2): 223-234. (in Portuguese, with English summary) ["The removal or substitution of riparian vegetation causes disturbance in physical environment, seasonal water flow and water chemical quality. These modifications can cause decrease in species richness by local extinctions. The aim of this study was to examine the effect of disturbance in the physical environment on the richness and species composition of Odonata adults in streams with different levels of conservation in the river Suiá-Missu basin, Mato Grosso, Brazil. Modifications in the aquatic systems affected the Odonata community, probably because their ecophysiological and behavioral requirements of adults and larvae. Anisoptera species, which require sunny environments because of their body size, had higher species richness in environments with low plant cover. On the other hand, Zygoptera species, which generally inhabit streams with dense vegetation, presented a decrease in richness in disturbed environments, as a result high sunlight radiation and/or variations in temperature. Hence, in both suborders, environmental perturbations do not need to be severe to change species composition, indicating that ecosystem services could be lost, even with only partial alterations in physical environment." 13854. Karthika, P.; Krishnaveni, N. (2014): Impact assessment of dragonfly diversity in different wetland ecosystems in Coimbatore with special reference to abiotic factors. *International Journal of Advanced Research* 2(2): 639-648. (in English) ["Coimbatore district possess many wetlands, amongst them Singanallur, Sulur, Kumarasamy and Narasampathy were selected for the present study. Physico-chemical parameters of the waters for four selected wetlands were carried out and it revealed that Singanallur and Sulur wetlands were highly polluted as it possessed the ranges beyond the permissible limits of WHO. Since dragonflies are the indicator and flagship species of the wetland ecosystem the diversity of dragonflies were analyzed with special reference to water quality parameters of the selected wetlands. According to the survey, totally 11 species of dragonfly, belonging to two families (Libellulidae and Aeshnidae) were identified. Among the selected four wetlands the diversity of dragonflies was high in Sulur and Singanallur where the pollution level was also high. The present study clearly indicated that the diversity of dragonflies was not dependent upon the water characters but vegetation (aquatic and marginal) could have influenced their abundance in these wetlands." 13855. Kim, M.J.; Jung, K.S.; Park, N.S.; Wan, X.; Kim, K.-G.; Jun, J.; Yoon, T.J.; Bae, Y.B.; Lee, S.M.; Kim, I. (2014): Molecular phylogeny of the higher taxa of Odonata (Insecta) inferred from COI, 16S rRNA, 28S rRNA, and EF1-a sequences. *Entomological Research* 44(2): 65-79. (in English) ["In this study, we sequenced both two mitochondrial genes (COI and 16S rRNA) and nuclear genes (28S rRNA and elongation factor-1a) from

71 species of Odonata that represent 7 superfamilies in 3 suborders. Phylogenetic testing for each two concatenated gene sequences based on function (ribosomal vs protein-coding genes) and origin (mitochondrial vs nuclear genes) proved limited resolution. Thus, four concatenated sequences were utilized to test the previous phylogenetic hypotheses of higher taxa of Odonata via Bayesian inference (BI) and maximum likelihood (ML) algorithms, along with the data partition by the BI method. As a result, three slightly different topologies were obtained, but the BI tree without partition was slightly better supported by the topological test. This topology supported the suborders Anisoptera and Zygoptera each being a monophyly, and the close relationship of Anisozygoptera to Anisoptera. All the families represented by multiple taxa in both Anisoptera and Zygoptera were consistently revealed to each be a monophyly with the highest nodal support. Unlike consistent and robust familial relationships in Zygoptera those of Anisoptera were partially unresolved, presenting the following relationships: (((Libellulidae + Corduliidae) + Macromiidae) + Gomphidae + Aeshnidae) + Anisozygoptera) + (((Coenagrionidae + Platycnemididae) + Calopterygidae) + Lestidae). The subfamily Sympetrinae, represented by three genera in the anisopteran family Libellulidae, was not monophyletic, dividing *Crocothemis* and *Deielia* in one group together with other subfamilies and *Sympetrum* in another independent group." 13857. Koch, K. (2014): Hand feeding: a method to increase the survival rate of *Orthetrum coerulescens* (Odonata: Libellulidae) in outdoor enclosures. *International Journal of Odonatology* 17(1): 1-6. (in English) ["Food intake rate and diet composition have a high impact on all organisms and affect individual fitness, fecundity and mortality. Specimens in enclosures have to be fed in an adequate way and with minimum stress for the specimens. Adult dragonflies are flying hunters. In enclosures, they are usually fed by adding different

kinds of adult dipterans. In this study, I additionally fed specimens of *Orthetrum coerulescens* by hand. Each specimen received one house fly or up to six fruit flies per day. This was less than an adult dragonfly would normally consume; however, this additional hand feeding was enough to significantly increase the survival rate of individuals, especially within the first 12 days of adult life. The maximum life span (subadult and adult) observed was about 60 days, for both hand-fed adults and those that were not hand fed." SPIE* 9055, *Bioinspiration, Biomimetics, and Bioreplication* 2014, 905504 (March 8, 2014), San Diego, California, USA; doi:10.1117/12.2045030. Conference Volume 9055 (in English) ["Insects are the most diverse natural flyers in nature, being able to hover and perform agile manoeuvres. Dragonflies in particular are aggressive flyers, attaining accelerations of up to 4g. Flight in all insects requires demanding aerodynamic and inertial loads be overcome. It has been proposed that resonance is a primary mechanism for reducing energy costs associated with flapping flight, by storing energy in an elastic thorax and releasing it on the following half-stroke. Certainly in insect flight motors dominated by inertial loads, such a mechanism would be extremely beneficial. However in highly manoeuvrable, aerodynamically dominated flyers, such as the dragonfly, the use of elastic storage members requires further investigation. We show that employing resonant mechanisms in a real world configuration produces minimal energy savings that are further reduced by 50 to 133% across the operational flapping frequency band of the dragonfly. Using a simple harmonic oscillator analysis to represent the dynamics of a dragonfly, we further demonstrate a reduction in manoeuvring limits of ~1.5 times for a system employing elastic mechanisms. This is in contrast to the potential power reductions of $\sqrt{2}/2$ from

regulating aerodynamics via active wing articulation. Aerodynamic means of energy storage provides flexibility between an energy efficient hover state and a manoeuvrable state capable of large accelerations. We conclude that active wing articulation is preferable to resonance for aerodynamically dominated natural flyers." (Authors)] Address: Chahl, J., School of Engineering, Univ. (2014): Benthic macroinvertebrates along the Czech part of the Labe and lower section of the Vltava rivers from 1996–2005, with a particular focus on rare and alien species. *Biologia* 69/4: 508-521. (in English) ["In the Czech part of the Labe River and the lower part of the Vltava River, we examined if the benthic macroinvertebrate composition changed from 1996 to 2005 due to expected improvements in water quality resulting from socioeconomic changes in the Czech Republic since the 1990s. Special attention was given to rare and alien species. The four biological metrics used (Number of taxa, BMWP, Number of sensitive taxa, and Number of EPT taxa) demonstrated that there was indeed an improvement in water quality as well as a slight improvement of the Labe microhabitats during the investigated period. An increasing Number of taxa over time was observed at most sites. Two main concurrent ecological processes are recently in progress in the Labe: a recovery of native species and an expansion of alien species, some of which are considered invasive. The caddisfly *Setodes punctatus* and the beetle *Pomatinus substriatus*, considered as regionally extinct in the Czech Republic until 2005, were rediscovered during our investigations. Findings of the crustacean *Hemimysis anomala* (invasive) and the chironomids *Stenochironomus* sp. and *Lipiniella* sp. were the first records of these taxa in the Czech Republic." (2014): A survey that established a baseline population data set for Odonata species in Jay Cooke State Park, Carlton County, Minnesota. *Duluth Journal of Undergraduate Research in Science* 2014: 13-16. (in English) ["In an effort to create a baseline population data set of Odonata in Jay Cooke State Park

a survey was conducted from May 29, 2013 to September 26, 2013 by using hand-netting techniques, in the field identification on live specimens, as well as proper treatment, storage and documentation of caught specimens. The purpose of this survey was to create an online accessible data set that can be used in the future for research on topics such as climate change, watershed health and other ecological issues being that Odonata are bioindicators of ecosystem health due to their obligate aquatic nymph forms. Only 3 adult males were collected of each species found to ensure no damage to future populations. Contrasted to population data previously reported there were 11 species added from the 2013 survey to the list of documented species found in Carlton County. These newly documented 11 species were part of the 35 different species caught from a total of 67 specimens collected." (Author)] Address: Larson, Kendra, Swenson College of Science and Engineering, University of Minnesota Duluth, USA. E-mail: Lars4094@d.umn.edu

13866. Letsch, H.; Gottsberger, B.; Ware, J. (2014): Ancient biogeography and evolution of dragonflies (Odonata: Anisoptera). *BioDivEvo2014 - Joint conference — 15th Annual Meeting of the Society of Biological Systematics (GfBS), 22nd International Symposium of the German Botanical Society (DBG), "Biodiversity and Evolutionary Biology" — Dresden · March 24 – 27, 2014, Technische Universität Dresden, Germany.* This meeting is funded by the German Research Foundation. Publisher: Senckenberg Naturhistorische Sammlungen Dresden, Königsbrücker Landstraße 159 · 01109 Dresden · Germany; Editor-in-Chief: Uwe Fritz (Zoology) on behalf of the German Society for Biological Systematics (GfBS), Christoph Neinhuis (Botany) on behalf of Section „Biodiversity and Evolutionary Biology“, the German Botanical Society (DBG); Distributor: Senckenberg Naturhistorische Sammlungen Dresden, Königsbrücker Landstraße 159 · 01109 Dresden · Germany. ISBN 978-3-910006-49-2: 105. (in English) [Verbatim: From Early Triassic to Middle Jurassic, earth land masses were united in the supercontinent Pangaea. The Late Jurassic break-up of Pangaea into Laurasia (later giving rise to North America, Europe, and Asia), and Gondwana, (later South America, Africa, India, Antarctica, and Australia) led to increased diversification and the contemporary vicariant distribution of plants and animals. While the congruence of tetrapod evolution and continental fragmentation has been documented by recent phylogenetic and biogeographical studies, no work has been conducted until now to explicitly reconstruct the phylogenetic relationships and biogeography of insect groups in the context of ancient continental drift in the Mesozoic. In the present study, we want to explore the potential pangaeian appearance of dragonfly families (Odonata: Anisoptera) and their subsequent diversification in concordance to continental schisms. We compiled a comprehensive molecular data set, based on eight ribosomal RNA and protein

coding genes, representing all major dragonfly groups. Based on this data, tree reconstruction was conducted and divergence times of the anisopteran families were estimated. We additionally reconstructed ancestral areas to retrace their historical biogeography. Our phylogenetic reconstruction proposes Aeshnoidea as the first branch in Anisoptera and Petaluroidea as sister group to Cavilabiata, the latter being subdivided into Cordulegastroidea and Libelluloidea. Divergence time estimation clearly shows a pangaeian appearance and early radiation of all anisopteran superfamilies. The reconstruction of ancestral areas suggests North America as the cradle of all Anisoptera and hot spot for the early radiation of Gomphoidea and Petaluroidea. Libelluloidea probably emerged and primary radiated in Eurasia, with subsequent independent dispersal events to the southern continents. Our results suggest a persistent yet tenuous dispersal route between Eurasia and Africa in the Lower Cretaceous.] Address: Ware, Jessica, Department of Biological Sciences, Rutgers University, Newark, NJ, 07102, USA

13867. Li, F.; Kwon, Y.-S.; Bae, M.-J.; Chung, N.; Kwon, T.S.; Park, Y.-S. (2014): Potential impacts of global warming on the diversity and distribution of stream insects in South Korea. *Conservation Biology* 28(2): 498-508. (in English, with Spanish summary) ["Globally, the East Asian monsoon region is one of the richest environments in terms of biodiversity. The region is undergoing rapid human development, yet its river ecosystems have not been well studied. Global warming represents a major challenge to the survival of species in this region and makes it necessary to assess and reduce the potential consequences of warming on species of conservation concern. We projected the effects of global warming on stream insect (Ephemeroptera, Odonata, Plecoptera, and Trichoptera [EOPT]) diversity and predicted the changes of geographical ranges for 121 species throughout South Korea. Plecoptera was the most sensitive (decrease of 71.4% in number of species from the 2000s through the 2080s) order, whereas Odonata benefited (increase of 66.7% in number of species from the 2000s through the 2080s) from the effects of global warming. The impact of global warming on stream insects was predicted to be minimal prior to the 2060s; however, by the 2080s, species extirpation of up to 20% in the highland areas and 2% in the lowland areas were predicted. The projected responses of stream insects under global warming indicated that species occupying specific habitats could undergo major reductions in habitat. Nevertheless, habitat of 33% of EOPT (including two-thirds of Odonata and one-third of Ephemeroptera, Plecoptera, and Trichoptera) was predicted to increase due to global warming. The community compositions predicted by generalized additive models varied over this century, and a large difference in community structure in the highland areas was predicted between the 2000s and the 2080s. However, stream insect communities, espe-

cially Odonata, Plecoptera, and Trichoptera, were predicted to become more homogenous under global warming." (Authors)] Address: Park, Y.-S., Department of Biology, Kyung Hee University, Seoul, Republic of Korea. E-mail: parkys@khu.ac.kr

13868. Li, X.j.; Zhang, Z.-h.; Liang, Y.-h.; Ren, L.-q.; Jie, M.; Yang, Z.-g. (2014): Antifatigue properties of dragonfly *Pantala flavescens* wings. *Microscopy Research and Technique* 77(5): 356-362. (in English) ["The wing of a dragonfly is thin and light, but can bear high frequent alternating stress and present excellent antifatigue properties. The surface morphology and microstructure of the wings of *P. flavescens* were observed using SEM in this study. Based on the biological analysis method, the configuration, morphology, and structure of the vein were studied, and the antifatigue properties of the wings were investigated. The analytical results indicated that the longitudinal veins, cross veins, and membrane of dragonfly wing form an optimized network morphology and spacially truss-like structure which can restrain the formation and propagation of the fatigue cracks. The veins with multilayer structure present high strength, flexibility, and toughness, which are beneficial to bear alternating load during the flight of dragonfly. Through tensile-tensile fatigue failure tests, the results were verified and indicate that the wings of dragonfly *P. flavescens* have excellent antifatigue properties which are the results of the biological coupling and synergistic effect of morphological and structural factors." 13869. Liang, B.; Sun, M. (2014): Dynamic flight stability of a hovering model dragonfly. *Journal of Theoretical Biology* 348: 100-112. (in English) ["•Hovering flight of the model dragonfly is inherently unstable. •The instability is caused by the horizontal-velocity/pitch-moment derivative. •Damping force and moment derivatives weaken the instability considerably. •Forewing/hindwing interaction has little effect on the stability properties. •High stroke-plane angles affect how stability derivatives are produced. The longitudinal dynamic flight stability of a model dragonfly at hovering flight is studied, using the method of computational fluid dynamics to compute the stability derivatives and the techniques of eigenvalue and eigenvector analysis for solving the equations of motion. Three natural modes of motion are identified for the hovering flight: one unstable oscillatory mode, one stable fast subsidence mode and one stable slow subsidence mode. The flight is dynamically unstable owing to the unstable oscillatory mode. The instability is caused by a pitch-moment derivative with respect to horizontal velocity. The damping force and moment derivatives (with respect to horizontal and vertical velocities and pitch-rotational velocity, respectively) weaken the instability considerably. The aerodynamic inter-

action between the forewing and the hindwing does not have significant effect on the stability properties. The dragonfly has similar stability derivatives, hence stability properties, to that of a one-wing-pair insect at normal hovering, but there are differences in how the derivatives are produced because of the highly inclined stroke plane of the dragonfly." 13870. Lonkar, S.S.; Kedar, G.T. (2014): Macrozoobenthic diversity of three urban lakes of Nagpur, central India. *International Journal of Advanced Research* 2(4): 1082-1090. (in English) ["The present study was carried at three urban lakes of Nagpur City in Central India from September 2010 to August 2012 confirmed macrozoobenthic diversity of 30 species belonging to 4 different phylum, viz Platyhelminths, Annelida, Arthropoda, Mollusca. The most abundant species are observed in Phylum Arthropoda, Class Insecta as larvae, nymph and naids of the aquatic insects. The presence of species belonging to Phylum Mollusca are also more in number with the occurrence of Gastropoda and Pelecypoda. The occurrence of Phylum Annelida is prominent with class Oligochaeta and Hirudinea. The species belonging to Phylum Platyhelminths of class Turbellaria are least in study. The study suggests that the rich benthic fauna is due to the organic rich habitat in the three urban lakes of city." (Authors) Unspecified dragonfly zygopteran and anisopteran larvae are listed.] Address: Lonkar, S.S., Dept. of Zoology, Institute of Science, Nagpur-10, India

13873. Mäkinen, J. (2014): Hämeen Sudenkorennot [The dragonflies of Häme]. *Crenata* 7: 14-39. (in Finnish, with English summary) ["Distribution maps are presented for all 51 dragonfly species observed in the provinces of Kanta-Häme and Pajät-Häme (together known as Häme) in South Finland. Records made before 1980 and after that are shown with different map symbols. Contrary to many other areas in Finland the dragonfly fauna of Häme has been intensively studied during the past decades, offering the opportunity to analyse data for possible changes in species abundance. Statistical analyses performed by Janne Koskinen revealed a statistically significant decline of four species whereas seven species show a positive trend. The declining species are *Lestes dryas*, *Coenagrion armatum*, *Gomphus vulgatissimus* and *Leucorrhinia dubia*. Increasing species are *Calopteryx splendens*, *Coenagrion pulchellum*, *Brachytron pratense*, *Epithea bimaculata*, *Somatochlora flavomaculata*, *Libellula depressa* and *Leucorrhinia pectoralis*. Reasons for decline remain unclear. Although *Coenagrion armatum* has declined in many European countries it is still classified as „least concern species“ in Finland. The majority of the increasing species are considered to be „southern species“ and their increase might be a result of a northward shift of their distribution due to climate change. Since 1979 not less than eight species have been found in Häme for the first time, most of which already breed in the area, at least occasionally." (Author)] Address: Mäkinen, J., Metsänhoitajankatu 12 B 16, FI-00790 Helsinki, Finland. E-mail: makisenjussi@gmail.com

13879. McLennan, M.R. (2014): Chimpanzee insectivory in the northern half of Uganda's Rift Valley: do Bulindi chimpanzees conform to a regional pattern?. *Primates* 55: 173-178. (in English) ["Insects are a nutritious food source for many primates. In chimpanzees, insectivory is most prevalent among communities that manufacture tools to harvest social insects, particularly ants and termites. In contrast to other long-term study sites, chimpanzees (*Pan troglodytes schweinfurthii*) in Budongo Forest and Kibale National Park, Uganda, rarely eat insects and have small foraging tool kits, supporting speculation that infrequent insectivory—technically aided or otherwise—characterises chimpanzees in this part of Uganda's Rift Valley. To expand the dataset for this region, insect foraging was investigated at Bulindi (25 km from Budongo) over 19 months during two studies in 2007–2008 and 2012–2013. Systematic faecal analysis demonstrated that insectivory is a habitual foraging activity at this site. Overall levels of insect consumption varied considerably across months but were not predicted by monthly changes in rainfall or fruit intake. Unlike their Budongo and Kibale counterparts, Bulindi chimpanzees often consume ants (principally weaver ants, *Oecophylla longinoda*) and use sticks to dig out stingless bee (*Meliponini*) ground nests. In other respects, however, insectivory at Bulindi conforms to the pattern observed elsewhere in this region: they do not manufacture 'fishing' or 'dipping' tools to harvest termites and aggressive or hard-to-access ants (e.g., army ants, *Dorylus* spp.), despite availability of suitable prey. The Bulindi data lend support to the supposition that chimpanzees in this part of the Rift Valley rarely exploit termites and *Dorylus* ants, apparently lacking the 'cultural knowledge' that would enable them to do so most efficiently (i.e., tool use). The study's findings contribute to current debates about the relative influence of genetics, environment and culture in shaping regional and local variability in *Pan* foraging ecology." (Author) The diet also includes a few Odonata.] Address: McLennan, M.R., Faculty of Humanities and Social Sciences, Anthropology Centre for Conservation, Environment and Development, Oxford Brookes University, Gypsy Lane Campus, Oxford OX3 0BP, UK. 13882. Monteiro-Júniora, C.S.; Juen, L.; Hamada, N. (2014): Effects of urbanization on stream habitats and associated adult dragonfly and damselfly communities in central Brazilian Amazonia. *Landscape and Urban Planning* 127: 28-40. (in English) ["Highlights: •In Amazonia, most damselfly species appear to favor preserved environments. •Urbanization affects Zygoptera more than Anisoptera. •Even sites with only a little riparian vegetation harbour their own Odonata fauna. •The community of adult dragonflies and damselflies can provide a good measure to classify environments. •Maintaining riparian vegetation is important for conserving aquatic biota. Abstract: Thirty streams, located in Manaus in the central part of Brazilian Amazonia, were examined to evaluate the correlations between environmental integrity and the local communities of adult dragonflies and damselflies. The presence of damselflies would have a positive correlation with environmental integrity, and dragonflies a negative one due to their contrasting ecophysiological requirements. The environmental integrity of each site was estimated based on the Habitat integrity index (HII), which was modified for this study in an urban area. The hypothesis that would be differences in assemblage composition between streams in differently urbanized areas was supported, possibly because most damselfly species are considered to be specialists that are found in pristine habitats, whereas dragonflies seem to be generalists and are likely to be found in disturbed environments. The ordination indicated systematic differences in community composition based on the degree of conservation of the environment, with the communities

found in well-preserved habitats being distinct from those found in intermediate and degraded ones. Differences in the composition of odonate communities reflect differences in the integrity of the environment, but they can also provide a measure of the intensity of impacts, thus contributing to the development of effective conservation strategies. In addition, the HII, which is applied rapidly and easily, provides environmental managers with an objective measure of the degree of alteration of aquatic habitats. Maintenance of forest cover along watercourses is clearly essential for the conservation of hydrological resources and the aquatic organisms that depend on these environments." 13885. Na, Y.; Sun, C.; Li, T.; Li, Y. (2014): The Insect Oviposition Firstly Discovered on the Middle Jurassic Ginkgoales Leaf from Inner Mongolia, China. *Acta Geologica Sinica - English Edition* 88(1): 18-28. (in English) ["Although the evidence of insect oviposition on plant organs has been reported from the late Paleozoic to the Miocene, record from the middle Jurassic is still blank. This paper reports a significant evidence of insect oviposition on plant leaf from the middle Jurassic for the first time. The ovipositional scar is distributed on the abaxial surface of Sphenobaiera leaf (Ginkgoales) from the middle Jurassic Daohugou Formation of Inner Mongolia, China. A new ichnospecies *Paleoovoidus venustus* sp. nov. is described. The scar is elliptic to oval, ar-

ranged in longitudinal rows between leaf veins with almost regular distance, with its long axis paralleling to the leaf venation. This discovery adds new information to the morphology of insect endophytic oviposition probably produced by Odonata existed in a terrestrial ecosystem ~165 Ma ago. The new materials also provide important data for the study of insect reproductive biology, plant-insect interaction and coevolution, as well as understanding the paleoclimate and palaeoenvironment during that time in northeast China." 13886. Nava-Bolaños, A.; Sánchez-Guillén, R.A.; Munguía-Steyer, R.; Córdoba-Aguilar, A. (2014): Isometric patterns for male genital allometry in four damselfly species. *Acta ethol.* 17: 47-52. (in English) ["Studies have found that insect genitalic traits show negative allometry, i.e., are relatively small in relation to body size. One interpretation of this is that males use their genitalia to stimulate females. Thus, given the nature of damselfly copulation in which males physically reach the rival sperm that females have stored from previous matings, male genitalic traits are not expected to show negative allometry. To test this idea, we assessed (a) the rival sperm displacement function by the mating male and (b) allometry of aedeagal length of four damselfly species (*Argia anceps*, *Argia tezpi*, *Argia extranea*, and *Enallagma praevarum*). Sperm displacement was assessed by inspecting whether the aedeagus reached the rival sperm during copulation in mating pairs for the four species. To have a standard for comparing allometric patterns, allometry of aedeagal was compared to that of two non-genital traits, tibial, and fourth abdominal segment length. In all cases, the aedeagus was found to reach the rival sperm which supports the idea that stimulation is not the mechanism for sperm displacement but physical displacement. Aedeagal length was isometric, and its slope was lower in general compared to that of tibial length and fourth abdominal segment. Given that this isometric pattern is not common for other odonate species, our interpretation of these varying aedeagal scaling patterns in this insect order is that males' and females' sexual interests are in conflict (males are evolving an elongated aedeagus to reach rival sperm while females are evolving unreachable sperm storage organs to prevent displacement of stored sperm). This sexual conflict scenario would favour varying scaling patterns for aedeagal length in odonates. A final interpretation is that the risk of interspecific matings in damselflies, may also explain different species-specific, aedeagal allometries." 13888. Nkalubo, W.; Chapman, L.; Muyodi, F. (2014): Feeding ecology of the intensively fished Nile Perch, *Lates niloticus*, in Lake Victoria, Uganda. *Aquatic Ecosystem Health & Management* 17(1): 62-69. (in English) ["The diet of Nile Perch (8.0–121.0 cm total length [TL]) from the Ugandan waters of Lake Victoria was quantified through stomach content analysis of specimens collected from experimental catches and fish factory samples. A total of 7824 stomachs (5602 from experimental fishing and 2222 from factory samples) were examined, of which 34.8% contained food. Fish from the experimental catches were smaller (8.0–41.6 cm TL) and had a higher diversity of prey dominated by unidentifiable fish prey, haplochromine cichlids, *Rastrineobola argentea*, Odonata and *Caridina nilotica*, while larger fish (30.0–121.0 cm TL) from the factory samples had a predominance of fish remains and haplochromine cichlids. Nile Perch that had a high proportion of fish prey (versus invertebrates) in their stomachs showed a larger size for a given age, and were in a better condition ($K = 1.24$) than those that had primarily invertebrates ($K = 1.10$) in their stomachs. Nile Perch exhibited a much smaller size (15 cm versus 30 cm TL) at shift to piscivory in comparison to Nile Perch examined in earlier studies, when haplochromines were rare in Lake Victoria. The recovery of haplochromine cichlids coincident with declining Nile Perch densities illustrates the importance of developing sustainable management options that can define a proper balance between fishing mortality and Nile Perch predation." (Authors)] Address: Nkalubo, Winnie, National Fisheries Resources Research Institute, P.O. Box 343, Jinja, Uganda

13889. Outomuro, D.; Rodríguez-Martínez, S.; Karlsson, A.; Johansson, F. (2014): Male wing shape differs between condition-dependent alternative reproductive tactics in territorial damselflies. *Animal Behaviour* 91: 1-7. (in English) ["Highlights: •We explored the role of wing morphology in territory-holding potential. •We studied three species of *Calopteryx* damselflies in natural populations. •Wing shape differed between territorial and nonterritorial tactics. •The pattern of variation was

similar in hindwings, but not in forewings. Territorial contests between males without weaponry are based on costly displays and can result in condition-dependent alternative reproductive tactics that maximize male fitness. Physiological and morphological traits such as fat content, body size or the expression of secondary sexual traits have been shown to contribute to male territory-holding potential. When territorial contests are based on flight displays, wing morphology is expected to contribute to the territory-holding potential of a male through its effects on flight performance. We explored whether wing shape contributed to the territory-holding potential of males of three species of *Calopteryx* damselflies. Males of these species show two distinct, condition-dependent behavioural tactics: territorial and nonterritorial. Previous studies have shown that territorial males have higher fitness than nonterritorial males. We used mark-recapture to determine male tactics within the populations and compared wing shape, size and wing coloured spot size (a secondary sexual trait) between tactics. Territorial males of all three species had shorter and slightly broader hindwings than nonterritorial males. In two species, forewings of territorial males were longer and broader than forewings of nonterritorial males. Wing size and wing spot size did not differ between tactics. We suggest that the wing shape of territorial males might confer better flight manoeuvrability, which would be advantageous for territorial contests. Therefore, wing shape is likely to be an important trait contributing to territory-holding potential in condition-dependent alternative reproductive tactics based on flight displays." 13891. Piersanti, S.; Frati, F.; Conti, E.; Gaino, E.; Reborja, M.; Salerno, G. (2014): First evidence of the use of olfaction in Odonata behaviour. *Journal of Insect Physiology* 62(1): 26-31. (in English) ["Highlights: •We tested the attractiveness of prey odour in *Ischnura elegans* by behavioural assays. •We recorded responses to prey odour from single olfactory neurons in *I. elegans*. •The adults of *I. elegans* were attracted by olfac-

tory cues emitted by prey. •Antennal olfactory sensilla of *I. elegans* showed excitatory responses to prey odour. •Antennal olfactory sensilla are involved in Odonata predation. Dragonflies and damselflies are among the most ancient winged insects. Adults belonging to this order are visually oriented and are considered anosmic on the basis of neuroanatomical investigations. As a consequence, the chemical ecology of these predatory insects has long been neglected. Morphological and electrophysiological data demonstrated that dragonfly antennae possess olfactory sensilla. Additionally, a neuroanatomical study revealed the presence of spherical knots in the aglomerular antennal lobe that could allow for the perception of odour. However, the biological role of the antennal olfactory sensilla remains unknown, and no bioassay showing the use of olfaction in Odonata has been performed thus far. Here, we demonstrate through behavioural assays that adults of *Ischnura elegans* are attracted by olfactory cues emitted by prey; furthermore, using electrophysiological single-cell recordings, we prove that the antennal olfactory sensilla of *I. elegans* respond to prey odour. Our results clearly demonstrate the involvement of antennal olfactory sensilla in Odonata predation, thus showing, for the first time, the use of olfaction in Odonata biology. This finding indicates that the nervous system of Odonata is able to receive and process olfactory information, suggesting that the simple organisation of the antennal lobe does not prevent the use of olfaction in insects." 13892. Popova, O.N.; Haritonov, A.Yu (2014): Mass reproductive wanderings of dragonflies of the genus *Sympetrum* (Odonata, Libellulidae). *Entomological Review* 94(1): 21-28. (in English) ["The results of observing mass flights of some dragonflies of the genus *Sympetrum* forming tandems are presented. These tandems always fly against the wind, some of them landing for oviposition and then joining the flight again. This variant of migration behaviour has been unexplained until now. A hypothesis is proposed according to which synchronous mass flights of dragonfly tandems facilitate the most uniform oviposition in all the suitable biotopes. The general direction of the flight depends on the wind. As the wind direction changes, the flight course of the tandems changes accordingly, so that the dragonflies cross the same territory several times, which leads to a denser and more uniform distribution of eggs. It is proposed to refer to this variant of flight as reproductive wanderings. Such a dispersal strategy can maintain the most uniform population density and a more stable abundance of some dragonfly species in the territories with unstable humidity." (2014): Morphological and geographical traits of the British Odonata. *Biodiversity Data Journal* 2: e1041: 12 pp. (in English) ["Trait data are fundamental for many aspects of ecological research, particularly for modeling species response to environmental change. We synthesised information from the literature (mainly field guides) and direct measurements from museum specimens, providing a comprehensive dataset of 26 attributes, covering the 43 resident species of Odonata in Britain. Traits included in this database range from morphological traits (e.g. body length) to attributes based on the distribution of the species (e.g. climatic restriction). We measured 11 morphometric traits from five adult males and five adult females per species. Using digital callipers, these measurements were taken from dry museum specimens, all of which were wild caught individuals. Repeated measures were also taken to estimate measurement error. The trait data are stored in an online repository (<https://github.com/BiologicalRecordsCentre/Odonatatraits>), alongside R code designed to give an overview of the morphometric data, and to combine the morphometric data to the single value per trait per species data." 13894. Rada, B.; Šantic, M. (2014): Community structure of aquatic insects in the karstic Jadro River in Croatia. *Journal of Insect Science*: Vol. 14 | Article 54 : 10 pp. (in English) ["This study focused on the aquatic insect community in the longitudinal gradient and temporal scales of the Jadro River. The river was sampled for a period of ten years (2000– 2010), four times per year through the various seasons, along the river course. Sampling stations were selected in the upper, middle, and downstream parts of the river. A total of 21,852 specimens of aquatic insects belonging to six orders were obtained. The species determination confirmed 27 different species in the river. The data were analyzed by the multivariate methodologies of correspondence analysis and cluster analysis (unweighted pair group method with arithmetic mean) using the similarity index of Morosita for all ten years. Canonical correspondence analysis was applied to the data to check which of the measured physicochemical variables significantly explained community variation. According to those data, significant variables for the upper station were water temperature and dissolved oxygen, and chlorides was the significant variable for the lower stations." 13896. Reboredo-Fernández, A.; Prado-Merini, O.; García-Bernadal, T.; Gómez-Couso, H.; Ares-Mazás, E. (2014): Benthic macroinvertebrate communities as aquatic bioindicators of contamination by *Giardia* and *Cryptosporidium*. *Parasitology Research* 113(5): 1625-1628. (in English) ["Benthic macroinvertebrates (community composed mostly by aquatic forms of insects, such as stonefly nymphs, dragonfly nymphs, water bugs or beetle larvae) are often used in biological monitoring programmes to evaluate the ecological status of rivers and thus to indicate the repercussions of anthropogenic activities. The aim of the present study was to evaluate the use of this indicator community to detect human enteroprotzoan parasites that are transmitted via water. In total, 32 samples of macroinvertebrates were collected, with the aid of surber nets of mesh size 500 µm, from nine rivers in Galicia (NW Spain), on different occasions between 2005 and 2009. The samples were homogenised (0.04 M phosphate buffered saline, pH 7.2), sieved (150 and 45 µm mesh), and concentrated (by a diphasic method). Aliquots of the sediments were then analysed by a direct immunofluorescence technique with monoclonal antibodies against *Giardia* and *Cryptosporidium*. *Giardia* cysts were detected in one (3.1 %) of the samples and *Cryptosporidium* oocysts were detected in four (12.5 %) of the samples. This work is the first study carried out to investigate the presence of *Giardia* and *Cryptosporidium* in this benthic community. The results demonstrate that benthic invertebrates could be used as bioindicators of contamination by these waterborne protozoans. Moreover, as this aquatic organisms act as intermittent accumulators and its monitoring enables chronological analysis of perturbations, in both the short- and mid-term, this may represent a suitable alternative or complementary method to the usual techniques of detecting human and animal enteropathogens in water samples." 13897. Renner, S.; Perico, E.; Sahlen, G. (2014): Dragonflies (Odonata) in Subtropical Atlantic Forest frag-

ments in Rio Grande do Sul, Brazil. *Scientia Plena* 9(1): 1-8. (in English, with Spanish summary) ["One of the most endangered ecosystems in America is the Atlantic Forest, which demands emergency actions to protect its remnants as well its biodiversity. In this situation the species inventory can develop a management role for the future, determining specific areas that should be preserved as well the species composition and richness can be used as an indicator of a healthy ecosystem. The use of dragonfly species composition has proven its potential indication of quality habitats. The Odonata species actually still poorly known in the Neotropical region and has never been used as a tool to analyze the actual conditions of aquatic environments particularly in the Subtropical Atlantic Forest, which occurs in south of Brazil. A systematic survey was carried out in aquatic systems located at remnants of forest from March 2011 to February 2012. A total of 565 specimens belonging to 34 species, distributed in 5 families were sampled. Libellulidae was dominant, with 14 species, followed by Coenagrionidae, Gomphidae, Lestidae and Aeshnidae. Through inventory survey we deepen the Odonata composition knowledge and performed a statistic analysis." 13899. Roberts, D. (2014): Mosquito larvae change their feeding behavior in response to kairomones from some predators. *Journal of Medical Entomology* 51(2): 368-374. (in English) ["The efficacy of using predators for the biological control of mosquito disease vectors will be reduced if mosquito larvae respond to predator presence. The larvae of two mosquito species were investigated to study whether they responded to predator kairomones by increasing surface filter-feeding, which is a less active and thus less risky feeding strategy than bottom feeding. *Culex quinquefasciatus* Say is normally found in highly polluted water, where it will have little contact with predators. Except for some third instars, its larvae showed no response to four different types of predators. *Culiseta longiareolata* Macquart, living in rain-filled rock pools, is frequently attacked by a range of predators. All instars tested (second, third, and fourth

instars) strongly responded to chemicals from dragonfly nymphs (*Crocothemis erythraea*), damselfly nymphs (*Ischnura evansi*), and the fish *Aphanius dispar* Ruppel. However, they did not respond to final-instar water scorpions (*Nepa cinerea* L.), which would not feed on the mosquito larvae. Second- and third-instar *Cs. longiareolata* produced the same response to chopped up mosquito larvae as they did to dragonfly nymphs, but fourth instars produced a significantly stronger response to dragonfly nymphs—both those unfed and those fed in situ. Thus, *Cs. longiareolata* not only identified different predators and responded accordingly, but also responded to conspecific alarm pheromones. *Cx quinquefasciatus* showed little response to predators or to alarm pheromones from damaged conspecific larvae." 13900. Rotvit, L.; Jacobsen, D. (2014): Egg development of Plecoptera, Ephemeroptera and Odonata along latitudinal gradients. *Ecological Entomology* 39: 177-185. (in English) [(1) Interest in the effect of temperature on ecophysiological processes is growing. Using published data, a meta-analysis was carried out on the influence of temperature on duration of egg development of the aquatic insect orders Plecoptera, Ephemeroptera and Odonata in relation to latitudinal compensation. The aim was to test the hypotheses on thermal adaptation and countergradient variation. (2) The orders showed considerable differences in the response to temperatures along latitudinal gradients. Duration of egg development in Ephemeroptera and Plecoptera was negatively related to latitude at 15, 20 and 25 °C, and 5, 15, and 20 °C, respectively. This is interpreted as compensation for short summer seasons at high latitudes, a result that is in line with the countergradient variation hypothesis. (3) In contrast, the results for Odonata supported neither the thermal adaptation nor the countergradient variation hypothesis. Odonate eggs from higher latitudes developed more slowly than those from lower latitudes at 20 and 25 °C. It is likely that the high-latitude odonates have more time for eggs to develop, despite the shorter season, because the potential time constraint that lies in producing more generations per year at lower latitudes may override the effect of seasonal constraints at higher latitudes.] Address: Jacobsen, D., Freshwater Biological Laboratory, Dept of Biology, Univ- of Copenhagen, Universitetsparken 4, 2100 Copenhagen, Denmark. 13901. Schriever, T.A.; Cadotte, M.W.; Williams, D.D. (2014): How hydroperiod and species richness affect the balance of resource flows across aquatic-terrestrial habitats. *Aquatic Science* 76(1): 131-143. (in English) [Queen's Biological Station north of Kingston, Ontario, Canada (44.565977 N, -76.324223 W). "Ecosystem functioning is influenced by the flow of nutrients, detri-

tus, and organisms. Variation in these flows, like that found in temporary ecosystems, affects temporal and spatial patterns of community diversity and secondary production. We evaluated the influence of hydroperiod and ecosystem size on the bi-directional flow of subsidies from intermittent ponds and surrounding forests by quantifying litter deposition and the abundance and biomass of emerging insects and amphibians. In addition, we assessed whether amphibian and insect diversity influenced the magnitude of cross-habitat resource flux. We found substantial spatial and temporal variation in the magnitude, composition, and timing of cross-habitat resource subsidies. Overall, deposition into ponds far exceeded biomass exported via insect and amphibian emergence. We found a negative association between resource flux and the diversity of amphibians and insects. Different species groups contributed to flux patterns unequally, with insects having higher diversity but lower flux compared to amphibians. Organismal flux varied among ponds with amphibians having the highest flux in the shortest hydroperiod pond and insect flux was highest from an intermediate hydroperiod pond. This work reveals how variation in pond size and permanence affects species diversity and ecosystem flows. Species composition played a major role in flux differences across ponds. Further, given the general lack of research and conservation prioritization of temporary ponds, uncovering how these ponds contribute to cross-habitat linkages is necessary to develop fully integrated management strategies." Of the resulting 35 species, six species were new for the country, the record of *Cordulegaster vanbrinkae*

being the third locality in the world." (Authors)] Address: Snegovaya, Nataly, Zoological Institute NAS of Azerbaijan, proezd 1128, kvartal 504, Baku, AZ 1073, Azerbaijan. E-mail: snegovaya@yahoo.com

13904. Śniegula, S.; Drobniak, S.M.; Gołab, M.J.; Johansson, F. (2014): Photoperiod and variation in life history traits in core and peripheral. *Ecological Entomology* 39: 137-148. (in English) ["(1) In order to predict evolutionary responses to environmental changes one needs to identify the evolutionary potential in terms of genetic variation of traits and of the traits' plasticity. We studied genetic variance in life history traits and their reaction norms in response to manipulated photoperiods in central, northern, and northernmost peripheral populations of *L. sponsa*. After the central-marginal hypothesis, it is predicted that central populations will express the highest genetic variance. (2) Northern and northernmost populations showed the highest development and growth rates. All populations expressed shorter development and accelerated growth when raised in a northern compared with a central latitude photoperiod. The slopes of reaction norms differed between regions resulting in a region-by-photoperiod interaction. (3) There was genetic variation in development time; however, it did not differ across regions. There was no genetic variation in growth rate or in the plasticity of development time and growth rate to photoperiod. (4) Results did not support the central-marginal hypothesis. However, evidence was found that the development time has the potential to evolve at similar rates across study regions. In contrast, the growth rate seems to be genetically constrained for further evolution, probably because of a strong past directional selection on this trait. The presence of low genetic variation in the slope of the reaction norms could be a result of stabilising selection imposed by seasonality." 13907. Suhonen, J.; Korkeamäki, E.; Salmela, J.; Kuitunen, M. (2014): Risk of local extinction of Odonata freshwater habitat generalists and specialists. *Conservation Biology* 28(3): 783-789. (in English) ["Understanding the risk of a local extinction in a single population relative to the habitat requirements of a species is important in both theoretical and applied ecology. Local extinction risk depends on several factors, such as habitat requirements, range size of species, and habitat quality. We studied the local extinctions among 31 dragonfly and damselfly species from 1930 to 1975 and from 1995 to 2003 in Central Finland. We tested whether habitat specialists had a higher local extinction rate than generalist species. Approximately 30% of the local dragonfly and damselfly populations were extirpated during the 2 study periods. The size of the geographical range of the species was negatively related to extinction rate of the local populations. In contrast to our prediction, the specialist species had lower local extinction rates than the generalist species, probably because generalist species occurred in both low- and high-quality habitat. Our results are consistent with source-sink theory." (Authors)] Address: Suhonen, J., Section of Ecology, Department of Biology, University of Turku, FI-20014, Turku, Finland. E-mail juksuh@utu.fi

13908. Sushko, G.G. (2014): The zoogeographic composition of the insect fauna (Odonata, Coleoptera, Macrolepidoptera) in the raised bogs of the Belarusian Lakeland. *Entomological Review* 94(1): 40-48. (in English) ["The zoogeographic composition of insects in the raised bogs of the Belarusian Lakeland was investigated. The boundaries of this region coincide with those of the last glaciation and the distribution of raised bogs on the East European Plain. By the example of three model groups (Odonata, Coleoptera, and Macrolepidoptera) it was found that the insect fauna complexes in the bogs of the Belarusian Lakeland had a typical boreal pattern with prevalence of species with Euro-Siberian ranges, and also included large fractions of species

with Circumboreal and Circum-Arctoboreal ranges. The environmental conditions of bogs in the temperate zone of Europe facilitate the southward expansion of many cold-adapted species." 13909. Swaegers, J.; Mergeay, J.; Therry, L.; Bonte, D.; Larmuseau, M.H.D.; Stoks, R. (2014): Unravelling the effects of contemporary and historical range expansion on the distribution of genetic diversity in the damselfly *Coenagrion scitulum*. *Journal of evolutionary biology* 27(4): 748-759. (in English) ["Although genetic diversity provides the basic substrate for evolution, there are a limited number of studies that assess the impact of recent climate change on intraspecific genetic variation. This study aims to unravel the degree to which historical and contemporary factors shape genetic diversity and structure across a large part of the range of the range-expanding *C. scitulum*. A total of 525 individuals from 31 populations were genotyped at nine microsatellites, and a subset was sequenced at two mitochondrial genes. We inferred the importance of geography, environmental factors, and recent range expansion on genetic diversity and structure. Genetic diversity decreased going westwards, suggesting a signature of historical post-glacial expansion from east to west and the presence of eastern refugia. Although genetic differentiation decreased going northwards, it increased in the northern edge populations, suggesting a role of contemporary range expansion on the genetic make-up of populations. The phylogeographical context was proven to be essential in understanding and identifying the genetic signatures of local contemporary processes. Within this framework, our results highlight that recent range expansion of a good disperser can decrease genetic diversity and increase genetic differentiation which should be considered when devising suitable conservation strategies." 13910. Tabugo, S.R.M.; Torres, M.A.J.; Gorospe, J.G.; Amparado, R.F.; Demayo, C.G. (2014): Integrative approach in describing *Neurothemis* species using correlation analysis based on distances. *European Journal of Zoological Research* 3(1): 19-31. (in English) ["Describing species variation and delineation are fundamental to biology and much debate exists surrounding on what applied approach is appropriate. Species delineation now used separate elaborate datasets to quantify independently and test species criteria. However, the complexity of the speciation process has ushered the need to infuse studies with new tools and techniques capable of aiding in species delineation. Herewith, an integrative

approach using Correlation Analysis based on Distances was used to circumvent the traditional morphological analysis and provide a novel means of describing closely related complex species (sibling species) diversity using the genus *Neurothemis* as a case study. Correlation Analysis based on distances proved to be useful by looking into the relative contribution of each trait considered to species/group divergence and distinctiveness. Results demonstrate noted differences between female and male morphs. On one hand, females exhibited female-limited polymorphism which was suggested to have possibly evolved throughout sexual selection. On the other hand, polymorphism being limited to males mostly plays a role in male-male competition for access to females. Differences were attributed mainly by external morphological wing characters such as the fore-wing triangle, hind wing triangle, the radial planate, fore-wing subtriangle, number of anal loop 'sole cells', hind wing supertriangle, number of cross veins in the cubital space of the hind wing (behind the median space), wing pigmentation, shape of synthorax, shape of epiproct and shape of left and right cerci. Here, the utilization of a number of characters for species delineation proved to be effective in understanding variation and the nature of the *Neurothemis* species found in Iligan City." 13911. Takahashi, Y.; Nagata, N.; Kawata, M. (2014): Antagonistic selection factors induce a continuous population divergence in a polymorphism. *Heredity* 112(4): 391-398. (in English) ["Understanding the relative importance of selection and stochastic factors in population divergence of adaptive traits is a classical topic in evolutionary biology. However, it is difficult to separate these factors and detect the effects of selection when two or more contrasting selective factors are simultaneously acting on a single locus. In *I. senegalensis*, females exhibit colour dimorphism and morph frequencies change geographically. We here evaluated the role of selection and stochastic factors in population divergence of morph frequencies by comparing the divergences in colour locus and neutral loci. Comparisons between population pairwise F_{ST} for neutral loci and for the colour locus did not detect any stochastic factors affecting colour locus. Although comparison between population divergence in colour and neutral loci using all populations detected only divergent selection, we detected two antagonistic selective factors acting on the colour locus, that is, balancing and divergent selection, when considering geographical distance between populations. Our results suggest that a combination of two antagonistic selective factors, rather than stochastic factors, establishes the geographic cline in morph frequency in this system." 13912. Therry, L.; Lefevre, E.; Bonte, D.; Stoks, R. (2014): Increased activity and growth rate in the non-dispersive aquatic larval stage of a damselfly at an expanding range edge. *Freshwater Biology*: 1266-1277. (in English) ["While evolutionary changes in adult traits during range expansion have been recorded in many species, similar changes in the non-dispersive larval stage have only rarely been documented. Increased activity in the non-dispersive larval stage is an important ecologically relevant trait in aquatic communities that may be expected to evolve in the edge populations (i) as a result of the combination of spatial sorting in dispersal-related adult activity and a coupling between adult and larval behaviour and (ii) to meet higher energy demands to allow higher growth rates and a higher investment in costly dispersal-related traits. We specifically address whether activity is higher in the larval non-dispersive aquatic stage at an expanding range front by comparing larvae of replicated core and edge populations of the *Coenagrion scitulum* in three common garden experiments where larvae were reared from the egg stage. As expected, activity in the non-dispersive larval stage was consistently higher in the edge populations. Although changes in larval activity probably have consequences for ecological interactions, the higher activity was not associated with increased predation rates by dragonfly larvae, potentially because of associated compensatory changes in other antipredator mechanisms. We documented one of the few cases of a positive coupling of activity in the larval and adult stages. Yet, contrary to larval activity, adult activity did not differ between core and edge populations. This indicates that the higher larval activity we documented is not shaped by a coupling with adult activity. Instead, our results are consistent with the hypothesis that a higher energy need in edge populations shaped the higher larval activity. Edge larvae showed a higher growth rate which is expected to evolve at the initial low population densities in newly founded edge populations. Moreover, higher growth rate showed the expected positive covariation with larval activity. Increases in activity in the non-dispersive stage in edge populations at an expansion front should be included in the ongoing debate whether evolutionary changes at invasion fronts are driven by adaptive versus non-adaptive evolution. Moreover, they may have the potential to affect ecological interactions at expanding range fronts" (Authors).] Address: Therry, L., Laboratory of Aquatic Ecology, Evolution and Conservation, K.U. sect species are asymmetry in right and left shape. However, the function of such asymmetric male genitalia is still unclear. We found that the male genitalia of *Calopteryx cornelia* are morphologically symmetric just after emergence but asymmetric after reproductive maturation. Males remove rival sperm stored in the female bursa copulatrix (single spherical sac) and the following spermatheca (Y-shaped tubular sac) prior to their own ejaculation to prevent sperm competition. Males possess the aedeagus with a recurved head to remove bursal sperm and a pair of spiny lateral processes to remove spermathecal sperm. The right lateral process is less developed than the left, and sperm stored in the right spermathecal tube are rarely removed. Experiments involving surgical cutting of each lateral process demonstrated that only the left process functions in spermathecal sperm removal. Thus, males of *C. cornelia* are left-handed in their sperm removal behaviour at copulation." (2014): Diet of two invading gobiid species (*Proterorhinus semilunaris* and *Neogobius melanostomus*) during the breeding and hatching season: No field evidence of extensive predation on fish eggs and fry. *Limnologica - Ecology and Management of Inland Waters* 46: 31-36. (in English) ["One of the potential impacts of invasive gobies on native fish fauna is predation on eggs and fry. Therefore, the diet composition of two invading gobiid species, the tubenose goby *Proterorhinus semilunaris* and round goby *Neogobius melanostomus*, was examined in the Dyje river system (Danube basin, Central Europe, near Breclav, Czech Republic) during the 2011 reproductive season to ascertain the extent of gobiid predation on heterospecific and conspecific eggs and juveniles. Consumption of fish eggs and juveniles by invading gobies was very low. The diets of both species consisted largely of benthic macroinvertebrates, and particularly insect larvae. These results indicate that invading gobies in the Dyje river system are likely

to impact native fish fauna more through competitive effects than through direct predation on eggs and juveniles." (Authors) Odonata larvae are given as prey item of gobiid species. No quantitative estimates on the preyed larvae were provided] Address: Vašek, M., Institute of Vertebrate Biology, Academy of Sciences of the Czech Republic, v.v.i., Na Sádkách 7, 370 05 České Budějovice, Czech Republic. 13917. Wang, L.; Zhong, Z. (2014): Dynamics of the dragonfly wings raised by blood circulation. *Acta Mechanica* 225(4-5): 1471-1485. (in English) ["We investigate how the blood flow in the veins in the flapping wings of a dragonfly affects their dynamic response. An idealized model of an elastic tube conveying fluid and rotating around a fixed axis is adopted in this study, based on which governing partial differential equations of motion are obtained by invoking the extended Hamilton's principle. Separation of variables techniques and assumed modes method are employed to solve the resulting equations, and the stabilization analysis is performed to assess the stability of the system. In particular, the coupling effects of tube rotation, deformation, and the movement of the fluid inside are evaluated under different flow rates and rotation speeds. This demonstrates that if the blood in the dragonfly wings flows from humeral angle distally to the wing apex, a stabilization effect can be obtained, and the higher the blood flow rate is, the faster the system will be stabilized. Contrary cases are also studied for further validation of the model." 13918. Warren, R.W.; Hall, D.B.; Greger, P.D. (2014): Radionuclides in bats using a contaminated pond on the Nevada National Security Site, USA. *Journal of Environmental Radioactivity* 129: 86-93. (in English) [Nevada, USA; "Highlights: •Bats uptake radionuclides from a contaminated pond. •Tritium had highest concentrations but ¹³⁷Cs gave highest dose. •Tritium concentra-

tions in bats are approximately one-twentieth of that in the pond. •Population level effects are not expected based on RESRAD-Biota dose estimates. • It may be more appropriate to model the bats as riparian animals in RESRAD-Biota. Perched groundwater percolating through radionuclide contamination in the E Tunnel Complex on the Nevada National Security Site, formerly the Nevada Test Site, emerges and is stored in a series of ponds making it available to wildlife, including bats. Since many bat species using the ponds are considered sensitive or protected/regulated and little information is available on dose to bats from radioactive water sources, bats were sampled to determine if the dose they were receiving exceeded the United States Department of Energy dose limit of 1.0E-3 Gy/day. Radionuclide concentrations in water, sediment, and flying insects were also measured as input parameters to the dose rate model and to examine trophic level relationships. The RESRAD-Biota model was used to calculate dose rates to bats using different screening levels. Efficacy of RESRAD-Biota and suggested improvements are discussed. Dose to bats foraging and drinking at these ponds is well below the dose limit set to protect terrestrial biota populations." (Authors) Seven insect orders were sampled at or near a pond where bats were supposed to hunt for insects. Odonata were represented and obviously contaminated with anthropogen created radionuclides. However, there was not a direct evidence for bats preying on dragonflies, but only the assumption that Odonata may count to the diet of bats. Contamination of the aggregate "flying insects" with ¹³⁷Cs, ^{239/240}Pu, and ²⁴¹Am is documented in table 5: "it is plausible that the insects are the dominant source of americium in bats. Early life stages of certain sampled insects (e.g. of the orders Odonata, Diptera, and Neuroptera) are aquatic with potential to have a high amount of contact with pond sediment. The level of contact with sediment has been shown to be an important factor determining the relative concentrations of actinides in aquatic and emergent insects."] Address: Warren, R.W., National Security Technologies, LLC, 2621 Losee Rd., North Las Vegas, NV 89030-4129, USA. No. PD57, File No. FSC14/01: 5 pp. (in English) ["The Fisheries Scientific Committee, established under Part 7A of the Fisheries Management Act 1994 (the Act), is proposing to list *Austropetalia tonyana* - the Alpine Redspot Dragonfly, as a VULNERABLE SPECIES in

Part 1 of Schedule 5 of the Act. The listing of Vulnerable Species is provided for by Part 7A, Division 2 of the Act." (Author)] Address: Williamson, Jane, NSW Dept of Primary Industries – PO Box 1305 CROWS NEST NSW 1585, Australia. Email: fsc@dpi.nsw.gov.au

13922. Worthen, W.B.; Phillips, C.C. (2014): Are community patterns in flight height driven by antagonistic interactions? *International Journal of Odonatology* 17(1): 7-16. (in English) ["Large libellulid dragonflies often fly higher than smaller libellulids. We hypothesized that this size-related pattern in flight height might be caused by aggressive displacement. We tested this hypothesis by using a 30 m "dragonfly zip-line" to reel dead dragonfly decoys of four species of different sizes (*Erythemis simplicicollis*, *Libellula incesta*, *Pachydiplax longipennis*, and *Perithemis tenera*) along a shoreline at four different heights (20, 60, 100, and 140 cm), counting the number of investigations made by large patrolling *Libellula incesta* and *Libellula luctuosa* males. We hypothesized that decoys of smaller species would be investigated and attacked at higher frequency when they were reeled high, in the *Libellula* flight zone, than when they were reeled at their natural low height. This hypothesis was falsified; both *L. incesta* and *L. luctuosa* investigated high-flying decoys significantly less frequently than low-flying decoys. *Perithemis tenera* decoys were investigated less frequently than other decoys by both species, but *L. incesta* investigated *E. simplicicollis*, *P. longipennis*, and *L. luctuosa* decoys with increasing frequency whereas *L. luctuosa* investigated these three species at equal rates. These patterns correlate with the degree of morphological similarity between patrolling species and decoys, consistent with likely patterns of "mistaken identity" by patrolling *L. incesta* and *L. luctuosa* males. We suggest that patrolling males may preferentially investigate other low-flying males in the hopes of finding a mate-guarded female." 13925. Yue, X.D.; Miao, D.Q.; Cao, L.B.; Wu, Q.; Chen, Y.F. (2014): An efficient color quantization based on generic roughness measure. *Pattern Recognition* 47(4): 1777-1789. (in English) ["Author-Highlights: • Propose an efficient two-stage color quantization framework. • Applies the quantization in a precisely compressed colour space. • Propose the generic roughness measure for precise colour space compression. • Propose the algorithms of roughness thresholding and weighted Rough K-means. • Experimental results validate the high efficiency of the proposed method. Colour quantization is a process to compress image colour space while minimizing visual distortion. The quantization based on preclustering has low computational complexity but cannot guarantee quantization precision. The quantization based on postclustering can produce high quality quantization results. However, it has to traverse image pixels iteratively and suffers heavy computational burden. Its computational complexity was not reduced although the revised versions have improved the precision. In the work of colour quantization, balancing quantization quality and quantization complexity is always a challenging point. In this paper, a two-stage quantization framework is proposed to achieve this balance. In the first stage, high-resolution colour space is initially compressed to a condensed colour space by thresholding roughness indexes. Instead of linear compression, we propose generic roughness measure to generate the delicate segmentation of image colour. In this way, it causes less distortion to image. In the second stage, the initially compressed colours are further clustered to a palette using Weighted Rough K-means to obtain final quantization results. Our objective is to design a post-clustering quantization strategy at colour space level rather than pixel level. Applying the quantization in the precisely compressed colour space, the computational cost is greatly reduced; meanwhile, the quantization quality is maintained. The substantial experimental results validate the high efficiency of the proposed quantization method, which produces high quality colour quantization while possessing low computational complexity." (2014): Global warming favours light-coloured insects in Europe. *Nature Communications* 5:3874 | DOI: 10.1038/ncomms4874 | www.nature.com/naturecommunications: 9 pp, Suppl. (in English) ["Associations between biological traits of animals and climate are well documented by physiological and local-scale studies. However, whether an ecophysiological phenomenon can affect large-scale biogeographical patterns of insects is largely unknown. Insects absorb energy from the sun to become mobile, and their colouration varies depending on the prevailing climate where they live. Here we show, using data of 473 European butterfly and dragonfly species, that dark-coloured insect species are favoured in cooler climates and light-coloured species in warmer climates. By comparing distribution maps of dragonflies from 1988 and 2006, we provide support for a mechanistic link between climate, functional traits and species that affects geographical distributions even at continental scales. Our results constitute a foundation for better forecasting the effect of climate change on many insect groups." 13928. Pither, J. (1997): Responses in the habitat occupancy, movement behaviour, and wing morphology of two species of calopterygid damselflies to landscape structure. M.Sc. thesis, Acadia University, Wolfville: 177 pp. (in English) ["I examine the responses of *Calopteryx maculata* and *Calopteryx aequabilis*, to differences in landscape structure. I performed surveys to determine patterns of stream occupancy in relation to habitat characteristics measured at small spatial scales, and the medium-scale characteristic of distance to forest. I show that the relative importance of these habitat characteristics differs among species and between survey years. The changes over time are consistent with weather patterns. I then examine the relative abilities of these two species to move through forest and pasture landscapes. Previous work had suggested that *C. maculata* uses forest as a resource more consistently than *C. aequabilis*. Results from manipulative experiments show that the connectivity of pasture landscapes is higher than forest landscapes for *C. maculata*. There was no detectable difference in connectivities for *C. aequabilis*. These results have implications regarding the relative propensities of individuals to disperse within the structurally different landscapes. I examine the wing morphologies of *C. maculata* and *C. aequabilis* individuals collected from landscapes of differing structure. I show that the fore and hindwings of *C. maculata* individuals are consistent in their asymmetric distributions (left - right) across landscapes. The forewings of *C. aequabilis* individuals inhabiting a highly fragmented landscape exhibited a significantly higher degree of asymmetry, and were significantly shorter overall, than those inhabiting a moderately fragmented landscape. Forewings of female *C. maculata* individuals collected from high connectivity (pasture) landscapes were slightly longer than those from low connectivity (forest) landscapes." 13935. Slotton, D.G.; Ayers, S.M.; Suchanek, T.H.; Weyand, R.D. Liston, A.M. (2004): Mercury bioaccumulation and trophic transfer in the Cache Creek Watershed of California, in relation to diverse aqueous mercury exposure conditions. A component (Component 5B) of the multi-institution Directed Action research project: Assessment of Ecological and Human Health Impacts of Mercury in the San Francisco Bay-Delta Watershed. A CALFED Bay-Delta Program Project. October 1999 – September 2003. Final Report: January 25, 2004: 74 pp. (in English) [USA; "Water and biota were sampled throughout the Cache Creek watershed during a 20 month period between January 2000 and August 2001. A range of mercury (Hg) exposure conditions were investigated in relation to several mining and natural Hg point sources in the watershed. The study was conducted to provide foundational information and baseline monitoring data for future point source remediation efforts and TMDL regulation. Seasonal aqueous sampling was conducted in conjunction with Hg loading studies. Mercury was characterized in adult game fishes and native fishes throughout the watershed. Bioaccumulation of methylmercury

(MeHg) in several taxa of aquatic insect and small fish bioindicators was compared to diverse aqueous Hg exposure conditions and to corresponding fillet muscle Hg in the larger fishes. The Turkey Run/Abbott complex of Hg mines and the Sulfur Creek complex of Hg mines and geothermal springs were confirmed to be dominant point sources of elevated total Hg (THg), MeHg, and MeHg bioaccumulation in the watershed. In the main stem of Cache Creek, fish Hg increased by over 100% downstream of inflows from the primary remedial targets. Fish Hg reached concentrations to over 6.00 ppm in portions of the watershed. Aqueous Hg parameters varied spatially by over three orders of magnitude between control sites and tributaries near point sources. Seasonal order of magnitude shifts were seen, greater for raw THg. Partly due to the large range of concentrations, general correlations were found between the different aqueous Hg parameters. On a same-site basis, strongest correlations were found between raw and filtered fractions of both THg and MeHg and between TSS and THg. While aqueous MeHg was broadly associated with general spatial patterns in aqueous THg (re loading), variable processes of methylation were indicated to play an important role in some MeHg concentrations. On a whole watershed basis, including all individual paired seasonal samplings, aqueous raw and filtered THg and MeHg all showed substantial apparent correlations with aquatic insect and small fish MeHg bioaccumulation. However, the system-wide apparent correlations were found to be driven largely by clusters of high Hg vs low Hg site data. On an individual site basis, most of the apparent correlations broke down, with recent, seasonally averaged aqueous raw MeHg concentration remaining as by far the best predictor of aquatic insect and small fish MeHg. However, the form of the relationship with raw aqueous MeHg, as well as aqueous: biotic bioaccumulation factors (BAFs), varied between main stem and tributary sites. Study results strongly support the development of site-specific relationships for any predictive applications. Aqueous, invertebrate, and small fish MeHg were found to be seasonally dynamic, with different patterns at different sets of sites. This complicated linkages to large fish MeHg, which required the temporal pooling, by site, of aqueous and lower trophic data. Among similar sites, pooled data provided general linkages directly between unfiltered aqueous MeHg and large fish muscle Hg. Wider-ranging linkages were exhibited between MeHg in bioindicator organisms and large fish muscle. Results of this study indicate that the most useful environmental samples for regulatory and remediation monitoring for Hg include unfiltered aqueous MeHg and short-lived, relatively easily obtainable, low trophic level biota, in addition to larger fish of human health concern." (Authors) The analysis includes at family level Calopterygidae, Coenagrionidae, Gomphidae, and Libellulidae. 13943. Donnelly, N. (2006): Still looking for warthogs. *Argia* 18(1): 23-25. (in English) [Extensive report on an odonatological trip in early 2006 to South Africa.] Address: Donnelly, T., 2091 Partridge Lane, Binghamton, NY 13903, USA. E-mail: tdonnel@binghamton.edu

13944. Donnelly, N. (2006): Another note on *Stylurus scudderii* oviposition. *Argia* 18(3): 19. (in English) [Nature Reserve La Verendrye, N Ottawa, Canada, 1992; "... *Stylurus scudderii* males were patrolling the stream in their characteristic deliberate manner. I suddenly saw a female (my first!) patrolling near the edge. It was the fattest-bodied gomphid that I think I have ever seen. Think of a flying cigarette, black with bright yellow markings. I followed the female as she flew into a culvert about 50 feet away. I ran up to the road and crossed it to watch the female appear on the other side. Except she did not appear. Baffled, I went back to see if she made a U-turn and headed out the entrance. I still didn't see her. Then I saw her. She was ovipositing near the mid-point of the culvert and continued to do so for a minute or so. The culvert was about 5 feet in diameter (I should have measured it) and the water was about 6 inches deep. I wonder how many dragonflies oviposit in culverts?" (Author)] Address: Donnelly, T., 2091 Partridge Lane, Binghamton, NY 13903, USA. E-mail: tdonnel@binghamton.edu

13945. Godwin, J.; Krotzer, S. (2006): "Cave dragonfly" found in Alabama. *Argia* 18(3): 20. (in English) [ISA. Verbatim: On 19 August 2006, while exiting the Keel Sinks entrance to the Tony Sinks cave system located within the Sharp-Bingham Mountain Preserve in Jackson County in extreme northeastern Alabama, one of us (JG) encountered a dragonfly perched on a wall of the entrance pit to the cave system. The phenomenon of odonates utilizing caves as roosts, ostensibly as thermal refugia, has been reported in the literature (for example see Corbet, 1999), but it is apparently a fairly rarely documented event. ... The dragonfly was discovered at about 1600 h, perched on the wall of the pit ca. 5 m below the lip, on the cooler portion of the pit wall, well below the thermocline. Light conditions at the time were subdued but far from approaching darkness. Lethargic and easily captured by hand, the specimen was sent to SK, who identified it as a female *Somatochlora tenebrosa*. This largely crepuscular species would seem to be a likely candidate

to seek out a thermal refuge during the long, hot days of an Alabama summer!] Address: Krotzer, S., 2238 Haysop Church Road, Centreville, AL 35042, USA. E-mail: rskrotze@southernco.com

13948. Honcu, M.; Roztocil, O. (2006): Important species of dragonflies (Odonata) in the region of česká Lípa (Northern Bohemia, Czech Republic) in 2003-2005. *Vážky 2005: sborník referátu VIII. celostátního semináře odonatologu ve Žďárských vrších : seminár usporádaly ve dnech 23.-26.6.2005 Správa CHKO Žďárské vrchy, ZO CSOP Vlašim a Vlastivedné muzeum a galerie v České Lípe / editor sborníku Lubomír Hanel. -- Vyd. 1. -- Vlašim: ZO CSOP Vlašim, 2006. ISBN 80-86327-52-3: 49-63. (in Czech, with English summary) ["Faunistic records of dragonflies made during the excursions of the VIII. allstate meeting of odonatologists in June 2005 in the Žďárské vrchy – hills. In the course of several field trips detected in the visited five faunistic squares No. 6261, 6360, 6361, 6362, 6461 a collection of 26 species of dragonflies, a number which represents about 32,5 % of all the dragonfly species known in the whole Czech Republic. Common species prevail, noteworthy is the detection of following species: *Leucorrhinia pectoralis*, listed in "Natura", found in two places, *Somatochlora arctica*, *Orthetrum albistylum*, *Cordulegaster boltonii*, *Leucorrhinia rubicunda*, *Leucorrhinia dubia*, *Coenagrion hastulatum* a *Lestes dryas*. The date of the meeting was chosen to facilitate the finding of representants of the family *Leucorrhinia* and also of the family *Aeshna* but, unfortunately, the representants of this second family did not appear. In addition to the excursions organised in the course of the meeting Mr. Hesoun detected one exuvium of *Symptetrum fonscolombii* at the borders of the faunistic squares No. 6260 and 6261; the correctness of the determination had been approved by Dr. A. Dolný. The list of detected species is as follows: *Calopteryx virgo*, *Lestes viridis*, *L. sponsa*, *L. dryas*, *Platycnemis pennipes*, *Pyrrhosoma nymphula*, *Erythromma najas*, *Coenagrion hastulatum*, *C. puella*, *Enallagma cyathigerum*, *Ischnura elegans*, *Anax imperator*, *Cordulegaster boltonii*, *Cordulia aenea*, *Soma-**

tochlora metallica, *S. arctica*, *Libellula quadrimaculata*, *L. depressa*, *Orthetrum cancellatum*, *O. albistylum*, *Symptetrum vulgatum*, *S. flaveolum*, *S. danae*, *Leucorrhinia dubia*, *L. rubicunda*, and *L. pectoralis*." 13958. Mitra, A.; Phuntsho, P. (2006): A report on the Odonata diversity of Bumdeling Wildlife Sanctuary, Trashigang, Eastern Bhutan. Ministry of Agriculture, Thimphu: 58 pp. (in English) ["Conclusion: The present study reflects the rich entomological diversity of the conservation areas in Bhutan in respect of Odonata. With the nine new records during the present study, 40 species and subspecies of dragonflies are known from Bhutan till date (see checklist). Two of them have been found new to world.. It's a clear indication for the government to start with this type of projects in the field of invertebrates that constitute the lion's share of the living species on earth, With the on going trends of modernization, it's time now for Bhutan to know its actual strength of biodiversity, 10 explore, and to document it for making effective plans to conserve them in situ, before it is too late to start. Nature Conservation Division, should as early as possible set up a museum to preserve the type specimens produced from this kind of studies. However, as far as the Odonata fauna of Bhutan is concerned, the study remains fairly incomplete as the middle and west Bhutan are still unexplored." (Authors) Regrettably, the "grey paper" also includes the detailed descriptions of two new damselfly taxa: *Anisopleura bella* Mitra & Phuntsho 2006 and *Acia-grion olympicum bumdelingsis* Mitra & Phuntsho 2006. It is questionable if these descriptions formally can be accepted as they are not made in any publication available to any taxonomist.] Address: Mitra, A., Department of Zoology, Sherubtse College, KANGLUNG, Bhutan. 13969. Headon, C.M.; Hall, R.J. (2007): A multivariate analysis of factors affecting mercury availability in dragonfly nymphs (Order: Odonata) inhabiting wetland ecosystems. <https://ia601509.us.archive.org/5/items/AMultivariateAnalysisOfFactorsAffectingMercuryAvailabilityInDragonfly/MercuryInDragonflyNymphs.pdf>; 42 pp. (in English) ["Fifteen wetlands were examined to determine the influence of sediment and water chemical parameters on mercury bioavailability in dragonfly nymphs (Order: Odonata; suborder: Anisoptera; Genus: *Cordulia*). Wetland types included mineral poor fens, circumneutral minerotrophic fens and marshes. Mercury concentrations in dragonfly nymphs ranged from 0.041 to 0.402 ug.g-1 dry mass and were significantly ($p < 0.001$) different among the 15 wetlands. Multivariate statistical procedures showed that sediment total sulfur (S) concentration explained the greatest amount of the among wetland variation in Hg concentrations in anisopteran nymphs. With increasing concentrations of total S in the sediments there was a decrease in nymph Hg concentrations. Surface water chemistry appeared not to have a direct effect on Hg bioavailability." 13973. Misof, B.; Niehuis, O.; Bischoff, I.; Rickert, A.; Erpenbeck, D.; Staniczek, A. (2007): Towards an 18S phylogeny of hexapods: Accounting for group-specific character covariance in optimized mixed nucleotide/doublet models. *Zoology* 110: 409-429. (in English) ["The phylogenetic diversification of Hexapoda is still not fully understood. Morphological and molecular analyses have resulted in partly contradicting hypotheses. In molecular analyses, 18S sequences are the most frequently employed, but it appears that 18S sequences do not contain enough phylogenetic signals to resolve basal relationships of hexapod lineages. Until recently, character interdependence in these data has never been treated seriously, though possibly accounting for the occurrence of biased results. However, software packages are readily available which can incorporate information on character interdependence within a Bayesian approach. Accounting for character covariation derived from a hexapod consensus secondary structure model and applying mixed DNA/RNA substitution models, our Bayesian analysis of 321 hexapod sequences yielded a partly robust tree that depicts many hexapod relationships congruent with morphological considerations. It appears that the application of mixed DNA/RNA models removes many of the anomalies seen in previous studies. We focus on basal hexapod relationships for which unambiguous results are missing. In particular, the strong support for a "Chiasmomyaria" clade (Ephemeroptera+Neoptera) obtained in Kjer's [2004. Aligned 18S and insect phylogeny. *Syst. Biol.* 53, 1-9] study of 18S sequences could not be confirmed by our analysis. The hexapod tree can be rooted

with monophyletic Entognatha but not with a clade Ellipura (Collembola+Protura). Compared to previously published contributions, accounting for character interdependence in analyses of rRNA data presents an improvement of phylogenetic resolution. We suggest that an integration of explicit clade-specific rRNA structural refinements is not only possible but an important step in the optimization of substitution models dealing with rRNA data." (Authors) The list of species studied includes 42 Odonata species/samples.] Address: Misof, B., Abt. Ent., Zool. Forschungsmus. A. Koenig, Adenauerallee 160, 53113 Bonn, Germany. 13985. Parkko, P.; Metsälä, P. (2008): Täplälampikorennon *Leucorrhinia pectoralis* esiintyminen Kymenlaaksoissa [Occurrence of *Leucorrhinia pectoralis* in Kymenlaakso, SE Finland.]. *Crenata* 1: 30-33. (in Finnish) [Up to 2000 only 20 sites for *L. pectoralis* were known in Kymenlaakso province in south-east Finland. By the end of 2007 already 40 sites were known. The increase is partly due to increased observing activity, but undoubtedly this species is also invading new sites in Kymenlaakso. [Note by abstractor: The same is true also elsewhere in southern Finland]. (Asmus Schröter)] Address: Parkko, P., Hirveläntie 49, FI-45910 Voikkaa, Finland

13986. Abu Hassan, A.; Dieng, H.; Satho, T.; Boots, M.; Al Sariy, J.S.L. (2010): Breeding patterns of the JE vector *Culex gelidus* and its insect predators in rice cultivation areas of northern peninsular Malaysia. *Tropical Biomedicine* 27(3): 404-416. (in English) ["Japanese encephalitis (JE) virus activity is an important cause of viral encephalitis in Southeast Asia. In Malaysia, JEV activity has been first detected in *Culex gelidus* in 1976. Since then, no study has fully addressed the seasonal dynamics of this mosquito. As irrigated rice production expands, the incidence of JEV vectors, particularly *Cx. gelidus* is expected to increase. We surveyed Penang Island to determine the breeding patterns of *Cx. gelidus* and their potential insect predators, in relation to habitat/niche and rice growing period. Six rice fields proper (RFP) and related drainage canals (DC) were visited through three cultivation cycles (CCs) over 17 months. Weekly visits were performed to each of the 36 sites and mosquito larvae and aquatic insects were sampled from RFP and DCs using dippers. *Culex gelidus* was abundant in RFP and almost absent in DCs. Its densities usually were high during the first and 3rd CC and when the RFs were in Fp, Pp and Gp. In DCs, the mosquito was abundant during Mp, e.g., 2nd CC. Predators, especially those belonging to the families Corixidae, Coenagrionidae and Dytiscidae, were more present in RFP. Predator numbers usually were high during the first CC; in some cases predator abundance peaked during other CCs, e.g., corixids and dytiscids. In RFP, neither corixids nor coenagrionids showed any positive correlation with densities of *Cx. gelidus*. However, dytiscids' population peaked when the mosquito densities were on the rise. These observations suggest that *Cx. gelidus* is active during the period of rice cultivation. Operational vector control through bio-control or with insecticides near the end of the rice cultivation season in RFP may prove beneficial in reducing the density of *Cx. gelidus*, but also the amount of bio-agent or insecticide applied on riceland." (Authors)] Address: Abu Hassan, A., School of Biological Sciences, Universiti Sains Malaysia, Penang, Malöaysia. E-mail: aahassan@usm.my

13987. Girgin, S.; Kazancy, N.; Dügel, M. (2010): Relationship between aquatic insects and heavy metals in an urban stream using multivariate techniques. *Int. J. Environ. Sci. Tech.* 7(4): 653-664. (in English) ["In the study, the relationship between some aquatic insect species (Ephemeroptera, Plecoptera, Trichoptera and Odonata) and some heavy metals (cadmium, lead, copper, zinc, nickel, iron and manganese) and boron were assessed using data obtained from the Ankara Stream, which flows through Ankara, the capital city of Turkey and receives high organic and industrial wastes. Sampling was carried out monthly along the Ankara Stream in 1991. Environmental data were used to explain biological variation using multivariate techniques provided by the program canonical correspondence analysis ordination. The ordination method canonical correspondence analysis was ap-

plied to evaluate the relationships between environmental variables and distribution of aquatic insect larvae. Data sets were classified by two way indicator species analysis. In this study, aquatic insecta communities have been shown by canonical correspondence analysis ordination as related to total hardness, pH, cadmium, lead, copper, zinc, nickel, iron, manganese and boron. Cadmium, lead, copper and boron exceeded limits of the United States Environmental Protection Agency criteria for aquatic life. Trichopteran, *Dinarthrum iranicum* was an indicator of two way indicator species analysis and was placed close to the arrow representing copper. Odonate, *Aeshna juncea* was an indicator of two way indicator species analysis in site 10 and was placed close to the arrows representing manganese, lead, and nickel. Trichopteran, *Cheumatopsyche lepida* and odonate, *Platycnemis pennipes* were indicators of two way indicator species analysis for sites 6, 7, 11, 14, 15, 18 and were placed close to the arrows representing cadmium, boron, iron and total hardness." (Author) As *A. juncea* is no stream-dwelling species, the identification of this species and some more from the taxa list in table 2 is questionable. (Martin Schorr)] Address: Girgin, S., Biology Department, Gazi Education Faculty, Gazi University, Teknikokullar, Ankara, Turkey. Email: sonmez.girgin@gmail.com

13988. Grand, D. (2010): *Zygonyx torridus* (Kirby, 1889) sur le rio Cabriel, provinces de Albacete, Cuenca et Valencia (Espagne): distribution et observations biologiques (Odonata, Anisoptera, Libellulidae). *Martinia* 36 (3/4): 78-90. (in French, with English summary) ["Some investigations were conducted from the end of May to the end of September between 2006 and 2010, on a section of 122 km along the rio Cabriel (provinces of Albacete, Cuenca and Valencia). Recently evaluated as « Vulnerable » in Europe, *Z. torridus* is an Afrotropical species with a discontinuous distribution area around the Mediterraneans. Big larval and adult populations are encountered along rio Cabriel. This paper deals with some aspects of its poorly known biology such as emergences, behaviour, distribution and sex-ratio." 13989. Ishizawa, N. (2010): Effect of the environmental conditions at rice paddies on the emergence and the oviposition in *Sympetrum frequens* (Selys). *New Entomol.* 59(3/4): 48-52. (in Japanese, with English summary) ["It was cleared that emergence from the rice paddies was affected by the temperature of the water. The number of emergence from the rice paddy at the north side, of which water temperature was higher than that at the south side and being shone by the sun earliest in the morning, counted 232 and outnumbered that of the south (76) and the emergence was skewed to the paddy that was shone earlier by the sun in the morning (the difference was significant, $p < 0.001$). After rice-planting the number of emergence at the rice plant was more than that at other plants near the ridge of rice paddies. The average height of emergence was ca. 8 cm, and that at rice plant was just a little higher than that at other plants

near the ridge, however, the difference was not significant. Also, in the reproductive season the temperatures of the standing water at rice paddies were inclined to be higher at the north side than at the south side, and the number of oviposition pairs was 61, significantly more than that at the south ($p < 0.001$). Oviposition tended to be skewed to the early sunlit rice paddies in the morning. *S. frequens* has a propensity to prefer sunlit paddies at the seasons of emergence and reproduction." 13990. Wesner, J.S. (2010): Seasonal variation in the trophic structure of a spatial prey subsidy linking aquatic and terrestrial food webs: adult aquatic insects. *Oikos* 119: 170-178. (in English) ["Research over the past decade has established spatial resource subsidies as important determinants of food web dynamics. However, most empirical studies have considered the role of subsidies only in terms of magnitude, ignoring an important property of subsidies that may affect their impact in recipient food webs: the trophic structure of the subsidy relative to in situ resources. This may be especially important when subsidies are composed of organisms, as opposed to nutrient subsidies, because the trophic position of subsidy organisms may differ from in situ prey. I explored the relative magnitude and trophic structure of a cross-habitat prey subsidy, adult aquatic insects (including Odonata), in terrestrial habitats along three streams in the south central United States. Overall, adult aquatic insects contributed more than one-third of potential insect prey abundance and biomass to the terrestrial habitat. This contribution peaked along a permanent spring stream, reaching as high as 94% of abundance and 86% of biomass in winter. Trophic structure of adult aquatic and terrestrial insects differed. Nearly all adult aquatic insects were non-consumers as adults, whereas all but one taxon of terrestrial insects were consumers. Such a difference created a strong relationship between the relative contribution of the prey subsidy and the trophic structure of the prey assemblage: as the proportion of adult aquatic insects increased, the proportion of consumers in the prey assemblage declined. Specific effects varied seasonally and with distance from the stream as the taxonomic composition of the subsidy changed, but general patterns were consistent. These findings show that adult aquatic insect subsidies to riparian food webs not only elevate prey availability, but also alter the trophic structure of the entire winged insect prey assemblage." 13991. Brix, K.V.; DeForest, D.K.; Adams, W.J. (2011): The sensitivity of aquatic insects to divalent metals: A comparative analysis of laboratory and field data. *Science of the Total Environment* 409: 4187-4197. (in English) ["Laboratory studies have traditionally indicated that aquatic insects are relatively insensitive to metals while field studies have suggested them to be among the most sensitive aquatic invertebrate taxa. We reviewed and synthesized available studies in the literature to critically assess why this discrepancy exists. Despite the intense effort to study the effects of metals on aquatic biota over the past several decades, we found studies specific to insects to still be relatively limited. In general, the discrepancy between laboratory and field studies continues with few efforts having been made to elucidate the ecological and physiological mechanisms that underlie the relative sensitivity (or insensitivity) of aquatic insects to metals. However, given the limited data available, it appears that aquatic insects are indeed relatively insensitive to acute metal exposures. In contrast, we suggest that some aquatic insect taxa may be quite sensitive to chronic metal exposure and in some cases may not be protected by existing water quality criteria for metals. The discrepancy between laboratory and field studies with respect to chronic sensitivity appears to largely be driven by the relatively short exposure periods in laboratory studies as compared to field studies. It also appears that, in some cases, the sensitivity of aquatic insects in field studies may be the result of direct effects on primary producers, which lead to indirect effects via the food chain on aquatic insects. Finally, available evidence suggests that diet is an important source of metal accumulation in insects, but to date there have been no conclusive studies evaluating whether dietary metal accumulation causes toxicity. There is a clear need for developing a more mechanistic understanding of aquatic insect sensitivity to metals in long-term laboratory and field studies." (Authors) The review includes references to Odonata.] Address: Brix, K.V. c/o EcoTox 575 Crandon Blvd., #703 Key Biscayne, Florida 33149, USA. E-mail: kbrix@rsmas.miami.edu

14000. Naraoka, H. (2011): Diurnal changes of the copulation duration and the ovipositing female number of *Ischnura asiatica* Brauer (Odonata: Coenagrionidae). *Journal of the natural history of Aomori* 16: 1-4. (in Japanese) ["The copulation duration and the oviposition hour were studied in natural population of *I. asiatica* at Aomori-ken northern Japan. The copulation was observed between ca. 5:00h and 16:00h. The total duration of copulation was $192m38s \pm 74m35s$ ($n=59$) in mean and divided into three stages (I: $188m34s \pm 70m41s$, II: $1m35s \pm 39s$, III: $16m05s \pm 4m28s$, $n=47$). The oviposition was observed between ca. 11:00h and 16:30h with a peak from 12:30h to 16:00h. The copulation duration was negatively correlated ($P < 0.001$) with the time of day, stage I being shorter towards the end of the day. The shortening of copulation duration before the oviposition hour is thought as "copulation guarding". But, the shortening after the onset of oviposition may be based on the number of mature eggs of the female and the remaining oviposition hour in the day at the time of copulation." 14001. Nyheim, M.T. (2011): Biotilgjengelighet og opptak av antimon, kadmium, kobolt og sink i øyenstikkernymfer (Odonata, Anisoptera) som funksjon av økende veisaltkonsentrasjoner - et tracereksperiment. MSc. thesis, Norwegian University of Life Sciences: 73 pp, XII . (in Norwegian, with English summary) ["Because of the long winters in Norway, the amount of road salt needed to keep the roads ice-free is high. A large part of this road salt ends up in ponds close to the roads. High concentration of salt may increase the mobilization of heavy metals in sediments and effect biota living in the ponds. This thesis investigates how road salt in the aqueous phase affects the mobility of Co, Cd, Sb and Zn in sediment and how this affects the accumulation of these metals in nymphs of Odonata. This was done using ^{60}Co , ^{109}Cd , ^{125}Sb and ^{65}Zn and tracer technique in a laboratory experiment. Nymphs of dragonflies (Anisoptera) was exposed to moderate contaminated sediment and water with different salt concentrations (0, 500, 5000 og 10 000 mg NaCl/L). Sequential extraction was used on the sediments to investigate the mobility and bindings of the metals. For ^{60}Co og ^{109}Cd a positive correlation was identified between the salt concentration and activity in the aqueous phase, and between the salt concentration and the fractions that is assumed to be bioavailable in sequential extraction. ^{125}Sb seemed to be tightly bound to the sediment and were not mobilized by road salt in the aqueous phase. Due to low activity of ^{65}Zn in the sediment it was hard to draw any conclusions for this metal. The nymphs accumulated ^{109}Cd , ^{60}Co and

125Sb, while 65Zn showed none accumulation. Based on values of the bioaccumulation factor (BAF), the ranking of the accumulation of the different metals appeared to be as follows: 60Co > 109Cd ~ 125Sb > 65Zn. An increase in salt concentration in the aqueous phase did not lead to an increase in the accumulation of 60Co and 109Cd in the nymphs, rather the opposite trend was observed for these metals. This was not true for 125Sb which had the lowest accumulation in the control group with no added road salt. For 65Zn the activity in the aqueous phase and in the nymphs was so low that it was hard to draw any conclusions from the results. Autoradiography and measurements of nymphs that changed their exo-skeleton showed that the accumulation of either 60Co or 109Cd, or both of these metals, was in both internal organs and tissues and exo-skeleton." (Author)] Address: Nyheim, Mari

14002. Revenga, J.E.; Campbell, L.M.; Kyser, K.; Klassen, K.; Arribère, M.A.; Ribeiro Guevara, S. (2011): Trophodynamics and distribution of silver in a Patagonia Mountain lake. *Chemosphere* 83: 265-270. (in English) ["Silver (Ag) ions are among the most toxic metallic ions to aquatic biota. In southern Argentina, fish from Patagonian lakes have liver Ag concentrations [Ag] among the highest ever reported globally. Silver concentration in phytoplankton from Lake Moreno ($1.82 \pm 3.00 \mu\text{g g}^{-1}$ dry weight, DW) was found to be significantly higher than [Ag] in zooplankton ($0.25 \pm 0.13 \mu\text{g g}^{-1}$). Values in snails and decapods ($0.60 \pm 0.28 \mu\text{g g}^{-1}$ and $0.47 \pm 0.03 \mu\text{g g}^{-1}$ respectively), were higher than in insect larvae ($0.28 \pm 0.39 \mu\text{g g}^{-1}$ for Trichoptera). We examined trophic transfer of Ag in the biota using stable nitrogen and carbon isotopes ratios ($\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ respectively). Silver concentrations in the biota of Lake Moreno were not associated with any particular C source, as assessed by $\delta^{13}\text{C}$. Hepatic [Ag] significantly increased with trophic position, as measured by $\delta^{15}\text{N}$, within the brook trout sample set. Biodilution of Ag was observed between primary producers and small forage fish when whole body [Ag] was analyzed. Nevertheless, when considering whole food web biomagnification and hepatic [Ag] of top predator fish, a significant positive regression was found between [Ag] and trophic position, as measured by $\delta^{15}\text{N}$. The importance of species-specific and tissue-specific considerations to obtain more information on Ag trophodynamics than that usually presented in the literature is shown. To the best of our knowledge, this is the first study in assessing Ag trophodynamics and tissue-specific biomagnification in a whole freshwater food web." (Authors) Only two specimens "Odonata" were analysed containing 0,03 and 0,1 $\mu\text{g g}^{-1}$ Ag concentrations.] Address: Revenga, J.E., Centro Regional Universitario Bariloche (CRUB), Universidad Nacional del Comahue, Quintral 1250, 8400 Bariloche, Argentina. 14006. Andrew, R.J.; Verma, P.; Thaokar, N. (2012): Seasonal variation and mite infestation in the anisopteran dragonflies of Gorewada lake of Nagpur City, India.

Vidyabharati International Interdisciplinary Research Journal 1(1): 1-10. (in English) ["A field study throughout the year (2010-2011) was undertaken at Gorewada lake of Nagpur city (which supplies water to the city) to study the seasonal activity pattern of anisopteran dragonflies. Although a total of 33 anisopterans were detected, we could study the following three parameters- flight period, reproductive behaviour, breeding habitats and mite parasitism of twenty species. The result indicates a distinct variation in the breeding site and flight period of the species observed. Such variation in the choice of breeding habitat allows the species to avoid competitive pressure for breeding and larval microhabitats. Only six species (*Acisoma panorpoides*, *Brachythemis contaminata*, *Crocothemis servilia*, *Diplacodes trivialis*, *Neurothemis t. tulia* and *Trithemis pallidinervis*) were found to be parasitized with mite *Arrenurus* spp. mostly on the ventral region of the thorax and abdomen." (Authors)] Address: Andrew, R.J., Post Graduate Dept of Zoology, Hislop College, Nagpur (M.S.), India

14007. Bates, L.M. (2012): Investigating the bioaccumulation of methylmercury in invertebrates from Saskatchewan prairie pothole wetlands. Ph thesis. The University of Regina, Canada, 3737 Wascana Parkway, Regina, SK S4S 0A2: 113 pp-["Deposition of atmospheric mercury (Hg(II)) to remote areas is an environmental health concern. Mercury is transferred to aquatic habitats from the atmosphere through fallout and precipitation and from surrounding land surfaces in runoff. Once present in a wetland, Hg(II) can be converted by microbial activity to methylmercury (MeHg), which is a harmful neurotoxin that bioaccumulates in foodwebs. Wetlands are important sites of methylation and MeHg concentrations in the water of prairie wetland habitats can be elevated compared to other systems. Within these habitats, invertebrates are an important food resource for many waterfowl species and may act as an indicator for the level of contamination within higher trophic levels. In 2007 and 2008, invertebrates were collected from wetlands on three land use types: agricultural lands, grasslands and organic agricultural lands. Organisms were identified to order (Gastropoda, Corixidae, Odonata, and Dytiscidae / Notonectidae) and categorized into functional feeding groups (FFGs; scraper, omnivore or predator). Samples were analyzed for total Hg, MeHg and stable isotopes of nitrogen ($\delta^{15}N$) and compared among invertebrate taxa and land use types. MeHg concentrations generally increased with trophic level. Gastropoda were significantly lower in MeHg concentrations than the other taxa. The $\delta^{15}N$ values did not correlate well with MeHg levels seen in invertebrate taxa, but did confirm invertebrate trophic levels. In general, MeHg concentrations were higher in invertebrate taxa from organic ponds than those from grassland ponds and lowest in invertebrates from ponds on traditional agricultural lands. Differences in MeHg concentrations with land use effects were apparent for all invertebrate groups collected, with significant differences observed in Corixidae. Changes in MeHg

concentrations in invertebrates in response to land management practices may be used to identify wetland habitats that may favour Hg methylation and may allow for prediction of contamination levels in biota of the prairie pothole region." (Author)] Address: Bates, Lara Michelle

14009. Craves, J.A. (2012): A preliminary list of the Odonata of Wayne Co.. *Michigan Birds and Natural History* 9(1): 7-16. (in English) ["Wayne Co. is located in southeastern Michigan at ~ lat 42°15'N, long 83°20'W. It covers 622 sq mi (1611 km). Encompassing Detroit and its immediate suburbs, it is heavily urbanized. There are 3 large rivers in county. The Rouge River drains into the Detroit River, which itself forms the eastern boundary of the county. The Huron River drains into Lake Erie near the mouth of the Detroit River. Unfortunately, 84% of historic wetlands in the county have been lost (Wooley 1998), and less than 3% of the original coastal wetlands remain along the Detroit River (Manny et al. 1988). This Odonata list is compiled from the Michigan Odonata Survey (MOS) database at the University of Michigan Museum of Zoology (UMMZ), a literature search, and my own records obtained during summer 2001. The list contains 75 species; 29 Zygoptera (damselflies) and 46 Anisoptera (dragonflies). Specimens are required by the MOS for official placement on the state or a county list. Of the 75 listed species, 19 are represented only by literature or sight records. I've noted these unvouchered species, and they can be considered "unofficial" until a voucher is received by MOS. If my record was the first for Wayne Co. (18 species), it will be noted as a new county record. For 5 of these new records, I did not obtain a voucher specimen. Two published records are not included. *Gompheshna furcillata* (Hagen) was reported by Hagen (1875). With the only confirmed records in the state from the Upper Peninsula and northern Lower Peninsula, this record is probably in error. *Arigomphus submedianus* (Williamson) was reported by Hagen (1885) as *G. submedianus* (*pallidus*). This is the only record for the state and considered questionable (O'Brien 1998). Following the main list are 48 species that have been found in 1 or more of the neighbouring counties which might be expected in Wayne Co. Approximate flight dates for adults have been provided. Depending on the number of specimen records, dates given are for southeast Michigan (Wayne, Monroe, Washtenaw, Oakland, and/or Macomb counties), statewide (Michigan data from O'Brien 2001), or from Ohio (OOS 2000). I provide dates from my own records from Wayne Co. if they represent dates outside others given. The flight date ranges are approximate.

Bear in mind that dragonfly collections are still limited, and many collectors focus their field work in mid-summer; early and late dates for some species are probably not accurately represented. The Ohio Odonata Survey web site (OOS 2000) provides excellent graphs, useful for seeing not only date ranges, but also peak flight dates of adults in that state." 14011. Feulner, G. (2012): Cross Dressing Damsels. *Gazelle* 27(12): 4-5. (in English) ["The landscaped grounds at Emirates Towers have never been a hotbed of biodiversity. The mostly exotic landscape plants and the active grounds crew see to that. But the pond on the Sheikh Zayed Road side supports a population of dozens of Evans' Bluetail damselfly *Ischnura evansi* (*Cyperus alternifolius*, the umbrella sedge), especially at the southern end. When I visited in mid-November, the population had a somewhat peculiar look. In the first place, many of the damsels present were rather pale or had slightly odd colours instead of the customary pale green eyes and thorax. This was probably because they were recently molted from the larval stage, consistent with the large number of small exuviae (the shed larval skins) found on the lower stems of the sedges; I collected some for reference. But in addition, almost all of the individuals had a pale blue band near the end of the abdomen (the "tail"). This is normally characteristic of males, but closer inspection showed that many of these blue-banded individuals were in fact females, and some of them could be found copulating with blue-banded males. Within the genus *Ischnura* (Bluetails), females of many species are known to have several different colour morphs. One of those is a so-called 'androchrome' morph, which mimics male colouration, including the blue band. In *I. evansi* this is apparently not infrequent. The androchrome morph was previously encountered in *I. evansi* at Ruwayyah, among more conventional females (see 'Damsel in Disguise' in the March 2011 *Gazelle*). More recently I found an androchrome female at a 'wild' site, in a small population at a well-vegetated waterfall pool along the mountain front near Juweif, in northern Oman. But why it should predominate in the Emirates Towers population is unknown. In more than an hour of observation I saw only a single drab female and a single orange one – normally

two of the more common colour morphs. The androchrome females also seemed to adopt male-like behaviour by perching in prominent places at the pool for extended periods, even when they were not feeding or ovipositing." (Author)] Address: Feulner, G.R., P.O. Box 31045, Dubai, United Arab Emirates. E-mail: grfeulner@gmail.com

14012. Fröhlich, A.; Hauswirth, L.; Joest, R. (2012): Natur aus zweiter Hand - Steinbruch Lohner Klei. 14013. Kelliher, J.S. (2012): The distribution of heavy metals in known and potential Hine's emerald dragonfly (*Somatochlora hineana*) habitat near the Viburnum Trend mining district of southeast Missouri, USA. U.S. Department of the Interior, Fish and Wildlife Service, Southeast Missouri Lead Mining District, Natural Resource Damage Assessment and Restoration: 22 pp. (in English) ["The Viburnum Trend mining district in southeast Missouri, USA is one of the largest producers of lead in the world. Previous biological surveys in the district have found evidence demonstrating metal exposure of birds, insects, fish and crayfish. This study examined heavy metal concentrations in the sediment and water of freshwater wetlands known to be or potentially occupied by the federally endangered *S. hineana*. Sediment samples were collected from thirteen sites to assess the potential exposure of the dragonfly to mining-derived metals. Water samples were also collected at the sampling sites when sufficient surface water was available for collection. Concentrations of metals (lead, zinc, cadmium, nickel, et al) were analyzed in the surface water and sediment. Mean concentrations of lead in sediments were significantly greater ($P < 0.01$) at sites potentially impacted by mining compared to reference sites. Sediment concentrations of lead exceeded consensus-based threshold effects concentrations at eight of ten sites potentially impacted by mining. Concentrations of dissolved metals in surface water samples did not exceed Aquatic Life Criteria established by the State of Missouri. These findings suggest that metals associated with mining activities in the Viburnum Trend may have the potential to negatively impact Hine's Emerald Dragonfly populations in and around the district." (Author)] Address: Kelliher, J.S. c/o U.S. Department of the Interior, Fish and Wildlife Service, Southeast Missouri Lead Mining District, Natural Resource Damage Assessment and Restoration, 5600 American Blvd. West, Suite 990, Bloomington, MN 55437-1458, USA

14014. King, S.; Flint, O.S. (2012): *Sympetrum ambiguum* (Odonata: Libellulidae) to be removed from the Minnesota list of Odonata. *Argia* 24(1): 2-3. (in English) [R.P. Currie had corrected the identification to a female *Sym-*

petrum obtrusum.] Address: Flint, O.S., Dept of Ent. MRC-169, National Museum of Natural History, Washington, DC, 20013-7012, USA. E-mail: flinto@si.edu

14017. Leivas, P.T.; Leivas, F.W.T.; Moura, M.O. (2012): Diet and trophic niche of *Lithobates catesbeianus* (Amphibia: Anura). *Zoologia* 29(5): 405-412. (in English) ["*L. catesbeianus* is an invasive anuran introduced in Brazil that is associated with the displacement and the decline of populations of native species worldwide. There is evidence that biological invasions are facilitated by certain attributes of the invading species, for instance niche breadth, and that invasive species have a broader ecological niche with respect to native ones. We designed a study to ascertain the temporal, ontogenetic, and sex differences in the niche dynamics of the American bullfrog. We sampled monthly from June 2008 to May 2009 in the state of Paraná, southern Brazil. For each individual, we gathered biometric and stomach content data. We then estimated the niche breadth of the juveniles and adults, and compared it between the sexes. A total of 104 females and 77 males were sampled. *L. catesbeianus* has a generalist diet, preying upon invertebrates and vertebrates. Even though the diet of the studied population varied seasonally, it did not differ between the sexes nor did it respond to biometric variables. Niche breadth was more restricted in the winter than in the autumn. The trophic niche of juveniles and adults did not overlap much when compared with the trophic niche overlap between males and females. Adult males and females had a considerable niche overlap, but females had a broader trophic niche than males in the winter and in the spring. These niche characteristics point to an opportunistic predation strategy that may have facilitated the process of invasion and establishment of this species in the study area." (Authors) 131 of the 181 stomachs include insects, of which 24 contained Odonata. Obviously, in most cases this must be imagoes while only in one case larvae were involved.] Address: Leivas, P.T., Programa de Pós-Graduação em Ecologia e Conservação, Universidade Federal do Paraná. 14018. Mitra, A.; Choden, K.; Dorji, Y.; Penjor, T.; Dorji, R.; Subedi, K.; Dorji, P. (2012): Odonata of Samdrup Choling Dungkhag in Samdrup Jongkhar, Bhutan. *Bhutan journal of research & development Autumn 2012*: 125-141. (in English) ["Several field visits were undertaken between February and June, 2012, at different Odonata habitats in and around Samdrup Choling Dungkhag under Samdrup Jongkhar Dzongkhag, mainly at Pemathang, Phuntshothang, Martshala and Dewathang. A total of 83 specimens of Odonata were collected comprising of 40 species and subspecies including 19 new records for Bhutan, thereby extending the list of Odonata known from Bhutan to 75. One of the *Coelliccia* species seemed to be new to science and will be confirmed after further study. The present study recorded four species namely, *Coelliccia svihleri*, *Protosticta himalaica*, *Rhinocypha cuneata* and *Chlorogomphus mortoni*, which were designated as 'Data Deficient' during the recent most red list assessment in eastern Himalaya carried out by IUCN. However, the study on the seasonal diversity of Odonata in Samdrup Choling Dungkhag remained incomplete being limited to only five months. 56 of the 75 species and subspecies of Odonata known from Bhutan arc recorded only from Eastern and South-eastern parts. A major portion of Bhutan remains odonatologically unexplored." (Authors)] Address: Mitra, A., Dept Zool., Sherubtse Coll., Kanglung, Bhutan. E-mail: amitodonata@yahoo.com

14019. Myrup, A.R. (2012): A survey of the Odonata fauna of Zion National Park. *Argia* 24(2): 5-10. (in English) [Utah, USA. "During the summer of 2011, 25 species of Odonata were documented from Zion National Park, belonging to seven families and 17 genera. Thirteen of these were previously unrecorded from Zion NP. This brings the Zion National Park list of Odonata to 37 species belonging to seven different families and 23 genera. ... No new additions were added to the Utah State Odonata Checklist. Although many streams in Zion NP were not surveyed, a better understanding of the distribution and habitat preferences of odonates in Taylor Creek, North Creek, Pine Creek, Weeping Rock Stream and the East Fork Virgin River was obtained from this study in Zion National Park. Several of the odonates found in Zion NP have narrow habitat requirements, and it is comforting to know that, at least here, these habitats and the precious water they contain are protected. Due to their natural state and inaccessibility, many of the streams in the Virgin River drainage (165.5 river miles) have been designated as "Wild and Scenic Rivers" by the Omnibus Public Lands Management Act of 2009." 14022. Okulewicz, A.; Sitko, J. (2012): Parasitic helminths – probable cause of death of birds. *Helminthologia* 49(4): 241-246. (in English) ["Parasitic helminths were the probable cause of death of 41 passeriform birds (29 adults and 12 juveniles in their first year of life) caught in the net during the spring and autumn ringing (1986 – 2010). The birds (1 Chaffinch *Fringilla coelebs*, 1 House Martin *Delichon urbica*, 2 Blue Tit *Cyanistes caeruleus*, 9 Great Tit *Parus major*, 3 Willow Tit *Poecile palustris*, 1 Great Reed *Acrocephalus arundinaceus*, 1 Chiffchaff *Phylloscopus collybita*, 3 Blackcap *Sylvia atricapilla*, 2 Dunnock *Prunella modularis*, 1 Magpie *Pica pica*, 5 Robin *Erithacus rubecula*, 9 Common Blackbird *Turdus merula* and 3 Song Thrush *T. philomelos*) were caught in the environs of Přešov (Czech Republic). The helminths: trematodes, tapeworms, nematodes and hook worms, were located in the intestine, glandular and muscular stomach, cloaca, rectum, gall bladder, liver, pulmonary cavity, air sac, nasal and orbital cavity and subcutaneous tissue of the hosts. The intensity of invasion with different species of parasites was up to 734 per host. Some parasites *Brachydistomum ventricosum*, *Mosesia sittae*, *Aprocta cylindrica*, *Diplotrina tridens* were acquired at the wintering grounds. All the helminths were heteroxenous, with development cycle involving intermediate hosts (invertebrates) which are part of the birds' diet. ... Trematode *Collyriclum faba* is a parasite of subcutaneous tissue of Passeriformes, its intermediate hosts are snails and water insects (Odonata, Plecoptera, Ephemeroptera, Trichoptera)."] (Authors)] Address: Okulewicz, Anna, Dept of Parasit., Inst. of Genetics & Microbiol., Wrocław Univ., Przybyszewskiego 63/77, 51-148 Wrocław, Poland, E- mail: anna.okulewicz@microb.uni.wroc.pl

14023. Pavlova, M.; Pehlivanov, L.; Kazakov, S.; Varadinova, E.; Vidinova, Y.; Tyufekchieva, V.; Uzunov, Y. (2012): Changes in the aquatic communities in the Rhodopes mountain landslide lakes (South Bulgaria) for the last 40 years. I. Taxonomic composition of macrozoobenthos, zooplankton and fish communities. *Acta zool. bulg.*, Suppl. 4: 187-195. (in English) ["The biodiversity of aquatic communities (macrozoobenthos, zooplankton and fish) in 5 of Smolyanski and 2 of Chairski landslide lakes was studied in spring and summer of 2010. A total of 19 taxa of different taxonomic level of macrozoobenthos and zooplankton were reported for the first time in the studied lakes. The enriched list included 4 new planktonic species (of Rotifera type) and 15 new macrozoobenthic taxa (4 species of Oligochaeta, 2 species of Bivalvia, one ge-

nus of Ephemeroptera, one species of Plecoptera, 4 species, 1 genera and 2 families of the Trichoptera groups). Five fish species were registered belonging to two families in the composition of the ichthyofauna of the studied lakes. The similarities in the species composition of the macrozoobenthos and zooplankton among the lakes and in comparison with previous investigations were assessed. The statistically significant differences found for the macrozoobenthos composition in comparison with the published in 1975 revealed two completely different communities. Moreover, this applied also to the zooplankton community which fundamentally differed from that found in 1975. The large number of taxa reported for the first time was probably due to the long period of time since the last studies (more than 40 years) and the changes in the ecological conditions in the lakes. A more refined examination of the ecosystem functioning could provide more comprehensive data about the processes in these lakes of high conservation value." (Authors) *Pyrrhosoma nymphula* and *Coenagrion pulchellum* are listed in table 3.] Address: Pavlova, Milena, Inst. of Biodiversity & Ecosystem Research, Bulgarian Academy of Sciences, 2 Yurii Gagarin str., 1113 Sofia, Bulgaria. E-mail: mnp.iber@gmail.com

14024. Porst, G.; Naughton, O.; Gill, L.; Johnston, P.; Irvine, K. (2012): Adaptation, phenology and disturbance of macroinvertebrates in temporary water bodies. *Hydrobiologia* 696: 47-62. (in English) ["The temporal transition of species dominance following disturbances is strongly influenced by taxon life histories. In temporary water bodies, seasonal progression can be rapid. The community response of aquatic littoral invertebrate communities to disturbance was measured across four temporary water bodies (turloughs) representing a hydroperiod gradient in the karst landscape of western Ireland. Three distinct turlough wet-phases were identified based on macroinvertebrate taxon richness and community composition: filling, aquatic and drying phase. Invertebrates able to recolonise the turlough environment quickly upon flooding from refugia (e.g. sink-holes or little puddles) or resting stages within the turlough basin demonstrated highest proportion in abundances during the initial filling phase. Over time, the number of actively dispersing invertebrates, generally occupying turloughs only for a part of their life-cycle, increased. Hydroperiod had a significant effect on macroinvertebrate taxon richness, with short hydroperiods supporting low faunal diversity. Influence of hydrological disturbance generally decreased with progression of the annual wet phase, indicated by a decrease in taxon richness variation and an increase of biodiversity with time. Our study highlights the importance of life-cycle strategies of species for the occurrence of fairly predictable and periodically occurring seasonal patterns, and emphasizes the importance of ecological disturbances for colonisation cycles." (Authors) The list of taxa includes *Lestes* sp.] Address: Porst, Gwendolin, Zool. Dept, School of Natural Sciences, Trinity College Dublin, Dublin 2, Ireland. E-mail: porst@igb-berlin.de

- 14028.** Revenga, J.E.; Campbell, L.M.; Arribére, M.A.; Ribeiro Guevara, S. (2012): Arsenic, cobalt and chromium food web biodilution in a Patagonia mountain lake. *Ecotoxicology and Environmental Safety* 81: 1-10. (in English) ["Mussels, *Diplon chilensis*, from Lake Moreno, a double-basined mountain lake in southern Argentina, is known to have elevated concentrations of chromium (Cr, >25 $\mu\text{g g}^{-1}$ dry weight DW) and arsenic (As, 35 $\mu\text{g g}^{-1}$ DW), attributed to untreated sewage. To further understand the trophodynamics of Cr, As and cobalt (Co), we investigated concentrations and transfer throughout the food web in each basin of Lake Moreno. Each basin differs in morphology in that the gently-sloping Lake Moreno West has more littoral habitat than deeper Lake Moreno East with its higher proportion of pelagic habitat. Despite the morphological differences, both basins share similar water quality parameters and species assemblages. As a result, Lake Moreno provides an exceptional opportunity to compare trophodynamics of elements that enable us to hypothesize pelagic-littoral habitat coupling in response to lake morphology as the underlying factor influencing both Cr pathway and Co and As trophodynamic modelling. Using stable isotopes of nitrogen ($\delta^{15}\text{N}$) and carbon ($\delta^{13}\text{C}$) to characterize metals trophodynamics in each basin, biodilution of As, Cr and Co were indicated by negative regressions. This is confirmed by elevated As, Co and Cr concentrations in phytoplankton (11.3 \pm 5.7, 7.4 \pm 4.9, 44.5 \pm 40.7 $\mu\text{g g}^{-1}$ DW respectively), while zooplankton and biofilm had the next elevated concentrations. Those elevated concentrations are in contrast with lower concentrations in sport fish such as rainbow trout (0.5 \pm 0.5, 0.2 \pm 0.3, 1.8 \pm 1.2 $\mu\text{g g}^{-1}$ DW). Higher concentrations of Cr in fish were associated with higher proportion of benthic/littoral prey items in western basin, and were confirmed by significant correlation with $\delta^{13}\text{C}$ values. Arsenic, Co and Cr concentrations in fish, while elevated, do not pose health risks to human or wildlife consumers. Highlights: *Biodilution of As, Cr and Co is shown in the biota of both basins of Lake Moreno. *Cr pathways differed between basins. *Different proportions of benthic/littoral preys in fish diet explained Cr pathways. *Higher trophic level in the biota from 1 basin obscured metals transfer modeling. *Lake morphology explained differences in both metal pathways and modeling." (in English) ["The only dragonfly observed during November's Dubai-Abu Dhabi desert field trip proved to be an interesting one. The two dragonfly species most commonly seen over desert sands in the UAE are the widespread *Pantala flavescens*, a strong flier that has a worldwide distribution, and *Anax ephippiger*, which in our area has an annual swarming period centered on January. Both of these species patrol relatively high above the ground and seldom perch. The dragonfly seen near Endurance Village was, however, a

female *Sympetrum fonscolombii*, a Palaearctic (northern) species, and it was perched on a clump of Desert Knot-grass (*Pennisetum divisum*). The earliest reports of this insect in the UAE and northern Oman were of scattered individuals, all seen in November, suggesting a possible seasonal phenomenon, but later reports by European visitors included spring occurrences as well. Additional local attention confirmed a major influx in November 2009, evidently a migration of sorts, reported in The National newspaper, when hundreds of these insects were reported by numerous observers across the UAE, from Abu Dhabi, Al Ain and Dubai to Kalba on the East Coast. Potential observers should note, however, that *S. fonscolombii* is just one of seven 'red' dragonflies that can all be found in the UAE. All of the others are resident and all but one are much more common – *Pantala flavescens*, *Crocothemis erythraea*, *Trithemis annulata*, *T. arteriosa*, *T. kirbyi* and *C. sanguinolenta*. In most of these species, it is only the male that is red; the female is normally a less conspicuous colour." (Authors)] Address: Feulner, G.R., P.O. Box 31045, Dubai, United Arab Emirates. 14034. Stoyanova, T.; Traykov, I.; Yaneva, I.; Bogoev, V. (2012): Accumulation of heavy metals in the macrozoobenthos of the Luda River, Bulgaria. *Biotechnology & Biotechnological Equipment* 26(3): 2981-2986. (in English) ["Heavy metals are among the most common environmental pollutants. Their long-term environmental chronic stress leads to negative impacts on the diversity and abundance of benthic invertebrates. The Luda River, a left tributary to the Struma River, flows through the north-western slopes of Pirin Mountain. An abandoned uranium mine is located in the upper parts of the water-

shed. The aim of this study was to assess the accumulation of heavy metals in the macrozoobenthos of the river. Four sites were sampled for river state assessment and from two of them additional macrozoobenthic samples were collected for heavy metal analysis in October 2011. In the lower reaches, the reduction of potential habitats, due to sand deposition, and the diversion of river waters showed stronger effect on the benthic communities than the abandoned mine. The benthic invertebrates below the mine were characterized with increased contents of Cr, Ni, Co, Zn, Cd, Pb and Cu. The results suggested that the metals accumulated in benthic organisms originate mostly from the water, whereas the accumulated Cd, Cu, Zn and Ni originate from the sediments. Supposedly, there is also biomagnification in the food web." 14036. Tamm, J. (2012): *Cordulegaster bidentata* in Hessen mit besonderer Berücksichtigung ihrer Bindung an den geologischen Untergrund (Odonata: Cordulegastriidae). *Libellula* 31(3/4): 131-154. (in German, with English summary) ["*C. bidentata* in Hesse, Germany, with emphasis on its dependence on geology (Odonata: Cordulegastriidae) – Distribution of *C. bidentata* in various areas of Hesse has been mapped from 2006 to 2011. The species has only been found on hill slopes in large mainly deciduous forests, where it is widely distributed and locally common. It is strictly bound to forest springs and their uppermost outflows. Its presence was found to be clearly correlated with the geological conditions. Palaeozoic sediments (greywacke, argillite slates) are well colonized in general. Bunter sandstone is partly colonized, partly not. Basalt areas are not colonized at all. The occurrence of the species seems to depend mainly on a sufficient quantity of sandy sediments in the springs and upper forest streams, where the larvae exclusively live. These sediments are a result of weathering of the original stone substratum and of water erosion, which al-

so means an effect of slope incline. That makes it understandable that *C. bidentata* settles well on Middle, but not on Lower and Upper Bunter sandstone. Acid water and soil conditions are suspected to exclude this odonate species mainly from larger coniferous forests. *C. bidentata* could be mapped efficiently in both larval and adult stages, but in the latter only, if mapping was exclusively concentrated on this species. It could be found quite easily not only at the springs, but also at the maturation sites, which are situated close to the springs. All these ways of finding the species allow mapping it in large areas quite quickly." (Author)] Address: Tamm, J., Elgershäuser Straße 12, D-34131 Kassel, Germany. E-mail: jochen.tamm@t-online.de

(2012): Evaluación ecológica del río Lliquino Través de macroinvertebrados acuáticos, Pastaza, Ecuador. *Revista de Ciencias (Facultad de Ciencias Naturales y Exactas Universidad del Valle)* 16: 31-45. (in Spanish, with English summary) ["Over the last 10 years, the Lliquino river, an affluent of the Pastaza river from the Ecuadorian Amazon basin, has been subjected to anthropological impacts due to colonization and mineral extraction activities. This study sought to measure this aquatic eco-system's ecological health by monitoring its waters using macroinvertebrates as bioindicators of environmental quality for five consecutive years (2008 – 2012). During this period, it was possible to determine that the river's ecological health remains in good condition, despite removal of petroleum material in the zone, which shows that apparently this activity is not as aggressive compared to extraction of minerals or heavy metals. The presence and dominance of some taxa indicators of good environmental conditions such as: Ephemeroptera (*Mayobaetis* sp., *Farodes* sp., *Leptohyphes* sp.), Trichoptera (*Smicridea* sp., *Chimarra* sp.), Plecoptera (*Anacroneria* sp.), and Megaloptera (*Corydalus* sp.). It is noteworthy that some of the taxa recorded in this study are not common in the macroinvertebrate assemble. For this reason, it is necessary to promote the creation of monitoring programs aimed at assessing the ecologic health conditions of these important populations needed to maintain the aquatic life ecosystem." (Authors) The following Odonata taxa are listed: *Limnocois*, *Macrothemis*, *Dythemis*, *Progomphus*, *Agriogomphus*, *Phyllogomphoides*, and *Acanthagrion*.] Address: Terneus, E., Universidad Internacional del Ecuador

14039. von Tschirnhaus, J.; Schulz, U. (2012): The male dimorphic damselfly *Paraphlebia zoe* (Odonata: Megapodagrionidae) in a Mexican cloud forest: site fidelity and

related behavioural aspects. *Mitteilungen der Deutschen Gesellschaft fuer Allgemeine und Angewandte Entomologie* 18: 301. (in German, with English title) ["Odonates have a wide and complex repertoire of territorial and reproductive behaviour. The males of some species even show evidence of correlated dimorphism in their morphology and behaviour. This has been proven for the Neotropical *Paraphlebia quinta* for example, and more recently for *P. zoe*, too. *P. zoe* is endemic to Mexico and occupies specialized habitats such as seepages located in mountain cloud forests. The dimorphic males of *P. zoe* are black-winged (BW) or hyaline-winged (HW). On a small stream within a cloud forest in the Mexican state of Puebla, 410 *P. zoe* adult males (BW and HW) and females were individually marked. The duration for which individuals remained at a given site was determined over a 66-day period and the dispersal distances and directions of marked males leaving the sites of initial observation were studied. Territorial behaviour of the different male phenotypes was observed during surveys. BW males were found to have high site fidelity, holding small territories for at least 66 days. HW males occupied larger areas and were present within these for shorter periods. Females were not found to have site fidelity. Site changes among BW males occurred infrequently and distances were mostly short. BW males generally perched close to the ground and behaved aggressively towards BW males and towards HW males, whereas HW males perched in higher vegetation and only behaved aggressively towards individuals of their own phenotype." 14040. Weissinger, R.H.; Perkins, D.W.; Dinger, E.C. (2012): Biodiversity, water chemistry, physical characteristics, and anthropogenic disturbance gradients of sandstone springs on the Colorado Plateau. *Western North American Naturalist* 72(3): 393-406. (in English, with Spanish summary) [USA; "Springs located on the Colorado Plateau are highly threatened and represent a small percentage of the landscape; yet they are disproportionately important to diverse native flora and fauna. The relationships between anthropogenic disturbance, aquatic macroinvertebrate species composition, and environmental variables at these springs have received little study. We selectively visited 40 sandstone springs in southeastern Utah and southwestern Colorado to span a range of impacts. We classified the springs into impact categories based on a spring impact score, and we measured biodiversity (aquatic macroinvertebrates), water chemistry (nutrients, dissolved O₂, pH, specific conductivity, temperature, turbidity, coliform bacteria [*Escherichia coli*]), physical characters (solar radiation, substrate, vegetation cover, bank stability, discharge), and presence of anthropogenic disturbance. *Escherichia coli* abundance was higher in high impact categories, and turbidity increased with increasing disturbance. No differences in total N, total P, specific conductivity, flow, dissolved O₂, pH, or substrate

were found among the impact categories. Vegetation cover was higher in low impact categories than in moderate and high impact categories, while potential annual and growing-season solar radiation was lower in low impact categories than in high impact categories. Global and subsequent multiple response permutation procedure (MRPP) comparisons suggested strong differences in aquatic macroinvertebrates between low and high impact springs and no difference at moderate impact springs. Mean taxa richness (alpha-diversity), total taxa richness (beta-diversity), and percent of taxa richness composed of shredders peaked at moderate disturbance levels. The percentage of non-insect taxa richness was reduced in high impact categories, and Odonata were higher in low impact categories than in high impact categories. All high impact springs had both livestock use and vehicle use (roads or off-highway vehicles), and our data suggest that disturbances caused by one or both of these uses alter the aquatic macroinvertebrate assemblage. We suggest that disturbance may increase macroinvertebrate richness, where a mix of tolerant and intolerant species co-occur, until macroinvertebrate richness reaches a threshold; after surpassing this threshold, macroinvertebrate diversity decreases." 14041. Wesner, J.; Billman, E.J.; Belk, M.C. (2012): Multiple predators indirectly alter community assembly across ecological boundaries. *Ecology* 93(7): 1674-1682. (in English) ["Models of habitat selection often assume that organisms choose habitats based on their intrinsic quality, regardless of the position of these habitats relative to low-quality habitats in the landscape. We created a habitat matrix in which high-quality (predator-free) aquatic habitat patches were positioned adjacent to (predator-associated) or isolated from (control) patches with single or two species of caged predators. After 16 days of colonization, larval insect abundance was reduced by 50% on average in both the predator and predator associated treatments relative to isolated controls. Effects were largely similar among predator treatments despite variation in number of predator species, predator biomass, and whether predators were native or nonnative. Importantly, the strength of effects did not depend on whether predators were physically present. These results demonstrate that predator cues can cascade with equal strength across ecological boundaries, indirectly altering community assembly via habitat selection in intrinsically high-quality habitats. ... Nonnative brown trout (*Salmo trutta*) and a native dragonfly (*Ophiogomphus severus*) were the predators in this experiment." 14042. Wiles, W.; Bolek, M.G. (2012): Damselflies (Odonata: Zygoptera) as paratenic hosts of *Serpinema* cf. *trispinosum* (Leidy, 1852) (Nematoda: Camallanidae). Pos-

ter: <http://www.matthewbolek.com/Students/Wiles%20and%20Bolek%20RMCP%202012.pdf>: (in English) ["Third-stage juveniles of the nematode *Serpinema* cf. *trispinosum* (Leidy, 1852) were collected from the mid-gut of four species of adult damselflies from Teal Ridge, a non-irrigated restored semi-permanent wetland located in Stillwater, Oklahoma. This is the first record of *Serpinema* juveniles from damselflies. *Serpinema trispinosum*, adults have been reported from 15 species of North and Central American freshwater turtles, whereas microcrustaceans such as copepods serve as intermediate hosts in this nematode's life cycle. Our review of the literature indicates that this nematode has also been reported from a single species of aquatic snail in Canada, a single species of cichlid fish from Mexico and five species of amphibians from North and South America suggesting that a wide range of invertebrates and vertebrates may serve as paratenic hosts in the life cycle of this nematode. Dietary studies of the 15 species of freshwater turtles reported as definitive hosts for *S. trispinosum* indicate that aquatic insects including damselflies are more commonly reported in turtle diet studies than are fish or amphibians. Since larval damselflies predominantly feed on microcrustaceans our discovery of *S. cf. trispinosum* in damselflies may reflect the importance of damselflies as paratenic hosts of turtle parasites in this genus." 14043. Zia, A.; Awan, Z.J.; Astori, Z.H. (2012): Boreal Odonata of Pakistan. Lambert Academic Publishing: 69 pp. (in English) ["In order to study diversity of boreal Odonata in Pakistan two separate studies were carried out during the years 1994 - 1997 & 2006 - 2008. Among these, first study carries data for whole of northern areas, however second study was conducted only in two districts of northern areas with following localities, District Gilgit (Danyore, Sultanabad) and Astor (Yougham, Boomroy, Kharbay, Pakora, Moorgulum, Gorikot). In both of these studies there is a gap of almost a decade. Results of these two independent studies are merged together to study population fluctuation in common collected species (of both studies) with respect to time. As a whole thirty one species were collected from Gilgit-Baltistan. Among these *Orthetrum sabina*, *Pantala flavescens*, *Aeshna juncea* and *Megalestes major* (recorded in both studies) were collected in large numbers in the first study but they were appeared to decrease in next one. This shows a decreasing trend in their population that might be a result of (a) Increased deforestation and urbanization resulting in destruction of their breeding places. (b) A ravaging earthquake was faced in country during the year 2005 that resulted in disappearance of many of the springs and other freshwater spots of the area. Besides this, each study added some new records for the country's Odonata fauna. It highlights the scope to explore more species from the area by undertaking hectic surveys in future. Conservation measures are also needed to conserve some endangered species of the area." 14045. Afzan Azmi, W.; Jennings, J. (2013): The impact of management practices of exotic willows (*Salix* spp.) on aquatic invertebrate communities in south Australian freshwater streams. *Journal of Sustainability Science and Management* 8(1): 43-52. (in English) ["The impact of willows, their removal and subsequent revegetation on aquatic invertebrate communities were examined in two freshwater streams in the Mount Lofty Ranges, South Australia. We hypothesized that lower abundance, species diversity and changes in functional feeding groups would occur where willows were present and have been removed. Unexpectedly, invertebrate abundance was significantly higher when willows were present in both streams. The introduced hydrobiid snail (*Potamopyrgus antipodarum*) was the most dominant taxon overall and was significantly more abundant under willows in both streams. More than half of total abundance under willows was contributed by scrapers (mostly *P. antipodarum*) as willow roots are presumed to provide a more stable habitat from high currents and have increased food availability compared with other vegetation. Where willows were removed and not revegetated, there were lower invertebrate species numbers and diversity in both streams. The removal of willows influenced not only loss of habitat, but also an increase in light intensity, decline in water quality and food availability. Our findings conclude that the presence of willows also reduces species numbers and diversity. Large scale willows removal may need special management considerations in order to reduce the impact on aquatic invertebrate communities. Similar trends in total abundance were observed in both streams for Trichoptera, Ephemeroptera and Coleoptera. However, fewer Odonata and Hemiptera were recorded in Sixth Creek than Deep Creek, but slightly more bivalves were found in Sixth Creek (1.2%) than in Deep Creek (0.8%)."] (Authors)] Address: Afzan Azmi, Wahizatul, Dept of Biol. Sciences, Faculty of Science and Technology, Universiti Malaysia Terengganu, 21030 Kuala Terengganu, Terengganu, Malaysia. E-mail: wahizatul@umt.edu.my

14046. Alvial, I.E.; Tapia, D.H.; Castro, M.J.; Duran, B.C.; Verdugo, C.A. (2013): Analysis of benthic macroinvertebrates and biotic indices to evaluate water quality in rivers impacted by mining activities in northern Chile. *Knowledge and Management of Aquatic Ecosystems*

(2012) 407, 01: 16 pp. (in English, with French summary) ["Catchments in the semiarid regions are especially susceptible to environmental perturbation associated with water scarcity, hydrological variations and overuse by anthropogenic activities. Using multivariate analysis to relate environmental and biological data, and diversity and biotic indices (ChBMWP, ChIBF), we analyzed the macroinvertebrate composition of 12 rivers of the semiarid region of northern Chile. A non-metric multidimensional scaling for macroinvertebrate taxa and a principal component analysis for environmental variables strongly separated upstream sites (e.g. Vacas Heladas and Malo Rivers), which presented low pH and high dissolved metal concentrations, from other sites. Effectively, CCA showed that metals and low pH, associated with the altitudinal gradient, determined the distributional patterns of macroinvertebrates in the Elqui catchment. The causes of these particular conditions could be related to geological processes and human impact. The biotic indices applied to the sampling sites corroborated and reflected these characteristics, with La Laguna and Turbio Rivers showing a diverse macroinvertebrate community and moderate to good water quality, and the Claro River showing favourable conditions for the development of aquatic biota, indicating its better quality relative to other stations. To the middle and low part of the basin, a change in the composition of the community was observed, with species that suggest an impact by an increase in organic matter, due to agricultural activities and urban settlements concentrated in this area. Our results suggest that macroinvertebrate taxa in northern Chile may be exceptional species, adapted to unfavourable geochemical conditions, and emphasize the need for protection of the semiarid basins of the region." (Authors) Taxa are treated at the family level. Rare Gomphidae and Aeshnidae were sampled at only one site with alkaline waters and low metal concentrations.] Address: E-mail: ingrid.alvial@ceaza.cl

14047. Andrew N.R.; Hill, S.J.; Binns, M.; Bahar, M.H.; Ridley, E.V.; Jung, M.-p.; Fyfe, C.; Yates, M.; Khusro, M. (2013): Assessing insect responses to climate change: What are we testing for? Where should we be heading? *PeerJ* 1:e11; DOI 10.7717/peerj.11: 19 pp. (in English) ["To understand how researchers are tackling globally important issues, it is crucial to identify whether current research is comprehensive enough to make substantive predictions about general responses. We examined how research on climate change affecting insects is being assessed, what factors are being tested and the localities of studies, from 1703 papers published between 1985 and August 2012. Most published research (64%) is generated from Europe and North America and being dedicated to core data analysis, with 29% of the studies analysed dedicated to Lepidoptera and 22% Diptera: which are well above their contribution to the currently identified insect species richness (estimated at 13% and 17% respectively). Research publications on Coleoptera fall well short of their proportional contribution (19% of publica-

tions but 39% of insect species identified), and to a lesser extent so do Hemiptera, and Hymenoptera. Species specific responses to changes in temperature by assessing distribution/range shifts or changes in abundance were the most commonly used methods of assessing the impact of climate change on insects. Research on insects and climate change to date is dominated by manuscripts assessing butterflies in Europe, insects of economic and/or environmental concern in forestry, agriculture, and model organisms. The research on understanding how insects will respond to a rapidly changing climate is still in its infancy, but the current trends of publications give a good basis for how we are attempting to assess insect responses. In particular, there is a crucial need for broader studies of ecological, behavioural, physiological and life history responses to be addressed across a greater range of geographic locations, particularly Asia, Africa and Australasia, and in areas of high human population growth and habitat modification. It is still too early in our understanding of taxa responses to climate change to know if charismatic taxa, such as butterflies, or disease vectors, including Diptera, can be used as key-stone taxa to generalise other insect responses to climate change. This is critical as the basic biology of most species is still poorly known, and dominant, well studied taxa may show variable responses to climate change across their distribution due to regional biotic and abiotic influences. Indeed identifying if insect responses to climate change can be generalised using phylogeny, functional traits, or functional groups, or will populations and species exhibit idiosyncratic responses, should be a key priority for future research. ... When the number of studies were compared to the identified species richness within each Order, Lepidoptera, Diptera, Orthoptera, Colembola, and Odonata have a proportionally higher percentage of papers assessing their responses to climate change relative to number of species identified, whilst Coleoptera, Hymenoptera, and Hemiptera have a proportionally lower percentage of papers assessing their responses to climate change relative to number of species identified." (2013): A biologically inspired facilitation mechanism enhances the detection and pursuit of targets of varying contrast. 4th joint international conference on swarm, evolutionary and memetic computing (SEMCCO) & fuzzy and neural computing (FANCCO), Chennai, India, 19 - 21 December: 9 pp. (in English) ["Many species of flying insects detect and chase prey or conspecifics within a visually cluttered surround, e.g. for predation, territorial or mating behaviour. We modelled such detection and pursuit for small moving targets, and tested it within a closed-loop, virtual reality flight arena. Our model (dragonfly) is inspired directly by electrophysiological recordings from 'small target motion

detector' (STMD) neurons in the insect brain that are likely to underlie this behavioural task. The front-end uses a variant of a biologically inspired 'elementary' small target motion detector (ESTMD), elaborated to detect targets in natural scenes of both contrast polarities (i.e. both dark and light targets). We also include an additional model for the recently identified physiological 'facilitation' mechanism believed to form the basis for selective attention in insect STMDs, and quantify the improvement this provides for pursuit success and target discriminability over a range of target contrasts." 14049. Belluco, S.; Losasso, C.; Maggioletti, M.; Alonzi, C.C.; Paoletti, M.G.; Ricci, A. (2013): Edible insects in a food safety and nutritional perspective: A critical review. *Comprehensive Reviews in Food Science and Food Safety* 12: 296-313. (in English) ["Increasing world population worsens the serious problem of food security in developing countries. On the other hand in industrialized countries, where the problem of food security is of minor concern, health problems related to food refer to 2 main factors: food safety and environmental sustainability of food production. For these reasons, new ways must be found to increase yields while preserving food quality, natural habitats, and biodiversity. Insects could be of great interest as a possible solution due to their capability to satisfy 2 different requirements: (i) they are an important source of protein and other nutrients; (ii) their use as food has ecological advantages over conventional meat and, in the long run, economic benefits. However, little is known on the food safety side and this can be of critical importance to meet society's approval, especially if people are not accustomed to eating insects. This paper aims to collect information in order to evaluate how insects could be safely used as food and to discuss nutritional data to justify why insect food sources can no longer be neglected. Legislative issues will also be discussed. ... Parasitological hazards: Parasites represent another potential hazard in relation to insect consumption. Their presence has been well documented in a recent review about foodborne intestinal flukes in southeast Asia (Chai and others 2009). The great importance of this work is linked to the geographical area investigated, where there is a long, widespread tradition of insect consumption. Six out of 65 species of intestinal flukes considered in the paper were isolated from insect samples. Among these is *Phanerocephalus bonnei* (Lecithodendriid), 1st described at a human autopsy in 1951 in Jakarta, Indonesia and later found in monkeys in Malaysia and India in 1962. This fluke was then reported in 15 human autopsies in Udornthani Provincial Hospital in northeast Thailand. Subsequently, the same fluke infection was found to have a high prevalence in other countries. Metacercariae were discovered in naiads and adult dragon and damselflies, insects which are commonly eaten in these parts of the world. The same insect can harbor the

fluke, *Prosthodendrium molenkampii* (Lecithodendriid), which characteristically has 12 to 30 vitelline follicles on each anterolateral side. First isolated from 2 human autopsies by Lie Kian Joe in 1951 in Jakarta, Indonesia, this fluke was then found in 14 human autopsies in Udonrathani Provincial Hospital, Thailand. Later, high prevalence was reported in different areas of northeast Thailand. In Laos PDR, a total of 8899 adult specimens were recovered from 52 infected people residing along the Mekong riverside areas of Vientian Municipality, and Savannakhet, Khammoune, and Saravane Provinces. Metacercariae were discovered in naiads and adult Odonata in Thailand. Another member of this genus, *Phaneropsolus spinicirrus*, was described in 1991 as a new species from a human infection case in northeast Thailand." (Authors)] Address: Paoletti, M.G, Biol. Dept., via Bassi 58 b, Padova Univ. 35100-Padova, Italy. E-mail: paoletti@bio.unipd.it

14050. Bergmann, T.; Rach, J.; Damm, S.; DeSalle, R.; Schierwater, B.; Hadrys, H. (2013): The potential of distance-based thresholds and character-based DNA barcoding for defining problematic taxonomic entities by CO1 and ND1. *Molecular Ecology Resources* 13(6): 1069 -1081. (in English) ["The mitochondrial CO1 gene (cytochrome c oxidase I) is a widely accepted metazoan barcode region. In insects, the mitochondrial NADH dehydrogenase subunit 1 (ND1) gene region has proved to be another suitable marker especially for the identification of lower level taxonomic entities such as populations and sister species. To evaluate the potential of distance-based thresholds and character-based DNA barcoding for the identification of problematic species-rich taxa, both markers, CO1 and ND1, were used as test parameters in odonates. We sequenced and compared gene fragments of CO1 and ND1 for 271 odonate individuals representing 51 species, 22 genera and eight families. Our data suggests that (i) the combination of the CO1 and ND1 fragment forms a better identifier than a single region alone; and (ii) the character-based approach provides higher resolution than the distance-based method in Odonata especially in closely related taxonomic entities." 14052. Bogdan, H. V.; Covaciu-Marcov, S.-D.; Gaceu, O.; Cicort-Lucaciu, A.-S.; Ferenti, S.; Sas-Kovács, I. (2013): How do we share food? Feeding of four amphibian species from an aquatic habitat in south-western Romania. *Animal Biodiversity and Conservation* 36.1: 89-99. (in English, with Spanish summary) [The study area was located near Maru village, in the Tarcu Mountains, in south-western Romania (45° 27' 26.21" N/22° 26' 42.13" E). "The feeding of four amphibian species (*Triturus cristatus*, *Lissotriton vulgaris*, *Bombina variegata*, *Pelophylax ridibundus*) was studied in 2011, in south-western Romania. The diet of the newts was uniform and mostly composed of aquatic preys. The diet of the anurans was more diversified, comprising more prey taxa, mostly terrestrial. The trophic niches of the two newt species overlapped highly but differed from those of the anurans. The trophic niches of the anurans differed from one another. The differences among the four species' diets were determined by the use of different trophic resources, originating from different environments, and by their different sizes. The newts' diet was less diversified because the

aquatic habitat was small and poor in trophic availability. The anurans used the aquatic habitat as a base from where they captured terrestrial preys in the surrounding terrestrial environment." (Authors) The list of prey also includes unspecified Odonata.] Address: Covaciu Marcov, S.-D., Dept. of Biology, Fac. of Sciences, Univ. of Oradea, Universitatii str. 1, Oradea 410087, Romania. 14053. Brinesh, R.; Janardanan, K.P. (2013): The life history of *Pleurogenoides malampuzhensis* sp. nov. (Digenea: Pleurogenidae) from amphibious and aquatic hosts in Kerala, India. *Journal of Helminthology* 88(2): 230-236. (in English) ["The life-cycle stages of *Pleurogenoides malampuzhensis* sp. nov. infecting the Indian bullfrog *Hoplobatrachus tigerinus* (Daudin) and the skipper frog *Euphlyctis cyanophlyctis* (Schneider) occurring in irrigation canals and paddy fields in Malampuzha, which forms part of the district of Palakkad, Kerala, are described. The species is described, its systematic position discussed and compared with the related species, *P. gastroporus* (Luhe, 1901) and *P. orientalis* (Srivastava, 1934). The life-cycle stages, from cercaria to egg-producing adult, were successfully established in the laboratory. Virgulate xiphidiocercariae emerged from the snail *Digoniostoma pulchella* (Benson). Metacercariae are found in muscle tissues of dragonfly nymphs and become infective to the frogs within 22 days. The pre-patent period is 20 days. Growth and development of both metacercariae and adults are described." (Authors)] Address: Brinesh, R., Parasitology laboratory, Dept of Zoology, University of Calicut, Kerala, India

14054. Buczyński, P.; Zawal, A.; Stępień, E., Buczyńska, E.; Pešić, V. (2013): Contribution to the knowledge of dragonflies (Odonata) of Montenegro, with the first record of *Ophiogomphus cecilia* (Fourcroy, 1785). *Annales Universitatis Mariae Curie-Skłodowska (Sectio C)* 63(2): 57-71. (in English, with Polish summary) ["Authors discuss the collection of larvae and imagines of Odonata which was collected during hydrobiological and acarological studies conducted in Montenegro in 2010 and 2012. The material encompasses 28 dragonfly species of which *Ophiogomphus cecilia* has been recorded obolevn this country for the first time. The updated checklist of the dragonflies of Montenegro was also provided." 14055. Chiandetti, I.; Fiorenza, T.; Zandigiacomo, P. (2013): *Nehalennia speciosa* (Charpentier): una specie a rischio di estinzione sul territorio italiano (Odonata, Coenagrionidae). *Bollettino Soc. Naturalisti "Silvia Zenari", Pordenone* 37/2013: 113-121. (in Italian, with English summary) ["*Nehalennia speciosa*: a species at risk of extinction on the Italian territory. *N. speciosa* is a rare species considered threatened in several European countries. In 2009 in Italy, the species was detected only in four peat bogs of the Tilverinum morainal amphitheatre

and in one swamp in the Carnic area in the Friuli Venezia Giulia region, while the populations of two sites in the Lombardia region are considered extinct. In the period 2010-2013, as part of the Project "Odonata Atlas of Friuli Venezia Giulia", periodic samplings were conducted in the five Friulian sites, where the species had already been found. In the morainal area, adults and exuviae of *N. speciosa* were observed only in the peat bog of Lazzacco (Pagnacco municipality, UD). In the nearby peat bogs of Brazzacco and Chialcinat (Moruzzo municipality, UD), individuals of the species were not detected, while a single adult male was found in 2012 in the peat bog of Modoletto (Pagnacco municipality, UD). In the Carnic area, adults were never detected in the swamp of Cima Corso (Ampezzo municipality, UD). Possible causes for the decline of the species are the progressive burial of some peat bogs, almost completely overgrown with marsh vegetation, and the occurrence of non-native fish fauna. The situation of *N. speciosa* in Italy is very critical, since a viable population is only present in the peat bog of Lazzacco, characterized by a very small area. Therefore, it is urgent to start an environmental restoration program to create or recreate suitable habitats for the reproduction of *N. speciosa*." 14056. Choe, L.-J.; Han, M.-S.; Kim, M.; Choe, K.-J.; Kang, K.-K.; Na, Y.-E., Kim, M.-H. (2013): Characteristics communities structure of benthic macroinvertebrates at irrigation ponds, within paddy field. *Korean Journal of Environmental Agriculture* 32(4): 304-314. (in Korean, with English summary) ["Ecological functions of irrigation ponds were well known fact that important for biodiversity conservation in agricultural ecosystems. However, many irrigation ponds were destructed with changes of agricultural environment. The objective of this study is to appreciate the importance of ecological functions of irrigation pond. Furthermore, it presented to useful information for restorations of irrigation pond from analyses of correlations between benthic macroinvertebrate communities and locational factors of irrigation ponds. Benthic macroinvertebrate sampling was conducted from 2010 to 2012 at 15 study ponds. Comparisons of benthic macroinvertebrates diversity approached species richness and density, and statistical analyses were performed using independent t-test. A total of 131 species / 137,118 individuals of benthic macroinvertebrates were recorded during study period. Dominant taxa of benthic macroinvertebrates included Coleoptera, Hemiptera, and Odonata. Generally, benthic macroinvertebrate diversity in mountain region and existing ponds were showed higher than open field and created ponds, respectively. DCA ordination showed that benthic macroinvertebrate community was most correlated with locational characteristics of irrigation pond, and it correlated with bank type and age of pond. In conclusions, in order to restore ecological irrigation pond, it is necessary to consider environmental factors such as locational characteristics and bank types."

14057. Curry, C. (2013): The role of habitat and dispersal in shaping the biodiversity of riverine insect assemblages. Dissertation, University of New Brunswick, Faculty of Science, Department of Biology: XI + 217 pp, app.. (in English) [New Brunswick, Canada. "Given limited resources, biomonitoring programs are touted as a source of biodiversity information for conservation planning in riverine ecosystems. However, the degree to which patterns revealed by biomonitoring are reflected in unsampled mesohabitats and undersampled taxonomic groups has not been fully addressed. Differences in dispersal capacity among taxonomic groups, in particular, may result in divergent patterns of biodiversity at landscape and regional scales. I sought to address the suitability of biological monitoring data in freshwater biodiversity assessment, and to test the prediction that the degree of spatial structuring in aquatic insect assemblages is inversely related to their dispersal capacity. My thesis comprises four articles. The first addresses whether macroinvertebrate biodiversity patterns in riffles, the target mesohabitat of Canada's national aquatic biomonitoring program, are reflective of those in riverine wetlands. The second addresses whether biodiversity in a group of insects that is abundant in biomonitoring samples (Trichoptera) reflects that of an underrepresented group (Odonata). The third tests the above prediction by comparing the degree of spatial structuring in the weakly dispersing Trichoptera and the stronger dispersing Odonata. The final article investigates regional and national aquatic insect biodiversity patterns utilizing the national biomonitoring dataset, and seeks to evaluate the influence of scale on the observation of spatial structuring aquatic insect assemblages. Several key findings emerged from this work: 1) Patterns of invertebrate taxon richness and beta diversity in riffles poorly reflect those in riverine wetlands. 2) Odonata and Trichoptera biodiversity were not always congruent, however, differences in abundance among groups may account for weak correlations. 3) Both Odonata and Trichoptera assemblages demonstrate relatively weak spatial structuring at a landscape (i.e. 5th order catchment) scale. The weak explanatory ability of spatial variables was also apparent at a regional scale, as just one of the Water Survey of Canada sub drainages within the Pacific drainage demonstrated a significant spatial component in aquatic insect assemblage variation. These findings suggest caution in the application of biomonitoring data to conservation planning. Although landscape and regional scale structuring of aquatic insect communities may be weak, it does not preclude the existence of smaller scale spatial structuring driven by local dispersal processes." 14058. Davenport, J.M.; Chalcraft, D.R. (2013): Increasing conspecific density weakens the ability of intermediate predators to develop induced morphological defences to top predators. *Freshwater Biology* 59(1): 87-99. (in English) ["(1) Intraguild predation is common in nature, but it is unclear how species that both compete and eat each other can persist together. One possibility is that intermediate predators possess inducible morphological defences that protect them from top predators while not compromising their ability to compete with top predators. (2) The ability of intermediate predators to develop morphological defences may be compromised in environments with a high density of conspecifics because of reduced resource availability and predation risk due to the saturating functional response of top predators. Furthermore, since morphological defences take time to develop, the type and extent of morphological defences may vary during development. (3) We conducted an experiment to measure the phenotypic responses of an intermediate predator (larvae of the salamander *Ambystoma opacum*) to the presence of a caged top predator (larvae of *Anax* spp.) throughout ontological development in environments that differed in the density of conspecifics present. We also assessed how intermediate predators, reared in the different environments, differed in their vulnerability to top predators and ability to deplete their food resources. (4) We found that *Anax* induced morphological defences in *A. opacum*, but the extent of morphological change declined with the density of conspecifics. Moreover, some morphological traits disappeared, while others appeared just prior to *A. opacum* metamorphosis. The change in *A. opacum* phenotype in response to *Anax* made *A. opacum* less vulnerable to predation by *Anax* but had no significant effect on the foraging ability of *A. opacum*. (5) Our study demonstrates that top predators can induce phenotypes in intermediate predators that reduce their vulnerability to top predators while not compromising their ability to feed on a common prey. An increase in intermediate predator density, however, could diminish the ability of intermediate predators to develop the full suite of morphological defences. The inability to develop the full suite of morphological defences may reduce the probability of persistence with top predators." 14059. Diedericks, G.; Simaika, J.; Roux, F. (2013): A survey of adult Odonata along the Crocodile-Inkomati River main stem from source to ocean. A pilot project to determine the application of the Dragonfly Biotic Index (DBI) as an indicator of river health. Draft: 56 pp. (in English) ["Results: A total of 80 species were recorded along the 29 sampling points on the Crocodile-Inkomati River from an elevation of 2,100 to 20 m a.s.l. This represents 49.4% of all species known to occur in South Africa. Of the 118 species expected to occur, 32.2% were not encountered. A table with the sites visited, the total DBI score (Σ DBI), number of species, and average DBI 17 score per site (ADBI) are included below (Table 3) and the results illustrated graphically (Figure 4). A species accumulation chart, indicating species that were ex-

pected per site compared to those observed are shown in Figure 17. In general, adult Odonata species diversity was low at the headwaters, increasing longitudinally downstream, with several 'spikes', which tend to indicate increases in species diversity. Very low total DBI scores were recorded at the Sterkstroom (660 – 680 m a.s.l.), Kamagugu (560 – 580 m a.s.l.), Tenbosch Weir (120 – 140 m a.s.l.) and Moamba (60 – 80 m a.s.l.) sites. High diversity was recorded at the Montrose (780 – 800 m a.s.l.), Botanical Gardens (600 – 620 m a.s.l.), Crocodile Gorge (380 – 400 m a.s.l.) and Malelane (280 – 300 m a.s.l.) sites. The highest ADBI was recorded at headwater sites Verlorenvlei (2,080 – 2,100 m a.s.l.), Elandshoek (2,020 – 2,040 m a.s.l.) and Valyspruit (1,840 – 1,860 m a.s.l.). Threatened species were recorded in the Crocodile Gorge, Malelane, Crocodile Bridge and the Inkomati River below Lake Chuali." 14060. Dumont, H.J. (2013): Phylogeny of the genus *Ischnura* with emphasis on the old world taxa (Zygoptera: Coenagrionidae). *Odonatologica* 42(4): 301-308. (in English) ["COI and ITS DNA fragments were used to gain insight into the phylogenetic relationships within *Ischnura*. The genus is recovered as monophyletic, and the 24 species-level taxa considered (about one third of the total) suggest the existence of 2 main clades, here called the *I. elegans* and *I. pumilio* groups. Each group has a core number of about 4-5 species, while the placement of most others is not well resolved and will require further study. However, for a number of taxa, their relationship within the species group is clarified. This is true of formerly enigmatic species like *I. aralensis*, but also of *I. fontaineae*, *I. evansi*, and others. *I. aurora* is found to be only distantly related to *I. rubilio* and both certainly deserve full species status and occupy disjunct geographic ranges. *Ischnura nursei* is confirmed as a true *Ischnura*. *I. graellsii* and *I. saharensis*, although closely related to *I. elegans*, appear to be good species." 14061. Fontanarrosa, M.S.; Collantes, M.B.; Bachmann, A.O. (2013): Aquatic insect assemblages of man-made permanent ponds, Buenos Aires City, Argentina. *Neotropical Entomology* 42(1): 22-31. (in English) ["Freshwater habitats are important elements within urban green space and they are endangered by various types of human activity. With the aim to increase the knowledge about species biodiversity in urban ecosystems, we characterised the assemblages of aquatic insects in four permanent man-made ponds in Buenos Aires city (Argentina) during a 1-year period. We recorded 32 species with *Sigara* spp. (Hemiptera) as the most abundant. The removal of aquatic vegetation from the studied ponds may have affected both the establishment and perma-

nence of the insect community. Swimmers were the dominant group in the studied sites, followed by burrowers and sprawlers, and only a few strictly climbers were collected. Therefore, all sampled ponds were dominated by collectors (principally gatherers), secondarily by predators and only few shredders were detected, which was much affected by the removal of macrophytes. Non-parametric abundance indexes estimated a number of species very close to the observed number in each site. Conversely, the incidence indexes estimated more species because there were many more taxa present only in one sample than those represented by few individual in a sample. Our data provides some insights on the community of man-made ponds that can improve the management of these aquatic urban habitats. Considering that macrophytes affect animal assemblages due to their role as physical structures that increase the complexity or heterogeneity of habitats, they should not be removed by authorities in order to promote biodiversity." (Authors) Odonata are listed at family level: Libellulidae, Coenagrionidae.] Address: Fontanarrosa, M.S., Lab Limnología, Depto Ecología, Genética y Evolución, FCEN, UBA CONICET, Ciudad Universitaria Pab II, 4° piso, C1428EHA, Buenos Aires, Argentina. 14062. Fuisz, T.I.; Vas, Z.; Túri, K.; Körösi, A. (2013): Photographic survey of the prey-choice of European Bee-eaters (*Merops apiaster* Linnaeus, 1758) in Hungary at three colonies. *Ornis Hungarica* 21(2): 38-46. (in English, with Hungarian summary) ["Prey choice of European Bee-eaters was monitored via taking pictures of parent birds carrying prey items to their perches in front of the nests between 2011 and 2013 at three colonies in Hungary: at Pócsmegyer, Nagykarácsony and Albertirsa. All the colonies were studied in the breeding season, and prey items were identified from the digital images taken of adults carrying food for their chicks. During the three years 25 days were spent with collecting photographic data, and from the thousands of pictures taken 805 were suitable for analysis. On 775 photographs the prey item was identified at least to order level. Combining data from all the colonies hymenopterans were by far the most often consumed insects (50%), followed by dragonflies (17%), while beetles, orthopterans, lepidopterans and dipterans each contributed approximately 7-9% of the consumed prey. Prey composition showed marked differences between the individual colonies, although the ratio of hymenopterans was everywhere high. Bee-eaters at Pócsmegyer, probably due to the abundance of aquatic habitats nearby on the Danube shore, consumed almost as much dragonflies as hymenopterans, and ate very few orthopterans. While at the Albertirsa colony, surrounded by agricultural fields and meadows in a more arid environment, hymenopterans dominated the prey, and orthopterans were almost as often consumed as dragonflies. Lepidopterans constituted approximately 8% of Bee-eaters' diet in all colonies. From an insect ecological viewpoint, our study provides valuable data on the spe-

cies pool that might be at risk of predation by Bee-eaters, and enables us to roughly estimate the predation pressure on some taxa, and in certain cases even on species by these birds." 14064. Greenwalt, D.; Labandeira, C. (2013): The amazing fossil insects of the Eocene Kishenehn Formation in northwestern Montana. *Rocks & Minerals* 88(5): 434-441. (in English) [USA "Approximately 46 million years ago, shortly after the green and red mudstones that now form the mountains of Glacier National Park completed their slow slide eastward from Canada, a series of strong earthquakes created a long north-south rift valley along what is now the western border of the park. As the valley filled with run-off from adjacent mountains, Lake Kishenehn, a 100-mile-long lake, was formed. Today, the North and Middle forks of the Flathead River erode their way through the mile-thick sediments of that ancient lake and expose carbon-rich oil shale and siltstone that comprise the steep cliffs on either side of the river. It is within these shales of the Kishenehn Formation that scientists from the Smithsonian Institution are collecting what are arguably some of the most exceptional insect fossils in the world. ... Seven orders of insects (including Odonata [dragonflies], Lepidoptera [butterflies and moths], Dermaptera [earwigs], Isoptera [termites], Collembola [springtails], Psocoptera [bark lice], and Neuroptera [lacewings and others]) account for less than 0.2 percent of all the Kishenehn fossil insects. Several factors may have contributed to this distribution of insect types. Members of the families Lepidoptera, Dermaptera, Isoptera, Psocoptera, and Collembola are not aquatic insects, and their near absence from the sediments of Lake Kishenehn is not unexpected. Perhaps the most important factor involved in the selective preservation of Kishenehn insects is their size. ... Large insects, such as grasshoppers and dragonflies, are too big to be buried by a single layer of sediment and are therefore exposed to predation and other processes that destroy the insect before it can be entombed. The only fossils of dragonflies in the Kishenehn Formation are wing fragments, structures that are very flat and thin that can be embedded within a single layer." 14065. Guan, Z.; Dumont, H.J.; Yu, X.; Han, B.-P.; Vierstraete, A. (2013): *Pyrrhosoma* and its relatives: a phylo-

genetic study (Odonata: Zygoptera). *International Journal of Odonatology* 16(3): 247-257. (in English) ["The placement and relationships of the red-and-black zygopteran *Pyrrhosoma*, currently considered to be part of the *Teinobasinae*, has long been uncertain. DNA fragments (COI and ITS) reveal that *Pyrrhosoma* s.s. is restricted to the West Palaearctic, with two morphologically distinct name-bearing clades (*nymphula*, *elisabethae*), and with a morphologically indistinct third clade in the Middle Atlas, Morocco, that might be close to the common ancestor of all three. *Chromagrion*, the closest relative of *Pyrrhosoma*, is found in North America, not in South Asia. Two isolated Chinese taxa (*tinctipenne* and *latiloba*) are morphologically similar to *Pyrrhosoma*, but their molecular distance is so large that a new genus, *Huosoma*, is required to accommodate them. Past climate change is suggested as the driver of the biogeography and evolution of this group of zygopterans. The origin of the Moroccan isolate and of *elisabethae* might predate the glaciations, and be of Pliocene age. The much wider disjunction between the American and South Asian groups and the western group suggests an older, perhaps Miocene age." (Authors)] Address: Dumont, H.J., Univ. Gent, Inst. 14066. Gutiérrez-Fonseca, P.E.; Ramírez, A.; Umaña, G.; Springer, M. (2013): *Macroinvertebrados dulceacuícolas de la Isla del Coco, Costa Rica: especies y comparación con otras islas del Pacífico Tropical Oriental*. *Rev. Biol. Trop. (Int. J. Trop. Biol.)* 61(2): 657-668. (in Spanish, with English summary) ["Freshwater macroinvertebrates from Cocos Island, Costa Rica: species and comparison with other islands of the Eastern Tropical Pacific. Cocos Island is an oceanic island in the Eastern Pacific, at 496km from Cabo Blanco, Costa Rica. This 24km² island is surrounded by a protected marine area of 9640km². It was declared National Park in 1978 and a World Heritage by UNESCO in 1997. Freshwater macroinvertebrate fauna was collected in 20 sites covering three rivers (Genio, Chatam and Sucio) and two creeks (Minuto and an unnamed creek behind the park rangers' house). Tank bromeliads or phytotelmata were also examined for aquatic macroinvertebrates. Physicochemical parameters were determined in 13 study sites. Additionally, a comparison with other islands in the Eastern Tropical Pacific was conducted to determine the most important factors controlling the diversity in Tropical Pacific islands. A total of 455 individuals were collected belonging to 20 taxa (mostly identified to genus level) from 15 families of aquatic insects. Other macroinvertebrates such as Palaemonid shrimps, Hidrachnida and Oligochaeta were also collected. The family Staphylinidae (Coleoptera) was the most abundant, followed by Chironomidae (Diptera). Diptera was the order of insects with the highest taxonomic richness. A relationship between distance and the number of families was observed supporting the premises of the Theory of island Biogeography. This relationship was improved by correcting area by island elevation, indicating that mountainous islands had the rich-

est faunas, potentially due to high cloud interception that feeds freshwater environments favouring the establishment of aquatic fauna. Physicochemical variables were similar in all sites, possibly due to the geology and the absence of significant sources of pollution on the island." (Authors) The following Odonata taxa are listed: *Argia*, *Coenagrionidae*: genus 1 and genus 2, *Tramea calverti*, and *Triacanthagyna caribbea*] Address: Gutiérrez-Fonseca, P.E., Depto Biol., Univ. de Puerto Rico-Río Piedras, San Juan, Puerto Rico, 00931-3360. 14067. Hoving, C.L.; Lee, Y.M.; Badra, P.J.; Klatt, B.J. (2013): Changing climate, changing wildlife a vulnerability assessment of 400 species of greatest conservation need and game species in Michigan. Michigan Department of Natural Resources. Wildlife Division Report No. 3564: 82 pp. (in English) ["Michigan's climate has been warming, and the warming trend is accelerating. The best available science indicates the acceleration is likely to continue, and warming in the next 40 years will be roughly 10 times as fast as the warming over the past 100 years in Michigan. Michigan wildlife face myriad conservation challenges, including land use change and habitat loss, habitat fragmentation, competition from invasive exotic species, altered ecological processes, and a rapidly changing climate. This report focuses on the effect of a rapidly changing climate. In 2010, the Michigan Natural Features Inventory (MNFI) received funding from the Michigan Department of Environmental Quality Coastal Management Program to assess vulnerability of 180 animal and plant species in the coastal zone using the Climate Change Vulnerability Index (CCVI) developed by NatureServe. MNFI assessed a total of 198 species including 131 animal species and 67 plant species. The Michigan Department of Natural Resources (DNR) Wildlife Division used State Wildlife Grants and Pittman-Robertson funds to assess vulnerability of 281 animal species using the same methods. Twelve animal species were assessed by both MNFI and the Michigan DNR. All resident terrestrial game species and all Species of Greatest Conservation Need (SGCN) (with enough life history data) were assessed. Vulnerable species are those expected to experience reductions in range extent or abundance by 2050 due to climate change. The CCVI analysis suggests that 17% of terrestrial game species and 61% of terrestrial and aquatic Species of Greatest Conservation Need (SGCN) are vulnerable. Other conservation threats or programs aside, these species will likely experience range or population reductions due to climate change. Vulnerable species included important game species, such as moose (*Alces americanus*), Vulnerable SGCN include conservation icons, such as the Karner blue butterfly (*Lycaeides melissa samuelis*) and common loon (*Gavia immer*). The full list of species' vulnerabilities is in the Appendices. Other vulnerability analyses suggest that ecological communities in Michigan will change dramatically as species respond individually. Some characteristic northern species, such as spruce, fir, and birch may fade from the landscape. Quak-

ing aspen (*Populus tremuloides*) is predicted not to regenerate and compete with the same health and vigor in a warmer and drier Michigan. Other species, such as red maple (*Acer rubrum*) and some oaks (*Quercus* spp.) and hickories (*Carya* spp.), are expected to do better in a warming climate. This analysis focuses on vulnerabilities of individual species, independent of changes in habitat or competitive interactions. The CCVI predicts the strength and direction of the influence of a changing climate. Management action (or inaction) can offset or reinforce the climate influence. The CCVI is a useful first step in climate adaptation, but it is only one tool to use to develop climate adaptive management plans for species or habitats. Initial suggestions of management actions are provided to help managers begin thinking about how these adaptive plans can be formulated. However, adaptation (e.g., climate-smart management) will need to be context specific; it will depend on existing management goals, priorities, funds, and local site conditions." (Authors) CCVI tool for these climate vulnerable species included the caveat that the "Species may expand range in assessment area." Populations of these species may decrease globally, but increase in Michigan if their populations shift northward. The only Odonata listed is *Somatochlora hineana*, and it is assessed as "EV – Extremely Vulnerable".] Address: Hoving, C.L., Michigan Dept of Natural Resources, Wildlife Division

14068. Katayama, M. (2013): Differential survival rates of damselfly larvae in the presence of newt and dragonfly predators. *International Journal of Odonatology* 16(2): 177-182. (in English) ["*Paracercion melanotum* has been found to be the most abundant species in damselfly larval communities on Okinawa-zima Island in southwest Japan. To clarify differential susceptibility to predation, a possible factor affecting relative population densities in larval communities, between *P. melanotum* and a less common damselfly species, *Ischnura senegalensis*, laboratory experiments were conducted using three abundant predator species: the sword-tailed newt (*Cynops ensicauda popei*), anisopteran larvae (*Crocothemis servilia servilia*), and a planktivorous fish (*Poecilia reticulata*). *P. melanotum* survived predation by the newt and the dragonfly well compared to *I. senegalensis*. Fishes consumed approximately equal numbers of the two damselfly species. From these results, the newt and the dragonfly were suggested as the most probable predators regulating damselfly larval communities on Okinawa-zima Island. Predators could be a crucial factor determining relative abundance in damselfly larval communities." 14071. Mellone, U.; López-López P; Limiñana, R.; Urios, V. (2013): Summer pre-breeding movements of Eleonora's Falcon *Falco eleonora* revealed by satellite telemetry: implications for conservation. *Bird Conservation International* 23(4): 487-494. (in English) ["Recent advances in bird tracking technologies are revealing that migratory birds use temporal staging sites other than breeding and wintering areas, and these areas deserve conservation ef-

orts. *F. eleonora* is a long-distance migratory raptor that breeds colonially on islands and is considered a priority species for conservation. Anecdotal observations indicate that during the pre-breeding period, Eleonora's Falcons stay in inland areas far away from the colonies, but, to date there are no detailed data concerning the connectivity between these areas and breeding colonies. Using satellite telemetry, we analysed data from four summering events belonging to three individuals breeding in two colonies in the Western Mediterranean (Spain). All of them made inland movements in areas up to c.400 km distant from the respective breeding colonies, visiting several habitats, from forests to arable lands, probably taking advantage of high densities of insects. Perturbations occurring in these areas could threaten Eleonora's Falcons with serious consequences at the population level. We suggest that conservation measures implemented at breeding and wintering grounds may not suffice and that temporary staging areas should be identified at a larger scale and deserve protection as well. ... It is remarkable that the peak of insect abundance, particularly Coleoptera as well as Odonata, occurs in the inland areas visited by Eleonora's Falcons just during the pre-breeding period (Cano 2001, Belenguer et al. 2004), providing an adequate food supply until the beginning of the autumn migration of passerines that form their main resource during breeding (Walter 1979). It has been reported that Eleonora's Falcons prey particularly upon the Common Cockchafer *Melolontha melolontha* (Cano 2001, Belenguer et al. 2004), an abundant insect that shows demographic explosions in June in some years." 14072. Meyer-Rochow, V.B.; Chakravorty, J. (2013): Notes on entomophagy and entomotherapy generally and information on the situation in India in particular. *Applied Entomology and Zoology* 48(2): 105-112. (in English) ["Indian tribals use insects in a variety of ways. Species containing valuable protein, easily digestible fats, and considerable amounts of vitamins and minerals are consumed; others serve as raw material for folk remedies. Such uses need to be documented, because tribal communities are increasingly discarding their age-old practices. Research into this field can benefit India and the rest of the world in several ways. Traditional communities need to be shown to appreciate the value of their customs and that to look after their environment (lest many of the useful insects will disappear) is not a luxury, but a necessity. Moreover, studying food insects and therapeutically important species can lead to economic spin-offs and would allow countries like India to develop ways to sustainably use this abundant natural resource." 14074. Mole, B. (2013): Matter & energy: Material inspired by dragonfly wings bursts bacteria: Prickly synthetic surface could serve as antimicrobial coating on medical implants. *Science News* 184(13): 11. (in English) [Verbatim: Tiny spikes on a silicon surface can stab and kill any bacteria that make contact, researchers report November 26 in *Nature Communications*. Scientists could foil infectious bacteria by using the new surface architecture as a coating on medical devices and food-processing equipment. Microbiologist Elena Ivanova of Swinburne University of Technology in Hawthorn, Australia, and colleagues designed the nanoarchitecture by taking cues from bacteria-free surfaces in nature such as insect wings. Using scanning electron microscopy, the team discovered that dragonfly wings have protrusions, just 240 nanometers tall, which appeared to pop bacterial cells that tried to attach to the wing. By etching light-absorbing black silicon, Ivanova and her team created similar spikes, 500 nanometers tall and just 20 to 80 nanometers thick. When the researchers exposed bacteria or bacterial spores to the silicon surface, they found that it killed microbes quickly. On average, each square centimeter of silicon destroyed around half a million bacterial cells every minute. Black silicon, which engineers typically use in solar panels and light sensors, is cheap and easy to manipulate, Ivanova says. Creating the nanostructured surface takes just five minutes, she says. The researchers believe that nanostructured silicon could coat items such as medical implants to prevent infectious bacteria from hitchhiking into patients. The coating process "seems pretty straightforward and versatile," says nanchemist Thomas Webster of Northeastern University in Boston. Though Webster would like to see more data on the physical forces that actually cause the bacteria to pop, he says modelling the new material from insect wings is a novel approach for finding ways to kill harmful bacteria. "There's a lot of promise for nanoscale features to reduce bacterial growth without antibiotics," he adds.] Address: not stated

14078. Nummi, P.; Paasivaara, A.; Suhonen, S.; Pöysy, H. (2013): Wetland use by brood-rearing female ducks in a boreal forest landscape: the importance of food and habitat. *Ibis* 155: 68-79. (in English) ["Habitat use by birds may be related to single or interacting effects of habitat characteristics, food resources and predators, but little is known about factors affecting habitat use by wetland species in boreal ecosystems. We surveyed brood-

rearing females and ducklings of four common boreal duck species to assess the effects of habitat structure and food resources on the use of wetlands by brood-rearing ducks. Although wetland use by duck broods was related to habitat structure and food abundance, their relative importance varied among duck species. For the Common Goldeneye *Bucephala clangula*, a diving duck, aquatic invertebrates and large emerging insects were the most important factors associated with wetland use. Common Teal *Anas crecca* broods were observed more often on wetlands with greater Dipteran emergence, whereas in Mallard *Anas platyrhynchos* both habitat structure and large emerging insects were important. The occurrence of Eurasian Wigeon *Anas penelope* broods was related to emerging Diptera and habitat structure but the associations were not strong. The varying habitat and food requirements of common duck species could influence the success of wetland management programmes, and consideration of these factors may be particularly important for initiatives aimed at harvested species or species of conservation concern." 14080. Orr, A. (2013): Predation on butterflies and other insects by breeding rainbowbirds ('*Merops ornatus*': Meropidae) in South-East Queensland. *The Australian Entomologist* 40(3): 119-130. (in English) ["The diet of a family of Rainbowbirds ('*Merops ornatus*' Latham) nesting in the Currimundi Environmental Park, southern Queensland, was investigated over approximately four months. Three birds were involved, a breeding pair and a helper male. Insect prey was monitored photographically with 836 items being recorded. The recorded diet of the adults before hatching and that brought to the nestlings

differed considerably, with Hymenoptera being the most important adult prey class for adults, both numerically and in terms of biomass. However, few honeybees ('*Apis mellifera*' Linnaeus) were eaten by adults. Conversely, the most important components of the nestling diet in terms of biomass were cicadas, dragonflies (Anisoptera) and various Diptera. Large numbers of honeybees were also brought to the nestlings during their later development, particularly by the female bird and these comprised almost all the Hymenoptera fed to the nestlings. Lepidoptera, chiefly butterflies of all families, formed a minor but conspicuous part of the diet, particularly of the adults. Relatively fewer were fed to the nestlings, possibly because of the abundance of cicadas and dragonflies in the foraging territory." 14082. Saha, N.; Aditya, G.; Saha, G.K. (2013): Prey preferences of aquatic insects: potential implications for the regulation of wetland mosquitoes. *Medical and Veterinary Entomology* 28(1): 1-9. (in English) ["Wetlands are potential sites for mosquito breeding and are thus important in the context of public health. The use of chemical and microbial controls is constrained in wetlands in view of their potential impact on the diverse biota. Biological control using generalist aquatic insects can be effective, provided a preference for mosquito larvae is exhibited. The mosquito prey preferences of water bugs and larvae of odonate species were evaluated using chironomid larvae, fish fingerlings and tadpoles as alternative prey. Manly's selectivity (a_i) values with 95% confidence intervals (CIs) were estimated to judge prey preference patterns. Multivariate analysis of variance (manova) and standardized canonical coefficients were used to test the effects of density on prey selectivity. The a_i values indicated a significant preference ($P < 0.05$) in all of the insect predators tested for mosquito larvae over the alternative prey as a density-dependent function. On a comparative scale, chironomid larvae had the highest impact as alternative prey. In a multiple-prey experiment, predators showed a similar pattern of preference for mosquito larvae over alternative prey, reflecting a significant ($P < 0.05$) niche overlap. The results suggest that, in a laboratory setting, these insect predators can effectively reduce mosquito density in the presence of multiple alternative prey." Dissertation, North Carolina Agricultural and Technical State University, Greensboro, North Carolina: 115 pp. (in English) ["The damselfly belongs to the same insect family as the dragonfly that inspired the development of Micro Air Vehicles (MAVs). Understanding the morphological, mechanical and structural properties of wings, veins and membranes of fly would provide guidelines to develop efficient MAVs. Lack of test methodologies inhibited the progress. The objective of this research was to develop the above methodologies and then measure the properties of veins, membranes and wings of damselflies. The research yielded four test methodologies: fluorescence spectroscopic analysis to map the morphology of vein; axial nanoindentation test to measure indentation properties; micro tension test to measure tensile properties of microscopic components; and a unique vibration test of wings to measure natural frequency, stiffness and air damping factor. Axial indentation test contrasts the transverse indentation used in the past, whose results were corrupted by surface roughness and flexibility of veins. Veins were found to be made of two layered, elliptical tubular members. The thickness of inner and outer layers was about 8 and 5 μm , respectively and corresponding indentation moduli were 8.42 and 16.00 GPa. The modulus of veins agreed with those of human bones. The tensile modulus and strength of veins ranged from 14 to 17 GPa and 232 to 285 MPa, respectively. The damselfly wing was found to vibrate under bending and torsional deformations, the natural frequency (in air) ranged from 130 to 178 Hz, the wing stiffness ranged from 0.18 to 0.30 N/m with the air damping ratio from 0.67 to 0.79. Pathway to develop a material of matching properties is also presented." (Author)]

(2013): Freshwater biodiversity in the rivers of the Mediterranean Basin. *Hydrobiologia* 719: 137-186. (in English) ["We review the diversity of freshwater organisms in the Mediterranean Basin (hereafter Med), particularly from streams and rivers. We present available information on the richness, endemism, and distribution of each freshwater organism group within the Med, and make a comparison with Palearctic diversity. Approximately 35% of known Palearctic freshwater species and more than 6% of the World's freshwater species are present in the Med. A high degree of endemism is found in the Med freshwater biota. These data, together with the degree to which many freshwater species are threatened, support the inclusion of the Med among World biodiversity hotspots. Nevertheless, knowledge of Med biodiversity is still incomplete, particularly for some taxa. Regarding to the spatial distribution of species within the Med, the richest area is the North, although patterns differ among groups. A comparison of the ecological and biological traits of endemic and non-endemic species of three riverine groups (Ephemeroptera, Plecoptera, and Trichoptera) revealed that endemic species have several strategies and mechanisms to face typical mediterranean-climate conditions, such as drought, when compared to non-endemic species. We briefly analyse the conservation status of the region's biodiversity. Finally, we present some future challenges regarding the knowledge and protection of Med freshwater biodiversity." 14091. Van Dijk, T.C.; Van Staalduinen, M.A.; Van der Sluijs, J.P. (2013): Macro-invertebrate decline in surface water polluted with Imidacloprid. *PLoS ONE* 8(5): e62374. doi:10.1371/journal.pone.0062374: 10 pp. (in English) ["Imidacloprid is one of the most widely used insecticides in the world. Its concentration in surface water exceeds the water quality norms in many parts of the Netherlands. Several studies have demonstrated harmful effects of this neonicotinoid to a wide range of non-target species. Therefore we expected that surface water pollution with imidacloprid would negatively impact aquatic ecosystems. Availability of extensive monitoring data on the abundance of aquatic macro-invertebrate species, and on imidacloprid concentrations in surface water in the Netherlands enabled us to test this hypothesis. Our regression analysis showed a significant negative relationship ($P < 0.001$) between macro-invertebrate abundance and imidacloprid concentration for all species pooled. A significant negative relationship was also found for the orders Amphipoda, Basommatophora, Diptera, Ephemeroptera and Isopoda, and for several species separately. The order Odonata (represented by *Ischnura elegans*, *Erythromma najas* and *E. viridulum*) had a negative relationship very close to the significance threshold of 0.05 ($P = 0.051$). However, in accordance with previous research, a positive relationship was found for the order Actiniedida. We used the monitoring field data to test whether the existing three water quality norms for imidacloprid in the Netherlands are protective in real conditions. Our data show that macrofauna abundance drops sharply between 13 and 67 ng l⁻¹. For aquatic ecosystem protection, two of the norms are not protective at all while the strictest norm of 13 ng l⁻¹ (MTR) seems somewhat protective. In addition to the existing experimental evidence on the negative effects of imidacloprid on invertebrate life, our study, based on data from large-

scale field monitoring during multiple years, shows that serious concern about the far-reaching consequences of the abundant use of imidacloprid for aquatic ecosystems is justified." 14092. Vanschoenwinkel, B.; Buschke, F.; Brendonck, L. (2013): Disturbance regime alters the impact of dispersal on alpha and beta diversity in a natural metacommunity. *Ecology* 94(11): 2547-2557. (in English) ["Disturbance and dispersal are two fundamental ecological processes that shape diversity patterns, yet their interaction and the underlying mechanisms are still poorly understood and evidence from natural systems is particularly lacking. Using an invertebrate rock pool metacommunity as a natural model system, we studied potential interactive effects of disturbance regime and patch isolation on diversity patterns of species with contrasting dispersal modes (passive vs. active dispersal). Isolation and disturbance regime had negative synergistic effects on alpha diversity; both directly, by excluding late successional species from isolated patches; and indirectly, by modulating establishment success of generalist predators in well connected patches. Unimodal relationships between isolation and alpha diversity, as predicted by mass effects, were only detected for passive dispersers in frequently disturbed patches and not in active dispersers. For passive dispersers, indications for a positive effect of isolation and a negative effect of disturbance on beta diversity were found, presumably due to differences in deterministic succession and stochastic colonization-extinction dynamics among different patch types. Our findings illustrate that interactions between dispersal rates and disturbance regime are important when explaining species diversity patterns in metacommunities and support the idea that diversity in frequently disturbed habitats is more sensitive to effects of dispersal-based processes." 14093. Vidal-Abarca, M.R.; Sánchez-Montoya, M.M.; Guerrero, C.; Gómez, R.; Arce, M.I.; García-García, V.; Suárez, M.L. (2013): Effects of intermittent stream flow on macroinvertebrate community composition and biological traits in a naturally saline Mediterranean stream. *Journal of Arid Environments* 99: 28-40. (in English) ["Highlights: •We studied the effect of flow intermittence on macroinvertebrate community in a naturally saline stream. •Flow intermittence promoted loss of drought-intolerant macroinvertebrate taxa and led to an increase in flier taxa richness at the intermittent site. •Macroinvertebrate community at the intermittent site was a subset of the community found in perennial sites. •Flow intermittence has important consequences to assess ecological quality. As saline streams are geographically widespread in arid and semiarid regions, flow intermittence frequently occurs as another stressor factor apart from salinity.

Rambla Salada is a temporary naturally saline stream with an intermittent reach upstream. This stream is an ideal scenario to study the effects of intermittent stream flow on macroinvertebrate community composition and biological traits in a naturally saline Mediterranean stream. This study analysed three sites with different hydrological regimes (one intermittent and two perennials). Flow intermittence exerted low pressure on the macroinvertebrate composition and biological traits which led to the loss of drought-intolerant species and taxa rather than acting as a selective force to promote desiccation-resistant taxa. Macroinvertebrate community at the intermittent site was a subset of the community found in perennial sites, and the presence of flier taxa at this site helped avoid flow cessation. These minor changes have consequences to assess the ecological quality of these saline temporary streams in the context of the Water Framework Directive, given the major differences revealed by some indices between the intermittent and perennial sites as the former obtained lower values due to the presence of few desiccation-intolerant species, which significantly increased the value of those biological indices. ... In this sense, Heteroptera, Coleoptera and Diptera are the most diverse groups inhabiting saline streams and on the contrary Ephemeroptera, Trichoptera, Odonata, Crustaceans, Hydrachnidia and Mollusca taxa are scarce (Mellado-Díaz et al., 2008 and Millán et al., 2011)." 14094. Wei, H.H.; New, T.H. (2013): CFD analysis of bio-inspired corrugated aerofoils. Proceedings of ICFD11: Eleventh International Conference of Fluid Dynamics December 19-21, 2013, Alexandria, Egypt : 6 pp. (in English) ["Adapting aerospace solutions engineered by nature to improve technologically advanced products has become increasing popular as researchers attempt to come up with implementations that are simple and robust. Dragonfly wings have corrugated cross-section profiles which instead of hindering flight, actually exhibits superior flight performance by reducing the flow separation bubble even under static flight conditions. A computational fluid dynamics study was conducted to investigate this phenomenon at a Reynolds number of 14 000 by comparing a corrugated aerofoil with the NACA010 aerofoil. The results show a clear reduction of the separation bubble and increased lift for the corrugated aerofoil." 14095. Wiles, C.M. (2013): Parasite community structure in 5 species of damselflies (Odonata: Zygoptera) from Teal ridge, Stillwater Oklahoma. M.Sc. thesis, Oklahoma State University: 114 pp. (in English) ["Few ecological

studies exist on parasite community structure in insects and compared to other invertebrate and vertebrate groups, insects have been largely ignored in studies on parasite community structure. This is surprising because some insects, such as odonates, have become model systems for studies on host parasite interactions, and there is a desperate need for descriptive studies on their parasite community structure. In this study I examined 530 individual damselflies of five species (*Argia apicalis*, *Enallagma civile*, *Ischnura hastata*, *Ischnura verticalis*, and *Lestes disjunctus australis*) for their parasites and report parasite community structure parameters for these hosts. All damselflies were collected from Teal Ridge a semi-permanent wetland located in Stillwater, Oklahoma during the summer and fall of 2010-2012. I report the first record of juvenile *Serpinema cf. trispinosum* nematodes, along with new host records and geographical distribution information for gregarine parasites from Oklahoma damselflies. The parasite compound community of this odonate assemblage consisted of a total of 549 individual parasites, comprised of seven taxa including; five species of gregarines, two species of helminths, and one species of mite. None of the individual parasite species were host specific to a single damselfly species and all parasite species infected at least two species of damselflies. Average parasite species richness was low among the four species of damselflies ranging from a low of $0.2 + 0.4$ (0-2) for *I. hastata* to a high of $0.3 + 0.6$ (0-2) for *E. civile*. There was no relationship in damselfly size and parasite abundance, intensity, or species richness among any of the damselfly species examined. This study indicates that the parasite community structure of damselflies was most similar to Mariluan, 2012 study on the parasite communities of benthic aquatic insects and drastically differed in terms of standard measures of parasite community structure in vertebrate hosts which are much higher in terms of parasite prevalence, mean abundance, mean intensity and species richness." 14096. Woodford, D.J.; Barber-James, H.M.; Bellingan, T.A.; Day, J.A.; de Moor, F.C.; Gouws, J.; Weyl, O.L.F. (2013): Immediate impact of piscicide operations on a Cape Floristic Region aquatic insect assemblage: a lesser of two evils? *Journal of Insect Conservation* 17(5): 959-973. (in English) ["The piscicide rotenone is used as a conservation tool to remove alien fishes from rivers, though there is controversy over its effects on aquatic insects. An alien fish removal operation in the Rondegat River, Cape Floristic Region, South Africa, allowed the immediate impact of rotenone on an aquatic insect community in a region with high conservation values to be quantified. The insect community within the treated river was sampled in February 2011 (1 year before rotenone operations), February 2012 (1 week before) and March 2012 (1 week after). Insects were collected using kick sampling across multiple biotopes, together with samples from individual stones. We considered rotenone-precipitated losses to be those taxa captured a week before

treatment but absent after, and assessed the endemism of lost species to determine the conservation impact of the rotenone. Species richness decreased significantly following treatment, even though many rare taxa were not recorded immediately prior to treatment. Of the 85 taxa identified, 18 were lost including five endemic to the mountain range which the river drains. Ephemeroptera were most severely affected, with a significant loss of density on stones post-rotenone and six out of 20 species missing. Since half the missing taxa were recorded upstream of the treatment area, recovery of diversity is likely to be relatively rapid. Given that alien invasive fish negatively affect both fish and aquatic insect communities in South Africa, the long-term positive conservation impact of removing these fish is likely to outweigh the short-term negative effects of the piscicide. ... Odonata, Trichoptera, Coleoptera and Diptera appeared largely unaffected by the rotenone operations." 14097. Zschille, J.; Stier, N.; Roth, M.; Mayer, R. (2013): Feeding habits of invasive American mink (*Neovison vison*) in northern Germany — potential implications for fishery and waterfowl. *Acta Theriologica* 59(1): 25-34. (in English) [lowland area "Lewitz", located about 20 km southeast of the city of Schwerin (Mecklenburg-Western Pomerania, northern Germany, 53°26 N, 11°36 E). "In order to collect ecological data of invasive American mink (*Neovison vison*) at a fishpond area in northeastern Germany, we conducted a telemetry study in which 14 mink were radio-tracked. During this project, 2,502 scats from radio-tracked individuals were collected in the period from October 2003 to October 2005. Investigated mink principally prey on fish, small mammals and birds (eggs inclusive), whereas amphibians, reptiles and invertebrates were caught infrequently. Analysing mink scats of different seasons, we found significant seasonal variations of diet composition. In spring, fish, mammals and birds were hunted in similar amounts. During summer, birds made up the main part of the diet followed by mammals. In autumn, the proportion of birds in the mink diet decreased, whereas fish gained in importance. This trend continued during the winter period, when mink preyed almost exclusively on fish. Amphibians, crustaceans, insects, molluscs and reptiles were found only occasionally in scat samples. Among birds, the mink preyed mainly on the Eurasian Coot (*Fulica atra*) followed by the Mallard (*Anas platyrhynchos*). Mammalian prey was clearly dominated by the water vole (*Arvicola terrestris*) and among fish, mink hunted especially perch (*Perca fluviatilis*), roach (*Rutilus rutilus*) and carp (*Cyprinus carpio*). Results clearly demonstrate that mink is an opportunistic predator, which hunts its prey according to availability and vulnerability, respectively. Despite the high portions of fish in their autumn and winter diet, the economic damage caused by mink seems to be negligible. However, high predation rates on birds during the breeding sea-

son indicate a potential negative impact of mink on waterfowl." 14100. Al-Shami, S.A.; Siti Nurhanani, H.; Che Salmah, M. R.; Salman, A.; Nur Huda, A.; Abu Hassan, A. (2014): Developmental instability in Odonata larvae in relation to water quality of Serdang River, Kedah, Malaysia. *Life Science Journal* 11(7): 152-159 (in English) ["We examined the fluctuating asymmetry (FA) in larvae of two Odonata genera; *Pseudagrion* sp. and *Onychothemis* sp. living in a relatively polluted river as a tool for water quality assessment. Larval and water samples were collected monthly from January to June 2008. Various water parameters including pH, temperature, velocity, nitrate, phosphate, biochemical oxygen demand (BOD), chemical oxygen demand (COD), total suspended solid (TSS), and ammonium-N content were recorded. Composite effect of selected water parameters expressed as Water Quality Index (WQI) was also calculated. FA indices [(FA), absolute asymmetry (AbsFA), composite fluctuating asymmetry (CFA)] of the first and second antennal segments of *Onychothemis* sp. and last tarsal segment of *Pseudagrion* sp. hind legs were calculated. We found that high FA levels in the selected traits for the two Odonata species were associated with deterioration in the water quality (WQI). BOD and pH were positively correlated with high FA indices in the antennal segments of *Onychothemis* sp. The FA levels calculated as FA indices of last tarsal segment of *Pseudagrion* sp. hind legs were positively correlated with ammonium-N, phosphate, and COD. We concluded that selected traits of the odonate

taxa are useful bioindicators as the incidence of fluctuating asymmetry in their larvae was strongly associated with deterioration in the water quality of the river." (2014): Comparative study of the Chatham Islands Odonata, II: Morphometric and molecular comparison between *Xanthocnemis tuanuii* Rowe, 1981 and *X. zealandica* (McLachlan, 1873) with notes on the taxonomic position of *Xanthocnemis sinclairi* Rowe, 1987 (Zygoptera: Coenagrionidae). International Dragonfly Fund - Report 75: 1-27. (in English) ["We compared Chatham Island endemic species *Xanthocnemis tuanuii* to its congeners from the New Zealand South Island: *X. zealandica* (newly collected specimens) and *X. sinclairi* (type specimens plus newly collected material). Two independent tests were performed - geometric morphometrics and molecular. Both analyses were consistent in supporting the status of *X. tuanuii* as a good species. Species differed statistically in the following morphological traits: head (dorsal view), male appendages (dorsal, lateral, posterior and ventral views), thorax (dorsal view), and penis (dorsal and lateral view). In addition to the original diagnostic features (mainly shape of the male superior appendages), a new morphological character is suggested here which reliably distinguishes the species based on the shape of the inferior appendages. There was no statistical support for the species status of *X. sinclairi*. The only feature reported as diagnostic (lower lobe of male superior appendages) was found to be variable and insufficient to warrant the previously proposed taxonomic rank for *X. sinclairi*. Molecular analysis of specimens showing identical appendages to the *X. sinclairi* holotype grouped them with *X. zealandica* specimens. Therefore *X. sinclairi* is synonymised with *X. zealandica*." 14103. Appel, E.; Gorb, S.N. (2014): Comparative func-

tional morphology of vein joints in Odonata. *Zoologica* (Schweizerbart) 159: 104 pp. (in English) ["The authors present a thorough study on the distribution of resilin-bearing wing vein joints in wings of Odonata. 22 species of 20 different families of dragonflies and damselflies, showing various wing morphologies and flight kinematics, are examined and reveal interesting evolutionary trends. Dragonflies and damselflies show an exceptional high lift production and are some of the most maneuverable flying insects. The important role of their corrugated wing profile in increasing lift production has been shown in various studies. As odonate wings lack internal muscles, their aerodynamic performance relies on passive deformations, such as pleat angle widening and camber formation. The rubber-like protein resilin has been shown to play a crucial role in wing joint flexibility. Thus, it may be assumed that the specific distribution of either stiff or flexible, resilin-bearing vein joints may influence the overall wing deformation during flight. Using fluorescence light microscopy and scanning electron microscopy, the dorsal and ventral wing sides of different species are compared with respect to the distribution patterns of four types of vein joints, five types of resilin patches, and joint-associated spines. The results reveal a significant difference between dragonflies and damselflies. Variations of the distribution patterns suggest a classification into five different pattern groups. Their occurrence within the two suborders shows some evolutionary trends and gives insight into the wing functionality. In particular, we discussed how the combination of joint morphology, kinematics, and wing morphology may allow different passive wing deformations during flight. This study, generously illustrated with 53 mostly coloured figures is of great interest to biologists studying insect flight, functional morphology, and evolution of Odonata. Furthermore, the described distribution patterns of different vein joints in combination with wing shape and flight kinematics may possibly inspire their biomimetic imitation in micro air vehicles (MAV)." (2014): Seasonal shift in the diet composition of European Bee-Eaters *Merops apiaster* at the northern edge of distribution. *Ardeola* 61(1): 161-170. (in English, with Spanish summary) ["*M. apiaster* forage almost exclusively on airborne insects caught on the wing. The availability of this food might be temporally limited due to adverse weather conditions, especially at climatically sub-optimal breeding sites. We determined seasonal variation in the diet composition in adult and nestling bee-eaters at the species' northernmost breeding colonies by analysing food remains from pellets and by direct observation. Adult bee-eaters preyed on a wide range of insect species with more than 97% belonging to the taxonomic orders Hymenoptera, Odonata and Coleoptera. We observed consistent seasonal changes in adult

diet composition from the pre-incubation to the late chick rearing period. The dry mass proportion of dragonflies decreased remarkably in the adult diet as chick rearing started, whereas the consumption of small Hymenoptera increased by the end of the chick provisioning period. Additionally, we found differences in the diet composition of adults and nestlings. The higher amount of bumblebees and dragonflies in the nestling diet was temporally associated with a decrease of these components in the adult diet, indicating that breeding birds preferentially feed larger prey items to their offspring than those that they consume themselves." 14105. Atwood, T.B.; Hammill, E.; Srivastava, D.S.; Richardson, J.S. (2014): Competitive displacement alters top-down effects on carbon dioxide concentrations in a freshwater ecosystem. *Oecologia* 175(1): 353-361. (in English) ["Climate change and invasive species have the potential to alter species diversity, creating novel species interactions. Interspecific competition and facilitation between predators may either enhance or dampen trophic cascades, ultimately influencing total predator effects on communities and biogeochemical cycling of ecosystems. However, previous studies have only investigated the effects of a single predator species on CO₂ flux of aquatic ecosystems. In this study, we measured and compared the individual and joint effects of predatory damselfly larvae (*Mecistogaster modesta*) and diving beetles on total prey biomass, leaf litter processing, and dissolved CO₂ concentrations of experimental bromeliad ecosystems. Damselfly larvae created strong trophic cascades that reduced CO₂ concentrations by ~46 % relative to no-predator treatments. Conversely, the effects of diving beetles on prey biomass, leaf litter processing, and dissolved CO₂ were not statistically different to no-predator treatments. Relative to multiplicative null models, the presence of damselfly larvae and diving beetles together resulted in antagonistic relations that eliminated trophic cascades and top-down influences on CO₂ concentrations. Furthermore, we showed that the antagonistic interactions between predators occurred due to a tactile response that culminated in competitive displacement of damselfly larvae. Our results demonstrate that predator identity and predator-predator interactions can influence CO₂ concentrations of an aquatic ecosystem. We suggest that predator effects on CO₂ fluxes may depend on the particular predator species removed or added to the ecosystem and their interactions with other predators." 14107. Ball-Damerow, J.E.; M'Gonigle, L.K.; Resh, V.H. (2014): Changes in occurrence, richness, and biological traits of dragonflies and damselflies (Odonata) in California and Nevada over the past century. *Biodiversity and Conservation* 23(8): 2107-2126. (in English) ["Increases in water demand, urbanization, and severity of drought threaten freshwater ecosystems of the arid western United States. Historical assessments of change in assemblages over time can help determine the effects of these stressors but, to date, are rare. In the present study, we resurveyed 45 sites originally sampled in 1914-1915 for Odonata adults throughout central California and northwestern Nevada, USA. We examined changes in species occurrence rates, taxonomic richness, and biological trait composition in relation to climate changes and human population increases. While species richness at individual sites did not change significantly, we found that odonate assemblages have become more similar across sites. Homogenization is a result of the expansion of highly mobile habitat generalists, and the decline of both habitat specialists and species with an overwintering diapause stage. Using a multi-species mixed-effects model, we found that overall occurrences of Odonata increased with higher minimum temperatures. Habitat specialists and species with a diapause stage, however, occurred less often in warmer regions and more often in areas with higher precipitation. Habitat specialists occurred less often in highly populated sites. Life history traits of Odonata, such as dispersal ability, habitat specialization, and diapause, are useful predictors of species-specific responses to urbanization and climate change in this region." 14114. Bhuyan, B. (2014): Monsoon prediction: the use of traditional knowledge. *Sai Om Journal of Science, Engineering & Technology* 1(7): 1-6. (in English) ["India is traditionally an agrarian country wherein, the farm sector accounts for 14 percent of the country's nearly \$2 trillion economy, with two-third of it's 1.2 billion populace living in rural areas. Indian agriculture is highly dependent on rain wherein, half of the country lacks irrigation facility. At the same time, almost 75% of the rain in India arrives during the four rainy months of monsoon season. Thus highly dependent on rain, the people in different part of the country from time immemorial have developed various traditional means and ways for the prediction of monsoon rain over the country. These knowledge of monsoon prediction are based on various tacit knowledge such as direction of winds and temperature, shape and type of clouds, various

bio indicators such as flowering of some particular plants, typical behaviour of birds, animals and insects, position of celestial bodies, almanac etc. This particular study has been done to look into many such traditional knowledge of prediction of monsoon based on literature available from different sources. The study reveals that many such indigenous practices prevails in almost every part of the country and people especially, the farmers, rely on these information to large extent and adjust their agricultural activity accordingly. Thus, it is felt that if this indigenous knowledge is combined with the latest space and information technology, the prediction of the various weather and climate related phenomena will be more accurate and efficient. This will in turn help mitigating various climate induced disaster such as flood, drought, famine etc to great extent. Dragonfly flying in a group at three to four meters from the ground level indicates rain in the evening." (Author)] Address: Bhuyan, B., Senior Research Scholar, CSRD / SSS / JNU, New Delhi, India. (2014): Intraspecific, interspecific, and seasonal differences in the diet of three mid-sized carnivores in a large Neotropical wetland. *Acta Theriologica* 59(1): 13-23. (in English) ["The diet and partitioning of food resources among mid-sized mammalian carnivores is poorly known, especially in the tropics. We evaluated the resource partitioning between *Leopardus pardalis* (ocelot), *Cerdocyon thous* (crab-eating fox), and *Nasua nasua* (brown-nosed coati) in the Pantanal of Brazil. Between December 2005 and February 2008, we collected data necessary to better understand interspecific, intraspecific, and seasonal variability in diet. Food habits were assessed by analysis of feces (n = 293) collected from known individuals (n = 128), and differences in dietary composition were evaluated through nonmetric dimensional scaling using the Jaccard similarity index. The main diet differences were observed between the specialist ocelot and the more generalist crab-eating fox and brown-nosed coati. Crab-eating foxes and brown-nosed coatis preyed on arthropods, fruits, and vertebrates whereas ocelots preyed almost entirely on vertebrates, mainly rodents and snakes. Ocelots' consumption of snakes was the highest ever recorded, as was the extent of carnivory by brown-nosed coatis. For the crab-eating fox and the brown-nosed coati, there were large differences between the use of fruits and animal foods in the wet and dry season. Yet for both species there were no significant differences in the diets of males and females. Despite the conspicuous sexual dimorphism and spatial segregation that are typical of brown-nosed coatis, the results do not support the hypothesis that size dimorphism is primarily an adaptation to reduce intersexual competition for food. Rather, dimorphisms and patterns of space use may be more related to competition among males for access to females." (Authors) The diet of the crab-eating fox also includes some Odonata.] Address: de Cassia Bianchi, Rita, Depto de Biologia Aplicada à Agropecuária, Univde Estadual

14116. Blakely, T.J.; Eikaas, H.S.; Harding, J.S. (2014): The SingScore: a macroinvertebrate biotic index for assessing the health of Singapore's streams and canals. *Raffles Bulletin of Zoology* 62: 540-548. (in English) ["Worldwide, lotic ecosystems have been greatly modified by urbanisation, which has resulted in the impairment of physico-chemical conditions and the degradation of benthic communities. Singapore represents one of the most densely populated and urbanised nations globally, with more than 7,000 people per km². Despite this high degree of urbanisation, relatively large forested areas remain in the Central Catchment Nature Reserve (CCNR) in the centre of the country. Thus, Singapore's lotic systems range from highly-impacted concreted canals in residential and commercial areas, to mildly-impacted, sand-dominated and forested streams within the CCNR. Although the use of macroinvertebrate biotic indices has a long history in freshwater ecology and they are now widely established in monitoring regimes around the world, few biotic indices have been developed for the tropics. This is particularly the case for Southeast Asia. We present the SingScore, a new biotic index developed for measuring the health of Singapore's lotic ecosystems using stream macroinvertebrates. We conducted extensive surveys of the macroinvertebrate communities inhabiting 47 study sites within streams, rivers and canals throughout Singapore's mainland, and measured a suite of physical and chemical parameters at all sites. We collected 59,116 macroinvertebrates, belonging to 74 different taxonomic groups (68 families and 6 higher taxa). Using multivariate ordination techniques and weighted averaging, we assigned tolerance scores (ranging from 1: pollution tolerant; to 10: pollution sensitive) to each of the 74 macroinvertebrate taxa. The SingScore was then calculated by summing the tolerance scores of all taxa present at a site and dividing by the number of taxa present at that site. The SingScore was multiplied by a constant of 20 to give SingScores between 0 and 200. We propose four likely water quality categories for running waters in Singapore: Poor (SingScore < 80), Fair (80–99), Good (100–119) and Excellent (120+). We envisage that the SingScore will enable more accurate monitoring of the health of Singapore's streams, rivers and canals." (Authors) The list of taxa includes Odonata, all at family level.] Address: Blakely, Tanja, Boffa Miskell, PO Box 110, Christchurch 8053, New Zealand

14117. Bode-Oke, A.; Zeyghami, S.; Dong, H. (2014): Effect of shape on wing kinematics control in dragonfly maneuvering flight (Abstract: L6.00007). *Bulletin of the American Physical Society*, 67th Annual Meeting of the APS Division of Fluid Dynamics, Volume 59, Number 18, Sunday–Tuesday, November 23–25, 2014; San Francisco, California: (in English) [Verbatim: Flying insects execute aerial maneuvers through fine modulations in their wing kinematics. It's yet not known that to what extend

the wing kinematics can be controlled and altered by the insect. To investigate the question, we recorded a yaw turn maneuver of a dragonfly in free flight. Our measurements show that this flight consists of two kinematically and dynamically distinct phases; acceleration and deceleration. In a systematic study, we first clipped the left forewing and then the right forewing of the same dragonfly and recorded its yaw turn maneuver. The signatures (in kinematics and dynamics) of the two identified phases stay unchanged by wing damage but the duration of both phases extends. The rotational velocity of the body drops dramatically by wing damage which implies the dragonfly is incapable of controlling the wing kinematics to achieve similar performance as in the intact wing. Our results suggest that the wing kinematics control is tightly influenced by the wing shapes and the aerodynamics of flapping flight.] Address: not stated

doi:10.1186/2191-0855-4-3: 9 pp. (in English) ["The design of biomaterial surfaces relies heavily on the ability to accurately measure and visualize the three-dimensional surface nanoarchitecture of substrata. Here, we present a technique for producing three-dimensional surface models using displacement maps that are based on the data obtained from two-dimensional analyses. This technique is particularly useful when applied to scanning electron micrographs that have been calibrated using atomic force microscopy (AFM) roughness data. The evaluation of four different surface types, including thin titanium films, silicon wafers, polystyrene cell culture dishes and dragonfly wings confirmed that this technique is particularly effective for the visualization of conductive surfaces such as metallic titanium. The technique is particularly useful for visualizing surfaces that cannot be easily analyzed using AFM. The speed and ease with which electron micrographs can be recorded, combined with a relatively simple process for generating displacement maps, make this technique useful for the assessment of the surface topography of biomaterials." 14121. Boulaaba, S.; Zrelli, S.; Boumaiza, M.; Rossaro, B. (2014): Relationships between physical and chemical factors and aquatic macroinvertebrates in perennial streams in the arid northern mountain basin El Batinah, Oman. *Journal of Entomological and Acarological Research* 46: 50-58. (in Arabia, Oman, arid zone, wadi, macroinvertebrates.) ["The relationships between physical properties, water chemistry and aquatic macroinvertebrates were investigated in riffles of four perennial streams in the arid northern Oman. Samples were collected monthly in autumn, winter and spring with a Surber net. Thirty two invertebrate taxa were recorded, most species are widely distributed, but few species with

very restricted distribution were also captured. Diptera followed by Pulmonata, Coleoptera and Odonata were the most represented taxa, Trichoptera and Heteroptera were a significant component only in one station (the Fezeh), where the lowest mean water temperature (23°C) was recorded. In the dry months from May to October, aquatic macroinvertebrates were completely absent. In order to summarise the community response some biotic indices were calculated. The highest diversity was observed in the Fezeh station. A seasonal gradient was also observed, with the highest diversity values in January, April, and December. The low faunal diversity was attributed to the high air and water temperature and the hydrological regime instability. A between station and a between month coinertia analysis was carried out, to analyse the response to spatial and seasonal factors. The first coinertia axis was correlated with altitude and substrate composition, while the second axis was correlated with air and water temperature. The present research emphasizes the urgency for preserving the less disturbed wadis in arid zones, because, despite their species poorness, their uniqueness in faunal composition requires special attention. The presence of few endemic species with very restricted distribution highlights the topicality and the value in investigating these areas, allowing the increase of our knowledge on biodiversity, ecology and biogeography about the benthic macroinvertebrates living in these extreme habitats." (Authors) The list of Odonata comprises of *Anax imperator*, *A. parthenope*, *A. ephippiger*, *Boyeria irene*, *Paragomphus genei*, *Orthetrum sabina*, *Sympetrum fonscolombii*, *Trithemis kirbyi*, and *Macromia splendens*. *B. irene* and *M. splendens* have definitely been misidentified.] Address: Rossaro, B., DeFENS, Dipartimento di Scienze per gli Alimenti, la Nutrizione e l'Ambiente, Università di Milano, Italy. 14122. Brookshire, B. (2014): Comparison of Odonata populations in natural and constructed emergent wetlands in the Bluegrass region of Kentucky. Poster presentation, Scholarship week. Eastern Kentucky University, April, 14-18 2014: 1 p. (in English) ["Wetlands provide valuable hydrological functions and provide valuable niches for many small species of animals, including dragonflies (Biebighauser 2011). Without wetlands serving as reproductive habitat the dragonfly population would decrease exponentially. Research has shown that in the past forty years Kentucky has lost up to 80% of its own natural wetlands (Brown & Richter 2012). Wetlands provide: •Niches for small mammals, insects, amphibians and birds •Hydrology and flood prevention for surrounding areas •Habitat and resting areas for Migratory Waterfowl. Odonates could be important to discovering many of the variations between natural and artificial wetlands. Dragonflies and Damselflies are sensitive to environmental conditions, therefore they can act as biological indicators. My objective in this research is to measure the Odonata populations at various natural and artificial emergent wetlands and to compare these populations to

biotic and abiotic variables such as hydrology, vegetation types and wetland condition. I believe that if the wetlands being studied prove to be healthy then the dragonfly and damselfly populations at the individual wetlands will be high in species richness and diversity, while the wetlands that are less healthy will have a low species richness and diversity." (Author) For details see: <http://encompass-eku.edu/context/swps/article/1026/type/native/viewcontent>] Address: Brookshire, Brittany, Department of Biological Sciences, Eastern Kentucky University, 521 Lancaster Ave, Richmond, KY 40475, USA

14123. Brown, C. A.; Anang, Y.; Okorie P. N. (2014): Role of the construction industry In promoting mosquito breeding in and around the Accra metropolis, Ghana. *International journal of scientific & technology research* 3(7): 94-100. (in English) ["A wide range of water-holding containers are exploited by mosquito vector as sites for oviposition of eggs and larvae development. The study was aimed at determining the role of the construction industry in promoting mosquito breeding in and around the Accra metropolis, Ghana. A two-month larval survey was carried out at selected construction sites in and around the Accra metropolis. Routine daily larval sampling was done from mosquito breeding sites at the construction sites using the dipper method. Larvae samples were collected from sites such as small pools of water collection and concrete water containers. The larval population was estimated for each breeding site and the physical and chemical characteristics of the breeding sites were recorded. The presence of other aquatic fauna and flora were also noted and recorded. Water samples for a total of 30 different construction sites were sampled. Seventy percent (21/30) of the breeding sites sampled were positive for mosquito larvae. A total of 1475 mosquito larvae comprising of the three main genera: *Culex*, *Aedes* and *Anopheles* were collected. *Culex* species occurred in all the breeding sites and made up 54.1% of the overall sample collection, followed by *Aedes* species (28.1%) and *Anopheles* species (17.8%). A number of other fauna and flora, non-target organisms, were observed both at the sites and in the collected samples. These included Odonata nymphs, Notonectidae, water snail (*Bulinus* species), tadpoles and algae. The results of this study indicate that residential development sites should be strongly considered for inclusion in the local mosquito surveillance and control programs in order to reduce the public health risk related to the construction industry." (Authors).] Address: Brown, C.A., Dept of Medical Lab. Sciences, School of Allied Health Sciences, P. O. Box KB 143, Accra, Ghana. E-mail: cabrown@chs.edu.gh

Cham, S.; Nelson, B.; Parr, A.; Prentice, S.; Smallshire, D.; Taylor, P. (2014): Atlas of Dragonflies in Britain and Ireland. Field Studies Council for the Biological Records Centre, Centre for Ecology & Hydrology (eds.), with the British Dragonfly Society. 280 pp. (in English) [Produced in partnership with the British Dragonfly Society and DragonflyIreland, this full colour hardback book (approx. 290 pages) represents five years work by volunteers and partner organisations to map the distribution of damselflies and dragonflies throughout Britain and Ireland. As well as summarising the distribution of over 1 million dragonfly records, the Atlas includes: •Species accounts, including maps, for all 56 resident and immigrant species recorded in Britain and Ireland. •Four pages devoted to each resident species. •Sections on habitats, conservation, distribution changes and phenology. •High quality colour photographs of all species and their habitats.

14127. Charest, P.; Savard, M. (2014): Découverte de l'épithète de Brunelle au Québec, une libellule secrète. *Le Naturaliste canadien* 138(2): 16-25. (in French, with English summary) ["The collection of dragonfly exuviae along the Batiscan and Trenche Rivers in the Mauricie region of Québec in 2012 and 2013, lead to the first record of *Neurocordulia michaeli* for the province. This species, which was recently described by Brunelle (2000), has a more northern distribution than *Neurocordulia yamasakanensis*. Both these shadowdragons are more frequent in the temperate zone than the Québec records suggest. The lack of observations is due largely to the secretive and crepuscular nature of the adults, which means that they are less likely to be encountered during standard dragonfly surveys. The results of this study show that the larvae of both species can co-occur along the same stretches of river in the Laurentian foothills. An illustrated species identification key based on the characteristics of their exuviae is provided." (Authors)] Address: Charest, Pierrette. chapie1@globetrotter.net

14128. Chiavacci, S.J.; Bednarz, J.C.; Benson, T.J. (2014): Does flooding influence the types and proportions of prey delivered to nestling Mississippi Kites? *The Condor* 116(2): 215-225. (in English, with Spanish summary) ["Mississippi Kites (*Ictinia mississippiensis*) nesting in the Mississippi Alluvial Valley, USA, have consistently exhibited poor reproductive success, reduced average clutch

sizes, and evidence of food stress during brood-rearing, raising concerns about population viability. Unlike populations elsewhere, kites nesting in the bottomland forests of this region face dynamic, anthropogenically altered hydrologic conditions that may be affecting the availability of important prey. Therefore, we quantified nestling diets and examined factors thought to be directly influencing the types and proportions of prey delivered to kite nestlings. Specifically, we sought to identify variables affecting the delivery of annual cicadas, the dominant prey item fed to kite chicks in numerous systems, as cicada emergence from subterranean burrows is known to be delayed by flooding. Using time-lapse video, we documented nestling diets and evaluated predictors of diet variability in east-central Arkansas, USA. We found that the delivery of cicadas increased with day of year, and was greatest during the driest of 4 study years. In contrast, the delivery of dragonflies, the numerically dominant prey item, declined with day of year, but increased with water level, and was lowest during the driest year. Although water level was not a strong predictor of the delivery of cicadas, interannual variation in the pattern of cicada deliveries suggests that flooding reduced the availability of this prey item to kites. Also, despite diverse nestling diets, the provisioning of dragonflies and a variety of other arthropods suggests that kites responded functionally to an absence of cicadas. The temporal patterns in prey deliveries that we detected imply that kite nestling diets in bottomland forests of the Mississippi Alluvial Valley may be influenced by water-level impacts on arthropod phenology and abundance. ... Nestling diet data recorded in 2004 and 2005 included 7 nests and 2,849 prey deliveries, the majority of which were cicadas (52.1%) and dragonflies (26.1%)." (Authors)] Address: Chiavacci, S.J. 14130. Cigognini, R.; Gallesi, M.M.; Mobili, S.; Hardersen, S.; Sacchi, R. (2014): Does character displacement

demonstrate density dependent expression in females? A test on the wing shape of two species of European damselflies. *Evol. Ecol.* 28: 941-956. (in English) ["Character displacement (CD) is the evolutionary process which leads to the divergence in trait expression of closely related species in regions where species co-occur, compared to allopatric populations. In Europe CD has been investigated in males of *Calopteryx splendens* and *C. virgo* and has been related to species recognition. If species recognition is relevant for males, also females should benefit from CD. The most obvious differences between females of these two species are wing profile and colour. We sampled females from allopatric and from sympatric populations with different relative abundances of these species. Wing shape and pigmentation were evaluated for each damselfly. CD was found in wing profile but not in wing transparency. The relative abundance of species significantly affected CD, but with a different pattern in each species. The prediction that wing shape become more different from the allopatric state when the species was relatively rare, but more similar to the allopatric state when the species was common was evident only for *C. splendens*. Wing shape changes might increase differences in flying patterns making males more effective to discriminate between heterospecific females. So, CD we observed may be the result of a selection directed to reduce interspecific reproductive interference."
