(2008): Changes in fish diets and food web mercury bioaccumulation induced by an invasive planktivorous fish. *Ecological Applications*, 18(8) Suppl., 2008: A213-A226. (in English) ["The invasion, boom, collapse, and reestablishment of a population of the planktivorous threadfin shad in Clear Lake, California, USA, were documented over a 20-yr period, as were the effects of changing shad populations on diet and mercury (Hg) bioaccumulation in nearshore fishes. Threadfin shad competitively displaced other planktivorous fish in the lake, such as inland silversides, young-of-year (YOY) largemouth bass, and YOY bluegill, by reducing zooplankton abundance. As a result, all three species shifted from a diet that was dominated by zooplankton to one that was almost entirely zoobenthos. Stable carbon isotopes corroborated this pattern with each species becoming enriched in $\delta^{13}C$, which is elevated in benthic vs. pelagic organisms. Concomitant with these changes, Hg concentrations increased by ~50% in all three species. In contrast, obligate benthivores such as prickly sculpin showed no relationship between diet or $\delta^{13}C$ and the presence of threadfin shad, suggesting that effects of the shad were not strongly linked to the benthic fish community. There were also no changes in Hg concentrations of prickly sculpin. The temporary extirpation of threadfin shad from the lake resulted in zooplankton densities, foraging patterns, isotope ratios, and Hg concentrations in pelagic fishes returning to pre-shad values. These results indicate that even transient perturbations of the structure of freshwater food webs can result in significant alterations in the bioaccumulation of Hg and that food webs in lakes can be highly resilient." - 9359.** Fraker, M.E. (2008): The dynamics of predation risk assessment: responses of anuran larvae to chemical cues of predators. *Journal of Animal Ecology* 77: 638-645. (in English) ["1. While the antipredator behaviour of prey has been well studied, little is known about the rules governing the predation risk assessment of prey. In this study, I measured the activity levels of predator-naïve green frog (*Rana clamitans*) tadpoles during and after exposures to the chemical cue of predatory larval dragonflies (*Anax longipes* and *A. junius*). I then used the lengths of the time lags from the end of the cue exposures until the tadpoles returned to a control level of activity as an index of the perceived risk of the tadpoles. 2. While tadpoles always responded upon exposure to the *Anax* chemical cue by strongly reducing their activity level, their perceived risk increased asymptotically over time during the initial period of the cue exposure. Tadpoles of all size classes perceived increasing risk in proportion to chemical cue concentration, but the length of time that tadpoles responded during cue exposure and the length of their post-exposure time lags decreased with increasing body mass. 3. The results suggest that the perceived risk of green frog tadpoles varies over time and does not correspond directly to their behavioural response (i.e. activity level). However, their perceived risk does appear to vary in accordance with the predation risk associated with the *Anax* chemical cue and the reliability of the information from the cue, and therefore may be predictable." - 9362.** Holzenthal, R. (2008): Nature's Design Identified. University of Minnesota, Department of Entomology, Newsletter 2008: 1-2-7. ["From October 9 through November 7, the Paul Whitney Larson Gallery in the St. Paul Student center was infested by insects. Well, actually it was infested by insect illustrations and pinned specimens from the Insect Museum. The Department of Entomology sponsored an exhibition entitled Nature's Design Identified: An Exhibition of Insect Illustrations With an estimated one million different species, insects are the most diverse group of organisms on Earth. In order to identify such a vast array of species, taxonomists rely on the exquisitely accurate illustrations of the insect's complex anatomy. It is this meticulous design that determines each individual species' identity. Based on the Entomology course "Scientific Illustration of Insects (ENT 5051)," the exhibition displayed examples of scientific illustration ranging from delicately hand-drawn pen and ink drawings from of the early twentieth century to digital artwork design by today's University of Minnesota students. Both 'traditional' and digital illustrations were displayed. Traditional techniques used include pen and ink, coquille board, watercolour, and mixed use of acrylic paint and coloured pencils; digital illustrations were created in Adobe Illustrator using the pen tool to create weighted line illustrations as well as the gradient mesh tool to create more complex illustrations in black and white and colour. Adobe Photoshop was used to render highly realistic colour digital paintings using primarily the digital brush and varying its hardness, opacity and colour were displayed. The illustrations were displayed alongside pinned specimens of the actual insects portrayed. Contributions to the University of Minnesota Insect Collection began in 1879 with specimens of insects and spiders from the North Shore of Lake Superior. During the last 130 years, the Collection's holdings have grown from a regional collection of 3,000 specimens to a major national and international resource of almost 3,700,000 specimens. In the most recent survey, the Collection ranked as the 8th largest university-affiliated insect collection in North America. Enhancing the Collection's status as an outstanding research facility are 7 resident taxonomists, computerized inventory management and specimen databases, a large departmental library, and a molecular taxonomy laboratory. Research projects associated with the Collection have broad taxonomic and geographic scope. Faculty and graduate student research focuses on both aquatic and terrestrial insect groups and includes taxonomic, phylogenetic, and applied questions. The Collection is the mainstay of graduate training in systematic entomology at the University of Minnesota. Artists included in the exhibition were: Courtney Amundson, Roger Blahnik, Louise Bush, Lourdes Chamorro, Kevin Denny, Lydia M. Hart, Ralph Holzenthal, Sharolyn Kawakami, Kris Kuda, Haude Levesque, Stephanie Lyon, Julie Martinez, Rufus H. Pettit, Manuel Ramirez Desiree Robertson." (Eds.): Aquatic Insects: Challenges to Populations: Proceedings of the Royal Entomological Society's 24th Symposium. Cabi Publishing. 332 pp: 36-54. (in English) ["Cannibalism has strong impacts on population structure and population dynamics. Dragonfly larvae are important predators in aquatic systems and cannibalism is common in these larvae. Dragonflies are therefore an important model system that can be used for a thorough understanding of the dynamic interactions that shape community structure in aquatic systems. In this review we bring up the costs and benefits of cannibalism in general terms. We then briefly discuss important mechanism that affects the intensity and degree of cannibalism in dragonfly larvae: intraspecific density, alternative prey, habitat structure, size structure and time constraints. Thereafter we review general theoretical models that consider the population dynamics of cannibalism. We also provide some empirical evidence for the model predictions by using dragonfly larvae as examples. Finally, we suggest some avenues for further research on cannibalism." 9372. Meyer, C.K.; Whiles, M.R. (2008): Macroinvertebrate communities in restored and natural Platte River slough wetlands. *J. N. Am. Benthol. Soc.* 27(3): 626-639. (in English) ["Wetlands in the central Platte River basin provide numerous ecosystem services but have been diminished and degraded by agricultural practices and development. Wetland restoration is increasingly common in this region, but the success of restorations is virtually unknown. We sampled macroinvertebrates during spring 2003 and 2004 in restored (5–16 y old) and natural slough wetlands to assess restoration success. Simple measures (e.g., total abundance, biomass, diversity) were all similar in restored and natural wetlands. Communities were similar in natural and restored wetlands, but we observed some taxonomic differences. For example, abundances of *Helisoma* and *Pisidium* and abundance and biomass of amphipods were higher in natural than in restored wetlands, and leeches were collected only in natural wetlands. These results suggest that dispersal ability is a biotic filter limiting recovery and that these noninsects are good candidates for assessing recovery. Functional structure on the basis of abundance was similar between natural and restored wetlands, but some differences in biomass-based estimates were evident. For example, relative biomass of collector-filterers was higher in natural than in restored wetlands in 2003. Multivariate analyses indicated that factors such as hydroperiod might be more important than restoration status in shaping wetland macroinvertebrate communities. Furthermore, drought conditions constrained our sampling efforts and influenced temporal patterns, thereby underscoring the need for multiyear studies, especially under extreme environmental conditions. Our results indicate that wetland macroinvertebrate communities in this region are resilient and recover rapidly after restoration, but that ongoing restoration and management efforts should focus on hydrology, which might limit recovery in restorations and is a critical factor shaping wetland macroinvertebrate communities." (Authors) Taxa, including Odonata, are treated at the order level.] Address: Meyer, C.K., Dept of Zoology & Center for Ecology, Southern Illinois Univ. 9379. Sahuquillo, M.; Miracle, M.R.; Rieradevall, M.; Kornijów, R. (2008): Macroinvertebrate assemblages on reed beds, with special attention to Chironomidae (Diptera), in Mediterranean shallow lakes. *Limnetica* 27(2): 239-250. (in English, with Spanish summary) ["Macroinvertebrate assemblages on reed beds, with special attention to Chironomidae (Diptera), in Mediterranean shallow lakes Macroinvertebrates associated to reed-beds (*Phragmites australis*) in six shallow natural water bodies along the 220 km of coast of the Comunidad Valenciana (Spain) were studied. These sites were selected to reflect different trophic states, but also, and due to the natural variability of mediterranean wetlands, they greatly differ in salinity and hydroperiod. To unify the sampling, reed bed was chosen to provide data from a habitat common to all wetlands, including the most eutrophic ones where submerged macrophytes have disappeared due to water turbidity. Individual submerged stems of *Phragmites australis* were sampled along with the surrounding water. The animal density found refers to the available stem surface area for colonization. Forty-one taxa were recorded in total, finding Chironomidae to be the most important group, quantitatively and qualitatively. In freshwater sites it was observed an increase in macroinvertebrate's density at higher trophic states. Nevertheless each studied region had a different fauna. The PCA analysis with macroinvertebrate groups distinguished three types of environment: freshwaters (characterized by swimming insect larvae, collectors and predators, oligochaetes and Orthocladiinae), saline waters (characterized by crustaceans and Chironominae) and the spring pool, which shares both taxa. Chironomids were paid special attention for being the most abundant. A DCA analysis based

on the relative abundance of Chironomids reveals salinity as the main characteristic responsible for its distribution, but trophic state and hydrological regime were also shown to be important factors." (Authors) The study includes *Ischnura elegans* and *Sympetrum fonscolombii*.] Address: Sahuquillo, Maria, Dept. de Microbiologia i Ecologia. (in English) ["Despite New York City's mountains of concrete and dense population, its natural areas provide an important refuge for many species of wildlife. Most of the city's undeveloped land is in the borough of Staten Island, much of it in private ownership. As these green spaces quickly disappear, parkland becomes essential to the continued survival of local wildlife species. The 110-acre Ocean Breeze Park is a unique natural area in northern Staten Island supporting an incredible diversity of flora and fauna. Originally an estuarine salt marsh, the site was filled in, over time developing into a complex of seasonal freshwater wetlands within open, sandy uplands. An unusual habitat type in the metropolitan area, Ocean Breeze Park has the highest odonata species count in the city for any one year in recent times, including three New York State rare species, *Ischnura ramburii*, *I. hastata*, and *Libellula needhami*. [...] As recent survey work took place only in 2007, further exploration of the park will likely yield more interesting finds of both invertebrate and vertebrate species." (Authors)] Address: Stanley, Susan, New York City Dept of Parks & Recreation, Natural Resources Group, New York, NY, USA

9384. Termaat, T.; Groenendijk, D.; Bouwman, J. (2008): Monitoring dragonflies Europe: report on a successful symposium. *Vlinders* 4/2008: 6-7. (in Dutch) ["The International Symposium on Monitoring Dragonflies in Europe took place in Wageningen on 13th and 14th June 2008. The symposium was one of many activities organised this year by Dutch Butterfly Conservation to mark their 25th anniversary. We wanted to bring people together, to exchange experiences and discuss the possibilities of a European monitoring project. We had invited people from as many countries

as possible whom we knew were already involved in monitoring, or those hoping to be so in the future; 35 people came from eleven countries! On the first day, we heard lectures about how dragonfly work was organized in the various countries, whether monitoring was carried out, and if so, how? At the end of the day, there was a discussion on the easiest and most practical way of combining current initiatives to create a European monitoring network. The excursion to the wetland De Weerribben the next day gave the participants the chance to see typical lowland bog species. It was suggested that a congress be held every two years, with a wider choice of subjects. Portugal in 2010?" (Authors)] Address: Termaat, T., Rijnsteeg 8-10a, 6708 PP Wageningen, The Netherlands

(in French, with English summary) ["This paper presents the first results of Odonata surveys in the northern part of the Ariège department, France between the Ariège and Hers Vif rivers. During these surveys, a large population of *Coenagrion mercuriale* was recorded in the "Ariège plain" and few individuals of *Oxygastra curtisii* were seen on the Hers Vif river." (Authors)] Address: Tessier, M., 62 chemin del prat, 31320, Auzeville-Tolosane, France. E-mail: marc.tessier3@free.fr

9387. Todd, J.H.; Ramankutty, P.; Barraclough, E.I.; Malone, L.A. (2008): A screening method for prioritizing non-target invertebrates for improved biosafety testing of transgenic crops. *Environ. Biosafety Res.* 7: 35-56. (in English) ["We have developed a screening method that can be used during the problem formulation phase of risk assessment to identify and prioritize non-target invertebrates for risk analysis with any transgenic plant. In previously published protocols for this task, five criteria predominated. These criteria have been combined by our method in a simple model which assesses: (1) the possible level of risk presented by the plant to each invertebrate species (through measurements of potential hazard and exposure, the two principal criteria); (2) the hypothetical environmental impact of this risk (determined by the currently known status of the species' population in the ecosystem and its potential resilience to environmental perturbations); (3) the estimated economic, social and cultural value of each species; and (4) the assessed ability to conduct tests with the species. The screening method uses information on each of these criteria entered into a specially designed database that was developed using Microsoft Access 2003. The database holds biological and ecological information for each non-target species, as well as information about the transgenic plant that is the subject of the risk

assessment procedure. Each piece of information is then ranked on the basis of the value of the information to each criterion being measured. This ranking system is flexible, allowing the method to be easily adapted for use in any agro-ecosystem and with any plant modification. A model is then used to produce a Priority Ranking of Non-Target Invertebrates (PRONTI) score for each species, which in turn allows the species to be prioritized for risk assessment. As an example, the method was used to prioritize non-target invertebrates for risk assessment of a hypothetical introduction of *Bacillus thuringiensis* (Bt) Cry1Ac-expressing *Pinus radiata* trees into New Zealand." (Author) *Antipodochlora braueri* was selected as one of 80 test species.] Address: Todd, Jacqui, The Horticulture and Food Research Institute of New Zealand Limited, Mt Albert, Private Bag 92169, Auckland Mail Centre, Auckland 1142, New Zealand. (in Spanish, with English summary) ["Dragonfly diversity was estimated in the Agricultural Center Cotove (Santafé de Antioquia-Colombia). Active capture using an entomological net was used. Each transect was located perpendicular to the water body, for a length of approximately 200 m and a lateral extension of 8 m. Twenty Odonata species were registered, from 5 families and 15 genus. Libellulidae showed the biggest abundance and richness, with 65 specimens that represent 53.7% of the total abundance, and 12 species that represent 60% of the registered community. The alpha diversity was high in the forest in reference at crop; however, the low abundances register highlight the need for greater sampling effort in cultivating, for a better estimate of gamma diversity; the beta diversity was of 12 species and the complementary index was of 0.6, it indicates that the Odonata's fauna is characteristic and distinctive for each use of soil." (Author)] Address: Altamiranda Saavedra, M., Universidad Nacional de Colombia, Sede Medellín. Facultad de Ciencias. A.A. 3840, Medellín, Colombia. E-mail: marianoaltamirandas@hotmail.com

9397. Brydegaard, M.; Guan, Z.; Wellenreuther, M.; Svanberg, S. (2009): Insect monitoring with fluorescence lidar techniques: feasibility study. *Applied Optics* 48(30): 5668-5677. (in English) ["We investigate the possibilities of light detection and ranging (lidar) techniques to study migration of *Calopteryx splendens* and *C. virgo*. Laboratory and testing-range measurements at a distance of 60 m were performed using dried, mounted damselfly specimens. Laboratory measurements, including color photography in polarized light and spectroscopy of reflectance and induced fluorescence, reveal that damselflies exhibit reflectance and fluorescence properties that are closely tied to the generation of structural color. Lidar studies on *C. splendens* of both genders show that gender can be remotely determined, especially for specimens that were marked with Coumarin 102 and Rhodamine 6G dyes. The results obtained in this study will be useful for future field experiments, and provide guidelines for studying damselflies in their natural habitat using lidar to survey the air above the river surface. The findings will be applicable for many other insect species and should, therefore, bring new insights into migration and movement patterns of insects in general." 9398. Byers, C.J.; Eason, P.K. (2009): Conspecifics and their posture influence site choice and oviposition in the damselfly *Argia moesta*. *Ethology* 115(8): 721-730. (in English) ["Finding a suitable oviposition site can be costly because of energy and time requirements, and ovipositioning can be dangerous because of the risk of predation and harassment by males. *A. moesta* oviposits, contact-guarded by her mate, on vegetation in streams. Oviposition aggregations are commonly observed in this species, despite their territorial nature during other behaviours. We conducted experiments in the field to test the hypothesis that aggregations are the result of conspecific attraction. In the first experiment, two oviposition sites (sycamore leaves) were provided, one with models of ovipositing pairs, and one without. In the second experiment, one leaf again had ovipositing models, while the other had models of uncoupled males and females in a resting posture. In both experiments, damselfly pairs preferred the site with ovipositing models. In general, they visited the ovipositing models first more often than expected by chance, stayed longer there, were more likely to oviposit there, and laid a greater total number of eggs there. These results support the hypothesis that conspecific attraction is responsible for ovipositing aggregations in *A. moesta* and that posture is an important cue for attraction. Using conspecific cues could be a beneficial strategy to save in search costs while taking advantage of the presence of ovipositing conspecifics to dilute the effects of harassment and predation." (2009): Bewertung des österreichischen Bodenseeuferes auf der Grundlage libellenkundlicher Untersuchungen. *Schriftenreihe Lebensraum Vorarlberg* 59: III, 43 pp. (in German, with English summary) ["The ecological status of the littoral areas of Lake Constance in Austria was assessed by a dragonfly survey. A key element of the approach, which is oriented towards the Water Framework Directive (WFD), is the Odonata Habitat Index. The assessment is based on the comparison between the status quo and a reference condition derived from current and historical data on dragonflies and macrophytes. A total of 28 species were recorded at 15 investigation sites, 25 species were classified as autochthonous. The ecological status of the lake shore section was ranked as class II ("good ecological status") in the 5-tiered WFD classification scheme." (Authors)] Address: Chovanec, A., Krottenbachgasse 68, A-2345 Brunn am Gebirge, Austria.

9401. Ciemiński, J.; Zdanowski, B. (2009): Changes in the zoobenthos structure in a system of heated lakes in central Poland. *Arch. Pol. Fish.* 17: 221-238. ["The aim of the study was to identify changes in the quality and quantity structure of the zoobenthos assemblages inhabiting the lakes, channels, and basins that comprise the cooling system of a power plant in central Poland. By comparing the invertebrate fauna occurring on the freshwater clam *Sinanodonta woodiana* (Lea) and the macrophyte *Vallisneria spiralis* (L.), the significance of exotic species in the development of invertebrate macrofauna species was demonstrated. The zoobenthos inhabiting the channels was poorer quantitatively and qualitatively than was the lake zoobenthos. Factors that determined this included thermal and oxygen conditions and water flow. Elements that enriched the development of the zoobenthos and the zooperiphyton included populations of alien zebra mussel *Dreissena polymorpha* Pallas and *S. woodiana*, and assemblages of *Myriophyllum spicatum* L. and *Ceratophyllum demersum* L. In comparison to thirty years ago, the quality of the bottom fauna in the system has decreased." (Authors)] The study includes records of *Platycnemis pennipes*, *Coenagrion pulchellum*, *Calopteryx virgo*, and *Calopteryx* sp.] Address: Zdanowski, B., Department of Hydrobiology, The Stanislaw Sakowicz Inland Fisheries Institute in Olsztyn, ul. Oczapowskiego 10, 10-718 Olsztyn, Poland. E-mail: bzdanowski@infish.com.pl

- 9402.** Clopton, R.E. (2009): Phylogenetic relationships, evolution, and systematic revision of the septate gregarines (Apicomplexa: Eugregarinorida: Septatorina). *Comparative parasitology* 76(2): 167-190. (in English) ["A phylogenetic hypothesis was constructed with the use of ssu rDNA sequence data from 27 eugregarine species parasitizing a variety of arthropod hosts and habitats. The data were used to address higher-level character transitions, identify clades, recognize supraspecific taxonomic groups, assess the existing gregarine classification, and assess the effects of host metabolic pattern and habitat transitions on the radiation of the septatorinid gregarines. [...] Trophozoites, gamonts, and gametocysts of *Geneiorhynchus manifestus* were collected as part of the original type series collection from naiads of *Anax junius* collected from Beaver Slide Pond, Big Sandy Creek Unit, Big Thicket National Preserve, Polk County, Texas, USA (30°38'49"N; 96°17'64"W) in February 2006. [...] Trophozoites, gamonts, and gametocysts of *Prismatospora evansi* were collected from naiads of *Anax junius* collected from Collins Pond, Big Sandy Creek Unit, Big Thicket National Preserve, Polk County, Texas, USA. (30°47'78"N; 94°12'81"W) in February 2006. [...] Trophozoites, gamonts, and gametocysts of *Hoplorhynchus acanthatholius* were collected from adults of *Enallagma civile* collected from Optimist Lake, Auburn, Nemaha County, Nebraska, USA (40°23'94"N; 95°50'24"W) during July–August 2007. [...] Hemimetabolic insect life cycles are found only in truly aquatic insect orders. In the analysis presented herein, hemimetabolic hosts are exploited only by the Actinocephalidae. Patterns of host-stadium specificity are more complex in this group. Host-stadium specificity is observed in species of *Prismatospora* and *Geneiorhynchus*, which infect dragonfly naiads (Anisoptera) but not in species of *Hoplorhynchus*, which infect damselfly naiads and adults (Zygoptera). As a general trend, anisopterans are strong fliers with comparatively large home ranges, and zygopterans are weak fliers with small home ranges. Adult anisopterans are rarely infected, probably because they are exploiting a different, perhaps nonaquatic, resource base than are their naiads. Although physiologically hemimetabolic, from a gregarine's point of view anisopteran hosts are holometabolic ecological actors, whereas zygopteran hosts are hemimetabolic ecological actors." - 9409.** Dolson, R.; McCann, K.; Rooney, N.; Ridgway, M. (2009): Lake morphometry predicts the degree of habitat coupling by a mobile predator. *Oikos* 118: 1230-1238. (in English) ["Habitat coupling is an ecosystem process whereby semi-discontinuous habitats are connected through the movement of energy and nutrients by chemical, physical or biological processes. One oft-cited example is that of littoral pelagic coupling in lakes. Theory has argued that such habitat coupling may be critical to food web dynamics, yet there have been few empirical studies that have quantified ecological factors that affect the degree of habitat coupling in ecosystems.

Specifically, the degree to which habitat coupling occurs across important physical gradients has largely been ignored. To address this, we investigate the degree of littoral habitat coupling (i.e. the degree to which a top predator lake trout, *Salvelinus namaycush*, derives energy from the littoral zone) along a gradient of lake shape, where lake shape modifies the relative quantity of coupled epilimnetic benthic and pelagic habitats within each lake. Herein we demonstrate that littoral habitat coupling is intensified in simple circular lakes compared to their reticulate counterparts in seven Canadian Shield lakes. Although the more reticulate lakes had larger areas of epilimnetic benthic habitat, littoral food sources comprised 11% compared to 24% of lake trout diet in reticulate and circular lakes, respectively. This heightened interaction in circular lakes also appears to translate into increased omnivory in more circular lakes compared to reticulate lakes such that lake trout of circular lakes have a significantly lower trophic position than lake trout of reticulate lakes ($F_{1,5} = 6.71$, $p = 0.05$). These results suggest that it is the accessibility of littoral production via thermal refugia, and not the amount of littoral production, that determines the degree to which lake trout couple littoral and pelagic habitats in lakes. [...] Due to low snail abundance in some lakes, littoral grazing [sic] benthic invertebrate specimens (Odonata and Ephemeroptera, $n = 6-8$ per lake) were incorporated into the littoral carbon baseline signature." ((Authors)] Address: Dolson, Rebecca, Dept of Integrative Biology, Univ. of Guelph, Guelph, ON, N1G 2W1, Canada. E-mail: rebecca.dolson@gmail.com

9410. Dominiak, P.; Michalczuk, W. (2009): Two species of biting midges (Diptera: Ceratopogonidae) new to the Polish fauna. *Dipteron* 25: 8-13. (in Polish, with English summary) (http://pte.au.poznan.pl/dipteron/biuletyn/vol25/Dipteron_vol_25.pdf) ["*Forcipomyia paludis* (Macfie, 1936) and *Monohalea estonica* Remm, 1965 are recorded from Poland for the first time. As a result the number of biting midges species in the Polish fauna increased to 215. Females are briefly diagnosed and illustrated, geographical distribution analysed and Odonata hosts of parasitic *Forcipomyia paludis* reviewed." 9417. Gallardo, B.; Gascon, S.; Garcia, M.; Comin, F.A. (2009): Testing the response of macroinvertebrate functional structure and biodiversity to flooding and confinement. *J. Limnol.* 68(2): 315-326. (in English) ["The aim of the present study was to investigate the relative importance of flooding- and confinement-related environmental features in explaining macroinvertebrate trait structure and diversity in a pool of wetlands located in a Mediterranean river floodplain. To test hypothesized trait-environment relationships, we employed a recently implemented statistical procedure, the fourth-corner method. We found that flooding-related variables, mainly pH and turbidity, were related to traits that confer an ability of the organism to resist flooding (e.g., small body-shape, protection of eggs) or recuperate faster after flooding (e.g., short life-span, asexual reproduction). In contrast, confinement-related variables, mainly temperature and organic matter, enhanced traits that allow organisms to interact and compete with other organisms (e.g., large size, sexual reproduction) and to efficiently use habitat and resources (e.g., diverse locomotion and feeding strategies). These results are in

agreement with predictions made under the River Habitat Templet for lotic ecosystems, and demonstrate the ability of the fourth-corner method to test hypothesis that posit trait-environment relationships. Trait diversity was slightly higher in flooded than in confined sites, whereas trait richness was not significantly different. This suggests that although trait structure may change in response to the main environmental factors, as evidenced by the fourth-corner method, the number of life-history strategies needed to persist in the face of such constraints remains more or less constant; only their relative dominance differs." (Authors) Odonata (Coenagrion) were more abundant in confined habitats.] Address: Gallardo, Belinda, Pyrenean Institute of Ecology (CSIC), Avda. Montañana 1005, 50192 Zaragoza, Spain. 9418. Groenendijk, D.; Plate, C. (2009): Positive population trends for odonates. *Vlinders* 3/2009: 22-24. (in Dutch, with English summary) ["The Dutch Monitoring Scheme shows that, in general, the year 2008 can be regarded as a good year for odonates. Monitoring routes have been set out in various habitats, along streams, ponds and pools, and across peat bogs. The population trends in the coastal dunes seem to differ from those calculated for inland water bodies, being quite negative for common species. Inland, the improved water quality results in higher numbers of odonates. In addition, some rare species benefit from the improved water quality of their habitats. The monitoring results confirm that dragonflies are useful indicators of the habitat quality of Dutch wetlands." 9423. Kalyoncu, H.; Gülboy, H. (2009): Benthic macroinvertebrates from Darýören and Isparta streams (Isparta/Turkey) – Biotic indices and multivariate analysis. *Journal of Applied Biological Sciences* 3(1): 79-86. (in English) ["During 2003 -2004, seventy-two samples were collected from 6 sampling points on Isparta stream basin (Isparta/Turkey). Macrozoobenthic organisms and physico-chemical parameters were investigated to assess the impact of the pollution on macrozoobenthos assemblages. Ecological methodologies (species richness, diversity and family biotic indices and multivariate analysis) were employed to assess the impact of the pollution on macrozoobenthic assemblages. During the study, totally 27293 specimens were collected from six sampling points. These belonged to 83 taxa distributed into 6 taxonomic groups as follows: Plathelminthes, Mollusca, Annelida, Crustacea, Insecta, and Arachnida. Biological oxygen demand, NH4-N, NO3-N, NO2-N SO4, conductivity, total hardness and turbidity parameters were measured higher in the 3rd and 6th sampling points, while dissolved oxygen amount was the lowest in these. pH was variable. In this study, the number of species is the highest at station 1, which is also reflected by Margalef and Shannon-Weaver indices. As the amount of pollution is higher at stations 3 and 6, the number of species is fewer in these stations compared to the others. Sampling points 1, 2, 4 and 5 were of good water quality levels. Changes in water quality levels were better reflected by species richness, diversity indices and principal component analysis than pollution indices in Isparta stream." (Authors) Odonata taxa are treated at the genus level with the exception of *Epallage fatime*.] Address: Kalyoncu, H., S. Demirel University Faculty of Arts and Sciences Department of Biology 32260 Isparta, Turkey. E-mail: kalyoncu@fef.sdu.edu.tr

9424. Kato, Y.; Takemon, Y.; Hori, M. (2009): Invertebrate assemblages in relation to habitat types on a floating mat in Mizorogaike Pond, Kyoto, Japan. *Limnology* 10(3): 167-176. (in English) ["Abiotic environmental variables and invertebrate assemblages were compared among four habitat types (bare hollow, sphagnum-rich hollow, pool, and mat edge) on a floating mat in Mizorogaike Pond, Kyoto. We found differences in abiotic environments between two hollows and two inundated habitats (pool and mat edge); pH was significantly lower in hollow habitats than in inundated habitats, and water depths were significantly shallower in sphagnum-rich hollows than in inundated sites. The composition of invertebrate assemblages in the hollow was distinct from that in the inundated habitats. The abundances of some dominant invertebrate taxa or functional feeding groups on the floating mat differed between the hollows and inundated habitats, and were correlated with water temperature, pH and depth. These results indicate that

habitat heterogeneity created by the coexistence of hollows and inundated habitats contributes to species diversity on the floating mat in Mizorogaike Pond. A comparison of the pH values in different wetlands revealed that both bog- and fen-specific components coexist within this system. In order to adequately manage and conserve peatland ecosystems, it is necessary to consider the importance and vulnerability of both hollows and inundated habitats in peatlands." (Authors) *Ceriagrion melanurum* was significantly more abundant at mat edges than in pools and the two types of hollows. The following taxa have been recorded in the nymphal stage: *Ceriagrion nipponicum*, *Aciagrion migratum*, *Lestes sponsa*, *Sympetrum speciosum speciosum*, *S. eroticum eroticum*, *S. pedemontanum elatum*, *Nannophya pygmaea*, *Crocothemis servilia*, *Libellulidae*] Address: Kato, Y., Laboratory of Animal Ecology, Dept. of Zoology, Graduate School of Science, Kyoto Univ., Kitashirakawa-oiwake, Sakyo, Kyoto 606-8502, Japan. 9427. Kim, W.-K.; Kob, J.H.; Park, H.C.; Byun, D. (2009): Effects of corrugation of the dragonfly wing on gliding performance. *Journal of Theoretical Biology* 260 (4): 523-530. (in English) ["We investigate the aerodynamic performance of the dragonfly wing, which has cross-sectional corrugation, via a static 2-dimensional unsteady simulation. Computational conditions are $Re = 150, 1400, \text{ and } 10,000$ with angles of attack ranging from 0° to 40° . From the computational results, lift coefficients are increased by the wing corrugation at all Reynolds number. However, the corrugation has little influence on the drag coefficients. The flows such as vortex in the valley of corrugation and near the edge of the corrugation are locally different from those of an elliptic wing. However, such local flows have little influence on the time averaged wing performance. From the numerical experiment presented in this study, it is determined that suction side corrugations of the wing have very little influence on increase of the lift coefficient at a positive angle of attack." 9430. Levy, D.-E.; Seifert, A. (2009): Simplified dragonfly airfoil aerodynamics at Reynolds numbers below 8000. *Phys. Fluids* 21: 17 pp. (in English) ["Effective aerodynamics at Reynolds numbers lower than 10000 is of great technological interest and a fundamental scientific challenge. The current study covers a Reynolds number range of 2000–8000. At these Reynolds numbers, natural insect flight could provide inspiration for technology development. Insect wings are commonly characterized by corrugated airfoils. In particular, the airfoil of the dragonfly, which is able to glide, can be used for two-dimensional aerodynamic study of fixed rigid wings. In this study, a simplified dragonfly airfoil is numerically analyzed in a steady free-stream flow. The aerodynamic performance (such as mean and fluctuating lift and drag), are first compared to a "traditional" low Reynolds number airfoil: the Eppler-E61. The numerical results demonstrate superior performances of the corrugated airfoil. A series of low-speed wind and water tunnel experiments were performed on the corrugated airfoil, to validate the numerical results. The findings indicate quantitative agreement with the mean wake velocity profiles and shedding frequencies while validating the two dimensionality of the flow. A flow physics numerical study was performed in order to understand the underlying mechanism of corrugated airfoils at these Reynolds numbers. Airfoil shapes based on the flow field characteristics of the corrugated airfoil were built and analyzed. Their performances were compared to those of the corrugated airfoil, stressing the advantages of the latter. It was found that the flow which separates from the corrugations and forms spanwise vortices intermittently reattaches to the aft-upper arc region of the airfoil. This mechanism is responsible for the relatively low intensity of the vortices in the airfoil wake, reducing the drag and increasing the flight performances of this kind of corrugated airfoil as compared to traditional low Reynolds number airfoils such as the Eppler E-61." (Authors)] Address: Seifert, A., School of Mechanical Engineering, Faculty of Engineering, Tel-Aviv University, Tel Aviv 69978, Israel

9431. Lok, A.F.S.L.; Orr, A.G. (2009): The biology of *Euphaea impar* Selys (Odonata: Euphaeidae) in Singapore. *Nature in Singapore* 2: 135-140. (in English) [According to specimens deposited in the Zoological Reference Collection (ZRC), Raffles Museum of Biodiversity Research, National University of Singapore, *Euphaea*

impar was first recorded in Singapore in 1992 at Nee Soon Swamp Forest. The typical habitat of *E. impar* in Singapore is usually near relatively pristine, clear, shallow-flowing streams in primary or secondary forest, with a sandy or slightly muddy substrate with accumulations of detritus and leaf litter, and sometimes with large rocks. The stream banks are usually well-vegetated, providing suitable perches from which the males guard their territory. The vividly-coloured males are somewhat more frequently encountered because they are usually seen along streams, whereas the duller females are usually encountered in the shady undergrowth. Typically, there are three main types of habitats of *E. impar* in Singapore: firstly sandy, clear-water streams with dense marginal vegetation, secondly, a muddy braided stream system at the lower reaches of the Sime Road Forest where the canopy consists predominantly of pulai paya (*Alstoma spathula*) and has a relatively open undergrowth, thirdly, small forest streams with muddy bottoms (especially in the Nee Soon Swamp Forest). *E. impar* is very sensitive to movement, making approaching it for photographing difficult, with the subject flying higher and higher when disturbed. Flash photography also can be very difficult with this species and requires careful and prolonged stalking until the subject becomes accustomed to the flash and ceases to fly away with each discharge.] Address: Lok, A., Dept Biol. Sciences, National University Singapore, 14 Science Drive 4, Singapore 117543, Republic of Singapore. E-mail: dbsloks@nus.edu.sg

9432. Lopez, J.A.; Scarabotti, P.A.; Medrano, M.C.; Ghirardi, R. (2009): Is the red spotted green frog *Hypsiboas punctatus* (Anura: Hylidae) selecting its prey? The importance of prey availability. *Revista de Biología Tropical* 57(3): 847-857. (in English) ["Notwithstanding, the lack of food resources data in many studies of amphibians feeding has led to partial understanding of frog feeding strategies. In this study we evaluate the trophic selectivity of a *Hypsiboas punctatus* population from a Middle Paraná River floodplain pond in Argentina, and discuss the importance of prey availability data when interpreting results from diet analysis. We analyzed the gut contents of 47 *H. punctatus* adults and compared frog's diet with the environmental food resources. Prey availability was estimated by systematically seep-netting the microhabitat where anurans were localized foraging. We identified 33 taxonomic categories from gastrointestinal contents. Numerically, the most important prey categories were dipterans, followed by hemipterans, homopterans and coleopterans. The diet similarity between males and females was high and no statistical differences in diet composition were found. The most abundant food resources in the environment were dipterans, coleopterans, homopterans and collembolans. In order to assess whether frogs were selecting their preys, we calculated Pianka's niche overlap index and Jacobs' electivity index comparing gut contents to prey availability data. Trophic niche overlap was medium but significantly higher than expected by chance. The electivity index indicated that *H. punctatus* foraged dipterans slightly above their environmental abundance. Among the secondary preys, hemipterans were foraged selectively, homopterans were consumed in the same proportion to their occurrence in the environment, coleopterans were foraged quite under their availability and collembolans were practically ignored by frogs. Without food resources data, *H. punctatus* could be classified as a specialist feeder, but dipterans

also were quite abundant in the environment. Our results show that *H. punctatus* fit better as a generalist feeder, foraging on their main food item and some secondary preys in similar proportion to their environmental availability; even though other secondary preys are being selectively preferred or ignored by frogs. Our data illustrate the importance of including the resource availability data on diet studies to improve the understanding of amphibian feeding ecology." (Authors) Compared with the food availability, Odonata (Coenagrionidae) are used quite rarely.] Address: Scarabotti, P.A., Instituto Nacional de Limnología (CONICET - UNL), Ciudad Universitaria "Paraje El Pozo", (3000) Santa Fe, provincia de Santa Fe, Argentina. 9441. Nishu, S. (2009): Exuviae of *Pseudothemis zonata* placed on the trees distant from the pond shore. *Sympetrum Hyogo* 11: 28-31. (in Japanese, with English summary) [Japan; "Fifteen exuviae of *P. zonata* were found on the tree trunks some distance far from the shore of Gonoike Pond in Akashi Park on June 20, 2008. Measurements of the distance between the shore and the exuviae were made. The results revealed that the larvae travelled the distance of 2.89m to 5.88m with the average of 4.99m through the wall of the pond, horizontal part and the tree trunk of 2.36m high above the water surface. The angles of posture were mostly over 90°, and it seems that this species likes to emerge in overhang posture. The shore of this pond is not high enough for the emergence, and the adjacent land is almost flat, thus they walked in search of overhang wall

until at last climbed to such high." (Author)] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. E-mail: Snishu@mx2.nisiq.net

9442. Nishu, S.; Yoshihiko, Y (2009): The survey results of *Macromia daimoji* along Izushi River in 1997. *Sympetrum Hyogo* 11: 22-26. (in Japanese, with English summary) [Japan; "*M. daimoji* had been recorded along Izushi River during 1993-2004, but the flood caused by Typhoon No.23 swept the population of this species away in October 2004. It was revealed through the survey carried out in 2009 that a small population of this species is established. The survey results carried out by Yamazaki in 1997 on all odonate species are added, which will give a suitable measure for evaluating the recovery after the typhoon."] Address: Nishu, S., 247 Gunge Shonomoto, Mikage-cho, Higashinda-ku, Kobe, Hyogo, 658-0057, Japan. These records increase the regional list of Odonata to 50 species. The possible/to expect presence of *Anax parthenope* and *Trithemis annulata* is outlined.] Address: Robin, J., 6 rue du Stade, 82370 Corbarieu, France. E-mail: robin-jerome@voila.fr

9449. Rosa, B.F.J.V.; Martins, R.T.; de Oliveira, V.C.; Alves, R. (2009): Phoretic association between larvae of *Rheotanytarsus* (Diptera: Chironomidae) and genera of Odonata in a first-order stream in an area of Atlantic Forest in southeastern Brazil. *Zoologia* 26(4): 787-791. (in English) ["In this note, the occurrence of phoresy between larvae of *Rheotanytarsus* sp. (Diptera: Chironomidae) and larvae of *Heteragrion* sp. (Odonata: Megapodagrionidae) and of unidentified genera of Calopterygidae (Odonata) collected in a first-order stream in an area of Atlantic Forest in southeastern Brazil is reported. During the dry season of 2007 and the rainy season of 2008, with the aid of a Surber sampler, 15 samples of each of the following mesohabitats were collected: litter from riffle areas, litter from pool areas and sediment in pool areas. Eighty-five Odonata larvae were obtained, 10 (11.76%) with cases of phoresy by *Rheotanytarsus* sp.. These chironomids were associated with only one specimen of Megapodagrionidae, whereas the other larvae were recorded in association with Calopterygidae. Most of the Odonata with cases of phoresy by *Rheotanytarsus* sp. were recorded in the dry season. In the present study, the absence of the phoretic association with other potential hosts for *Rheotanytarsus* sp. found in the samples indicates a possible preference of these larvae for Odonata, which accounted for only 2.42% of the collected macroinvertebrates in litter and sediment." 9456. Smiroldo, G.; Balestrieri, A.; Remonti, L.; Prigioni, C. (2009): Seasonal and habitat-related variation of otter *Lutra lutra* diet in a Mediterranean river catchment (Italy). *Folia Zool.* 58(1): 87-97. (in English) ["To investigate time- and spatial related variations in the composition of otter *Lutra lutra* diet, a total of 838 faecal samples was collected in the upper catchment of the Agri

River (Basilicata region, southern Italy), and analysed. Data were split up according to the four seasons and between the main river and three of its tributaries. Fish and amphibians formed the bulk of otter diet, their consumption being inversely correlated. Trophic niche breadth was positively correlated with the frequency of occurrence of fish, whilst it was negatively correlated to that of amphibians and the altitude of the sampling stations. The frequency of consumption of fish did not vary through the year, whilst amphibians were mainly eaten during their hibernation and breeding period. Otter diet along the four main rivers differed significantly, the species being mainly piscivorous on the main river, whilst relying on alternative food resources on its tributaries, where habitat features or human interference reduced fish abundance. Fish availability seems to represent the main factor determining the composition and diversity of otter diet." (Authors) Odonata have a minor importance as food of the otter.] Address: Prigioni, C., Dipartimento di Biologia Animale, Università di Pavia, Piazza Botta 9, 27100 Pavia, Italy. (2009): Effects of the pyrethroid insecticide gamma-cyhalothrin on aquatic invertebrates in laboratory and outdoor microcosm tests. *Ecotoxicology* 18(2): 211-224. (in English) ["The sensitivity of a range of freshwater lentic invertebrates to gamma-cyhalothrin (GCH), a single enantiomer of the synthetic pyrethroid lambda-cyhalothrin, was assessed in single species

laboratory tests and an outdoor multi-species ecosystem test. The most sensitive species in the laboratory single species tests with GCH was *Chaoborus obscuripes* (96 h EC50: 3.8 ng/l). The species sensitivity distribution curve, based on the laboratory 96 h EC50 acute toxicity data for eight species, gave a median HC5 value for GCH of 2.12 ng/l. The NOECcommunity derived from the multi-species ecosystem test was 5 ng/l, and the insects *Chaoborus* sp. and *Caenis* sp. were identified as the most sensitive species. The results indicate that the median HC5, based on eight species selected to include those known to be sensitive to pyrethroids, provided a good estimation of the NOECcommunity for GCH. Furthermore, the results for GCH indicated that the endpoints typically used in higher-tier risk assessments for pesticides in Europe (HC5 and NOECcommunity) were consistent with expectations when compared to the equivalent endpoints for the racemate LCH." (Author) Zygotera tested were a mixture of at least four species (*Coenagrion puella/pulchellum*, *Enallagma cyathigerum*, *Ischnura* sp., *Coenagrion* sp.)] Address: van Wijngaarden, R.P.A., Dept for Water and Climate, Alterra, PO Box 47, 6700 AA Wageningen, The Netherlands. Box 12211, Research Triangle Park, NC 27709-2211: IV, 19 pp. (in English) ["Insect predators accomplish difficult visual tasks with tiny visual systems, and may provide important information for machine vision and remote sensing applications in variable light environments. We studied the visual system of *Megalagrion xanthomelas*, which possesses 1.5mm diameter eyes with 360 field of view, lives in dark habitats, and detects small objects against complex backgrounds. We accomplished four objectives: 1) Mapped regional variation in light sensitivity and spatial resolving power across the thousands of individual sensory units. Compound eyes (multiple, non-focusing lenses) may inspire microsensor array design. 2) Developed methods to quantify light heterogeneity viewed by the sensor array in nature along four principle viewing directions. These spectroradiometric measurements provide critical data on limits to target detection imposed by ambient brightness and colour contrast. 3) Established colour as an essential sensory channel for target discrimination in insect vision, especially when light levels are too dim to detect achromatic contrast. 4) Discovered that damselflies extend the performance range of their eyes through behavioural means, pointing their high-resolution frontal regions toward backgrounds against which visual targets will appear most conspicuous. This behaviour may provide insight for the design and deployment of artificial sensory systems for target detection in low light." 9463. Wyn, B.; Kidd, K.A.; Burgess, N.M.; Curry, R.A. (2009): Mercury biomagnification in the food webs of acidic lakes in Kejimikujik National Park and National Historic Site, Nova Scotia. *Canadian Journal of Fisheries and Aquatic Sciences* 66(9): 1532-1545. (in English, with French summary) ["Mercury (Hg) concentrations in fish from acidic lakes (pH < 6.0) are typically elevated above those from near-neutral systems. It is unknown whether high biomagnification rates through the supporting food web can explain elevated Hg concentrations in top predators from low pH lakes. To investigate this, we collected yellow perch (*Perca flavescens*), brown bullhead (*Ameiurus nebulosus*), banded killifish (*Fundulus diaphanous*), golden shiner (*Notemigonus crysoleucas*), and littoral and pelagic invertebrates from four acidic lakes in Kejimikujik National Park and Historic Site (KNPNHS), Nova Scotia, Canada, and analyzed them for total Hg and methyl Hg (MeHg), and $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ to determine sources of energy and trophic position, respectively. Mercury biomagnification rates (slopes of $\log\text{Hg}$ versus $\delta^{15}\text{N}$) varied significantly among the four lakes but did not explain the among-lake differences in perch Hg; these slopes were also within the range published for near-neutral systems. Rather, Hg concentrations in yellow perch (i.e., predatory fish) in KNPNS were higher in lakes with higher MeHg in lower-trophic-level organisms and suggest that processes influencing Hg uptake at the base of the food web are more important than rates of food web biomagnification for understanding the variation in concentrations of this contaminant among top predators." "The $\delta^{15}\text{N}$ data indicated distinct trophic levels in these four lakes of KNPNS. Limnephilids and heptagenids typically had the lowest mean $\delta^{15}\text{N}$ (e.g. 1.45 \pm 0.43 and 2.26 \pm 0.78, respectively, in North Cranberry), illustrating that that these invertebrates were primary consumers (Table 3-2, Figures 3-2 \pm 3-5). The dragonfly nymph, *Aeshna umbrosa*, had the highest $\delta^{15}\text{N}$ of the invertebrates (e.g. 4.32 \pm 0.12 in North Cranberry; Figures 3-2 \pm 3-5), which was between 2 and 3. higher than that of the limnephilids and heptagenids, suggesting that this invertebrate preys upon other invertebrates. All fish in these lakes had $\delta^{15}\text{N}$ values that were 3 - 6. higher than the littoral invertebrates, suggesting that most fishes were insectivorous or omnivorous, relying either partially or completely on near-shore invertebrates. In particular, this degree of enrichment suggests that fish were likely feeding on the most $\delta^{15}\text{N}$ enriched littoral macroinvertebrates (e.g. *Aeshna umbrosa*). Fish in each lake had similar $\delta^{15}\text{N}$ (Table 3-4; Figures 3-2 \pm 3-5). The large yellow perch were typically more enriched than the smaller individuals, but the mean $\delta^{15}\text{N}$ of yellow perch was not related to the diversity or type of fishes present. The invertebrates and fishes in North Cranberry Lake had the highest $\delta^{15}\text{N}$, while those in Pebblelogitch had the lowest $\delta^{15}\text{N}$; the differences among lakes were reduced when the data were adjusted for baseline $\delta^{15}\text{N}$."] Address: Wyn, Brianna, Biology & Canadian Rivers Inst., Univ. 9467. Aroviita, J.; Mykrä, H.; Hämäläinen, H. (2010): River bioassessment and the preservation of threatened species: Towards acceptable biological quality criteria. *Ecological Indicators* 10: 789-795. (in English) ["A central objective of environmental management is to maintain biodiversity, including populations of threatened species. Freshwater ecosystems are increasingly assessed by their biotic properties, but whether the resulting classifications of biotic condition are sufficient to protect species with conservation status has received very little consideration. We used data from 225 reference and impacted river sites from Finland to examine whether the occurrence and abundance of threatened macroinvertebrate species (TS) are associated with a commonly used estimate of biological condition (Observed-to-Expected number of predicted taxa of macroinvertebrates or O/E-ratio of taxonomic completeness, based on a predictive model). We suggest that a minimal acceptable condition below which restoration is needed, equivalent to, e.g. 'good' ecological status described by the European Union Water Framework Directive, should also ensure the occurrence of TS populations. We therefore followed conventional procedures for condition assessment, and examined two classifications by using the 10th or 25th percentiles of a reference O/E-distribution as alternative upper boundaries for the acceptable condition. The number and abundance of TS, and occurrence of individual TS showed positive relationships with the O/E. However, particularly if the 10th percentile threshold was used, there were only few occurrences and low abundance of TS in the

suggested 'good' condition. The results imply that conventional criteria for satisfactory condition may not be sufficient for preservation of threatened river macroinvertebrates. However, our approach could bring an objective, meaningful, and societally acceptable means for setting site quality criteria in freshwater assessment." (Authors) *Ophiogomphus cecilia* occurred at 5% of the 96 sites with minimum alteration by human activities and therefore adjudged to be in reference or best-available condition, and at 3% of impacted sites (n = 134).] Address: Aroviita, J., University of Jyväskylä, Department of Biological and Environmental Science, P.O. 9469. Belevich, O.E.; Yurchenko, Yu.A. (2010): Variability of *Aeshna juncea* Linnaeus, 1758 and taxonomic status of *Ae. undulata* Bartenev, 1930 (Odonata, Aeshnidae). *Eurasian entomological journal* 9(1): 13-18. (in Russian, with English summary) ["Analysis of diagnostic characters (colouration of labrum and thorax, structure of anal appendages and penis) used in the description of *Aeshna undulata* showed that each is more or less inherent to *A. juncea*. It was shown that the size and location of penis structure elements of *A. juncea* strongly depended upon digestion time in alkali. The posterior plate (pp) and hamular folds shape, which according to A. N. Bertnev distinguish *A. undulata* and *A. juncea*, are variable. It was established that the structure of the medial plate (ip) remains unchanged, but the shape of the male *A. juncea* varies considerably and cannot serve as a reliable diagnostic feature. The shape of the appendages of the hamular process (hp) of the genitalia of *Ae. undulata* is identical to that of *A. juncea*. We are of the opinion that A. N. Bertnev erroneously described a young male *A. juncea* as a new species, and therefore propose the synonymy *A. juncea* = *A. undulata*, syn. n." 9470. Berti, J.; Gonzalez, J.; Navarro-Bueno, E.; Zoppi, E.; Gordon, E.; Delgado, L. (2010): Larval seasonality of the mosquito *Anopheles aquasalis* (Diptera: Culicidae) and other insects associated to its habitat in Sucre, Venezuela. *Revista de biología tropical* 58(2): 777-787. (in Spanish, with English summary) ["*Anopheles aquasalis* Curry is considered the main vector of human malaria in Northern Venezuela. A longitudinal study was

carried out in the coastal areas of the Paria Peninsula, Sucre state. The larval habitats of *A. aquasalis* were classified as: 1--Brackish mangrove, and 2--Freshwater herbaceous swamp. Field surveys of mosquito larvae and aquatic insects (including Coenagrionidae, Aeshnidae and Libellulidae) were carried out in the same breeding sites over a one-year period, between January and December 1999. At each site, 30 samples of *Anopheles* larvae and aquatic insects were taken monthly. Simultaneously with mosquito larvae sampling, five selected variables of water were measured: conductivity, salinity, dissolved oxygen, temperature and pH. Seasonal and temporal variations of *A. aquasalis* larvae and aquatic insects were determined in the two larval habitats. For the entire study period, the abundance of larvae was higher in the mangrove. Correspondence analysis showed a strong relation between some chemical factors of water and larval abundance. The abundance of *A. aquasalis* larvae in both seasons, was positively correlated with water salinity, pH and conductivity, and negatively and with dissolved oxygen in the dry season. The presence of larvae was positively correlated with the presence of *Avicenia germinans*. In the mangrove there was a positive association between larvae abundance and Scirtidae family abundance and a negative correlation between larvae abundance and monthly precipitation (Spearman), as well as a significant negative correlation between Gerridae abundance and monthly precipitation. In the herbaceous swamp, there were not significant associations between *A. aquasalis* larvae abundance and abundance of others aquatic insects associated to habitat." 9472. Bolek, M.G.; Tracy, H.R.; Janovy, J. (2010): The role of damselflies (Odonata: Zygoptera) as paratenic hosts in the transmission of *Halipegus eccentricus* (Digenea: Hemiuridae) to anurans. *J. Parasitol.* 96(4): 724-735. (in English) [During July–August 2007 and 2008, 19 larvae and 122 adult *Lestes unguiculatus*, 140 adult *Ischnura verticalis*, and 55 teneral and adult *Enallagma civile*, were collected from Nevens Pond and examined for *Halipegus* sp. metacercariae. "*Halipegus eccentricus* is a common hemiurid trematode in the eustachian tubes of North America frogs. However, the life cycle of this species has never been completely elucidated. Studies on *H. eccentricus* suggest that it has a 3-host life cycle. Here, we show through fieldwork and host specificity experimental infections that the life cycle of *Halipegus eccentricus* utilizes 4 hosts. Metamorphosed anurans become infected with *H. eccentricus* by feeding on infected damselflies; worms reside in the stomach of anurans, migrate to the eustachian tubes within 32–39 days post-exposure (DPE), and release eggs 50–60 DPE. Cystophorous cercariae develop in *Physa gyrina* snails within 32–35 DPE, infect

ostracod (*Cypridopsis* sp.) second intermediate hosts, and develop to metacercariae. Fifteen- to 19-day-old metacercariae from ostracods are infective to both damselfly larvae and metamorphosed anurans. Field surveys of damselflies and tadpoles, along with laboratory exposure of damselfly larvae, metamorphosed anurans, and tadpoles with infected ostracods, indicated that only metamorphosed anurans and damselflies become infected with *H. eccentricus*, whereas field-collected tadpoles and laboratory-exposed tadpoles were never infected with *H. eccentricus*. Because little morphological change occurred in the metacercaria stage of *H. eccentricus* between the ostracod second intermediate host and damselfly host, and metamorphosed anurans became infected with *H. eccentricus* metacercariae recovered from both host groups, we suggest that odonates serve as paratenic hosts in this life cycle. Additionally, our field work and experimental infections provide data on the use of odonates as the route of infection by another North American *Halipegus* sp. that matures in the stomach of frogs. Our data indicate that when the life cycles are known, the use of odonates as the route of infection to anurans is common in the life cycles of *Halipegus* spp., and all species exhibit remarkable infection site fidelity in their amphibian hosts." 9473. Borisov, S.N. (2010): Autumnal migrations of dragonflies in the Chokpak Pass of West Tien-Shan, observed and actual flight measurements. *Eurasian entomological journal* 9(1): 7-18. (in Russian, with English summary) [Kazakhstan; obligate migrations of *Anax ephippiger*, *A. parthenope*, and *Sympetrum fonscolombii*, were studied using ornithological traps established in Chokpak pass (N 42.530, E 70.605) in Western Tien-Shan. The correlation between flight and cold air fronts is described, and the inequality of dragonfly migration intensity in different years was defined by ornithological trap data. These findings can explain the actual change in number of migrating dragonflies in different years, and the characteristics of dragonflies falling into traps according to winds from different directions. Noticeable above-ground flights were registered only with south-west headwinds. However, numbers observed or trapped may provide only an approximate measure of dragonfly autumnal movements since a large proportion occur at higher altitudes.] Address: Borisov, S.N., Institute of Systematics & Ecology of Animals, Russian Academy of Sciences, Siberian Branch, Frunze str. 11, Novosibirsk 630091 Russia. 9474. Bots, J.; van Dongen, S.; de Bruyn, L.; van Houtte, N.; van Gossum, H. (2010): Clutch size and reproductive success in a female polymorphic insect. *Evolutionary Ecology* 24(5): 1239-1253. (in English) ["Differences in reproductive success (RS) between different groups of individuals are of interest to researchers studying natural and sexual selection. Since it is often not feasible to quantify RS in the wild, researchers make use of proxies instead. One such proxy is clutch size. However, research on species providing parental care (mainly birds and mammals) has learned that a large clutch size does not guarantee a large number of offspring. In contrast, much less is known on the link between clutch size and RS for species lacking parental care, such as many reptiles and insects. Here, we ask whether clutch size provides a satisfactory estimate of

RS for a polymorphic insect. Our study species is *Enallagma cyathigerum* showing two distinct female morphs for which RS (estimated by clutch size) has been studied to evaluate the evolutionary role of sexual conflict. However, in this system not only among family variation in offspring viability, but also differences between female morphs, may affect how clutch size relates to offspring number and quality. To evaluate the use of clutch size as estimate of RS, we examined how clutch size correlated with subsequent success measures of developing offspring by rearing damselfly from eggs to adults under two laboratory food treatments. In both treatments, we detected that clutch size correlated well with offspring number early in larval life, but that this relation is reduced by among family variation in survival in later developmental stages. Clutch size was moderately correlated with the number of offspring that successfully metamorphosed to winged adults. Patterns did not differ between female morphs and the nature of the correlation could not be explained from offspring quantity-quality trade-offs." 9476. Braune, E.; Martens, A.; Richter, O.; Söndgerath, D.; Suhling, F. (2010): A spatially explicit model for interacting populations of dragonflies in arid Namibia. In: Schmiedel, U. & Jürgens, N. [Eds.]: *Biodiversity in southern Africa. Volume 2: Patterns and processes at regional scale.* Klaus Hess Publishers, Göttingen & Windhoek: 289-294. (in English) ["In order to understand the spatial and seasonal distribution of dragonflies in western Namibia we developed a model framework based on habitat suitability models, a local population dynamic model of interacting species and a dynamic landscape model combined with a spatially explicit model. Local population dynamics as well as the spatial patterns of the aggregated model showed good accordance with field data. Therefore, the model approach may be useful for the identification and understanding of dragonfly spatial patterns as well as for predicting future spatial patterns, which are influenced by changes in the water balance due to climate change.] Address: Suhling F., Inst. Geoökologie, TU Braunschweig, Langer Kamp 19c, D-38102 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

9477. Buss, D.F.; Vitorino, A.S. (2010): Rapid Bioassessment Protocols using benthic macroinvertebrates in Brazil: evaluation of taxonomic sufficiency. *J. N. Am. Benthol. Soc.* 29(2): 562-571. (in English) ["Rapid Bioassessment Protocols (RBPs) have been widely used to assess the ecological health of aquatic ecosystems. Specific aims of RBPs for wadeable streams are to indicate the ecological condition of a stream using low-

cost protocols to allow long-term and widespread routine monitoring. Our study was part of an ongoing effort to test and standardize a protocol using benthic macroinvertebrates as indicators of the water quality of Wadeable streams in southeast Brazil. One of the most controversial issues during RBP development is deciding the taxonomic resolution that should be used. We evaluated how well genus-, family-, and order-level taxonomic resolution detected a gradient of impairment. All 3 taxonomic resolutions statistically discriminated reference, intermediately impaired, and impaired sites based on assemblage structure, water-quality classification, and biotic index responses. Analysis at the genus level was more effective than analysis at other levels of taxonomic resolution for discriminating sites that varied in degradation conditions, especially when considering biotic index responses, but the lack of comprehensive taxonomic keys and information about the ecology of those genera hinder their widespread use in bioassessments. On the other hand, analyses at the order level had lower discriminating power to separate reference sites from intermediately impaired sites when considering biotic index responses. Analyses at the family level gave results similar to results at the genus level, and we support its use in a RBP program for this region, at least until better keys and autoecological knowledge are available." (Author) Odonata - without further specification - are said to be considered at the genus level.] Address: Vitorino, A.S., Laboratório de Avaliação e Promoção da Saúde Ambiental, Instituto Oswaldo Cruz, Fundação Oswaldo Cruz – FIOCRUZ, Av. 9478. Capellan, E.; Nicieza, A.G. (2010): Constrained plasticity in switching across life stages: pre- and post-switch predators elicit early hatching. *Evolutionary Ecology* 24(1): 49-57. (in English) ["The timing of many life history events shows phenotypic plasticity in response to the risk of predation. Theory predicts that increased risk of mortality in an early stage should select for switching earlier, while a higher risk after the transition should select for switching later. Here we examined the effects of stage-specific predation risk on the timing of hatching of *Rana temporaria*. Embryos were exposed to chemical cues from either an egg predator (*Haemaphysalis sanguisuga*) or a tadpole predator (*Aeshna cyanea*) to evaluate three specific hypotheses: (1) a fixed intermediate response, (2) a 'fixed predator' response (i.e., either anticipation or delay), and (3) a specific predator response (both anticipation and delay). *Rana temporaria* embryos did not discern between pre- and post-hatching specific predators, and they hatched prematurely regardless predator type. These results suggest that *R. temporaria* embryos respond to predation risk in a fixed way by hatching early, and that they use cues stemming from injured conspecifics, which provides a simple, conservative mechanism of risk assessment. In conclusion, our data are not anticipated by the theoretical consideration that organisms should spend less time in more dangerous environments, but they confirm an invariable adjustment of hatching time in response to an inscrutable predation risk (response to a fixed-predator) in connection with a consistent mechanism mediating the perception of predation risk." 9479. Chalmers, V. (2010): Light trap session and reptile moonwalk. *Gazelle*, Dubai 25(5): 4-5. (in English) [Prior may 2010 (not data are available to the abstracter), a mercury vapour light trap was installed at the Al Ain Zoo roundabout, UAE. "Dragonflies were also seen at the light trap and Bob Reimer identified them as a female *Anax ephippiger* and two female *Anax parthenope* dragonflies."] Address: Chalmers, Valerie; not stated

9480. Chara-Serna, A.M.; Chara, J.D.; Zuniga, M.; Pedraza, G.X.; Giraldo, L.P. (2010): Clasificación trófica de insectos acuáticos en ocho quebradas protegidas de la ecorregión cafetera colombiana. *Universitas Scientiarum* 15(1): 27-36. (in Spanish, with English summary) ["Trophic classification of aquatic insects in eight sheltered streams of the Colombian coffee ecoregion. Objective. To determine the trophic structure of the aquatic insect assembly associated to eight streams in the Colombian coffee-growing ecoregion. Materials and methods. Aquatic insects were collected in eight forested streams located in La Vieja river basin. The taxa collected were assigned to dietary groups according to a regional classification based on the gut content analysis of aquatic insects associated to forested streams of the Otún river basin. Results. 2019 individuals belonging to 73 taxa were collected and 60 were classified into dietary groups. The most abundant group was collectors (55%), followed by shredders (31%) and predators (10%). Scrapers represented only 0.05% of the sample and the remaining 3,95% could not be classified due to lack of information. Conclusions. The dominance of collectors and shredders reveals the importance of coarse particulate organic matter (leaf litter) as a food resource for the insect fauna. Similarities between the trophic structure of this community and other communities studied in similar streams, suggest the possibility of a common pattern for Andean streams. This study evidenced the lack of knowledge on trophic ecology of tropical aquatic insects; 50% of the taxa collected did not have this kind of information for the tropics and 20% had no information neither for the tropics nor temperate zones." (Authors) Odonata are treated at the genus level.] Address: Chará-Serna, Ana M., Centro para la Investigación en Sistemas Sostenibles de Producción Agropecuaria - CIPAV, Carrera 25 No. 6-62 Cali, Colombia. 9486. De Knijf, G.; Demolder, H. (2010): Odonata records from Alentejo and Algarve, southern Portugal. *Libellula* 29(1/2): 61-90. (in English, with German summary) ["During two field trips in summer 2008 and spring 2009 to the Alentejo and Algarve in southern Portugal, we altogether recorded 42 species of Odonata at 112 localities. All localities were classified in one of the following five categories: streams, rivers, ponds and pools, reservoir lakes, and brackish waters. Seventeen species are categorised as rheophilous and twelve as having a clear preference for standing waters. Remarkable records of *Lestes dryas*, *Onychogomphus forcipatus*, *O. uncatatus*, *Paragomphus genei*, *Orthetrum chrysostigma*, *O. coerulescens*, *O. nitidinerve*, *O. trinacria*, *Diplacodes lefebvrii*, *Brachythemis impartita* and *Zygonyx torridus* are presented in detail and discussed, and a regional distribution map is provided for most of them. With 35 species, the Odonata fauna of southern Portuguese streams and rivers is rich and diverse. This diversity can be explained by the high naturalness of many fluvial systems, resulting in a high degree of variation in velocity and substrate, and by the regionally warm climate. Nearly all endemic and threatened species are restricted in the region to running waters. This demonstrates very well the great importance of streams and rivers for dragonflies and the international responsibility of Portugal to protect and conserve these habitats. Despite their rarity in southern Portugal, ponds and pools harbour relict populations of several northern species like *Lestes dryas* and *Libellula quadrimaculata* at the limits of their distribution. However, today these ponds are endangered by intensification of agriculture and the loss of traditional land use practices and should also be protected." 9487. Deubelius, K.; Jödicke, R. (2010): *Leucorrhinia caudalis* in Nordwestdeutschland (Odonata: Libellulidae). *Libellula* 29(1/2): 1-12. (in German, with English summary) ["In 2009, *L. caudalis* was recorded from four lakes in Lower Saxony north and east of Bremen, Germany, for the first time. Reproduction in one of the lakes was proved by several exuviae. An analysis of all records from Lower Saxony showed that only the flood plain of the river Elbe in the Wendland area may be part of the permanent range of the species. All other records from the 20th century indicate short-term populations, some of which having been only inadequately documented. Since the turn of the millennium, the species was recorded from six localities in Lower Saxony, which may be interpreted in terms of a turnaround in the hi-

therto observed decline of the species. Hence, similar news from other parts of Germany and adjacent countries is supported." (Authors)] Address: Deubelius, K., Am Kapellenberg 7, D-28759 Bremen, Germany. E-mail: KadeeHB@t-online.de

9488. Dijkstra, K.D.; Boudot, J.-P. (2010): First update of the Atlas of the Odonata of the Mediterranean and North Africa: *Orthetrum machadoi* new to the Palaearctic and *Agriocnemis sania* new to the Egyptian Nile Valley. *Libellula* 29(1/2): 107-125. (in English, with German summary) ["Twenty-four species of Odonata were found in the Egyptian Nile Valley and Western Desert in May 2009, which represents 71 % of the fauna confirmed for African Egypt. *Agriocnemis sania* Nielsen, 1959 was recorded in the lower valley and delta of the Nile. This suggests that a doubtful old record of a damaged *Agriocnemis exilis* Selys, 1872 from Port Said referred to *A. sania*, and that *A. exilis* should be removed from the checklist of Egyptian, North African and Mediterranean Odonata. *Agriocnemis sania* is new to African Egypt and should be downgraded from «Regionally Extinct» to «Endangered» on the IUCN North African Red List. *Orthetrum machadoi* Longfield, 1955 was discovered in the Siwa Oasis and is new for Egypt and the Palaearctic at large. The site is over 2600 km from the nearest known locality in Ethiopia, and, like the sympatric and sometimes syntopic *Acisoma panoroides* Rambur, 1842, can be considered as a tropical relict from (a) pluvial period(s), more than 6,000 years ago, when the Sahara was considerably wetter. The overall proportion of observed Afrotropical species was 71 %, whereas the Palaearctic element was only 25 %." (Authors)] Address: Dijkstra, K.D., Curator of invertebrates, National Zoological Collection of Suriname, University of Suriname, P.O. Box 9212, Paramaribo, Suriname. 9496. Gabriels, W.; Lock, K.; De Pauw, N.; Goethals, P.L.M. (2010): Multimetric Macroinvertebrate Index Flanders (MMIF) for biological assessment of rivers and lakes in Flanders (Belgium). Limnologica 40: 199-207. (in English) ["The European Water Framework Directive requires that member states assess all their surface waters based on a number of biological elements, including macroinvertebrates. Since 1989, the Flemish Environment Agency has been using the Belgian Biotic Index for assessing river water quality based on macroinvertebrates. Throughout the years, the Belgian Biotic Index has proven to be a reliable and robust method providing a good indication of general degradation of river water and habitat quality. Since the Belgian Biotic Index does not meet all the requirements of the Water Framework Directive, a new index, the Multimetric Macroinvertebrate Index Flanders (MMIF) for evaluating rivers and lakes was developed and tested. This index was developed in order to provide a general assessment of ecological deterioration caused by any kind of stressor, such as water pollution and habitat quality degradation. The MMIF is based on macroinvertebrate samples that are taken using the same sampling and identification procedure as the Belgian Biotic Index. The index calculation is a type-specific multimetric system based on five equally weighted metrics, which are taxa richness, number of Ephemeroptera,

Plecoptera and Trichoptera taxa, number of other sensitive taxa, the Shannon–Wiener diversity index and the mean tolerance score. The final index value is expressed as an Ecological Quality Ratio ranging from zero for very bad ecological quality to one for very good ecological quality. The MMIF correlates positively with dissolved oxygen and negatively with Kjeldahl nitrogen, total nitrogen, ammonium, nitrite, total phosphorous, orthophosphate and biochemical and chemical oxygen demand. This new index is now being used by the Flemish Environment Agency as a standard method to report about the status of macroinvertebrates in rivers and lakes in Flanders within the context of the European Water Framework Directive." (Authors) Taxa taken into account for calculating the Multimetric Macroinvertebrate Index Flanders, with their respective tolerance scores (TS), ranging from 10 for very pollution sensitive to 1 for very pollution tolerant taxa. With reference to Odonata the sensitive index is as follows: *Aeshna* 6, *Brachytron* 7, *Calopteryx* 8, *Cercion* 7, *Ceriagrion* 7, *Coenagrion* 6, *Cordulegaster* 9, *Cordulia* 7, *Crocothemis* 7, *Enallagma* 7, *Epithea* 7, *Erythromma* s.s. 7, *Gomphus* 7, *Ischnura* 6, *Lestes* 7, *Leucorrhinia* 7, *Libellula* 7, *Nehalennia* 7, *Onychogomphus* 7, *Ophiogomphus* 7, *Orthetrum* 7, *Oxygastra* 7, *Platycnemis* 7, *Pyrrosoma* 7, *Somatochlora* 7, *Sympetma* 7, *Sympetrum* 7.] Address: Gabriels, W., Flemish Environment Agency (VMM), A. 9500. Groenendijk, D. (2010): Mysterious and beautiful, the Northern Emerald. *Vlinders* 3/2010: 18-21. (in Dutch, with English summary) ["*Somatochlora arctica* is one of the least known and rarest dragonflies of north-west Europe; in the Netherlands it is listed as a threatened species. One of the most characteristic species of living raised bog, its decline has been paralleled by the loss and degradation of such wetland habitat. We set up a Species Protection Plan which came into action in 2005. Seven Dutch populations are now known. Priority was given to locating the breeding grounds and understanding the adult's behaviour. Both males and females were seen frequenting small pools of about a metre deep. The surface was almost completely covered with rather dried out looking *Sphagnum* moss, often with other bog plants growing in it. We saw females ovipositing, and found larvae in various stages and their empty skins (exuviae). These pools have been targeted for conservation measures. On the short term, managers are given on-site advice either on how to protect them or how to dig new ones, depending on the local situation. On the long term, it is important that hydrological plans for the restoration of the bog include such pools, thus ensuring suitable breeding grounds for this rare and beautiful species." 9501. Grome, N.M. (2010): Neural basis of visually evoked head and wing movements in dragonflies. *FASEB Journal* 24: 988.16. (in English) ["Dragonflies make their living by foraging on flying insects. We are using two approaches to study their prey capture behavior. (1) Using close-up, high speed video, we are recording the head movements of dragonflies (*Sympetrum vicinum*) to the movement of small moving images that simulate prey items. Our study shows that dragonflies use two distinct types of head/eye movements, tracking and saccades. The former are smooth movements that stabilize the moving prey image. The latter are jerky movements that may be involved in distance estimation. (2) Using intracellular penetration and recording, we are studying a group of neurons that are thought to guide prey capture. By controlling their activity with current pulses we are studying the wing steering movements that they elicit. Injection of a fluorescent dye, Lucifer Yellow, into these neurons allows us to study their dendritic structure within the dragonfly's brain." 9502. Hamamoto, M.; Ohta, Y.; Hara, K.; Hisada, T. (2010): Basic design strategy for stiffness distribution on a dragonfly-mimicking wing for a flapping micro aerial vehicle. *Advanced Robotics* 24(5-6): 861-877. (in English) ["A basic configuration of a flexible wing is derived from that of a real dragonfly. To realize the development of a flapping micro aerial vehicle, it is essential to study real insects' flight. In particular, the

sophisticated structure of the wing contains many helpful hints for the solution of the efficiency. However, to solve the fluid-structure interaction problem between wing deformation and the surrounding airflow has been quite difficult, and the study of the ultimately light wing has been inhibited. We analyzed this problem using a novel numerical simulation — finite element analysis based on the arbitrary Lagrangian-Eulerian method, which can treat the interactive behaviour accurately. A comparison of wing deformations and surrounding airflows for 13 wing models, actuated in the same way as is hovering by a real dragonfly and having one-third to 23 times the Young's modulus of a real dragonfly wing, indicated that the real wing positioned on the lower border of the zone where the flight efficiency was sustained. It was also observed that the wingtip area, the attitude of which plays a dominant role in determining the efficiency, was mainly supported by the structural stiffness of a shallow groove that crosses the wing diagonally." 9504. Hughes, M. (2010): Effects of Zebra Mussel colonization on dragonfly larvae burying behavior. Thesis submitted to the faculty of Wesleyan University in partial fulfillment of the requirements for the Degree of Bachelor of Arts with Departmental Honors in Biology Middletown, Connecticut April: 55 pp. (in English) ["Invasive species have caused massive ecological and economic damage throughout the world. In North America, zebra mussels (*Dreissena polymorpha*) native to Eastern Europe invaded aquatic ecosystems in the 1980s, altering ecological communities and harming human infrastructure. Zebra mussels have been found attached to dragonfly larvae, decreasing the likelihood of successful emergence as adults. This study assesses the negative impacts zebra mussel colonization has on dragonfly larvae by testing the effects of colonization on dragonfly burying behavior. *Macromia illinoensis* larvae and zebra mussels were collected and tested at Douglas Lake, Michigan in July and August 2009. Weather and water temperature affected uncolonized burial time, but not uncolonized burial depth. Uncolonized burial time, head width, and body area were predictors of which individual dragonflies got colonized. Once individuals were colonized, their burial depth was impaired, which could lead to early mortality. Because dragonflies link aquatic and terrestrial ecosystems, increased early mortality of dragonflies could cause cascading effects across ecosystems." (Author)] Address: not stated

9505. Hunt, P.A.; Blust, M.; Morrison, F. (2010): Lotic Odonata of the Connecticut River in New Hampshire and Vermont. *Northeastern Naturalist* 17(2): 175-188. (in English) ["Several riverine species in the insect order Odonata are recognized as being of conservation con-

cern in the Northeast. Along the Connecticut River, most data on these species have come from the southern portion of the river that passes through Connecticut and Massachusetts, while the northern portion has been poorly sampled until recently. In this paper, we summarize recent surveys along the Vermont—New Hampshire stretch of the river and place these in the context of known distributional data for the river as a whole. Our focus is on species typical of large rivers, with a particular focus on members of the family Gomphidae. Also included is information on the first Vermont or New Hampshire records of three species — *Enallagma antennatum*, *E. durum*, and *Stylurus amnicola* — and the first upper river records for several other species." 9506. Ippolito, A.; Sala, S.; Faber, J.H.; Vighi, M. (2010): Ecological vulnerability analysis: A river basin case study. *Science of the Total Environment* 408: 3880-3890. (in English) [Italy, "Assessing and quantifying ecosystem vulnerability is a key issue in site-specific ecotoxicological risk assessment. In this paper, the concept of vulnerability, particularly referred to aquatic ecosystems is defined. Sensitivity to stressors, susceptibility for exposure and recovery capability are described as component of vulnerability of biological communities. The potential for habitat changes must also be considered in ecosystem vulnerability assessment. A procedure based on the application of an ecosystem vulnerability index is proposed. The method allows the assessment of vulnerability of riverine ecosystems to multiple stressors. The procedure is applied to two river systems in northern Italy: River Serio, subject to strong human pressure, and River Trebbia, in semi-natural conditions, as reference system. Macrozoobenthos is chosen as the indicator community. The actual quality of River Serio was evaluated as the result of the multiple stressor pressure on the reference system. Values and limitations of the approach are discussed." (Authors) Taxa, including Odonata, are treated at the order level.] Address: Vighi, M., Department of Environmental Sciences, University of Milano Bicocca, Piazza della Scienza, 1, 20126 Milano, Italy. 9508. Kalniņš, M. (2010): Dragonfly (Odonata) conservation in Latvia. XXVIII Nordic - Baltic Congress of Entomology. Abstract book: 49. (in English) [Verbatim: "Until now, there are altogether 59 species of nine dragonfly families known in Latvia including one irregularly immigrated species – *Sympetrum fonscolombii* and one species with unclear status – *Aeshna caerulea*. Although dragonflies represent a faunistically well investi-

gated group of insects in Latvia, the data of threatened and protected species regional distribution is still insufficient as compared with other dragonflies species. There is also few ecological data available on dragonflies of Latvia. Published data, the collections of different institutions, the data collected during the project „Analysis of the Specially Protected Nature Territories in Latvia and Establishing of EMERALD/Natura 2000 Network” in 2001-2002 and material collected by Latvian entomologists up to 2009 have been used in the analysis of the distribution and habitat preference. Data on dragonflies were collected by using a hydrobiological net or entomological net, or by direct observations. The material was collected from 1998 to 2009. Both historical and recent data, totally 10885 records of all dragonfly species, were included in a Microsoft Office Access database hold by the author. There are altogether 16 species are protected by national and European legislation or included in Red Data book of Latvia. They are: *Lestes virens*, *Ischnura pumilio*, *Pyrrhosoma nymphula*, *Nehalennia speciosa*, *Aeshna mixta*, *A. isosceles*, *A. viridis*, *Anax imperator*, *Gomphus flavipes*, *Ophiogomphus cecilia*, *Cordulegaster boltonii*, *Epitheca bimaculata*, *Libellula fulva*, *Leucorrhinia albifrons*, *L. caudalis*, *L. pectoralis*. Specially protected natural areas of Latvia are geographical territories, that are under special state-level protection, in order to safeguard and maintain biodiversity of nature – rare and typical ecosystems, habitats for rare species, landscapes, that are peculiar, beautiful and characteristic for Latvia, geological and geomorphological formations, as well as territories, significant for recreational and educational purposes. The protected areas are classified according following categories: strict nature reserves, nature parks, nature reserves, national parks, biosphere reserves, natural monuments, areas of protected landscapes. Altogether in Latvia there are 684 (excluding nature monuments – veteran trees) specially protected natural areas certified by law or regulations of the Cabinet of Ministers. The half of these protected areas has been established as Natura 2000 – protection areas of European level also." 9513. Keller, D.; Brodbeck, S.; Flöss, I.; Vonwil, G.; Holderegger, R. (2010): Ecological and genetic measurements of dispersal in a threatened dragonfly. *Biological Conservation* 143: 2658-2663. (in English) ["*Leucorrhinia caudalis* is a rare dragonfly, threatened throughout its European distribution. The species was formerly widespread in the Swiss lowlands, but only a single population remained in the 1980s. However, a spread has recently been observed, with additional ponds being colonised, sometimes at considerable distance. Despite this evidence of recent long-distance dispersal, it is unknown whether *L. caudalis* regularly moves among ponds or whether this is a rather rare event. A combination of an ecological mark-resight and a population genetic study was applied to investigate contemporary dispersal and the genetic footprint of the recent population history of *L. caudalis* in Switzerland. DNA for genetic microsatellite analysis was extracted from exuviae. The mark-resight study and the genetic analysis gave congruent results. They showed that *L. caudalis* is mostly a sedentary species, with only a few contemporary dispersal events over distances up to 5 km being observed. The genetic analysis was in agreement with the recent population history of the Swiss populations. The oldest and largest population showed large genetic diversity and acted as source population for the recent spread of *L. caudalis* in Switzerland. Recurrent gene flow among this source population and close populations caused substantial local genetic variation in the latter, as well as low population differentiation. The two recently founded distant populations (30 km distance) were genetically less diverse and highly differentiated. These distant populations and another recently colonised population also expressed signatures of genetic bottlenecks." (Authors)] Address: Keller, Daniela, WSL Swiss Federal Research Institute, Zürcherstr. 111, CH-8903 Birmensdorf, Switzerland. E-mail: mailto:daniela.keller@wsl.ch

9514. Korte, T. (2010): Current and substrate preferences of benthic invertebrates in the rivers of the Hindu Kush-Himalayan region as indicators of hydromorphological degradation. *Hydrobiologia* 651(1): 77-91. (in English) ["The study introduces an approach to obtaining information about the preferences of benthic invertebrates for substrate and current velocity in a region with little prior knowledge of benthic invertebrates. These preferences are then used for river assessment. Substrate-specific sampling of 271 reference sites was conducted in lower mountainous and lowland areas of the Hindu Kush-Himalaya region. Statistical analysis revealed significant preferences for substrate type and current velocity for 50 taxa of Ephemeroptera, Plecoptera, Trichoptera, Coleoptera, Diptera, Odonata, Mollusca, and Oligochaeta. A 20-point system was developed to assign scores for substrate and current preferences. Scores from seven taxa of Ephemeroptera and Trichoptera revealed low ecological potential in response to habitat alteration. These data were used to develop four preference metrics. The Lithal metric is composed of 34 taxa with significant preferences for stony substrates (fine gravel to bedrock size). The Lithophile metric contains 21 taxa with strong statistical links to stony substrates, which were also found on other substrates. The Lithobiont metric consists of 13 taxa exclusively found on stones. The Lotic metric consists of 11

taxa with significant preferences for moderate-to-fast current velocities. Multi-habitat sampling was conducted at 181 sites reflecting a hydromorphological gradient. The Mann-Whitney U test and box-and-whisker plots were applied to test the relationship of the new metrics to hydromorphological stress. Of the four new metrics, the Lithal, Lithophile, and Lotic were able to detect impacts of hydromorphological degradation." 9516. Landwer, B.H.P.; Sites, R.W. (2010): The larval Odonata of ponds in the Prairie region of Missouri. *Transactions of the American entomological society* 136(1-2): 1-105. (in English) ["Despite a proliferation of regional faunistic treatments throughout North America in recent years, knowledge of the Odonata fauna of Missouri has lagged behind that of other midwestern states. Samples of larval Odonata were collected from 105 ponds in the Prairie Region of Missouri over three sampling periods: Fall 1998, Spring 1999, and Summer 1999. Some ponds were sampled during more than one sampling period, resulting in a total of 117 unique pond and sampling period combinations. Sites were selected from Missouri Department of Conservation owned lands and the University of Missouri owned Baskett Wildlife Area. Within each pond, sampling was conducted separately in each distinct vegetational mesohabitat. Supplemental rearing of difficult or uncommon taxa was carried out in the laboratory. More than 30,000 specimens, representing 51 species, 22 genera, and 6 families of larval Odonata were collected from ponds in the Prairie Region of Missouri. Overall, the ponds of the Prairie Region supported a generalized Odonata community, with a relatively small number of species being found in a large number of ponds. Presented here is a faunistic inventory of the larval Odonata of ponds in the Prairie Region of Missouri, with mesohabitat associations and a taxonomic key to suborders, families, genera, and species known or expected to occur there." analyzed the diet of the previously unstudied Mexican mud turtle during 2003 and 2004. Analysis was conducted separately by sex and age (immature vs. adults) and seasons (rainy vs. dry). Gastric contents and fecal samples were used in combination for more complete results. Based on 57 samples (32 stomach flushes and 25 from feces), *K. integrum* is a generalist–opportunist in alimentary habits, feeding on 27 categories of food. Plant material, Coleoptera, Odonata, Diptera, and mixed animal matter were the most important components. Overall dietary diversity was similar between adults and juveniles and between the two sexes, but juveniles differed between seasons. In similarity analysis we found a shift in diet between seasons. Females shifted from being primarily carnivorous during the rainy season to being primarily herbivorous during the dry season, while males were carnivorous during both seasons. The data suggest that this turtle feeds opportunistically on available prey items rather than on a few preferred food items." 9523. Maes, D.; Titeux, N.; Hortal, J.; Anselin, A.; Declerck, K.; De Knijf, G.; Fichet, V.; Luoto, M. (2010): Predicted insect diversity declines under climate change in an already impoverished region. *J. Insect Conservation* 14: 485-498. (in English) ["Being ectotherms, insects are predicted to suffer more severely from climate change than warm-blooded animals. We forecast possible changes in diversity and composition of butterflies, grasshoppers and dragonflies in Belgium under increasingly severe climate change scenarios for the year 2100. Two species distribution modelling techniques (Generalised Linear Models and Generalised Additive Models), were combined via a conservative version of the ensemble forecasting strategy to predict present-day and future species distributions, considering the species as potentially present only if both modelling techniques made such a prediction. All models applied were fair to good, according to the AUC (area under the curve of the receiver operating characteristic plot), sensitivity and specificity model performance measures based on model evaluation data. Butterfly and grasshopper diversity were predicted to decrease significantly in all scenarios and species-rich locations were predicted to move towards higher altitudes. Dragonfly diversity was predicted to decrease significantly in all scenarios, but dragonfly-rich locations were predicted to move upwards only in the less severe scenarios. The largest turnover rates were predicted to occur at higher altitudes for butterflies and grasshoppers, but at intermediate altitudes for dragonflies. Our results highlight the challenge of building conservation strategies under climate change, because the changes in the sites important for different groups will not overlap, increasing the area needed for protection. We advocate that possible conservation and policy measures to mitigate the potentially strong impacts of climate change on insect diversity in Belgium should be much more pro-active and flexible than is the case presently." karonesischen Inseln (Odonata: Libellulidae). *Libellula* 29(1/2): 91-106. (in English, with German summary) ["12 new records of *S. nigrifemur*, taken during October 2008 in Madeira, are presented. These are included in a compilation of all available record of this species, published and unpublished, from the Macaronesian Islands. Altogether 220 dated records have been investigated that originate from three Macaronesian archipelagoes - Madeira, Ilhas Selvagens and Canary Islands - and are distributed on nine islands: Madeira (86 records), La Gomera (73), Tenerife (37), Gran Canaria (10), La Palma (7), Selvagem Grande (3), Ilhas Desertas (3; Deserta Grande, 2, & Ilheu Chao, 1) and Lanzarote (1). Autochthony of *S. nigrifemur* can be assumed in Madeira, La Palma, Tenerife, La Gomera and Gran Canaria. Seen vertically, records were taken from sea level to 1,600 m, and breeding sites were recorded from sea level up to 1,300 m. Adult *S. nigrifemur* are on the wing throughout the year. Larval records were taken in February, April, August and October. Emergence was recorded in April and May as well as in August, September and October. Oviposition was seen in the winter months from November until March and in July, and old individuals were explicitly noted only from early March to late April. In our eyes the most likely phenological scenario is a bivoltine development with a rapid larval summer generation." (Authors)] Address: Malkmus, R., Schulstr. 4, D-97859 Wiesthal, Germany

[Eds.]: *Biodiversity in southern Africa. Volume 2: Patterns and processes at regional scale.* Klaus Hess Publishers, Göttingen & Windhoek: 70-74. (in English) ["Natural perennial surface water in the interior parts of Namibia only occurs at widely separated springs around mountains. These waters host a very diverse and unique Odonata assemblage, which is threatened due to the habitat restriction of several species, as well as by recent habitat loss and degradation. Species occurring permanently at these waters, including *Crocothemis sanguinolenta*, *Orthetrum julia*, and *Trithemis stictica* differ significantly in seasonality, dispersal and life cycle characteristics from species colonising temporary waters. Their larvae grow slowly and they are present in these habitats as larvae throughout the year. This presence is the key factor why invaders with rapid development, which are dominant elsewhere, do not outcompete these species in these unique habitats. There is significant potential for stream dragonfly species to act as indicators for threatened freshwater wetlands in arid Namibia and they may also serve as an indication of the sustainable use of water resources, including the evaluation of measures to rehabilitate environments." Impact and Management of Invasive Alien Species in the Bonin Islands: 139-144. (in English) ["There are many endemic species in the Japanese Ogasawara Islands. However, many of these endemic species are likely to disappear as a result of reduction of habitat and the introduction of exotic species. Odonates are included within this category of species at risk. If the decrease in endemic odonates is due to a decrease in aquatic habitat, we have only to provide artificial ponds to conserve these species. In this study, we provided artificial ponds as a habitat for odonates in Chichi-jima and Ani-jima, Ogasawara Islands. We then examined the possibility of protection and enhancement of odonate populations. Endemic odonates were found in the natural ponds of Ani-jima and Ototo-jima. In Ani-jima, they could be collected both in the artificial and natural ponds. The artificial pond could provide habitat for endemic odonates. However, in Chichi-jima, few odonates could be collected both in the artificial and natural ponds. Here, invasive species, such as *Gambusia affinis* and *Anolis carolinensis*, are found, which considered to prey upon odonate larvae and adults. Extermination of invasive species may be necessary to conserve the endemic odonates in Chichi-jima. Reprinted from Yoshimura M, Okochi I (2005) Bulletin of FFPRI 4:45-51, with permission of FFPRI." 9530. Meusemann, K.; von Reumont, B.M.; Simon, S.; Roeding, F.; Strauss, S.; Kück, P.; Ebersberger, I.; Walz, M.; Pass, G.; Breuers, S.; Achter, V.; von Haeseler, A.; Burmester, T.; Hadrys, H.; Wägele, W.; Misof, B. (2010): A phylogenomic approach to resolve the arthropod tree of life. *Molecular Biology and Evolution* 27 (11): 2451-2464 (in English) ["Arthropods were the first animals to conquer land and air. They encompass more than three quarters of all described living species. This extraordinary evolutionary success is based on an astoundingly wide array of highly adaptive body organizations. A lack of robustly resolved phylogenetic relationships, however, currently impedes the reliable reconstruction of the underlying evolutionary processes. Here, we show that phylogenomic data can substantial-

ly advance our understanding of arthropod evolution and resolve several conflicts among existing hypotheses. We assembled a data set of 233 taxa (including Odonata) and 775 genes from which an optimally informative data set of 117 taxa and 129 genes was finally selected using new heuristics and compared to the unreduced data set. We included novel EST data for eleven species and all published phylogenomic data augmented by recently published EST data on taxonomically important arthropod taxa. This thorough sampling reduces the chance of obtaining spurious results due to stochastic effects of undersampling taxa and genes. Orthology prediction of genes, alignment masking tools, and selection of most informative genes due to a balanced taxa-gene ratio using new heuristics were established. Our optimized data set robustly resolves major arthropod relationships. We received strong support for a sister group relationship of onychophorans and euarthropods, and strong support for a close association of tardigrades and cycloneuralia. Within pancrustaceans, our analyses yielded paraphyletic crustaceans and monophyletic hexapods, and robustly resolved monophyletic endopterygote insects. However, our analyses also showed for few deep splits that were recently thought to be resolved, for example the position of myriapods, a remarkable sensitivity to methods of analyses." 9531. Munguia-Steyer, R.; Cordoba-Aguilar, A.; Romo-Beltran, A. (2010): Do individuals in better condition survive for longer? Field survival estimates according to male alternative reproductive tactics and sex. *Journal of Evolutionary Biology* 23(1): 175-184. (in English) ["There is a gap in terms of the supposed survival differences recorded in the field according to individual condition. This is partly due to our inability to assess survival in the wild. Here we applied modern statistical techniques to field-gathered data in two damselfly species whose males practice alternative reproductive tactics (ARTs) and whose indicators of condition in both sexes are known. In *Paraphlebia zoe*, there are two ART: a larger black-winged (BW) male which defends mating territories and a smaller hyaline-winged (HW) male that usually acts as a satellite. In this species, condition in both morphs is correlated with body size. In *Calopteryx haemorrhoidalis*, males follow tactics according to their condition with males in better condition practicing a territorial ART. In addition, in this species, condition correlates positively with wing pigmentation in both sexes. Our prediction for both species was that males practicing the territorial tactic will survive less longer than males using a nonterritorial tactic, and larger or more pigmented animals will survive for longer. In *P. zoe*, BW males survived less than females but did not differ from HW males, and not necessarily larger individuals survived for longer. In fact, size affected survival but only when group identity was analysed, showing a positive relationship in females and a slightly negative relationship in both male morphs. For *C. haemorrhoidalis*, survival was larger for more pigmented males and females, but size was not a good survival predictor. Our results partially confirm assumptions based on the maintenance of ARTs. Our results also indicate that female pigmentation, correlates with a fitness component – survival – as proposed by recent sexual selection ideas applied to females." (Authors)] Address: Córdoba-

9532. Murphy, J.T.; Hu, H. (2010): An experimental study of a bio-inspired corrugated airfoil for micro air vehicle applications. *Experiments in Fluids* 49(2): 531-546 (in English) ["An experimental study was conducted to investigate the aerodynamic characteristics of a bioinspired corrugated airfoil compared with a smooth-surfaced airfoil and a flat plate at the chord Reynolds number of $Re_C = 58,000-125,000$ to explore the potential applications of such bio-inspired corrugated airfoils for micro air vehicle designs. In addition to measuring the aerodynamic lift and drag forces acting on the tested airfoils, a digital particle image velocimetry system was used to conduct detailed flowfield measurements to quantify the transient behavior of vortex and turbulent flow structures around the airfoils. The measurement result revealed clearly that the corrugated airfoil has better performance over the smooth-surfaced airfoil and the flat plate in providing higher lift and preventing large-scale flow separation and airfoil stall at low Reynolds numbers ($Re_C < 100,000$). While aerodynamic performance of the smooth-surfaced airfoil and the flat plate would vary considerably with the changing of the chord Reynolds numbers, the aerodynamic performance of the corrugated airfoil was found to be almost insensitive to the Reynolds numbers. The detailed flow field measurements were correlated with the aerodynamic force measurement data to elucidate underlying physics to improve our understanding about how and why the corrugation feature found in dragonfly wings holds aerodynamic advantages for low Reynolds number flight applications." 9537. O'Brien, M. (2010): *Arigomphus submedianus* (Odonata: Gomphidae) to be removed from the Michigan list of Odonata. *Argia* 22(3): 16-17. (in English) ["It was based solely on Hagen's 1885 paper on nymphal forms of Odonata. That record (under "*Gomphus pallidus*") is from a nymph in alcohol supposedly collected in Detroit, Michigan, 6 June 1879, by H.G. Hubbard. Hagen states that the various nymphal specimens he listed represent "four different moults." Given the status of knowledge of Gomphid nymphs at the time, and subsequent work on the group, I would say that common sense dictates that the Hagen "record" which has been propagated throughout the literature (and in the Byers [1927] and Kormondy [1958] Michigan lists), and has been a questionable record by the Michigan Odonata Survey (1997), be stricken from the Michigan list. With all the collecting that has taken place over the last 100 years, and not a single *Arigomphus submedianus* caught in Michigan, it's plain to me that the record is an error. To believe that a casual collector caught this in the Detroit area, far from any typical habitat and based on a larval specimen when the taxonomy of the larvae was imprecise at best, flies in the face of scientific scrutiny. Hagen may have been the father of North American Odonatology, but like any scientist, he was not perfect. It's time to be rid of this mistake that keeps getting propagated in the literature."] Address: O'Brien, M., Insect Division, Museum of Zoology, University of Michigan, Ann Arbor, MI 48109-1079, USA. 9539. Outomuro, D.; Torralba-Burrial, A.; Ocharan, F.J. (2010): Distribution of the Iberian Calopteryx damselflies and its relation with bioclimatic belts: Evolutionary and biogeographic implications. *Journal of Insect Science* 10(61): 16 pp. (in English) ["Using bioclimatic belts as habitat and distribution predictors, the present study examines the implications of the potential distributions of the three Iberian Calopteryx-taxa, with the aim of investigating the possible consequences in specific interactions among the species from a sexual selection perspective and of discussing biogeographical patterns. To obtain the known distributions, the literature on this genus was reviewed, relating the resulting distributions to bioclimatic belts. Specific patterns related to bioclimatic belts were clearly observed in the Mediterranean region. The potential distribution maps and relative frequencies might involve latitudinal differences in relative abundances, *C. virgo meridionalis* being the most abundant species in the Eurosiberian region, *C. xanthostoma* in the northern half of the Mediterranean region and *C. haemorrhoidalis* in the rest of this region. These differences might explain some previously described latitudinal differences in secondary sexual traits in the three species. Changes in relative abundances may modulate interactions among these species in terms of sexual selection and may produce sexual character displacement in this genus. *C. v. meridionalis* distribution and ecological requirements explain its paleobiogeography as a species which took refuge in Iberia during the Würm glaciation. Finally, possible consequences in species distributions and interactions are discussed within a global climate change context." (in English) ["Animals facilitate macrophyte seed dispersal in various ways despite specializations of macrophytes for water dispersal. Previous diet analyses of freshwater aquatic turtles revealed that several North American turtle species consume a variety and abundance of seeds among other plant material and animal prey. We quantified the dietary habits of *C. picta picta* in a Massachusetts lake to examine if these animals included hydrophyte seeds in their diet and evaluate their capacity as passive seed-dispersal agents. Fifty-four turtles were trapped and housed to collect feces. Examination of feces revealed a diverse diet with comparatively high frequencies of animal, plant, and algal matter. 857 seeds of at least nine plant species were egested (among 87% of turtles), with all but five (99%) seeds visibly intact. Seeds of *Nuphar* (473) and *Decodon* (305) were most abun-

dant in the feces. Life-history characteristics of both *C. p. picta* and *Nuphar* suggest an effective endozoochorous seed dispersal association. [...] The most frequent animal prey were dipteran larvae (mostly ceratopogonid midges) and odonate larvae (mostly libellulid dragonflies), egested by 83% and 60% of the turtles, respectively." 9544. Petrin, Z.; Schilling, E.G.; Loftin, C.S.; Johanson, F. (2010): Predators shape distribution and promote diversification of morphological defenses in *Leucorrhinia*, Odonata. *Evolutionary Ecology* 24(5): 1003-1016. (in English) ["Predators strongly influence species assemblages and shape morphological defenses of prey. Interestingly, adaptations that constitute effective defenses against one type of predator may render the prey susceptible to other types of predators. Hence, prey may evolve different strategies to escape predation, which may facilitate adaptive radiation of prey organisms. Larvae of different species in the dragonfly genus *Leucorrhinia* have various morphological defenses. We studied the distribution of these larvae in relation to the presence of predatory fish. In addition, we examined the variation in morphological defenses within species with respect to the occurrence of fish. We found that well-defended species, those with more and longer spines, were more closely associated with habitats inhabited by predatory fish and that species with weakly developed morphological defenses were

more abundant in habitats without fish. The species predominantly connected to lakes with or without fish, respectively, were not restricted to a single clade in the phylogeny of the genus. Our data is suggestive of phenotypic plasticity in morphological defense in three of the studied species since these species showed longer spines in lakes with fish. We suggest that adaptive phenotypic plasticity may have broadened the range of habitats accessible to *Leucorrhinia*. It may have facilitated colonization of new habitats with different types of predators, and ultimately, speciation through adaptive radiation." 9545. Piersanti, S.; Rebor, M.; Gaino, E. (2010): A scanning electron microscope study of the antennal sensilla in adult Zygoptera. *Odonatologica* 39(3): 235-241 (in English) ["Scanning electron microscope studies of the antennal flagella of *Coenagrion puella* and *Ischnura elegans* (Coenagrionidae), *Platycnemis pennipes* (Platycnemididae), *Lestes barbarus*, *L. viridis* (Lestidae), *Calopteryx virgo* and *C. haemorrhoidalis* (Calopterygidae) reveal the presence of pits containing sensilla on the latero-ventral side of the antenna. All these pits are the opening of deep cavities bearing the same sensilla previously described on Anisoptera antennae. These sensilla are represented by: (i) coeloconic porous sensilla, visible on the antennal surface, whose structure is in agreement with that reported for single walled olfactory receptors, and by (ii) two types of sensilla styloconica (type-1 and type-2), located at the bottom of the cavities and sharing common features typical of thermo-hygroreceptors. The present data allow us to extend previous considerations on the sensory role of the dragonfly antennae to the whole order Odonata, suggesting that olfaction, together with the ability to perceive temperature and humidity, are the main sensory functions of the antennae of these insects." 9546. Polacik, M.; Reichard, M. (2010): Diet overlap among three sympatric African annual killifish species *Nothobranchius* spp. from Mozambique. *J. Fish Biol.* 77 (3): 754-768. (in English) ["The diet patterns of three *Nothobranchius* species (*N. furzeri*, *N. orthonotus* and *N. rachovii*), small, short-lived annual killifish from temporary pools in African savannah were investigated. Four sites with contrasting fish density and water surface area were sampled in 2008 and 2009 in southern Mozambique. Stomach content analysis showed that all the species examined were generalists, with diets largely based on aquatic invertebrates. The same invertebrate prey categories were consumed by all three species, but their relative proportions varied across species. The largest species, *N. orthonotus*, showed the most distinct diet and consumed vertebrates (juvenile lungfish *Protopterus annectens* and larval Amphibia) and a relatively high proportion of Odonata, Coleoptera and Ephemeroptera larvae. The diet of the other two species (*N. furzeri* and *N. rachovii*) showed a stronger overlap, did not include vertebrates, but was rich in small crustaceans (Cladocera, Copepoda, Ostracoda and Conchostraca). Mosquito (Diptera) larvae formed only a negligible part of the diet of all the three species." (Authors)] Address: Polacik, M., Institute of Vertebrate

Biology, Academy of Sciences of the Czech Republic, Kvetná 8, 603 65 Brno, Czech Republic. E-mail: polacik@ivb.cz

9547. Raebel, E.M.; Merckx, T.; Riordan, P.; Macdonald, D.W.; Thompson, D.J. (2010): The dragonfly delusion: why it is essential to sample exuviae to avoid biased surveys. *Journal of Insect Conservation* 14(5): 523-533. ["Odonate populations and species numbers are declining globally. Successful conservation requires sound assessments of both odonate distributions and habitat requirements. Odonates have aquatic (larval) and terrestrial (adult) stages, but most surveys that are used to inform conservation managers are undertaken of the adult stage. This study investigates whether this bias towards adult records in odonate recording is misinterpreting the environmental quality of sites. The habitat focus is farmland ponds, a key feature of agricultural landscapes. We tested whether or not, adult, larval and exuvial surveys lead to similar conclusions on species richness and hence on pond quality. Results showed that pond surveys based upon larvae and exuviae are equally suitable for the reliable assessment of presence/absence of odonates, but that adult surveys are not interchangeable with surveys of larvae/exuviae. Larvae were also found at ponds with no emerging individuals due to changes in habitat quality, therefore presence of exuviae remains the only proof of life-cycle completion at a site. Ovipositing females were recorded at all ponds where exuviae were totally absent hence adult surveys over-estimate pond quality and low-quality ponds are functioning as ecological traps. Highly mobile and generalist species were recorded at more locations than other species. Adult surveys also bias recording towards genera, species and populations with non-territorial mate-location strategies. Odonate biodiversity monitoring would benefit from applying the best survey method (exuviae) to avoid wasting valuable financial resources while providing unbiased data, necessary to achieve conservation objectives." 9548. Rantala, M.J.; Honkavaara, J.; Suhonen, J. (2010): Immune system activation interacts with territory-holding potential and increases predation of the damselfly *Calopteryx splendens* by birds. *Oecologia* 163: 825-832. (in English) ["Activation of the immune system in insects has been shown to be costly in the laboratory setting, but experimental studies in the field are lacking. The costs of immunity in the wild may be different to those in the laboratory because animals in the wild are simultaneously subjected to a suite of selective agents. We have measured the costs of immune system activation in a wild population of the territorial damselfly *Calopteryx splendens*. Immune-challenged males were found to be less likely to be territorial and had lower overall survival rates than control or sham-manipulated males. Because territorial males have a higher mating success than nonterritorial males, this result suggests that immune-challenged males are also likely to suffer reduced mating success. However, the activation of the immune system as such did not increase predation risk; this occurred due to a combination of the former with a reduced territory-holding potential. As such, immune-challenged males not holding a

territory were most susceptible to predation by birds. The size of the wing spots, a known sexually selected male trait, predicted territorial behaviour in control and sham-manipulated males, but not in immune-challenged males. Our data show that immune system activation can have several costs acting in unison and that ubiquitous ecological interactions, such as predation, may affect trade-offs between immunity and other life history traits."(Authors)] Address: Rantala, M.J., Dept of Biology, University of Turku, FIN-20024 Turku, Finland. 9550. Richardson, J.S.; Zhang, Y.; Marczak, L.B. (2010): Resource subsidies across the land-freshwater interface and responses in recipient communities. *River Research and Applications* 26: 55-66. (in English) ["Fluxes of resource subsidies, such as terrestrial leaf litter to streams and adult aquatic insects to riparian predators, are examples of important links between adjacent ecosystems. The importance of these cross-ecosystem resource flows from donor systems to recipient consumers is increasingly recognized. Streams, especially small streams with their high edge ratio with the terrestrial system, provide excellent models for the study of subsidies and a large portion of this literature has been produced by aquatic scientists. Field experiments manipulating flows between small streams and their riparian areas (e.g. leaf litter, terrestrial invertebrates, and adult aquatic insects to riparian areas) have indicated that consumers in streams and riparian areas are highly dependent upon such subsidies and the value of the subsidies are further modified by patterns of retention and pathways of use. Experiments typically indicate rapid growth or demographic responses by consumers, indicating these populations are resource limited or at levels of incipient population limitation, and can capitalize on short-term resource pulses. More press manipulations are still necessary to determine the dynamical consequences of subsidies for recipient communities. The nature of the subsidy (e.g. species of litter or invertebrates) and its timing are also important details that need further study. Finally, there are opportunities to consider the evolution of life cycle timing (modelling), interception strategies by recipient populations and short-term and long-term responses of communities. [...] Linkages at the community level: Knight et al. (2005) demonstrated that the presence of predacious

fish in aquatic systems could lead to a trophic cascade in adjacent riparian ecosystems by suppressing the numbers of adult dragonflies. The numbers of dragonfly larvae can be suppressed directly through fish predation or indirectly through behavioural modifications resulting in fewer dragonfly adults. Such fish predation on dragonfly larvae indirectly facilitates terrestrial vegetation reproduction, because insect pollinators were released from the predation pressure of dragonfly adults. Hence, the numbers of pollinators were higher in riparian zones of fish-bearing ponds, where plants received more pollinator visits than plants near fish-free ponds (Knight et al., 2005). Similarly, Ngai and Srivastava (2006) demonstrated that aquatic communities in epiphytic bromeliads containing damselflies had lower rates of emergence of adults of detritivorous insects (chironomids, tipulids, scirtids). As a consequence of a difference in communities the type and rates of subsidies to the terrestrial environment constrained by the presence or absence of predators in the aquatic system. These examples indicate that strong biotic interactions between species can reverberate across ecosystem boundaries through consumer flows." (2010): Defining hotspots of characteristic species for multiple taxonomic groups in the Netherlands. *Biodivers. Conserv.* 19: 2517-2536. (in English) ["Biogeographical zonation based on single taxa poses major limitations on planning for nature conservation. This paper identifies biogeographical patterns of multiple taxa in the Netherlands, where no endemics are present at species level, on the basis of characteristic species. We used occurrence data on five species groups in order to identify spatially coherent, ecologically important regions. TWINSPAN was used to cluster grid squares according to similarity in species composition for each taxonomic group. Species that are characteristic of each of the clusters were identified using a preference index, and corresponding clusters among the taxonomic groups were identified with Kappa statistics. Regions containing characteristic species for several taxonomic groups were defined as 'hotspots'. Stepwise discriminant analysis was then used to characterize these hotspots according to differences in environmental conditions. The analysis yielded five regions that are clearly distinct in terms of species composition for individual taxonomic groups. Each region is characterized by a set of unique species that occur in the zonation of at least two of the taxonomic groups. Stepwise discriminant analysis revealed significant environmental differences among these regions. The concept of hotspots as operationalized in this study can make nature conservation planning more efficient. In combination, the hotspots defined here comprise the majority of the species occurring in the Netherlands for the studied groups. Therefore, this regionalization should be taken into account when prioritizing nature conservation efforts." (Authors) The study includes of hoverflies, herpetofauna, grasshoppers and crickets, dragonflies, and mosses.] Address: Kalkman, V.J., European Invertebrate Survey - Nederland, p/a Nationaal Natuurhistorisch Museum - naturalis, Postbus 9517, 2300 RA Leiden, The Netherlands. - 9559.** Shafroth, P.B.; Wilcox, A.C.; Hickey, L.J.T.; Andersen, D.C.; Beauchamp, V.B.; Hautzinger, A.; McMullen, L.E.; Warner, A. (2010): Ecosystem effects of environmental flows: modelling and experimental floods in a dryland river. *Freshwater Biology* 55: 68-85. (in English) ["1. Successful environmental flow prescriptions require an accurate understanding of the linkages among flow events, geomorphic processes and biotic responses. We describe models and results from experimental flow releases associated with an environmental flow program on the Bill Williams River (BWR), Arizona, in arid to semiarid western USA. 2. Two general approaches for improving knowledge and predictions of ecological responses to environmental flows are: (1) coupling physical system models to ecological responses and (2) clarifying empirical relationships between flow and ecological responses through implementation and monitoring of experimental flow releases. 3. We modelled the BWR physical system using: (1) a reservoir operations model to simulate reservoir releases and reservoir water levels and estimate flow through the river system under a range of scenarios, (2) one- and two-dimensional river hydraulics models to estimate stage-discharge relationships at the whole-river and local scales, respectively, and (3) a groundwater model to estimate surface- and groundwater interac-

tions in a large, alluvial valley on the BWR where surface flow is frequently absent. 4. An example of a coupled, hydrology-ecology model is the Ecosystems Function Model, which we used to link a one-dimensional hydraulic model with riparian tree seedling establishment requirements to produce spatially explicit predictions of seedling recruitment locations in a Geographic Information System. We also quantified the effects of small experimental floods on the differential mortality of native and exotic riparian trees, on beaver dam integrity and distribution, and on the dynamics of differentially flow-adapted benthic macroinvertebrate groups. 5. Results of model applications and experimental flow releases are contributing to adaptive flow management on the BWR and to the development of regional environmental flow standards. General themes that emerged from our work include the importance of response thresholds, which are commonly driven by geomorphic thresholds or mediated by geomorphic processes, and the importance of spatial and temporal variation in the effects of flows on ecosystems, which can result from factors such as longitudinal complexity and ecohydrological feedbacks. [...] While both Gomphidae and Ephemeroptera experienced flood-induced mortality, both groups rebounded in numbers after 2 weeks. We attribute the rapid return of gomphids to their ability to move back to the active stream channel, even when they were displaced into high flow channels that dried out postflood." 9560. Sherratt, T.N.; Laird, R.A.; Hassall, C.; Lowe, C.D.; Harvey, I.F.; Watts, P.C.; Cordero-Rivera, A.; Thompson, D.J. (2010): Empirical evidence of senescence in adult damselflies (Odonata: Zygoptera). *Journal of Animal Ecology* 79(5): 1034-1044. (in English) ["1. Age-dependent increases in mortality have been documented in a variety of species of insect under laboratory conditions. However, while strong statistical evidence has been presented for senescence in vertebrate populations in the wild, we know little about the rate and shape of senescence in wild populations of insects. 2. Odonates provide excellent candidate species for evaluating demographic senescence as they are large enough to be marked individually and they are easily re-sighted without recapture. The prevailing opinion – based entirely on qualitative examination of the declines in log numbers alive with time since marking – is that odonates exhibit age-independent daily survivorship. 3. Here, we examine mark-recapture data on *Coenagrion puella* over two consecutive seasons. For the first time, we evaluate and compare the fit of quantitative models that not only account for weather-dependent daily variation in daily re-sighting rates, but also age-dependent variation in daily survivorship. 4. Models with age-dependent declines in daily survivorship provide a more parsimonious explanation for the data than similar models without these age-dependent effects. In general, models in which mortality increases in an exponential (Gompertz) fashion explain the mark-recapture sequences more efficiently than a range of alternative models, including those in which mortality increases as a power function (Weibull) or reaches a plateau (logistic). These results are indicative of a general senescent decline in physiological functioning, which is particularly marked after 15 days as a mature adult. 5. Weather (temperature, sun and precipitation)

and initial mite load influenced the probability of daily re-sighting. Weather and mite load also influenced daily survivorship, but their effects differed between seasons. 6. Overall, fitting models with age as an explicit covariate demonstrates that odonates do indeed senesce. This contradicts previously held assumptions that Odonata do not exhibit age-dependent survivorship in the wild." 9561. Siepielski, A.M.; Hung, L.L.; Bein, E.E.B.; McPeck, M.A. (2010): Experimental evidence for neutral community dynamics governing an insect assemblage. *Ecology* 91(3): 847-857. (in English) ["The high levels of species diversity observed within many biological communities are captivating, yet the mechanisms that may maintain such diversity remain elusive. Many of the phenotypic differences observed among species cause interspecific trade-offs that ultimately act to maintain diversity through niche-based coexistence. In contrast, neutral community theory argues that phenotypic differences among species do not contribute to maintaining species diversity because species are ecologically equivalent. Here we provide experimental and observational field evidence that two phylogenetically very distant *Enallagma* species appear to be ecologically equivalent to one another. Experimental abundance manipulations showed that each species gains no demographic advantage at low relative abundance, whereas manipulations of total *Enallagma* abundance resulted in large increases in per capita mortality and large decreases in growth for both species. Moreover, demographic rates and relative abundances of multiple *Enallagma* species were uncorrelated with major environmental gradients in an observational study of 20 natural lakes. These are the expected patterns if species are ecologically equivalent. However, these results do not imply that all damselflies in these lakes are ecologically identical. Previous experimental results have demonstrated the operation of strong coexistence mechanisms maintaining *Enallagma* and its sister-genus *Ischnura* in these littoral food webs. Combined with a simple theoretical model we present, these results taken together show how both neutral and niche dynamics can jointly structure communities." 9562. Simaika, J.P.; Samways, M.J. (2010): Large-scale estimators of threatened freshwater catchment species relative to practical conservation management. *Biological Conservation* 143(2): 311-320 (in English) ["Freshwater ecosystems are among the most threatened in the world. In light of the threats to freshwater biodiversity, it is essential to map the distribution and status of species to ascertain their threat status for prioritizing conservation action. However, while there is agreement that the conservation of freshwater ecosystems depends on whole-catchment management, there are still a wide variety of large-scale mapping methods in use, the advantages and disadvantages of which have not been fully explored. This study shows that area estimation based on minimum convex polygons should not be encouraged for aquatic species. The IUCN definition of area of occupancy (AOO) is a useful term, albeit highly scale-dependent, for assessment of the total approximate area over which a species occurs.

However, for aquatic fauna, and perhaps many other organisms, assessment of occurrence should be based on the more accurate point-locality presences only. The IUCN extent of occurrence (EOO), for freshwater catchment species, should be redefined as 'the sum of the smallest hydrological units identified, of presently known, inferred or projected occurrences of a taxon, excluding cases of vagrancy, that are used to estimate the threat to a taxon'. A single hydrological unit is also the conservation or management unit. Here we suggest that this unit is the quaternary catchment. This new mapping approach is more appropriate and practical for use in both management planning and conservation action. We suggest that conservation managers and decision makers facilitate co-operation in freshwater mapping efforts by working at the same spatial scale, i.e. the same hydrological unit." 9563. Small, G.E.; Pringle, C.M. (2010): Deviation from strict homeostasis across multiple trophic levels in an invertebrate consumer assemblage exposed to high chronic phosphorus enrichment in a Neotropical stream. *Oecologia* 162(3): 581-590. (in English) ["A central tenet of ecological stoichiometry is that consumer elemental composition is relatively independent of food resource nutrient content. Although the P content of some invertebrate consumer taxa can increase as a consequence of P-enriched food resources, little is known about how ecosystem nutrient loading can affect the elemental composition of entire consumer assemblages. Here we examine the potential for P enrichment across invertebrate consumer assemblages in response to chronic high P loading. We measured elemental ratios in invertebrate consumers and basal food resources in a series of streams in lowland Costa Rica that range widely in P levels (2-135 µg l⁻¹ soluble reactive P). Streams with high P levels receive natural long-term (over millennia) inputs of solute-rich groundwater while low-P streams do not receive these solute-rich groundwater inputs. P content of leaf litter and epilithon increased fourfold across the natural P gradient, exceeding basal resource P content values reported in the literature from other nutrient-rich streams. Invertebrate consumers from the high-P study stream were elevated twofold in P content across multiple taxonomic and functional feeding groups, including predators. Our results strongly support the hypothesis that elevated P content in consumers feeding on P-enriched food resources is a consequence of deviation from strict homeostasis. In contrast to prior studies, we found that between-stream variation in P content of a given taxon greatly exceeded within-stream variation among different taxa, suggesting that environment may be as important as phylogeny in controlling consumer stoichiometry. Relaxing the assumption of strict homeostasis presents challenges and opportunities for advancing our understanding of how nutrient limitation affects consumer growth. Moreover, our findings may provide a window into the future of how chronic anthropogenic nutrient loading can alter stoichiometric relationships in food webs." Schmiedel, U. & Jürgens, N. [Eds.]: Biodiversity in southern Africa. Volume 2: Patterns and processes at regional scale. Klaus Hess Publishers, Göttingen & Windhoek: 64-69. (in English) ["Dragonflies are amongst the most well-studied and most recognised insects and there is an ongoing worldwide initiative in which the diversity and conservation status of all species are being assessed. In Africa, where about 900 species of Odonata occur, the southern part of the continent is currently the best surveyed for Odonata. In this chapter we analyse and depict biodiversity distribution patterns in the BIOTA transect area, from the Cape in the south to the Okavango River in the north, using Odonata databases for Botswana, Namibia and South Africa. We counted species numbers in each WWF Terrestrial Ecoregion and freshwater basin. Species numbers were highest in the Zambebian ecoregions followed by the Cape ecoregions, whereas the drier ecoregions had fewer species, except for a few outstanding localities. The proportions of range-restricted species were highest in the Cape and Zambebian ecoregions accounting for at least one third of the species, whereas all other ecoregions were almost exclusively populated by widespread species." (2010): Local extinction of dragonfly and damselfly populations in low- and high-quality habitat patches. *Conservation Biology* 24(4): 1148-1153. (in English, with Spanish summary) ["Understanding the risk of extinction of a single population is an important problem in both theoretical and applied ecology. Local extinction risk depends on several factors, including population size, demographic or environmental stochasticity, natural catastrophe, or the loss of genetic diversity. The probability of local extinction may also be higher in low-quality sink habitats than in high-quality source habitats. We tested this hypothesis by comparing local extinction rates of 15 species of Odonata between 1930-1975 and 1995-2003 in central Finland. Local extinction rates were higher in low-quality than in high-quality habitats. Nevertheless, for the three most common species there were no differences in extinction rates between low- and high-quality habitats. Our results suggest that a good understanding of habitat quality is crucial for the conservation of species in heterogeneous landscapes." 9570. Suhonen, J.; Honkavaara, J.; Rantala, M.J. (2010): Activation of the immune system promotes insect dispersal in the wild. *Oecologia* 162(3): 541-547. (in English) ["Dispersal has important ecological and evolutionary consequences but is a poorly understood behaviour. We experimentally tested whether activation of the immune system affects dispersal in male damselflies, *Calopteryx virgo*, from three natural populations. We show that males that contained an experimentally inserted artificial pathogen, a nylon monofilament implant, had higher dispersal rates and flew further than control males, but not further than sham manipulated males. Our data suggest that dispersal may reduce the risk of further infections if immune system activation indicates high parasite infection risk in the present habitat. We, thus, suggest that parasites may play an impor-

tant role in the evolution of host dispersal." (Authors)] Address: Suhonen, J., Section of Ecology, Department of Biology, University of Turku, 20014 Turku, Finland. E-mail: juksuh@utu.fi

9571. Togashi, H.; Suzuki, T.; Urabe, J. (2010): Spatial variations in chironomid larvae and dragonfly predation in pools on a Japanese high mountain moor. *Verh. Int. Ver. Limnologie* 30(9): 1357-1362. (in English) ["Our study clearly showed a negative impact of dragon-flies, *Aeshna juncea* and *A. nigroflava*, on the abundance of chironomid larvae, due largely to the impact on *Alotanypus*, which dominated the chironomid communities in the Shibakusa-Daira pools. The abundance of this genus when dragonfly nymphs were added was significantly lower than that in their absence. The effect index of post-manipulation was negatively correlated with dragonfly biomass. Thus, regardless of the pool, an increase in *Aeshna* abundance consistently reduced *Alotanypus* abundance. However, in the 3 other genera - *Tanytarsus*, *Procladius*, and *Chironomus* - no significant difference was detected between the effect indices of pre- and post-manipulation. This implies either that *Aeshna* do not prey heavily on these genera or that net effects of this predatory dragonfly on these genera differ among the pools. These possibilities imply that the abundance of *Aeshna* can be a factor differentiating the community structure of chironomid larvae among pools at the Shibakusa-Daira." 9572. Touchon, J.C.; Warkentin, K.M. (2010): Short- and long-term effects of the abiotic egg environment on viability, development and vulnerability to predators of a Neotropical anuran. *Functional Ecology* 24(3): 566-575. (in English) ["1. Environmental variation during development is common and often has long-lasting effects on phenotypes and survival. In organisms with complex life cycles, such effects may carry over from one life stage into the subsequent stages, affecting reproductive success and survival in both direct and indirect manners. Much research has focused on the transition from the larval to adult stages, but fewer studies have addressed how egg-stage variation may affect the larval stage, development to metamorphosis, and adult fitness. 2. We assessed the short- and long-term consequences of abiotic environmental variation during egg development of the Neotropical treefrog *Dendropsophus ebraccatus*. Typically, *D. ebraccatus* eggs are oviposited terrestrially on leaves above water and hydrated by rainfall. However, at our field site in Panama ~25% of terrestrial eggs become desiccated during development and ~19% become submerged underwater. In addition, in unshaded ponds *D. ebraccatus* lays eggs directly in water. We assessed immediate and carryover effects of egg development under hydrated, desiccated and submerged conditions. We measured morphology and vulnerability to predators at hatching and at three time points during the larval period. We also measured morphology at metamorphosis. 3. Submerged eggs hatched less developed and later and had higher baseline mortality after hatching than either hydrated or desiccated terrestrial eggs. By 10 days after hatching, the morphology of tadpoles from the three egg environments was indistinguishable. Nonetheless, the egg environment affected predation, with tadpoles from

submerged eggs being least vulnerable; later in development egg environment ceased to affect vulnerability. Tadpoles from all egg environments grew to a size refuge from dragonfly nymphs, whereas vulnerability to water bugs remained constant throughout development. At metamorphosis, froglets from submerged eggs were the largest and those from hydrated eggs were the smallest. 4. With anticipated climate change in the Neotropics, rainstorms are predicted to become more sporadic but larger when they do occur, potentially increasing the chances of both egg desiccation and flooding. The incidence of different egg environments may therefore change, potentially affecting amphibian phenotypes, interactions with predators, and survival across multiple life stages." 9573. Tsubaki, Y.; Samejima, Y.; Siva-Jothy, M.T. (2010): Damselfly females prefer hot males: higher courtship success in males in sunspots. *Behavioral Ecology and Sociobiology* 64(10): 1547-1554. (in English) ["Males of some territorial calopterygid damselflies show an elaborate courtship display that involves high-frequency wing-beats directed toward an incoming female. Although it has been suggested that female mate preference is based on some characteristics of male's courtship display, it is unclear whether the courtship display varies between males or is influenced by environmental conditions. We combined two recent technologies, thermographic imaging and high-speed digital videography, to show that the wing-beat frequency during courtship (i.e., courtship intensity) in a damselfly, *Mnais costalis*, is correlated with thorax temperature. Our data indicated that (1) male thorax temperature was associated with solar exposure in his territory, (2) environmentally derived thermal gain enhanced courtship intensity, (3) hotter males were more likely to copulate than others, and (4) female thorax temperature during oviposition within a territory was associated with solar exposure. Males with territories that have longer exposure to sun spots are expected to attain higher thorax temperatures for longer and so are able to successfully court more females. We suggest that females benefit from mating with hot males because they will be on a warmer territory while ovipositing. Hot males might also have greater mate guarding ability, and/or eggs may develop faster in warmer territories." 9574. Tsuchiya, K.; Hayashi, F. (2010): Factors affecting sperm quality before and after mating of calopterygid damselflies. *PLoS ONE* 5(3): e9904. doi: 10.1371/7 pp. (in English) ["Damselflies have a more complex sperm transfer system than other internally ejaculating insects. Males translocate sperm from the internal reproductive organs to the specific sperm vesicles, a small cavity on the body surface, and then transfer them into the female. To examine how the additional steps of sperm transfer contribute to decreases in sperm quality, we assessed sperm viability (the proportion of live sperm) at each stage of mating and after different storage times in male and female reproductive organs in two damselfly species, *Mnais pruinosa* and *Calopteryx cornelia*. Viability of stored sperm in females was lower than that of male stores even just after copulation. Male sperm vesicles were not equipped to main-

tain sperm quality for longer periods than the internal reproductive organs. However, the sperm vesicles were only used for short-term storage; therefore, this process appeared unlikely to reduce sperm viability when transferred to the female. Males remove rival sperm prior to transfer of their own ejaculate using a peculiar-shaped aedeagus, but sperm removal by males is not always complete. Thus, dilution occurs between newly received sperm and aged sperm already stored in the female, causing lower viability of sperm inside the female than that of sperm transferred by males. If females do not mate, sperm viability gradually decreases with the duration of storage. Frequent mating of females may therefore contribute to the maintenance of high sperm quality." 9575. van Strien, A.J.; Termaat, T.; Groenendijk, D.; Mensing, V.; Kery, M. (2010): Site-occupancy models may offer new opportunities for dragonfly monitoring based on daily species lists. *Basic and Applied Ecology* 11(6): 495-503 (in English) ["Monitoring biodiversity is necessary but difficult to achieve in practice, in part because standardized field work is often demanding for volunteer field workers. Collecting opportunistic data on presence and absence of species is much less demanding, but such data may suffer from a number of biases, such as variation in observation effort over time. Here we explore whether site-occupancy models may be helpful to reduce such biases in opportunistic data, especially those caused by temporal variation of observation effort and by incomplete reporting of sightings. Site-occupancy models represent a generalisation of classical metapopulation models to account for imperfect detection; they estimate the probability of sites to be occupied (and of the rates of change, colonisation and extinction rates) while taking into account imperfect detection of a species. The models require so-called presence-absence data from replicated visits for a number of sites (e.g., 20-50). We tested whether these models provide reliable trend estimates if collectors of opportunistic data do not report all species detected. We applied the models to three opportunistic datasets of dragonfly species (1999-2007) in the Netherlands: (1) one-species records, (2) short daily species lists and (3) comprehensive daily species lists. Trend estimates based on a fourth dataset from a standardized monitoring scheme were used as a yardstick to judge the results. The analyses showed that occupancy trends based on comprehensive daily species lists in combination with site-occupancy models were generally similar to those based on the monitoring scheme. But trends based on one-species records and short daily lists were too imprecise to be very useful. In addition, site-occupancy models lead to more realistic occupancy estimates than those obtained from conventional logistic regression analysis. We conclude that comprehensive daily species lists can be useful surrogates for monitoring schemes to assess distributional trends." (Authors) Address: van Strien, A.J., Statistics Netherlands, P.O. Box 24500, 2490 HA The Hague, The Netherlands. E-mail: asin@cbs.nl

9576. Varnosfaderany, M.N.; Ebrahimi, E.; Mirghafary, N.; Safyanian, A. (2010): Biological assessment of the Zayandeh Rud River, Iran, using benthic macroinvertebrates. *Limnologica* 40: 226-232. (in English) ["Benthic macroinvertebrate communities from the

middle of Zayandeh Rud River were analyzed monthly during 1 year at 8 stations, in order to assess changes in their diversity and richness in relation to water quality. Two major groups of sites based on similarity between macroinvertebrate communities were identified by cluster analysis. The performances of the original and revised BMWP score systems were assessed by comparing the community structure indices of benthic macroinvertebrates along with physico-chemical parameters of the water. The biotic indices (BMWP, ASPT, revised BMWP and ASPT) showed better correlation with water quality parameters than that of the richness and diversity indices. The revised ASPT had the highest correlation with water quality parameters. It seems that the application of the revised BMWP score system could be useful for assessment of the water quality in Zayandeh Rud River." 9582. Watts, P.C.; Keat, S.; Thompson, D.J. (2010): Patterns of spatial genetic structure and diversity at the onset of a rapid range expansion: colonisation of the UK by the small red-eyed damselfly *Erythromma viridulum*. *Biological Invasions* 12(11): 3887-3903. (in English) ["Species' geographic ranges may vary in size in response to a change in environmental conditions. The specific genetic consequences of range expansions are context dependent, largely depending upon the rate of colonisation as well as the origins and numbers of founders, and the time since colonisation. Like other "charismatic" taxa, such as birds and lepidopterans, the distributions of odonates are well-known through substantial monitoring programmes co-ordinated by various societies. The small red-eyed damselfly *E. viridulum* has undergone a substantial, northward range expansion in Europe in the last 30 years and has recently colonised two distinct areas in the UK. We quantify the immediate genetic consequences of this rapid colonisation by genotyping more than 1,400 *E. viridulum* from 39 sites across the northwest margin of this species' geographic range. Levels of genetic diversity and spatial structure are impacted by this species recent range expansion and non-equilibrium conditions that drive weak genetic divergence, even at regional spatial scales. Populations of *E. viridulum* become less diverse towards the edge of this species' distribution, presumably as a consequence of colonisation through a series of founder events. Specifically, there is a significant reduction in genetic diversity in the smallest, most recent focus of colonisation in the UK; however, there are generally low levels of genetic diversity across this *E.*

viridulum's northern range margin. While most populations are generally poorly differentiated, *E. viridulum* nonetheless consists of two distinct lineages that broadly differentiate between eastern and western Europe. Genetic divergence between the two UK colonisation foci are indicative of distinct immigration events from separate sources; however a general lack of spatial structure prevents us from pinpointing the specific origins of these migrant damselflies." (Authors) Address: Watts, P.C., School of Biological Sciences, The Biosciences Building, Crown Street, University of Liverpool, Liverpool, L69 7ZB, UK. E-mail: p.c.watts@liv.ac.uk

9583. Wellenreuther, M.; Vercken, E.; Svensson, E.I. (2010): A role for ecology in male mate discrimination of immigrant females in *Calopteryx damselflies*?. *Biological Journal of the Linnean Society* 100(3): 506-518. (in English) ["Sexual selection against immigrants is a mechanism that can regulate premating isolation between populations but, so far, few field studies have examined whether males can discriminate between immigrant and resident females. Males of the damselfly *C. splendens* show mate preferences and are able to force pre-copulatory tandems. We related male mate responses to the ecological characteristics of female origin, geographic distances between populations, and morphological traits of females to identify factors influencing male mate discrimination. Significant heterogeneity between populations in male mate responses towards females was found. In some populations, males discriminated strongly against immigrant females, whereas the pattern was reversed or nonsignificant in other populations. Immigrant females were particularly attractive to males when they came from populations with similar predation pressures and densities of conspecifics. By contrast, immigrant females from populations with strongly dissimilar predation pressures and conspecific densities were not attractive to males. Differences in the abiotic environment appeared to affect mating success to a lesser degree. This suggests that male mate discrimination is context-dependent and influenced by ecological differences between populations, a key prediction of ecological speciation theory. The results obtained in the present study suggest that gene-flow is facilitated between ecologically similar populations." 9585. Worthen, W.B. (2010): Flying Dragons: A colorful field experiment in resource partitioning. *The American Biology Teacher* September 72(7): 432-436. (in English) ["Several common dragonfly species perch at different heights. Using dowels as perches and simple chi-square tests, this pattern of resource partitioning can be described quickly and easily. Additional experiments can examine the effect of interspecific competition on perch selection, and the relationships between perching height, body size, and wing aerodynamics." (Author)] Address: Worthen, W.B., Dept of Biology, Furman Univ., Greenville, SC29613 USA. E-mail: worthen@furman.edu

9586. Yamada, Y.; Sasaki, H.; Harauchi, Y. (2010): Composition of road-killed insects on coastal roads around Lake Shikotsu in Hokkaido, Japan. *J. Rakuno Gakuen Univ.* 34(2): 177-184. (in English, with Japanese summary) ["Road-killed insects were collected 12 times along two environmentally different coastal roads of Lake Shikotsu, Hokkaido, Japan, from mid-June to mid-September in 2007. Route 276 is located 50-100 m distant from the lakeshore and separated from the water by woodland, whereas Route 453 is situated alongside the lakeshore; thus, flora along the two roadsides differ. In total, 2590.1 insects per kilometre were found along Route 276, whereas 2414.2 insects per kilometre were found on Route 453. When classified by order, the composition of the collected insects differed between the two roads: Lepidoptera (32.79%) was the dominant order on Route 276 followed by Coleoptera (25.29%) and Diptera (18.52%), whereas on Route 453, Coleoptera (25.47%) was the dominant order, followed by Diptera (21.33%) and Odonata (17.02%). The species composition of dragonflies and butterflies also differed between the roads. Our results suggest that differences in the composition of insects killed along roads are due to differences in roadside environments.] Address: Yamada, Y., Lab. of Entomol., Graduate school of Rakuno Gakuen Univ., Ebetsu, Hokkaido 069-8501, Japan

9587. Yoon, J.; Jong, M.N.; Heungtae, K.; Yeon, J.B.; Jae, G.K. (2010): *Nannophya pygmaea* (Odonata: Libellulidae), an endangered dragonfly in Korea, prefers abandoned paddy fields in the early seral [sic] stage. *Environ. Entomol.* 39(2): 278-285. (in English) ["To characterize habitats of *N. pygmaea*, which is endangered in Korea, we analyzed characteristics of surface water and soil, landscape properties, and vegetation types in 22 habitats in eight areas of Korea where nymphs of *N. pygmaea* have been found since 2005. We divided the habitats into two groups: DS (dwelling site) habitats, where *N. pygmaea* was observed at the time of the study, and PDS (past dwelling site) habitats, where *N. pygmaea* recently lived but is no longer found. The habitats were mostly located in former paddy fields on mountain slopes that have been abandoned for 3-7 yr. The main water sources for these habitats were ground water and surface runoff, and the water level was stable at 3-7 cm in depth. The habitats ranged from 300 to 1000 m² and were dominated by *Juncus effusus*, which formed tussock mounds. According to the hydrosere model of succession, *N. pygmaea* appeared mostly in the early stages of plant succession (the period 3-7 yr after the initiation of succession in former paddy fields) and *N. pygmaea* preferred habitats displaying the water and soil characteristics that are typical of the

early stages of succession in abandoned paddy fields. These results indicate that the primary habitats of *N. pygmaea* in Korea are recently abandoned paddy fields that are in an oligotrophic state. As succession proceeds in these habitats, *N. pygmaea* disappears. A habitat management program should be launched to conserve the habitats and populations of *N. pygmaea*." (Authors)] Address: Jae, G.K., Department of Biology Education, Seoul National University, Seoul 151-748, Korea. E-mail: jaegkim@snu.ac.kr.

9588. Zambrano, L.; Valiente, E.; Vander Zanden, M.J. (2010): Stable isotope variation of a highly heterogeneous shallow freshwater system. *Hydrobiologia* 646: 327-336. (in English) ["Food web structure is well known to vary widely among ecosystems. Recent research indicates that there can be a high degree of spatial heterogeneity within ecosystems as well. Xochimilco is a small heterogeneous freshwater system that has been transformed into a network of canals, small lakes, and wetlands. Located within Mexico City, this ecosystem has been intensively managed and highly impacted for more than 50 years. This system receives urban and agricultural runoff, with resulting impacts on water quality. The aquatic community is dominated by exotics such as carp (*Cyprinus carpio*) and tilapia (*Oreochromis niloticus*), though the system still supports endemic species such as the aquatic salamander, axolotl (*Ambystoma mexicanum*), and crayfish (*Cambarellus montezumae*), which are both endangered. In this study, we used carbon and nitrogen stable isotopes for the whole food web and gut content analysis from the exotic fishes to describe food web structure in different canals within Xochimilco. There were significant isotopic differences among canals. These differences may result from isotopic baseline differences as well as differences in actual food web structure: both are related to local spatial variation in water quality driven by nutrient inputs and exotic fishes. Within ecosystem variability is likely to be seen in other perturbed shallow systems as well, and should be explicitly considered in future food web studies." (Authors) There were no significant differences among years in carbon or nitrogen for Odonata. Most taxa did not show seasonal differences in $\delta^{15}N$, except for axolotl, which were higher in the rainy season, and Odonata, which were higher in the dry season.] Address: Zambrano, L., Depto de Zoología, Instituto de Biología, Universidad Nacional Autónoma de México, Ciudad Universitaria, México DF 04200, México. 9591. Zhang, Y.-y.; Xuan, W.-j.; Zhao, J.-l.; Zhu, C.-d.; Jiang, G.-f. (2010): The complete mitochondrial genome of the cockroach *Eupolyphaga sinensis* (Blattaria: Polyphagidae) and the phylogenetic relationships within the Dictyoptera. *Molecular Biology Reports* 37(7): 3509-3516. (in English) ["We present the complete mitochondrial DNA sequence of *Eupolyphaga sinensis*. This closed circular molecule is 15553 bp long and consists of 37 genes that encode for 13 inner membrane proteins, 2 ribosomal RNAs and 22 transfer RNAs. The genome shares the gene order and orientation with previously known Blattaria mitochondrial genomes. All tRNAs could be folded into the typical cloverleaf secondary structure, but the tRNA^{Ser} (AGN) appears to be missing the DHU arm. The A + T-rich region is 857 bp long and longer than other cockroaches. Based on the concatenated amino acid sequences of all protein coding genes of *E. sinensis* in conjunction with those 23 other arthropod sequences, we reconstruct the phylogenetic tree. Phylogenetic analyses shows that Blataria (including Isoptera) and the Mantodea are sister groups. Furthermore the relationship of the three basal clades of winged insects are different from the three previous hypotheses ((Ephemeroptera + Odonata) + Neoptera, Ephemeroptera + (Odonata + Neoptera), Odonata + (Ephemeroptera + Neoptera)). The Ephemeroptera (*Parafronurus youi*) clusters with the Plecoptera (*Pteronarcys princes*)."] (Authors)] Address: Jiang, G.-f., Jiangsu Key Laboratory for Biodiversity & Biotechnology, College of Life Sciences, Nanjing Normal University, Nanjing, 210046, China. 9597. Habdijia, I.; Radanovic, I.; Primc-Habdijia, B. (1997): Longitudinal distribution of predatory benthic macroinvertebrates in a karstic river. *Archiv für Hydrobiologie* 139(4): 527-546. (in English) ["The longitudinal distribution of predatory macroinvertebrates and their diversity were investigated on boulder, cobble and gravel substrates along the River Kupa, a karstic river in the NW Dinarid area (Croatia). Depending on substrate type and river section, the predator biomass constituted 6.9 % to 20.2 % of the total macro-invertebrate biomass. In the headwater streams more than 80 % of predator biomass was represented by rhyacophilid, perlid and perlodid larvae. In the upper river section *Hirudinea* species, rhyacophilids and the dipteran larva,

Atherix ibis, constituted approximately equal percentages of total predators. In the lower river section *Hirudinea* species, Odonata larvae, tanipod and ceratopogonid larvae were the most dominant predators. Along the river gradient the increase of predator biomass corresponded with the increase of scraper, collector-gatherer and filterer biomass. The Shannon index of diversity showed that the diversity of predators increased from the source area to the downstream reaches. A significant and positive association was found between diversity of predators and diversity of collector-gatherers. This positive relationship between predators and collector-gatherers may be interpreted as the diversity response of predators to the diversity of prey." (1998): Einfluß extremer Schwermetallbelastungen auf die Zusammensetzung der Makrobenthoszönose eines Mittelgebirgsbaches in einem ehemaligen Erzabbaugebiet des Raumes Overath (Bergisches Land). Decheniana 151: 173-182. (in German, with English summary) ["The effects on benthic invertebrates of the extremely with heavy metals contaminated creek Grünewaldbach (Nordrhein-Westfalen, Germany), impacted by wastes from past mining activities, were studied in 1995. As reference served a low impacted creek (Hellenthalbach), situated at a distance of 1.3 km. Both creeks are tributaries of the river Sülz. The organisms were exposed to high levels of Cd (up to 0.13 mg/L), Zn (up to

133 mg/L) and Ni (up to 2.18 mg/l) and lower concentrations of Pb and Cu. This led to a high elevated whole-body heavy metals bioaccumulation. The grazing species showed the highest and the carnivorous species the lowest concentrations. Severely influenced by heavy metals was the composition of the benthic community in the Grünewaldbach. Triclad, gammarids, mayflies, dragonflies and water beetles were absent. The most widespread organism was the caddisfly *Plectrocnemia conspersa*." (Authors) Larvae of *Cordulegaster boltonii* occurred in the low impacted creek Hellenthalbach; the mean (n=20) of heavy metals in dried bodymass in mg/kg is as follows: Cd: 5.6 (s=3.7), Pb: 28.1 (s=11), Cr: 1.9 (s=0.2), Cu: 43.3 (s=9.9), Ni: 4.9 (s=1.9), Zn: 193 (s=16).] Address: Dahmen, D., Burbacherstr. 263, 53129 Bonn, Germany

9606. Dudley, R. (1998): Atmospheric oxygen, giant Paleozoic insects and the evolution of aerial locomotor performance. *The Journal of Experimental Biology* 201: 1043-1050. (in English) ["Uniformitarian approaches to the evolution of terrestrial locomotor physiology and animal flight performance have generally presupposed the constancy of atmospheric composition. Recent geophysical data as well as theoretical models suggest that, to the contrary, both oxygen and carbon dioxide concentrations have changed dramatically during defining periods of metazoan evolution. Hyperoxia in the late Paleozoic atmosphere may have physiologically enhanced the initial evolution of tetrapod locomotor energetics; a concurrently hyperdense atmosphere would have augmented aerodynamic force production in early flying insects (including Protodonata). Multiple historical origins of vertebrate flight also correlate temporally with geological periods of increased oxygen concentration and atmospheric density. Arthropod as well as amphibian gigantism appear to have been facilitated by a hyperoxic Carboniferous atmosphere and were subsequently eliminated by a late Permian transition to hypoxia. For extant organisms, the transient, chronic and ontogenetic effects of exposure to hyperoxic gas mixtures are poorly understood relative to contemporary understanding of the physiology of oxygen deprivation. Experimentally, the biomechanical and physiological effects of hyperoxia on animal flight performance can be decoupled through the use of gas mixtures that vary in density and oxygen concentration. Such manipulations permit both paleophysiological simulation of ancestral locomotor performance and an analysis of maximal flight capacity in extant forms." (Author)] Address: Dudley, R., Dept of Zoology, University of Texas, Austin, TX 78712, USA. E-mail: rdudley@utxvms.cc.utexas.edu

9607. Finck, P. (1998): Der Einfluß von Probenahmezeitpunkt und -häufigkeit auf die Erfassung der Makroinvertebraten in Mittelgebirgsbächen. *Lauterbornia* 34: 245-254. (in German, with English summary) [The influence of sample timing and frequency on the recording of the macroinvertebrates in mountain brooks was studied by recording macroinvertebrates at two sites in the Eifel mountains in Northrhine-Westfalen, Germany. Additionally the dominance structures of the biocoenosis indicating different habitat requirements were analysed. Recommendations are given for a minimum standard to guarantee the relevance and validity of the results for physical planning: not less than 4 samples obligatory in March, May, June, and September. *Calopteryx virgo* and *C. splendens* are recorded for the studied brooks Ahbach and Klausenbach.] Address: Finck,

9609. Kossenko, S.M.; Fry, C.H. (1998): Competition and coexistence of the European bee-eater *Merops apiaster* and the Blue-cheeked bee-eater *Merops persicus* in Asia. *Ibis* 140(1): 3-13. (in English) ["Studies were conducted over a 10-year period on the supposedly similar European Bee-eater *Merops apiaster* and Blue-cheeked Bee-eater *M. persicus* breeding in mixed and separate colonies in four Asiatic countries (Turkmenistan, Uzbekistan, Tajikistan). In spring, *M. persicus* arrived a few days later and laid up to 2 weeks later than *M. apiaster*. Spatial distributions of the two species were positively associated. They were sympatric and syntopic: more than half of the local breeding ranges overlapped, and many birds bred within sight and sound of the congener. Intraspecific conflict was frequent, but in mixed colonies interspecific conflict was rare. Most *M. apiaster* nest burrows were dug into cliffs and most *M. persicus* ones into level ground, but dense mixed colonies occurred only in cliffs. Burrow architecture differed specifically. Diets were qualitatively similar at insect family level but different at the species level, partly because of local variation in availability and partly because of distinct preferences of *M. apiaster* for small beetles, ants and termites and of *M. persicus* for large dragonflies and cicadas. *Merops persicus* was less specialized than *M. apiaster* and had an airborne insect prey spectrum nearly twice as broad. Diets were more alike where the two birds foraged together than where they foraged separately. There was a high incidence of egg and nestling loss by predation and starvation. We speculate that each species may prove to breed more successfully in mixed than in monospecific colonies. We propose that the two bee-eaters do not compete for nest sites but may compete for food and coexist unaggressively by trading off food competition against improved breeding success in mixed colonies." (Authors)] Address: Fry, C.H., University of Aberdeen, Department of Zoology, Tillydrone Avenue, Aberdeen AB9 2TN, UK

9612. Dudley, R. (2000): The biomechanics of insect flight: form, function, evolution. Princeton Univ. Press, Princeton, N.J. ISBN-13: 978-0691044309: 476 pp. (in English) ["Here, Robert Dudley presents the first comprehensive explanation of how insects fly. The author relates the biomechanics of flight to insect ecology and evolution in a major new work of synthesis. The book begins with an overview of insect flight biomechanics. Dudley explains insect morphology, wing motions, aerodynamics, flight energetics, and flight metabolism within a modern phylogenetic setting. Drawing on biomechanical principles, he describes and evaluates flight behaviour and the limits to flight performance. The author then takes the next step by developing evolutionary explanations of insect flight. He analyzes the origins of flight in insects, the roles of natural and sexual selection in determining how insects fly, and the relationship between flight and insect size, pollination, predation, dispersal, and migration. Dudley ranges widely--from basic aerodynamics to muscle physiology and swarming behaviour--but his focus is the explanation of functional design from evolutionary and ecological perspectives." (Publisher) This is a comprehensive and definitive summary of the state of the art in the biomechanics of insect flight - including Odonata - through the late 1990's.] Address: Dudley, R., Dept of Zoology, Univ. of Texas, Austin, TX 78712, USA. 9614. Kourie, J.I.; Shorthouse, A.A. (2000): Properties of cytotoxic peptide-formed ion channels. *Am. J. Physiol. Cell. Physiol.* 278: C1063-C1087. (in English) ["Cytotoxic peptides are relatively small cationic molecules such as those found 1) in venoms, e.g., melittin in bee, scorpion toxins in scorpion, pilosulin 1 in jumper ant, and lycotoxin I and II in wolf spider; 2) in skin secretions (e.g., magainin I and II from *Xenopus laevis*, dermaseptin from frog, antimicrobials from carp) and cells of the immune system (e.g., insect, scorpion, and mammalian defensins and cryptidins); 3) as autocytoxicity peptides, e.g., amylin cytotoxic to pancreatic b-cells, prion peptide fragment 106–126 [PrP-(106–126)], and amyloid b-protein (AbP) cytotoxic to neurons; and 4) as designed synthetic peptides based on the sequences and

properties of naturally occurring cytotoxic peptides. The small cytotoxic peptides are composed of β -sheets, e.g., mammalian defensins, AbP, amylin, and PrP-(106–126), whereas the larger cytotoxic peptides have several domains composed of both α -helices and β -sheets stabilized by cysteine bonds, e.g., scorpion toxins, scorpion, and insect defensins. Electrophysiological and molecular biology techniques indicate that these structures modify cell membranes via 1) interaction with intrinsic ion transport proteins and/or 2) formation of ion channels. These two nonexclusive mechanisms of action lead to changes in second messenger systems that further augment the abnormal electrical activity and distortion of the signal transduction causing cell death. Alignment of the sequence of the scorpion defensin with the sequences of insect defensins (20). The defensins were characterized from species belonging to three insect orders: Diptera (a), Coleoptera (b), and Odonata (c). The scorpion defensin is closely related to the *Aeschna* defensin (c). Dashes indicate gaps to optimize the alignment. Identical amino acids are boxed. Boxes in bold represent the identical residues between *Aeschna* and scorpion residues." Braunschweig, Germany, July 13 & 14, 2004: (in English) ["The paper discusses how to obtain favourable 2D motion parameters for a flapping wing propulsion system. To find parameter sets with a high propulsion efficiency, two different approaches are considered: A biomimic approach is undertaken, where the motion parameters of a dragonfly are derived from slow motion Im material of a dragonfly in search flight condition with a flight speed of $U_1 = 1m/s$ and a Reynoldsnumber based on chord length of $Re = 800$. These are used to perform a Navier-Stokes-simulation of two moving airfoils representing the flow conditions at a position of $2=3$ of the wingspan. Then, a generic approach is undertaken, in which simple motion forms are analysed systematically to achieve a basic understanding of the

generation of thrust. For this investigation the flight conditions of a dragonfly in fast forward flight at $U_1 = 10\text{m/s}$ are studied. Both approaches result in a set of motion parameters which yield a good efficiency. They demonstrate two different ways to obtain essential knowledge for a potential propulsion system for micro air vehicles." 9633. Aletsee, M. (2005): Schutz und Renaturierung der "Palsen" als Grundlage für den Erhalt der Moorvegetation und gefährdeter Libellenarten im deutsch-belgischen Hohen Venn. Telma 35: 93-109. (in German, with English summary) ["The Hohe Venn contains a large number of so called palsen (mired relicts of palsa). Different types of oligotrophic and acidic mires have developed in the palsen. These mires often show a characteristic, radial ecological gradient. Simplified this gradient starts with a Sphagnum fallax-fazies, continues with an ombrotrophic stage of vegetation and ends in a central fen. Not influenced by humans these palsen are unique relict of a natural landscape with a large number of endangered species. They are very important especially as reproduction habitat for Odonata. On account of intensive drainage up to the middle of the 20th century a lot of palsen were influenced and some were destroyed. This paper points out the potential of renaturation of drained palsen by investigating the vegetation and by classifying the Odonata habitats by means of TWINSPAN-algorithm. In conclusion you can still find a reduced flora in restored palsen, but also an expansion of the typical, remained vegetation (Sphagnum fallax, Eriophorum angustifolium, Vaccinium oxycoccus). The marginal zone shows in both, flora and Odonata fauna, in one part more euryoecious species (Juncus effusus, Glyceria fluitans, Aeshna cyanea) and in the other part typical species of acid-dystrophic water (Carex echinata, C. canescens, Sphagnum fallax, Aeshna juncea, Leucorrhinia dubia, Coenagrion hastulatum, Sympetrum danae). On the other hand you can find highly specialized Odonata species like Aeshna subarctica and Somatochlora arctica as well as elements of the vegetation like Andromeda polifolia and Rhychospora alba only in not by human influenced palsen." 9635. Darwall, W.; Smith, K.; Lowe, T.; Vié, J.-C. (2005): The status and distribution of freshwater biodiversity in eastern Africa. IUCN SSC Freshwater Biodiversity Assessment Programme. IUCN, Gland, Switzerland and Cambridge, UK. Occasional Paper of the IUCN Species Survival Commission No. 31: viii + 36 pp. (in English) ["Biodiversity within inland water ecosystems in Eastern Africa is both highly diverse and of great regional importance to livelihoods and economies. However, development activities are not always compatible with the conservation of this diversity and it is poorly represented in the development planning process. One of the main reasons for inadequate representation of biodiversity is cited as a lack of readily available information on the status and distribution of inland water taxa. In a response to this need for information, the IUCN/SSC Freshwater Biodiversity Assessment Programme conducted a regional assessment of over 1,600 taxa of freshwater fishes, molluscs, odonates and crabs from Burundi, Kenya, Malawi, Rwanda, Tanzania and Uganda. In the process of the study, which is based on the collation and analysis of existing information, regional experts from five of these countries were trained in biodiversity assessment methods and, where appropriate, in field assessment and taxonomy. Distribution ranges have been mapped for the majority of species so providing an important tool for application to the conservation and development planning process. The full dataset is to be made freely available through the internet and through distribution on CD-ROM. Levels of regional endemism are notably high with 82% of fish and 74% of molluscs restricted to the region. Species diversity is also high and the major centres of diversity are the African Great Lakes of Malawi/Nyassa/Niassa, Tanganyika and Victoria, and in the Eastern Arc Mountain Range (for Odonata). Major threats are identified as loss and degradation of habitat, in particular from sedimentation due to deforestation and eutrophication, and the introduction of alien species. The centres of threatened species are the African Great Lakes and a number of East Coast river drainages. A major concern for the future is the potential impact of water resource developments such as for improved water supply, irrigation and provision of hydroelectric power. A gaps analysis found that inland waters are poorly protected within the existing Protected Areas network which is largely focused on terrestrial ecosystems. Forest Reserves were, however, observed to provide effective protection of watersheds at the headwaters of some river systems; it is recommended that their legal status be raised to provide a greater incentive for their effective management and for increasing the potential for attracting funds. Finally, it is most important that the data from this study are made available to the relevant decision makers and stakeholders in a format that can be easily understood and readily integrated within the decision making process. With this in mind a second major project has been initiated to extend the work to the rest of Africa and to develop a series of "Best Practice Guidelines" for the integration of biodiversity information within the development process." (Authors)] Address: IUCN Publications Services Unit, 219c Huntingdon Road, Cambridge CB3 0DL, UK. E-mail: books@iucn.org

The Environment Agency, Abu Dhabi, Dolphin Energy Limited. ISBN: 1-900724-74-X: 169-196. (in English) [Verbatim: "Although the early stages of dragonflies are totally dependent on fresh water, adult specimens can be found in a variety of habitats, including offshore islands and inland sand dunes. Indeed, for a desert country, the UAE has a remarkable and beautiful dragonfly fauna, reviewed most recently by Giles (1998), with some additions by Feulner (1999). Five species of damselflies (suborder Zygoptera) and 17 of dragonflies (suborder Anisoptera) are known from the Emirates with a further small number of species recognised from neighbouring areas of Oman and, therefore, also likely to be found in the UAE. After the Lepidoptera, the Odonata, including both damselflies and dragonflies proper, is probably the next most colourful insect group in the Emirates. Damselflies migrate at night, but during daytime they are usually not found far from water, as in the wadis of the Hajar Mountains. Particularly colourful damselflies include the endemic powder-blue damselfly *Arabicnemis caerulea* and the bright orange-red *Ceragrion glabrum*. Blues and red also predominate in the colours of the dragonflies. A striking example is the large and iridescent blue male of the emperor dragonfly *Anax imperator*, common wherever there is water for it to patrol. Equally large, the female is more dully coloured. The males of several species have reddish-marked wings and bodies, such as the purple-blushed, gully and orange darter dragonflies (*Trithemis annulata*, *T. arteriosa* and *T. kirbyi*, respectively). The young stages of all species of Odonata are spent in fresh water. Eggs may be simply dispersed at random over water or the female may insert single eggs into slits cut into the stems of aquatic plants. After hatching, the nymphs may spend several years growing and developing in the water, before climbing out and giving rise to the mature winged insect in a final spectacular moult. Both young and adults are carnivorous. The adults of dragonflies are very fast and manoeuvrable predators that attack even large insects on the wing. After the adults hatch out, they often migrate vast distances to find feeding areas and new bodies of water for reproduction to begin anew."] Address: Gillett, M., Dept Biochemistry, FMHS, UAE University, P.O. - 9640.** Liess, M.; von der Ohe, P.C. (2005): Analyzing effects of pesticides on invertebrate communities in streams. *Environmental Toxicology & Chemistry* 24(4): 954-965. (in English) ["The aim of this investigation was to find patterns in aquatic invertebrate community composition that are related to the effects of pesticides. Investigations were carried out in 20 central European streams. To reduce the site-specific variation of community descriptors due to environmental factors other than pesticides, species were classified and grouped according to their vulnerability to pesticides. They were classified as species at risk (SPEAR) and species not at risk (SPenotAR). Ecological traits used to define these groups were sensitivity to toxicants, generation time, migration ability, and presence of aquatic stages during time of maximum pesticide application. Results showed that measured pesticide concentrations of 1 : 10 of the acute 48-h median lethal concentration (LC50) of *Daphnia magna* led to a short- and long-term reduction of abundance and number of SPEAR and a corresponding increase in SPenotAR. Concentrations of 1 : 100 of the acute 48-h LC50 of *D. magna* correlated with a long-term change of community composition. However, number and abundance of SPEAR in disturbed stream sections are increased greatly when undisturbed stream sections are present in upstream reaches. This positive influence compensated for the negative effect of high concentrations of pesticides through recolonization. The results emphasize the importance of considering ecological traits and recolonization processes on the landscape level for ecotoxicological risk assessment." (Authors) Nine Odonata families and *Platycnemis pennipes*, *Aeshna cyanea* and *Cordulegaster boltonii* are classified as invertebrate at risk of being affected by pesticides.] Address: Liess, M., UFZ—Centre for Environmental Research, Permoserstr. 15, D-04318 Leipzig, Germany. - 9642.** Packauskas, R.J. (2005): Hudsonian Emerald Dragonfly (*Somatochlora hudsonica*): A technical conservation assessment. Prepared for the USDA Forest Service, Rocky Mountain Region, Species Conservation Project: 38 pp. (in English) ["*S. hudsonica* appears to be an uncommon species, both from the standpoint of its encounters with human beings as well as the number of specimens found in collections. Very little historical information or primary literature exists for this dragonfly, and it has never been studied in depth. Although the species is reported to be widely distributed across

Canada (Dunkle 2000), the only records of its occurrence in the continental United States place it at seven locales in Colorado, possibly three in Wyoming, and one in Montana. Most records are over 30 years old, and little or no documented collecting has been done at these sites since the originals. The paucity of records for this species, which may be due to a lack of collecting in areas where the species may occur, makes it suspect as a species of special concern. At this time, however, there is limited scientific evidence that either alleviates or warrants concern for its viability. The Hudsonian emerald dragonfly is considered a sensitive species in the Rocky Mountain Region of the USDA Forest Service. Primary Threats: As with other dragonflies, the main threat to the viability of this species would be the degradation of its aquatic habitat. Trees are an important component of areas surrounding the aquatic habitats of the Hudsonian emerald dragonfly since they provide areas for prey foraging by adults as well as shade that maintains lower water temperatures. Trees may also serve as mating areas. The loss of trees can occur through timber harvest, fuel reduction, or wildfires. Grazing by livestock may decrease perching or emergence vegetation for this species as well as degrade the aquatic habitat by increasing sedimentation. Sedimentation may also occur as a result of road construction or clear cutting. Tree harvest, grazing, and road construction can also help to produce nutrient runoff, increasing nutrient loads to the aquatic habitat, thus producing eutrophication. Use of pesticides, like piscicides and herbicides, can also serve to decrease population densities of the Hudsonian emerald dragonfly as well as populations of prey species when these chemicals enter the aquatic environment. Primary Conservation Elements, Management Implications and Considerations: Since this species is known from only a few limited areas, those areas and nearby aquatic habitats should be protected from management practices that would adversely affect them until more information on this species is forthcoming. Since the largest proportion (possibly 80 percent or more) of this species' life cycle is spent as larvae in the water, these aquatic stages are the most important to preserve in order to produce reproducing populations. Land management practices done in or around the areas currently inhabited by this species must be done thoughtfully to have as little impact on the aquatic habitats as possible. Adaptive land management methodologies, such as adjusting livestock grazing regimes in riparian or wetland areas, creating alternative livestock watering sources, and leaving timber harvest and fuel reduction buffers around known aquatic habitats for this species may be warranted. The main conservation focus should be to keep the known aquatic habitats (given in this paper) in mind when proposing management of any kind in these areas." (Author) The full paper is available at: <http://www.fs.fed.us/r2/projects/scp/assessments/hudsonianemeralddragonfly.pdf> Address: Packauskas, R.J., Dept. Biol. 9643. Schachtner, J.; Schmidt, M.; Homberg, U. (2005): Organization and evolutionary trends of primary olfactory brain centers in Tetraconata (Crustacea + Hexapoda). *Arthropod Structure & Development* 34: 257-299. (in English) ["The olfactory lobes of crustaceans and the antennal lobes of insects are the primary olfactory brain centers in Tetraconata. Recent publications considered the apparent lack of olfactory centers in se-

veral crustacean and insect taxa and structural differences in the organization of olfactory and antennal lobes as evidence for an independent origin of both brain areas. In depth comparison of species within and across tetraconate taxa, however, rather demonstrates that many characters of the organization of tetraconate olfactory centers are shared even among distantly related clades, but have been modified in various taxon-specific ways. From the available data and from comparison with the situation in chilopods, a closely related mandibulate outgroup, we conclude that an olfactory lobe organized into spheroidal glomeruli is a plesiomorphic character of the tetraconate brain. Shared features between decapod crustaceans and neopteran insects are cholinergic uniglomerular afferent neurons, a single large serotonin-immunoreactive neuron, multiglomerular GABAergic local interneurons, and projection neurons of similar morphology. Taxonspecific apomorphies include loss of olfactory sensilla and olfactory lobes in palaeopteran insects, certain branchiopod, maxillopod, and isopod crustaceans, profound changes in glomerular architecture in decapod crustaceans, and decomposition of glomerular boundaries in orthopteroid insects. In holometabolous insects, olfactory afferent projections from mouthpart sensilla are integrated into the antennal lobe and an increased tendency of contralateral connections is observed in lepidopterans and dipterans. Sexual dimorphism of antennal lobes, prominent in several neopteran insects, has most likely occurred convergently, and is not observed in malacostracan crustaceans." 9650. Buchwald, R.; Manzi, A.; Hunger, H. (2006): Habitatwahl von *Lestes dryas* und *Sympetrum flaveolum* in mittelitalienischen Karst-Hochebenen. In: Buchwald, R. (Hrsg.) (2006): Habitatwahl, Fortpflanzungsverhalten und Schutz mitteleuropäischer Libellen (Odonata). Ergebnisse der 23. Jahrestagung der Gesellschaft deutschsprachiger Odonatologen (GdO), 19.-21.3. 2004, Oldenburg. ISBN: 3-89995-278-2. 128 pp: 15-26. (in English, with German and Italian summaries) ["In numerous, both permanent and ephemeral (summer-dry) standing waters of karst plateaus of Central Italy, we studied the effect of various factors regarding their structure, hydrology, and vegetation on abundance, frequency, and reproduction of the odonate species *L. dryas* and *S. flaveolum*. Both species occur in a wide variety of waters and habitat types - however, with significant differences in frequency and abundance. The imagoes prefer waters with shallow shores which are covered by (brownish- or yellowish-) green vegetation dominated by the growth forms "rushes" (or similar) and "sedges". The vegetation height exceeds (30-) 35 cm (*L. dryas*) respectively 20 cm (*S. flaveolum*) along the edges and (30-) 35 cm (*L. dryas*) respectively (25-) 30 cm (*S. flaveolum*) in the central depressions. Compared to vegetation aspect and -colour and vegetation height in the central depressions, other parameters (e.g., area size, water level at the time of oviposition, density and cover of the vegetation, soil colour) play a subdominant

or no role at all for the colonisation by the studied species. These results are congruent with those from other regions of Europe to the greatest possible extent. From our findings, we derive a habitat selection hypothesis for the two species. This hypothesis should be tested by carrying out experiments designed to study the importance of each parameter individually." 9651. Ewers, M.; Buchwald, R. (2006): *Orthetrum coerulescens* zwischen Weser und Ems - Bestandssituation, Ökologie und Schutzmöglichkeiten. In: Buchwald, R. (Hrsg.) (2006): Habitatwahl, Fortpflanzungsverhalten und Schutz mitteleuropäischer Libellen (Odonata). Ergebnisse der 23. Jahrestagung der Gesellschaft deutschsprachiger Odonatologen (GdO), 19.-21.3. 2004, Oldenburg. ISBN: 3-89995-278-2. 128 pp: 84-91. (in German, with English summary) ["Actually only two populations of *O. coerulescens* are known in the Region Weser-Ems (western Lower Saxony, Germany). In the Börstel Forest (Lkr. Osnabrück) the species reproduces in a ditch, a spring brook and some ponds in a heath bog with *Erica tetralix*] the breeding habitats are characterized by flowing, summer-warm, acid water with low content of bases. In the Meerkanal (Lkr. Oldenburg), an outflow of a natural lake, a big population was detected in 1997 and intensively studied in 1999 and 2002. In a section of 900 meters up to 118 territorial males were counted showing a maximum abundance between 13.00 and 14.30 o'clock. The maximum density of males was observed in sections with little or no shade, medium velocity of flow, rich floating vegetation (e.g. *Potamogeton alpinus*), and adjacent extensive meadows/pastures or heaths. Despite the different structure of their water bodies and their vegetation, the two habitats have some characteristics in common, above all high water temperatures in winter and summer, open and flowing water courses, a small or medium cover of helophytes and hydrophytes and an extensive use of the surrounding landscape. In order to improve the situation of *O. coerulescens* in the study region it is proposed to keep open the breeding waters and to (re)create appropriate flowing waters near the two actual populations." Jahrestagung der Gesellschaft deutschsprachiger Odonatologen (GdO), 19.-21.3. 2004, Oldenburg. ISBN: 3-89995-278-2. 128 pp: 106-113. (in German, with English summary) ["The Helstorfer Moor, a small bog north of Hannover (Lower Saxony, Germany), has been exploited by peat cutting over some centuries. In a two-year-inventarisation 35 dragonfly species (Odonata) were found, among these many rare typical species of peat bogs (sensu Eb. SCHMIDT). After one single male had been discovered by Prys Witt, in 2003 a large population of the Graceful Dragonfly (*Nehalennia speciosa*) was found in the Helstorfer Moor,

situated in a distance of about 20 km from another population near Hannover. The imagoes of this species predominantly occur in the northern part of the bog, where the peat waters are hydrologically influenced by flowing water and/or adjacent springs. In the small larval ponds the Small Water-Hose (*Utricularia minor*) is the characteristic plant species. The peat water is strongly or weakly acid, the conductivity is below 100 μ S. The imagoes of *Nehalennia* were found in sections dominated by the Whistle Grass (*Molinia caerulea*), in part mixed with sparse stands of trees (*Pinus silvestris*, *Betula pubescens*). The habitat is part of a Nature Reserve of 410 hectares, well protected against external detrimental influences." (Authors)] Address: Gärtner, E., Drosselgasse 14, 31139 Hildesheim, Germany

9653. Geißler-Strobel, S.; Trautner, J.; Jooß, R.; Hermann, G.; Kaule, G. (2006): Informationssystem Zielartenkonzept Baden-Württemberg. Ein Planungswerkzeug zur Berücksichtigung tierökologischer Belange kommunalen Praxis. *Naturschutz und Landschaftsplanung* 38(12): 361-369. (in German, with English summary) ["Information System Target Species Concept in Baden-Württemberg- Tool to consider faunistic concerns in local planning practice This System is a web-based planning tool for designing zoological conservation and development concepts for target species. Intended to start in December 2006, it will be available within the web-space of the governmental 'Authority of Environment. Measurements and Nature Conservation' (www.lubw.baden-wuerttemberg.de). Target groups for the tool are local and regional authorities and their departments for planning, environmental protection and forestry as well as zoologists commissioned to produce expert reports. The planning tool has been developed to improve consideration of the essential aims of the Target Species Concept in municipal landscape planning. The tool assesses expert knowledge on the distribution and ecology of about 330 selected animal target species, applying the approach of assigning special conservation responsibilities for target species to local communities. The planning methodology derived from this knowledge supports the first steps of a planning process towards species and habitat oriented measures but it does not replace zoological investigations. In combination with the planning tool a two step approach to design community-based conservation concepts for target species has been developed and already tested to some extent. The first step allows to evaluate planning priorities and the relevance of many types of measures for the local area without extensive field work. This preliminary evaluation is based on the tool output, an overview inspection by qualified zoologists, and the analysis of existing faunistic data. The results of the first step can be used as a rough framework for action, particularly for the development of local landscape plans and of qualified "eco-accounts". The second step aims to specify the preliminary results more precisely e.g. concerning selected parts of a local community. This step generally requires additional field data. Partial results can be integrated as separate modules." 9654. Hall, L.W.; Killen, W.D.; Anderson, R.D. (2006): Characterization of benthic communities and physical habitat in the Stanislaus, Tuolumne, and Merced Rivers,

California. *Environmental Monitoring and Assessment* 115: 223-264. (in English) ["The primary goal of this study was to characterize physical habitat and benthic communities (macroinvertebrates, including Odonata) in the Stanislaus, Tuolumne and Merced Rivers in California's San Joaquin Valley in 2003. These rivers have been listed as impaired water bodies (303 (d) list) by the State of California due to the presence of organophosphate (OP) insecticides chlorpyrifos and diazinon, Group A pesticides (i.e., organochlorine pesticides), mercury, or unknown toxicity. Based on 10 instream and riparian physical habitat metrics, total physical habitat scores in the Stanislaus River ranged from 124 to 188 (maximum possible total score is 200). The highest total habitat score was reported at the upstream site. Tuolumne River physical habitat scores ranged from 86 to 167. Various Tuolumne River physical habitat metrics, including total habitat score, increased from downstream to upstream in this river. Merced River physical habitat scores ranged from 121 to 170 with a significant increase in various physical habitat metrics, including total habitat score, reported from downstream to upstream. Channel flow (an instream metric) and bank stability (a riparian metric) were the most important physical habitat metrics influencing the various benthic metrics for all three rivers. Abundance measures of benthic macroinvertebrates (5,100 to 5,400 individuals) were similar among the three rivers in the San Joaquin watershed. Benthic communities in all three rivers were generally dominated by: (1) Baetidae species (mayflies) which are a component of EPT taxa generally considered sensitive to environmental degradation; (2) Chironomidae (midges) which can be either tolerant or sensitive to environmental stressors depending on the species; (3) Ephemerellidae (mayflies) which are considered sensitive to pollution stress; and (4) Naididae (aquatic worms) which are generally considered tolerant to environmental stressors. The presence of 117 taxa in the Stanislaus River, 114 taxa in the Tuolumne River and 96 taxa in the Merced River implies that the benthic communities in these streams are fairly diverse but without a clear definition of benthic community expectations it is unknown if these water bodies are actually impaired." 9657. LeRoy Poff, N.; Olden, J.D.; Vieira, N.K.M.; Finn, D.S.; Simmons, M.P.; Kondratieff, B.C. (2006): Functional trait niches of North American lotic insects: traits-based ecological applications in light of phylogenetic relationships. *J. N. Am. Benthol. Soc.* 25(4): 730-

755. (in English) ["The use of species traits to characterize the functional composition of benthic invertebrate communities has become well established in the ecological literature. This approach holds much potential for predicting changes of both species and species assemblages along environmental gradients in terms of traits that are sensitive to local environmental conditions. Further, in the burgeoning field of biomonitoring, a functional approach provides a predictive basis for understanding community-level responses along gradients of environmental alteration caused by humans. Despite much progress in recent years, the full potential of the functional traits-based approach is currently limited by several factors, both conceptual and methodological. Most notably, we lack adequate understanding of how individual traits are intercorrelated and how this lack of independence among traits reflects phylogenetic (evolutionary) constraint. A better understanding is needed if we are to make the transition from a largely univariate approach that considers single-trait responses along single environmental gradients to a multivariate one that more realistically accounts for the responses of many traits across multiple environmental gradients characteristic of most human-dominated landscapes. Our primary objective in this paper is to explore the issue of inter-trait correlations for lotic insects and to identify opportunities and challenges for advancing the theory and application of traits-based approaches in stream community ecology. We created a new database on species-trait composition of North American lotic insects. Using published accounts and expert opinion, we collected information on 20 species traits (in 59 trait states) that fell into 4 broad categories: life-history, morphological, mobility, and ecological. First, we demonstrate the importance of considering how the linkage of specific trait states within a taxon is critical to developing a more-robust traits-based community ecology. Second, we examine the statistical correlations among traits and trait states for the 311 taxa to identify trait syndromes and specify which traits provide unique (uncorrelated) information that can be used to guide trait selection in ecological studies. Third, we examine the evolutionary associations among traits by mapping trait states onto a phylogenetic tree derived from morphological and molecular analyses and classifications from the literature. We examine the evolutionary lability of individual traits by assessing the extent to which they are unconstrained by phylogenetic relationships across the taxa. By focusing on the lability of traits within lotic genera of Ephemeroptera, Plecoptera, and Trichoptera, taxa often used as water quality indicators, we show how a traits-based approach can allow a priori expectations of the differential response of these taxa to specific environmental gradients. We conclude with some ideas about how specific trait linkages, statistical correlations among traits, and evolutionary lability of traits can be used in combination with a mechanistic understanding of trait response along environmental gradients to select robust traits useful for a more predictive community ecology. We indicate how these new insights can direct the research in statistical modeling that is necessary to achieve the full potential of models that can predict how multiple traits will respond along multiple environmental gradients." 9664. Ngai, J.T.; Srivastava, D.S. (2006): Predators accelerate nutrient cycling in a bromeliad ecosystem. *Science* 314: 963. (in English) ["The availability of nutri-

ents in ecosystems is determined by resource supply and recycling rates and affects important ecosystem properties (1–3). The relative roles of abiotic supply and food web configuration in determining resource-processing rates remain contentious and poorly understood. Under anthropogenic pressure, ecosystems are predicted to lose predators disproportionately, affecting ecosystem processes (4). Current ecological theory predicts that predator loss will affect nutrient cycling by changing prey abundance (density-mediated effects, as in a trophic cascade) (5) or prey foraging efficiency (trait-mediated effects) (6). These changes can further affect nutrient cycling by altering the species composition or size structure of the prey community. In this study, we examined the effects of predators on nutrient cycling by using the detritus-based insect community in bromeliads. We demonstrate that predation can have counterintuitive effects on nutrient cycling. Leaves of tank-forming bromeliads (e.g., *Vriesea* and *Guzmania* genera) are tightly interlocking, forming wells that collect water and leaf litter and provide habitat for aquatic insect larvae. The detritus not only supports the insect community but also provides a source of nutrients for the bromeliad. A natural gradient also exists in predation where the major predator, a damselfly larva (*Mecistogaster modesta*), becomes more abundant as the plant grows. Although it has been hypothesized that aquatic insects increase nutrient flux to the bromeliad, this relationship has never been documented. First, we ran fertilization experiments to determine whether nitrogen (N) or phosphorus (P) limit the productivity of the plant and insect components of this ecosystem. (7). Both tissue nutrient ratios and fertilization experiments showed that N, rather than P, primarily limits productivity of bromeliads and can limit insect productivity [Supporting Online Material (SOM) text and tables S1 and S2], so we focused on the effects of trophic structure on N cycling. Leaf detritus enriched in ^{15}N was used to trace the movement of N through the food web in bromeliads containing either no insects, detritivores only, or detritivores and predators. The presence of detritivores alone did not affect the amount of N entering bromeliads from the enriched detritus (Fig. 1A). However, in the presence of both detritivores and predators, there was a significant enrichment in ^{15}N in bromeliad leaves compared with plants containing detritivores alone, indicating that the presence of predators increased the flow of N from litter to bromeliads. This is surprising given that previous studies, consistent with the predictions of density or trait-mediated effects, have shown that predators decrease litter decomposition by reducing detritivore abundance (8) or by decreasing the foraging rate (9) of detritivorous arthropods. We hypothesize that the detritivorous insects, which pupate relatively rapidly, constitute a loss of litter-derived N for bromeliads when they emerge. A survey indicated that detritivorous insects generally have higher N:P ratios than those found in typical litter (Fig. 1B), suggesting that, as leaf litter is consumed, the insects will preferentially retain N in their body tissues and release P. Predation by longer-lived damselfly larvae converts the mobile pool of N contained in detritivores into fecal pellets that can be decomposed by microbes or leached to release N in a form available to the bromeliad. Thus, insects facilitate nutrient uptake by the plant, but only if both predators and detritivores are present. These results emphasize the importance of the temporal and spatial scales of dispersal for nutrient flux. The emergence of adult insects means that, although detritivores increase re-

source flux over larval time scales by releasing nutrients from litter, these insects act as a nutrient sink for bromeliads over their entire life span. The faster emergence rate of detritivores compared with that of predators allows predation to reduce the loss of N from the bromeliad. Although we use insects in bromeliads to examine biotic effects on nutrient cycling, our results can give insights into other systems where mobility differs between trophic levels. Some trophic interactions, for instance, involve migratory and nonmigratory species or species that undergo ontogenetic niche shifts. This mechanism may also apply if the prey species has a very different range size than its predator. Given the increased extinction risk of higher trophic levels, understanding the mechanisms whereby predators drive important ecosystem processes is critical in predicting anthropogenic impacts on natural systems." (in German, with English summary) ["*L. pectoralis* is a very rare species in the German federal state Baden-Württemberg. Stable, autonomous populations which do not depend on steady immigration of individuals from other populations exist exclusively in the southeastern region „Oberschwäbisches Hügel- und Moorland". As the species is listed in the Annexes II and IV of the European habitats directive, the populations of *L. pectoralis* in SW-Germany have been the subject of increased attention since 1997: Between 1997 and 2000, intensive investigations and management measures were financed by a LIFE-Nature-Project called "Endangered Dragonfly Species in SW-Germany". Dur-

ing the years 2001 through 2003, these actions were continued as projects financed by the "Bezirksstelle für Naturschutz und Landschaftspflege" Tübingen. The purpose of this paper is to evaluate the protection actions that have been taken during the last seven years. Since 1997, 67 management measures were undertaken in 14 different mire areas. The most urgent type of management action was the removal of dense vegetation from inhabited peat bogs (In 11 mires), followed by cutting trees and shrubs along the shorelines (in 8 mires), electrofishing (in 2 mires), and mowing of dense reed vegetation (*Phragmites australis*), removal of eutrophicated soil and extensification of grassland utilization in the surrounding of 1 reproduction site, respectively. Only in three mires the management measures showed no success so far, two of which are situated in a distance of many kilometres from the margin of the populated area and therefore more or less isolated. At all sites in which small populations were still present when the implementation of management measures started, the number of individuals of *L. pectoralis* increased on account of the actions taken. Whereas, in 1997, the species was recorded in only 20 peat waters located in 9 mires, it reproduced in 40 peat waters of 12 mires in 2003. These findings show that the balance of the species protection project *L. pectoralis* is positive. Nevertheless, further management actions will remain absolutely necessary in order to guarantee the long-term survival of the species in Baden-Württemberg. It is recommended to employ Wildermuth's rotation model, which has been successfully tested over many years in Switzerland." (Author) Address: Schiel, F.-J., Inst. (2006): Habitatwahl, Fortpflanzungsverhalten und Schutz mitteleuropäischer Libellen (Odonata). Ergebnisse der 23. Jahrestagung der Gesellschaft deutschsprachiger Odonatologen (GdO), 19.-21.3. 2004, Oldenburg. ISBN: 3-89995-278-2. 128 pp: 92-102. (in German, with English summary) ["The dragonfly fauna of some fishing ponds is recorded. These ponds have a regulated water feeding by a nearby rivulet, they remain filled with water throughout the year, there is no feeding of the fishes (like carps), which all are large enough for being taken by angle (no spawn), and a replacement for the output by fishing. The number of dragonfly species is rather high, but nearly no species are endangered, and most species have only small abundances. Only *Platycnemis pennipes* and *Gomphus pulchellus* in the region are favoured at these fishing ponds. Nevertheless these ponds enrich the dragonfly fauna in Westfalian lowlands, which are poor in natural stagnant water bodies." (in German) ["We examined the odonate assemblages of 11 water systems situated

within a protected remnant peat bog in the north-eastern part of Cloppenburg district, Lower Saxony, Germany in summer 2001. A total of 30 species was recorded, representing half of the species known to occur between the rivers Ems and Weser. 13 species (45%) are listed in the Red Data Books of either Germany and/or Lower Saxony. Two species, *Ceriatrigon tenellum* and *Aeshna subarctica*, are listed as endangered, with the former being confirmed to reproduce within the study site. Species richness at the water systems ranged from 5 to 18 species per system. Besides high densities of eurytopic species like *Lestes sponsa* and *Pyrrosoma nymphula*, we found some stenotopic species confined to acidic bogs occurring in lower numbers. The number of bog specialists found in our study area is in concordance with the situation of other bogs in early stages of regeneration. Regeneration of the investigated bog was initiated by measures in 1988. Subsequent measures like the sealing of drainages increased the ratio of bog specialists vs. generalist species in the study area. The occurrence of *Ceriatrigon tenellum* and *Aeshna subarctica* justifies taking measures in the future." (2006): *Habitatwahl, Fortpflanzungsverhalten und Schutz mitteleuropäischer Libellen (Odonata)*. Ergebnisse der 23. Jahrestagung der Gesellschaft deutschsprachiger Odonatologen (GdO), 19.-21.3. 2004, Oldenburg. ISBN: 3-89995-278-2. 128 pp: 63-64. ["*N. speciosa* was recorded in Switzerland from 1867 until 1990. Intensified search for the species during the subsequent years remained unsuccessful. The 17 localities where it was recorded partially in rather high numbers until the early seventies of the last century concentrated on a small area in the eastern Swiss Plateau. It is believed that *N. speciosa* became extinct because of desiccation of its formerly already damaged habitats during a long lasting dry period in 1976, combined with changes in the vegetation due to slow eutrophication. In view of strong regressive tendencies of the species in whole Europe the future of the species in the western Palearctic region depends largely on the conservation of the last large populations in southern Bavaria, Poland, Belorussia and perhaps also Russia." - 9680.** Kalniņš, M.; Medne, M. (2007): The spatial allocation of dragonflies (Odonata) communities in raised bogs of Latvia. Book of abstracts: Daugavpils University Institute of Systematic Biology. 4th International Conference "Research and Conservation of Biological Diversity in Baltic region". Daugavpils, 25 - 27 April, 2007. Daugavpils University Academic Press "Saule": 50. (in English) [Verbatim: "The communities of different dragonfly species and their spatial allocation have been poorly studied in Latvia. Research in dragonflies 'communities' spatial allocations in bogs were undertaken in Sudas bog, (Cesis district), Taures bog (Valka district) and Lielais Kemeru tirelis bog (Tukums and Riga districts) in 2005 - 2006. Individual researches were taken also in other bogs of Latvia. Research surveys included quantitative adult registration along 100 m long patches inspection. Sloughs registration in several habitats or groups of species has been done additionally. Different characteristic bog habitats were selected as patches for examination: large water pools complexes in open bog areas, lakes in the bogs inclusive lakes with woody coasts, lake with woody coasts located at the edge of bog, the watercourse at edge of bog, beavers over flooded watercourse in the dif of bog, complexes of water pools with woody edges and water pools in the middle of the wood. 26 dragonfly species were examined during current research: 20 species in Sudas bog, 6 species in Taures and 13 species in Lielais Kemeru tirelis bog. Major diversity of species has been registered near the watercourses with rich vegetation (14 species) and in large complexes of water pools (10 species). Lower diversity has been confirmed in bog lakes situated on open areas (7 species) and in open patches of the bog without water pools (3-4 species). *Sympetrum danae* has been registered in all examined patches of Sudas bog, *Libellula quadrimaculata*, *Lestes sponsa* and *Enallagma cyathigerum* – in 80 % of examined patches of Sudas bog. Meanwhile, *Anax imperator* was found only in water pools, but *Pyrrhosoma nymphula* – along watercourses with grassy coasts. Due to sloughs research also *Aeshna subarctica* was registered but during adult registration this species was found only in Taures bog."] Address: Kalniņš, M., Nature Protection Board, Eksporta iela 5, Riga, LV-1010, Latvia. - 9685.** Ott, J. (2007): Hat die Klimaänderung eine Auswirkung auf das Netz Natura 2000? - erste Ergebnisse aus Untersuchungen an Libellenzönosen dystropher Gewässer im Biosphärenreservat Pfälzerwald. Naturschutz und Biologische Vielfalt 46: 65-90. (in German) ["Dragonflies are suitable indicators for the quality of aquatic environments and for environmental changes. Dragonflies recently have been used as monitoring organisms to demonstrate the effects of climatic change, e.g. via the range expansion of southern species to the north or via the shifts within community composition. First results from a study in the transboundary biosphere reserve "Pfälzerwald-Vosges du Nord" are pre-

sented. The dragonfly fauna and the environmental conditions of the so called "Wooge", mainly dystrophic lakes (Natura 2000-code 3160), were monitored and compared with previous investigations. Most of these waters are part of the national Natura 2000 network. As a consequence of the effects of climatic changes and also synergistic effects (e.g. ground water extraction, drying/freezing out, lacking maintenance, increasing fragmentation) the aquatic systems have changed dramatically in the last couple of years. Water levels have dropped between one and two meters, reaching extreme situation in July 2006, where some waters even dried out completely. As a consequence, the dragonfly fauna also has changed: many of the stenoeccious and endangered moorland species, which are characteristic for the dystrophic waters, have disappeared from most of the waters (e.g. *S. arctica*, *A. juncea*, *L. dubia*, *C. hastulatum*). These species now are nearly extinct in the German part of the biosphere reserve. At the same time, these lakes have been colonised by generalists and widely distributed species, which are now dominating the waters and dragonfly communities (e.g. *O. cancellatum*, *L. depressa*, *G. pulchellus* - also *A. Imperator*) indicating the strong disturbance. Some of the waters even have dried out completely and, thus, totally lost their value for the aquatic fauna. In addition, species typical for astatic waters and thermophilic species like *Lestes virens*, *L. barbarus* and *Ischnura pumilio* are rapidly invading the area, indicating a change in the biological communities as well. If summer droughts and synergistic effects continue at current rates — and the scenarios show an ongoing impact in the region - and if no immediate management and mitigation measurements are undertaken, the remaining waters will lose their importance for the Natura 2000 network shortly and devalue this concept completely." 9687. Smith, A.J.; Bode, R.W.; Kleppel, G.S. (2007): A nutrient biotic index (NBI) for use with benthic macroinvertebrate communities. *Ecological Indicators* 7(2): 371-386. (in English) ["Aquatic macroinvertebrates have been among the principal biological communities used for freshwater monitoring and assessment for several decades, but macroinvertebrate biomonitoring has not incorporated nutrient measures into assessment strategies. Two nutrient biotic indices were developed for benthic macroinvertebrate communities, one for total phosphorus (NBI-P), and one for nitrate (NBI-N). Weighted averaging was used to assess the distributions of 164 macroinvertebrate taxa across TP and NO₃- gradients and to establish nutrient optima and subsequent nutrient tolerance values. Both the NBI-P and NBI-N were correlated with increasing mean TP and NO₃- values ($r = 0.68$ and $r = 0.57$, respectively, $p < 0.0001$). A three-tiered scale of eutrophication for TP and NO₃- (oligotrophic: ≤ 0.0175 mg/l TP, ≤ 0.24 mg/l NO₃-, mesotrophic: > 0.0175 to ≤ 0.065 mg/l TP, > 0.24 to ≤ 0.98 mg/l NO₃-, eutrophic: > 0.065 mg/l TP, > 0.98 mg/l NO₃-) was also established through cluster analysis of

invertebrate communities using Bray-Curtis (quantitative) similarity. Significant differences ($p < 0.0001$) were detected between median NBI-P and NBI-N scores among the three trophic states. Therefore, the nutrient biotic indices (NBIs) appear to accurately reflect changes in stream trophic state. Multimetric water quality assessments were also used to identify thresholds of impairment among the three trophic states. Hodges-Lehman estimation indicated that the greatest change in assessment results occurred between the mesotrophic and eutrophic states. The eutrophic state also represented the highest percentage of overall impairment. Therefore, the suggested threshold for nutrient impairment is the boundary between mesotrophic and eutrophic (0.065 mg/l TP and 0.98 mg/l NO₃-). The corresponding NBI-P score (6.1) and NBI-N score (6.0) for this threshold incorporate predictive capabilities into the NBIs. The NBI and index score thresholds of impairment will provide monitoring programs with a robust measure of stream nutrient status and serve as a useful tool in enforcing regional nutrient criteria." (Authors) The index includes "Ophiogomphus sp. and undetermined Gomphidae".] Address: Smith, A.J., New York State Department of Environmental Conservation, Stream Biomonitoring Unit, Albany, NY 12233-3502, USA. 9688. Staudacher, K.; Füreder, L. (2007): Habitat complexity and invertebrates in selected Alpine springs (Schütt, Carinthia, Austria). *Internat. Rev. Hydrobiol.* 92(4-5): 465-479. (in English) ["The invertebrate fauna from eight selected springs of the landslide area of Schütt (Carinthia, Austria) with contrasting environmental factors was investigated. The role of habitat structure on the community composition was studied with a particular focus on the spring-dwelling animals colonizing the aquatic and the adjacent aquatic-terrestrial transition zones. The crenocoenosis was predominantly composed of Chironomidae, Plecoptera, Trichoptera, Mollusca and Ostracoda and the number of spring-specialists was high. Habitat complexity, variable microhabitat composition and the concomitance of lotic and lentic areas in the eucrenal zone furthered a high species diversity and abundance. Even the aquatic-terrestrial transition zone was inhabited by high numbers of crenobionts and crenophiles. Moreover, the connectivity of aquatic and terrestrial habitats positively affected the structural and functional organisation of invertebrate assemblages in the spring biotopes." (Authors) The list of taxa includes *Cordulegaster bidentata* and *Aeshna cf. caerulea*.] Address: Staudacher, Karin, River Ecology and Invertebrate Biology, Institute of Ecology, University of Innsbruck, Technikerstr. 25, A-6020 Innsbruck, Austria. 9690. Bechly, G. (2008): Additions to the fossil dragonfly fauna from the Lower Cretaceous Crato Formation of Brazil (Insecta: Odonata). *Palaeodiversity* 3, Supplement: 11-77. (in English, with German summary) ["Several interesting new discoveries of fossil odonates from the Lower Cretaceous Crato Formation of NE Brazil are presented. Two new taxa of damselflies (*Euarchistigma peterknobli* n. sp. and *Santanagrion longipes* n. gen., n. sp.) are described, and a new specimen of *Euarchistigma marialuiseae* with preserved colour pattern, distinct from the type species, is featured. Among the dragonflies totally three new families (*Megaphlebiidae* n. fam., *Magnathemidae* n. fam., and *Cratopetaliidae* n. fam.), nine new genera, and ten new species (*Paracordulagomphus aberrans* n. gen., n. sp.; *Paracordulagomphus divergens* n. gen., n. sp.; *Pauciphlebia novaolindense* n. gen., n. sp.; *Cratogomphus erraticus* n. gen., n. sp.; *Cratohagenius erichweberi* n. gen., n. sp.; *Megaphlebia rayandressi* n. gen., n. sp.; *Magnathemis marcusthorhalli* n. gen., n. sp.; and *Cratopetalia whiteheadi* n. gen., n. sp.) are described. A further putative new dragonfly genus and species is discussed and featured, but not formally described because of the poor preservation of the single available specimen. The original descriptions of *Euarchistigma marialuiseae*, *Cratostenophlebia schwickerti*, *Eotanypteryx paradoxa*, *Paramesuropetala gigantea*, *Cordulagomphus hanneloreae* and *Cordulagomphus winkelhoferi* are emended with new data and supplemented with drawings and photos. The newly discovered counter plate of the holotype of *Cratopetala petruleviciusi* is featured. Some errors concerning collection numbers and depositions of fossil odonates in Martill et al. (2007) are corrected and new collection numbers are updated for the Senckenberg museum collection." (Author)] Address: Bechly, G., Staatliches Museum für Naturkunde, Abt. Paläontologie, Rosenstein 1, D-70191 Stuttgart, Germany. E-mail: bechly@gmx.de

9693. Geraeds, R.P.G. (2008): Larven van de Gewone bronlibel in de Rode Beek (Nationaal Park De Meinweg). *natuurhistorisch maandblad* 97(6): 129-132. (in Dutch, with English summary) ["The Meinweg nature reserve hosts the largest population of *Cordulegaster boltonii* in the Netherlands. The species is known to breed in three brooks in the reserve, the Bosbeek, Nartheciumbeekje and Venbeek brooks. The Rode Beek brook, also situated in this nature reserve, was never considered as a breeding water for this species. In October 2007, the Rode Beek brook was surveyed (with a net) to establish the presence of larvae of *C. boltonii*. The survey yielded 23 larvae in the stretch from the Dutch-German border, where the brook enters the Netherlands, to the Gitstapper water mill. The species was not found downstream of this mill, where the brook has been canalised and runs through open farmland, making it an unsuitable habitat for this species. The survey showed, however, that the brook does function as a breeding water for *C. boltonii* at the Meinweg reserve. The larvae we caught ranged in age from 1 to 4 or 5 years, proving that the Rode Beek brook actually hosts a population of *C. boltonii*." (Author)] Address: Geraeds, R.P.G., Bergstraat 70, 6131 AW Sittard, The Netherlands

9696. Hocking, D.J.; Semlitsch, R.D. (2008): Effects of experimental clearcut logging on gray treefrog (*Hyla versicolor*) tadpole performance. *Journal of Herpetology* 42: 689-698. (in English) ["Clearcutting detrimentally affects the populations of many amphibian species. However, Gray Treefrogs (*Hyla versicolor*) have shown a preference for breeding sites located in clearcuts near forested habitat. To test the implications of this preference, we examined Gray Treefrog tadpole performance in cattle tanks along a gradient from clearcut to forest habitat. We replicated this design at three experimental clearcut sites. Tadpole performance was measured as length of the larval period, size at metamorphosis, and survival. We also examined the influence of temperature, periphyton productivity, and invertebrate predator abundances (anisopteran and dyticide beetle larvae) on tadpole performance. Time to metamorphosis was shorter in the clearcuts, but metamorphs tended to be smaller than metamorphs in the forest tanks. Survival was also greater in the clearcuts than in the forest treatments. Higher temperatures in the clearcuts primarily contributed to tadpole performance whereas invertebrate predators did not appear to influence performance. Although clearcuts benefited tadpoles through higher survival and shorter larval periods, there are potential fitness consequences for small metamorphs emerging in clearcuts." 9701. Kochurova, T.I. (2008): The bottom invertebrates of small rivers in an area where pesticides were buried. *Inland Water Biology* 1(3): 287-295. (in English)

["The effect of Kilmezskii pesticide disposal site on the zoobenthos of Osinovka and Loban' rivers (the Vyatka River basin, Kirovskaya oblast) is reviewed. A faunistic list of water invertebrates in these rivers is published for the first time, qualitative and quantitative indices of zoobenthos development are given, and the condition of watercourses is assessed using bioindicative methods. The peculiarities of benthic communities of the Osinovka River and its tribute, i.e., a significant impoverishment of species composition, the simplification of structural organization, and low bioindicative indices, allow us to assume that the burial has a negative effect on zoobenthos condition." (Author) The following Odonata taxa are considered: *Calopteryx virgo*, *C. splendens*, *Platycnemis pennipes*, *Gomphus* sp., and *Somatochlora metallica*. Original Russian Text © T.I. Kochurova, 2008, published in *Biologiya Vnutrennikh Vod*, No. 3, 2008, pp. 93–101.] Address: Kochurova, T.I., Vyatka State University of Humanities, ul. Krasnoarmeiskaya 26, Kirov, 610002, Russia. A total of 52 odonate species was recorded; the species are treated in a monographic style providing information on distribution (detailed map), frequency, habitat, phenology, co-occurring species, and some cases also conservation measures and vernacular naming of species. The big population of *Coenagrion ornatum* is of more than regional importance] Address: Krach, J.E., Oberstimmerstr. 62, 85051 Zuchering, Germany. E-mail: JEKrach@gmx.de

9703. Lemelin, R.H. (2008): Dragonfly tourism. In: M. Lück (Ed.). *Encyclopedia of Tourism and Recreation in Marine Environments*. Wallingford, Oxfordshire: CABI: 145. (in English) [Verbatim: "Dragonfly Tourism: While the activity of enjoying (viewing, photographing, collecting) Odonata (dragonflies and damselflies) is a relatively new leisure phenomenon in Western society, in some Asian countries such as China and in Japan dragonflies have a long history of being involved in popular culture and are even raised as pets (Mitchell and Lasswell, 2005). Dragonfly gatherings (i.e. counts and educational outings) in North America and Europe are, however, increasing in popularity. For example, popular Odonata activities include the Valley Nature Centre's Annual Dragonfly Days in Weslaco, Texas, annual Odonata meetings (e.g. the Great Lakes Odonata Meeting) and counts (e.g. the Algonquin Park Odonata Count). Elsewhere, dragonflies are viewed in various sanctuaries found in Japan and the UK (Moore, 1997, 2001). The most notable dragonfly attraction may perhaps be the dragonfly awareness trails located in the National Botanical Gardens in Pietermaritzburg, South Africa (Suh and Samways, 2001). Individuals are also building 'dragonfly ponds' to attract Odonata to their homes (Moore, 2002). Conservative estimates place the number of Odonata enthusiasts belonging to a formal association at over 3000 worldwide. This number increases dramatically if one was to include participants in the growing number of dragonfly events. Facilitating the growth of these leisure activities, but more specifically the viewing of dragonflies, is the availability of field guides (Dunkle, 2000, Mead, 2003, Jones et al, 2006),

associations (e.g. Dragonfly Society of the Americas, Worldwide Dragonfly Association) and online verification of specimens (e.g. Digital Dragonflies). While concerns over the emerging role of Odonata in marine leisure activities (e.g. boat activity) have been noted (Samways, 2005), the greatest concerns over anthropogenic disturbances of Odonata in coastal areas are the loss of suitable habitat (i.e. drained wetlands) and declining water quality (Medland, 2004). Some coastal species may be particularly vulnerable. For example, the Seaside Dragonlet (*Erythrodiplax berenice*), found primarily along the Atlantic Coast from Venezuela's north to southern Canada, breeds mostly in brackish water (salt marshes and estuaries) in coastal areas (Mitchell and Lasswell, 2005; Fig. D6). Odonata are important bio-indicators for both aquatic and semi-aquatic habitats and they can be used as flagship species for tourism and leisure strategies (Moore, 1997)." 9715. Allen, K. (2009): The ecology and conservation of threatened damselflies. Integrated catchment science programme. Science report: SC040027/SR1: VII, 142 pp. (in English) ["Background: This report presents the results of an autecological study of *Ischnura pumilio* in south-west England. *I. pumilio* has a sparse, localised distribution in the UK and is classed as "scarce" in the British Red Data Book of Insects. The aim of this study was to raise the ecological understanding of this species to a similar level to that of other threatened odonates such as *Coenagrion mercuriale* with a view to better informing its conservation management. Fieldwork was conducted in the New Forest, Hampshire and at a variety of sites throughout Cornwall and Devon. Main objectives: The primary aim of this study was to examine the dispersal potential, survival rates, population sizes and habitat requirements of *I. pumilio* in the south of England. Similar work on other species, such as *C. mercuriale*, has been useful in guiding conservation efforts, but there are very few studies of *I. pumilio*. It is hoped that this study will inform conservation management and allow more effective monitoring and surveillance of this species. Results: Intensive mark-recapture (MRR) studies were conducted at two sites during 2005 and 2006. These revealed that, despite a reputation as long range dispersers, *I. pumilio* were generally very sedentary with movement characteristics similar to those of other similar sized odonates. No movement between sites was recorded and 88 per cent of individuals moved less than 50m (net) in their lifetime. Movement distance was inversely dependent on population density, indicating a tendency to move towards conspecifics or areas of more suitable habitat. The presence of parasitic mites (*Hydryphantes* spp.) significantly increased movement distance. Males consistently moved further than females. Longer intervals between captures resulted in greater movement distances. Surveys of vegetation and environmental factors were conducted at 31 sites with *I. pumilio* records from the previous 10 years. The species occurred at sites with a range of water depths, management regimes and levels of pH, grazing, pollution and disturbance. Occupied habitats generally had slow-flowing water, some bare ground at the water's edge and low levels of shade. A low overall count for odonate species was also associated with the presence of *I. pumilio*. Areas away from water were found to be important for the species and over 30 per cent of matings were recorded at least 10m from water. Existing sites should be actively managed up to 25m from water, and new habitat created, where possible, with dispersal potential in mind. Survival and recapture rates for Scarce Blue-tailed Damselflies and *C. mercuriale* were estimated using single and multistate MRR modelling techniques. The resulting rates were used to estimate population sizes for *I. pumilio* populations surveyed in 2005 and 2006, and two *C. mercuriale* populations in south England surveyed during 2001 and 2002. Survival generally decreased with age and time in the season and a negative effect of parasites was also indicated. Removing a leg for genetic analysis was not found to affect survival. The sex of mature individuals had no, or negligible ef-

fect on their survival rates. *Ischnura pumilio* was found to exist in much smaller populations than *C. mercuriale* and so may suffer greater levels of inbreeding. A comparison of monitoring methods showed that transect walk estimates were a reliable method of estimating abundance and provided a good basis for further work to develop a predictive relationship. Conclusions and recommendations: Despite the strength of some UK populations, such as Latchmoor, *I. pumilio* still requires conservation management at sites that have poorer quality habitat and smaller populations. Many populations are isolated, based on the range of movements observed in this study, and without dispersal to augment genetic diversity even strong populations are at risk of developing high levels of inbreeding. This study has examined several aspects of the species' ecology and is the first large scale study of *I. pumilio* that has been conducted. This report presents estimates of dispersal potential, survival rates and habitat requirements and discusses these with respect to the species' conservation management. Key findings and recommendations include: • The species was found at sites with a range of water depths, management regimes and levels of pH, pollution, grazing and disturbance. However, sites generally had slow-flowing water, with some bare ground in and around the water's edge and were relatively open in terms of shade from tall vegetation. • Management of areas away from water should be incorporated into any habitat management plan, as different individuals may be present and may exhibit different behaviours. A buffer of 25m may be sufficient for the necessary roosting, mating and feeding requirements of *I. pumilio*. • A monitoring program to establish the current status of these and other key odonate sites across the UK would be beneficial. Monitoring of adult *I. pumilio* at existing sites may be achieved using transect walks, which are a useful method for large-scale monitoring. • The ability of *I. pumilio* to colonise newly formed habitat is still open to question. No long-range dispersal movements were recorded in this study and no upward flight behaviour was observed. • In this report, the estimated maximum population sizes for the two studies of *C. mercuriale* are among the highest recorded for any damselfly. However, *I. pumilio* populations were much smaller and as such may be more at risk of genetic effects such as inbreeding." (2009): Foraging habitat selection, diet and nestling condition in Yellow Wagtails *Motacilla flava* breeding on arable farmland. *Bird Study* 56(2): 221-232. (in English) ["Yellow Wagtails (Aves) showed seasonally variable foraging preferences, favouring field margin and crop habitats, although habitat availability did not influence brood productivity ... Samples taken in June tended to be dominated by flies and beetles (both adults and larvae) While flies continued to dominate the diet in July, beetles were much less prevalent, and adult damselflies became increasingly frequent in samples. It is not known whether this shift is associated with changes in foraging habitat preference, or the relative scarcity of damselflies across the whole study area prior to strong emergences of the commonest species *Enallagma cyathigerum*, and *Ischnura elegans* in late June. The ability to switch between prey items and/or foraging habitats can be important in multi-brooded species that face sharp seasonal peaks in the abundance of invertebrate taxa." 9730. Jarju, L.B.S.; Fillinger, U.; Green, C.; Louca, V.; Majambere, S.; Lindsay, S.W. (2009): Agriculture and the promotion of insect pests: rice cultivation in river floodplains and malaria vectors in The Gambia. *Malaria Journal* 8(1): 12 pp. (in English) ["Background: Anthropogenic modification of natural habitats can create conditions in which pest species associated with humans can thrive. In order to mitigate for these changes, it is necessary to determine which aspects of human management are associated with the promotion of those pests. *Anopheles gambiae*, the main Africa malaria vector, often breeds in rice fields. Here the impact of the ancient practice of 'swamp rice' cultivation, on the floodplains of the Gambia River, on the production of anopheline mosquitoes was investigated. Methods: Routine surveys were carried out along 500 m transects crossing rice fields from the landward edge of the floodplains to the river during the 2006 rainy season. Aquatic invertebrates (including 'Zygoptera' and 'Anisoptera') were sampled using area samplers and emergence traps and fish sampled using nets. Semi-field experiments were used to investigate whether nutrients used for swamp rice cultivation affected mosquito larval abundance. Results: At the beginning of the rainy season rice is grown on the landward edge of the floodplain; the first area to flood with fresh water and one rich in cattle dung. Later, rice plants are transplanted close to the river, the last area to dry out on the floodplain. Nearly all larval and adult stages of malaria vectors were collected 0–100 m from the landward edge of the floodplains, where immature rice plants were grown. These paddies contained stagnant freshwater with high quantities of cattle faeces. Semi-field studies demonstrated that cattle faeces nearly doubled the number of anopheline larvae compared with untreated water. Conclusion: Swamp rice cultivation creates ideal breeding sites for malaria vectors. However, only those close to the landward edge harboured vectors. These sites were productive since they were large areas of standing freshwater, rich in nutrients, protected from fish, and situated close to human habitation, where egg-laying mosquitoes from the villages had short distances to fly. The traditional practice of 'swamp rice' cultivation uses different bodies of water on the floodplains to cultivate rice during the rainy season. A consequence of this cultivation is the provision of ideal conditions for malaria vectors to thrive. As the demand for locally-produced rice grows, increased rice farming will generate great numbers of vectors; emphasizing the need to protect local communities against malaria." 9731. Jongerius, S.R.; Lentink, D. (2009): Structural analysis of a dragonfly wing. *Experimental Mechanics* 50(9): 1323-1334. (in English) ["Dragonfly wings are highly corrugated, which increases the stiffness and strength of the wing significantly, and results in a lightweight structure with good aerodynamic performance.

How insect wings carry aerodynamic and inertial loads, and how the resonant frequency of the flapping wings is tuned for carrying these loads, is however not fully understood. To study this we made a three-dimensional scan of a dragonfly (*Sympetrum vulgatum*) fore- and hindwing with a micro-CT scanner. The scans contain the complete venation pattern including thickness variations throughout both wings. We subsequently approximated the forewing architecture with an efficient three-dimensional beam and shell model. We then determined the wing's natural vibration modes and the wing deformation resulting from analytical estimates of 8 load cases containing aerodynamic and inertial loads (using the finite element solver Abaqus). Based on our computations we find that the inertial loads are 1.5 to 3 times higher than aerodynamic pressure loads. We further find that wing deformation is smaller during the downstroke than during the upstroke, due to structural asymmetry. The natural vibration mode analysis revealed that the structural natural frequency of a dragonfly wing in vacuum is 154 Hz, which is approximately 4.8 times higher than the natural flapping frequency of dragonflies in hovering flight (32.3 Hz). This insight in the structural properties of dragonfly wings could inspire the design of more effective wings for insect-sized flapping micro air vehicles: The passive shape of aeroelastically tailored wings inspired by dragonflies can in principle be designed more precisely compared to sail like wings—which can make the dragonfly-like wings more aerodynamically effective." 9734. Liang, Z.; Dong, H. (2009): Computational study of wing-wake interactions between ipsilateral wings of dragonfly in flight. *American Institute of Aeronautics and*

Astronautics Paper 2009-4192: 7 pp. (in English) ["Bilateral and ipsilateral wing-wing interactions can be commonly observed in insect flights. As a representative example of ipsilateral wing-wing interaction, dragonflies in flight have been widely studied. It has been discovered that they utilize changes of phase between ipsilateral forewings and hindwings at different kinds of flying mode. In the current study, we present a direct numerical simulation of a modeled dragonfly in slow flight as reported in Azuma et al (1985). Realistic morphologies of wing, body, and kinematics are used for maximum including wing and body features of a dragonfly. This work aims to study the relations between waketopology and aerodynamic performance due to wing-wing and wing-wake interactions of dragonfly ipsilateral wings. Current high fidelity numerical results are also compared with lowerfidelity aerodynamic modeling method discussed in Azuma et al (1985).] Address: Dong, H., Department of Mechanical & Materials Engineering, Wright State University, Dayton, OH 45435, USA. 9736. Maiolini, B.; Carolli, M. (2009): Odonata in Trentino (NE-Italy): historical and recent data. *Studi Trentini di Scienze Naturali, Acta Biologica* 84: 11-18. (in English, with Italian summary) ["The historical presence of Odonata in Trentino was reconstructed using data from the collections of the Natural Science Museum of Trento and from existing literature. Recent (2006-2007) observations by the authors in selected biotopes were conducted to start an updated list of species for the Trento Province. Odonata are one of the most interesting invertebrate taxa due to their ecological and trophic features, which allow their use as good and useful indicators of the ecological quality of freshwater biotopes and their neighbouring areas, and of the impact of human activities. The updated database (1699 records) comprises 64 species (77% of the Italian species). Large part of the records regarded lowland areas, but altitudinal preferences in some Odonata species were evident. The database comprises common and widespread species, as *Aeshna juncea*, *A. cyanea*, *Platycnemis pennipes*, *Ischnura elegans*, *Sympetrum striolatum* and *Coenagrion puella*. Rare species were represented by *Epitheca bimaculata*, *C. ornatum*, *Sympetma paedisca*, *Leucorrhinia pectoralis*, *Ophiogomphus cecilia*, *Somatochlora flavomaculata*, *Sympetrum depressiusculum*. Some of these were recorded before the 50's only in floodplain wetlands of the Adige Valley, which were claimed in the second half of last century, thus causing a local extinction. Recent and spatially limited observations allowed recording the presence of 24 species." (Authors)] Address: Maiolini, B., Sezione di

Zoologia degli Invertebrati e Idrobiologia, Museo Tridentino Scienze Naturali, Via Calepina 14, 38122 Trento, Italia. E-mail: maiolini@mtsn.tn.it

9738. Nakamura, M.; Okamiya, T.; Hasegawa, M.; Hasegawa, M. (2009): Cooperative breeding in the endemic Madagascan Chabert's Vanga *Leptopterus chabert*. *Ornithological Science* 8: 23-27. (in English) ["To examine the breeding system of the endemic Madagascan Chabert's Vanga *Leptopterus chabert* (Aves), we studied the contributions made by adults to nest building, incubating, brooding, and feeding the young at six nests. The study was conducted during November and December in 1999, 2000, and 2005 at Ankara-fantsika Strict Nature Reserve. During the nest-building stage, two adults (perhaps a heterosexual pair) delivered nest materials. Two adults participated in incubating and brooding. During the nestling period, several (3-4) adults delivered food (mainly bees, dragonflies, and moths) to the nestlings at two nests. They also mobbed animals that approached the nest. During the post-fledging period, several (3-4) adults fed the fledglings in two family groups. These observations suggest that Chabert's Vangas are cooperative breeders in which several adults feed the young of one brood." 9739. Oliveira, D.E.; De Marco Jr., P. (2009): Is there a trade-off between the melanin allocated to the immune system and to camouflage on larvae of the dragonfly *Micrathyrina catenata* Calvert, 1909 (Odonata: Libellulidae)? *Neotropical Biology and Conservation* 4(3): 133-136. (in English, with Portuguese summary) ["In insects, the immune system responds to the presence of antigens involving them in melanin. However, the melanin is also allocated into the exoskeleton's pigmentation, used to camouflage. We aimed to test the existence of a trade-off between the allocation of melanin to the immune system and to camouflage on the larvae of *Micrathyrina catenata*. We conducted the study in the Reserva do km 41, 80 kilometer distant from Manaus, Amazonas, Brazil. We implanted a nylon line into the abdomen of 30 larvae and observed if had or not deposition of melanin in the line. We counted the number of individuals who responded to implant depositing melanin and, later, we took photos of the larvae's heads and calculate gray intensity. We used a t test for independent samples. 76% of larvae responded to treatment depositing melanin on the implants. There were no significant differences in the intensity of gray between the larvae that responded to the implants and those who did not responded. There is no trade-off to allocation of melanin for camouflage and for the immune system. This should happen because the immune system is not limited by the acquisition of resources or the camouflage's demand for melanin is not enough to influence the immune system." (Authors)] Address: De Marco, P., Laboratório Ecologia Teórica e Síntese, Departamento de Biologia Geral, Universidade Federal de Goiás, BR-

9742. Pick, C.; Schneuer, M.; Burmester, T. (2009): The occurrence of hemocyanin in Hexapoda. *FEBS J.* 276(7): 1930-1941. (in English) ["Hemocyanins are copper-containing, respiratory proteins that have been thoroughly studied in various arthropod subphyla. Specific O(2)-transport proteins have long been considered unnecessary in Hexapoda (including Insecta), which acquire O(2) via an elaborate tracheal system. However, we recently identified a functional hemocyanin in the stonefly *Perla marginata* (Plecoptera) and in the firebrat *Thermobia domestica* (Zygentoma). We used RT-PCR and RACE experiments to study the presence of hemocyanin in a broad range of ametabolous and hemimetabolous hexapod taxa. We obtained a total of 12 full-length and 5 partial cDNA sequences of hemocyanins from representatives of Collembola, Archeognatha, Dermaptera, Orthoptera, Phasmatodea, Mantodea, Isoptera and Blattaria. No hemocyanin could be identified in Protura, Diplura, Ephemeroptera, Odonata, or in the Eumetabola (Holometabola + Hemiptera). It is not currently known why hemocyanin has been lost in some taxa. Hexapod hemocyanins usually consist of two distinct subunit types. Whereas type 1 subunits may represent the central building block, type 2 subunits may be absent in some species. Phylogenetic analyses support the Pancrustacea hypothesis and show that type 1 and type 2 subunits diverged before the emergence of the Hexapoda. The copperless insect storage hexamerins evolved from hemocyanin type 1 subunits, with *Machilis germanica* (Archeognatha) hemocyanin being a possible 'intermediate'. The evolution of hemocyanin subunits follows the widely accepted phylogeny of the Hexapoda and provides strong evidence for the monophyly of the Polyneoptera (Plecoptera, Dermaptera, Orthoptera, Phasmatodea, Mantodea, Isoptera, Blattaria) and the Dictyoptera (Mantodea, Isoptera, Blattaria). The Blattaria are paraphyletic with respect to the termites." (Authors)] Address: Burmester, T., Biozentrum Grindel und Zoologisches Museum, Universi-

9743. Pivko Knežević, A. (2009): The evaluation of the effect of sewage treatment plant Celje on the river Savinja regarding longitudinal changes of macroinvertebrate community. Graduation thesis (University studies), University of Ljubljana, Biotechnical faculty, Dept. of Biology: 82 pp, 3 app. (in Slovenian, with English summary) ["The aim of our research was to evaluate effect of Central sewage treatment plant Celje (CSPC) on the river Savinja, Slovenia. We assumed that because of its nutrient content, discharge of CSPC causes changes in the number, diversity and structure of macroinvertebrate community in the river. We measured physical, chemical and biological parameters and sampled macroinvertebrates three times at three different locations (location Polule upstream of the CSPC and locations Tremerje and Laško downstream of the CSPC). We determined 80 taxa of macroinvertebrates. The values of Shannon – Wiener index of diversity showed high diversity at all tree researched locations. Values were the highest at location Tremerje, where also the most taxa were present. High diversity at location Tremerje was probably consequence of diverse substrat in the river bed. Saprobic index (SI) was low due to high aeration of water. Referring to values of SI, we can classify the studied part of river Savinja ti the 1. – 2. quality class. Value of SI was slightly increasing down the stream (from Polule to Laško). Analysis of macroinvertebrate functional feeding groups showed dominancy of detritivores, followed by grazers, miners, filtrators and predators. Cluster analysis of data showed that temporal differences were bigger than spatial differences. Seasonal impacts affected macroinvertebrate community more than environmental variables at different locations." (Author) The study includes the following odonate species: *Calopteryx splendens*, *Platycnemis pennipes*, *Gomphus vulgatissimus*, and *Onychogomphus f. forcipatus*.] Address: Pivko Knežević, Alijana, University of Ljubljana, Biotechnical faculty, Dept. of Biology, SI – 1000 Ljubljana, Večna pot 111, Slovenia

9744. Reels, G.T. (2009): Dragonfly emergence at a small newly-created pond in Hong Kong. *Hong Kong Entomological Bulletin* 1(2): 32-37. (in English) ["Dragonfly emergence was monitored at a small (0.02ha) pond in Hong Kong from March 2004 to July 2005. The pond was created in late 2003, with emergent vegetation established along the margin. Dragonfly exuviae were much more abundant in 2004 (597 exuviae in 12 species) than in 2005 (49 exuviae in three species). Exuviae abundance was highest in March in 2004; April in 2005. In 2004, exuviae were recorded until September; in 2005, they were not recorded after May. Exuviae were estimated to have an average persistence of 3.4 days in the field. Emergence patterns varied between species. Most aeshnids and libellulids emerged in March and April 2004, although *Anax guttatus* had a second pulse of emergence in June 2004; *Sinictinogomphus clavatus* and *Ictinogomphus pertinax* (Gomphidae), and *Epopthalmia elegans* (Corduliidae) were late emergers in 2004. Their exuviae first appearing in June or July. The two gomphid species emerged in greater numbers in April and May 2005. The dramatic decline of emergence in 2005 was probably due to the growth and proliferation of predatory fish in the pond. More dragonfly species were recorded as adults than as exuviae, suggesting adult immigration. Surveys of

adult dragonflies alone may not give a completely accurate impression of the value of particular ponds for breeding dragonflies." (Author)] Address: Reels, G.T., H-3-30 Fairview Park, Yuen Long, N.T. Hong Kong. E-mail: gtreels@cyberdude.com

9746. Strausfeld, N.J.; Sinakevitch, I.; Brown, S.M.; Farris, S.M. (2009): Ground plan of the insect mushroom body: functional and evolutionary implications. *J. Comp. Neurol.* 513(3): 265-291. (in English) ["In most insects with olfactory glomeruli, each side of the brain possesses a mushroom body equipped with calyces supplied by olfactory projection neurons. Kenyon cells providing dendrites to the calyces supply a pedunculus and lobes divided into subdivisions supplying outputs to other brain areas. It is with reference to these components that most functional studies are interpreted. However, mushroom body structures are diverse, adapted to different ecologies, and likely to serve various functions. In insects whose derived life styles preclude the detection of airborne odorants, there is a loss of the antennal lobes and attenuation or loss of the calyces. Such taxa retain mushroom body lobes that are as elaborate as those of mushroom bodies equipped with calyces. Antennal lobe loss and calycal regression also typify taxa with short nonfeeding adults, in which olfaction is redundant. Examples are cicadas and mayflies, the latter representing the most basal lineage of winged insects. Mushroom bodies of another basal taxon, the Odonata, possess a remnant calyx that may reflect the visual ecology of this group. That mushroom bodies persist in brains of secondarily anosmic insects suggests that they play roles in higher functions other than olfaction. Mushroom bodies are not ubiquitous: the most basal living insects, the wingless Archaeognatha, possess glomerular antennal lobes but lack mushroom bodies, suggesting that the ability to process airborne odorants preceded the acquisition of mushroom bodies. Archaeognathan brains are like those of higher malacostracans, which lack mushroom bodies but have elaborate olfactory centers laterally in the brain." (Authors) Two dragonfly species: *Calopteryx splendens*, *Libellula depressa* and one mayfly species: *Potamanthus luteus* were collected near streams and rivers in the vicinity of Würzburg, Bayern, Germany. *Perithemis tenera* (Odonata) and Japanese beetles (*Popillia japonica*, Scarabaeidae, Coleoptera) were collected in the Morgantown, West Virginia, region, USA.] Address: Strausfeld, N.J., Arizona Research Laboratories, Division of Neurobiology, University of Arizona, Tucson, Arizona 85721, USA. 9747. Strickland, G.; Strickland, J. (2009): Damsellies of Louisiana. The Entomology Club at Louisiana State University: 65 pp. (in English) ["The Odonata have been treated in many wonderful technical and popular guides at both the national and regional levels. Many of these guides provide detailed accounts of each species, including range maps, habitat information, and keys for

species identification. Style of illustration varies from guide to guide, but often photographs of specimens in situ are used. Although these photos are aesthetically pleasing, important characters for species level identification are frequently sacrificed in the process. In addition, the specimen's true life size can be hard to determine. Because of constraints placed on the size of the field guides, photos of specimens showing individual variation due to sex, age, etc. are typically only included when this variation is extreme. This book is not meant to replace other books, but to be used as a local and regional supplement to a field guide of your choice. [...] Gayle and Jeanell Strickland have worked tirelessly to compile each of these species plates. The checklist was compiled by Bill Mauffray. The main purpose of this book is to make Gayle and Jeanell's photographic plates available to a wider audience and especially to aspiring students of the Odonata. We are grateful for their peerless contributions to highlighting the fauna of Louisiana and allowing us to produce this book from their work." (Editors) The authors use a scanner to produce their brilliant figures. The method is introduced in detail. Supplemental material can be accessed at: <http://members.fotki.com/gstrick3/>] Address: Gayle & Jeanell Strickland, Baton Rouge LA, USA. E-mail: gstrick3@cox.net

9750. Utz, R.M.; Hilderbrand, R.H.; Boward, D.M. (2009): Identifying regional differences in threshold responses of aquatic invertebrates to land cover gradients. *Ecological Indicators* 9(3): 556-567. (in English) ["Conversion of land from natural to urban or agricultural cover degrades stream ecosystems and results in loss of biodiversity. We compared cumulative frequency distributions to measure responses to land use gradients for aquatic invertebrate taxa to agricultural, urban, and impervious surface cover gradients across the state of Maryland, USA. The technique identifies the upper limit threshold above which taxa cease to occur as well as a lower limit of detection of effect for negatively affected taxa. Urban development and impervious surface cover negatively affected the distributions of 44–56% of the 180 taxa tested, depending on region. Across similar taxa, negative responses occurred at lower levels of urban land covers in the Piedmont compared to the Coastal Plain physiographic province, which suggests that Piedmont aquatic biodiversity may be more vulnerable to urbanization. Most taxa were capable of tolerating high levels of agricultural development, although a number of common taxa in the Coastal Plain and Highlands regions were found to be agriculture-sensitive. Some taxa traditionally used as indicators were tolerant of very high levels of human-altered land uses, suggesting that such taxa require

examination prior to use as indicators of landscape stressors. Our analysis method appears to be sufficiently flexible and sensitive to be used for a variety of taxa and systems for stressor detection, ecosystem monitoring, and spatially explicit forecasts of taxa loss as watershed land cover changes." 9752. Wohlfahrt, B.; Vamosi, S.M. (2009): Antagonistic selection or trait compensation? Diverse patterns of predation-induced prey mortality due to the interacting effects of prey phenotype and the environment. *Evol. Biol.* 36: 386-396. (in English) ["Differentiation among closely related prey species may result from differing adaptations to heterogeneous environments. Many studies have focused on competition for shared resources as a major factor promoting differentiation, with considerably less attention focused on interacting effects of abiotic factors and predator-prey relationships. To further investigate the effects of interacting selective factors on the outcomes of mortality and survival in aquatic prey, we conducted interrelated laboratory studies examining the effects of water colour and plant density on predator-induced mortality in four dytiscid species (Coleoptera: Dytiscidae) that varied in body size (total body length), and body colouration pattern. Body size was more strongly phylogenetically conserved than colouration pattern, and larger body size generally resulted in decreased predator-induced mortality rates. In contrast, the effectiveness of body colouration patterns in decreasing prey mortality risk depended on water colour and prey body size. In clear water, small and patterned dytiscids had mortality rates equal to medium-sized plain beetles, thereby compensating for differences in mortality risk due to body size differences. Under dark water conditions, small dytiscids experienced higher mortality rates compared to medium-sized dytiscids; however, the effectiveness of colouration patterns in medium-sized beetles decreased to the point that it became detrimental to survival, revealing antagonistic selection. We suggest that colouration patterns are not ubiquitous in prey species and cospecialization in larger size and presence of colouration patterns does not generally result in higher prey survival, because the effectiveness of the two antipredator defences may be

restricted to certain phenotype environment combinations. Our results illustrate how interactions between prey phenotype and variable environmental conditions among habitats dominated by the same predator can lead to adaptive trade-offs, which can increase the number of possible outcomes of predator mediated selection." (Authors) Aeshna juncea larvae were used in laboratory experiments on predation-induced mortality in 4 dytiscid species (Coleoptera). Some notes on the larvae are provided based on brief and clear definitions of various types of their behaviour.] Address: Wohlfahrt, Bianca, Dept Biol. Sci., Univ. Calgary, 2500 Univ. - 9757.** Alcocer, J.; Bernal-Brooks, F.W. (2010): Limnology in Mexico. *Hydrobiologia* 644: 15-68. (in English) [The paper "deals with the geography, geology, and climate of the Mexican territory as the basis to further explain the development of Limnology as a science in this country. An early knowledge started with the Aztecs, with evidence of practical solutions for a life within a lake. After the conquest of the American territories by the Spaniards, the exploration of the new territories provided the main source of information relative to natural resources. In 1938, the Mexican government established the Estación Limnológica de Pátzcuaro and the pioneer studies appeared under the name of Spanish scientists not only here but also at the Universidad Nacional Autónoma de México and the Instituto Politécnico Nacional. During the 1970s, the participation of Mexican limnologists began and the attempt to build-up a conceptual framework in its own for lakes, reservoirs, and rivers. This article outlines the main limnological characteristics of Mexican water bodies, highlights the peculiarities of a transitional zone between the tropics and subtropics, and describes the government structure for management and administration. A fast development in this area of knowledge got underway with the creation of the Asociación Mexicana de Limnología in 1997 and the collaboration with international counterparts." - 9758.** Allen, K.A.; Le Duc, M.G.; Thompson, D.J. (2010): Habitat and conservation of the enigmatic damselfly *Ischnura pumilio*. *Journal of Insect Conservation* 14(6): 689-700. (in English) ["*Ischnura pumilio* is threatened in the UK and its habitat requirements are not well understood. This study tests previously held notions of the habitat requirements of *I. pumilio*, investigates the features of a habitat influencing odonate species composition and provides recommendations for habitat creation and management for *I. pumilio* persistence. Thirty-one sites across south west England with past *I. pumilio* records were surveyed in 2006. Environmental variables and odonate abundance were recorded. Odonate species composition and *I. pumilio* abundance were related to environmental variables using multivariate techniques and GLM. *Ischnura pumilio* was found at a wide variety of habitat types; key habitat features were a muddy substrate with some open ground, turbid water, and low levels of shade. It was associated with increased structural diversity of vegetation away from water but low maximum height; characteristic of early-successional sites. The variables predicting odonate composition were location, shade, level of disturbance, water depth, and cover of terrestrial dwarf shrubs and Sphagnum species. Vegetation height and structure were also highly influential to at least 20 m from water. This study indicates that odonate habitat management should include adjacent hinterland. Management for *I. pumilio* may be complicated by the species' use of two habitat types, each with associated problems. Furthermore, odonate species diversity was negatively associated with *I. pumilio* abundance, which may cause conflict of interest when managing habitats." 9763. Arribère, M.A.; Campbell, L.M.; Rizzo, A.P.; Arcagni, M.; Revenga, J.; Ribeiro Guevara, S. (2010): Trace elements in plankton, benthic organisms, and forage fish of Lake Moreno, northern Patagonia, Argentina. *Water, Air, & Soil Pollution* 212(1-4): 167-182. (in English) ["The Northern Patagonian Andean range shared by Chile and Argentina has numerous glacial oligotrophic lakes protected in a series of National Parks. Recent baseline surveys indicated that concentrations in muscle and liver tissues from various fish species from across Nahuel Huapi and Los Alerces National Parks in Argentina were comparable or higher than similar fish species from other parts of the world. As a result, Lake Moreno, in Nahuel Huapi National Park, was chosen to investigate multiple element sinks, trends, and transfer in a representative Patagonia aquatic food web. The metals and metalloids Ag, As, Ba, Br, Cs, Co, Cr, Fe, Hg, K, Na, Rb, Se, and Zn were analyzed in three size plankton fractions, submerged macrophytes, biofilm, insect larvae, amphipods, decapods, gastropods (snails), annelids (earthworms), and forage fish. Except for nanoplankton (10–53 µm; small-celled algae, rotifers) and microplankton (53–200 µm; larger algae, ciliates, zooplankton nauplii), which share elemental compositional similarities, each taxon category had its own distinctive compositional pattern, revealed by principal component analysis. Nano- and microplankton tend to be relatively elevated in some metals, including As, Co, Cr, Fe, Hg, Zn, and Rb, followed by biofilm. Shredder-scrapper Trichoptera (caddisflies) have higher concentration of most of the studied elements than other insect larvae taxa, especially carnivorous Odonata (Anisoptera, dragonflies), which were associated with lower elemental contents. Those trends point to an overall tendency for biodiminishing element concentrations with trophic level in the benthos of Lake Moreno." 9768. Beatty, C.; Fraser, S.; Pérez-Jvostov, F.; Sherratt, T. (2010): Dragonfly and damselfly (Insecta, Odonata) distributions in Ontario, Canada: Investigating the influence of climate change. *BioRisk* 5: Special issue: Monitoring climatic change with dragonflies: 225-241. (in English) ["We analysed temperature data and odonate distribution data collected in the province of Ontario, Canada, over approximately sixty years. Analysis of temperature data from 31 weather stations collected in the years 1945–2000 showed an overall significant increase in the minimum, maximum and mean monthly temperatures; these trends were not adjusted for changes in urbanisation. Comparison of county level presence/absence data for odonates from the 1950's and 2002 found a slight decrease in the northernmost distributions of some species, although no significant patterns were evident. Lower sampling coverage in the larger, more northerly counties in Ontario, as well as the

assessment of distributions based on county records may limit the sensitivity of our approach in detecting changes in odonate species distributions over time. Future work should focus on increasing the coverage, uniformity and geographic detail of available datasets, as well as evaluating range change through testing predictions based on the ecology and biogeography of odonate species." 9770. Betoux, O.; Beattie, R. (2010): *Iverya averyi* gen. nov. and sp. nov., a New Triadotypomorphan Species from the Middle Triassic at Picton, New South Wales, Australia. *Acta Geologica Sinica - English Edition* 84(4): 688-692. (in English) ["A new specimen assigned to the species *Iverya averyi* gen. nov. and sp. nov. is described. This species is considered as a triadotypomorphan insect, a poorly known group of Triassic stem-odonatans. Like other triadotypomorphans, this species exhibits an area between MA and MP that is comparatively broad, and a cubitoanal area involving an AA stem distinct from CuA + CuP + AA emitting several posterior branches. Diagnostic character states of the new species are listed. Although incomplete, the specimen provides new information on the wing morphology of triadotypomorphans. This discovery might contribute to better assessment of the phylogenetic position of triadotypomorphan species with respect to other stem-odonatans." 9771. Bieger, L.; Carvalho, A.B.P.; Strieder, M.N.; Maltchik, L.; Stenert, C. (2010): Are the streams of the Sinos River basin of good water quality? Aquatic macroinvertebrates may answer the question. *Braz. J. Biol.* 70(4, suppl.): 1207-1215. (in English, with Portuguese summary) ["The main objective of this study was the assessment of the water quality of the Sinos River basin (Rio Grande do Sul state, Brazil) through biotic indices based on the macroinvertebrate community ("Family Biotic Index – FBI", and "Biological Monitoring Working Party Score System – BMWP"). Three lower order streams (2nd order) were selected in each one of three main regions of the basin. In each stream, the samplings were performed in three reaches (upper, middle, and lower), totalling 27 reaches. Two samplings were carried in each reach over one year (winter and summer). A total of 6,847 macroinvertebrates distributed among 54 families were sampled. The streams from the upper region were of better water quality than the lower region. The water quality did not change between the upper, middle and lower reaches of the streams. However, the upper reaches of the streams were of better water quality in all the regions of the basin. The water quality of the streams did not vary between the summer and the winter. This result demonstrated that water quality may be analysed in both studied seasons (summer

and winter) using biotic indices. The analysis of the results allows us to conclude that the biotic indices used reflected the changes related to the water quality along the longitudinal gradient of the basin. Thus, aquatic macroinvertebrates were important bioindicators of the water and environmental quality of the streams of the Sinos River basin." 9774. Bried, J.; Mazzacano, C. (2010): Review of Wildlife Action Plans for Odonata conservation. *Argia* 22(4): 15-16. (in English) ["We found that the wildlife action plans have disturbing gaps. The first state wildlife action plans were developed in 2001-2005, when 441 distinct species were known from the US. Although nearly two-thirds (277) of these species were appointed as Species of Greatest Conservation Need (SGCN) overall (191 dragonfly and 86 damselfly species), over half the states neglected to assign dragonfly SGCN, damselfly SGCN, or both. Most (89%) of the 277 SGCN odonates were recognized as such in five or fewer states; 95 species (34%) were assigned in one state only, with Alaska and Hawaii contributing 30 of these. States in the west and south listed proportionately fewer odonate SGCN than those in the Great Lakes, Mid-Atlantic, and New England regions. We believe this reflects patterns of legal authority, information availability, and involvement by odonatists rather than geographic patterns of true conservation need. Nationally, it appears that few odonatists were involved in wildlife action plans relative to available expertise (potentially only -5% of DSA members), and that Odonata were underrepresented or omitted as SGCN in many states." (in English) [*Coenagrion scitulum* was discovered in Kent, UK on 21-VI-2010; after the record from 16-VI-2009 on the Channel Island Jersey, this is the second record of this species after 1953, the year the colony along the British coast near Hadleigh was wiped out by a sea water flood.] Address: not stated

9777. Chambers, C.P.; Whiles, M.R.; Rosi-Marshall, E.J.; Tank, J.L.; Royer, T.V.; Griffiths, N.A.; Evans-White, M.A.; Stojak, A.R. (2010): Responses of stream macroinvertebrates to Bt maize leaf detritus. *Ecological Applications* 20(7): 1949-1960. (in English) ["In the mid-western United States, maize detritus enters streams draining agricultural land. Genetically modified Bt maize is commonly planted along streams and can possibly affect benthic macroinvertebrates, specifically members of the order Trichoptera, which are closely related to target species of some Bt toxins and are important detritivores in streams. The significance of inputs of Bt maize to aquatic systems has only recently been recognized, and assessments of potential nontarget impacts on aquatic organisms are lacking. We conducted laboratory feeding trials and found that the leaf-shredding trichopteran, *Lepidostoma liba*, grew significantly slower when fed Bt maize compared to non-Bt maize, while other invertebrate taxa that we examined showed no negative effects. We also used field studies to assess the influence of Bt maize detritus on benthic macroinvertebrate abundance, diversity, biomass, and functional structure in situ in 12 streams adjacent to Bt maize or non-Bt maize fields. We found no significant differences in total abundance or biomass between Bt and non-Bt streams, and trichopterans comprised only a small percentage of invertebrate biomass at all sites (0–15%). Shannon diversity did not differ among Bt and non-Bt streams and was always low (H' range = 0.9–1.9). Highly tolerant taxa, such as oligochaetes and chironomids, were dominant in both Bt and non-Bt streams, and macroinvertebrate community composition (including "Odonata") was relatively constant across seasons. We used litterbags to examine macroinvertebrate colonization of Bt and non-Bt maize detritus and found no significant differences among litter or stream types. Our in situ findings did not support our laboratory results; this is likely because the streams we studied in this region are highly degraded and subject to multiple, persistent anthropogenic stressors (e.g., channelization, altered flow, nutrient and pesticide inputs). Invertebrate communities in these streams are a product of these degraded conditions, and thus the impact of a single stressor, such as Bt toxins, may not be readily discernable. Our results add to growing evidence that Bt toxins can have sublethal effects on nontarget aquatic taxa, but this evidence should be considered in the context of other anthropogenic impacts and alternative methods of pest control influencing streams draining agricultural regions." 9780. Chertoprud, M.V. (2010): Biogeographic zonation of the Eurasian fresh waters based on the macrobenthic faunas. *Journal of General Biology* 71(2): 144-162. (in Russian, with English summary) ["Spatial differentiation of the Eurasian freshwater faunas is analyzed based on the original and published data on the aquatic insects, crustaceans, and molluscs (about 8800 species in total). The Hacker-Dice similarity index is employed as a principal criterion of differentiation. The schemes of biogeographic zonation are constructed for the nine large macrobenthic taxa, namely, Odonata, Ephemeroptera, Plecoptera, Hemiptera, Coleoptera, Trichoptera, Malacostraca, Gastropoda, and Bivalvia. Discussed are principal discordances in distribution of three different ecological-systematic groups of the macrobenthos, namely, limnophylic insects, rheophylic insects, and crustaceans with molluscs. A generalized zonation system of the Eurasian fresh waters is elaborated, which is fundamentally divided into Palaearctic and Oriental Regions. The former is further divided into five subregions: Euro-Ob, Near East, Central Asia, Eastern Siberia, and Japan. The latter is divided into three subregions: Indo-Himalaya, China, and Malay. Preliminary classification of the provinces is also provided. Disagreements between the biogeographic systems of different authors are discussed." 9782. Cooper, I.A. (2010): Ecology of sexual dimorphism and clinal variation of coloration in a damselfly. *American Naturalist* 176(5): 566-572. ["Sexual selection, more so than natural selection, is posited as the major cause of sex differences. Here I show ecological correlations between solar radiation levels and sexual dimorphism in body color of a Hawaiian damselfly. *Megalagrion calliphya* exhibits sexual monomorphism at high elevations, where both sexes are red in color; sexual dimorphism at low elevations, where females are green; and female-limited dimorphism at midelevations, where both red and green females exist. Within a midelevation population, red females are also more prevalent during high daily levels of solar radiation. I found that red pigmentation is correlated with superior antioxidant ability that may protect from UV damage and confer a benefit to damselflies in exposed habitats, including males, which defend exposed mating habitats at all elevations, and females, which are in shaded habitats except at high elevation. This study characterizes the ecology of sexual dimorphism and provides a new, ecological hypothesis for the evolution of female-limited dimorphism." 9785. Crumrine, P.W. (2010): Body size, temperature, and seasonal differences in size structure influence the occurrence of cannibalism in larvae of the migratory dragonfly, *Anax junius*. *Aquatic Ecology* 44: 761-770. (in English) ["The aim of this study was to test the hypotheses that body size and seasonal differences in temperature and size structure influence cannibalism in larval dragonflies. In the first two experiments, larvae that were either similar or different in size were paired to examine the potential for intra- and intercohort cannibalism. In the third experiment, size structure of an assemblage of larvae and water temperature were manipulated to explore the seasonal dynamics of cannibalism. Cannibalism was common between individuals that differed in body size by one or more instars. Cannibalism also occurred between individuals similar in size but the rate varied across developmental stages. Results suggest that cannibalism may be most common when water temperatures are warm and late-instar larvae are present at high densities. These results highlight the importance of intra- and intercohort cannibalism as factors that can influence the population dynamics of generalist predators." (Author)] Address: Crumrine, P.W., Dept of Biological Sciences & Program in Environmental Studies, Rowan University, Glassboro, NJ 08028, USA. E-mail: crumrine@rowan.edu

9787. Damm, S.; Schierwater, B.; Hadrys, H. (2010): An integrative approach to species discovery in odonates: from character-based DNA barcoding to ecology. *Molecular Ecology* 19(18): 3881-3893. (in English) ["Modern taxonomy requires an analytical approach incorporating all lines of evidence into decision-making. Such an approach can enhance both species identification and species discovery. The character-based DNA barcode method provides a molecular data set that can be incorporated into classical taxonomic data such that the discovery of new species can be made in an analytical framework that includes multiple sources of data. We here illustrate such a corroborative framework in a dragonfly model system that permits the discovery of two new, but visually cryptic species. In the African dragonfly genus *Trithemis* three distinct genetic clusters can be detected which could not be identified by using classical taxonomic characters. In order to test the hypothesis of two new species, DNA-barcodes from different sequence markers (ND1 and COI) were combined with morphological, ecological and biogeographic data sets. Phylogenetic analyses and incorporation of all data sets into a scheme called taxonomic circle high-

ly supports the hypothesis of two new species. Our case study suggests an analytical approach to modern taxonomy that integrates data sets from different disciplines, thereby increasing the ease and reliability of both species discovery and species assignment." 9790. Davies, P.J.; Wright, I.A.; Findlay, S.J.; Jonasson, O.J.; Burgin, S. (2010): Impact of urban development on aquatic macroinvertebrates in south eastern Australia: degradation of in-stream habitats and comparison with non-urban streams. *Aquatic Ecology* 44: 685-700. (in English) ["Internationally, waterways within urban areas are subject to broad-scale environmental impairment from urban land uses. In this study, we used in-stream macroinvertebrates as surrogates to measure the aquatic health of urban streams in the established suburbs of northern Sydney, in temperate south eastern Australia. We compared these with samples collected from streams flowing in adjacent naturally vegetated catchments. Macroinvertebrates were collected over a 30-month period from riffle, edge and pool rock habitats and were identified to the family level. Macroinvertebrate assemblages were assessed against the influence of imperviousness and other catchment and water quality variables. The study revealed that urban streams were significantly impaired compared with those that flowed through naturally vegetated non-urban catchments. Urban streams had consistently lower family richness, and sensitive guilds were rare or missing. We found that variation in community assemblages among the instream habitats (pool edges, riffles and pool rocks) were more pronounced within streams in naturally vegetated catchments than in urban waterways." (Authors) Odonata are treated at the family level.] Address: Davies, P.J., Ku-ring-gai Council, Locked

9795. Dixon, J.R.; Gennard, D.E. (2010): The influence of meteorological conditions on the flight activity of the Blue-tailed Damselfly *Ischnura elegans* (Vander Linden), the Azure Damselfly *Coenagrion puella* (Linnaeus) and the Emerald Damselfly *Lestes sponsa* (Hanse-mann). *J. Br. Dragonfly Society* 26(2): 84-97. (in English) ["The flight activity was compared for *I. elegans*, *C. puella* and *L. sponsa* at an exposed pond and a sheltered pond at Rimac, Saltfleetby National Nature Reserve, Lincolnshire in July and August 1998. Meteorological conditions (air temperature, light intensity, cloud cover, wind speed and direction were investigated in relation to flight activity of the species. Flight activity of all three species increased with rising air temperature, light intensity and declining cloud cover. These factors appear to be the main ones that exert control on day to day variation in flight activity of these three species. Their relative importance varies from species to species, which is most likely to be due to the nature of the exoskeletons (which influences the rate of solar radiation absorption), size (which influences rate of warming and power requirements) and behaviour. Only *C. puella* showed any relationship between mating activity (tandem wheel flight) and meteorological conditions." 9796. Dogramaci, M.; DeBano, S.J.; Wooster, D.E.; Kimoto, C. (2010): A method for subsampling terrestrial invertebrate samples in the laboratory: Estimating abundance and taxa richness. *Journal of Insect Science* 10:25 (available online: insectscience.org/10.25): 17pp. (in English) ["Significant progress has been made in developing subsampling techniques to process large samples of aquatic invertebrates. However, limited information is available regarding subsampling techniques for terrestrial invertebrate samples. Therefore a novel subsampling procedure was evaluated for processing samples of terrestrial invertebrates collected using two common field techniques: pitfall and pan traps. A three-phase sorting protocol was developed for estimating abundance and taxa richness of invertebrates. First, large invertebrates and plant material were removed from the sample using a sieve with a 4 mm mesh size. Second, the sample was poured into a specially designed, gridded sampling tray, and 16 cells, comprising 25% of the sampling tray, were randomly subsampled and processed. Third, the remainder of the sample was scanned for 4-7 min to record rare taxa missed in the second phase. To compare estimated abundance and taxa richness with the true values of

these variables for the samples, the remainder of each sample was processed completely. The results were analyzed relative to three sample size categories: samples with less than 250 invertebrates (low abundance samples), samples with 250-500 invertebrates (moderate abundance samples), and samples with more than 500 invertebrates (high abundance samples). The number of invertebrates estimated after subsampling eight or more cells was highly precise for all sizes and types of samples. High accuracy for moderate and high abundance samples was achieved after even as few as six subsamples. However, estimates of the number of invertebrates for low abundance samples were less reliable. The subsampling technique also adequately estimated taxa richness; on average, subsampling detected 89% of taxa found in samples. Thus, the subsampling technique provided accurate data on both the abundance and taxa richness of terrestrial invertebrate samples. Importantly, subsampling greatly decreased the time required to process samples, cutting the time per sample by up to 80%. Based on these data, this subsampling technique is recommended to minimize the time and cost of processing moderate to large samples without compromising the integrity of the data and to maximize the information extracted from large terrestrial invertebrate samples. For samples with a relatively low number of invertebrates, complete counting is preferred." (Authors) Zygoptera only were caught in pan but not in pitfall traps.] Address: Dogramaci, M., Dept of Fisheries and Wildlife, Hermiston Agricultural Research and Extension Center, Oregon State University, Hermiston, OR 97838

9797. Dolný, A.; Drozd, P.; Petříková, M.; Harabiš, F. (2010): Sex ratios at emergence in populations of some Central European Gomphidae species (Anisoptera). *Odonatologica* 39(3): 217-224. (in English) ["At emergence (F-0) a significant bias for females was observed within the Moravian (Czech Republic) populations of *Gomphus flavipes*, *G. vulgatissimus* and *Ophiogomphus cecilia*. Males represented 45.6% of all specimens (43.5% in the first and 46.4% in the second research year). The results of the χ^2 test supported the female-biased sex ratio in populations of all 3 species. The sex ratio in populations varied significantly in time during the emergence season, caused by the fact that all 3 species demonstrated a significant protandric trend. The greatest changes in sex ratio during the emergence season were demonstrated by *G. flavipes* (coefficient value -0.007542); the smallest were recorded in *G. vulgatissimus* (CV -0.008617). Environmental impact did not prove to act be a factor which has an effect on the sex ratio of species with phenotypical determination of sex." (in English, with French summary) ["The interaction between predator and prey is an evolutionary arms race, for which early detection by either party is often the key to success. In aquatic ecosystems, olfaction is an essential source of information for many prey and predators and a number of cues have been shown to play a key role in trait-mediated indirect interactions in aquatic communities. Here, we review the nature and role of predator kairomones, chemical alarm cues, disturbance cues, and diet cues on the behaviour, morphology, life history, and survival of aquatic prey, focusing primarily on the discoveries from the last decade. Many advances in the field have been accomplished: testing the survival value of those chemicals, providing field validation of laboratory results, understanding the extent to which chemically mediated learning may benefit the prey, understanding the role of these chemicals in mediating morphological and life-history adaptations, and most importantly, the selection pressures leading to the evolution of chemical alarm cues. Although considerable advances have been made, several key questions remain, the most urgent of which is to understand the chemistry behind these interactions." (Authors) This review includes several references to Odonata.] Address: Ferrari, Maud, Department of Environmental Science and Policy, University of California, Davis, One Shields Avenue, Davis, CA 95616, USA. 9807. Fortin, B.L. (2010): Selenium dynamics in Canadian Rocky Mountain lakes. M.Sc. thesis, Department of Biological Sciences, University of Alberta, Edmonton: 142 pp. (in English) ["I investigated, water, invertebrates and fishes from lakes in Banff National Park and Kananaskis Country, Alberta for selenium (Se), an element known to be toxic to vertebrates. At some depths, Se concentrations in sediment exceeded recognized thresholds for bird and fish reproductive impairment. Se concentrations in water were over USEPA guidelines after spring melt runoff. In aquatic invertebrates, Se concentrations exceeded values known to

cause reproductive impairment in fish and bird predators. Se concentrations in all fish species exceeded known thresholds for reproductive impairment in avian consumers and the majority surpassed concentrations that would negatively affect wildlife and human consumers. Se concentrations in some fish species have significantly increased over the past 6-16 years. The strongest predictors of fish Se concentrations were growth rate, condition factor, age, weight, trophic position (within lakes) and vegetation type (among lakes). These results suggest that consumption advisories are desirable for several lakes in the Banff and Kananaskis area, and that Se concentrations in fish from other area lakes should be investigated." (Author) Odonata (= Aeshnidae, Coenagrionidae, Libellulidae) mean Se concentrations exceeded the established toxicity thresholds for fish and bird diets in all lakes. Mud Lake would be the only exception, where the mean Se concentration of Odonates was very close to, but did not exceed the threshold for fish reproductive impairment.] Address: Fortin, Barbra Linda, Dept Biol. (in Japanese, with English summary) [*M. costaris* was recorded in Imabari and Saijo city, eastern part of Ehime prefecture, Japan. This species has a limited distribution in Shikoku Island. In Ehime prefecture, it is thought living only in the middle part, thus it was categorized as threatened species. In general, any investigation on the distribution of this taxon is insufficient in eastern and northern part of prefecture, and the discovery of new habitats is likely. The taxonomic status of *Mnais costaris* Selys and *M. pruinosa* Selys still awaits clarification, and intensified field work can help to improve the data basis.] Address: Kobayashi, S., Professional Graduate Division of Arts and curator of Natural Ehime Prefectural Science Museum, Niihama, Ehime Prefecture, 792-0060, Japan

9811. Gahl, M.K.; Calhoun, A.J.K. (2010): The role of multiple stressors in ranavirus-caused amphibian mortalities in Acadia National Park wetlands. *Canadian Journal of Zoology* 88(1): 108-121. (in English, with French summary) ["Recent studies suggest that multiple sublethal stressors compromise amphibian immune systems and increase susceptibility to disease. We examined two aspects of multiple stressors and incidence of ranavirus-caused amphibian mortalities in free-living amphibian populations: (1) among-pond differences in physical, chemical, and biological stressors (eg. family

Belostomidae, order Hemiptera; family Dytiscidae, order Coleoptera; some suborder Anisoptera, order Odonata) that may exacerbate mortality events, and (2) temporal changes in within-pond stressors that coincide with mortality events. At the among-pond scale, we used principal components analysis and logistic regression followed by Akaike's information criterion (QAICc) to identify stressors associated with disease incidence. Of the stressors we investigated, aluminum, temperature, and conductivity were most correlated with outbreaks, but it was unclear whether they increased ranavirus-caused mortality events. Sublethal stressors were difficult to isolate in the field and few were significantly associated with ranavirus across all breeding ponds. Our results suggest that each wetland, because of varied physical, biological, and chemical settings, will have its own suite of stressors that sublethally affect amphibians." 9813. Goforth, C.L. (2010): Behavioural responses of *Enallagma* to changes in weather (Zygoptera: Coenagrionidae). *Odonatologica* 39(3): 225-234. (in English) ["Odonates exhibit a variety of weather associated behaviours, including abandoning ponds just before storms begin. They may be able to detect changes in weather that alert them to approaching storms and allow them to escape the water's edge before it begins to rain. *E. annexum* and *E. boreale* were observed at a Colorado marsh (USA) to determine which weather factors contributed to the weather-induced behaviours they exhibit. They were observed for 191 five-minute periods and their flight activity quantified. Weather parameters were measured during each interval to account for rapid changes in conditions. Based on results from multiple regression analysis, it is clear that light intensity is the strongest weather parameter affecting zygopteran flight activity, but temperature, wind speed, and the presence of rain are also significant. The 2 species exhibited pond abandonment behaviour during storms. It is likely that storms are dangerous to zygopterans and their apparent ability to detect impending storms is a survival mechanism. Alternatively, pond abandonment behaviour may be triggered by the same factors necessary to trigger roosting and the zygopterans simply return to their roosting sites during storms." - 9814.** Gomez-Anaya, J.A.; Novelo-Gutierrez, R. (2010): Richness and structure of an Odonata larval assemblage from Río Pinolapa, Tepalcatepec, Michoacán, Mexico in relation to their habitat characteristics. *Odonatologica* 39(4): 287-303. (in English) ["The odonate larval assemblage from Río Pinolapa (RP) in the municipality of Tepalcatepec, Michoacán, is described. Sampling was conducted twice in each season (8 trips in total), and additionally some physicochemical variables of the river channel were recorded. Strata (shores, riffles and eddies) and seasonal variation of assemblages are described and ecompared using classical diversity measures such as Shannon's diversity index, Simpson's diversity index as a dominance measure, Margalef's richness index and Pielou's evenness index. For comparing strata and seasonal diversity the Renyi's diversity profiles were used. A Cluster Analysis was performed on a Bray-Curtis similarity matrix to explore the faunal relationships among year seasons and strata. CCA was also performed to investigate the relationships between the physicochemical and species abundance matrixes. As results, 28 species (12 Zygoptera and 16 Anisoptera) were recorded as larvae. Most abundant species were *Erpetogomphus elaps*, *Brechmorhoga praecox* and *Phyllogomphoides luisi*. The highest number of species was registered in winter and the lowest in summer. Among strata the highest abundance was recorded in riffles, although the shoreline had the largest number of species. The most similar assemblages were those of autumn and winter. Shore habitats were more heterogeneous than eddies and riffles and this could explain the larger number of species. The Clench's model explains better the data. Additionally, we used the slope of cumulative number of species curve for assessing completeness of the RP list. CCA was significant, with pH, autumn, shoreline and riffles the most important variables. This means that species variation is related to physicochemical, temporal and strata conditions in RP." - 9815.** Gonzalez-Tokman, D.M.; Gonzalez-Santoyo, I.; Lanz-Mendoza, H.; Cordoba Aguilar, A. (2010): Territorial damselflies do not show immunological priming in the wild. *Physiological Entomology* 35(4): 364-372. (in English) ["Adaptive immunity allows vertebrates to gain protection against repeated pathogenic infections. Analogous responses (priming) have been recently uncovered in invertebrates. However, whether such responses are widespread is not known. The present study investigated the presence of immunological priming in males of a species whose phylogenetic position places it in one of the less derived insect orders. It is hypothesized that the efficiency of such a response could be related to animal condition, as assessed by the expression of a sexually selected ornament. *Hetaerina americana* Fabricius (Odonata: Calopterygidae) males bear a conspicuous ornament (a red wing spot), which is evolutionarily maintained via male territorial competition. Using field-collected animals, a group of males is challenged with bacteria before exposure to a higher dose of the same or a different bacteria, and survival is compared with that of infected males not previously challenged, as well as control groups. Gram-positive and Gram-negative bacteria are used. To explore how long priming may take to work, the second exposure is carried out either after 1 or 5 days. Red spot and body size are entered in the analysis as predictors of survival within and between groups. There is no difference in survival among groups, which suggests no priming effect. Overall, red spot and body size are not consistent in explaining survival." - 9819.** Harabiš, F.; Dolný, A. (2010): Ecological factors determining the density-distribution of Central European dragonflies (Odonata). *Eur. J. Entomol.* 107(4): 571-577. (in English) ["Habitat specificity is the most important factor affecting the regional distribution of dragonflies. Nevertheless, species with the highest specificity are not always the scarcest. Several important determinants of dragonfly density-distribution relationships were identified. Altitude preference and altitude range

are significantly associated with dragonfly distribution. Some of the species that are habitat specialists but occur over a wide range of altitudes should be classified as rare but not endangered. This very simple principle is based on the assumption that habitat specialists have a very limited number of suitable biotopes. Obviously, dragonflies with a marginal distribution prefer a narrow range of altitudes (especially in terms of temperature limitation) and biotopes (effect of biogeography, marginality). Surprisingly, there is no "critical" life stage that is significantly associated with the regional distribution of dragonflies, although most species spend most time in the larval stage. Knowledge of the dispersal ability of particular species is limited, although it could significantly affect species survival and distribution." 9821. Hassall, C.; Thompson, D.J. (2010): Accounting for recorder effort in the detection of range shifts from historical data. *Methods in Ecology & Evolution* 1(4): 343-350. (in English) ["1. Climate-induced range shifts have been detected in a large number of plant and animal taxa and a significant portion of these shifts have been found using records collected over a long period of time. However, the absence of standardized collecting procedures in some historical data sets introduces bias and skew into the data which can result in misleading conclusions. A range of different methods has been employed to account for this heterogeneity, but these methods have yet to be compared using a single data set. 2. We tested the accuracy of published methods for accounting for this heterogeneity. An extensive, heterogeneous data base of sightings of Odonata from the United Kingdom was analysed using four published methods to control for uneven recorder effort. For each method, five different range statistics were calculated. The results were compared and tested against changes in temperature over time to select the most accurate method. 3. Significant variation existed between results derived using different methods to account for uneven recorder effort. Range statistics were also shown to exhibit different biases to varying recorder effort, particularly those most commonly used in published studies. 4. A combination of existing methods is recommended to control for temporal variation in recorder effort. This focuses on random resampling of the more heavily recorded time period. A novel range statistic based on a gamma frequency distribution, which avoids the inherent bias of existing statistics, is suggested as a descriptor for range margins. 5. When the most robust methods to control for uneven recorder effort were combined with the most robust range statistics describing the range shift, British Odonata as a group were shown to be tracking isotherms between 1960 and 2005. 6.

Accurate description of past range shifts is essential for correct predictions of future trends and for making decisions concerning conservation priorities. We strongly recommend the use of the best performing methods outlined here to ensure consistency and accuracy in future studies." 9823. Hilling, B. (2010): Beautiful Demoiselle *Calopteryx virgo* resting with wings spread. *Atropos* 41: 57- [Verbatim: "On 17 May 2009 at Swallowfield, along the River Loddon south of Reading, I found a *C. virgo* resting with its wings open. It sat for some 30 minutes in this position, allowing photographs to be taken. Normally, of course, both species of demoiselle occurring in Britain rest with their wings characteristically folded above the body. It was a rather cold, mainly cloudy and occasionally wet day. In the first photographs the tip of one of the wings was obscured by a leaf; hoping to get better pictures I gently blew on the damselfly whereupon it closed its wings. To my great surprise a minute or so later it spread its wings as illustrated here, maintaining this position some further 25 minutes. Only when a very short interlude of sunshine came along did the insect fly."] Address: Hilling, B., 28 Hampton Road, Worcester Park, Surrey, KT4 8ET, UK

9824. Hoffmann, J. (2010): Do climate changes influence dispersal and population dynamics of dragonflies in the western Peruvian Andes? *BioRisk* 5: Special issue: Monitoring climatic change with dragonflies: 47-72. (in English) ["For nine dragonfly species (five aeshnids and four libellulids) all previous and verifiable data are related to the vertical climate zones and nature regions of the western Peruvian Andes and the Peruvian Pacific coast. Climate changes due to the El Niño and La Niña phenomena, as well as the global climate change have an influence on the different natural regions and also restrict aquatic biotopes. These changes influence the dispersal and behavior of some dragonflies and concern also loss of habitats as well as alterations of biotic and abiotic factors at and in water. However new waters and habitats also are formed in most nature regions. Specialists like *Rhionaeschna peralta*, a species of high mountain regions and the Puna, are not able to react to habitat losses by adaptation, while other species such as *R. maita* and *R. marchali* do colonize new habitats also in higher altitudes. While the here represented aeshnids change their distribution ranges within the vertical nature regions of the west Andes, this is suspected for three of the four libellulids (*Orthemis ferruginea*, *O. discolor* and *Pantala flavescens*) as latitudinally respectively longitudinally immigrations and expansions of their areals. For all species discussed, a seasonally earlier flight beginning is detectable, but for no species an extension of their flight time. Altogether, the above named three libellulid do react more flexibly and faster to the alterations by climate changes than the majority of the five aeshnid species. The influence of increased

UV-B and UV-A radiation possibly affects also the site occurrence of some species in high altitudes of the Andes." (Author)] Address: Hoffmann, J., Alauda, Wendenstr. 435, D-20537 Hamburg, Germany. E-mail: hoffmann.joa@t-online.de

9825. Holmes, P. (2010): Seasons' Summary. East Keswick Wildlife Trust Newsletter 35: 2. (in English) [East Keswick, Leeds, West Yorkshire, England. "A notable addition to the species of the Parish is that of *Orthetrum cancellatum*. One was seen on the bridle path down to the river and a group of about 25 were found at a pond on land owned by David Cook (permission had been given). This dragonfly is unusual in that it prefers bare ground on which to perch rather than prominent branches and twigs. Their usual range is south of The Wash with scattered populations up to the Humber so our sightings have confirmed its expansion northwards. Other species seen were Southern Hawker, a few of which were emerging from the Hirsts' garden pond, Emperor Dragonfly, Brown Hawker, 4-spot Chaser, Blue-tailed Damselfly, Common Blue and Azure Damselfly. During the day of the survey we did not visit Ox Close so did not see the Banded Demoiselles which had made their usual spectacular appearance." (Author)] Address: E-mail: paul@ox-close.co.uk

9826. Holomuzki, J.R.; Klarer, D.M. (2010): Invasive reed effects on benthic community structure in Lake Erie coastal marshes. *Wetlands Ecol. Manage.* 18: 219-231. (in English) ["We examined how dominance (% canopy cover) and invasion history of common reed, *Phragmites australis*, affected benthic macroinvertebrate diversity and density in 8 marshes along Lake Erie's southern shoreline. We also compared macroinvertebrate densities among patches (0.25 m²) of reed, cattail (*Typha* spp.), and native flora (e.g., *Sagittaria*, *Sparganium*) and epiphytic algal communities on submerged stems of reed and cattail. Narrow-leaf cattail (*T. angustifolia*) is also a common invasive plant to these wetlands, but does not greatly change plant community composition or ecosystem conditions like reed. Macroinvertebrate diversity (Shannon-Weaver H₀) was positively related to reed cover and was highest (4.6) in two marshes with *35- and 5-year invasion histories. Shading from high reed cover increased H₀-diversity, in part, by reducing the abundance of floating duckweed, which harboured many *Hyalella azteca* amphipods. Percent Ephemeroptera, Odonata, and Trichoptera was low to moderate across marshes, regardless of reed cover and invasion history. Macroinvertebrate density was not affected by reed cover or average plant stem density, and did not differ among plant types. However, epiphyton densities and % diatoms were greater on reed than on cattail, suggesting reed provides a better feeding habitat for microalgal grazers than *Typha*. Abundance rankings of common species in these diatom-dominated communities were also typically dissimilar between these plant types. Although % grazers was unrelated to epiphyton densities and % diatoms, grazer identity (snails) differed between natural and diked marshes, which had different microalgal food supplies. Our findings suggest that *Phragmites* does not necessarily adversely affect macroinvertebrate community structure and diversity and that invasion history alone has little effect on the H₀-diversity–reed dominance relationship." (Authors) Dominant odonates were *Anax junius*, *Drury*, *Ischnura verticalis*, and *I. posita*.] Address: Holomuzki, J.R., Department of Evolution, Ecol-

ogy, and Organismal Biology, Ohio State University, 1760 University Drive, Mansfield, OH 44906, USA. E-mail: holomuzki.3@osu.edu

9827. Huang, D.-Y.; Petrulevicius, J.F.; Nel, A. (2010): New morphological data from the Jurassic of Inner Mongolia confirms the damselfly aspect of *Protomyrmeleontidae* (Insecta: Odonatoptera). *Eur. J. Entomol.* 107(4): 615-620. (in English) ["*Protomyrmeleon daohugouensis* sp. n. and *Protomyrmeleon lini* sp. n., two new species of *Protomyrmeleontidae* from the Middle Jurassic of Jiulongshan Formation are the first Chinese representatives of this Mesozoic odonatopteran family. The type specimen of *P. lini* is exceptionally well preserved, showing several particular wing and body structures that were unknown, viz. unique shape of tarsal claws, extreme thoracic skewness, presence of three pairs of long spurs on all femora and tibiae. The type "A" (sensu Nel et al., 2005) of wing venation (i.e. with a very long bridge between IR₂ and RP_{3/4}) corresponds to that of the *protomyrmeleontid* fore wing. The nearly complete absence of the meso-metathoracic interpleural suture, newly discovered in the *Protomyrmeleontidae*, can be considered as a synapomorphy of the clade *Protozygoptera* + *Odonata*." 9828. Hunt, R.J.; Swift, M.C. (2010): Predation by larval damselflies on cladocerans. *Journal of Freshwater Ecology* 25(3): 345-351. (in English) ["We quantified the strike and capture efficiency, handling time, and functional response of *Enallagma hageni* and *Ischnura verticalis* larvae feeding on several sizes of the cladocerans *Polyphemus pediculus*, *Daphnia pulex*, and *Holopedium gibberum*. Both species were most efficient at capturing and ingesting *P. pediculus*, the smallest and most vulnerable prey, followed by *D. pulex*, a larger, faster prey. *H. gibberum* was rarely eaten due to a protective gelatinous sheath. The handling time was shortest for *P. pediculus* and longest for *D. pulex* due to a combination of size and carapace protection. Both damselfly species exhibited a Type II functional response with a maximum of 20-30 prey eaten per hour. Both *E. hageni* and *I. verticalis* larvae are efficient predators that selectively capture *P. pediculus* and small *D. pulex*; they avoid *H. gibberum*. Due to this differential predation, these larvae may substantially alter zooplankton community composition." 9832. Johnson, P.T.; Bowerman, J. (2010): Do predators cause frog deformities? The need for an eco-epidemiological approach. *Journal of Experimental Zoology Part B: Molecular and Developmental Evolution* 314B(7): 515-518. (in English) ["Renewed controversy has emerged over the likely causes and consequences of deformed amphibians, particularly those with missing limbs. The results of a series of experiments by Balengée and Sessions (2009) implicate aquatic predators (i.e. dragonfly larvae) in causing such abnormalities. Skelly and Benard (2010), however, argued that the small scale of these experiments and the absence of a correlation between predator abundance and deformity frequencies in natural amphibian populations undermine such a conclusion. Drawing upon our experiences with frog malformations, we suggest that the study of amphibian deformities has been hindered by two, inter-related problems. First, empirical studies often fail to critically define the expected baseline level of abnormalities and differentiate between "epidemic" and "endemic" frequencies of malformations. Second, recognizing the likelihood of multiple causes in driving amphibian malformations, continued research needs to embrace a "multiple lines of evidence" approach that allows for complex ethologies by integrating field surveys, diagnostic pathology, comparative modelling, and experiments across a range of ecological scales. We conclude by highlighting the results of a recent study that uses this approach to identify the role of aquatic predators (i.e., fishes and dragonflies) in causing high frequencies of deformed frogs in Oregon. By combining long-term data, comparative data and mechanistic experiments, this study provides compelling evidence that certain predators do cause deformities under ecologically relevant conditions. In light of continuing concerns about amphibian deformities and population declines, we emphasize the need to integrate ecological, epidemiological, and developmental tools in addressing such environmental enigmas." 9833. Juutinen, R. (ed.) (2010): Restoration decision-making in boreal spring complexes – an assessment of insect fauna and summary of the whole project. *Metsähallituksen luonnonsuojelujulkaisu*. Sarja A 193: 133 pp. (in Finnish, with Swedish and English summaries) ["Restoration of springs has been evoked as a tool for enhancing the natural state of disturbed springs. However, preliminary vegetation mapping as well as research and monitoring concerning restoration of springs has thus far been scarce. At 2008 Metsähallitus Natural Heritage Services launched a pilot project aiming to as-

sess the flora and fauna, natural state and restoration needs of 30 spring complexes. This publication presents the results for insect fauna and recommendations for restoration. In the first part of this publication it is assessed whether the natural state of a spring complex affects the overall abundance of individuals, species diversity, community structure and conservation value based on adult aquatic insects and/or semiaquatic flies. In addition, the chosen response variables are compared between aquatic insects and semiaquatic flies. Naturalness was not found to be among the most important factors affecting the overall abundance of individuals, species diversity, community structure and conservation value based on adult aquatic insects and/or semiaquatic flies. The spring complexes with highest conservation value were partially different, when based on aquatic insects or semiaquatic flies. The most important conclusion concerning restoration decision-making is that even seriously disturbed spring complexes can harbour valuable, endangered species. And, on the other hand, pristine spring complexes can be species-poor and harbour no taxa with high conservation value. In the second part, restoration needs and possibilities of the studied spring complexes based on flora and fauna, and other field data and subsequent analyses are assessed for each study site. Sites are presented in detail with maps and factors affecting restoration are discussed. Also, the required conservation measures concerning endangered or otherwise valuable species are stated. One aim of this project was to make possible a thorough and scientific monitoring of restoration success. Methods used are documented in detail and planned so that they can be accurately repeated. Species surveys conducted in 2008 thus serve as a baseline survey before restoration." (Author) *Coenagrion hastulatum*, *C. johanssoni*, *C. lunulatum*, and *Leucorrhinia dubia* were sampled at very few localities and in very small abundances.] Address: Juutinen, R., Metsähallitus, luontopalvelut, Finland. 9838. Kita, H. (2010): Charm of dragonflies. *Japic News* 313: 8-9. (in Japanese) [Verbatim: "Now the season of fresh green is coming. I like it so much. The season is also the one for rice sprouts and for rice planting. And in the season we see various insects in neighbouring nature, ponds and streams. Among them dragonflies are popular insects and here I will tell you about them. I have been engaged in public information in a pharmaceutical company. My job is to publicize charmingly correct and useful information to people. And I am very pleased if I can tell you a charm of dragonflies. I am a member of The Japanese Society for Odonatology, and have been studying the ecology of dragonflies, traveling from the north, Hokkaido, to the south of Iriomote Island or the Ogasawara Islands, almost all over Japan for taking photographs of them in nature. Japan is a long and narrow mountainous island, however, it is rich in water, and about 200 odonatas inhabit it. At Shiretoko I chased species of cool region being frightened of bears, and landed on a desert island of Ogasawara in a small boat and photographed an indigenous species there. As mentioned above, I am continuing travel for dragonflies besides working in a pharmaceutical company. It may be my life work. What makes me so much be interested in dragonflies? I think it is the

flight of them. The dragonfly is an insect with excellent flight ability. In Japan tomo is derived from "tobu bou", "tobu": to fly, and "bou": a stick that is a flying stick. Most of the life of dragonflies, though it varies by the species, is occupied by flight behaviour. Some dragonflies fly at a flight speed of more than 100 km/h, and they can catch preys in the air as well as they can fly so far a distance, and can copulate and lay eggs in the air and can hover or can turn a somersault so skillfully. The present day aerodynamics is not a match for their flight technique. The secret is due to the mechanism of the flight muscles and the wings. They have four thoracic muscles with each wings directly attached to it, and they can move them separately, different from other insects, therefore, they can fly straight without up and down movement like butterflies. Also the beautiful water habitat of them is attractive. In this season I am relieved with a sound of streams in neighbouring nature, and when a dragonfly will appear at such a scene, it will be much more the best. Thus, I cannot tell you all of the charms of dragonflies. Photographing dragonflies is my pleasure and expression of the charm of them. In my boyhood, I used reflex cameras with micro-lenses. But now, digital cameras became widespread. If you want to take ecological photos of dragonflies, you are required to use a digital reflex camera with a few conversion lenses of a micro 100 mm a wide lens, a fish-eye lens and a stroboscope. These apparatuses made us everybody enjoy readily insect photographing now. Since ancient times of Emperor "Jinmu" our land was called "Akitsu-shima". Akitsu is an old name of dragonfly, and its origin is when Emperor Jinmu looked out over the land from the hill of Asuka, it resembled the shape of copulation by dragonflies, or a lot of swarms of dragonflies were seen. Also, according to Kojiki, when Emperor Yuryaku visited Yoshino for hunting, a horsefly stung his arm, a dragonfly caught it and preyed. Then, he praised the dragonfly so much, and thereafter, dragonflies were called "kachi-mushi"; insect of victory, and became a representative of lucky insects. Dragonflies have been used for one of old wife's remedy, effects of whooping cough, tonsillitis and asthma. Kuro-yaki, char, and decoction are said to be useful for the effects. The species for it is said to be aka-tombo, *Sympetrum* species. Dr. Ogata, Akira, former president of The Pharmaceutical Society of Japan had investigated whether kuro-yaki of aka-tombo included the effect of sedation or not. He roasted aka-tombo at temperatures 200-300 degrees C for 34 hours, and then, after extraction by alcohol, he refined it, which had an effect of sedating the cramp of the muscle of the bronchi. He noticed that old wife's remedy was effective. Also, dried *Orthetrum* species seems to have been used for a tonic in Taiwan and China. Moreover, we might have used dragonflies for food according to a survey in the Taisho era (1910's). We ate insects such as locusts and larvae of wasps from long time ago, so dragonflies might have been an important source of protein. When people of ancient times saw aka-tombo flying in tandem over the rice paddies in the harvest time of autumn, they might have felt as if the aka-tombo delivered the harvest to them. Dragonflies were very familiar insects for us from ancient times. I hear the most popular children's song is "Aka-tombo" and the important and typical scenery of Japan for us seems to be aka-tombo perching on the harvested ears of rice. However, recently it is often said that dragonflies decreased. Now water environment was contaminated and beautiful water edges are being lost by exploitation here and there in Japan. Larvae of

dragonflies are underwater dwellers, and when the suitable water environment is lost, they cannot live. I experienced often that nice habitats were lost in a few years. The extremely decreasing of dragonflies may be largely due to the change of water environment. It is doubtful whether we can live in such an environment or not, where dragonflies cannot live as well as such scenery as that relieve us is lost. Dragonflies and nature seem to warn us." (Translation: Naoya Ishizawa)] Address: Kita, H., Takiyama 6-2-15-308, Higashikunime City, Tokyo, 203-0033, Japan.

9846. Langheinrich, U.; Braumann, F.; Lüderitz, V. (2010): Niedermoor- und Gewässerrenaturierung im Naturpark Drömling (Sachsen-Anhalt). *Waldökologie, Landschaftsforschung und Naturschutz* 10: 23-29. (in German, with English summary) [oas 30, "The Drömling Natural Park is the largest fen area in Central Germany. The management and development plan defines the re-wetting of fens, the preservation and development of extensively used wetlands and the improvement of the ecological status of water bodies as the main aims. In 11 areas, re-wetting already started or will start in the near future. Habitat quality of canals and ditches was enhanced by building shallow water zones and careful management. Function of canals and ditches changes stepwise from drainage to irrigation. Furthermore, new shallow ponds were created. This contribution presents examples for implementation of measures and first results of scientific evaluation. All the measures help to maintain and enhance aquatic and amphibic biodiversity and conservation value. A high total number of species correlates well with the occurrence of endangered species. 50 of such Red Lists species (including 14 Odonata species) were found among aquatic macroinvertebrates and 20 among aquatic macrophytes. These values are above average compared to other fens in Germany. However, the maintenance of diverse landscape and water body structure demands high management efforts. A rising problem for native diversity is the appearance of invasive neozoons." 9847. Leipelt, K.G.; Suhling, F.; Gorb, S.N. (2010): Ontogenetic shifts in functional morphology of dragonfly legs (Odonata: Anisoptera). *Zoology* 113: 317-325. (in English) ["Anisopteran leg functions change dramatically from the final larval stadium to the adult. Larvae use legs mainly for locomotion, walking, climbing, clinging, or burrowing. Adults use them for foraging and grasping mates, for perching, clinging to the vegetation, and for repelling rivals. In order to estimate the ontogenetic shift in the leg construction from the larva to the adult, this study quantitatively compared lengths of fore, mid, and hind legs and the relationships between three leg segments, femur, tibia, and tarsus, in larval and adult Anisoptera of the families Gomphidae, Aeshnidae, Cor-

dulegastridae, Corduliidae, and Libellulidae, represented by two species each (*Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Cordulegaster insignis*, *C. picta*, *Orthetrum cancellatum*, *Sympetrum sanguineum*, *Cordulia aenea*, *Somatochlora metallica*, *Aeshna cyanea*, and *Anax imperator*). We found that leg segment length ratio as well as ontogenetic shift in length ratios was different between families, but rather similar within the families. While little ontogenetic shift occurred in Aeshnidae, there were some modifications in Corduliidae and Libellulidae. The severest shift occurred in Gomphidae and Cordulegastridae, both having burrowing larvae. These two families form a cluster, which is in contrast to their taxonomic relationship within the Anisoptera. Cluster analysis implies that the function of larval legs is primarily responsible for grouping, whereas adult behavior or the taxonomic relationships do not explain the grouping. This result supports the previous hypothesis about the convergent functional shift of leg characters in the dragonfly ontogenesis." (Authors)] Address: Suhling F., Inst. Geoökologie, TU Braunschweig, Langer Kamp 19c, D-38102 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

9848. Lentink, D.; Jongerius, S.R.; Bradshaw, N.L. (2010): Chapter 14: The scalable design of Flapping Micro-Air Vehicles inspired by insect flight. In: D. Floreano, Zufferey, J.-C.; Srinivasan, M.V.; Ellington, C. (Eds.): *Flying Insects and Robots*. Springer-Verlag Berlin Heidelberg. 1st Edition. 2010, XII, 316 pp. ISBN: 978-3-540-89392-9: 185-205. (in English) ["Here we explain how flapping micro air vehicles (MAVs) can be designed at different scales, from bird to insect size. The common believe is that micro fixed wing airplanes and helicopters outperform MAVs at bird scale, but become inferior to flapping MAVs at the scale of insects as small as fruit flies. Here we present our experience with designing and building micro flapping air vehicles that can fly both fast and slow, hover, and take-off and land vertically, and we present the scaling laws and structural wing designs to miniaturize these designs to insect size. Next we compare flapping, spinning and translating wing performance to determine which wing motion results in the highest aerodynamic performance at the scale of hummingbirds, house flies and fruit flies. Based on this comparison of hovering performance, and our experience with our flapping MAV, we find that flapping MAVs are fundamentally much less energy efficient than helicopters, even at the scale of a fruit fly with a wing span of 5 mm. We find that insect-sized MAVs are most energy effective when propelled by spinning wings. [...] We used dragonfly wings (*Sympetrum vulgatum*) as an inspiration to develop design principles for such stiffer micro-wings with venation-like tear-stoppers." 9849. Lin, C.-P.; Chen, M.-Y.; Huang, J.-P. (2010): The complete mitochondrial genome and phylogenomics of a damselfly, *Euphaea formosa* support a basal Odonata within the Pterygota. *Gene* 468(1-2): 20-29. (in English) ["This study determined the first complete mitochondrial genome of a damselfly, *Euphaea formosa* (Insecta: Odonata: Zygoptera), and reconstructed a phylogeny based on thirteen protein-coding genes of mitochondrial genomes in twenty-five representative hexapods to ex-

amine the relationships among the basal Pterygota. The damselfly's mitochondrial genome is a circular molecule of 15,700 bp long, and contains the entire set of thirty-seven genes typically found in insects. The gene arrangement, nucleotide composition, and codon usage pattern of the mitochondrial genome are similar across the three odonate species, suggesting a conserved genome evolution within the Odonata. The presence of the intergenic spacer s5 likely represents a synapomorphy for the dragonflies (Anisoptera). Maximum parsimony, maximum likelihood, and Bayesian analyses of both nucleotide and amino acid sequences cannot support the three existing phylogenetic hypotheses of the basal Pterygota (Palaeoptera, Metapterygota, and Chistomyaria). In contrast, the phylogenetic results indicate an alternative hypothesis of a strongly supported basal Odonata and a sister relationship of the Ephemeroptera and Plecoptera. The unexpected sister Ephemeroptera + Plecoptera clade, which contradicts with the widely accepted hypothesis of a monophyletic Neoptera, requires further analyses with additional mitochondrial genome sampling at the base of the Neoptera." 9850. Locklin, J.L. (2010): Gregarine parasitism in dragonfly populations of Central Texas with an assessment of fitness costs in *Erythemis simplicicollis*. Ph.D. thesis, Dept. of Biology, Baylor University: XI, 88 pp. (in English) ["Dragonfly parasites are widespread and frequently include gregarines (Phylum Apicomplexa) in the gut of the host. Gregarines are ubiquitous protozoan parasites that infect arthropods worldwide. More than 1,600 gregarine species have been described, but only a small percentage of invertebrates have been surveyed for these apicomplexan parasites. Some consider gregarines rather harmless, but recent studies suggest otherwise. Odonate-gregarine studies have more commonly involved damselflies, and some have considered gregarines to rarely infect dragonflies. In this study, dragonfly populations were surveyed for gregarines and an assessment of fitness costs was made in a common and widespread host species, *Erythemis simplicicollis*. Adult dragonfly populations were surveyed weekly at two reservoirs in close proximity to one another and at a flow-through wetland system. Gregarine prevalences and intensities were compared within host populations between genders, among locations, among wing loads, and through time. Host fitness parameters measured included wing load, egg size, clutch size, and total egg count. Of the 37 dragonfly species surveyed, 14 species (38%) hosted gregarines. Thirteen of those species were previously unreported as hosts. Gregarine prevalences ranged from 2% – 52%. Intensities ranged from 1 – 201. Parasites were aggregated among their hosts. Gregarines were found only in individuals exceeding a minimum wing load, indicating that gregarines are likely not transferred from the naiaid to adult during emergence. Prevalence and intensity exhibited strong seasonality during both years at one of the reservoirs, but no seasonal trend was detected at the wetland. The seasonal trend at the reservoir suggests that gregarine oocyst viability parallels increasing host population densities and may be short-lived. Prevalence and intensity also differed between dragonfly populations at the locations. Regression analyses revealed that host species, host gender, month, and year were significant explanatory variables related to grega-

rine prevalence and intensity. The fitness parameters measured were not correlated with presence or intensity of gregarines, suggesting that either gregarines do not affect wing loading and egg production in *E. simplicicollis*, or that virulence depends on parasite intensity and/or the specific gregarine species infecting the hosts. Our results emphasize the importance of considering season, hosts, and habitat when studying gregarine-dragonfly ecology." 9851. Locklin, J.L.; Vodopich, D.S. (2010): Eugregarine parasitism of *Erythemis simplicicollis* (Say) at a constructed wetland: A fitness cost to females? (Anisoptera: Libellulidae). *Odonatologica* 39(4): 319-331. (in English) ["Eugregarine parasites infect a wide variety of invertebrates. Some authors suggest that eugregarines are rather harmless, but recent studies suggest otherwise. Among odonate-eugregarine investigations, Zygoptera have been more frequently studied than Anisoptera. Adult dragonfly populations were surveyed for eugregarines at a constructed, flow-through wetland system and the fitness cost of infection was assessed in a common and widespread dragonfly host species, *E. simplicicollis*. Populations were sampled weekly throughout the flight season. Host fitness parameters measured included wing load, egg size, clutch size, and total egg count. Of the 22 host species surveyed, 8 hosted eugregarines and 2 of these odonate species were previously undocumented as hosts. While eugregarine parasitism has been shown to exhibit seasonality, parasite prevalence and intensity in *E. simplicicollis* in this study showed no seasonal trend. The fitness parameters measured were not correlated with the presence or intensity of eugregarines. These findings suggest that either eugregarines do not affect wing loading and egg production in *E. simplicicollis*, or that virulence depends on parasite intensity and/or the specific eugregarine species infecting the hosts." 9852. Mabry, C.; Dettman, C. (2010): Odonata richness and abundance in relation to vegetation structure in restored and native wetlands of the prairie pothole region, USA. *Ecological Restoration* 28(4): 475-484. (in English) ["Over the past couple of decades, 2,200,000 ha of wetlands and grasslands have been restored in the prairie pothole region, USA. However, many restored and remnant wetlands in the region are dominated by two invasive plant species, reed canary grass (*Phalaris arundinacea*) and cattail (*Typha* spp.), which form dense monotypic stands. These restorations are usually evaluated as habitat for waterfowl and other birds; however, there is a need to evaluate their success for invertebrates. Odonata are ideal organisms to include in our evaluations of restored wetland habitat quality for both ecological and practical reasons. To examine the association between vegetation structure and odonate assemblages in shoreline vegetation of prairie pothole wetlands, we compared odonate richness and abundance in dense, monotypic stands to that of vegetation with diverse vertical structure. We also observed the use of these two different habitats by odonate species classified as "of conservation concern" in Iowa. Odonate species richness was substantially greater in the mixed-structure vegetation than in monotypic

stands. A similar trend was found in odonate species with a "vulnerable" or "uncommon" conservation status. The number of occurrences of species of conservation concern was four times greater in mixed than in monotypic vegetation. A comparison of our data to those collected in the 1990s for one monotypic vegetation site further supported this conclusion. Many odonate species are targets for conservation and can readily benefit from wetland restoration and reconstruction if the sites are managed for proper vegetation structure." 9854. Mäkinen, J. (2010): Kirja-arvostelu: Sami Karjalainen - Suomen sudenkorennot [Review of new edition of Suomen sudenkorennot (The Dragonflies of Finland) by Sami Karjalainen]. *Crenata* 3(1): 40. (in Finnish) [The publication of the first edition of Suomen sudenkorennot in 2002 raised the interest in dragonflies in Finland enormously. Finnish Dragonfly Society was founded few years later. There are a number of reasons why the publication of new edition is important. The book has been sold out for many years and no other Finnish guides are available. After the publication of the first edition significant changes in Finnish fauna and distribution areas of many species have happened. Also maps and flight charts are updated with new information. The new edition includes 92 new photos and 17 pages more than the first edition. Thirteen species from neighbouring areas are also presented in the book, including all Scandinavian species. All of them are presented with Finnish (vernacular) names for the first time. (Asmus Schröter)] Address: Mäkinen, J. E-mail: makisenjussi@gmail.com

9855. Mäkinen, J. (2010): Sudenkorennoille oma suojelualue [A nature reservation area for dragonflies]. *Crenata* 3(1): 38-39. (in Finnish) ["Finnish Dragonfly Society has started a project, which aims for a nature reservation area for dragonflies. Fundraising has already begun. When enough money has been collected, a bog with a good dragonfly fauna will be bought and then protected." (Asmus Schröter)] Address: Mäkinen, J. E-mail: makisenjussi@gmail.com

9856. Mäkinen, J.; Koskinen, J.; Tuohimaa, J. (2010): Sudenkorentokatsaus 2009 [Dragonfly review 2009]. *Crenata* 3(1): 8-33. (in Finnish with English summary) ["This article presents the most interesting dragonfly records from Finland in 2009. For each observed species the following information is presented: first and last records of the summer, greatest sums and northernmost records. Seven new provincial records were made: *Coenagrion lunulatum* was found for the first time in Keski-Pohjanmaa, *Aeshna crenata* in Pohjois-Savo, *Aeshna viridis* and *Orthetrum coerulescens* in

Uusimaa, *Orthetrum cancellatum* in Pohjois-Karjala and *Leucorrhinia albifrons* in Pohjois-Pohjanmaa. A map of Finnish biogeographical provinces is shown in the end of the article. Table 1 presents the total number of records of each species, as well as their rankings between 2007 and 2009. Most of the records for this article were gathered from Hatikka database (www.hatikka.fi). The records were made by 104 observers. Their names (abbreviations are used for the members of the Finnish Dragonfly Society) are presented in the end of the article." (Authors)] Address: Mäkinen, J. E-mail: makisenjussi@gmail.com

9857. Magoba, R.N.; Samways, M.J. (2010): Recovery of benthic macroinvertebrate and adult dragonfly assemblages in response to large scale removal of riparian invasive alien trees. *Journal of Insect Conservation* 14(6): 627-636. (in English) ["Invasive alien organisms can impact adversely on indigenous biodiversity, while riparian invasive alien trees (IATs), through shading of the habitat, can be a key threat to stream invertebrates. We ask here whether stream fauna can recover when the key threat of riparian IATs is removed. Specifically, we address whether IAT invasion, and subsequent IAT removal, changes benthic macroinvertebrate and adult dragonfly assemblages, for the worse or for the better respectively. Natural riparian zones were controls. There were statistically significant differences between stream reaches with natural, IAT-infested and IAT-cleared riparian vegetation types, based on several metrics: immature macroinvertebrate taxon richness, average score per macroinvertebrate taxon (ASPT), a macroinvertebrate subset (Ephemeroptera, Plecoptera, Trichoptera and Odonata larvae; EPTO), and adult dragonfly species richness. Reaches with natural vegetation, or cleared of IATs, supported greater relative diversity of macroinvertebrates than reaches shaded by dense IATs. Greatest macroinvertebrate ASPT and EPTO were in reaches bordered by natural vegetation and those bordered by vegetation cleared of IATs, and the lowest where the riparian corridor was IATs. Highest number of adult dragonflies species was along streams cleared of dense IATs. Overall, results showed that removal of a highly invasive, dense canopy of alien trees enables recovery of aquatic biodiversity. As benthic macroinvertebrate scores and adult dragonfly species richness are correlated and additive, their combined use is recommended for river condition assessments." 9858. Maltchik, L.; Stenert, C.; Bender Kotzian, C.; Marques Pires, M. (2010): Responses of odonate communities to environmental factors in southern Brazil wetlands. *Journal of the Kansas Entomological Society* 83(3): 208-220. (in English, with Portuguese summary) ["Odonate larvae play an important role in wetland systems, providing food for many fish species and birds. Besides, they are important predators in these ecosystems. However, studies of factors that determine odonate species richness and distribution in wetlands are scarce in the Neotropical region. The objectives of this study were to: 1) conduct a survey of the diversity of odonate larvae in southern Brazil wetlands, and 2) determine how much variation in odonate richness, abundance and composition is explained by wetland area, altitude, water conductivity and nitrate, hydroperiod, and dominant aquatic vegetation in 140 wetlands in

an extensive area of the Neotropical region (280,000 km², southern Brazil). A total of 4,039 individuals distributed among five families and 28 genera were collected. Libellulidae, Coenagrionidae and Aeshnidae were the families that showed the greatest richness. *Erythrodiplax* was observed in more than 70% of the sampled wetlands, and comprised 61% of individuals collected. Richness was negatively associated with wetland area and nitrate concentration. Odonate abundance was negatively associated with water conductivity and nitrate, and it was higher in aquatic beds than in emergent wetlands. Richness and abundance were higher in permanent than in intermittent wetlands. Variation in odonate composition was correlated with wetland altitude, area and water conductivity. Hydroperiod and dominant aquatic vegetation also influenced composition. Our results showed that southern Brazil wetlands are important habitats for 28 odonate genera, and that richness, abundance and composition are influenced mainly by hydroperiod, nitrate, and aquatic vegetation type. These results should be seen as important to determine the environmental factors that shape and maintain odonate diversity in southern Brazil wetlands." 9859. Marrocco, J.; Demasi, L.; Venkataraman, S. (2010): Investigating the structural dynamics implication of flexible resilin joints on dragonfly wings. San Diego State University Access proceedings 10-09: 6 pp. (in English) ["The practical application of relatively small, light weight micro air vehicles by biomimicry is of great interest to the engineering community. The goal of this research project is to improve the understanding of the structural construction of insect wings. A dragonfly insect has been chosen, as it has a very revealing structure and is an insect that has unique flight capabilities. Dragonfly wings are able to withstand the forces imposed upon them by the surrounding air, inertial forces caused by acceleration and decelerating their own weight. The basic design of a dragonfly wing is a pleated membrane stiffened by tubes at the apexes of the pleats, forming a particularly rigid and strong structure. This tubular pleated membrane provides a stiff structure along the length (span wise) direction of the wing and a flexible structure along the width (chord wise direction) of the wing. The tailoring flexibility in the wing is essential as it can play significant role in the aerodynamics wing airfoil shape it can achieve, in addition to the benefits of gust alleviations, and damage tolerance. The investigation into the material composition and architecture on the dragon fly wings revealed that while a large part of the wing structure is made of chitin protein, there is a regular pattern of joints on the wing made of less stiffer resilin protein. The focus of this effort is to understand the effect and implications of the resilin joints on the structural dynamics of the wing. To achieve this goal a finite element structural analysis tool has been used and a detailed model of the dragonfly wing was created. Main focus of the present analysis is to understand how the presence of flexible resin joints affects the natural vibration and mode shapes of the dragonfly wing." 9860. Martens, A.; Hazevoet, C.J. (2010): Dragonflies (Insecta, Odonata) of São Vicente, Cape Verde Islands: 10 species on a desert island. *Zoologia Caboverdiana* 1 (2): 112-115. (in English) [Records of the following species are documented and briefly discussed: *Lestes pallidus*, *Ischnura senegalensis*, *Anax ephippiger*, *A. imperator*, *Crocothemis erythraea*, *Orthetrum trinacria*, *Pantala flavescens*, *Sympetrum fonscolombii*, *Tramea limbata*, *Trithemis annulata*, and *Zygonyx torridus*.] Address: Hazevoet, C.J., Instituto de Investigação Científica Tropical - Jardim Botânico Tropical, Unidade de Zoologia, Rua da Junqueira 14, 1300-343 Lisboa, Portugal

9861. Martens, A. (2010): Ecology of the dragonflies at the westernmost spot of Africa, the island of Santo Antão, Cape Verde (Odonata). *International Journal of Odonatology* 13(2): 241-254, pl. IVa. (in English) ["From 12 to 25 August 2009, the odonate fauna of Santo Antão, Cape Verde was surveyed by recording adults and collecting larvae and exuviae at 26 localities, mostly situated in the northwest of the island. Based on the results of this survey and literature data on the Cape Verde it appears that the resident odonate fauna consists of only five species, namely *Anax imperator*, *Crocothemis erythraea*, *Orthetrum trinacria*, *Trithemis annulata* and *Zygonyx torridus*. Three additional species, *Anax ephippiger* and *Pantala flavescens*, which were recorded as single adults in this study, and *Sympetrum fonscolombii*, which was previously recorded in another study, represent seasonal invaders that do not establish permanent populations on the island. Surprisingly, there is no zygopteran species recorded from the island, although a few occur on the neighbouring islands. The breeding habitats of the resident odonates on the island comprise short perennial stream sections in large wadi beds ('ribeiras') that are intensely used for agriculture, as well as artificial irrigation tanks. The odonate assemblage is very uniform, although *Z. torridus* prefers micro-habitats with flowing water and *O. trinacria* is found only in micro-habitats with fine sediments. In the absence of fish, crabs and large water beetles, the larva of *A. imperator* appears to be the top predator in freshwater habitats." 9862. Matthews, J. (2010): Anthropogenic climate change impacts on ponds: a thermal mass perspective. *BioRisk* 5: Special issue: Monitoring climatic change with dragonflies: 193-209. (in English) ["Small freshwater aquatic lentic systems (lakes and ponds) are sensitive to anthropogenic climate change through shifts in ambient air temperatures and patterns of precipitation. Shifts in air temperatures will influence lentic water temperatures through convection and by changing evaporation rates. Shifts in the timing, amount, and intensity of precipitation will alter the thermal mass of lentic systems even in the absence of detectable ambient air temperature changes. These effects are likely to be strongest in ponds (standing water bodies primarily mixed by temperature changes than by wind), for whom precipitation makes up a large component of inflows. Although historical water temperature datasets are patchy for lentic systems, thermal mass effects are likely to outweigh impacts from ambient air temperatures in

most locations and may show considerable independence from those trends. Thermal mass-induced changes in water temperature will thereby alter a variety of population- and community-level processes in aquatic macroinvertebrates." 9863. Mauersberger, R. (2010): *Leucorrhinia pectoralis* can coexist with fish (Odonata: Libellulidae). *International Journal of Odonatology* 13(2): 193-204. (in English) ["The Palearctic libellulid *Leucorrhinia pectoralis* is generally considered to be a species inhabiting fish-free water bodies. Yet, a long-term monitoring study of 38 water bodies in NE Germany resulted in 16 species of fish being recorded in reproductive habitats of *L. pectoralis*, with *Rutilus rutilus* and *Carassius carassius* as the most numerous and widespread fish species. Only 14 water bodies were certainly or probably without fish. The seasonal numbers of exuviae of *L. pectoralis* at the water bodies ranged between 0.1 and 136 per 10 m of bank section. The abundance of *L. pectoralis* was higher in fish-free water bodies (an average of 28.0 exuviae/10 m) than in fish-inhabited waters (1.7 exuviae/10 m). The emergence success of *L. pectoralis* depended on the density and species composition of the fish. If only one non-piscivorous fish species (*Carassius carassius*, *Tinca tinca*) was present at low density, the abundance of exuviae averaged 6.5/10 m. In water bodies containing a multispecies fish fauna that included piscivorous species, combined with high fish density only 0.7 exuviae/10 m were found on average. At localities where the fish fauna was dominated by *Perca fluviatilis* virtually no emergence of *L. pectoralis* occurred." 9866. Mbabazi, D.; Makanga, B.; Orach-Meza, F.; Hecky, R.E.; Baliwa, J.S.; Ogutu-Ohwayo, R.; Verburg, P.; Chapman, L.; Muhumuza, E. (2010): Intra-lake stable isotope ratio variation in selected fish species and their possible carbon sources in Lake Kyoga (Uganda): implications for aquatic food web studies. *African Journal of Ecology* 48(3): 667-675. (in English, with French summary) ["The stable isotopes of nitrogen ($\delta^{15}\text{N}$) and

carbon ($\delta^{13}\text{C}$) provide powerful tools for quantifying trophic relationships and carbon flow to consumers in food webs; however, the isotopic signatures of organisms vary within a lake. Assessment of carbon and nitrogen isotopic signatures in a suite of plants, invertebrates, and fishes in Lake Kyoga, indicated significant variation between two sites for $\delta^{13}\text{C}$ (paired $t = 6.305$; $df = 14$, $P < 0.001$ and $\delta^{15}\text{N}$ paired $t = 1.292$; $df = 14$; $P < 0.05$). The fish fauna in Bukungu was generally more $\delta^{13}\text{C}$ enriched (mean $\delta^{13}\text{C} = -16.37 \pm 1.64\text{‰}$) than in Iyingo (mean $\delta^{13}\text{C} = -20.80 \pm 2.41\text{‰}$) but more $\delta^{15}\text{N}$ depleted (mean $\delta^{15}\text{N} = 5.57 \pm 0.71\text{‰}$) than in Iyingo (mean $\delta^{15}\text{N} = 6.92 \pm 0.83\text{‰}$). The simultaneous shifts in phytoplankton and consumer signatures confirmed phytoplankton as the major source of carbon for the food chain leading to fish. Limited sampling coverage within lakes may affect lake wide stable isotope signatures, and the same error is transferred into trophic position estimation. Consideration of potential intra-lake spatial variability in isotope ratios and size is essential in evaluating the spatial and trophic structure of fish assemblages." 9870. Monroe, E.M.; Lynch, C.; Soluk, D.A.; Britten, H.B. (2010): Nonlethal tissue sampling techniques and microsatellite markers used for first report of genetic di-

versity in two populations of the endangered *Somatochlora hineana* (Odonata: Corduliidae). *Annals of the Entomological Society of America* 103(6): 1012-1017. (in English) ["Techniques for obtaining DNA noninvasively or nonlethally are highly desirable in molecular genetic studies of protected species, and several advances have been made in these types of sampling and extraction techniques. Insects present a unique set of difficulties in this regard that are not present when working with most vertebrates. This study evaluated the effectiveness of several nonlethal sampling techniques for larval and adults of the federally listed endangered dragonfly *Somatochlora hineana*. Fecal pellets and shed exuviae from captive *S. hineana* larvae did not provide high enough quality DNA for microsatellite analyses. Invasive, but nonlethal, wing clips from adults and tarsi from larvae provided high-quality DNA that amplified 10 microsatellite markers for this species. Ten loci were polymorphic in 94 specimens with four to 14 alleles per locus. Two populations in WI had average observed heterozygosity of 0.47, which is within the range reported for other odonates. Our sampling techniques and these new microsatellite markers provide an essential tool for determining the genetic structure of *S. hineana* populations throughout its range." (Authors)] Address: Monroe, Emy, Department of Biology, University of South Dakota, 414 E. Clark Avenue, Vermillion, SD 57069, USA. E-mail: emy.monroe@usd.edu.

9871. Morimoto, M.; Yamamura, Y.; Watanabe, M. (2010): Conservation ecology of the brackish water damselfly, *Mortonagrion Hirosei* Asahina: Dynamics of a newly established reed community (Zygoptera: Coenagrionidae). *Odonatologica* 39(4): 333-340. (in English) ["The endangered *M. Hirosei* perches in the understory of dense reed communities in brackish water. To aid the conservation of a population, a new reed community (2110 m²) was established in abandoned rice paddy fields adjacent to the original, threatened community (500 m²) by transplanting reed rhizomes in January 2003; brackish water was supplied to the new community. It was assessed whether the new community developed into a suitable habitat for *M. Hirosei* by comparing it to the original community in 2005. Shoot height, density, and aboveground biomass of the reeds and relative light intensity in the community were measured periodically during the growing season. Reed height and biomass were significantly lower in the new community than in the original one. This suggests that 3 yr after transplantation the new community was still underdeveloped. However, shoot density and relative light intensity in the understory were not significantly different between the two communities. Thus, the new reed community was offered in 2005 to *M. Hirosei* adults as a suitable habitat." (Authors)] Address: Yamamura, Y., College of Science, Ibaraki University, Mito, Ibaraki 310-8512, Japan. E-mail: yama@mx.ibaraki.ac.jp

9872. Mousat, F.; Dumont, H.J.; Karrom, M.; Ali, N.M. (2010): Dragonflies from northern Syria (Insecta: Odonata). *Zoology in the Middle East* 51: 105-112. (in English) ["Nineteen stations distributed across the northern part of Syria were inventoried for dragonflies between 2006 and 2010. About 37 species were recorded, and four species are added to the list of known Syrian species. Because of a generalized decrease in the water quality of Syrian rivers, and an increasing number of rivers falling dry, lotic species such as the calopterygids have suffered and the remaining populations have be-

come reduced to disjunct islands. *Calopteryx splendens hyalina*, once extending from Lake Hula to the Wadi Af-rin, now appears to have become extinct in the Orontes valley, and only survives in few short Syrian coastal rivers." 9873. Müller, G.A.; Name, F.T.; Pacheco, F.C.L.; Marcondes, C.B. (2010): Analysis of an alternative method for the study of bromeliad-associated fauna in plants with different foliar organization. *Anais da Academia Brasileira de Ciências* 82(4): 903-906. (in English, with Portuguese summary) ["The efficiency of an alternative method of collection (by suction of water) for the study of Culicidae and Chironomidae (Diptera), Scirtidae (Coleoptera) and Coenagrionidae (Odonata; Leptagrion sp1 and sp2) in bromeliads with different foliar architecture in a restinga at Florianópolis, SC, Brazil, was studied. The alternative method was less efficient to collect Culicidae and Chironomidae (Wilcoxon test $p < 0.05$) and was more efficient to Scirtidae and Coenagrionidae (Wilcoxon test $p > 0.05$) from *Aechmea lindenii*. This method was less efficient to collect insects of all groups from *Vriesea friburgensis* (Wilcoxon test $p < 0.05$). The alternative method was efficient to estimate the diversity of these insects in both species of bromeliads. The higher mobility of immature forms of beetles and dragonflies, and the availability of only one tank in *Aechmea lindenii*, contrasting to several tanks in *Vriesea friburgensis* that help the suction of these immature, probably influenced the results, which indicated that the suction method should not replace the dismantling in the study of Culicidae and Chironomidae. This method can be useful to get immature forms of Scirtidae and Coenagrionidae in one-tank bromeliads." 9876. Nagy, H.B. (2010): Population dynamics of *Libellula fulva* Müller, 1764 in the lowland creeks of landscape Bihari-sík. PhD-thesis, University of Debrecen: VIII, 113 pp. (in Hungarian, with English summary)

[Hungary; "In quantitative ecology few invertebrates are better study targets than dragonflies and damselflies. Dragonflies were used as model organisms in the development of mark-recapture methods, because their study yielded in a relatively short period large amount of data. I carried out my studies on two sites located near two lowland creeks, in the Bihar Plain, Hajdú-Bihar County, Hungary between 2002 and 2007. [...] In the first part of my dissertation I estimated the population sizes for each study day and year, for the comparison of the two populations studied at the two sites. In the second part I analysed the effect of males' density on their mating behaviour. For this analysis I determined the number of assessed matings (mating frequency) and fights (fight frequency) per individual from the daily number of matings which was divided by the daily estimated population sizes. Then I compared the mating and fight frequency in the function of the yearly population sizes between the two sites. In the third part I studied how the temperature and rainfall affected daily male density, their fight and mating habits and site fidelity. In the last part of the dissertation I analysed whether there could be a discrepancy between the body size of males in the smaller and larger populations; and whether there could be any correlation between the body size and behaviour of males. My results showed that the populations near Ártánd were significantly smaller than the populations near Bojt. The density of males did not affect their intraspecific aggression, but at higher population densities males mate less than at lower ones. In the case of the larger population the site fidelity of males decreased as compared to the smaller population. The frequencies of matings and fights showed a weak significantly positive correlation with the daily mean temperatures. The number of larger and medium sized males was higher in the site near Bojt than near Ártánd, where the frequency of larger males corresponded with the frequency of smaller ones." (2010): Breeding ecology of the Purple Heron *Ardea purpurea* in Numidia, north-eastern Algeria. *Ostrich* 81(3): 189-196. (in English) ["During 2002-2007, we assessed the status of the Purple Heron *Ardea purpurea* in Numidia, Algeria by surveying all the major wetlands in the region. We located six distinct breeding sites; four of these were not previously known. We also investigated nest site selection and determined the species' reproductive success at Dakhla, a dunary pond during two successive years (2006 and 2007). The egg laying period was comparable to that reported for southern Europe (March-May) and a seasonal change of breeding success was recorded. A growth curve was derived for developing nestlings and the impact of an ectoparasite (mite) infestation upon nestling's growth was considered. We also examined 73 food boluses regurgitated by nestlings and identified 329 prey items. Fish, mainly *Gambusia holbrooki* and *Cyprinus carpio*, dominated by mass, whereas insects, mainly aquatic Coleopteran larvae and aeshnids (Odonata), were the most frequent prey (67.1%). Loss of habitat is identified as a major threat to the future of colonial herons in Algeria." (Authors)] Address: Nedjah, R., Laboratoire de Recherche et de Conservation des Zones humides, Dept de Biologie, University of Guelma, Guelma, Algeria

9881. North East Scotland Biological Records Centre (2010): Dragonflies and Damselflies: a distributional atlas for Aberdeenshire, Aberdeen City, Moray and the Cairngorms 1900-2008. North East Scotland Biological Records Centre: II, 44 pp. (in English) ["This colourful A5 booklet is an interesting new addition to the growing range of county dragonfly atlases. It differs from many in not being the result of a specific survey or driven by key individuals; rather it is essentially a 'summary statement' of all the dragonfly records from the region that are currently held on the National Biodiversity Network (NBN) database, and is dedicated to the International Year of Biodiversity. There is a brief introduction to dragonflies and to recording, then for each species

there follows a short summary of identification features and habitat preference, a detailed flight period diagram based on local data, a summary map of past/present national distribution, and a detailed (1km grid square resolution) map of local distribution that also shows key geographical features. Records are assigned either to 'confirmed breeding' or to 'presence', but are not subdivided by time period due to the scarcity of information from many areas — a familiar problem for much of Scotland, though this is gradually being overcome. There are several strengths to this book and relatively few errors or omissions, most of which arise out of the need for succinctness. Unfortunately the photograph illustrating a female *Sympetrum striolatum* is a *S. danae*. In the section on *Aeshna caerulea* the authors could have been more strongly dismissive of erroneous English records that have somehow recently appeared in the NBN database, though this fortunately doesn't affect their own regional treatment. This publication serves both as a statement of the known biodiversity of Odonata in northeast Scotland, and more importantly as an incentive for further study. It is a well-produced and professional example of what can be done with modern data handling and publishing packages, and I would strongly recommend it to all dragonfly-watchers who are ever likely to visit the Aberdeenshire area, or who have an interest in Scotland in general." (taken from: Adrian Parr, *Atropos* 41: 48-49, 2010)] Address: Available free from NESBReC whilst stocks last. 9882. Oertli, B. (2010): The local species richness of dragonflies in mountain waterbodies: an indicator of climate warming? *BioRisk* 5: Special issue: Monitoring climatic change with dragonflies: 243-251. (in English) ["With climate warming, many Odonata species are extending their geographical area. In Switzerland, as in many parts of the world, this phenomenon may lead to a regional increase in species richness. The local richness (the richness of individual waterbodies) is also expected to increase, particularly in the alpine or subalpine areas where the waterbodies are particularly species-poor. Based on the species richness recorded in 109 waterbodies scattered all across Switzerland, a model is presented here relating the local species richness (adult dragonflies) to environmental variables, including the mean annual air temperature. This model predicts a sharp increase in species richness for alpine or subalpine waterbodies, which is expected to double or even treble before the end of this century. This increase would mainly be the consequence of the immigration of eurythermal species extending their geographical range, together with potential local extinctions of the cold stenothermal species." (Author)] Address: Oertli, B., University of Applied Sciences Western Switzerland, École d'Ingénieurs HES de Lullier, 150 route de Presinge, CH-1254 Jussy / Geneva, Switzerland. (2010): Predator effects in predator-free space: the remote effects of predators on prey. *The Open Ecology Journal* 3: 22-30. (in English) ["Predators can have remote effects on prey populations that are connected by migration (i.e. prey metapopulations) because predator-mediated changes in prey behavior and abundance effectively transmit the impact of predators into predator-free prey populations. Behavioral changes in prey that might give rise to remote effects are altered rates of migration or activity in the presence of predation risk (called non-consumptive effects, fear- or μ -driven effects, and risk effects). Changes in prey abundance that may result in remote effects arise from changes in prey density due to direct predation (i.e.

consumptive effects, also called N-driven effects and predation effects). Remote effects provide a different perspective on both predator-prey interactions and spatial subsidies, illustrating how the interplay among space, time, behavior, and consumption generates emergent spatial dynamics in places where we might not expect them. We describe how strong remote effects of predators may essentially generate "remote control" over the dynamics of local populations, alter the persistence of metapopulations, shift the importance of particular paradigms of metacommunity structure, alter spatial subsidies, and affect evolutionary dynamics. We suggest how experiments might document remote effects and predict that remote effects will be an important component of prey dynamics under several common scenarios: when predators induce large changes in prey dispersal behavior, when predators dramatically reduce the number of prey available to disperse, when prey movement dynamics occur over greater distances or shorter timescales than predator movement, and when prey abundance is not already limited by competitors or conspecifics." (Author) The paper also includes references to Odonata.] Address: Orrock, J.L., Department of Zoology, University of Wisconsin, Madison, WI, 53706, USA. E-mail: jorrock@wisc.edu

9887. Ott, J. (2010): Zur aktuellen Situation der Moorlibellen im «Pfälzerwald» – wie lange können sie sich in Zeiten des Klimawandels noch halten?. *Annales scientifiques de la réserve de Biosphère transfrontalière Vosges du Nord-Pfälzerwald* 15 (2009-2010): 123-139. (in German, with French and English summary) ["In this contribution, the situation is analyzed with regard to mire dragonflies in the German part of the Pfälzerwald-Vosges du Nord Biosphere Reserve, in which a comparison is made between their distribution up to 2007 and their development in the past few decades. While most types of mires were still fairly widespread up until the nineteen-eighties, they have since shrunk significantly, something which is attributable to a number of causes (among other, biotope degradation). In most recent years, this regression process has been accelerated still further due to the extreme dryness in 2003 and the general climate change. Most types are now only found in isolated waters and/or have very small populations. Possible regeneration and resettlement processes are hindered by other communities, which have been established in the meantime in the water bodies, and these water bodies also have changed their structure (succession processes involving water and riverbank vegetation). The dystrophic ponds areas (FFH habitat type, Natura 2000-Code 3160) are in this context not only losing their unique features, but also their significance for the Natura 2000 network, which is very well indicated by the dragonfly coenoses." 9889. Ott, J. (2010): Dragonflies and climatic change - recent trends in Germany and Europe. *BioRisk 5: Special issue: Monitoring climatic change with dragonflies: 253-286.* (in English) ["In this paper the trends of dragonfly expansions during the last decades in Germany and Europe are summarized. It is shown, that there is a general expansion of many species to the north: Mediterranean species expanded to Central and Northern Europe, whereas some African species expanded to Southern Europe, some are even new to the continent. In general this means an increase of biodiversity, but looking at the ecological effects, in the medium term a decrease can be expected for moorland and alpine species. Dragonflies can be regarded as a good indicator group for climatic change. Already now in some areas or regions negative effects on waters bodies and their dragonfly communities can be observed and more will occur if e.g. temperature rises or precipitation decreases. The consequences for nature conservation strategies - such as the NATURA 2000 network - are outlined and the general need for monitoring programmes is emphasised." 9891. Owens, D.C. (2010): Seasonal variation in terrestrial insect subsidies to tropical streams and implications for the diet of *Rivulus hartii*. *Natural Resources, School of Dissertations & Theses in Natural Resources, University of Nebraska, USA: VIII, 73 pp.* (in English) [Trinidad; "Terrestrial invertebrates subsidize fish diets in lotic ecosystems. Seasonality strongly influences terrestrial invertebrate abundance in temperate regions and alters their delivery to streams. Seasonal changes in the tropics are characterized by distinct wet and dry periods, with marked variation in invertebrate abundance. However, little is known about how these seasonal changes affect invertebrate subsidies and their ecological consequences for tropical streams. We measured the effect of rainfall and canopy density on terrestrial invertebrate falling input, as well as seasonal variation in falling input, benthic and drifting invertebrate, and *Rivulus hartii* (Hart's *Rivulus*) diet composition during both the wet and dry seasons at three stream sites in Trinidad. Rates of input of terrestrial invertebrates showed seasonal trends in biomass and abundance. Rainfall magnitude and canopy density were directly correlated with falling input. The delivery of terrestrial invertebrates increased from an average of 52 mg m⁻² day⁻¹ to 72 mg m⁻² day⁻¹ from wet to dry season. Conversely, average benthic invertebrate

abundance and biomass decreased from 382 mg m⁻² in the dry season to 130 mg m⁻² in the wet season, presumably due to displacement and mortality resulting from severe flow conditions. A 75% increase in drifting invertebrate biomass was driven by a terrestrial invertebrate biomass that more than doubled during the wet season. Prey selectivity in *Rivulus* diets mirrored this seasonal variation in prey invertebrate availability, as percent composition of terrestrial invertebrate volume in *Rivulus* guts also doubled during the wet season. We conclude that terrestrial invertebrates are a substantial energetic subsidy for tropical river ecosystems, and the spatial and temporal variation in delivering these resources from wet to dry season have profound effects on consumer-resource dynamics." (Author) Macrozoobenthic taxa including Odonata are treated at the order level. 9893. Parr, A. (2010): Monitoring of Odonata in Britain and possible insights into climate change. *BioRisk 5: Special issue: Monitoring climatic change with dragonflies: 127-139.* (in English) ["The history of recording and monitoring of Odonata in Britain is briefly described. Results are then presented which suggest that the country's Odonata fauna is currently in a period of flux, in a manner consistent with the actions of a high-level regulatory factor such as climate change. The ranges of many resident species are shifting. *Leucorhinia dubia* has recently been lost from southern England, but many species are presently expanding their ranges to the north and west, some (such as *Aeshna mixta* and *Anax imperator*) with considerable speed. In addition to these changes, a number of 'southern' species have started to appear in Britain for the very first time. These include *Lestes barbarus*, *Erythromma viridulum* (which has now become a locally-common resident in southeast England), *Anax parthenope* and *Crocothemis erythraea*. In addition to these distributional changes, some recent trends in flight times are also discussed. Evidence indicates that many species are now emerging significantly earlier than in the past, though trends relating to the end of the flight period are less clear cut." (2010): Macroinvertebrates in low-order streams in two fragments of Atlantic Forest in different states of conservation, in the State of São Paulo (Brazil). *Braz. J. Biol.* 70(3, suppl.): 899-909. (in English, with Portuguese summary) ["The presence of a riparian forest is one of the main factors that act directly on the ecology of a fluvial system, and the relation of the forest and the lotic environments might have an important influence on the distribution of the macroinvertebrates. In this context, the benthic macroinvertebrate communities in four low-order streams in São Paulo (Brazil) were analysed, with the aim of assessing the state of recovery of the surrounding forest fragments. The benthic organisms were sampled in the winter, a period of low rainfall. Of the 6,331 specimens of macroinvertebrates collected, 124 taxa belonging to 48 families were identified. The results showed greater diversity in the Canchim Farm streams and greater abundance in the Lake Park streams. Cluster analysis showed that the stream Canchim distanced itself from the others, being considered reference." (Authors) Taxa including Odonata are treated at the genus level.] Address: Paula, M.C., Programa de Pós-graduação em Ecologia e Recursos Naturais, Universidade Federal de São Carlos – UFSCar, Rod. - 9897.** Perez-Bilbao, A.; Alonso, A.I.; Garrido, J. (2010): Phenology of aquatic insects in a protected wetland (Natura 2000 network) in northwestern Spain. *Limnetica* 29(2): 379-386. (in English, with Spanish summary) ["The aim of this study was to gather new data about the life cycle phenologies of several species of aquatic insects in the "Gándaras de Budino" (Galicia, NW Spain) protected wetland, included in the Natura 2000 network. During an annual cycle (2004-2005), three shallow lakes and four streams were sampled monthly using a semi-quantitative sampling method. The body lengths of the larvae and nymphs of thirteen species were measured, and their life cycles were analysed. All species had univoltine or semivoltine cycles. Additionally, a possible correlation between larval and nymphal lengths and water temperature was examined. We found a significant correlation for two species: the water beetle (*Noterus laevis*) and the dragonfly (*Boyeria irene*)." (Authors) The following Odonata species have been studied: *Coenagrion mercuriale*, *C. puella*, *Pyrrhosoma nymphula*, *Calopteryx virgo*, *Boyeria irene*, *Onychogomphus uncatatus*, and (*Cordulegaster boltonii*.) - 9899.** Plotnikova, S.I. (2010): About the olfactory system of the dragonfly *Aeschna* genus. *Journal of Evolutionary Biochemistry and Physiology* 46(4): 420-421. (in English) [Original Russian Text © S. I. Plotnikova, 2010, published in *Zhurnal Evolyutsionnoi Biokhimi i Fiziologii*, 2010, Vol. 46, No. 4, p. 352. Verbatim: Strausfeldt [1] thinks that of the most essential significance in life of insect are two systems of the subesophageal ganglion — the visual and the olfactory ones. The olfactory system in dragonflies is poorly developed. However, in 17 dragonfly species [2] organs of chemical perception were observed, and later, on antennae of *Libellula depressa*, chemoreceptor celoconical sensillae were revealed [3] after which they were found to perceive some odors in imago [4]. In the *Aeshna* sp. larva, we have managed to trace the nerve from antenna to the subesophageal ganglion and to reveal on it a nodule, in which sensory fibers of antenna receptors are terminated. It has its own interneurons and the interneuron connecting this nodule with lateral protocerebrum [5]. When visiting laboratory of Invertebrate Neurophysiology of Sechenov Institute of Evolutionary Physiology and Biochemistry. Strausfeldt examined the total methylene blue-stained preparations of A.A. Zavarrin and found in neuropil of this nodule the olfactory glomerulus, which confirmed our point of view of the nodule olfactory significance. It is also to be noted that, besides, this nodule contains motor neurons of antenna muscles and that it is connected with the β -lobe of the mushroom body. The most interesting is connection of the nodule with aid of the interneuron with lateral protocerebrum. The cerebral branching of this interneuron is going forwards along the lateral protocerebrum and is spreading onto its significant part; the same area of lateral protocerebrum contains lateral processes of Canyon cells. Thus, there is present here the characteristic chain of the neurons that have been described by Strausfeldt [1] in other insects in the olfactory nervous system: the olfactory bulb (it corresponds to the nodule on the olfactory nerve), protocerebrum and Canyon cells in the area, in which in other insects and in the *Aeshna* imago (the Strausfeldt's preparation) there is located the mushroom body calyx. Thus, the general plan of structure of the *Aeshna* olfactory system is the same as in other insects, but its nuclei are expressed poorly. The weak development of the *Aeshna* olfactory system is compensated by development of its visual system that has not only the huge visual blades, but also unites all structures of the subsophagal ganglion. It seems that the strong development of the visual system resulted in development of the unique locomotion providing the high rate and maneuver flight allowing this ancient insect genus to survive until our time."] Address: Plotnikova, S.I., Sechenov Institute of Evolutionary Physiology and

(2010): Population dynamics and migration in the dragonfly *Libellula quadrimaculata* L., 1758 (Odonata, Libellulidae). *Eurasian entomological journal* 9(2): 231-238. (in Russian, with English summary) [ISEA SO RAN Biological Station near Chany Lake, Russia; Long-term data of population dynamics and spatial distribution of *L. quadrimaculata* are provided. "Counts of dragonflies, conducted from 1972 to 2009, demonstrate that *L. quadrimaculata* population size varied significantly during this period, the minimum density being 250 times lower than the maximum one (i.e. 0.04 vs 10 larval specimens per 1 m²). The population density correlates with the water supply of the region, the dragonfly numbers reaching their highest values in one or two years after a maximum water level. A mass migration in *L. quadrimaculata* which occurred in the southwestern part of the West-Siberian Plain in the Ishym River Valley, is described in detail. The reason for the mass migrations is an excessive growth in population density. As a result, a mass exodus from native habitats takes place which not only optimizes their population size but also increases the input of chemical elements and organic matter into the soil ecosystem from eutrophic water bodies." 9904. Ratti, J.; Vachtsevanos, G. (2010): A biologically-inspired micro aerial vehicle. Sensing, modeling and control strategies. *Journal of Intelligent and Robotic Systems* 60(1): 153-178. (in English) ["This paper introduces a novel framework for the design, modeling and control of a Micro Aerial Vehicle (MAV). The vehicle's conceptual design is based on biologically-inspired principles and emulates a dragonfly (Odonata-Anisoptera). We have taken inspiration from the flight mechanism features of the dragonfly and have developed indigenous designs in creating a novel version of a Flapping Wing MAV (FWMAV). The MAV design incorporates a complex mechanical construction and a sophisticated multi-layered, hybrid, linear/non-linear controller to achieve extended flight times and improved agility compared to other rotary wing and FWMAV Vertical Take Off and Landing (VTOL) designs. The first MAV prototype will have a ballpark weight including sensor payload of around 30 g. The targeted lifting capability is about twice the weight. The MAV features state of the art sensing and instrumentation payload, which includes integrated high-power on-board processors, 6DoF inertial sensors, 3DoF compasses, GPS, embedded camera and long-range telemetry capability. A 3-layer control mechanism has been developed to harness the dynamics and attain complete navigational control of the MAV. The inner-layer is composed of a 'quad hybrid-energy controller' and two higher layers are at present, implementing a linear controller; the latter will be replaced eventually with a dynamic adaptive non-linear controller. The advantages of the proposed design compared to other similar ones include higher energy efficiency and extended flight endurance. The design features elastic storage and re-use of propulsion energy favouring energy conservation during flight. The design/modeling of the MAV and its kinematics & dynamics have been tested under simulation to achieve desired performance. The potential applications for such a high endurance vehicle are numerous, including air-deployable mass surveillance and reconnaissance in cluster and swarm formations. The efficacy of the design is demonstrated through a simulation environment. The dynamics are verified through simulations and a general linear controller coupled with an energy based non-linear controller is shown to operate the vehicle in a stable regime. In accordance with specified objectives a prototype is being developed for flight-testing and demonstration purposes." 9905. Rawson, A.; Lim, R.P.; Tremblay, L.A.; Warne, M.S.J.; Ying, G.-g.; Laginestra, E.; Chapman, J.C. (2010): Benthic macroinvertebrate assemblages in remediated wetlands around Sydney, Australia. *Ecotoxicology* 19(8): 1589-1600. (in English) ["To investigate potential high organisational level impacts of persistent organic pollution in the wetlands in the Sydney Olympic Park (SOP) remediated site, the benthic macroinverte-

brate assemblages of seven wetlands within SOP and two off-site reference wetlands were examined. Sediment cores were collected, stained and preserved from each study site and the macroinvertebrates identified to the appropriate taxonomic level (class, order, family, subfamily) (in Odonata: Coenagrionidae & Corduliidae). Data were analysed for taxon richness and macroinvertebrate abundance and multivariate techniques were used to identify chemical/physical characteristics of the sediment, which were important influences on the differences in the assemblage between study sites. Macroinvertebrate abundance was highly variable between study sites and taxon richness was low across all sites. Oligochaetes, nematodes, ostracods and chironomids were the most common taxa found and were the most important in influencing differences between the macroinvertebrate assemblages among the study sites. Sediment grain size and chemical characteristics of the sediments (RPAH, RPCB, TCDDeq and heavy metal concentrations) were important in separating the study sites based on taxon richness and abundance. Canonical correspondence analysis separated the macroinvertebrate assemblages at newly two created wetlands from those at other study sites including the urban reference sites. Increased sediment POP contamination (particularly as measured TCDDeq and RDDT concentrations) is a likely contributor in excluding pollution sensitive taxa and, therefore, alterations to benthic macroinvertebrate assemblages. Further, the influence of TOC suggests the significance of catchment inputs in contributing to changes in macroinvertebrate assemblage. The SOP remediation led to the establishment of wetlands with benthic communities representative of those expected in urban wetlands." 9907. Resende, D.C.; De Marco, P. (2010): First description of reproductive behavior of the Amazonian damselfly *Chalcopteryx rutilans* (Rambur) (Odonata, Polythoridae). *Revista Brasileira de Entomologia* 54(3): 436-440. (in English, with Portuguese summary) ["Polythoridae comprise a widespread group of species in the New World tropics, but little is known about their behav-

ior or life history. Here, we described the reproductive behavior of Amazonian *Chalcopteryx rutilans*, using mark-recapture techniques. Males were resident and territorial, though we found disputes (complex flight manoeuvres) to be rare. Trunks (rotting wood) were important to male persistence in sites, as these are the locations preferred by females for oviposition. The mating system of *C. rutilans* may be comparable to the resource limitation category, described by Conrad & Pritchard (1992), where males cannot control female access to oviposition sites. So, female choice becomes important and apparently, the observed displays (in which males flash the coppery coloration of their hind wings) may be related to attraction of females to territories, as in a lek system." 9910. Rosset, V.; Lehmann, A.; Oertli, B. (2010): Warmer and richer? Predicting the impact of climate warming on species richness in small temperate waterbodies. *Global Change Biology* 16: 2376-2387. (in English) ["Climate change is expected to affect communities worldwide. Many studies focus on responses at the regional level and show an increase in species richness. However, less is known about the consequences of climate change at the local scale (in ecosystems). Small waterbodies, such as ponds, could play an important role for the assessment of the impact of future changes in climate at the local level. We evaluated here the potential changes due to climate warming in the species richness for various groups (plants, snails, beetles, dragonflies, amphibians) across 113 lowland and high altitude ponds in Switzerland. We modelled the relationships between species richness and environmental variables (including temperature) and predicted species

richness changes for the end of the century (2090–2100; using the A2 IPCC scenario). Temperature rise could significantly increase pond species richness. For the five taxonomic groups pooled, species richness would potentially increase from 41 to 75 (183%) in lowland ponds. In presently species-poor high altitude ponds, the potential increase would be particularly marked, with a proportional increase (1150%; from 14 to 35 species) almost double that in lowland areas. A strong increase in species richness also resulted from models including changes in additional variables, such as land-use or water quality. Future reductions in water quality (e.g. increase in nutrients) may limit the predicted increase in lowland species richness or, conversely, result in a greater increase in species richness in high altitude areas. Nutrient enrichment is shown to affect the taxonomic groups differentially, with plant species richness the most negatively influenced. Climate warming could therefore affect species richness of temperate ponds not only regionally, but also at the local, within ecosystems-scale; species richness could increase markedly in temperate regions, and especially so at higher altitude." 9913. Samways, M. (2010): Impacts of extreme weather and climate change on South African dragonflies. *BioRisk* 5: Special issue: Monitoring climatic change with dragonflies: 73-84. (in English) ["The absence of ice sheets for many millions of years, yet variable topography and changing climate, has generated considerable biodiversity in South Africa. There is no evidence to date that anthropogenic climate change has affected odonate populations in the region. One reason is that the highly varying weather and climate constitutes considerable background noise against which any effects of

modern climate change must be measured. Evidence is accumulating that the Holocene interglacial and gradual warming has left some species with isolated populations in montane areas among a matrix of arid land. Many South African odonate species are remarkably vagile and elevationally tolerant, readily immigrating into and emigrating from pools during wet and dry phases respectively. Some species take this movement to greater extremes by moving the southern margins of their geographical range back and forth with varying climate. After floods, populations of riverine odonates can recover within a year, although where the riparian corridor has been stripped of its trees, the recovery is very slow. Various synergistic impacts, particularly from invasive alien woody plants, area severe impact on many riverine species, and reducing their ability to respond positively to changing environmental conditions. Large-scale removal of these woody aliens is greatly benefiting the odonates' ability to survive in the short-term and to restore natural corridors for movement in the face of possible future climatic changes." (Author)] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

9914. Samways, M.; Niba, A. (2010): Climate and elevational range of a South African dragonfly assemblage. *BioRisk* 5: Special issue: Monitoring climatic change with dragonflies: 85-107. (in English) ["Elevation and climate are interrelated variables which have a profound affect on biota. Flying insects such as dragonflies can rapidly disperse and optimal habitat conditions at appropriate elevations. Such behaviour is likely to be especially important in geographical areas which are subject to major climatic events such as El Niño. Accordingly, we studied dragonflies and environmental variables in a series of reservoirs over an elevational range of 100–1350 m a.s.l. at the same latitude on the eastern seaboard of South Africa. The aim was to determine how elevation and climate (as regional processes), as well as local factors, influence species assemblage variability, habitat preference and phenology. Certain environmental variables strongly explained the main variation in species assemblage. These included local factors such as pH, marginal grasses, percentage shade, exposed rock, marginal forest and to a lesser extent, marshes and flow. Different species showed various tolerance levels to these variables. Elevation and climate as regional processes had very little influence on dragonfly assemblages in comparison with these environmental factors. These odonate species are essentially sub-tropical, and are similar to their tropical counterparts in that they have long flight periods with overlapping generations. Yet they also have temperate characteristics such as over-wintering mostly as larvae. These results indicate evolutionary adaptations from both temperate and tropical regions. Furthermore, most were also widespread and opportunistic habitat generalists. The national endemics *Pseudagrion citricola* and *Africallagma sapphirinum* only occurred at high elevations. However, the endemic *Agriocnemis falcifera* was throughout all elevations, suggesting regional endemism does not necessarily equate to elevational intolerance. Overall, the results suggest that many millennia of great climatic variation have led to a highly vagile and elevation-tolerant dragonfly assemblage which readily occupies new water bodies. Such an assemblage is likely to be highly tolerant of global climate change, so long as there is sufficient water to keep the

reservoirs at a constant level." (Authors)] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

9915. Samways, M.J. (2010): The rare Ghost Duskdarter dragonfly *Zyxomma petiolatum* on Desroches Island, Seychelles. *Phelsuma* 18: 98. (in English) [Verbatim: "On each evening at dusk, between 11th and 21st April 2010, the rare *Zyxomma petiolatum* was hawking the northern shoreline of coralline Desroches Island, Amirantes, Seychelles. It also attempted to lay eggs in swimming pools. What is surprising is that this sandy island is virtually waterless, with only a small pool for tortoises. These dragonfly individuals may have come from the granitic Seychelles, where it has been recorded (Bowler 2006). However, its rarity there, and in Asia (Bedjaniè et al. 2007), does not make it a normal candidate for migratory behaviour, suggesting that there is also a chance that it might be breeding in very small semi-permanent pools on Desroches Island. The only other odonate recorded on Desroches at the same time, was *Tramea limbata*, a well-known long-distance migrant."] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. 9916. Sarfaty, A.; Pruett-Jones, S. (2010): Coloration indicates body size in *Calopteryx maculata* (Odonata: Calopterygidae). *International Journal of Odonatology* 13(2): 167-180. (in English) ["*Calopteryx maculata* has become a model system for studying behaviour and reproduction in odonates. Its iridescent coloration is thought to be important in intraspecific interactions but no study has yet measured coloration in a quantitative manner. In a recent study, Fitzstephens & Getty (2000. *Animal Behaviour* 60: 851-855) showed that lipid levels predict coloration as determined by Munsell chips, such that fat males were blue and lean males were green. In this study we quantified color in *C. maculata* with a spectrometer to test the prediction of Fitzstephens & Getty (2000) using quantitative measures. We found that body size, but not lipid levels, correlates with color. In our study, larger males were green and smaller males blue. Territorial males did not differ from non-territorial males in color, size, or lipid levels. Coloration thus predicts size in male *C. maculata*, but the significance of this in intraspecific interactions remains unclear." 9918. Schlotmann, F. (2010): Arealerweiterung der Gemeinen Winterlibelle (*Sympecma fusca*) (Odonata: Libellidae) in Rheinhessen – eine Folge der Klimaänderung und von anthropogener Gewässerunterhaltung. *Fauna und Flora in Rheinland-Pfalz* 11(4): 1385-1396. (in German, with English summary) ["Due to findings in the early 1980 decade in Rheinhessen (Rhineland-Palatinate, Germany) *S. fusca* had a distribution gap that has been explained by climatic parameters and a lack of woodland. New investigations have shown that since 1984 the species has silently expanded its range across

the whole region of about 1400 square kilometers. *S. fusca* prefers shallow ponds of anthropogenic origin that are in an early stage of natural succession and typically have developed reed or cattail stands along the littoral zone. This kind of habitat can be frequently found in flood retention basins and nature conservation ponds and the species seems to be profiting much of these types of stagnant waters. Additionally, the effects of the man-made climate change are thought to be a reason for the expansion. In contrast to most literature statements the winter habitats in Rheinhessen cannot be wooded areas, because these are missing in the region. Wintering seems to take place in habitats of the open landscape like hedges and elements of fallow land. The pioneer character of the species is pointed out." Eine vergleichende Sensitivitätsanalyse. *Naturschutz und Landschaftsplanung* 42(10): 293-303. (in German, with English summary) ["Risk Assessment of Animal Species of the EU Habitats Directive in View of Climate Change: Climate change presumably means greater vulnerability for many animal species of the Habitats Directive. This susceptibility was comparatively estimated for all German animal species of the Habitats Directive based on a uniform database of ecological traits using a uniform methodology. The estimated additional vulnerability was analysed with reference to the Red List status for Germany, the Annexes of the Habitats Directive, to species group and habitat constellation. The results show that endangerment increases in line with the Red List status. Species of Annex II are more endangered than species of Annex IV or V. Beetles are probably more vulnerable than other species groups. Species essentially requiring small structures (mainly butterflies, beetles) are additionally endangered, followed by species requiring aquatic habitats and surroundings or species found exclusively in aquatic habitats. Species which do not necessarily require unfragmented habitats but at least specific or limited habitat patches, or species with a large home range appear to be less vulnerable. The consequences for the conservation of species within Natura 2000 are discussed." (Authors) The analysis includes five odonate species: *Coenagrion hylas*, *C. ornatum*, *Ophiogomphus cecilia*, *Oxygastra curtisii*, *Sympecma paedisca*.] Address: Schlumprecht, H., Büro für ökologische Studien, Oberkonnorsreuther Str. 6a, 95448 Bayreuth, Germany. 9923. Shieh, S.-H.; Chi, Y.-S. (2010): Factors influencing macroinvertebrate assemblages in artificial subtropical ponds of Taiwan. *Hydrobiologia* 649: 317-330. (in English) ["Macroinvertebrate assemblages and its association with environmental factors at the 11 artificial subtropical ponds of Taiwan were examined using the multivariate analysis software STATICO. The aims of the study were to determine whether spatial and seasonal variation of macroinvertebrate assemblages changed seasonally, to examine which environmental factors determined the spatial and temporal structure of macroinvertebrate assemblages, and to compare between-pond variations in the taxon composition of macroinvertebrates. Macroinvertebrates were collected seasonally by a corer and a sweep net in 2007, and 13 physical and chemical factors were measured at the same time. A total of 31 macroinvertebrate taxa were collected during the sampling period, and the most dominant taxa were Chironomidae (31.7% of total animal abundance) and Tubificidae (22.4%). STATICO identified pond size, pond depth, sediment depth, and altitude as the major abiotic factors and *Bufo melanostictus* (Amphibia) as the major biotic factor to influence macroinvertebrate assemblages at these ponds. These factors changed with seasonality. For example, the abundance of *B. melanostictus* was the most important factor during the spring but became much less important in other seasons. According to the spatial distribution patterns of macroinvertebrate assemblages, macroinvertebrates could be split into two groups based on their dispersal. The active dispersers, such as insect taxa, were strongly associated with pond size and the passive dispersers, such as non-insect taxa, were strongly associated with the pond depth and/or sediment depth. The results of this study suggested that pond size might influence macroinvertebrate assemblages through their dispersal mechanisms and that the environmental factors which influenced the macroinvertebrate assemblages most changed with seasons in this study area." (Authors) Odonata were represented by nine taxa.] Address:

9924. Siraj, S.; Yousuf, A.R.; Bhat, F.A.; Parveen, M. (2010): The ecology of macrozoobenthos in Shallabugh wetland of Kashmir Himalaya, India. *Journal of Ecology and the Natural Environment* 2(5): 84-91. (in English) ["Macrozoobenthos comprise of an important group of aquafauna by way of their contribution to ecosystem stability, besides acting as potential bioindicators of trophic status. Being efficient energy converters, they constitute an important link in the aquatic food web. In view of importance of such an aquatic bioresource, on one hand, and scarcity of information about them, on the other, the present study aimed at working out the species composition, distribution pattern and abundance of macrozoobenthos in relation to several physico-chemical parameters of the Shallabugh wetland of Kashmir Himalaya. The data collected on various physico-chemical parameters showed wide seasonal and site-specific fluctuations. Dissolved oxygen concentration fluctuated between 3 - 12 mg/l, while as free CO₂ ranged from 1 - 19 mg/l showing also high values of bicarbonates of Ca and Mg, nitrogen and total phosphorus. The pH of the wetland remained mostly alkaline but at the emergent macrophytic site it showed a slight acidic trend (6.6) in during late summer. Benthos of the Shallabugh wetland was represented by Arthropoda, Annelida and Mollusca, and was studied in relation to abiotic and biotic factors for one year. Perusal of the results revealed that Arthropoda, Annelida and Mollusca were represented by 10, 7 and 6 species respectively. The abundance of some specific pollution indicator species, especially Annelids such as *Limnodrilus* sp, *Tubifex tubifex* and *Branchiura sowerbyii*, is depictive of transition in trophic status of the wetland from meso- to eutrophy. In view of the eutrophication-induced changing biotic community structure, the present study calls for urgent management and restoration of the Shallabugh wetland ecosystem." (Authors) "*Lestes spec.*" larvae were recorded only once at site W2.] Address: Siraj, S., Centre of Research for Development (CORD), University of Kashmir, Srinagar, J & K, India, 190006. E-mail: mashah75@yahoo.com.

9925. Skvortsov, V.E. (2010): The dragonflies of Eastern Europe and Caucasus: An illustrated guide. KMK Scientific Press Ltd. Moscow. ISBN: 9785873176571: 623 pp. (in bilingual Russian and English) [Reviewed by Asmus Schröter:

Mainly due to the language barrier 20 years after the fall of the Iron Curtain both exchange and cooperation between Odonatologists from Europe and Russia and the successor states of the former Soviet Union still remains on an unsatisfying low level. The result is a considerable mutual lack of knowledge of the respective Odonata fauna of the other side's part of the world. Whilst on the one hand European Russia and the Caucasus region faunistically are still largely terra incognita for most of the European odonatologists, their Russian speaking colleagues on the other hand are frequently unaware of the situation in the West. According to the book author's introduction one of the aims of his work is to function as a link between Russian and English-speaking Odonatologists and in this perspective this consequently bilingual guide of the Odonata fauna of European Russia and the Caucasus region conceptually fills this gap.

The book to be discussed covers the European part of Russia, stretching to the Yamal Peninsula and Tyumen Province in the east. Moreover, the territories of Moldova, Estonia, Lithuania, Latvia, Belarus, Ukraine and Georgia, Armenia and Azerbaijan are considered.

Almost all of the 120 species which are subject of the book are depicted, including numerous detail drawings of appendages, secondary genitalia, wings, larvae and other features substantial for determination. Beside the author's introduction and a concise and well illustrated introduction on morphology of imago and larvae, the main part of the book consists of a dichotomous identification key. The key is organized from suborder down to species level, whereas each species additionally is shortly described in an extra chapter, supplying information on flight period, measurements, distribution and ecology whenever available.

As a special feature of the key and probably a novelty in dragonfly guides, diagnostic traits of the larvae and wing venation (whenever available) are incorporated in the key.

The chapters following the key offer distribution maps based on more than 350 localities, a list of localities, toponyms and administrative items. With extra schemes in a larger scale in some species special attention is paid to the complicated situation of the species rich Caucasus region. The book ends with species annotations and comments on distribution and a list of references.

When first paging through, the most conspicuous feature of the voluminous book is without doubt the more than 2000 (!) aesthetically appealing drawings and illustrations, which alone makes the book a remarkable piece of odonatological artwork. These drawings were made exclusively for this book. Some images, however, show unrealistic proportions, f. ex. the much too big terminalia of the males in *Coenagrion australocaspicum* (page 200) and *ponticum* (208), the inadequately big head in the depicted male of *Cordulegaster insignis charpentieri* (374) etc.

However, the majority of the drawings in view of accuracy and clarity satisfy high scientific demands.

Generally the book's importance as a profound and comprehensive fully illustrated diagnostic key for Russian speaking people interested in the dragonflies of the region cannot be assessed highly enough, as to date no up-to-date dragonfly guide for the region was available.

As the level of odonatological exploitation in the considered region, compared to the Asian part within the area of the former Soviet Union, curiously still remains on a lower level, the book hopefully will have a positive effect on the faunistic survey of the region encouraging more people interested in nature to deal with dragonflies.

As far as the authors second aim is concerned - to provide a complete revision of the faunistic data of European Russia and the Caucasus especially for non-Russian speaker - unfortunately the book does not meet the requirements.

Beside many unnecessary spelling errors, even very eye catching ones in bold headlines, f. ex. "*Cordulegasler*" (359), in author names, f. ex. "*Kolentai*" (359) or species names, f. ex. constantly "*stirolatum*" (459 onwards), several inconsistencies concerning the contents hamper the reader, f. ex. an incomplete list of abbreviations (23), not allowing the interpretation of several ab-

brevisions in the section "general distribution" in species descriptions, f. ex. MDT, ME, TEA, AM etc.

The same goes for missing entries concerning the navigation of the headers and footers of the key, f. ex. in *Onychogomphus lefebvrei* (346) no indication to the annotation on page 593 is given, the latter being written inconsistently on one and the same page (346) "*lefebvrei*" (species description) and "*lefebvrei*" (footer below) etc.

Several contents are incorrect displayed, f. ex. *Onychogomphus assimilis* is stated for Lagodekhi NE Georgia in the species annotation (593; i. e. Bartenev 1932), but this is not plotted on the species distribution map (583).

Data given for several species concerning the status in the region are blurred and lost in vagueness, f.ex. in *Onychogomphus lefebvrei*:

Whilst the genus introduction (340) ["The only species widespread over the region is *O. forcipatus*; however, three other species occur in its Caucasus part where field separation of all the congeners is complicated."] implicitly mentions this species as part of the regional fauna and thus leads to the assumption, that *O. lefebvrei* definitively occurs in Caucasus, it is relativised in the following annotation "only reported from NW Caucasus; no exact data cited" (593). Thus, the reader is left in the lurch about the status of *O. lefebvrei* in the region and it remains unclear for which reason this species is dealt with at all etc.

Other data are out of date and incorrect, f. ex. in *Ophiogomphus*:

Four North Asian members of the genus *Ophiogomphus* are known from the area of the former Sowjet Union, not only three! (338/339): *O. cecilia* (Geoffroy in Fourcroy, 1785) (= *O. serpentinus* (Charpentier, 1825), *O. obscurus* Bartenev, 1909, *O. reductus* Calvert, 1898 and *O. spinicornis* Selys, 1878. For *O. spinicornis* in Russia see Kosterin (2003). Even though the latter three are not very likely to be found in the covered area, they are now widely accepted as full species (inter alia Asahina (1979), Haritonov & Borisov (1990).

Moreover, several species included in the key do decidedly not occur in the considered region, but have been recorded in adjacent areas and countries and might be considered as hopeful candidates to be discovered once. Those species are marked with an asterisk, and thus being clearly designated as such. However, at least some of the included species marked with an asterisk, like *Oxygastra curtisii* and *Somatochlora borisi*, are in hardly any respect connected to the region and according to the author included just on account of interest to show the fascinating taxonomical variety of dragonflies (16/17). However, I would have cautioned the author from doing so, as the pure mention of such species bearing no relation to the region or the content of the book at all, is just another unnecessary source of misunderstanding.

The same applies for the dubious Lithuanian record of *Sympetrum eroticum* (Stanionyte 1989) which, although clearly marked with an asterisk, should have better been neglected at all.

Some further species are presented in a very general way and a more precise and differentiated contemporary presentation or at least the attempt to do so would have been desirable:

Gomphus flavipes: Unfortunately no indication on the occurrence of *Gomphus ubadschii* Schmidt, 1953 (sub

(*Gomphus flavipes lineatus* Bartenev, 1929) is given and only the nominate taxon is considered (337). *Lineatus* was described from Poti/Georgia by Bartenev (1929) and it appears likely that all records of *flavipes* from Transcaucasia in fact pertain to *ubadschii*.

Aeshna juncea: The bewildering phenotypical variability of *A. juncea* in the Caucasus region and the doubtful status of two regional taxa *atshischgho* Bartenev, 1929 and *crenatooides* Bartenev, 1929 are mentioned shortly (285), but unfortunately no new information or interpretation is given. Especially against the background of recent records of specimens of *A. juncea* of the "mongolica-type" with distinctly enlarged yellow thorax pattern in adjacent NE Turkey

(<http://www.libellen.org/epallage/pubs/juncea.html>)

further information on distribution and colouration of Caucasian populations would have been highly appreciated. From this perspective "the comma-like spot below spiracle" presented as diagnostic feature in the key (274) to separate *subarctica* from *juncea* may apply elsewhere, but should be treated with some caution in the Caucasus region.

However, such weak points are of minor importance and do not affect the general quality of the book. Much more serious in this context is, however, the frequent uncritical reviewing and subsequent repeating of obviously or probably erroneous records. Undoubtedly, the book boasts an impressive amount of data and contains the essence of virtually the complete literature relevant for the region and one can easily imagine the huge amount of work behind it. However, one main problem - beside the language barrier - most of the European Odonatologists are constantly facing while dealing with (mainly old) faunistic data from Russia and the Caucasus, are the numerous doubtful records and unclear status of several taxa described from the region. In this respect the book unfortunately does hardly provide any progress as it does largely not represent the current state of knowledge and unfortunately contains such doubtful data throughout. Considering the stated aim of the author on the one hand, to improve the insufficient communication between East and West (9), and the nature of many of the erroneous data presented on the other hand, one could easily get the impression, that the author itself became a victim of insufficient exchange with colleagues from elsewhere as obvious errors like *Cordulegaster princeps* etc. might easily have been avoidable just by a few words from an expert of the region. Those mistakes cast a shadow on the pleasure to read and work with this otherwise useful book.

The following seven species and taxa dealt with in identification key and species description, which are presented as part of the fauna of the area covered by the book are either doubtful or with the outermost probability erroneous and should be therefore deleted from the species list at all:

1. *Platycnemis latipes*: Stated for Kabardino-Balkaria (Russian Caucasus).

P. latipes is a western Mediterranean Endemic confined to Iberia and France and definitively not part of Russia and adjacent countries. According to the cited reference (594) ([Byuleten' gosudarstvennogo muzeya Gruzii] 6:85-96) another specimen from that area was considered (...) "a form of *P. pennipes* closely resembling *P. latipes*." However, obviously the same goes for that particular specimen stated as *P. latipes*. Another explanation

might be confusion with the similar regional congener *P. dealbata*.

2. *Coenagrion mercuriale*: Stated for Armenia, Azerbaijan and Belarus (588/589). This species has been rejected by Tally et al. (2004) from the checklist of Armenia, and Dijkstra (2006: 110) consider even all records of *C. mercuriale* from Eastern Europe to be erroneous. Hence, the occurrence of this western Mediterranean species in the Caucasus region generally seems to be most unlikely.

3. *Onychogomphus forcipatus unguiculatus*: Both taxa *albotibialis* and *unguiculatus* are stated for Caucasus (593). However, Boudot et al. (1990) outlined the nature and distribution of the subspecies of *Onychogomphus forcipatus*, whereupon the taxon *O. f. unguiculatus* is confined to the western Mediterranean and is replaced by *O. f. albotibialis* in Asia Minor. Therefore, *O. f. unguiculatus* is certainly not part of the regional fauna. As far as the Caucasus is concerned Reinhardt (1992) and Schröter (2010b) decidedly assigned specimens from Georgia to *O. f. albotibialis*.

4. *Gomphus davidi*: *G. davidi* is stated for Caucasus without further information (336). However, *Gomphus davidi* is a Levantine Endemic restricted to a small range within Turkey, Israel, Jordan, Lebanon and Syria (Suhling & Müller 1996, Kalkman 2006, Boudot et al. 2009) and most probably does neither occur nor will ever be expected in the Caucasus or elsewhere within the region covered by this book.

5. *Cordulegaster princeps*: *C. princeps* is an endemic confined to the Middle and High Atlas of Morocco (Boudot 2001, Van Pelt (2006), Boudot et al. 2009) and thus the stated record from Tbilisi/Georgia is with the outermost certainty erroneous and one could hardly imagine another Palaearctic dragonfly species, whose occurrence in Georgia is as unlikely as this.

6. *Cordulegaster coronata*: Included in the diagnostic key (364) and in the species description (367), but no further information or data are given - "no regional data" (367), "no local record" (590). However, this Central Asian species is very unlikely to occur within the considered region. In addition to all this, images which should depict *Cordulegaster coronata* are erroneous and both images of the male in top and lateral view (375) do for sure not show this species! *C. coronata* has a much yellower overall appearance and the yellow abdominal markings do laterally not descend onto the underside of the segments, every segment additionally shows yellow apical patches and on segments 8 and 9 very distinctive shaped yellow "double-7 spots" are present. For accurate drawings of males of *C. coronata* see Fraser (1929), Schmidt (1961) and for photos of both sexes Schröter (2010a).

7. *Brachythemis impartita* (Karsch, 1890) (see: Dijkstra & Matushkina, 2009: sub *B. leucosticta*): *Brachythemis impartita* has an Afrotropical distribution and comes closest to the considered region in the Near East, where it is locally very common. Notably only a few records from adjacent southern Turkey are known to date (Kalkman 2006, Dijkstra 2006). Although a wandering individual could not be excluded a priori, the cited very old single record (586; referring to Bartenev 1912d) appears to be erroneous beyond doubt.

(2010): Effects of a diesel spill on freshwater macroinvertebrates in two urban watercourses, Wiltshire, UK. *Water and Environment Journal* 24(4): 249-260. (in English) ["The impacts of a spill of approximately 9800 L of diesel on a small stream and the River Ray (near Swindon, Wiltshire, UK) were examined using kick-net sampling of freshwater macroinvertebrate families at impacted and reference sites. Initial impacts (10 days after the spill) 50 m downstream of the spill were severe, with only 9% survival of individuals (excluding oligochaete worms) and 56% survival of invertebrate families. The percentage survival of macroinvertebrates increased progressing downstream from the spill, with no detectable impacts beyond approximately 4 km downstream. The crustacean families Asellidae and Gammaridae were particularly sensitive to the diesel spill. The recovery of the macroinvertebrate community was assessed 13.5 months after the spill. At this time, recovery was almost complete, with only minor impacts at the sites closest to the spill. The use of live laboratory sorting of samples from impacted sites provided essential information on the impacts of the diesel spill." (in English) ["According to the movements of the male abdomen, the copulation process in *I. asiatica* is divided into 3 stages (I, II and III). The mean duration of each stage was 75.8 ± 8.8 min, 6.4 ± 0.3 min and 15.8 ± 0.9 min for stage I, II and III, respectively (S.E.). No sperm transfer was found during stage I. The prolonged duration in stage I was related to the time of onset of copulation. Sperm was transferred into the bursa copulatrix during stage II. Although stage III was a phase without apparent abdominal movement, the sperm transfer was continued, following the sperm migration from the bursa copulatrix to the spermatheca. Immediately after copulation termination, the estimated number of sperm was $64,500 \pm 4,425$ in the bursa copulatrix and $43,143 \pm 6,397$ in the spermatheca (S.E.). The role of each stage in copulation will be discussed from the viewpoint of sperm competition." (in English) ["Negative frequency-dependent selection (NFDS) is one of the most powerful selective forces maintaining genetic polymorphisms in nature. Recently many prospective cases of polymorphisms by NFDS have been reported. Some of them are very complicated, although strongly supportive of the NFDS. Here we investigate NFDS in wild populations of the dimorphic damselfly *Ischnura senegalensis*, in which females occur as andromorphs and gynomorphs. Specifically, we (1) test fitness responses to morph frequencies, (2) built a simple population genetic model, and (3) compare the observed and predicted morph-frequency dynamics. Fitnesses of the two morphs are an inverse function of its own frequency in a population, and are about equal when their frequencies are similar. Thus the conditions necessary for NFDS are satisfied. The long-term field surveys show that the morph frequencies oscillate with a period of two generations. Morph frequencies in a small population undergo large oscillations whereas those in a large population do small oscillations. The demographic properties of the observed dynamics agree well with those of our model. This example is one of the simplest confirmed cases of NFDS maintaining genetic polymorphisms in nature." 12 species in Category B and 3 species in Category C (former breeding species not recorded since 1970). The discovery of at least four *Coenagrion scitulum* adults in Kent during June and July 2010 and the identification of two exuviae from the same species, require *C. scitulum* to be moved from Category C to Cat. B (vagrant species)." (Authors)] Address: Taylor, Pam, Decoy Farm, Decoy Rd, Potter Heigham, Norfolk, NR29 5LX, UK

9937. Termaat, T.; Kalkman, V.; Bouwman, J. (2010): Changes in the range of dragonflies in the Netherlands and the possible role of temperature change. *BioRisk 5: Special issue: Monitoring climatic change with dragonflies: 155-173.* (in English) ["The trends of 60 Dutch dragonfly species were calculated for three different periods (1980–1993, 1994–1998 and 1999–2003). Comparing period 1 and period 3 shows that 39 of these species have increased, 16 have remained stable and 5 have decreased. These results show a revival of the Dutch dragonfly fauna, after decades of ongoing decline. The species were categorized in different species groups: species with a southern distribution range, species with a northern distribution range, species of running waters, species of fenlands and species of mesotrophic lakes and bogs. The trends of these different species groups were compared with the all-species control group. As expected, a significantly higher proportion of the southern species show a positive trend than the all-species group. In the northern species group on the contrary, a significantly higher proportion of the species show a negative trend than the all-species group. Different explanations for these results are discussed, such as climate change, improved quality of certain habitats and degradation of other habitats. It is likely that the observed increase of southern species is at least partly caused by the increasing temperatures. The less positive picture of the northern species group is probably more influenced by other environmental factor than directly by climate change. Three out of six southern species which have become established since 1990 have done so during the aftermath of large invasions. It is concluded that dragonflies are well capable of using changing climate circumstances to colonise new habitats." 9939. Tom, K.R.; Newman, M.C.; Schmerfeld, J. (2010): Modeling mercury biomagnification (South River, Virginia, USA) to inform river management decision making. *Environmental Toxicology and Chemistry 29: 1013-1020.* (in English) ["Mercury trophic transfer in the South River (VA, USA) was modelled to guide river remediation decision making. Sixteen different biota types were collected at six sites within 23 river miles. Mercury biomagnification was modelled using a general biomagnification model based on $\delta^{15}N$ and distance from the historic mercury release. Methylmercury trophic transfer was clearer than that for total Hg and, therefore, was used to build the predictive model ($r^2_{prediction} = 0.76$).

The methylmercury biomagnification factors were similar among sites, but model intercept did increase with distance down river. Minimum Akaike's Information Criterion Estimation (MAICE) justified the incorporation of distance in the model. A model with a very similar biomagnification factor to the South River (95% confidence intervals [CI] = 0.38–0.52) was produced for a second contaminated Virginia river, the North Fork Holston River (95% CI = 0.41–0.55). Percent of total Hg that was methylmercury increased monotonically with trophic position. Trophic models based on $\delta^{15}N$ were adequate for predicting changes in mercury concentrations in edible fish under different remediation scenarios." (Authors) Organisms analyzed from the South and Holston Rivers (VA, USA) include "Gomphidae" and "Zygoptera".] Address: Newman, M.C., College of William and Mary—VIMS, Gloucester Point, Virginia 23062, USA. 9940. Trockur, B.; Boudot, J.-P.; Fichet, V.; Goffart, P.; Ott, J.; Proess, R. (2010): Atlas der Libellen / Atlas des libellules (Insecta, Odonata). *Fauna und Flora in der Großregion / Faune et Flore dans la Grande Région, Band 1; Hrsg./Éd.: Zentrum für Biodokumentation (Landsweiler-Reden): 201 pp.* (Bilingual in German and French, with English summary) ["All data on dragonflies collected in the databases of the five partner regions of the „Sar-Lor-Lux+-region" have been put together and on this basis, actual maps have been compiled. Existing databases of four regions were completed with the data up to the year 2006. Furthermore, for the first time ever, a database on dragonflies was established for the German federal state Rhineland-Palatinate. Concerning the depiction of the total number of 117 053 records, two time spans are compared: before 1990, and from 1990 onwards whereupon 70 % of all records originate from the second period. In the „Großregion", a total of 75 species are known, whereas in each of the three big regions (regarding their extension) Wallonia, Lorraine and Rhineland-Palatinate, 67 species have been detected. On the basis of the total number grid cells (10x6 minutes, about 134 km² each grid cell) where a species was recorded, a simple analysis of the most common and the rarest species is conducted, as well as of the species with the biggest increase and the biggest decline during the two time spans which have been compared. In addition, maps showing the "dragonfly hotspots" (areas with a high number of different species) in the "Großregion" were created by summarizing all species per grid cell. All species listed in the different Red Lists and in the Annexes II and IV of the EC Habitats Directive are presented in a table. Range expansions or changes within the faunas - observed or expected - are described and discussed; some remarkable species of the "Großregion" are presented and described. All species are described in a single chapter by one of the five authors — representing the five regions — who were also responsible for the photos of the species and typical biotopes thus emphasizing the cross-border cooperation. Finally, the experiences made in compiling the atlas are discussed and suggestions for further cross-border cooperation are presented." (Authors)] Address: Zentrum für Biodokumentation, Am Bergwerk Reden 11, 66578 Schiffweiler, Germany. E-mail: info.biodoku@lua.saarland.de

9941. White, E.L.; Corser, J.D.; Schlesinger, M.D. (2010): Distribution and Status of the Odonates of New York. A Partnership between The Nature Conservancy

and the NYS Department of Environmental Conservation, 625 Broadway, 5th Floor Albany, NY 12233-4757: 424 pp. (in English) ["The New York Dragonfly and Damselfly Survey (NYDDS) began in 2005, spanned five field seasons through 2009, and relied heavily on citizen scientists to help collect data over a large geographic area. Its primary goal was to document the current distribution of all odonate species in New York State. This cooperative project between the New York State Department of Environmental Conservation (NYSDEC), Division of Fish, Wildlife and Marine Resources, and the New York Natural Heritage Program was funded through New York State Wildlife Grant T-2-1 in cooperation with the U.S. Fish and Wildlife Service Division of Wildlife and Sport Fish Restoration. Survey efforts were directed toward under-surveyed regions, areas with potential high diversity, and locations with potential for harboring Species of Greatest Conservation Need (SGCN). NYDDS volunteers were trained at workshops held throughout the state during the summers of 2005-2007. The training was designed for beginners from all walks of life and focused on basic odonate biology, taxonomy, and identification, as well as field capture and specimen preservation techniques. Nearly 300 people were trained at these workshops, some of whom were NYSDEC or NY Natural Heritage staff. We focused most of our survey efforts on adults rather than larvae due to their relative ease of identification. Surveys were completed from April through October in or near aquatic breeding habitats such as lakes, ponds, bogs and fens, rivers and streams, marshes, swamps, and forest seeps. Wooded areas and fields near aquatic habitats were also fruitful survey sites, as adults use these areas to mature, roost, and forage. We took many steps to ensure that data received from volunteers were accurate. Participants were provided with a list that noted, for each species (and in some cases, for each sex) the level of verification necessary for record confirmation (observation, photograph or specimen). These photo and specimen vouchers were verified by odonate experts. Our five-year sampling effort yielded many important finds. Most notable were five species added to the list of known odonates for the state, bringing the cumulative total to 194 species, one of the highest diversities of any U.S. state. Owing to the efforts of entomologists, odonatologists, and odonate enthusiasts prior to the NYDDS, New York has records extending back to the late 1800s. This existing county distribution information was compiled by odonatologist Thomas Nick Donnelly of the Dragonfly Society of the Americas in 1999 and again in 2004. We were unable to confirm the presence of 15 of the 189 Odonata species ever documented in New York by Donnelly, and every one of these species was rare in the state to begin with. Participants visited over 2,170 survey sites statewide and a total of 4,383 surveys were conducted, including repeat visits. We confirmed over 18,000 individual species records based on our verification protocol. NYDDS yielded 1,111 new county records beyond these preexisting data. Each county's documented richness increased by 18 species on average, and we documented at least 75 species in two-thirds of New York's 62 counties. A list was compiled for each county as well as a distributional map and phenology chart for all 194 species and full species accounts are included for all 48 SGCN. We calculated draft S-ranks for rare species using NatureServ's Element Rank Calculator and we found that of N's 194 odonate species, 26% are likely to be ranked as critically imperiled (S1) or imperiled

(S2). Surveys for the state historical *Williamsonia lintneri* were unsuccessful, but produced leads in the Grafton and Rome areas. We completed at least five group surveys in western NY for the Federally Endangered *Somatochlora hineana* in appropriate habitat; we did not confirm the species, and it seems unlikely to be present, with the nearest known population occurring in Michigan. Multiple surveys have often been required before the presence of *S. hineana* was confirmed at new sites discovered in Wisconsin and other states, so future survey work may yet prove fruitful. Surveys for New York's state-threatened damselflies in Suffolk county revealed two new sites for *Enallagma recurvatum* (previously known from nine ponds), seven new sites for *Enallagma pictum* (previously known from three ponds), and *Enallagma minusculum* is known from three locations (two in Suffolk county and one in Queens). These surveys will inform the development of a Recovery Plan for these species. Analyses of survey effort showed that the state was sampled sufficiently to document its odonate fauna. Similarly, each of the state's seven ecoregions was well sampled, while some counties could have used additional survey effort. Such counties where additional survey effort would be most productive were identified and survey effort, ecological and biogeographical explanations were forwarded as possible reasons for the apparent lower species richness in western vs. eastern New York. Since odonates are noted indicators of water quality, biodiversity, and ecological change, our findings should help inform future conservation efforts in freshwater habitats. Along with previous distribution information, this report provides baseline information on the distribution and status of odonates in New York against which to measure future change. Much like the 2000-2005 Breeding Bird Atlas followed up on the 1980-1985 Atlas, leading to some highly informative analyses of distributional shifts, we hope that in the future this survey effort will be similarly revisited to assess shifts in odonate distributions. Monitoring of this sort may be the only way to know whether we are maintaining New York's dragonfly and damselfly biodiversity in the face of continuing global change." (Authors)] Address: White, E., NYSDEC-DFWMR, NY Natural Heritage Program, 625 Broadway, 5th Floor, Albany, NY 12233-4757, USA: E-mail: nydds@gw.dec.state.ny.us

9942. Wildermuth, H. (2010): *Somatochlora flavomaculata* als Beute von Radnetzspinnen (Araneae: Araneidae). *mercuriale* 10: 43-46. (in German, with English summary) [Switzerland; *S. flavomaculata* "has been recorded three times deadily entangled in orb webs. In all cases ovipositing females were concerned, in two of them also males were caught, probably after they had grasped an ovipositing female. The findings are discussed with respect to gender-specific predation-proneness of *S. flavomaculata* by orb-web spiders." (Author)] Address: Wildermuth, H., Haltbergstr. 43, 8630 Rütli, Switzerland. 9943. Wildermuth, H. (2010): Ein Dreigespann der Großen Moosjungfer (*Leucorrhinia pectoralis*). *mercuriale* 10: 47-48. (in German) [Intraspecific triple connection in *Leucorrhinia pectoralis* (Odonata: Libellulidae).] Address: Wildermuth, H., Haltbergstr. 43, 8630 Rütli, Switzerland. E-mail: hansruedi@wildermuth.ch

9944. Wildermuth, H. (2010): Monitoring the effects of conservation actions in agricultural and urbanized landscapes – also useful for assessing climate change?.

BioRisk 5: Special issue: Monitoring climatic change with dragonflies: 175-192. (in English) ["Various methods for measuring the success of conservation actions and for evaluating aquatic habitats are outlined, based on quantified dragonfly monitoring. They are discussed with respect to their practicability and information value, counts of adult males and especially of exuviae yielding the most valuable results. These are presented by actual examples of mire ponds, streams, ditches and rivers from central Europe, making allowance for the dynamics of the habitats and their dragonfly community. Records of detailed data, if repeated subsequently at the same localities with the same methods, are considered a useful basis for preparation of distribution maps and for comparison of the fauna over the time. Fauna shifts in horizontal and vertical distribution over the time should be judged critically with respect to climate change as they could also be caused by anthropogenic habitat changes." (Author)] Address: Wildermuth, H., Haltbergstr. 43, 8630 Rütli, Switzerland. E-mail: hans-ruedi@wildermuth.ch

9945. Willigalla, C.; Fartmann, T. (2010): Libellen-Diversität und -zöosen in mitteleuropäischen Städten. Ein Überblick. *Naturschutz und Landschaftsplanung* 42(11): 341-350. (in German, with English summary) ["Since 1986 nearly 30 Odonata surveys in cities have been published in Central Europe. 77% (62 species) of the total Odonata fauna of Germany have been found in cities. This high Odonata species richness can be explained by the structural richness due to the high natural diversity of habitats within the biogeographical regions of the cities. However, increased urbanization leads to homogenization of the Odonata fauna. The Odonata assemblages of the cities are more similar than those of not built-up areas, which was indicated by a significantly higher Sørensen coefficient. Within the city borders an urban gradient can be observed. To the city centre the total number of species and the proportion of specialists markedly decreases. In the cities' centers, the Odonata communities only occur rudimentarily, and not even the 21 most frequent species have been found in all cities. The highest species diversity in cities was reported before 1975 with a decreasing trend thereafter. Since the 1990ies the number of species recorded in cities has increased again, probably because of the improvement of the total quality of lotic waters. Approximately 37% of the total Odonata fauna of Germany can be classified as "urbano-neutral" to moderately "urbano-philous". Correspondingly, 63% of all species are restricted to non-sealed areas and can be classified as (moderately) urbanophobe." (Authors)] Address: Willigalla, C., Willigalla - Ökologische Gutachten, Am großen Sand 22, D-55124 Mainz, Germany. E-mail: christoph@willigalla.de

9946. Worthen, W.B. (2010): Emergence-site selection by the dragonfly *Epitheca spinosa* (Hagen). *South-eastern Naturalist* 9(2): 251-258. (in English) ["Odonates are vulnerable during emergence, when they shed their exuvia to take flight as adults. Emergence-site selection should adapt to the local mortality risks. Here, I characterized emergence-site selection of *E. spinosa* by noting the substrate, height, and distance from water of exuviae in a 300 m × 5 m plot at Weston Lake, Congaree National Park, Hopkins, SC, USA. Of the 82 *E. spinosa* exuviae sampled, 52 (63.4%) were found on trees with corky bark (*Nyssa aquatica* [Water Tupelo], *Nyssa biflora* [Swamp Tupelo], *Fraxinus penn-*

sylvanica [Green Ash]), while no exuviae were found on the peeling, flaky trunks of *Taxodium distichum* (Bald Cypress) or the smooth, platy trunks of *Acer rubrum* (Red Maple). However, 26 (31.7%) exuviae were on *T. distichum* pneumatophores. This pattern was significantly different from the relative abundances of these substrate types ($\chi^2 = 19.8$, $df = 3$, $P < 0.001$). Most exuviae (93.9%) were on substrates touching the water, suggesting that larvae climb directly from the water to their emergence site. The mean height of exuviae on trees was 3.3 ± 1.37 m, with a range from 1.8–7.7 m. High-climbing by *E. spinosa* larvae may be an adaptation to flooding at Weston Lake; major flood events (>3 m) are common (5 of the last 10 years) during their March–April emergence period." (Author)] Address: Worthen, W.B., Biology Dept, Furman Univ., Greenville, SC 29613, USA. E-mail: wade.worthen@furman.edu

9947. Zawal, A.; Czachorowski, S. (2010): Dragonflies (Odonata) and caddisflies (Trichoptera) of water reservoirs in the suburban landscape of Swinoujscie (north-west Poland). *Natura Montenegrina, Podgorica* 9(3): 481-488. (in English) ["In 2007, ten dragonfly species and eight caddisflies species were recorded in periodical water reservoirs situated at the site where a liquefied natural gas terminal was going to be constructed. The encountered dragonfly and caddisfly fauna was typical of periodical reservoirs. Three communities of these insects were differentiated. Faunistic similarities among the reservoirs only partly corresponded to habitat diversity and reservoir types, which might indicate that species composition depends also on colonization processes, which are well described by the model of ecological islands." 9953. Cannings, R.A.; Cannings, S.G. (2011): Chapter 10: Odonata (dragonflies and damselflies) of the montane Cordillera ecozone. In: *Assessment of Species Diversity in the Montane Cordillera Ecozone*. Edited by G.G.E. Scudder and I.M. Smith. Royal British Columbia Museum: 1-31 (in English). ["The Odonata are energetic aerial predators of other insects; the aquatic larvae are voracious predators of invertebrates and small vertebrates. Over 5500 species of the order are described worldwide; the Montane Cordillera Ecozone supports about 40% of the Canadian fauna. A checklist and systematic overview of the Suborders Zygoptera and Anisoptera, their 10 families and 81 species (19 of which are listed as potentially endangered, threatened, or vulnerable), and an analysis of their biogeographic elements are presented. Twenty-eight species of Boreal origin (35%) are recorded. Of these, 13 (16%) are Widespread Boreal, 9 (11%) are Southern Boreal, 4 (5%) are Northern Boreal, and 2 (3%) are Western Boreal. Transition species total 18 species (22%) and there are 12

(15%) Cordilleran species. Nine species (11%) are Western, 8 (9%) are Austral, and 6 (8%) are widespread species according to our definitions. Ecozone aquatic habitats and their typical species are divided into 12 categories: large lakes (wave-washed shores with little vegetation), small lakes and ponds (floating, but little emergent vegetation), alkaline ponds, ephemeral ponds, cattail/bulrush marshes (including margins of lakes and ponds), sedge marshes, small peatland ponds with aquatic moss, three types of fens, streams and springs. Stress on dragonfly populations is discussed under the headings of draining of wetlands, flooding of wetlands, fish introductions, lakeshore modifications, livestock disturbance, hot springs development, logging, and climate change. Recommendations for inventory and taxonomic research are noted." (Authors) Address: Cannings, R.A., Royal British Columbia Museum, 675 Belleville Street, Victoria, BC, V8W 9W2, Canada

9954. Chakravorty, J.; Ghosh, S.; Meyer-Rochow, V.B. (2011): Practices of entomophagy and entomotherapy by members of the Nyishi and Galo tribes, two ethnic groups of the state of Arunachal Pradesh (North-East India). *Journal of Ethnobiology and Ethnomedicine* 2011, 7:5 doi:10.1186/1746-4269-7-5: 35 pp. (in English) [We prepared a consolidated list of edible and therapeutic insects used in Arunachal Pradesh (N.E. India) by two tribal societies (i.e., the Nyishi of East Kameng and the Galo of West Siang). The list is based on thorough, semi-structured field-interviews with 20 informants of each tribal group. At least 81 species of local insects, belonging to 26 families and five orders of insects, namely Coleoptera (24 species), Orthoptera (17 species), Hemiptera (16 species), Hymenoptera (15 species) and Odonata (9 species), are being used as food among members of these two indigenous societies. However, Nyishi use overall more species of insects as food than Galo people do and consume mostly Coleoptera and Hemiptera; amongst the Galo, on the other hand, Odonata and Orthoptera dominate. The selection of the food insects amongst the Nyishi and Galo is dictated by traditional tribal beliefs as well as the taste and availability of the insects. Depending on the species, only particular or all developmental stages are consumed. Some food insects may be included in the local diet throughout the year, others only when seasonally available. Commonly specimens are being prepared for consumption by roasting, frying or boiling. Twelve species of insects are deemed therapeutically valuable by the locals and are being used by the tribes investigated to treat a variety of disorders in humans and domestic animals. Members of the Galo use a greater number of insect species for remedial purposes than the Nyishi. With the degradation of natural resources, rapid population growth, and increasing influence of 'westernization', the traditional wisdom of entomophagy and entomotherapy is at risk of being lost. There is thus an urgent need to record the role insects play as components of local diets and folk remedies and to assess insect biodiversity in the light of these uses." 9956. Feld, C.K.; Tangelder, M.; Klomp, M.J.; Sharma, S. (2011): Comparison of river quality indices to detect the impact of organic pollution and water abstraction in Hindu Kush-Himalayan rivers of Nepal. *Journal of Wetlands Ecology* 4: 112-127. (in English) ["Several assessment methods exist for river quality classification in the Hindu Kush-Himalayan region. While rapid field bioassessment (RFB)1 applies on-site screening protocols, more sophisticated multi-habitat sampling (MHS) is employed to generate biotic scores using benthic macroinvertebrates as bioindicators. This study presents the comparison of River Quality Classifications (RQC) according to i) 40 RFB records based on two slightly different RFB protocols and ii) 20 qualitative benthic macroinvertebrate samples used to calculate two different scores (average scores per taxon; ASPT). Sensory attributes, such as odour, colour, foam and epilithic algal cover, were used in addition to biological samples for RFB. All samples were taken at two river basins in Nepal, the Punyamata river (12 stations, stressor: organic pollution) and the Khimti river (8 stations, stressor: damming and water abstraction). RQCs revealed organic pollution to impact benthic invertebrate communities in the Punyamata river, while the impact of water abstraction and damming was not detectable in the Khimti basin based on the methods compared. Furthermore, a pollution gradient was clearly detectable based on 66 macroinvertebrate families and genera found in our samples. Our results confirm the applicability of RFB protocols and scoring systems to assess the impact of organic pollution in Nepalese rivers. Further research, however, will be required to adjust the protocols and taxon scores to assess also the impact of other stressors present in the region." (Authors) Gomphidae is the only Odonata family included in the study. No species names are represented.] Address: Feld, C.K., University of Duisburg-Essen, Faculty of Biology and Geography, Applied Zoology/Hydrobiology, D-45117 Essen, Germany. 9957. Fredricks, T.B.; Giesy, J.P.; Coefield, S.J.; Setton, R.M.; Haswell, M.M.; Tazelaar, D.L.; Bradley, P.W.; Moore, J.N.; Roark, S.A.; Zwiernik, M.J. (2011): Dietary exposure of three passerine species to PCDD/DFs from the Chippewa, Tittabawassee, and Saginaw River floodplains, Midland, Michigan, USA. *Environmental Monitoring and Assessment* 172(1-4): 91-112. (in English) ["Dietary exposure of house wrens (*Troglodytes aedon*), tree swallows (*Tachycineta bicolor*), and eastern bluebirds (*Sialia sialis*) to polychlorinated dibenzofurans (PCDFs) and polychlorinated dibenzo-p-dioxins (PCDDs) near Midland, Michigan (USA) was evaluated based on site-specific data, including concentrations of residues in bolus samples and individual invertebrate orders and dietary compositions by study species. Site-specific dietary compositions for the three species were similar to those reported in the literature, but differed in their relative proportions of some dietary items. Oligochaeta (non-depurated) and Brachycera (Diptera) con-

tained the greatest average concentrations of SPCDD/DFs of the major site-specific dietary items collected via food web-based sampling. Average ingestion values of SPCDD/DFs from site-specific bolus-based and food web-based dietary concentrations for nestlings at study areas (SAs) were 6- to 20-fold and 2- to 9-fold greater than at proximally located reference areas (RAs), respectively. Average ingestion values of total 2,3,7,8-tetrachlorodibenzo-p-dioxin equivalents (TEQWHO?-?Avian) from site-specific bolus-based and food web-based dietary concentrations for nestlings at SAs were 31- to 121-fold and 9- to 64-fold greater than at proximally located RAs, respectively. Estimates of SPCDD/DFs and TEQWHO?-?Avian tissue concentrations based on nestling dietary exposures were greater than those measured. Plausible explanations include nestling metabolism of 2,3,7,8-tetrachlorodibenzofuran and assimilation rates of less than the 70% assumed to occur over the nestling growth period. Profiles of the relative concentrations of individual PCDD/DF congeners in samples of invertebrates and bolus at SAs on the Tittabawassee River downstream of the source of contamination were dominated by 1,2,3,4,6,7,8,9-octachlorodibenzo-p-dioxin (22% to 44%) and 2,3,7,8-tetrachlorodibenzofuran (18% to 50%)." 9958. Gäde, G.; Simek, P.; Fescemyer, H.W. (2011): Adipokinetic hormones provide inference for the phylogeny of Odonata. *Journal of Insect Physiology* 57(1): 174-178. (in English) ["Adipokinetic neuropeptides from the corpora cardiaca of 17 species of Odonata encompassing mainly the families Corduliidae and Libellulidae were isolated and structurally elucidated using liquid chromatography coupled with ion trap electrospray ionization mass spectrometry. It became evident that all species of the family Corduliidae studied express the peptide code-named Libau-AKH (pGlu-Val-Asn-Phe-Thr-Pro-Ser-Trp amide), which is also present in all but one libellulid species, *Erythemis simplicicollis* which expresses Erysi-AKH (pGlu-Leu-Asn-Phe-Thr-Pro-Ser-Trp amide). This divergence from all other Libellulids is due to a nonsynonymous missense single nucleotide polymorphism (SNP) in the nucleotide coding sequence (CDS) of prepro-AKH CDS and supports the polyphyletic nature of Sympettrinae and other subfamilies of libellulids. Despite this exception, these findings then support the hypothesis that Corduliidae and Libellulidae are closely related as stated in most phylogenies. The presence of Anaim-AKH (pGlu-Val-Asn-Phe-Ser-Pro-Ser-Trp amide) in Macromiidae likely distinguishes species in this family from Corduliidae. Current molecular genetic phylogenies and our AKH findings suggest that *Syncordulia gracilis*, which expresses Anaim-AKH, does not belong in Corduliidae. Evolution of AKHs in anisopteran Odonata are likely due to nucleotide substitution involving nonsynonymous missense SNPs in the CDS of prepro-AKH." 9959. Gorb, S.N. (2011): Insect-Inspired Technologies: Insects as a Source for Biomimetics. Vileinskas, A. (Ed.): *Insect Biotechnology. Biologically-Inspired Systems*, 2011, Volume 2, Part 3: 241-264. (in English) ["The understanding of functional principles of insect materials, structures, sensors, actuators, locomotion,

control systems, and behaviour is of major scientific interest. On the other hand, this basic knowledge is also highly relevant for technical applications. One of the greatest challenges for today's engineering science is miniaturization. Insects have solved many problems correlated with extremely small size, during their evolution. Zoologists, entomologists, morphologists, and neurobiologists have collected a huge amount of information about the structure and function of such living micro-mechanical systems. This information can be utilized to mimic them for industrial applications. Insect solutions may be applied in the following main technology areas: (1) materials science and technology, (2) surface science, (3) science of adhesives, (4) optics, (5) photonics, (6) sensorics, and (7) robotics. A few selected examples are discussed in this chapter, but with over one million described species as a source for inspiration, one can expect many more ideas from entomological science for biomimetics." (Author) The paper includes references to Odonata.] Address: Gorb, S.N., Functional Morphology and Biomechanics, Zoological Institute, Christian-Albrecht University of Kiel, 24098 Kiel, Germany. 9960. Honkavaara, J.; Dunn, D.W.; Ilvonen, S.; Suhonen, J. (2011): Sympatric shift in a male sexual ornament in the damselfly *Calopteryx splendens*. *Journal of Evolutionary Biology* 24(1): 139-145. (in English) ["Character displacement is a process by which interactions between two species that exhibit similar traits, results in geographical patterns of trait divergence in one or both species. These traits evolve to reduce costs of interspecific interactions in sympatry and thus differ from their condition in allopatry. In male damselflies *Calopteryx splendens*, large wing spots are sexually selected. However, in sympatric populations with *Calopteryx virgo*, wing spot size decreases as *C. virgo* abundance increases. The stability of this pattern is unclear, because previous studies have focused on sympatric populations with potentially fluctuating relative abundances. We studied the wing spot sizes of *C. splendens* in both sympatric and allopatric populations. Our data show that male *C. splendens*' wing spots are larger in allopatry than in sympatry with *C. virgo*. We suggest that both interspecific aggression and avoidance of interspecific reproductive interactions may result in this pattern, although their relative importance remains unclear." 9961. Kuitunen, K.; Kotiaho, J.S.; Luojumäki, M.; Suhonen, J. (2011): Selection on size and secondary sexual characters of the damselfly *Calopteryx splendens* when sympatric with the congener *Calopteryx virgo*. *Canadian Journal of Zoology* 89(1): 1-9. (in English) ["Male mating success is often determined by body size or secondary sexual characters because of female mate choice or competition for females. In addition to intraspecific interactions, interspecific interactions may interfere with intraspecific selection. In this study, we investigated sexual selection on size and sexual characters of male banded demoiselle (*Calopteryx splendens* (Harris, 1780)) in wild populations sympatric with the beautiful demoiselle (*Calopteryx virgo* (L., 1758)). As secondary sexual characters, male *C. splendens* have pigmented wing spots whose size appears to be under positive selection. Male *C. virgo* resemble male *C. splendens* that have the largest wing spots, leading to

interspecific male-male aggression and possibly also to heterospecific matings via mistaken species recognition. If interspecific interactions interfere with intraspecific sexual selection on wing-spot size of *C. splendens*, their effects should increase with the increasing relative abundance of *C. virgo*. Our results did not show the expected positive selection on wing-spot size in *C. splendens*, suggesting that interspecific interactions might interfere with sexual selection. Also, we observed no relationship between the strength of interspecific sexual selection and the relative abundance of *C. virgo*. However, there was a positive intraspecific density-dependent sexual selection for larger size. Although the present results are tentative, we suggest that interspecific interactions should be considered along with intraspecific selection when studies of sexual selection are performed in the wild." 9962. Mishra, A.S.; Nautiyal, P. (2011): Factors governing longitudinal variation in benthic macroinvertebrate fauna of a small Vindhyan river in Central Highlands ecoregion (central India). *Tropical Ecology* 52(1): 103-112, 2011: 103-112. (in English, with Portuguese and Spanish summary) ["Variation in the taxonomic composition of benthic macroinvertebrate fauna was examined in the Paisuni river at four stations (P1 to P4) located longitudinally along the river, with P1 being nearest the source of origin. The fauna was dominated by insects at all the stations. Total density increased from P1 to P3, decreased at P4 and differed significantly among the stations. Increase in the relative abundance from P1 to P4 was observed for Baetidae, Chironomidae and Gomphidae, and a decrease for Leptophlebiidae, Heptageniidae, Neophemeridae, Rhyacophilidae and Thiaridae. Ordination analysis indicated that Rhyacophilidae was the characteristic taxon at P1, Thiaridae at P2 and Chironomidae at stations P3 and P4. Ordination also revealed that current velocity, substratum and landuse were the major environmental factors influencing the relative composition of macroinvertebrates. The longitudinal variation in taxonomic composition and assemblages showed a change of trophic status due to direct human interference at P2. Collectors were abundant at all stations but predominated the assemblages from P3 to P4. The balance between collectors, scrapers and predators shifted to predominance by collectors indicating heterotrophic conditions at P3 and P4 in contrast to autotrophic conditions at P1 and P2. Hence, two ecological zones are evident in the Paisuni river." (Authors)] Address: Mishra, A.S., Aquatic Biodiversity Unit, Department of Zoology, H.N.B. 9964. Outomuro, D.; Johansson, F. (2011): The effects of latitude, body size, and sexual selection on wing shape in a damselfly. *Biological Journal of the Linnean*

Society 102(2): 263-274. (in English) ["Under natural selection, wing shape is expected to evolve to optimize flight performance. However, other selective factors besides flight performance may influence wing shape. One such factor could be sexual selection in wing sexual ornaments, which may lead to alternative variations in wing shape that are not necessarily related to flight performance. In the present study, we investigated wing shape variations in a calopterygid damselfly along a latitudinal gradient using geometric morphometrics. Both sexes show wing pigmentation, which is a known signal trait at intra- and interspecific levels. Wing shape differed between sexes and, within the same sex, the shape of the hind wing differed from the front wing. Latitude and body size explained a high percentage of the variation in wing shape for female front and hind wings, and male front wings. In male hind wings, wing pigmentation explained a high amount of the variation in wing shape. On the other hand, the variation in shape explained by pigmentation was very low in females. We suggest that the conservative morphology of front wings is maintained by natural selection operating on flight performance, whereas the sex-specific differences in hind wings most likely could be explained by sexual selection. The observed sexual dimorphism in wing shape is likely a result of different sex-specific behaviours." 9966. Scheibler, E.E.; Ciocco, N.F. (2011): Distribution of macroinvertebrate assemblages along a saline wetland in harsh environmental conditions from Central-West Argentina. *Limnologica - Ecology and Management of Inland Waters* 41(1): 37-47. (in English) ["The goal was to examine how macroinvertebrate taxonomic richness and density respond to spatial-temporal changes and to the influence of water physicochemical characteristics along the Bañado Carilauquen (BC). Benthic samplings were conducted seasonally and environmental parameters were recorded in five reaches of the BC. Cluster analysis was applied to compare taxonomic richness among sites. Community structure and spatial-temporal variation were explored using logarithmic regression. CCA was applied to explore the relationship between species and environmental variables. A total of 36 taxa were identified, predominantly insects. A growing gradient of conductivity and hardness was registered between headwaters (HD; relatively soft waters) and outlet (OL; very hard and saline waters). Total

density of taxa showed significant differences among sampling sites and climate seasons. A decline in richness and density was observed from HD to OL. The spatial conductivity gradient is the major factor modulating macroinvertebrate distribution along this saline arid wetland. With the exception of the headwaters, hard, eutrophic, polysaprobic and contaminated waters such as those of the BC represent critical conditions for the development of macroinvertebrate assemblages." (Authors) Odonata taxa in the Bañado Carilauquen are: *Rhionaeshna absoluta* and *Ischnura fluviatilis*.] Address: Scheibler, Erica, IADIZA, CCT CONICET Mendoza, sede Cricyt. Avda. Ruiz Leal s/n. 9967. Simaika, J.P.; Samways, M.J. (2011): Comparative assessment of indices of freshwater habitat conditions using different invertebrate taxon sets. *Ecological Indicators* 11(2): 370-378. (in English) ["Monitoring changes in population levels of a wide range of species in biodiversity research and conservation requires practical, easy-to-use and efficient assessment and monitoring methods. Dragonflies (Insecta: Odonata) are a valuable tool for assessing aquatic systems and have been used as indicators of ecological health, ecological integrity, and environmental change, including climatic change, as well as indicators of habitat recovery. We field-tested a freshwater ecological integrity index, the Dragonfly Biotic Index (DBI), based on dragonfly assemblages at the local scale, and compared the DBI to a biodiversity index (average taxonomic distinctness, AvTD) as well as to a standard freshwater benthic macroinvertebrate-based freshwater health index (South African Scoring System, using Average Score Per Taxon, ASPT). We sampled 20 river sites, selected a priori. Adult dragonflies and benthic macroinvertebrates were collected using standardized methods. Environmental variables were collected in situ, and water samples taken. Temperature and pH were the most important physical environmental variables in explaining the assemblage structure, and we found significant abiotic-biotic relationships, as well as biotic-biotic relationships. Overall, dragonflies were more sensitive to changes in river condition than were macroinvertebrates, in part because they were responding at the species rather than higher taxonomic level. AvTD scores did not show any significant relationship with changes in river condition. Furthermore, sites with low biotic scores (indicating disturbance) had high AvTD values. In contrast, DBI site value and ASPT scores were highly significantly correlated. We conclude that dragonfly assemblages in the form of a DBI are an excellent tool for environmental assessment and monitoring freshwater biodiversity, with the potential to replace labour-intensive benthic macroinvertebrate-based freshwater quality assessments, such as SASS." 9968. Anders, U.; Ruppell, G. (1997): Zeitanalyse der Balzflüge europäischer Prachtlibellen-Arten zur Betrachtung ihrer Verwandtschaftsbeziehungen (Odonata, Calopterygidae). *Entomologica Generalis* 21(4): 253-264. (in German, with English summary) ["The courtship flights of males of *Calopteryx virgo*, *C. splendens*, *C. xanthostoma* and *C. haemorrhoidalis* where filmed with a slow motion camera in N' Germany and S' France. The shots where taken under unmanipulated conditions as well as in a provoked situation, with a fixed female. The parameters wingbeat frequency and phase relationship from hind- and forewings where studied. The most important differences are: In *C. splendens* and *C. xanthostoma* the fore- and hindwings move nearly absolutly counterwise. That means, while the forewings are at the start of the upstroke, the hind-wings are at the start of the downstroke. So here the phase relationship is 180°. Phase relationship in *C. virgo* is 100°. Here the forewings reach the changing points before the hindwings. *C. haemorrhoidalis* move the hindwings nearly synchronously to the forewings but with a very small amplitude. In reference to the wingbeat frequency and the continuity of the phase relationship, the *Calopteryx*-males court more intensively in the unmanipulated situation, than in the provoked one. With respect to the studied parameter, there is no difference between *C. splendens* and *C. xanthostoma*, in contrast to *C. haemorrhoidalis* and *C. virgo*, which are different to each other and to the first two." 9971. Arnaud, L. (1999): La compétition spermatique chez les insectes: les stratégies d'assurance de la paternité et la préséance du sperme. *Biotechnol. Agron. Soc. Environ.* 3(2): 86-103. (in French, with English summary) ["Sperm competition in insects: paternity assurance and sperm precedence. The prediction that insects, as a result of polyandry, extreme sperm longevity within the female and high efficiency of sperm utilisation at fertilisation, are preadapted to sustain a very high level of sperm competition is demonstrated across numerous studies. In many insects, males have evolved strategies to decrease sperm competition risk. Paternity assurance mechanisms such as mating plugs or mate guarding do not necessarily influence the number of eggs laid by the female but are taken by male to reduce the probability of his sperm to be preceded by the sperm of another male. Each of these mechanisms influencing mating has an adaptative significance in promoting male reproductive success. However, female insects are polyandrous and they play an active role in mate choice and in discrimination between the ejaculates of different males. Also, they have co-evolved strategy to increase their own reproductive success and to counteract the costs resulting from paternity assurance mechanisms. They can control paternity before copulation (pre-copulation, pre-insemination), during copulation, and because fertilisation takes place within their bodies after insemination, and after fertilisation through selective abortion. A male's reproductive success can be determined as the product of his mating success (mate per lifetime) and his fertilisation success (average number of progeny sired per mate). Male fertilisation success is generally studied in terms of sperm precedence where the proportion of the female progeny fathered by a given male is examined. Sperm precedence can be studied using different methods, each having advantages and disadvantages. Although female insects behave polyandrously, most sperm competition studies investigate sperm precedence when only two males are mated with a female. To determine if the results obtained in double-mating experiments fit well with reality, it is thus important to examine last-male mating

success in experiments where females are mated with more than two males. Moreover, within a species, high fertilisation success variations are observed between males of different populations or even of the same population. These variations result from interaction between factors such as sperm number, sperm length, pre- and/or post-copulatory female choice, paternity assurance mechanism efficiency, female sperm storage organ morphology, etc." (Author) The paper includes many references to Odonata.] Address: Arnaud, L., Unité de Zoologie générale et appliquée. 9973. Cannings, R. (2000): Dragons and Damsels in the Columbia/Kootenay Region. *Boreus* 20(2): 9-10. (in English) [Verbatim: "Fire-breathing dragons and damsels in distress at Cranbrook? Knights in shining armour riding to the rescue from Fort Steele? Not likely. Just a handful of keen biologists and volunteers searching for dragonflies and damselflies (the insect Order Odonata) for the Royal British Columbia Museum's Living Landscapes project in the Columbia Basin. As part of the project, the Museum, the B.C. Conservation Data Centre (CDC) (Ministry of Environment, Lands and Parks) and Parks Canada joined forces to study the dragonflies of southeastern British Columbia. Parks Canada enthusiastically provided logistic and financial support for the inventory in the four national parks in the region. The area we explored is the Columbia River Basin exclusive of the Okanagan River drainage. In British Columbia this area is commonly called "The Kootenays" after the Kootenay River -- the largest of the Canadian tributaries of the Columbia River. Through 1998 and 1999 we criss-crossed the region to document occurrence and habitat requirements of the dragonflies of the Kootenays (in the rest of the article I use the term "dragonflies" to include the closely related damselflies). Although the Museum had dragonfly specimens and a species list for the region that represented our knowledge up to 1997, no comprehensive survey for dragonflies had ever been made; some of the recorded populations were known only from collections made almost a century ago. Dragonflies are invertebrates that seldom receive the attention they deserve from biologists and resource managers. But they are of great ecological importance. They are major predators in aquatic habitats, often dominating the large invertebrates, especially in fish-free systems. Both the underwater larvae and the flying adults live mainly along the edges of water bodies, thriving in the rich and sensitive interface between land and water. Many species are habitat-specific and their presence can be used to characterize healthy wetlands of all sorts. Furthermore, unlike most invertebrates, dragonflies are identifiable in the field by experts, and surveys can proceed with speed and effi-

ciency. Finally, because they are large, colourful, diurnal creatures with fascinating behaviour, dragonflies are excellent subjects for nature interpretation programs and public education about aquatic ecosystems in general. The Living Landscapes Project is designed to take the museum's resources to the diverse regions of the province, stimulating local residents and organizations to conceive their own research projects and participate in the Museum's research, collections and public programming activities. In the Columbia Basin we wanted to improve our scientific knowledge about British Columbia dragonflies, and we were keen to gather information for use in wetland management and conservation planning -- issues of great concern in the region. But we also wanted to create simple educational materials that would promote the understanding of dragonflies and their relationship to diverse and healthy wetland habitats. In addition to the main report on the internet, complete with photographs and distribution maps of every species, we decided to produce slide shows and videos for distribution to parks, naturalist groups and schools. Finally, we had a long-term goal -- to involve a few residents of the regional community in the detailed study of dragonflies and the long-term monitoring of selected species and localities. The region, with its maze of deep valleys and high mountains, is rich in dragonfly habitats. Mountain fens and bogs, trickling springs, warm lake beaches, grassland alkali ponds and rich cattail marshes all beckoned. We added nine dragonflies to the fifty-seven species that were listed from the Columbia Basin before the start of the project. The additions were: *Calopteryx aequabilis*, *Lestes forcipatus*, *Coenagrion interrogatum*, *Stylurus olivaceus*, *Somatochlora cingulata*, *S. forcipata*, *S. minor*, *S. walshii* and *Leucorrhinia glacialis*. The inventory also improved our understanding of the status of other species rarely recorded in the Columbia Basin. Thirteen are considered rare and of management concern, based on collections in museums. However, with increased study, species such as *Aeshna tuberculifera* and *S. cingulata* proved to be more widespread than initial records suggested. Dean Nicholson, a Cranbrook volunteer, found *Gomphus graslinellus* at Wasa Lake in the Rocky Mountain Trench, far to the east of the only other regional record at Christina Lake. *Argia vivida* is a Kootenay specialty, because its Canadian range is centred in the region and because it is restricted there to the outlets of hot springs that are such a feature of the area's mountain ridges. Although we found a few new populations of *Argia*, it's still considered vulnerable -- it has been eliminated from some springs and most of the others are threatened by development. *C. aequabilis*, *L. forcipatus* and *S. forcipatus* are species new to British Columbia. *Calopteryx* represents a new family of Odonata for British Columbia: the *Calopterygidae*. This spectacular damselfly, with its metallic green body and brown-banded wings, had been recorded as close to British Columbia as Stevens County, Washington; for several decades we had suspected that it lived in the streams of the Boundary district. However, we had not managed to find it there until July 1999, when Leah Ramsay (wide-eyed with amazement!) discovered it dancing along Christina Creek, the outlet of Christina Lake. In 1998, in a wetland near Donald in the Rocky Mountain Trench, Leah also found *Lestes forcipatus*, not confirmed elsewhere in Canada west of Manitoba. Here is a good example of an uncommon species that had been overlooked simply because it was not expected and because it closely resembles the wide-

spread and abundant *L. disjunctus*. Since the discovery, more localities were found, and some of our old specimens of *L. disjunctus* have been re-identified as *L. forcipatus*. Inventories do not simply gather new records; they force curators to re-evaluate old collections! Finding *S. forcipata* was a goal that had eluded us for years. In the 1920s Edmund Walker of the Royal Ontario Museum had collected this elusive dragonfly about three kilometres from the British Columbia/Alberta boundary in Banff National Park. This ancient collection had remained the only record west of Manitoba. Surely it also had to live in "small spring runs following devious courses" (as Walker had described the habitat) west of the Continental Divide. After much searching, we finally came across it in Kicking Horse Pass, Yoho National Park). Gord Hutchings, a long-time RBCM volunteer, netted a dragonfly hovering over a small trickling seep near Ross Lake. "This looks different!" he yelled, slogging back to the rest of us examining a boggy pond. Sure enough -- *S. forcipata*! Two years and much searching later, we now have mapped the species at three peatland sites in Yoho and Kootenay National parks. This emerald is clearly a sparsely distributed member of the Rocky Mountain dragonfly community, and an inhabitant of an apparently rare habitat as well. The 66 species now known from the Columbia Basin represent 76% of the 87 species recorded from British Columbia, and 33% of the 201 recorded in Canada. At least six more species are thought to occur in the region, and several more than that will probably be added to the list. With more study of Columbia Basin dragonflies, especially by the enthusiastic residents who continue to monitor some special habitats, our understanding of these important and lovely insects will surely grow. The full report of this project, complete with photographs and distribution maps of the species, is found at <http://www.livinglandscapes.bc.ca/cbasin/wwwdragon/pdf/dragonflies4.pdf>. 9974. Cannings, R. (2000): Dragonfly Society of the Americas Annual Field Meeting. 27 July-1 August 2000, Nanaimo and points East. *Boreus* 20(2) (<http://www.sfu.ca/biology/esbc/boreus/Bor202.html>): ?-?. (in English) [Verbatim: "The 2000 annual field meeting of the Dragonfly Society of the Americas was held in Nanaimo. Every year, the Society organizes a field meeting somewhere in North America; this one was a first for Western Canada. Thirty-two participants came from as far away as Florida, Texas, Vermont, North Carolina and even England to observe, collect and talk about the dragonfly fauna of British Columbia and the world. On 28 July, unfortunately, the sky was overcast and a light rain was falling – not a good omen for entomologists who pray for sun. Once the rain stopped and the temperature rose, dragonflying would be good, but in the meantime, one group who were keen see something moving went to Nanoose Bay to look for birds. Between watching Merlins and Peregrine Falcons they managed to record *Aeshna multicolor*, *Anax junius* and *Sympetrum pallipes*, species that the second group, which headed right to dragonfly habitat, failed to record. The larger group went off to the Nanaimo Lakes watershed. They were rewarded with improving weather and managed to find 15 species including *Cordulegaster dorsalis*, *Ophiogomphus occidentis*, *Somatochlora semicircularis* and *S. walshii*. For the locals, the highlight was

confirming that *Lestes forcipatus* indeed occurred on the BC coast – it had been overlooked all these years in the hordes of the widespread *L. disjunctus*. The next day at this site others found two more species, one of them *A. tuberculifera*. Saturday 29 July dawned with much better weather. The group headed north to Hamilton Marsh near Coombs. Collectors and photographers spread out over this large, rich fen and managed to see 25 species – *A. canadensis*, *A. interrupta*, *A. palmata*, *A. multicolor*, *Pachydiplax longipennis*, *S. obtrusum* and *S. occidentale* were abundant. The specialty of the site, *A. tuberculifera*, was finally caught. Later, at Bowser Bog, a peatland species, *Aeshna sitchensis*, excited the southerners. Evening meetings took care of business. In addition, various members showed photographs of foreign faunas. Explaining the local fauna, Rob Cannings gave an overview of the dragonflies of British Columbia. He showed slides of species from representative families found in the province and his biogeographical maps indicated how diverse this part of North America truly is. The field trip to the Okanagan Valley the next day showed us some of this diversity. On Sunday (30 July) morning the crowd dispersed, some heading home via Vancouver or Victoria, others continuing on the field trip to the Okanagan Valley. The weather was sunny and hot for the rest of the meeting. Half the group drove up to Cypress Provincial Park to see a *Tanypteryx hageni* colony, the only one known in Canada. A few burrows, complete with larvae, were found in the mud and moss of a road cut; adults were yet to emerge. Part of the group, led by Syd Cannings, drove east via Rolley Creek in the Fraser River Valley to look for *Octogomphus specularis*. A second bunch under the watchful eye of Rob Cannings, headed up the Coquihalla Highway from Hope, eager to find high altitude species near the summit of Highway 97C on the plateau east of Okanagan Lake. The highlight here among the fens and ponds (some of the latter man-made dug-outs for watering cattle) was *Somatochlora hudsonica*; this is the most so otherly record of the species in British Columbia. *S. albicincta* and *S. minor* were also collected, along with *Coenagrion resolutum*, *A. sitchensis*, and other species. *S. semicircularis*, a common Cordilleran species, literally swarmed in the Beaked Sedge fens. The night was spent to the south at Oliver. On Monday (31 July), a small group keen to see *S. hudsonica* returned to the area at the summit of Highway 97C; they were not disappointed – *Somatochlora* and *Aeshna* abounded. The main crew visited the bottomlands of the Okanagan River north of Osoyoos. Along the oxbows and main river channel cruised *Macromia magnifica* and *O. occidentis*. *Erythemis collocata*, a rarity here at the extreme northern limit of its range, swarmed over its favourite pond and a lone *Pachydiplax longipennis*, a common species to the south but a new species to the Interior of British Columbia, appeared here, too. *Libellula forensis* and *L. pulchella* were abundant. In the afternoon, collectors split up and went off in various directions into the pine and fir-clad hills surrounding the valley. Many species, including *A. eremita*, *A. interrupta*, *A. multicolor*, and *S. costiferum*, were recorded. At a dry sedge marsh a lucky group recorded *S. madidum*, *L. dryas* and a population of *A. constricta*, the latter another common species to the south that is scarce here at its northern outposts. The last day (1 August) again dawned clear and warm; at 05:00 it was already about 80 degrees F and by 06:30 *A. multicolor*, was flying around the motel parking lot (the afternoon temperature in the valley reached about

100 degrees). But we were heading high in the hills to the northeast to escape the heat and find more northern species. Dick Cannings and his 13 year-old son Russell, Okanagan residents, led the day's jaunt to several lakes and fens over dusty gravel logging roads. John Abbott of Texas provided a memorable quote as he anticipated the dragonflies to come -- "There'd better be plenty of 'em and they'd better be easy to catch!" At Solco Lake, a sunny and quiet oasis in the Engelmann Spruce/ Lodgepole Pine woods at 5500 feet, the high-lights were *Somatochlora cingulata* (common, and for once, flying along the shore and easy to catch) and *C. interrogatum*. We stopped at two fens dominated by Beaked Sedge, *A. juncea* and *S. semicircularis*. One of them had a sluggish stream and lots of *S. minor*. Both had adjacent mossy, rather dry areas thick with *A. sitchensis*. At each place a single *S. whitehousei* showed up, the most southerly records in British Columbia – even more surprising because appropriate habitat couldn't be found anywhere." (Author) (<http://www.sfu.ca/biology/esbc/boreus/Bor202.html>) Address: Cannings, R.A., Royal British Columbia Museum, 675 Belleville Street Victoria, British Columbia V8W 9W2. Canada. 9975. Cannings, S.G. (2000): The Quebec Emerald out West. *Boreus* 20(2): 11. (in English) [Verbatim. "In the summer of 2000, staff from the B.C. Conservation Data Centre (Ministry of Environment, Lands & Parks) and the Royal B.C. Museum organized a dragonfly survey of east-central British Columbia. This was the first year of a larger northern B.C. inventory, part of the Royal B.C. Museum's Living Landscapes project, and partly funded by a grant from the Habitat Conservation Trust Fund. See the article by Rob Cannings in this issue that discusses a similar dragonfly inventory in the Columbia/Kootenay region in 1998-99. Dragonflies are one of our best-known insect groups, but this vast study area of snowy mountains, boggy and marshy valleys, and plateaus awash with warm lakes was literally a big blank spot on our dragonfly distribution maps for the province. We knew that we might find that some of the 'rare' dragonflies on our provincial list are more common than we previously thought (and we did, but that's another story), but we weren't prepared for the discovery of the year! It all began with the capture of an odd-looking female emerald (a medium-sized, dark-metallic dragonfly with brilliant green eyes) in the huge fens near the headwaters of the Parsnip River north of Arctic Lake. That one was put back in the collection box with the plan of checking on it further when time allowed, but then forgotten for the moment. Two days later, I teamed up with Sid Dunkle, a dragonfly expert from Texas, and we drove to a fabulous set of terraced fens near timberline at McBride. The common dragonflies there were, *Somatochlora whitehousei*, a rarely-collected beast of shallow fen pools. Sid was ecstatic with these northern specialties, and we even added the very rare *Leucorhinia patricia*, to our list as well! But then Sid caught a female emerald that was unfamiliar to him and I realized that it was the same as the one I had caught a couple of days earlier. We scratched our heads for a while, then resumed searching for more. Soon I caught a male, which was certainly different than any other emerald I had ever seen! We eliminated candidate species one after another and were soon faced with the amazing conclusion that this was a Quebec Emerald! *Somatochlora brevicincta*, is one of the Holy Grails of northern dragonflies—known for many years from only

two localities in a remote area of central Quebec, it has been recently located in a handful of peatlands in Newfoundland, Nova Scotia, New Brunswick, and Maine. Despite these recent discoveries, to find it in British Columbia was unexpected, to say the least—and we've now challenged our colleagues from Alberta to Ontario to fill in the huge gap in central Canada! We continued searching, but after another day of trembling fen-treading we still had found only a handful of specimens. The day after that we returned to the Parsnip River, but arrived there shortly after a tremendous cloudburst had just cleared, and very few dragonflies were flying. We did, however, find a couple more Quebec Emeralds patrolling the rich fens there! And to top things off, during the following week my brother Rob Cannings and Andrew Harcombe found them at two more sites in the Rocky Mountains north and east of McBride. Nowhere are these dragonflies common, and we certainly did not find them in most of the 'appropriate'-looking fens we sampled. Their full distribution and habitat requirements remain a mystery, both within British Columbia and across the boreal and sub-boreal regions of North America. We'll be out again this summer, searching and hoping!" (Author)] Address: Cannings, S.G., Canadian Wildlife Service, 91780 Alaska Highway, Whitehorse, YT, Y1A 5B7, Canada

9986. Kalkman, V.J.; Wasscher, M.T. (2003): Rare dragonfly species in the Netherlands in 1998. *Brachytron* 7(1): 15-23. (in Dutch, with English summary) ["The submitted Dutch records of a selected number of rare dragonfly species are reviewed annually. Acceptability is judged independently by each of the committee members, based on the documentation available (e.g. descriptions, drawings and pictures). In this report the records of 1998 are presented. Of each accepted record the province, nearby city, date(s), number, sex and observers are given. In addition, not (yet) accepted records and records received without documentation are listed. Highlights of the odonatological year 1998 were undoubtedly the records of the first adult specimens of *Gomphus flavipes* since 1902. These records made clear that the larva found in 1996, which constituted the first record since 1902, was the forerunner of the return of this species in The Netherlands. Remarkable was the discovery of two populations of *Somatochlora arctica* on one single day bringing the known number of populations to three. In the dune-area a population of *Leucorhinia pectoralis* was found after absence as breeding species for several decades. Also the first records ever for *Sympecma fusca* for the dune-area were made. In 1998 the third and fourth Dutch records of *Anax parthenope* were made. One of which constituted the highlight of the day for an excursion of 25 members of the Dutch Society for the Study of Dragonflies (NVL)."] (Authors)] Address: Kalkman, V.J., European Invertebrate Survey - Nederland, p/a Nationaal Natuurhistorisch Museum - naturalis, Postbus 9517, 2300 RA Leiden, The Netherlands. 9987. Schlüter, T. (2003): Fossil insects in Gondwana – localities and palaeodiversity trends. *Acta zoologica cracoviensia*, 46(suppl. – Fossil Insects): 345-371. (in English) ["The faunal history of insects in the various fragments of Gondwana is presented. The first part of the paper summarizes the current knowledge of its insect-bearing localities, particularly their stratigraphy and fossil content, emphasizing the record of the higher systematic groups. The second part discusses some trends of their palaeobiodiversity as evidenced from the above mentioned sites. Generally, the knowledge of the fossil Gondwanan insect faunae is still much lower than that of the Laurasian ones, but has considerably increased over the last decade. Altogether about 85 localities are known from Gondwana, with a maximum of sites in Permian and a minimum in Jurassic times. Best represented is South America. Fossil insects of Gondwana are probably less known than those of Laurasia due to inadequate exploration rather than unfavourable conditions for the formation of deposits." (Author) Many references to Odonata are made.] Address: Schlüter, T., UNESCO Nairobi Office; P. O. Box 30592 Nairobi, Kenya. E-mail: Thomas.Schlueter@unesco.unon.org

9988. Sinakevitch, I.; Douglass, J.K.; Scholtz, G.; Loesel, R.; Strausfeld, N.J. (2003): Conserved and convergent organization in the optic lobes of insects and isopods, with reference to other Crustacean taxa. *J. Comp. Neurol.* 467: 150-172. (in English) ["The shared organization of three optic lobe neuropils—the lamina, medulla, and lobula—linked by chiasmata has been used to support arguments that insects and malacostracans are sister groups. However, in certain insects, the lobula is accompanied by a tectum-like fourth neuropil, the lobula plate, characterized by wide-field tangential neurons and linked to the medulla by uncrossed axons. The identification of a lobula plate in an isopod crustacean raises the question of whether the lobula plate of insects and isopods evolved convergently or are derived from a common ancestor. This question is here investigated by comparisons of insect and crustacean optic lobes. The basal branchiopod crustacean *Triops* has only two visual neuropils and no optic chiasma. This finding contrasts with the phyllocarid *Nebalia pugettensis*, a basal malacostracan whose lamina is linked by a chiasma to a medulla that is linked by a second chiasma to a retinotopic outswelling of the lateral protocerebrum, called the protolobula. In *Nebalia*, uncrossed axons from the medulla supply a minute fourth optic neuropil. Eumalacostracan crustaceans also possess two deep neuropils, one receiving crossed axons, the other uncrossed axons. However, in primitive insects, there is no separate fourth optic neuropil. Malacostracans and insects also differ in that the insect medulla comprises two nested neuropils separated by a layer of axons, called the Cuccati bundle. Comparisons suggest that neuroarchitectures of the lamina and medulla distal to the Cuccati bundle are equivalent to the eumalacostracan lamina and entire medulla. The occurrence of a second optic chiasma and protolobula are suggested to be synapomorphic for a malacostracan / insect clade. [...] Columnar and stratified arrangements of centrifugal terminals are seen in dragonflies, such as *Aeshna Canadensis*, the lamina of which comprises discrete rows of optic cartridges each supplying a sheet of axons into the first optic chiasma (see, Meinertzhagen, 1976). In *Aeshna* (Fig. 4E), each centrifugal GABAergic ending bifurcates to provide a system of tangential processes and systems of climbing fibers to

three or four optic cartridges. These fibers end as beaded tufts at the level of the incoming receptor axons (Fig. 4E)." (Authors)] Address: Strausfeld, N.J., ARL, Division of Neurobiology, Univ. of Arizona, Tucson, AZ, 85721, USA. E-mail: flybrain@neurobio.arizona.edu

9989. Smith, S.G.F. (2003): Ionocytes in the dragonfly nymph *Erythemis simplicicollis* (Say). Proceeding of the ninth symposium on the natural history of the Bahamas: 135-138. (in English) ["Nymphs of *E. simplicicollis* are known to inhabit brackish water environments as well. Presence and location of ionocytes, or ion transport cells, were compared in nymphs of two different species, *Anax junius* (a freshwater species) and *E. simplicicollis*. The nymphs were held in tanks of three different salinities for a total of thirteen days, and then subjected to a silver nitrate staining technique to allow us to identify ionocytes on the gill tissues. Patches of ionocytes were found at the base of the rectal gill leaflets in *E. simplicicollis*. No similar patches were observed in *A. junius* nymphs, regardless of salinity. Patch density of ionocytes in *E. simplicicollis* increased as the salinity increased, which suggests that this species is able to respond to changes in salinity." (Author)] Address: Smith, Sherilyn, Dept of Biology, Le Moyne College, Syracuse, NY 13214, USA

9990. Benard, M.F. (2004): Predator-induced phenotypic plasticity in organisms with complex life histories. *Annu. Rev. Ecol. Evol. Syst.* 35: 651-673. (in English) ["Predator-induced phenotypic plasticity is widespread in nature and includes variation in life history, morphology, and behaviour. In organisms with complex life histories, predator-induced phenotypic plasticity in the larval period has been widely documented. Several models predict how organisms should alter their size at and time to metamorphosis in response to an increased risk of predation. A survey of empirical studies finds that these theoretical predictions are frequently met. However, no one model performs the best. Additionally, there are several results not predicted by any model. Predator-induced plasticity in metamorphic traits may be related to predator-induced changes in larval morphology and behaviour. Predictions of predator effects on larval traits are generally met, except for direct costs of predator-induced morphological phenotypes. Future work should incorporate more detailed studies of growth rate, morphology, and behaviour during the larval period, as well as studies of size-specific mortality rates in the presence and absence of predators." (Author) This review includes references to Odonata.] Address: Benard, M.F., Section of Evolution and Ecology, Center for Population Biology, Univ. of California, Davis, California 95616, USA. (in English) ["Abundance, density and richness of insects in Kazhakuttom Grama Panchayat of Kerala was studied using transect and quadrat methods. During the present investigation, 94 species of insects belonging to 42 families of 9 orders were located." Odonata were treated at the family level and represented by five taxa (5.31%).] Address: Balakrishnan, M., Department of Biology, Addis Ababa University, Post Box No. 1176, Addis Ababa, Ethiopia; E-mail: balak212@yahoo.com

9994. Alonso, A.; Camargo, J.A. (2005): Estado actual y perspectivas en el empleo de la comunidad de macroinvertebrados bentónicos como indicadora del estado ecológico de los ecosistemas fluviales españoles. Ecosistemas 14(3): 87-99. (in Spanish, with English summary) ["Fluvial ecosystems are nowadays affected by several anthropogenic activities. Impounded and channelized rivers, organic matter pollution, eutrophication, and mining activities, among others, cause changes in the structure and function of biological communities inhabiting rivers and streams. Benthic macroinvertebrate communities are sensitive to those environmental impacts. These communities enclose invertebrates that dwell the bottom substrate and that can be detected with the naked eye. The study of those communities permits to assess the health of fluvial ecosystem. In this article we review the main traits of macroinvertebrate communities that are used as environmental indicators, and we show several cases of Spanish fluvial bioassessments. Besides the future necessities in fluvial macroinvertebrate bioassessment are discussed." (Authors) *Cordulegaster boltonii*] Address: Alonso, A., Dpto. Interuniversitario de Ecología. (in Russian, with English summary) ["An increase in the number of *L. macrostigma* in the lower reaches of the Karasuk river (forest-steppe of Novosibirsk Ob-last') during 2000-2001 is recorded. Formerly, only a single record in 1973 had been recorded. Possible reasons for number fluctuations are discussed. Extreme variation in

wing venation is shown." (Author)] Address: Borisov, S.N., Siberian Zoological Museum, Institute of Systematics and Ecology of Animals, Russian Academy of Sciences, Siberian Branch, Frunze str. 11, Novosibirsk 630091 Russia. E-mail: borisov-s-n@yandex.ru

9996. Elliott, N.B.; Smith, D.L.; Smith, S.G.F.; Carey, E. (2005): Establishment of the National Bahamian Entomological collection. Proceedings of the 10th Symposium on Natural History of the Bahamas: 34-36. (in English) [437 specimens are included into the collection and based on material in 2003; no details other than geographic are dealt with. The specimens are listed according the 13 islands of the Bahamas: New Providence, Cat Island, Acklins, Great Inagua, Mayaguana, North Andros, South Andros, Grand Bahama, Eleuthera, Long Island, Great Exuma, Great Abaco, San Salvador] Address: Smith, D.L., Department of Biology Le Moyne College Syracuse, NY 13214, USA

9997. Geraeds, R.P.G.; Schaik, V.A. van (2005): Ecological aspects of the dragonfly *Ophiogomphus cecilia* along the river Roer: monitoring exuviae in 2002 and 2003 and a comparison of survey methods. Natuurhistorisch Maandblad 94(1): 1-6. (in Dutch, with English summary) ["In the year 2000, a population of *O. cecilia* was discovered along the river Roer. Since monitoring exuviae of this species along the banks of the Roer is hampered by the limited accessibility of the terrain, we used a boat (provided by the local water board) to hold surveys in 2002 and 2003. Four of such boat surveys in each of these years, during June, July and August, yielded 86 exuviae of *Ophiogomphus cecilia*. By contrast, 47 land surveys during the same period only yielded another 19 exuviae. This indicates that boat surveys are the most suitable method, allowing more locations to be accessed and monitored. Most larvae emerge vertically (59%) and close to the banks (0-0.25 m). They preferably seem to emerge amid the vegetation. The average length of the exuviae was 29.5 mm.] Address: Schaik, V.A. van, Hoosveld 56, 6075 DB Herkenbosch

10012. Gärtner, E.; Olthoff, M.; Scherzer, H. (2006): Die Libellenfauna des Helstorfer Moores (Niedersachsen) unter besonderer Berücksichtigung eines Reliktvorkommens der Zwerglibelle (*Nehalennia speciosa*) und deren Habitatstruktur. Telma 36: 133-154. (in German, with English summary) ["The Helstorfer Moor, a small bog north of Hannover (Lower Saxony, Germany), has been exploited by peat cutting over some centuries. In a two-year-inventarisation 35 Odonata species were found, among these many rare typical species of peat bogs. After one single male had been discovered by Pryswhitt, in 2003 a large population of *Nehalennia speciosa* was found in the Helstorfer Moor, situated in a distance of about 20 km from another population near Hannover. The imagoes of this species predominantly occur in the northern part of the bog, where the peat waters are hydrologically influenced by flowing water and/or adjacent springs. In the small larval ponds *Utricularia minor* is the characteristic plant species. The peat water is strongly or weakly acid, the conductivity is be-

low 100 μ S. The imagoes of *Nehalennia* were found in sections dominated by *Molinia caerulea*, in part mixed with sparse stands of trees (*Pinus silvestris*, *Betula pubescens*). The habitat is part of a Nature Reserve of 410 hectares, well protected against external detrimental influences." (Authors)] Address: Olthoff, M., Naturförderstation im Kreis Coesfeld, Borkener Str. 13, 48653 Coesfeld, Germany. E-Mail: matthias.olthoff@gmx.de

10013. Handke, K.; Adena, J.; Handke, P. (2006): Landschaftsökologische Untersuchungen auf dem Golfplatz Achim (Niedersachsen). Ein Vergleich mit dem Ausgangsbestand und einem Referenzgebiet. *Naturschutz und Landschaftsplanung* 38(7): 214-224. (in German, with English summary) ["On the golf course in Achim (ca. 113 ha) (near Bremen, Lower Saxony, Germany) and on an adjacent reference site (ca. 294 ha) an ecological survey was conducted in 2004. The investigation comprised habitat types, endangered plant species, breeding birds, amphibians, dragonflies, butterflies and grasshoppers. About 35 ha of the golf-course are intensively used whilst the remaining area consists of poor grassland, afforestation sites, and more than 70 water areas. On the golf-course five endangered plant and 43 animal species were identified. Compared to 1996 13 species of the Red Data Book have disappeared and 34 species were registered for the first time. As expected mainly breeding birds of the open agricultural landscape have disappeared whilst particularly amphibians and dragonflies have newly colonised the golf course area, and bird species of hedges and woodlands have expanded. Ornithological importance has slightly increased. Compared to the former conditions the amount of habitat types of very high and high value has markedly increased (1995: 4.6%, 2004: 25%). Furthermore, the poor grassland sites and most of the water areas and their shores developed positively. The large amphibian populations of species like newt (*Triturus cristatus*) and natter jack (*Bufo calamita*) as well as a dragonfly fauna of national importance have also to be pointed out. All in all, the investigations reveal a positive development of fauna and flora on the golf-course area. Compared to the reference site the golf course has a significantly higher importance for habitat types and fauna. The study shows that the potential for nature conservation measures is high on oligotrophic grounds and that various animal species colonise such areas in a short time period." (Authors)] Address: Handke, K., Riedenberg 19, 27777 Ganderkesse, Germany. E-mail: k.handke@oekologische-gutachten.de

10024. Romstöck-Völkl, M.; Völkl, W.; Rebhan, H.; Franke T.; Krug, R. (2006): Auswirkungen einer naturschutzorientierten Teichwirtschaft im NSG Craimoosweiher. Ergebnisse einer zehnjährigen Untersuchung auf Libellenfauna und Unterwasservegetation. Naturschutz und Landschaftsplanung 38(8): 251-258. (in German, with English summary) ["Between 1995 and 2005 the effects of near-natural fish farming (main fish species: carp) on odonate fauna and submersed vegetation were studied in the nature reserve "Craimoosweiher" in Northern Bavaria, Germany. The natural potential of carp increase has been estimated to approx. 150 kg/ha related to a water area of 14 ha. This potential was reached with a stocking rate of only 1500 - 2000 specimens K2 (=* two year old carps) (approx. 600 and 1000 kg input, according to fish size). Increased stocking rate led to reduced carp growth. Further, the biomass reduction could not be raised by a higher stocking rate. A total of 28 odonate species was recorded in the pond, with 15 species occurring in all years of investigation. The average annual species number was relatively constant and varied between 16 and 23 species. However, winter draining in 1996 and 2003 led to a subsequent reduction in the density of all damselfly species. The population density of *Erythromma najas* was influenced most conspicuously; *Erythromma viridulum* and *Coenagrion pulchellum* completely disappeared after winter drainage. The species-rich submersed vegetation (13 species of Angiospermae, 2 species of Bryophyta-Hepaticae, 3 species of Characeae) was dominated by *Ceratophyllum submersum* and *Najas minor*. Like the odonate fauna, the submersed vegetation was negatively influenced by winter drainage. However, the plant species recovered faster than the odonates. Additionally, high fish density (especially roach) led to a decrease in submersed vegetation density and species number. At the same time this decrease of vegetation had a negative influence on the odonate fauna. A reduction of fish density enhanced both submersed vegetation and odonate fauna. The case study "Craimoosweiher" allows the conclusion that freshwater fishery and nature conservation measures not necessarily contradict each other."] Address: Völkl, W., Ökologische Planung, Hohe Eiche 6, 95517 Seybothenreuth, Germany. 10033. Benton, T.; Dobson, J. (2007): The Dragonflies of Essex. Lopinga Books: XII + 228 pp. (in English) ["Nineteen years have passed since Ted Benton produced the first Dragonflies of Essex, as good as it was this volume far surpasses it in scope and production. A hard backed washable and illustrated cover conceals 228 pages with numerous colour photographs and distribution maps. A chapter on biology and conservation is followed by a very useful illustrated guide to many of the best Essex sites for Dragonflies. The main body of the book, the species accounts includes sections on identification, flight period, habits, distribution and conservation. Excellent photographs of each species are included within the accounts as well as an Essex distribution map of each species. Early records are also discussed at the conclusion of each account. Chapter four is devoted to a history of dragonfly recording in Essex, dealing with many notable entomologists from Victorian times until the present day. There are appendices on former Essex species, possible future arrivals and a couple of rare species as well as a plant list. An extensive bibliography is included and the whole is fully indexed. All in all a first class book essential for all Essex field naturalists as well as dragonfly specialists. It is well bound and produced on quality paper, place your order today." 10046. Gallardo, B.; Garcia, M.; Cabezas, A.I.; Gonzalez, E.; Ciancarelli, C.; Gonzalez, M.; Francisco A. Comin, F.A. (2007): First approach to understanding ri-

parian wetlands in the Middle Ebro River floodplain (NE, Spain): Structural characteristics and functional dynamics. *Limnetica* 26(2): 373-386. (in English) ["In Spring of 2005, the relationships between the physical and chemical characteristics of the aquatic and benthic environments and macroinvertebrate assemblages in seven wetlands representative of the floodplain of the Middle Ebro River (NE Spain), were analyzed. The selected wetlands differed in their hydrological connectivity, local environmental conditions and anthropic influence. Through multivariate analyses, two environmental gradients and three main wetland groups were detected. The hydrological connectivity differences generate a heterogenous landscape of structurally and functionally different wetlands in the Ebro Middle floodplain. Confined wetlands, such as older ox bow lakes, showed higher salt and organic matter contents and lower macroinvertebrates' density and biodiversity than did the other wetlands. This suggests that confinement and lack of disturbance events have led to water salinization and eutrophication, habitat homogenization and natural succession of the communities towards more adapted structures with lower biodiversity. Wetlands that still maintain some functional relationship with the river, such as newer ox bow lakes, constructed wetlands, and backwaters, show a higher inorganic nutrient concentration and suspended solids. They also show higher taxa richness and evenness, which suggests that higher disturbance frequencies enhance habitat's heterogeneity and resource availability, and therefore primary and secondary production that allow adapted and opportunistic species to coexist. The progressive flow regulation tends to homogenise this complex system, endangering its conservation. Therefore, the key processes identified here should be taken under consideration for the planning and execution of ecological monitoring, management and restoration." (Authors) Odonata are treated at the order level.] Address: Gallardo, Belinda, Pyrenean Institute of Ecology (CSIC). Avda. de Montañana 1005, Zaragoza. 50192. Spain: E-mail: belinda@ipe.csic.es

10047. Geraeds, R.P.G.; Schaik, V.A. van (2007): De Gevlekte glanslibel langs de Venbeek, De situatie in 2005 en 2006 en een overzicht van de begeleidende Libellenfauna. *Natuurhistorisch Maandblad* 96(7): 198-201. (in Dutch, with English summary) [*Somatochlora flavomaculata* along the Venbeek brook. Situation in 2005 and 2006 and an overview of the accompanying dragonfly fauna. "The Venbeek brook is a shallow, spring-fed and slowly flowing ditch in an agricultural area in the western part of the 'De Meinweg' National Park. It has a rich vegetation and features a thick (10 to 40 cm) layer of organic sediment covering a sandy bottom. The site was surveyed regularly in both years from May till October, mostly in June. *S. flavomaculata* was found along the Venbeek brook in June and July, which is the main flight period in the Netherlands. On 10 June 2005, 19 males were counted, the largest number of males seen on a single day in these two years. Most mating wheels were seen in June, especially in 2005. Males were seen most frequently, often patrolling patrolling above richly vegetated parts of the ditch or above land near bushes and trees. Only once, on 30 June 2006, was an ovipositing female observed; its behaviour is described in this article. *S. flavomaculata* is accompanied by 28 other dragonfly species along the Venbeek brook, some of which are rare or even very rare in the province of Limburg. Examples include *Calopteryx virgo*, *Brachytron pratense* and *Cordulegaster bol-*

tonii. Hence, this particular brook can be regarded as a very important dragonfly habitat. This is somewhat remarkable because it is basically a straight ditch flowing through farmland, which is normally not the best habitat for rare dragonflies. Nevertheless, its special characteristics have resulted in the occurrence of many dragonfly species." (Authors)] Address: Schaik, V.A. van, Hoosveld 56, 6075 DB Herkenbosch

10048. Geurten, R.H.; Nordström, K.; Sprayberry, J.D. H.; Bolzon, D.M.; O'Carroll, D.C. (2007): Neural mechanisms underlying target detection in a dragonfly centrifugal neuron. *Journal of Experimental Biology* 210: 3277-3284. (in English) ["Visual identification of targets is an important task for many animals searching for prey or conspecifics. Dragonflies utilize specialized optics in the dorsal acute zone, accompanied by higher-order visual neurons in the lobula complex, and descending neural pathways tuned to the motion of small targets. While recent studies describe the physiology of insect small target motion detector (STMD) neurons, little is known about the mechanisms that underlie their exquisite sensitivity to target motion. Lobula plate tangential cells (LPTCs), a group of neurons in dipteran flies selective for wide-field motion, have been shown to take input from local motion detectors consistent with the classic correlation model developed by Hassenstein and Reichardt in the 1950s. We have tested the hypothesis that similar mechanisms underlie the response of dragonfly STMDs. We show that an anatomically characterized centrifugal STMD neuron (CSTMD1) gives responses that depend strongly on target contrast, a clear prediction of the correlation model. Target stimuli are more complex in spatiotemporal terms than the sinusoidal grating patterns used to study LPTCs, so we used a correlation-based computer model to predict response tuning to velocity and width of moving targets. We show that increasing target width in the direction of travel causes a shift in response tuning to higher velocities, consistent with our model. Finally, we show how the morphology of CSTMD1 allows for impressive spatial interactions when more than one target is present in the visual field." uviae, and teneral adults of *T. virginia* in Matsuyama City, Ehime Prefecture in springs of 2005 and 2007. These observations indicated, for the first time, that this species over-wintered as larval stages in Ehime Prefecture." (Authors)] Address: not stated in English

10051. Irusta, J.B. (2007): *Ecologia comportamental reprodutiva de Diastatops obscura Fabricius (Insecta, Odonata)*. Tese apresentada, Universidade Federal do Rio Grande do Norte: 99 pp. (in partly bilingual Portuguese and English) ["In this thesis I discuss the reproductive behaviour and ecology of the libellulid *Diastatops Obscura Fabriciás*, 1775, (Insecta: Odonata) in natural conditions. Populations of this species were studied on the middle stretch of the Pitimbu River, Pamaririm municipality, Rio Grande do Norte, Brazil, during four discontinuous periods between 2002 and 2004. The objectives include the description of strategies and behaviours of both sexes, with especial interest in the intra-male competition for territories and females, the mate selection by females and the importance of male body size and other secondary characters on their reproductive success; from an adaptationist point of view. It was observed that the behaviour of males and females in the reproductive areas are interrelated: the males came earlier to compete for the best territories and the females waited the result of that competition to be fertilized by dominants males, which preferably occupied areas near the river margin. The reproductive success of males with territories on the margin, estimated by number of copulations, ovipositions and days acting as territorial, was better than obtained by more separated territorial males and by satellite males. The body size of males is an important factor for the copulation and opposition taxes and for the number of territorial days, favouring the biggest individuals. I also discuss the apparently importance of wing brilliance and wing integrity on male reproductive success. On intersexual relationships, I proved that females of *D. obscura* participate in mate selection, rejecting non-territorial males or substituting their sperm for other of higher status." (Author)] Address: Irusta, J.B., Univ Fed Rio Grande Norte, Sect Psychobiol, Dept Physiol, Caixa Postal 1511, Campus Univ, BR-59072970 Natal, RN, Brazil. E-mail: banuelos@ufrnet.br

10053. Kakichi, K.; Kakichi, K.; Futahashi, R. (2007): The first collecting records of *Tholymis tillarga* (Fabricius, 1798) (Libellulidae) from Toyama prefecture, Honshu, Japan. *Tombo* 50: 60. (in Japanese, with English summary) [24-VII-2007 and 17-VIII-2007; "Two males of *T. tillarga* were captured at Miyaaa in Himi-shi, Toyama Prefecture, Honshu, Japan. This is the first record from Toyama Pref., and the northernmost record of this species from Japan." (Authors)] Address: Futahashi, R., Fujiwara Lab., Univ. Tokyo, Biosci. Bldg 501, Kashiwa, Chiba, 377-8562, Japan

10054. Karube, H. (2007): The southernmost record of dragonfly in Japanese territory. *Tombo* 50: 76. (in Japa-

nese) [Bruno Bird Island (20°25'31"N, 136°4'11"E), *Pantala flavescens*, 12-17.X.2007] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan. E-mail: paruki@nh-kanagawa-museum.jp

10055. Karube, H. (2007): Occurrence of a new species of the genus *Procordulia* (Anisoptera, Corduliidae) from northern Vietnam. Tombo 50: 47-50. (in English, with Japanese summary) [*Procordulia asahinai* sp. nov. is described from northern Vietnam. "It is related to *P. artemis* Lieftinck, 1930, which has been recorded from high altitude mountain zones of West Malaysia, Sumatra, and Java. But it is distinguished from the latter by the following characters: 1) larger and stouter body, 2) rather robust superior appendages with developed triangular lateral projections in male, 3) longer cerci in female, 4) female valvula valvae with rounded apices. Discovery of this new species demonstrates the expansion of the known distribution limit of *Procordulia* to about 1,800 km north in Asian Continent." (Author)] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan. E-mail: paruki@nh-kanagawa-museum.jp

10056. Karube, H. (2007): On the scientific name of the Japanese name "Kiioharabiro-tombo". Tombo 50: 71-72. (in Japanese) [*Lyriothemis tricolor* Ris, 1916] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan. E-mail: paruki@nh-kanagawa-museum.jp

10057. Kawashima, I.; Sasamoto, A. (2007): Descriptions of the last two instar larvae of *Heliaeschna filostyla* Martin, 1906 (Anisoptera, Aeshnidae, Aeshninae) from Sulawesi Island, Indonesia. Tombo 49: 9-14. (in English, with Japanese summary) ["The external morphology of the last two instar larvae of *Heliaeschna filostyla* from Sulawesi Island, Indonesia are described and illustrated for the first time. The external characters of these last instar larvae are compared with those of two species belonging to the same tribe, *Gynacantha japonica* from the mainland of Japan and *G. ryukyuensis* from the Ryukyu Islands, SW Japan." (Authors)] Address: Kawashima, I., 1-50-9 Nagasawa, Yokosuka, Kanagawa, 239-0842 Japan

10058. Keppner, E.J.; Keppner, L.A. (2007): Dragonflies and Damselflies (Odonata) of the St. Andrew Bay Ecosystem and Bay County, Florida. For: St. Andrew Bay Environmental Study Team, Inc. and Friends of St. Andrew Bay: 14 pp. (in English) ["The St. Andrew Bay ecosystem supports a significant number of species of odonates considering that the collection currently has 49% of the total number of species reported from Florida. The presence of the number of species of odonates is indicative of the variety of aquatic habitats that the area supports. The inventory establishes the presence of a number of species not previously reported from Bay County or the ecosystem (24 Anisoptera and 23 Zygoptera) including Phantom Darner, Swamp Darner, Laura's Clubtail, Gray Petaltail, etc. Keppner and Keppner (in press) provide a list of the new records for Bay County, Florida. The survey extended the range of two species, Everglades Sprite and Phantom Darner in Florida. Collecting will continue in an attempt to document the species listed as possibly occurring in the county and ecosystem. Anyone who collects a specimen of odonate can aid in this endeavour to document the species in Bay County and the St. Andrew Bay ecosys-

tem by depositing the specimen(s) in our collect or another collection that will be available for examination by interested individuals." (Authors)] Address: Keppner, E. J., c/o The St. Andrew Bay Environmental Study Team, PO Box 2465, Panama City, Florida 32402, USA

10059. Kita, H.; Ozono, A. (2007): Notes on the oviposition of a libellulid species, *Brachythemis contaminata* (Fabricius, 1793) in Ishigaki-jima Is., Yaeyama Isis., SW Ryukyus. Tombo 49: 33-34. (in Japanese, with English summary) ["'Contact flying oviposition into water' of *B. contaminata* has been recorded on Ishigaki-jima Is. Oviposition "occurred just after copulation, with females settling on twigs projecting from the water surface or on floating reed leaves. Eggs were attached via the distal abdominal segments onto the surface of these plant materials, as reported by Muraki (1990)." (Authors)] Address: not stated in English

10060. Krassilov, V.; Silantjeva, N.; Hellmund, M.; Hellmund, W. (2007): Insect egg sets on angiosperm leaves from the Lower Cretaceous of Negev, Israel. *Cretaceous Res.* 28: 803-811. (in English) ["Egg set impressions on fossil leaves, a new field of palaeontological research, links insect palaeoecology with that of the host plant. Zygopteran egg sets from the Albian of Makhtesh Ramon, central Negev, Israel, were deposited on narrow leaves of an angiospermous *Acaciaephyllum*-like morphotype. Their pattern resembles the extant and Tertiary "Coenagrionid Type", attesting to evolutionary conservatism of this oviposition mode since the time of early angiosperms. A comparison with the Palaeozoic-Jurassic proto-Odonata egg sets suggests a change in oviposition modes in several steps that can be related to the evolution of wetlands. The Albian remains are among the earliest of a modern aspect supposedly related to the advent of angiosperms. A wetland source community has been previously suggested for *Acaciaephyllum*-like leaves on taphonomic grounds, and the finding of damselfly egg sets provides additional evidence in favour of such a habitat, thus having a bearing on the palaeoecology of Early Cretaceous angiosperms." (Authors)] Address: Krassilov, V., Inst. Evol., Univ. Haifa, Mount Carmel, Haifa-31905, Israel

10061. Lagunov, A.V. (2007): "Red Book" species of invertebrates Ilmen Reserve (south Ural). *Bulletin of the Orenburg State University* 12: 76-82. (in Russian) [Russia; *Calopteryx virgo*, *C. splendens*, *Ischnura aralensis*, *Aeshna viridis*, *Leucorrhinia albifrons* and *Ophiogomphus cecilia* are listed as rare in the reserve.] Address: Lagunov, A.V., Ilmensky state reserve, Ural branch of Russian Academy of Science, Miass, Russia. E-mail: lagunov@ilmeny.ac.ru

10062. Macaulay, D. (2007): Survey of the Odonate Fauna in Kakwa Wildland Park - June - July, 2006. Prepared for the Alberta Natural Heritage Information Centre, Parks Resource Management Coordination Branch, Alberta Tourism, 2nd Floor, Oxbridge Place, 9820 - 106 Street, Edmonton, Alberta T5K 2J6, Canada: 27 pp. (in English) ["A total of 21 odonate species were found during the 2006 survey of the Kakwa WP. ... There may be as many as 52 odonate species that occur in the area. Most of the species recorded for Kakwa WP were common and have wide distributions across Canada. Of the 21 species recorded, 10 are either rare or uncommon. The rare species were *Aeshna septentrionalis* (S1-rank), *Somatochlora forcipata* (S1-rank), and *S. kennedyi* (S1-rank). The uncommon species

were *Aeshna subarctica* (S2-rank), *A. sitchensis* (S3-rank), *S. albicincta* (S2-rank), *S. franklini* (S2-rank), *S. whitehousei* (S2-rank), *S. hudsonica* (S3-rank) and *Enallagma hageni* (S3-rank). The Kakwa WP odonate survey was successful and a wide variety of species were found. The diversity of suitable habitats in the park supports a diversity of odonate species. Future surveys in the park, if conducted over the course of the spring and summer months, would likely add several more species to what is currently known." (Author)] Address: not stated

10063. Matsuhira, K. (2007): A new record of *Sympetrum fonscolombii* from Amami-Ōshima Is., Amami Islands. Tombo 49: 28. (in Japanese) [21-IV-2006, Japan] Address: not stated in English

10064. Matsuhira, K. (2007): The first record of *Rhipidolestes okinawanus* (Asahina, 1951) from Yoro-jima Is., Amami Islands. Tombo 49: 44. (in Japanese) [Japan, 17-VI-2006.]

10065. Móra, A.; Barnucz, B.; Boda, P.; Csabai, Z.; Cser, B.; Deák, C.; Papp, L. (2007): On the macroinvertebrate fauna of inflows of Lake Balaton. Acta biol. Debrecina Oecol. Hung. 16: 105-167. 10075. Shimizu, N. (2007): A record of nocturnal oviposition in *Boyeria maclachlani* (Selys) (Aeshnidae: Brachytroninae). Tombo 50: 74-75. (in Japanese, with English summary) ["Nocturnal oviposition behaviour was observed for the first time in *Boyeria maclachlani*. I observed a female of this species to lay eggs from 18:45 to 20:35 in August 21, 1995 (Sunset Time: 18:36 PM). Next year and later, I observed 16 females to lay eggs at nighttime: a latest example among them lasted until 21:05 on August 13, 2000 (Sunset Time: 18:44 PM)."] (Author)] Address: not stated in English

10076. Shivakumar, K.N.; Lingaiah, S. (2007): Ultra lightweight materials for bio inspired microsystems. 16th International Conference on Composite Materials kyoto, Japan: 7 pp. (in English) ["Ultra lightweight nanofiber fabrics play a vital role in the development of Microsystems. Polyacrylonitrile, polybenzimidazole and Nylon-66 polymer based ultra lightweight nanofiber fabrics were produced using electrospinning technique. SEM characterization showed that the diameter of Nylon-66 nanofibers varied from 50-300 nm. The average modulus and strength of Nylon-66 nanofiber fabric was 2.4 GPa and 154 MPa respectively. An attempt to build dragonfly's wing using carbon fiber as grid and electrospun fabric as skin was made. Three types of phenomenological dragonfly wings such as carbon fiber grid, electrospun Nylon-66 nanofiber fabric bonded carbon fiber grid and commercial Nylon-6 film bonded carbon fiber grid were made. The flexural stiffness to weight ratio of electrospun Nylon-66 fabric bonded wing was 160% higher than that of commercial Nylon-6 film bonded wing. This shows the potential application of ultra lightweight electrospun nanofiber fabric for building Microsystems." 10079. Verberk, W.C.E.P.; Kuper, J.T.; Lamers, L.P.M.; Christianen, M.J.A.; Esselink, H. (2007): Restoring fen water bodies by removing accumulated organic sludge: what are the effects for aquatic macroinvertebrates?. Proc. Neth. Entomol. Soc. Meet. 18: 115-124. (in English) [Only *Pyrrhosoma nymphula* and *Erythromma najas* are mentioned. They are associated with dredged water bodies. "Pristine freshwater fens harbour many species of aquatic macroinvertebrates. Effects of eutrophication and desiccation have strong negative impacts on macroinvertebrate assemblages. To restore degraded fens, the removal of accumulated organic sludge by dredging seems a necessary step. However, degraded fens may harbour relic populations of rare and characteristic species as was found for raised bogs and shallow soft water lakes. This study investigates the effectivity of dredging by comparing dredged and undredged water bodies in two areas (SW & MP). To help interpret the observed differences, a third least impacted area is sampled in addition (WD). Abiotic conditions clearly differed between areas, but when comparing dredged and undredged water bodies, only turbidity was lower in dredged water bodies. Coverage of submerged vegetation was higher in dredged water bodies, especially in MP. For aquatic macroinvertebrates, strong differences between dredged and undredged water bodies were found for both SW and MP. Dredged water bodies in MP resembled WD most strongly, in abiotic conditions, vegetation, and invertebrates. Nevertheless, a number of species commonly occurring in WD were mainly associated with undredged water bodies, indicating incomplete restoration of certain key factors. Results indicate that dredging contributes to ecological restoration of fens. To maximise effectiveness of dredging, internal and external supply of nutrients should be minimized, removal of organic sludge should be near-complete, while retaining small patches of vegetation and recesses as sources of individuals to facilitate recolonisation. Furthermore, this study shows that taking fauna into account can yield new information which is not uncovered by researching solely abiotic conditions and vegetation. In contrast to raised bogs and shallow soft water lakes, no relic populations of rare and characteristic species were found in degraded, undredged fen water bodies. These differences may be related to differences in ecosystem functioning, with characteristic fen species having a lower persistence and a higher recolonisation rate." (Authors)] Address: Verberk, W. 10082. Zhou, Z.-h. (2007): Taxonomic and faunistic studies on the superfamily Calopterygoidea from China (Odonata: Zygoptera). *Special Zoology*, Institute of Entomology, Guizhou University, Guiyang, China: VII + 80 pp. (in Chinese, with English summary) ["The present dissertation is a systematic study on the superfamily Calopterygoidea from China. It mainly deals with the morphology, taxonomy and faunal analysis of the Chinese Calopterygoidea. Totally 4 families, 20 genera and 84 species are treated in the taxonomic part, of which 2 new species and 1 first female record are described: 1 new combination is proposed as well. The new taxa are listed as follows: New species: *Mnais leigongshanus* sp. nov., *Bayadera unimaculata* sp. nov.; new combination: *Rhinocypha maolanensis* (Zhou and Bao, 2002) comb. nov.; first female record: *Rhinocypha maolanensis* (Zhou and Rao, 2002) comb. nov. The faunal structures of the Chinese Calopterygoidea at generic and specific levels were examined. 20 known genera only constitute 3 types of distribution in zoogeographic regions in the world. Among them, 12 genera are distributed in Oriental region, which make up 60%. while 7 genera in Oriental + Palaearctic region, accounting for 35%. 20 genera in total distribute in Oriental region, accounting for 100%. It is clear that Oriental genera make up the majority of the Chinese Calopterygoidea at genera level. 84 known species of Chinese Calopterygoidea are mainly distributed in Oriental region, in which the number of species makes up 83.33% of Chinese species in total. All the known species constitute 16 types of distribution in seven Chinese zoogeographic sub-regions. Among them, 16 species are present only in Central China sub-regions, 15 in South China sub-regions, 10 in Central China + South China sub-regions, 9 in Southwest China sub-regions, 9 in Southwest China + South China sub-regions, 8 in Central China + South China + Southwest China sub-regions, accounting for 19.05%, 17.86%, 11.90%, 10.71%, 10.71% and 9.52%, respectively. It is obvious that Oriental species make up the majority of Chinese Calopterygoidea at species level and they distribute mainly in Central China and South China sub-regions." (Author) "Please note that this thesis may not constitute a published work in terms of Article 8 of the CODE. So, the two new species group names are not yet available names and should not be included in catalogues. Moreover, Haomiao Zhang and I have some doubts of their status as valid species." 10084. Borisov, S.N. (2008): Anthropogenic influence on the dragonfly fauna (Odonata) in an oasis of Pamir-Alai. *Siberian Journal of Ecology* 15(1): 43-52. (in Russian, with English summary) ["Development of irrigation in the plains around the Pamir-Alai caused the formation of new habitats for Odonata: numerous water bodies of artificial irrigation systems which are unique in the hydrological regime. They serve as the main and often sole biotopes for the larvae. Thus, a number of initially mountainous rheophil and eurytopic oxyphilic species became able to adjust to the desert zone when warm water flows - channels and aryks - appeared there. The mountainous and boreomontan limnophilic species survive the least anthropogenic action. The negative anthropogenic action is connected with the disappearance or change of natural biotopes of dragonflies. It is essential in the submountain zone for stenoecic obligate rheophilic and hemerophobic species that do not populate artificial water flows." (Author)] Address: Borisov, S., Institute of Systematics and Ecology of Animals, Russian Academy of Sciences, Siberian Branch, Frunse str. 11, Novosibirsk 630091 Russia. 10086. Cannings, R.A. (2008): Grassland dragonflies. *BC Grasslands (Summer 2008)*: 15-17. (in English) ["Wherever grasslands are punctuated by ponds, marshes or lakeshores, dragonflies can be abundant. While they usually fly or perch around the edge of water bodies, many also move far into the dry, grassy landscape, especially when they are hunting for prey or when young adults are awaiting sexual maturity. [...] Of the 87 species known in British Columbia, Canada at least 50 can be found around grassland waters, although not all of these are common or widespread. [...] There is no specialized dragonfly fauna in BC grasslands. The species that occur in the grasslands are the same as those found in marshes and on pond edges in other ecosystems around the province. However, some dragonflies are more often found in grassland waters than are their close relatives, and a few are able to withstand the high salinities of alkaline ponds, typical of many of our dry grassland habitats." (Author) Following this introduction, the paper introduces typical Odonata family wise.] Address: Cannings, R.A., Royal British Columbia Mus., 675 Belleville Street Victoria, British Columbia V8W 9W2. 10087. Cooper, I.A. (2008): Ecological causation of sex differences and a female-limited dimorphism in Hawaiian damselflies. PhD thesis, Faculty of the University Graduate School, Dept of Biology, Indiana University: VI + 98 pp + app. (in English) ["Evolution theory posits that sexual selection, more so than natural selection, drives sex differences, such as bright males and intersexual mimicry. However, female-limited dimorphism has not been fully explained by sexual selection even though this phenomenon includes what appears to be intersexual mimicry of bright males. This dissertation presents evidence that natural selection over an eco-

logical gradient may explain sexual dimorphism and female-limited dimorphism in a damselfly species, as well as macroevolutionary patterns of sexual dimorphism throughout a damselfly genus. I documented new cases of female-limited colour dimorphism in the endemic Hawaiian *Megalagrion* damselflies. Two species, *M. calliphya* and *M. hawaiiense*, contain a typical, green female morph (gynomorph) as well a red female morph (andromorph) that is similar in colour to the males. In *M. calliphya*, I describe habitat differences between the sexes and patterns of colour variation in males and females over an elevational gradient on Hawaii Island that varies in temperature and solar radiation. Using transplant experiments, I determined that body temperature does not differ between the female morphs according to hue, although it is affected by body brightness. Therefore, environmental temperature is not a selective agent on the female-limited dimorphism. However, solar radiation may select for red individuals, including andromorphs, under exposed conditions. A comparison of antioxidant ability between the female morphs as well between males over an elevational gradient indicated that red pigmentation is an effective antioxidant that may enable red individuals to exist where free radicals are produced from high radiation levels. Finally, I extend the ecological explanation for the female-limited dimorphism to patterns of sex differences throughout the *Megalagrion* genus as well a case of female-limited dimorphism in a distantly related species (*Nehalennia irene*). 10093. Shivakumar, K.N.; Lingaiah, S.; Sadler, R.L. (2008): Ultra lightweight material for building microsystems. American Institute of Aeronautics and Astronautics: 8 pp. (in English) ["Electrospinning technology was used to produce ultra lightweight nanofiber fabrics from Nylon-66. The fiber diameter ranged from 50-300 nm depending on the collector speed, polymer concentration, distance, and the voltage. Tensile properties were conducted using a specially designed test specimen and fixture, and micro tension test machine. The average tensile modulus and strength were 960 MPa and 60.7 MPa, respectively, which are 6 to 10 times higher than those reported in the literature. This nanofiber fabric was used as a membrane to construct a dragonfly wing from a carbon grid. The specific flexural stiffness to nanofiber fabric wing was 260% of commercial Nylon-6 film wing. This study demonstrates a potential application of using electrospun nanofiber fabrics for microsystems." Mahony (eds): Proceedings of the 2008 Australasian Conference on Robotics & Automation, December 3 - 5, 2008, Canberra, Australia. ISBN 978-0-646-50643-2: 6 pp. (in English) ["This paper focuses on the design of an electro-mechanical device for studying the aerodynamic behaviour of flapping wings. The experimental device is designed to mimic the flight behaviour of dragon fly. Wing flapping speed is precisely controlled by controlling the motor speed. Wing flapping amplitude could be varied by changing the rotating arm length. Wing rotation amplitudes during down- and up- stroke could be different and are controlled separately by two different springs. A six degree of freedom sensor is placed at the wing root to collect the force and torque data. The test of a wing with a dragonfly hind-wing contour but enlarged 11 times, showed the device met the

design expectation, and further more, the phase-averaged data for lift force in one flapping cycle had the similar pattern as the ones obtained via CFD simulations as well as the one calculated based on a real dragonfly's flight behaviour." (in English) ["Phylogenies of major groups of insects based on both morphological and molecular data have sometimes been contentious, often lacking the data to distinguish between alternative views of relationships. This paucity of data is often due to real biological and historical causes, such as shortness of time spans between divergences for evolution to occur and long time spans after divergences for subsequent evolutionary changes to obscure the earlier ones. Another reason for difficulty in resolving some of the relationships using molecular data is the limited spectrum of genes so far developed for phylogeny estimation. For this latter issue, there is cause for current optimism owing to rapid increases in our knowledge of comparative genomics. At least some historical patterns of divergence may, however, continue to defy our attempts to completely reconstruct them with confidence, at least using current strategies." (Authors) The Palaeoptera problem (Odonata, Ephemeroptera, and their extinct stem lineages, along with the extinct Palaeodictyoptera) is discussed in detail.] Address: Whitfield, J.B., Department of Entomology, University of Illinois, Urbana, Illinois 61821, USA. 10098. Amoroso, N.A.; Chalcraft, D.R. (2009): PS 78-28: Effects of dragonfly colonization history on the biodiversity of aquatic communities. The 94th ESA Annual Meeting (August 2 - 7, 2009) (in English) [Verbatim: "Background/Question/Methods: It is clear that current interactions among species in a system can have an important role in controlling the biodiversity of that system. Some studies, however, have shown that the timing of species arrival to a community could influence the strength of species interactions within ecological communities. Such priority effects should be important in frequently disrupted environments, such as temporary ponds, which provide opportunities for new collec-

tions of species to colonize the refilled pond. In temporary ponds, the top predators are often larval dragonflies but their presence is dependent, in part, on the timing in which adult dragonflies find and oviposit in the pond. We tested the hypothesis that the biodiversity of aquatic invertebrates present in temporary ponds is influenced by the arrival time of larval dragonflies. Specifically, we hypothesize that ponds with early-arriving dragonflies will have a lower biodiversity of aquatic insects compared to ponds where dragonfly colonization is continuously inhibited or where dragonflies arrive late in the summer. To test this hypothesis, we experimentally altered the timing in which dragonflies could oviposit eggs into artificial ponds (modified stock tanks). After a four month period, the insect biodiversity of each pond was sub-sampled and quantified. Results / Conclusions: We found that ponds allowing early dragonfly colonization produced more metamorphosed dragonflies than ponds preventing early dragonfly colonization. Preliminary results suggest that ponds with only late-arriving dragonflies had more late-instar dragonflies than ponds always allowing dragonfly colonization. The fewest late-instar dragonflies were found in ponds with only early-arriving dragonflies. Hence, early-arriving dragonflies appear to inhibit late-arriving individuals. In addition, dragonfly oviposition caused differences in insect communities among ponds, yet dragonfly arrival time does not influence total insect species richness in ponds. We found that ponds which prevented dragonfly colonization had greater beetle species richness than ponds allowing dragonfly colonization but dragonfly arrival time did not influence beetle richness. Total abundance of beetles did not vary among treatments. Trends indicate that chironomid abundance is greatest in ponds with only late-arriving dragonflies and least in ponds where dragonflies can continuously oviposit. These results suggest predatory dragonflies have important effects on insect assemblages in ponds. The timing of dragonfly arrival, however, seems to play an important role in influencing the abundance of some taxa (e.g., dragonflies or flies) but did not affect the abundance or biodiversity within other taxa (e.g., beetles) or in the number of insect species found." 10100. Baker, R.L.; McGuffin, M.E. (2009): Technique and observer presence affect reporting of behaviour of damselfly larvae. *Jl N. Am. benthol. Soc.* 26(1): 145-151. (in English) ["We experimentally tested for systematic biases in techniques commonly used to study behaviour of larval aquatic insects. We determined whether larval Zygoptera responded to the presence of an observer and whether live observation missed some behaviours. We found significant differences between behaviours recorded during live observations and behaviours videotaped in the absence of an observer. All behaviours, except Rotate, were exhibited less frequently in the presence of an observer. These results suggest that larvae respond to the presence of observers as if they were predators. Live observation also missed some behaviours. The duration of Crawl For-

ward, which can be very subtle, and the frequency of Rotate, which can be very rapid and is easily missed, were greater when recorded from the videotape than by a live observer. Wherever possible, use of video recording systems is preferable over reliance on live observations." (Authors)] Address: Baker, R.L., Dept Ecol. & Evol. Biol, Univ. Toronto, Mississauga, ON, M5S 3B2. 10103. Chaput-Bardy, A.; Fleurant, C.; Lemaire, C.; Secondi, J. (2009): Modelling the effect of in-stream and overland dispersal on gene flow in river networks. *Ecological Modelling* 220(24): 3589-3598. (in English) ["Modelling gene flow across natural landscapes is a current challenge of population genetics. Models are essential to make clear predictions about conditions that cause genetic differentiation or maintain connectivity between populations. River networks are a special case of landscape matrix. They represent stretches of habitat connected according to a branching pattern where dispersal is usually limited to upstream or downstream movements. Because of their peculiar topology, and the increasing concern about conservation issues in hydrosystems, there has been a recent revival of interest in modelling dispersal in river networks. Network complexity has been shown to influence global population differentiation. However, geometric characteristics are likely to interact with the way individuals move across space. Studies have focused on in-stream movements. None of the work published so far took into consideration the ability of many species to disperse overland between branches of the same network though. We predicted that the relative contribution of these two dispersal modalities (in-stream and overland) would affect the overall genetic structure. We simulated dispersal in synthetic river networks using an individual-based model [using *Calopteryx splendens*]. We tested the effect of dispersal modalities, i.e. the ratio of overland/in-stream dispersal, and two geometric parameters, bifurcation angle between branches and network complexity. Data revealed that if geometrical parameters affected population differentiation, dispersal parameters had the strongest effect. Interestingly, we observed a quadratic relationship between p the proportion of overland dispersers and population differentiation.

We interpret this U-shape pattern as a balance between isolation by distance caused by in-stream movements at low values of p and intense migrant exchanges within the same branching unit at high values of p . Our study is the first attempt to model out-of-network movements. It clearly shows that both geometric and dispersal parameters interact. Both should be taken into consideration in order to refine predictions about dispersal and gene flow in river network.] Address: Chaput-Bardy, Audrey, Laboratoire Paysages et Biodiversité, UFR Sciences, 2 Bd Lavoisier, 49045 Angers cedex 01, France. 10105. de Araujo, N. A. de; Pinheiro, C.U.B. (2009): Ecological relations between the ichthyologic fauna and the ciliary vegetation of the lacustrine area of Low Pindaré River in the Baixada Maranhense Region and their implications on the sustainability of regional fishing. *Boletim do laboratório de hidrobiologia* 22: 55-68. (in Portuguese, with English summary) ["The lacustrine area of Penalva, in the Baixada Maranhense region, is formed by the lakes Cajari, Capivari, Lontra and Formoso, which encompass a diversified ciliary vegetation. Those environments, subject to the influence of seasonal floods, provide a variety of habitats for shelter, reproduction and feeding of fish species. Some of the fish species, as they feed from fruits and seeds from ciliary plant species they help in the process of seed dispersion, contributing to the reproductive success of the plants. This research aimed at studying the relationship between the ichthyologic fauna of the lacustrine area of Penalva and the ciliary vegetation and its implications in the sustainability of the regional fishing. More specifically, to analyze the relationship among the different plant species and the reproductive period, feeding habits and shelter of the fish species, investigating which species are dependent on the ciliary vegetation and which species function as seed dispersers. The methodology included, in a first phase, interviews with fishermen (key informants), by using semi-structured questionnaires, to record the traditional knowledge on fish and vegetation. In a second phase, monthly collections of fish specimens from the lakes Cajari and Capivari were carried out in the period April, 2007 to June, 2008; following the collections, the specimens were taken to laboratory analyses. The results showed that fishermen possess a vast knowledge on the relationship between the ichthyofauna and the regional ciliary vegetation, making clear the dependence between fish and plants. In this study eleven fish species were identified as seed dispersers of eleven ciliary plant species. In the rainy season, when extensive vegetation areas are flooded, the biggest number of fish specimens was recorded with full stomachs, as well as the biggest number of males and females in the maturation phase, confirming the importance of the ciliary forests for the ichthyofauna." (Author) Odonata are treated at the order level.] Address: Pinheiro, C.U.B., to de Oceanografia e Limnologia, Av. dos Portugueses s/n, Campus do Bacanga, CEP 65080-040, São Luís-MA, Brazil. 10107. Geraeds, R.P.G. (2009): De Gaffellibel langs de Vlootbeek. *Natuurhistorisch Maandblad* 98(6): 121-125. (in Dutch, with English summary) ["The green Snaketail along de Vlootbeek brook: discovery of the third dutch population in a canalised brook. On 3 May 2008, twelve larvae of *Ophiogomphus cecilia* were caught along the upper stretches of the Vlootbeek brook in Posterholt (NL), near the German border. Two more larvae were caught in the German Kitschbach brook, which is connected to the Vlootbeek. In the course of July, 18 exuviae were found along the Vlootbeek. This brook is the third location in the Netherlands where this species has been found, the other two being the Roer and Swalm rivers. Both are large, naturally meandering streams, whereas the Vlootbeek is a canalised brook. At the sites where the finds were made, the brook is 1 to 1.5 m wide and 10 to 30 cm deep. The water quality is not too good, as it contains high levels of sulphate, nitrate, phosphate, copper and nickel. The oxygen level is favourable, however. Almost all of the larvae and exuviae were found along a 300 m stretch of the brook, where the substrate is dominated by sand that locally contains grit. Upstream and downstream of this location, the substrate was covered with algae in May, while the substrate further downstream is dominated by silt, making these stretches of the Vlootbeek unsuitable for the larvae of the Green Snaketail. The algae had disappeared in July. Although the occurrence of the Green Snaketail is normally associated with larger natural rivers and brooks, we now find that the species also occurs in small, canalised streams with a mediocre water quality. The oxygen level appears to be an important factor for the larvae of this species. The other two locations where this species has been found, the Roer and Swalm rivers, are also characterised by relatively poor water quality (with high levels of nutrients) but favourable oxygen levels." (Author) Larvae also were found in the near situated Kitschbach (Nordrhein-Westfalen, Germany).] Address: Geraeds, R.P.G., Bergstraat 70, 6131 AW Sittard, The Netherlands

10108. Groppali, R. (2009): Odonati europei e riscaldamento globale. *Studi Trent. Sci. Nat.*, 86: 115-118. (in Italian, with English summary) ["European Odonata and

global warming - Odonata used as biological indicators can give data about global warming: some species can fly over long distances and quickly respond to environmental changes. In Europe the consequences of this phenomenon could be: dominance of southern origin species in areas with continental climate (e.g. actually in north-western Germany the dominant species are mediterranean), northward expansion of occupied areas (e.g. in Lombardy are increasing 7 southern species, and 16 in Europe) or displacement to higher altitudes in the mountains, local extinction of relict mountain populations, living in south-European territories with isolated populations, or of microthermic species in plain territories, with 7 threatened species, phenological modifications (larval life length and adult emergence moment, flight times, perhaps passage from mono- to bivoltinism). If also some elements can disturb the analysis, e.g. the increase of suitable habitat for some expanding species, the available data examination, including recent studies in southern Sardinia, confirms the variations originated from climatic warming in Europe, also with the recent colonisation of 4 African species." 10109. Karube, H. (2009): Present status of Odonata species at Ogasawara Islands and conservation effort to preserved endangered endemic species. *Japanese journal of limnology* 70(3): 239-245. (in Japanese) ["The five endemic species of Odonata inhabiting the oceanic islands of Ogasawara have been rapidly declining from the mid-1980s. The reason for that decline is likely due to predation by an invasive alien species, 'green anoles'. Currently, almost all the endemic Odonates have gone extinct from the main islands of Chichi-jima and Haha-jima. Although these endemic Odonates have still managed to survive in a few satellite islands, there are only small aquatic habitats which readily dry up when severe droughts hit Ogasawara. Our recent efforts to construct artificial conservation ponds in these satellite islands appear to be effective. Three endemic species are currently breeding in those ponds, and the total population has increased. Based on these encouraging results, we continue to stress the importance of an integrated action plan, including the development of areas protected from green anoles predation and the construction of more permanent ponds." 10117. Obolewski, K.; Strzelczak, A. (2009): Epiphytic fauna inhabiting *Stratiotes aloides* in a new lake of the Slowiński National Park (Smoldzińskie lake, Poland). *Ecology & Hydrobiology* 9(2-4): 257-267. (in English) ["Qualitative and quantitative structure of phytophilous macrofauna inhabiting *Stratiotes aloides* L. have been studied in a newly formed Smoldzińskie Lake in the area of the Slowiński National Park during vegetation period (V-IX) in year 2008. Jointly 27 taxa (including *Aeshna grandis* and *Calopteryx* sp.) inhabiting the studied plant species were identified and their number varied in time. The highest amount of epiphytic fauna taxa was observed in June (22) and September (20) while the lowest in August (13). The quality of lake waters significantly influenced both density and biomass of fauna inhabiting and mining the leaves of water soldiers. On the basis of qualitative and quantitative structure of epiphytic fauna, the quality of lake waters was assessed, which - according to BMWP-PL index - corresponded to class III. The analyses of benthofauna inhabiting pleustonic vegetation, as a part of biomonitoring, seem to complete the ecological assessment of aquatic ecosystems." 10121. Sadeghi, S.; Mohammadalizadeh, J. (2009): Additions to the Odonata fauna of Iran. *Iranian Journal of Science & Technology, Transaction A*, Vol. 33, No. A4: 355-359. (in English) [Forty eight species of Odonata from 46 sampling sites in Iran were recorded bet-

ween early May 2001 to mid June 2002. *Libellula fulva*, *Sympetrum sinaiticum*, and *Paragomphus sinaiticus* are recorded from Iran for the first time.] Address: Sadeghi, S., Department of Biology, College of Sciences, Shiraz University, Shiraz, Iran

10122. Schaik, V.A. van; Geraeds, R.P.G. (2009): The emergence period of the *Gomphus vulgatissimus* - A three year study along the river Roer, The Netherlands. *Natuurhistorisch Maandblad* 98(8): 153-158. (in Dutch, with English summary) ["From 2001 to 2003, a 150 m stretch of the river Roer was examined to analyse some aspects of the emergence period of *G. vulgatissimus*. Exuviae were collected every other day, from the start till the end of the emergence period. During these three years, 1585 exuviae were collected: 385 in 2001, 510 in 2002 and 690 in 2003. The emergence period seems to be very constant over the years, lasting 31 to 35 days. It took 8(9) to 11(12) days (average 9) for 50% of the population to emerge (EM50). The overall sex ratios in 2001, 2002 and 2003 were 1.0 (49.9% females), 0.7 (57.3% females) and 0.8 (55.2% females), respectively. The sex ratios changed during the emergence period. From the start of emergence until the moment when EM50 was reached, the sex ratios were 1.5 (40.6% females), 1.1 (48.4% females) and 0.9 (52.5% females) in 2001, 2002 and 2003, respectively. During the period from EM50 until the end of emergence, the sex ratios were 0.6 (63.5% females), 0.4 (71.6% females) and 0.7 (59.2% females), respectively. The predominance of females in this period was significant in all three years." (Authors)] Address: Schaik, V.A. van, Hoosveld 56, 6075 DB Herkenbosch, The Netherlands

10123. Seemann, R. (2009): Otto le Roi (1878 - 1916) – Zoologe aus Leidenschaft. *Archiv der Freunde der Naturgeschichte in Mecklenburg XLVIII*: 5-70. (in German, with English summary) [Otto le Roi was one of the most profiled German odonatologists in the early 20th century with an extraordinary broad knowledge in many zoological groups. "Correspondence can give information about people's lives and about contemporary history. Both aspects can also be taken from the correspondence between the Mecklenburger Otto Hermann Held (1875 - 1945) and the Rhinelander by choice, Otto August le Roi (1878 -1916). 214 letters and cards from Otto le Roi dating from between 1899 and 1916 have survived in the scientific inheritance of the apothecary and ornithologist Otto Held, kept in the archives of the federal state natural history collections at the MÜRITZEUM in Waren. The paper concerned here centres on the versatile zoologist Dr. Otto le Roi, whose promising scientific career as assistant to the Bonn zoologist Professor Alexander Koenig ended at the eastern front in the First World War in October 1916. With the aid of further records and publications, an attempt has been made to trace the short life of le Roi, who initially in 1896 started training to become an apothecary. Scientific curiosity that became evident at an early stage and a special passion for ornithology influenced his further development. He made contact with numerous notable scientists in order to learn and to gain ideas for his scientific work. Two personalities had a formative influence on the life of le Roi: Johannes Thienemann and Alexander Koenig. Le Roi made the acquaintance of Thienemann, who was in charge of the ornithological station at former Rossitten, during a fairly long stay on the Kurische Nehrung (Courland Spit) in 1902. Professor Alexander Koenig became le Roi's teacher, mentor and fatherly

friend in Bonn. As assistant at the Koenig Museum and a member of the Deutsche Ornithologische Gesellschaft (German Ornithological Society), the zoologist le Roi, who had meanwhile received a doctorate, was given the possibility of working with the most notable zoologists of that time. The war, however, put an end to this promising research scientist existence." (Author) Le Roi has written 12 papers and notes referring to Odonata. Some of these papers belong to the most cited German odonatological papers.] Address: Seemann, Renate, Naturhistorische Landessammlung im MÜRITZEUM Waren, Zur Steinmole 1, 17192 Waren, Germany

10125. Wang, Y.; Kalyanasundaram, S.; Young, J. (2009): Effects of angle-of-attack on lift and thrust. Experimental study via test apparatus with passive wing rotation. *Proceedings of the 6th WSEAS International Conference on FLUID MECHANICS (FLUIDS'09)* ISSN: 1790-5095: 126-139. (in English) ["This paper focuses on the effect of mean angle-of-attack (AOA) on aerodynamic forces of flapping wings. The study was conducted with the aid of a test bench, which provided an active flapping motion in a vertical stroke plane and meanwhile a passive rotating motion about the longitudinal axis of the tested wing having the planform of a dragonfly's hindwing. AOA effect was studied together with the wing stiffness effect using Taguchi's DOE method in order to extract the major effects with minimum expenditure both in labor and time. The experimental results indicated that during downstroke, the lift decreased with the decreasing of the overall AOA monotonically, but thrust increased. However, during upstroke, the relationship between the effects of mean AOA and aerodynamic forces were not monotonic: larger and smaller AOAs were beneficial to the lift; smaller AOA was detrimental to the thrust; and the effect of larger AOA on thrust was close to the one caused by medium AOA." Aliberti Lubertazzi, M.A.; Ginsberg, H.S. (2010): Emerging dragonfly diversity at small Rhode Island (U.S.A.) wetlands along an urbanization gradient. *Urban Ecosystems* 13(4): 517-533. (in English) ["Natal habitat use by dragonflies was assessed on an urban to rural land-use gradient at a set of 21 wetlands, during two emergence seasons (2004, 2005). The wetlands were characterized for urbanization level by using the first factor from a principal components analysis combining chloride concentration in the wetland and percent forest in the surrounding buffer zone. Measurements of species diversity and its components (species richness and evenness) were analyzed and compared along the urbanization gradient, as were distributions of individual

species. Dragonfly diversity, species richness, and evenness did not change along the urbanization gradient, so urban wetlands served as natal habitat for numerous dragonfly species. However, several individual species displayed strong relationships to the degree of urbanization, and most were more commonly found at urban sites and at sites with fish. In contrast, relatively rare species were generally found at the rural end of the gradient. These results suggest that urban wetlands can play important roles as dragonfly habitat and in dragonfly conservation efforts, but that conservation of rural wetlands is also important for some dragonfly species." 10132. Bonifait, S.; Villard, M.-A. (2010): Efficiency of buffer zones around ponds to conserve odonates and songbirds in mined peat bogs. *Ecography* 33(5): 913-920. (in English) ["Patch isolation resulting from habitat loss and fragmentation generally has detrimental effects on associated species. Peatlands may be especially sensitive to such effects because peat mining results in drastic changes in the hydrology of natural remnants. This study aimed to assess the efficiency of conservation zones surrounding ponds in mined bogs for two taxa: songbirds and odonates. We compared songbird distribution and odonate assemblages between ponds isolated by peat mining (n=6-12) and control ponds (n=11-13) located in natural bogs. Birds did not show major responses to pond isolation, whether in terms of their relative abundance or reproductive activity. However, longer-term data would be required to confirm this trend. In contrast, odonate abundance, as estimated from exuviae, was higher in natural ponds than in isolated ones. Some taxa, especially bog specialists, were more sensitive than others. Hence, pond isolation by peat mining significantly altered the structure of odonate assemblages. Pond size also influenced odonate abundances and distribution. Effective conservation of bog ponds should account not only for variations in the response of different taxa, but also for pond structural diversity, which influence species response to isolation." 10133. Borisov, S.N. (2010): Geographic variations in the life cycle of *Sympecma paedisca* (Brauer, 1877) (Odonata, Lestidae) in the plains of Central Asia. *Euroasian entomological journal* 9(2): 249-254. (in Russian, with English summary) ["Latitudinal changes in life cycle of *Sympecma paedisca* from forest-steppe zone of South Siberia (53° N) to deserts of Tadjikistan depression (37° N) are shown. The species is univoltine with long-term imaginal period, including aestivation and hi-

bernation. To the south, the reproductive period of the species is moderately extended and moved to spring-time. Latitudinally there is a more significant change in the ratio of aestivation and hibernation period duration. In the northern part, the areal time from exclusion to imago wintering covers less than 3 months and the imago winters for 7 months, while in southern part these periods last 6 and 4 months respectively. During the pre-reproductive period dragonflies make bidirectional migrations. Aestivation appeared far from where the imago emerged from its pupa, but the wintering imago returns to these habitats. In the plains (forest-steppe) of Siberia, dragonfly migrations are shorter than in central Asia. Dragonflies from the former, after emergence, move to the mountains for the whole summer period, and return to the plains in late autumn. This strategy avoids the high summer temperatures experienced in the central Asian plains. However, some dragonflies remain in the plains throughout the summer in habitats from where they emerged from their pupae." (Author)] Address: Borisov, S.N., Siberian Zoological Museum, Institute of Systematics and Ecology of Animals, Russian Academy of Sciences, Siberian Branch, Frunze str. 11, Novosibirsk 630091 Russia.

10134. Boudot, J.-P. (2010): Abondance, synchronisme et sex-ratio à l'émergence chez *Epitheca bimaculata* (Charpentier, 1825) en Lorraine (NE France) (Odonata, Anisoptera: Corduliidae). *Martinia* 26(1-2): 9-17. (in French, with English summary) ["Population size in *Epitheca bimaculata* varies considerably with space and time in Lorraine (northeast France). However, emergences are always synchronized with an EM50 index ranging from 4 to 6 days, irrespective of the population size. The daily sex ratio (male to female ratio) shows a constant imbalance in favour of females throughout the emergence time, with values ranging from 0.59 to 0.97 and an overall value of 0.74 at the end of emergence (i.e. 42% of males, 58% of females). These results are compared to published data from other countries and the reasons for such a constant imbalance in sex ratio are discussed. The hypotheses of i) a segregation of male and female according to banks orientation, ii) a differential phenology between males and females, do not account for such an imbalance, which is a frequent trend in Anisoptera, particularly Corduliidae." 10138. Collier, A.; Nair, V.; Taylor, S.; Zettler, J. (2010): Apparent risk of predation by dragonfly naiads (Odonata: Libellulidae) inhibits tadpole growth (*Rana sphenoccephala*). *BIOS* 81(2): 45-54. (in English) ["We reared 120 *Rana sphenoccephala* tadpoles in 1.5 m long chambers (10 tadpoles per chamber) made from vinyl rain gutters. The chambers contained predatory late-instar dragonfly naiads (Odonata: Libellulidae) confined at one end in clear tubes drilled with aeration holes. The number of confined predators varied between control ($n = 0$), low ($n = 1$), and high density conditions ($n = 5$). Tadpoles were free to swim throughout each chamber, although food was isolated at one end adjacent to the predator tubes. In an additional high density predator condition, food was isolated at the opposite end of the chamber away from the predator tubes. There were a total of three replicates for each of the four conditions. Tadpoles from each condition were individually weighed (g) and their total length (mm) was recorded at regular intervals throughout the trial. Tadpoles raised in the high density condition with multiple predators surrounding their only food source were significantly shorter in length and weighed significantly less than those reared in all other conditions. When multiple predators and larval food were isolated at opposite ends of the chamber, tadpole growth did not statistically differ from that of control animals. Tadpoles raised with multiple predators surrounding their food also possessed slightly deeper tails, although these results were not statistically significant. Our results suggest that the inhibition of tadpole growth observed in this study may be linked to behavioral changes when perceived predation risks are high." (Authors)] Address: Collier, A., Dept Biology, Armstrong Atlantic State Univ., 11935, Abercorn Street, Savannah, GA, 31419, USA. E-mail: alex.collier@armstrong.edu

10139. Curtis, A.E.; Paton, P.W.C. (2010): Assessing detection probabilities of larval amphibians and macroinvertebrates in isolated ponds. *Wetlands* 30(5): 901-914. (in English) ["Isolated ponds provide vital habitat for an array of vertebrates and invertebrates (including Libellulidae, excluding Damselflies). Given the potential decline in protection of isolated ponds and the increase in urbanization in northeastern North America, knowledge of the condition of this aquatic resource is essential for developing revisions to existing regula-

tions, conservation efforts, and restoration initiatives. We were interested in the ability of rapid assessment methods, which require only one site visit, to estimate the condition of isolated ponds. During 2008, we conducted dip-net surveys at 10-day intervals from mid-May to late July 2008 at each of 36 isolated ponds in Rhode Island. We calculated detection probabilities for larval amphibian species and predatory macroinvertebrate families and assessed factors influencing detection probabilities. Most taxa displayed distinct seasonal phenologies in detection probabilities. Pond depth and vegetative characteristics also influenced detection probabilities of many taxa. Based on seasonal variation in detection probabilities, rapid assessment methods would not be effective to monitor overall biodiversity of isolated ponds in southern New England. Rather, multiple visits would be required to estimate occupancy rates of pond-breeding amphibians or aquatic macroinvertebrates if they were used as ecological indicators of pond condition." 10142. Dlugolecki, L. (2010): A characterization of seasonal pools in Central Oregon's high desert. MSc Thesis, Oregon State University: XIV + 76 pp. (in English) ["Seasonal wetlands in arid and semi-arid lands provide an important source of surface water in otherwise dry lands. Central Oregon's high desert, located in the Northern Great Basin (NGB) is dotted with hundreds of seasonal pools, locally called playas. The playas hold water or snow during parts of winter and spring but typically dry up during summer months. The mechanisms of seasonal pool hydrology, especially in the NGB, are poorly understood and have not been thoroughly examined. There is high seasonal variability and inter-annual variability in surface water amounts in the playas. [...]"] (Author) The thesis includes a list of aquatic macroinvertebrates observed during the 2007 inventory period and the frequency of observation at a playa. Odonata are treated at the genus/species level (*Anax junius*, *Rhionaeschna californica*, *Libellula pulchella*, *L. satura-*

ta.)] Address: Laura Dlugolecki, Laura, U.S. Environmental Protection Agency, Office of Water (4100T), Healthy Watersheds Project, 1200 Pennsylvania Avenue, N.W., Washington, D.C. 20460, USA

(2010): *Nehalennia speciosa* (Charpentier, 1840) dans la Grande Cariçaie: une population singulière d'importance internationale (Odonata: Coenagrionidae). *Entomo Helvetica* 3: 189-203. (in French, with English and German summaries) ["A population of *N. speciosa*, one of the most endangered odonate species of Europe, was detected in 2007 in the nature reserves named 'Grande Cariçaie' on the southern shore of Lake Neuchâtel, Switzerland. In order to secure adequate maintenance measures of the habitat aimed at the conservation of this species, corresponding investigations were conducted in 2008. The purpose of these studies was on one hand to specify the local distribution and the ecological requirements of *N. speciosa* and on the other hand to evaluate the impact of mowing the marsh meadows on the attractiveness of the different sites within the colonized area. 29 transect runs comprising 6466 m in length allowed to sample 30 ha of the marsh. In total 391 individuals of *N. speciosa* were recorded on an area of 9 ha, 94 % of them being situated within flooded stands of large sedges (Magnocaricion). Marsh meadows without maintenance are not colonized. The number of years after cutting the vegetation in maintained allotments is not decisive for the habitat choice. The singularities of the species' local ecology, the importance of the population on the European scale and the modalities of conservation of *N. speciosa* in the nature reserves of the Grande Cariçaie are discussed." (Author)] Address: Gander, Antoine, Grande Cariçaie, ch. de la Cariçaie 3, CH-1400 Cheseaux-Noréaz, Switzerland. E-mail: a.gander@grande-caricaie.ch

10152. Garrison, M. (2010): Damselflies of Chicago-land. A Photo Field Guide, version 1. Published by The Field Museum, Chicago. 140 pp. (in English) [Introduction: 5; Basic anatomy: 10; Life cycle: 17; Mating: 19;

10153. Garrison, R.W.; Ellenrieder, N. von; Louton, J.A. (2010): Damselfly genera of the New World: An illustrated and annotated key to the Zygoptera. Johns Hopkins University Press; 1 edition. ISBN-10: 0801896703. 528 pp. (in English) ["This book follows by four years its companion volume on the Anisoptera of the New World by the same authors (Garrison et al. 2006, reviewed in *Florida Entomologist* 90: 290-291). Although about the same number of genera (124 Anisoptera, 118 Zygoptera) are treated in the two books, the dragonflies are treated in 368 pages with 1626 figures, the damselflies in 490 pages with 2586 figures. This points out the considerably greater degree of work and detail the authors put into the second volume. In addition, while preparing to write and writing this volume, the first two authors have become the pre-eminent odonate taxonomists of the New World tropics, publishing no fewer than 17 papers (since 2000) to clarify the taxonomy of numerous groups, some of them large. Before this, the largest family, Coenagrionidae, was a taxonomic quagmire, and now a fair modicum of order has emerged from the chaos. How else to build a key to genera that actually works? This book easily lives up to the expectations

promised by the dragonfly volume, including comprehensive, extremely well illustrated keys; detailed morphological descriptions of each genus; and brief descriptions of natural history wherever known. The writing is clear, but its conciseness fails to convey how much work at the microscope must have gone into the keys and descriptions. And most of us will be unable to imagine the amount of time that went into producing the figures. They are meticulous and superb, by the standards of any scientific illustrator. They are lavishly provided, often more than one species in a genus. I am constantly engaged by the morphological diversity of damselflies that one can see under magnification, and this book shows it all. Many of them were used before, in their recently published papers, but the majority appear uniquely in this book. Having worked with the authors on several genera, I can add that they are impeccably accurate. The three-dimensional rendering of medio-dorsal views of terminal appendages is so much

more helpful than the old standard of dorsal and lateral views that one wonders why the excellent illustrators of a century ago didn't come up with it. There are a lot more photos in this book than in the dragonfly book, 81 vs. 24, and the beauty and variety of New World damselflies are shown off to the fullest. All the families are represented, and there was a real effort made to get all the genera. Many have not been photographed. Everything about this volume invites the term "comprehensive." The maps of generic ranges are of great value to the biogeographer and might be used to point out poorly surveyed regions. The long list of references provides access to the taxonomic and biological literature of all New World damselflies, and to that all-important opportunity to identify specimens to species. The list that attributes a locality to every figure is a nice touch. If there are mistakes in the volume, I did not find them with my level of scrutiny. The very timely Appendix lists additions and corrections to the Anisoptera volume, and such a list will doubtless be generated for this volume in a few years. Like Philip Corbet's grand book on Odonata (Corbet 1999), the two superb volumes from these authors are perfectly placed to show us what still needs to be done: 1) databasing and georeferencing existing collections to give an even clearer picture of regional biodiversity; 2) many more surveys and much more collecting over neotropical regions that are still poorly known; 3) modern taxonomic revisions of genera that have not yet received that treatment; and 4) sets of keys to species, especially regional keys such as those by Lencioni (2005, 2006). Finally, regional photo-illustrated field guides to all species!" (Dennis Paulson). Orders: The Johns Hopkins University Press, 2715 North Charles Street, Baltimore, Maryland 21218-4363, USA

10154. Gauquie B. (2010): Habitats de l'Orthetrum brun (Orthetrum brunneum) et de l'Orthetrum bleuissement (Orthetrum coerulescens) sur le territoire du Parc naturel des Plaines de l'Escaut et dans le bassin carrier tournois. Les naturalistes Belges 91(3-4): 37-53. (in French, with English summary) ["During this last five years, I undertook a specific search on two rare Orthetrum species in Belgium, *O. coerulescens* and *O. brunneum*, both recently discovered in Western Hainaut province. The exploration area is Tournai and the territory of the Natural Park of the Plains of the Scheide, which extends east to west from Bernissart to Antoing. *O. brunneum* was found on five sites and *O. coerulescens* on three sites. Following data analysis, it seems that in the region *O. coerulescens* is more a stenotopic species, selecting only limestone quarries and *O. brunneum* is an eurytopic species, occupying more varied environments, nevertheless at least four abiotic parameters characterize in common the breeding sites of the two species: a sunny environment, a shallow water, with good physico-chemical conditions and constantly renewing seepage, or flow resurgence. If these ecological requirements are met, it appears that, among other factors (biotic or abiotic), the vegetation structure is of crucial importance for the reproduction of either species. At sites with still water, *O. brunneum* proves to be a pioneer species essentially, eventually disappearing when the vegetation becomes too high. For *O. coerulescens*, eutrophication is really a non-favorable factor, but the vegetal cover did not appear to be influential." (Author)] Address: Gauquie B., Chargé de mission Recherches et milieux naturels, Parc naturel des Plaines de l'Escaut, rue des Sapins 31, 7603 Bon-Secours, Belgium. E-mail: bgauquie@plainesdelescaut.be

10155. Goffart, P. (2010): Southern dragonflies expanding in Wallonia (south Belgium): a consequence of global warming? BioRisk 5: Special issue: Monitoring climatic change with dragonflies: 109-126. (in English) ["The occurrence of seven southern Odonata species (*Crocothemis erythraea*, *Lestes barbarus*, *Sympetrum fonscolombii*, *Anax parthenope*, *Coenagrion scitulum*, *Aeshna affinis*, *S. meridionale*) has been watched in Wallonia over the last two decades (from 1981 to 2000). They have clearly expanded in the meantime and this pattern is still highly significant when the data are corrected for the increase of sampling efforts. Moreover, reproduction evidences have been collected recently (from 1993 onwards) for all these species and several settled and have now resident populations in Wallonia. In a second step, all present regular and irregular resident species of Wallonia were looked for change in range size and observation rate per visit between two six years periods of a survey and monitoring scheme, from 1989 to 2000. Analysis was achieved on grid cells visited at the right time at both periods, a procedure designed to neutralize the spatio-temporal heterogeneity of sampling. The comparison of results in relation to the distribution types of species and their habitat preferences show a significant global trend toward an increase for southern species during the investigated time interval, contrasting with other groups of species. If there is a tendency to rise for species preferring eutrophic still waters, this proves to be clearly due to the southern species sub-group, the other dragonflies of this habitat type showing a stable or even decreasing trend. Three distinct hypotheses are examined and discussed as possible explanations of the expansion pattern of southern species: (1) global warming, (2) change in aquatic habitats, especially eutrophication, and (3) intrinsic population dynamics. The rise of temperatures appears to be the main factor explaining the observed expansions." (Author)] Address: Philippe Goffart, P., Observatoire de la Faune, de la Flore et des Habitats (OFFH), Département de l'Étude du Milieu naturel et agricole (DEMna), Service Public Wallon (SPW) - DGARNE - Direction de la Nature et de l'Eau, Avenue Maréchal Juin, 23, B-5030 Gembloux, Belgium. 10160. Horváth, G.; Blaho, M.; Egri, A.; Kriska, G.; Seres, I.; Robertson, B. (2010): Reducing the maladaptive attractiveness of solar panels to polarotactic insects. *Conservation Biology* 24(6): 1644-1653. (in English, with Spanish summary) ["Human-made objects (e.g., buildings with glass surfaces) can reflect horizontally polarized light so strongly that they appear to aquatic insects to be bodies of water. Insects that lay eggs in water are especially attracted to such structures because these insects use horizontal polarization of light off bodies of water to find egg-laying sites. Thus, these sources of polarized light can become ecological traps associated with reproductive failure and mortality in organisms that are attracted to them and by extension with rapid population declines or collapse. Solar panels are a new source of polarized light pollution. Using imaging polarimetry, we measured the reflection-polarization characteristics of different solar panels and in multiple-choice experiments in the field we tested their attractiveness to mayflies, caddis flies, dolichopodids, and tabanids. At the Brewster angle, solar panels polarized reflected light almost completely (degree of polarization $d = 100\%$) and substantially exceeded typical polarization values for water ($d = 30-70\%$). Mayflies (Ephemeroptera), stoneflies (Trichoptera), dolichopodid dipterans, and tabanid flies (Tabanidae) were the most attracted to solar panels and exhibited oviposition behaviour above solar panels more often than above surfaces with lower degrees of polarization (including water), but in general they avoided solar cells with nonpolarizing white borders and white grates. The highly and horizontally polarizing surfaces that had nonpolarizing, white cell borders were 10- to 26-fold less attractive to insects than the same panels without white partitions. Although solar panels can act as ecological traps, fragmenting their solar-active area does lessen their attractiveness to polarotactic insects. The design of solar panels and collectors and their placement relative to aquatic habitats will likely affect populations of aquatic insects that use polarized light as a behavioural cue." 10162. Imler, E.; Olberg, R.; Leonardo, A. (2010): 3D reconstructions and flight statistics of dragonfly prey-capture trajectories. Abstracts of the 9th International Congress of Neuroethology, Salamanca (Spain) 2-7 August 2010. P 395: 649. (in English) ["Dragonflies are among evolution's finest aerial hunters; intercepting prey in mid-air, they rarely miss their targets. Most previous studies of dragonfly prey capture have taken place outdoors and have been limited by environmental variability and availability of adult dragonflies in these situations. These single camera studies have been restricted to 2D analyses, and have missed long complex flights due to the narrow field-of-view (FOV) required by outdoor conditions. To enable more sophisticated studies of prey capture, we have constructed a fully indoor flight arena that can be used to study dragonfly behaviour in a controlled environment. The flight arena is 5.5m x 4m x 4.5m in size, and is illuminated to 10mW/cm². The end result is a bright, windless, temperature and humidity controlled environment in which adult dragonflies can forage year round. Individual animals gained up to 100mg of weight per day, and lived as long as 3 weeks. We have focused our studies on libellulid dragonflies (*L. lydia*, *L. luctuosa*), because they will forage readily from a single perch positioned in the focal zone of a high speed camera array (2 cameras; 1000fps). We have analyzed over 150 prey capture trajectories of both the dragonfly and its prey (*Drosophila*) in a 3D recording volume of ~1m³, with sub-millimeter tracking accuracy. Foraging success rates were ~80%, with a mean flight time of 361 ± 124ms – on the order of 15 wing strokes. Dragonfly flight accelerations were very high, over double those of its prey (dragonfly: mean acceleration 18 m/s², max 75 m/s²; *Drosophila*: mean acceleration 8 m/s², max 42 m/s²). When the dragonfly failed to catch its prey, mean flight times increased by 20%, and mean accelerations increased by 10% (dragonfly) and 30% (*Drosophila*). The data suggest the presence of a narrow "trigger zone" above and slightly forward of the dragonfly's head, which most prey pass through in the moments before a foraging flight begins." (2010): Vertical distribution of benthic macroinvertebrates in a meromictic lake (Lake Czarne, Drawieński National Park). *Oceanological and Hydrobiological Studies* XXXIX(4): 99-106. (in English) ["Investigations of the distribution of benthic macroinvertebrates in Lake Czarne were conducted in fall 2005 and spring 2006. Samples were taken in three transects (at a depth of 0.5 m and at 5 m intervals). It was noted that macrobenthos only inhabit depths to 10 m. Laminar sediments from 15 m to 29 m indicate that macrobenthos never inhabit the deepest part of the lake in spite of temporary oxygen abundance (between 15 and 20 m during the winter and spring mixing periods). The largest diversity and biomass of macrozoobenthos was observed in the littoral zone at a depth of 0.5 m. At a depth of 5 m in the characean stands and at a depth of 10 m the number and biomass of benthic macroinvertebrates were significantly smaller. The reason for the decrease of benthos density seems to be gradual oxygen depletion." (Authors) Odonata larvae could be found up to a depth of app. 5 m. Odonata occurred at densities of 15 ind./m².] Address: Klimaszuk, P., Department of Water Protection, University of Adam Mickiewicz ul. Umultowska 89, 61–614 Poznań, Poland. E-mail: pklim@amu.edu.pl

Abstracts of the 9th International Congress of Neuroethology, Salamanca (Spain) 2-7 August 2010. P 363: 235. (in English) [Verbatim: "Dragonflies are nature's consummate aerial predators; flying at extremely high speeds, they catch small moving insect prey; escapes are rare. We have constructed the first indoor dragonfly flight arena in order to unravel the computations and circuit dynamics underlying this remarkable behaviour. We will present data from an array of high speed cameras that allows us to reconstruct the trajectory of the dragonfly and its prey (*Drosophila*). From these data, we can test quantitatively the hypothesis (Olberg et al., 2000) that dragonflies use a strategy of proportional navigation to intercept their prey. Starting with the three-dimensional coordinates of the dragonfly and its prey, we calculate the azimuthal and elevational line-of-sight position of the prey as a function of time. The numerical derivatives of these line-of-sight vectors are then estimated, and their drift rates are compared to the dragonfly's acceleration vector normal to its bearing. The extent to which these numbers are consistent with different models of proportional navigation and other guidance laws will be discussed." (Authors)] Address: Olberg, R.M., Dept Biol. Sciences, Union College, Schenectady, NY 12308, USA. E-mail: olbergr@union.edu

10175. Lopez Salmeron, A.; Mendoza-Cuenca, L. (2010): Efecto del parasitismo por ácaros acuáticos en la adecuación de *Argia* sp. (Odonata: Coenagrionidae). *Biológicas* 12(2): 122-128. (in Spanish, with English summary) ["In the late three decades a deep interest in theoretical and empirical knowledge of sexual selection, have showed that it is common in nature. In dragonfly species such as *Argia* sp. (Odonata: Coenagrionidae), where males did not perform any precopulatory display and the sexual harassment to females occurs very frequently, we would expect that females use traits to discriminate between males. We evaluated, using capture-recapture marking and through behavioral observations, if mites attack affects individual survival of *Argia* sp. from one population with high levels of parasitism by aquatic mites, and also if parasitism levels could be used by females to discriminate among males. Our results showed that mites attack males with higher intensity, despite females are bigger and could potentially

house a higher number of mites. Parasitism by aquatic mites reduces both individual survival of males and females and male's mating success, and bigger males are less attacked, have a higher survival and obtain higher numbers of matings. These results suggest that females could use male size as an indicator to their capacity to resist the attack from mites." (Authors)] Address: Mendoza-Cuenca, L. E-mail: lmendoza@lca.unam.mx

10176. Martens, A. (2010): New Odonata records from Atiu and Rarotonga, with an overview of the species known from the Cook islands. *Notulae odonatologicae* 7(6): 57-59. (in English) ["In September and October 1995, 6 species were collected at Atiu and 4 at Rarotonga. Of these 5 species are recorded for the first time from Atiu. The odonate fauna of the Cook Islands is poorly known; an island-annotated list of the hitherto recorded 9 species is presented." 10181. Mikolajewski, D.J.; De Block, M.; Rolff, J.; Johansson, F.; Beckerman, A.P.; Stoks, R. (2010): Predator-driven trait diversification in a dragonfly genus: covariation in behavioral and morphological antipredator defense. *Evolution* 64(11): 3327-3335. (in English) ["Proof for predation as an agent shaping evolutionary trait diversification is accumulating, however, our understanding how multiple antipredator traits covary due to phenotypic differentiation is still scarce. Species of the dragonfly genus *Leucorrhinia* underwent shifts from lakes with fish as top predators to fishless lakes with large dragonfly predators. This move to fishless lakes was accompanied by a partial loss and reduction of larval spines. Here, we show that *Leucorrhinia* also reduced burst swimming speed and its associated energy fuelling machinery, arginine kinase activity, when invading fishless lakes. This results in patterns of positive phylogenetic trait covariation between behavioral and morphological antipredator defense (trait cospecialization) and between behavioral antipredator defense and physiological machinery (trait codependence). Across species patterns of trait covariation between spine status, burst swimming speed and arginine kinase activity also matched findings within the phenotypically plastic *L. dubia*. Our results highlight the importance of predation as a factor affecting patterns of multiple trait covariation during phenotypic diversification." 10182. Mill, P.; Brooks, S.; Parr, A. (2010): 26. Dragonflies (Odonata) in Britain and Ireland. In: Maclean, N. (Ed.): *Silent Summer; The State of Wildlife in Britain and Ireland*. Cambridge University Press: 471-494. (in English) ["Although three species of dragonfly became extinct in Britain and Ireland in the 1950s, the outlook for most of the present resident species is favourable, providing that appropriate freshwater habitat is increased and pollution reduced. A number of species are extending their range northwards, mostly as a result of overall temperature increase, but at least one also as a result of reduction in river pollution. Three northern species are showing some sign of a retraction northwards of their southern range margins and this could lead to a serious problem if temperatures continue to rise. A further species currently restricted to the East Anglian coast is threatened by projected sea-level rise. According to IUCN criteria, of our 39 breeding species (17 zygopteran and 22 anisopteran) two are classed as 'endangered', four as 'vulnerable' and six as 'near threatened' in Britain. One of these 'near threatened' species is classed as 'vulnerable' in Ireland and Ireland

has a further species classed as 'vulnerable'. One resident species in Britain has become established only this century and a further two species have begun breeding on a regular basis and may become established as permanent residents in the near future.] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK. 10185. Nordström, K.; Bolzon, D.; O'Carroll, D. (2010): Slow facilitation of small target motion responses. Abstracts of the 9th International Congress of Neuroethology, Salamanca (Spain) 2-7 August 2010. P 393: 617. (in English) [Verbatim: "Many insect species pursue small moving targets, e.g. the predatory dragonflies chase and capture small prey. To overcome the inherently limited resolution of the compound eye, many insects that pursue targets have developed acute zones. The optical specializations are accompanied by neural hardware giving selective responses to small targets. In the dragonfly lobula (3rd optic ganglion) small target motion detectors (STMD) respond to small moving targets (1-3°), with no response to larger bars or to wide-field stimuli (1,2). STMDs are exquisitely sensitive neurons, detecting targets with an effective neural contrast as low as 2% (3). This performance is especially impressive considering the ability to respond to small targets against moving backgrounds, and the lack of sustained responses to clutter within moving natural scenes. What mechanisms provide STMDs with a high-enough gain to allow responses to low-contrast targets, while still avoiding breakthrough responses to target-like features in natural backgrounds? It is possible that a summation mechanism plays a role, enabling responses to build up as targets move continuously across the receptive field. To investigate the presence of facilitation mechanisms, we record intracellularly from the recently characterized Centrifugal STMD1 (CSTMD1) (2,4). Its large centrifugal axon allows for more stable recordings than usual for STMDs. We show that CSTMD1 has a slow facilitation mechanism where responses continue to grow for several hundred milliseconds as targets move across the receptive field. This gives a partial explanation for the ability of STMDs to respond to low contrast targets: only continuous motion of a target with the correct spatiotemporal profile allows responses to continue to build up to maximum firing frequencies. 10187. Olberg, R.; Leonardo, A. (2010): Towards wireless monitoring of neural activity during dragonfly prey interception flights. Abstracts of the 9th International Congress of Neuroethology, Salamanca (Spain) 2-7 August 2010: 25. (in English) [Verbatim: "In response to an insect passing overhead, the foraging dragonfly takes off on an interception trajectory, aiming a point ahead of the flying prey. If the potential prey deviates in its flight path, the dragonfly corrects its own course so that the bearing to the prey is held constant, a strategy that ensures interception. During the foraging flight the dragonfly adjusts its head angle to maintain the prey's image centered on the dorsal fovea of its compound eye. Eight pairs of identified neurons are implicated in controlling the dragonfly's flight path as it intercepts its flying prey. These target-selective descending neurons (TSDNs) descend from the brain of the dragonfly to the thoracic ganglia. They show directionally selective responses to small objects moving relative to the dragonfly. Their receptive fields are located in the dorso-frontal quadrant of the visual field, the region that views prey during the foraging flight. Intracellular stimulation of any of these neurons evokes small adjustments in wing position and attitude. Details of the neural control of prey interception are not obvious. For example, because the dragonfly rotates its head to fixate the prey's image, the signal that indicates the prey's drift is probably very brief. In addition, the dragonfly must factor in its own head angle in determining the bearing of the prey. To more fully understand the neural underpinnings of this complex flight behavior, we are developing the means to monitor TSDN activity from a dragonfly in free flight. Extracellular TSDN activity will be recorded from the mesothoracic ganglion, amplified and transmitted from a lightweight telemetry chip mounted on the dragonfly. Neuronal activity will be correlated with the 3-dimensional trajectories of the dragonfly and its flying prey, reconstructed from high-speed video recordings. Our goal in this approach is to understand how visual information is translated into steering commands for interception in a freely flying insect." (Authors)] Address: Olberg, R.M., Department of Biological Sciences, Union College, Schenectady, NY 12308, USA. E-mail: olberg@union.edu

10188. Olberg, R.; Imler, E.; Seeman, S.; Shulman, D.; Worthington, A. (2010): The responses of target-selective descending neurons in the dragonfly to 3-dimensional object movements outdoors under blue sky.

Abstracts of the 9th International Congress of Neuroethology, Salamanca (Spain) 2-7 August 2010: 76. (in English) [Verbatim: "Dragonflies make their living by foraging on flying insects. Eight pairs of identified neurons are implicated in controlling the dragonfly's flight path as it intercepts its flying prey. These target-selective descending neurons (TSDNs) descend from the brain of the dragonfly to the thoracic ganglia. They show directionally selective responses to small objects moving relative to the dragonfly. Their receptive fields are located in the dorso-frontal quadrant of the visual field, the region that views prey during the foraging flight. When stimulated intracellularly with high-frequency, depolarizing current pulses, each of these neurons evokes small adjustments in wing position and attitude. To understand the behavior of the TSDNs under more natural environmental conditions, we studied their responses outdoors, under blue sky, to the movement of opaque white beads of three sizes (2, 4, and 8 mm) around the immobilized dragonfly. The bead movements were videotaped (100 frames/s) for 3-dimensional reconstruction of their paths. The extracellularly recorded TSDN spikes were sorted and correlated with bead positions and velocities. We recorded from dragonflies of two genera: *Aeshna* (which forages from continuous flight) and *Pachydiplax* (which takes off to forage from a perch). The outdoor recordings revealed several new properties of the neurons and their receptive fields, three of which are presented here. (1) Receptive fields are not identical between genera, a result that may be related to their markedly different foraging strategies. (2) Three-dimensional receptive field reconstruction showed that size selectivity varies with object distance. (3) The higher light levels and ambient temperatures outdoors resulted in TSDN spike rates of 900 Hz or greater, much higher than have ever been observed in laboratory experiments." Esp. Ent.* 33(3-4) (2009): 299-319. (in Spanish, with English summary) ["Latitudinal morphological patterns in Iberian *Calopteryx* Leach, 1815 (Odonata, Calopterygidae) populations: possible environmental and evolutionary factors. - The morphological clines related with latitudinal or altitudinal gradients, generally caused by natural selection, can be modified by sexual selection, especially when it plays a major role in interpopulation divergence. Two species of *Calopteryx* damselflies [*C. virgo* merid-

ionalis, *C. xanthostoma*] were studied at three different latitudes in the Iberian Peninsula. Latitudinal patterns in size and secondary sexual traits were recorded. A modified converse Bergmann rule explains size patterns. Patterns in secondary sexual traits are better explained by a balance between sexual selection processes within and between the two species. These processes are influenced by latitudinal differences in relative abundances, in the sense that the most abundant species displaces the traits of the other species because of sexual interference, in order to reduce reproductive effort costs between species. Differences in relative abundances are supported by the distribution frequencies of both species in the Iberian Peninsula. The third Iberian species might cause a reinforcement polymorphism in one of the species studied." 10194. Poulin, B.; Lefebvre, G.; Paz, L. (2010): Red flag for green spray: adverse trophic effects of Bti on breeding birds. *Journal of Applied Ecology* 47(4): 884-889. (in English) ["The expanding use of selective pest-control agents provides a unique opportunity to study food web interactions in the field while addressing major environmental issues. *Bacillus thuringiensis israelensis* (Bti) is the most commonly used microbial agent to control mosquitoes worldwide. Using breeding house martins *Delichon urbicum* as a model species, we assessed the effect of Bti spraying on foraging rates and chick diet prior to and during 3 years of Bti spraying in the Camargue, France. Some 9051 feeding flights and 14 857 prey items were recorded in the early, mid and late nesting season at up to three control and three treated sites. Breeding parameters were assessed during 1 year at two control and two treated sites. [...] Nematocera, Araneae and Odonata were taken significantly more often at control sites, whereas Hymenoptera (flying ants) accounted for a larger portion of the diet at treated sites (Table 2). ... Because Odonata and Araneae are favourite prey of swallows' nestlings (Foelix 1996; McCarty & Winkler 1999), and major predators of Nematocera (Foelix 1996; Corbet 1999), their lower intake at treated sites suggests an indirect effect of Bti treatments through the food web." 10195. Principe, R.E.; Gualdoni, C.M.; Oberto, A.M.; Raffaini, G.B.; Corigliano, M.C. (2010): Spatial-temporal patterns of functional feeding groups in mountain streams of Córdoba, Argentina. *Ecología Austral* 20: 257-268. (in English) ["Trophic structure of benthic communities is influenced by the availability of food resources which indeed may be conditioned by stream size, shading and substrate. This study aims to analyze the distribution of macroinvertebrate Functional Feeding Groups in different habitats of mountain streams (Córdoba, Argentina) and to assess the environmental variables conditioning this distribution at the habitat level. Four streams were sampled in two hydrological periods (high and low discharge) and three benthic samples were taken in riffles and runs of coarse and fine substrate. Gathering collectors were dominant in most of the habitats, streams and periods except in riffles during the low water period in which filtering collectors dominated. At the habitat level, current velocity, substrate, abundance of macroalgae and twigs and leaves were the most important variables explaining functional feeding group distribution. Functional feeding group abundances varied in relation to the stream, the hydrological period and the habitat. The dominance of collectors demonstrates the importance of the role of this functional group and that fine detritus is the main food resource in these lotic ecosystems. The phenology and life history of the species, and the amount and type of organic matter retained in each habitat may explain the observed spatial-temporal patterns." (Authors) Odonata - including "*Progomphus* sp." are treated at the family level.] Address: Principe, Romina, Univ. 10196. Reels, G. (2010): Dragonfly surveys in Hainan, China, 2007-2008. *Agrion* 14(2): 34-38. (in English) ["The first field trip (18-26 May 2007) centred on sites in and around Yinggeling Nature Reserve in central Hainan, with two days at Ganzaling Nature Reserve in southern Hainan. The next trip (17-23 June 2007) was to the Wanning region of southeast Hainan. This was followed by two trips to Wuzhishan Nature Reserve (16-23 April and 8-14 August 2008); the latter trip also involving sites between Wuzhishan and Wanning, and in the Wanning region. In total, 28 days of field work were conducted, and 98 species recorded (vouchered, photographed, or, in the case of common and easily-recognised species, unambiguously sighted). Four species had not previously been found in Hainan (the first three of these were reported by Wilson et al., 2008): *Lestes praemorsus*, *Rhyothemis obsolescens*, *R. pluto* and *Zyxomma petiolatum*. New locality records were made for five interesting species previously known from only a single location in Hainan: *Rhinagrion hainanense* and *Nannophyopsis clara* (first reported by Wilson & Reels, 2001) *Dysphaea gloriosa* and *Rhipidolestes cyanoflavus* (first reported by Wilson et al., 2008), and *Hylaeothemis clementia* (unpublished; Dragonfly surveys in Hainan, China, 2007-2008 Graham Reels one male collected by Bosco Chan at Yinggeling, 2005; det. by G.T. Reels – the first specimen of this genus for China). By an extraordinary coincidence, a female specimen of a new *Sinosticta* species that was subsequently named *S. sylvatica* Yu & Bu, 2009, was collected by team member Hilario Padilla on the same date (25 May 2007) that Yu Xin, working completely independently, collected the first of his two males, and both records were made in Yinggeling, by groups unaware of each other's existence! The following year, I found this species to be quite common around Wuzhishan." (Author)] Address: Reels, G., H-3-30 Fairview Park, Yuen Long, Hong Kong. E-mail: gtreels@gmail.com

10197. Relyea, R.A. (2010): COS 53-2: New effects of Roundup® on amphibians: Predation, stratification, and induction of tadpole morphology. The 95th ESA Annual Meeting (August 1-6, 2010): (in English) [Verbatim: "Background/Question/Methods: To understand the impacts of anthropogenic chemicals on natural communities, we often must base our predictions on short-term, single-species tests that are conducted as part of the regulation process. While a valuable first-step, these tests tell us little about the impacts of contaminants under more natural conditions. Thus, many ecotoxicologists have moved to testing contaminants under more natural conditions where natural stressors are abundant. Among the many natural stressors, predator stress is a common one whose interactions with pesticides have only been examined under laboratory conditions. Using two mesocosm experiments, I examined how predation stress interacted with the effects of Roundup®, the most widely applied herbicide in the world. The first experiment, conducted with three spring-breeding species of anurans, crossed four concentrations of Roundup with the presence of no predators, caged adult newts, or caged dragonfly larvae. The second experiment, conducted with three species of summer-breeding anurans, crossed four concentrations of Roundup with the presence of no predators, caged dragonfly larvae, or lethal dragonfly larvae. Results/Conclusions: In the first experiment, Roundup and the caged-predator treatments had interactive effects on

tadpole survival, mass, and relative morphology. Increased herbicide concentrations caused increased tadpole mortality, but the amount of mortality decreased in the presence of caged dragonflies. Tadpole mass exhibited little effect of the herbicide when no predators or caged newts were present, but mass declined with higher herbicide concentrations when caged dragonflies were present. Not surprisingly, the cues from caged dragonflies induced adaptive morphological changes in the tadpoles. What was surprising is that the herbicide induced the same morphological changes in the tadpoles as the larval dragonflies. In the second experiment, Roundup and the predator treatments also had interactive effects. Increased herbicide concentrations again caused increased mortality and the amount of mortality again declined with caged dragonflies. With lethal dragonflies, however, there mortality was reduced similarly across all herbicide concentrations. Tadpole mass increased with higher herbicide concentrations when predators were absent, was unaffected by the herbicide when caged dragonflies were present, and decreased with higher herbicide concentrations when lethal dragonflies were present. Once again, the morphology of the tadpoles was induced similarly by caged dragonflies and the herbicide. Collectively, these results suggest that the effects of Roundup on larval amphibians can differ tremendously depending on community context. Moreover, the herbicide is somehow able to induce anti-predator responses." (Author)] Address: Relyea, R.A., Dept Biol. Sci., Univ. of Pittsburg, Pittsburgh, Pennsylvania 15260, USA. 10198. Righi-Cavallaro, K.O.; Roche, K.F.; Froehlich, O.; Cavallaro, M.R. (2010): Structure of macroinvertebrate communities in riffles of a Neotropical karst stream in the wet and dry seasons. *Acta Limnologica Brasiliensia* 22(3): 306-316. (in English, with Portuguese summary) ["Aim: Our study evaluated the effects of physical and chemical variables and seasonality on diversity and structure of the macroinvertebrate fauna in riffles of a Neotropical chalk stream; Methods: Sampling was performed during the dry (September 2003) and rainy (March 2004) seasons, in five sites. Five samples were taken at each point with a Surber sampler. Physical and chemical variables were also evaluated; Results: Temperature, pH, orthophosphate and total nitrogen were very similar for both seasons, while riffle length, conductivity, alkalinity, ammonia, phosphorus and leaf litter had different values. The total number of organisms collected was 25114 belonging to at least 50 families. Insects dominated in the samples. The highest abundance was found for the dry period. Temporary stretches were sampled in rainy season in order to complement the faunal inventory; Conclusions: The environmental seasonality was an important factor for structuring the macroinvertebrate fauna, with a significant difference between the invertebrate compositions in the sampling periods. The results of this study demonstrate the influences of seasonality on the temporal variation of communities." 10205. Sites, R.W.; Vitheepradit, A. (2010): Recovery of the freshwater lentic insect fauna in Thailand following the tsunami of 2004. *The Raffles Bulletin of Zoology* 58(2): 329-348. (in English) ["The tsunami of 26 December 2004 inundated the coastlines of many Southeast Asian countries, including Thailand. The force of the surge was devastating to the extent that hundreds of thousands of humans were killed, whereas the effect on non-human biota, including insects, remains largely unreported. Along the Andaman Sea coastline of Thailand, we sampled lentic (pond) habitats within the area directly affected by the tsunami and other reference ponds slightly inland to determine the rate and trajectory of community recovery following extirpation. Our first samples were taken five months after the tsunami, which marked the end of a dry season. By that time, many impacted ponds already had substantial freshwater recharge through rainfall, and conductivity had fallen to approximately 10% that of seawater. An insect community with a mean richness of 20 taxa was present already, whereas the unaffected inland ponds had a mean richness of 27 taxa. Insect tolerance to salinity in general appears to be greater and taxonomically more widespread than previously considered. Three additional sampling periods were spaced over the next 12 months. Two-way ANOVA tests for species richness among higher taxa revealed significant differences among sampling periods for total Insecta and four orders separately (Odonata, Hemiptera, Coleoptera, and Diptera), and six subordinate taxa (Anisoptera, Zygoptera, Gerridae, Notonectidae, Dytiscidae, and Chironomidae). Patterns of species richness in impacted ponds across sampling periods were evaluated with Discriminant Function Analysis separately using ordinal and family richness values. Using ordinal richness values, 55.0% of the ponds were classified to the correct sampling period, whereas when using family richness values, 92.5% of the ponds were classified correctly. A parsimony analysis was performed to evaluate community succession and recovery trajectory. Numerous tangential trajectories are evident, suggesting that the

communities of the impacted ponds are not assembling toward the taxonomic composition of the unaffected ponds, but to one or more alternative stable states. Taxonomic composition was evaluated also by clustering Jaccard's Similarity scores. On each of the four sampling dates and overall, fidelity of pond type based on the taxonomic composition is distinct, suggesting that the community in the impacted ponds has not demonstrated any signs of shifting toward that of the unaffected ponds. In addition to the evaluation of inundated and unaffected pond communities, a series of peat swamps that had been collected in 1994 and 1995 were resampled to obtain comparable post-tsunami data. We found only 16 of the 33 taxa previously recorded and substantially fewer individuals." (in English) ["Despite the importance of foraging activity for the growth/predation risk trade-off, studies that demonstrated predator-induced survival selection on foraging activity under semi-natural conditions are relatively rare. Here, we tested for fish-induced selection for reduced foraging activity in two larval *Enallagma* damselflies using a field enclosure experiment. Fish imposed considerable mortality in both damselfly species and survival selection on foraging activity could be detected in *Enallagma geminatum*. We did not detect selection in *Enallagma hageni*, probably because this species already was not eating very much in the absence of fish compared to *E. geminatum*. Both species responded strongly to the presence of predators by reducing their foraging activity. The documented survival selection on foraging activity was detected despite the already low activity levels in fish lake prey species and despite strong predator-induced plasticity in this trait." 10216. Villanueva, J.R.; Mohagan, A.B. (2010): Diversity and Status of Odonata across Vegetation Types in Mt. Hamiguitan Wildlife Sanctuary, Davao Oriental. *Asian Journal of Biodiversity* 1(1): 35-45. (in English) ["Diversity and status of Odonata in Mt. Hamiguitan Wildlife Sanctuary was determined after a year of sampling in five vegetation types: agroecosystem (400 masl), dipterocarp (900 masl), montane (1200 masl), mossy (1400 masl) and pygmy (1600 masl) using 2-Km transect walk sampling to provide information on species richness trend and ecological status of Odonata. Study showed 31 species with 94% endemism for damselflies and 33.3% for dragonflies. Species richness and endemism were low in agroecosystem $H' = 0.631$ and 1 endemic; high and increasing in the dipterocarp $H' = 2.298$ and 4 endemic to dense montane forest with $H' = 3.056$ and 18 endemic; decreasing in mossy $H' = 2.036$ and pygmy $H' = 1.846$. The effects of disturbance on diversity showed highest in agroecosystem ($d = 83\%$), mossy and pygmy had intermediate value $d = 27\%$ and $d = 24\%$. Low disturbance was observed in Montane $d = 10\%$, dipterocarp $d = 18.5\%$. Bray-curtis similarity index for species composition showed four discernible clusters of habitats. Results suggest that Odonata has preference for dense forest, undisturbed vegetation, optimum temperature and presence of aquatic habitat." 10218. Waldhauser, M.; Mikat, M.; Dolny, A. (2010): *Coenagrion ornatum* (Sélys, 1850) (Odonata, Coenagrionidae) distribution and ecology in the Czech Republic – new information based on records in 2010.

Sborník referátů XIII. celostátního semináře odonatologů v Podyjí: 91-107. (in Czech, with English summary) ["The distribution of *C. ornatum* in the Czech Republic is far more extensive than considered up to 2009. Before 2008 only one recent population from the Piletický brook watershed and five historical records from Bohemia and Moravia were known. In 2009 twenty-five new localities with *C. ornatum* were discovered. Thirty-five new localities with *C. ornatum* were discovered in 2010. These localities are distributed in Bohemia as well as in southern Moravia which means further confirmation of this species distribution within the whole area of Moravia and Silesia. Furthermore, three localities with larvae occurrence were discovered in Bohemia. The new *C. ornatum* localities are situated mostly in open farmland or mining areas at altitudes below 250 m a.s.l. *C. ornatum* prefers sunny parts of brooks and amelioration ditches with lush littoral vegetation (e.g. *Sparganium erectum*, *Veronica beccabunga*, *Potamogeton* spp., *Berula erecta*). However, it also occurs along degraded and regulated sections of the streams where the vegetation is dominated by *Phalaris arundinacea* and *Urtica dioica*." 10219. Wesolek, B.E.; Genrich, E.K.; Gunn, J.M.; Somers, K.M. (2010): Use of littoral benthic invertebrates to assess factors affecting biological recovery of acid- and metal-damaged lakes. *Journal of the North American Benthological Society* 29(2): 572-585. (in English) ["Biological recovery of aquatic ecosystems from acidification damage is a slow process. In lakes near the massive Cu and Ni smelters in Sudbury, Canada, the delays might be caused by residual metals, habitat damage, altered predator-prey interactions, or other persistent ecological stressors. Assessments of benthic invertebrate communities in 24 Sudbury lakes were conducted to evaluate the relative importance of these delaying factors" (The analysis includes Odonata which are treated at the order level). "At the time of sampling, all lakes had chemically recovered to a pH >6.0, but they varied widely in the duration of time above this threshold and in current metal concentrations, watershed contributions of organic matter, littoral habitat composition, and fish community composition. A model developed with redundancy analyses (RDA) of 4 groups of environmental variables (i.e., water chemistry, fish communities, physical lake descriptors, and littoral habitat) accounted for 74.9% of the variance in benthic invertebrate community metrics across these environmental gradients. Fish species richness, duration of pH recovery, and % boulder habitat were the most significant variables and explained 22%, 9%, and 8% of the variance in benthic invertebrate community metrics, respectively. Damaged systems clearly need sufficient time to recover from severe disturbances. However, our study suggests that remediation techniques, such as manipulation of predator-prey interactions through fish introductions, might speed the recovery of benthic invertebrate communities." (Authors)] Address: Wesolek, B.E., Cooperative Freshwater Ecology Unit, Biology Dept, Laurentian Univ., 935 Ramsey Lake Road, Sudbury, Ontario, Canada, P3E 2C6. E-mail: bxwesolek@laurentian.ca

10221. Yu, W.-y.; Li, Z.-h.; Huan, G.c.; Lu, J. (2010): On fauna and diversity of Odonata in Nanjing, Jiangsu province. Resources and Environment in the Yangtze Basin 19(5): 514-521. (in Chinese, with English summary) [43 (+ 2 taxa) Odonata species were caught between 2005 to 2008 at seven localities near Nanjing, China. The characteristic of the fauna is that Oriental species take the most part. There are 13 species belonging to Oriental, which accounted for 28.89% in total. Palearctic species, which accounted for 11.11% in total. Calculating species richness (S), species composition similarity (Cs) and species diversity index (H' / H) for the seven habitats showed that the species richness decreased in the following sequence: Zijin Mountain (30) = Lao Mountain (30) > Jianguan Mountain (24) > Jiangxinzhou Alluvion (19) > Fang Mountain (18) > Donglu Mountain (13) > Jinniu Lake (9); the species diversity decreased in a different sequence: Jianguan Mountain (2.9298) > Zijin Mountain (2.9150) > Lao Mountain (2.7258) > Fang Mountain (2.6574) > Jiangxinzhou Alluvion (2.5478) > Donglu Mountain (1.9025) > Jinniu Lake (1.6700). The dragonfly species composition between Fang Mountain and Donglu Mountain had the highest similarity (0.7742), while Jinniu Lake and Lao Mountain had the lowest similarity (0.4103).] Address: Yu, W.-y., Dept of Life Science, Nanjing Xiaozhuang College, Nanjing 211171, China

10225. Abbott, J.C. (2011): Dragonflies and Damselflies (Odonata) of Texas. Odonata Survey of Texas. Vol. 5: 323 pp. (in English) ["This is the fifth volume of the Dragonflies and Damselflies (Odonata) of Texas to be published and serves as an update of records including all those reported in 2010. As with earlier volumes, this book is meant to serve as a guide to the distributions and seasonality of all 238 species occurring in the state. The interest in dragonflies and damselflies in North America, and Texas specifically, continues to grow as does our knowledge of the fauna. Judging by the increasing number of records submitted since 2005, The Odonata Survey of Texas (OST) appears to be a success. I hope this volume continues to increase interest and excitement for the Odonata fauna in Texas." (Author) These compilation of data is organised in the following chapters: Statistical Summary of Odonata in Texas (page 1), Abundance & Distribution of Texas Odonata (page 3), Diversity of Texas Odonata by County (page 4), Checklist of Dragonflies & Damselflies of Texas (page 5), Dragonflies and Damselflies of Texas Conservation Ranks (page 8), Seasonality of Odonata in Texas (page 12), Dragonflies & Damselflies of Texas Listed by County (page 29), Distribution Maps of Texas Odonata (page 69), Appendix: Collection Guidelines for the Odonata Survey of Texas (page 308), The Dragonfly Society of the Americas Guidelines for Collecting (page 309), Specific Collecting & Preservation Instructions (page 311), Guidelines for Field Notes & Data Recording (page 313), Odonata Field Guides, Resources, Societies, & Suppliers (page 316), Glossary of Terms Relating to Odonata (page 318), and Index to Maps (page 320)] Address: Abbott, J.C., Patterson Labs 219, School of Bio. Sci., University of Texas, Austin TX 78712, USA. E-mail: jcabbott@mail.utexas.edu

10226. Abbott, J.C.; Hibbits, T.D. (2011): *Cordulegaster sarracenia*, n. sp. (Odonata: Cordulegasteridae) from east Texas and western Louisiana, with a key to adult Cordulegasteridae of the New World. Zootaxa 2899: 60-68. ["*C. sarracenia* is described from spring seepages in pitcher plant bogs of southeast Texas and western Louisiana. It is most closely related to *C. sayi* of the *C. diastatops* group. It is unique among all North American species of its genus in having the mesepimeral and metepimeral stripes distinctly paler than the mesepisternal stripes in combination with yellow bands on S3-8 that are interrupted middorsally by the carina." 10229. Barry, M.J. (2011): Effects of copper, zinc and dragonfly kairomone on growth rate and induced morphology of *Bufo arabicus* tadpoles. *Ecotoxicology and Environmental Safety* 74(4): 918-923. (in English) ["It is well documented that many amphibian species can detect chemical signals from predatory invertebrates and subsequently develop alternate phenotypes that are protective against predation. The effects of metallic pollutants on the development of predator-induced morphology have not previously been reported. Tadpoles of the Arabian toad *Bufo arabicus* were exposed for 20 days to copper (0, 10 or 100 µg/L), zinc (0, 10 or 100 µg/L) and kairomones of larval dragonflies (*Crocothemis erythraea* 1 dragonfly/12 L) in a fully crossed design. The effects of these treatments of growth and body shape were measured. Measured copper concentrations after 24 h were 4.25 µg/L±1.30 (10 µg/L nominal) and 34.9 µg/L±2.15 (100 µg/L nominal). Measured zinc concentrations were 3.04 µg/L±0.1 (10 µg/L nominal) and 26.3 µg/L±12.3 (100 µg/L nominal). Tadpoles exposed to 34.9 µg/L copper were significantly lighter and had a shorter body length than other groups. There was no direct effect of zinc on growth or tadpole shape. Tadpoles exposed to dragonfly kairomones were heavier, wider and had deeper bodies when viewed laterally and had longer tails but overall length was not affected. At 4.25 µg/L copper differences between the control and predator-exposed phenotypes increased but at 34.9 µg/L the phenotypes converged, indicating that copper may inhibit the induced response." 10230. Bauer, S.; Nolet, B.A.; Giske, J.; Chapman, J.W.; Åkesson, S.; Hedenström, A.; Fryxell, J.M. (2011): Cues and decision rules in animal migration. In: Milner-Gulland, E.J., Fryxell, J.M.; Sinclair, A.R.E. (eds.): *Animal Migration. A Synthesis*. Oxford University Press: 68-87. (in English) [The paper provides a concise compilation on current knowledge in insect migration. Odonatological text passages are: "Some insect migrations are highly noticeable; among the most impressive of natural phenomena are the mass migrations in enormous cohesive swarms of a few species (e.g. the desert locusts *Schistocerca gregaria*, the dragonfly *Aeshna bonariensis*, and the monarch butterfly *Danaus*

plexippus), which rival the largest flocks and herds of migratory birds and mammals in terms of biomass, and far exceed them in total numbers. [...] Green darner dragonflies have a number of simple decision rules that guide their autumn migrations along the eastern seaboard of North America in a favourable, southerly direction (Wikelski et al. 2006). They initiate migratory flights on days following two preceding nights of dropping temperatures, which are highly likely to be associated with persistent northerly air flows, and then simply fly in the downwind direction while avoiding being carried over large water bodies (and thus out to sea). [...] Odonata have regular, bidirectional seasonal long-distance migrations that involve movements that are directed in predictable ways but not targeted at a specific site or region." (Authors)] Address: Bauer, Silke, Netherlands Institute of Ecology (NIOO-KNAW), PO Box 1299, 3600 BG Maarssen, The Netherlands

10231. Bolliger, J.; Keller, D.; Holderegger, R. (2011): When landscape variables do not explain migration rates: An example from an endangered dragonfly, *Leucorhinia caudalis* (Odonata: Libellulidae). *Eur. J. Entomol.* 108(2): 327-330. (in English) ["*L. caudalis* is a dragonfly species threatened throughout Europe. Despite evidence of the recent extension of its distribution range, it is unknown whether *L. caudalis* regularly or hardly ever migrates among ponds. The contemporary migration patterns of the species were investigated using Bayesian assignment tests and the migration rates related to landscape structural and thematic variables (distance between ponds, forest area, area of water body, area of hedgerow). Migration rates of *L. caudalis* are independent of any landscape element. Thus, landscape structure is not a barrier or corridor for migration in this species. The tendency of *L. caudalis* to disperse is largely independent of the nature of the landscape, at least at the scale of the present study." 10232. Bonnaud, E.; Medina, F.M.; Vidal, E.; Nogales, M.; Tershy, B.; Zavaleta, E.; Donlan, C.J.; Keitt, B.; Le Corre, M.; Horwath, S.V. (2011): The diet of feral cats on islands: a review and a call for more studies. *Biological Invasions* 13(3): 581-603. (in English) ["Cats are among the most successful and damaging invaders on islands and a significant driver of extinction and endangerment. Better understanding of their ecology can improve effective management actions such as eradication. We reviewed 72 studies of insular feral cat diet from 40 islands worldwide. Cats fed on a wide range of species from large birds and medium sized mammals to small insects with at least 248 species consumed (27 mammals, 113 birds, 34 reptiles, 3 amphibians, 2 fish and 69 invertebrates). Three mammals, 29 birds and 3 reptiles recorded in the diet of cats are listed as threatened by the IUCN. However, a few species of introduced mammals were the most frequent prey, and on almost all islands mammals and birds contributed most of the daily food intake. Latitude was positively correlated with the predation of rabbits and negatively with the predation of reptiles and invertebrates. Distance from landmass was positively correlated with predation on birds and negatively correlated with the predation of reptiles. The broad range of taxa consumed by feral cats on islands suggests that they have the potential to impact almost any native species, even the smallest

ones under several grams, that lack behavioral, morphological or life history adaptations to mammalian predators. Insular feral cat's reliance on introduced mammals, which evolved with cat predation, suggests that on many islands, populations of native species have already been reduced." (Authors) The list of prey items also considers (unidentified) Odonata.] Address: Bonnaud, E., Mediterranean Institute for Ecology and Palaeoecology (UMR CNRS/IRD), Aix-Marseille University (Université P. Cezanne), Bâtiment Villemin, Domaine du Petit Arbois, Avenue Philibert, BP 80 13545 Aix-en-Provence cedex 04, France. E-mail: elsa.bonnaud@univ-cezanne.fr

10233. Brodin, T.; Drotz, M.K. (2011): Larval behavioral syndrome does not affect emergence behavior in a damselfly (*Lestes* congener). *Journal of Ethology* 29(1): 107-113. (in English) ["Activity is a key behavioural trait that often mediates a trade-off between finding food for growth and evading predation. We investigated how activity of the damselfly *Lestes* congener is affected by larval state and predator presence and if larval behavioural type (BT) can be used to predict larval emergence behaviour. Activity level of individual larvae was studied without predators at two different physiological states (hungry, fed) and in two predator treatments (familiar or unfamiliar predator cues). Larvae did not adjust their activity depending on state or when subjected to unfamiliar predator cues but a general reduction in activity was seen in the familiar predator treatment. Hence, active individuals remained active compared to their conspecifics, independent of state or predator treatment illustrating the presence of a behavioural syndrome. However, we found no correlation between larval BT and emergence behaviour. Active individuals did not differ from less active individuals in any emergence characteristics. The results illustrate that the larval BT occurs in many situations keeping active larvae active even in maladaptive situations. Furthermore, we show that damselfly emergence behaviour can be completely decoupled from larval BT, indicating a loss of stability in individual BT during critical stages in ontogeny." (Authors)] Address: Brodin, T., Dept of Ecology and Environmental Science, Umeå University, S-90187 Umeå, Sweden. E-mail: tomas.brodin@emg.umu.se

10234. Burrone, N.E.; Marione, M.C.; Freire, M.G.; Schweigmann, N.; Loetti, M.V. (2011): Invertebrate communities from different wetland types of Tierra del Fuego. *Insect Conservation and Diversity* 4(1): 39-45. (in English) ["1. Loss or deterioration of wetlands, which represent highly valuable environments, is a worldwide phenomenon. Sustainable management of wetlands, however, requires detailed understanding of the factors controlling their communities. The present study report the taxonomic composition and richness of invertebrate assemblages in different wetland types in Tierra del Fuego. 2. Aquatic invertebrates from 79 freshwater wetlands in Tierra del Fuego were inventoried in January 2001 and 2002 (austral summer). All wetlands were classified into six categories: roadside pools, floodplain pools, flooded quarries, peatland ponds, beaver ponds and large ponds. The wetland type effect on the taxonomic richness was analysed by one-way ANOVA. To identify wetland types with similar invertebrate communities, cluster analysis has been performed using occurrence frequency of each taxa in each wetland type and the Jaccard similarity index. 3. A total of 35 taxa were identified, including 21 microcrustaceans, 12 insects

(including "Anisoptera"), 1 gastropod and 1 cnidarian. Copepods and cladocerans were among the most frequent taxa (occurrence frequency >40%) in most wetland types. No significant differences in taxonomic richness were found among wetlands types ($P = 0.076$). The cladogram based on invertebrate taxonomic composition resulting from similarity in taxonomic composition among wetland types showed three distinct clusters; one included flooded quarries, peatland ponds, beaver ponds and floodplain pools, the second one the large ponds and the third one roadside pools. 4. Our results suggest that the wetland types studied have different conservation values, like the clusters obtained in the cladogram show. Artificial wetlands, such as the roadside pools, could play an important role in maintaining connectivity between isolated fragments of pristine, natural wetlands." 10237. Cielocha, J.; Cook, T.J.; Clopton, J. (2011): Host utilization and distribution of Nubenocephalid gregarines (Eugregarinorida: Actinocephalidae) parasitizing *Argia* spp. (Odonata: Zygoptera) in the Central United States. *Comparative Parasitology* 78(1): 152-160. (in English) ["Gregarine host specificity has been the cornerstone of gregarine taxonomy for nearly a century. Several laboratory experiments have accepted strict host specificity by failure to cross-infect distantly related hosts with unrelated gregarine species. These empirical studies are not feasible for all gregarine hosts, especially nondomesticated groups. Additionally, studies of gregarine distributions have always focused on insect hosts of disparate groups, rather than targeting potential hosts species within a single genus and their congeneric gregarines. This study addresses host utilization of nubenocephalid gregarines parasitizing the odonate genus *Argia*. Populations of 9 species of adult *Argia* were collected, dissected, and observed for gregarine infection during the April–September flight seasons in 2007 from 17 localities in the central United States. On average, 2.5 species of *Argia* were collected at each locality. A species of *Nubenocephalus*—*Nubenocephalus nebraskensis*, *Nubenocephalus secundus*, or *Nubenocephalus* spp.—was collected from every infected population of *Argia* except for the *Argia vivida* popula-

tion at Prairie Dog Town Fork-Red River, Randall County (Co.), Texas, U.S.A. *Nubenocephalus secundus* utilizes at least 7 of the 9 argid hosts sampled whereas *N. nebraskensis* was collected from only 2 argid species. Only *Argia translata* was observed to host both *N. secundus* and *N. nebraskensis*. These patterns of host utilization by nubenocephalid gregarines represent an ecotypic gregarine assemblage rather than a vicariant assemblage, demonstrating that nubenocephalid gregarines do not differentiate between species of *Argia* as hosts." (Authors)] Address: Cielocha, Joanna, Dept of Biological Sciences, Sam Houston State Univ., Huntsville, Texas 77341-2166, USA. E-mail: biotjc@shsu.edu

10239. Dijkstra, K.-D.B.; Clausnitzer, V.; Mézière, N.; Kipping, J.; Schütte, K. (2011): Chapter 5. The status and distribution of dragonflies and damselflies (Odonata) in central Africa. In: *The Status and Distribution of Freshwater Biodiversity in Central Africa* Brooks, E.G. E., Allen, D.J. and Darwall, W.R.T. (Compilers): 62-76. (in English) ["Equatorial Africa is naturally dominated by almost continuous Guineo-Congolian lowland rainforest, which has a gradual transition of riverine forests and woodland into peripheral savannahs. The highest odonate diversity in tropical Africa is found here : all African countries with well over 200 species have a considerable portion of this forest within their borders (Dijkstra and Clausnitzer 2006). Although many species range throughout Africa's forested heart, it can be subdivided into four main areas of endemism (Dijkstra 2007a), of which only the more westerly Upper Guinea lies outside the central Africa assessment region (see Dijkstra et al. 2010). The three others are (1) the Lower Guinea, with the Cameroon highlands as its focus, (2) the Congo Basin, and (3) the slope east of the Congo River towards the Albertine Rift. Each area, which agree reasonably with the freshwater ecoregions of Thieme et al. (2005), is discussed separately below, as is the large area of more open habitats to the south of the rainforest belt that dominates Katanga and adjacent Angola and Zambia. Central Africa has the richest, but also the least known and probably (currently) least imperilled, odonate fauna in Africa. Therefore this report focuses primarily on what we do and, especially, do not know. Much emphasis is given on recent discoveries, including collection work conducted as part of the central African freshwater biodiversity assessment and fieldwork by the authors in Cameroon and Gabon (all results otherwise still unpublished). We attempt to provide information on all threatened (or Near Threatened) and Data Deficient species in the region, their status being Least Concern unless indicated." 10242. Dolny, A.; Barta, D.; Lhota, S.; Rusdianto; Drozd, P. (2011): Dragonflies (Odonata) in the Bornean rain forest as indicators of changes in biodiversity resulting from forest modification and destruction. *Tropical Zoology* 24(1): 63-86. (in English) ["Dragonfly assemblages represent sensitive indicators of environmental conditions including the water environment and forest structure. However, an understanding the ecology of tropical forest odonates remains one of the most significant gaps in our knowledge of the order. We sampled odonates at Sungai Wain Protection Forest, East Kalimantan, Indonesia. Relatively high dragonfly species richness (88 species) was found during 35 survey days divided between two seasons. Seasonal differences in the species diversity were fairly small, in accordance with the fact that the climate in Kalimantan is generally stable. The highest species diversity was observed in intact primary forest: 60% of all recorded species were found there and 32% of all species were exclusive to this habitat. The proportion of biotope specialists decreased along the gradient - intact primary forest, slightly degraded primary forest, secondary forest, heavily degraded forest and non-forest. The ordination obtained from detrended correspondence analysis showed, along the main axis, a gradient in community similarity corresponding to the degree of forest degradation. The evidence indicates that, within the applied spatial scale, any forest degradation results in fewer species, with a pronounced change in the species composition, and an overall reduction in taxonomic diversity." (in English) ["*Coeliccia southwelli* sp. nov. is described from Mount Dulit, Miri and Kapit Divisions, Sarawak, Malaysian Borneo. It belongs to the borneensis-group of species, and is the sixth species from this group to

be described from Borneo. New material of other borneensis-group species is put on record." (Authors)] Address: Dow, R.A., 6 Bramley Avenue, Coulsdon, Surrey, CR5 2DP, UK. E-mail: rory.dow@virgin.net

10244. Doxon, E.D.; Davis, C.A.; Fuhlendorf, S.D. (2011): Comparison of two methods for sampling invertebrates: vacuum and sweep-net sampling. *Journal of Field Ornithology* 82(1): 60-67. (in English, with Spanish summary) ["With numerous invertebrate sampling techniques available, deciding which technique to use under certain circumstances may be difficult. Many researchers interested in invertebrate abundance and availability relative to the foraging ecology of birds may use a technique (e.g., vacuum sampling or sweep-netting) without understanding the impacts their choice may have on the samples collected and the ability of the method to meet research objectives. We compared the characteristics, including overall biomass, morphospecies richness, average size, diversity, and body length categories, of invertebrates collected using a sweep-net and a Dietrick vacuum sampler along paired transects in Woodward County, Oklahoma, from May to July 2007 and 2008. These sampling techniques differed in the taxa collected, with the orders Diptera, Homoptera, and Hymenoptera dominating vacuum samples and the orders Homoptera, Orthoptera, and Araneae dominating sweep-net samples. Although morphospecies richness was similar for the two techniques, the mean size of invertebrates collected and overall invertebrate biomass were greater for sweep-netting than vacuum sampling. Vacuum sampling was more effective at collecting small (e.g., <5 cm) invertebrates, whereas sweep-netting captured large (>5 cm) orthopteran and lepidopteran larvae at higher rates. Thus, our results indicate that neither sampling method effectively sampled all invertebrate families and investigators should be aware of the potential biases of different sampling techniques and be certain that the technique selected will allow study objectives to be met." (Authors) Comparing the mean relative biomass collected for Odonata by vacuum sampling and sweep-netting, no significant differences resulted.] Address: Doxon, Elizabeth, Department of Natural Resource Ecology and Management, Oklahoma State University, 008C Agricultural Hall, Stillwater, Oklahoma 74078, USA. 10245. Eckberg, J.R. (2011): Las Vegas Wash Invertebrate Inventory, 2000-2010. Prepared for: Research and Environmental Monitoring Study Team, Las Vegas Wash Coordination Committee: VI + 22 pp, appendix. (in English) ["This report summarizes previously documented, as well as undocumented, invertebrate specimens identified along the Las Vegas Wash (Wash), where this wildlife group has a significant impact on ecological components. Four of the six major environmental resource categories laid out in the Las Vegas Wash Comprehensive Adaptive Management Plan are impacted by invertebrates: water quality, soils, vegetation, and fish and wildlife. Living in both aquatic and terrestrial environments, many invertebrates serve as indicators of environmental quality in both areas. Insects are the primary pollinator for many plants along the Wash and provide many other benefits such as controlling herbivores and seed dispersal. Many insects can be primary consumers of plant material and secondary consumers of other insects. They are also the food source for a wide variety of birds, small mammals, fish, reptiles and amphibians. Cataloging these species will

help researchers by providing baseline information and will provide managers' information on the species impacted by work being done. Further study of this animal group is needed to better understand their true impact on the ecological system at the Wash." (Author) The following Odonata are listed in an appendix: *Anax junius*, *Rhionaeschna multicolor*, *Hetaerina americana*, *Argia* sp. *A. alberta*, *A. moesta*, *A. sedula*, *A. vivida*, *Enallagma civile*, *Ischnura cervula*, *I. denticollis*, *Erpetogomphus compositus*, *Erythemis collocata*, *Libellula comanche*, *L. luctuosa*, *L. saturata*, *Orthemis ferruginea*, *Pantala hymenaea*, *Sympetrum corruptum*, *Tramea lacerata*, *T. onusta*.] Address: Eckberg, J.R., Southern Nevada Water Authority, 100 City Parkway, Suite 700, Las Vegas, Nevada 89106, USA

10246. Everard, M.; Fletcher, M.S.; Powell, A.; Dobson, M.K. (2011): The feasibility of developing multi-taxa indicators for landscape scale assessment of freshwater systems. *Freshwater Reviews* 4: 1-19. (in English) ["The use of bird assemblages as wetland indicators is now well established in the UK. An indicator based on a single taxonomic group can, however, have limitations. Conversely, a multi-taxa approach can potentially provide a more robust reflection of the health of fresh waters. In this paper, we consider the inherent suitability of different taxonomic groups for inclusion in a multi-taxa indicator, based upon taxon characteristics, species richness and prevalence across a range of freshwater habitats, and their practical suitability, based upon quality and quantity of available data. We conclude that, in addition to birds, there are six candidate groups of taxa throughout the world that are currently suitable for inclusion in a multi-taxa indicator. These are: mammals, amphibians and reptiles, fish, dragonflies and damselflies (based on adult recording), benthic macroinvertebrates and macrophytes. Of these taxa, all but amphibians and reptiles and fish are suitable for inclusion in a UK indicator. The types and limitations of currently available datasets are reviewed. We provide recommendations for advancing this approach in the assessment of freshwater systems. [...] Odonata are part of the aquatic macroinvertebrate fauna as larvae, but as adults they are also very suitable as candidates for inclusion in a multi-taxa indicator, as they are easy to see and distinguishable in the field, and provide information about the status of the terrestrial shoreline of habitats as well as the underwater component. Most are also highly mobile, and they will rapidly colonise new or restored sites and abandon impacted sites. Worldwide, the dragonfly and damselfly fauna is relatively well known (Kalkman et al., 2008), and their conspicuous nature and often high alpha diversity makes them an attractive option for biomonitoring. Adult Odonata are the most thoroughly recorded emergent aquatic invertebrates in the UK. The Dragonfly Recording Network is co-ordinated by the British Dragonfly Society and operates within guidelines based upon recommendations given by the National Biodiversity Network. However, the quantity and spread of data is not currently adequate to be considered a robust national monitoring programme." 10247. Feindt, W.; Damm, S.; Hadrys, H. (2011): Speciation in the neotropical giant damselfly *Megaloprepus caerulatus* reflects forest fragmentation (Pseudostigmatidae: Odonata). In: Niekisch, M. & B. Streit (Eds.): Status and future of tropical biodiversity. Conference of

the Society for Tropical Ecology, Gesellschaft für Tropenökologie e.V. - gto, Goethe University, 21 - 24 February 2011, Frankfurt a. M., Programme & Abstracts: 190. (in English) [Verbatim: "Increasing fragmentation rates of tropical forests disturb ecological dynamics and result in loss of biological and genetic diversity. Odonates, which are sensitive indicator organisms, face the destruction of tropical forests as probably the most important threat (Kalkman et al. 2008). Due to their complex life cycle and specific habitat preferences odonates come to know an increasing importance for measuring environmental health and identifying driving factors controlling biodiversity. *Megaloprepus caerulatus* the world's largest damselfly is widespread in the Neotropics from the South of Mexico to Bolivia (Davies & Tobin 1984, Finke & Hedström 2008). It is highly restricted to primary forests and old grown secondary forests, which provide water filled tree holes needed for reproduction. Females exclusively oviposit in water filled tree holes, which are defended by males. The size and the density of these microhabitats ultimately affect larval abundance and survivorship (Fincke 2006) resulting in changes in population size and structure. We used two mitochondrial sequence marker (ND1 and 16S rDNA) and microsatellites to analyze the population structure and diversities between populations covering the northern range of *M. caerulatus* between Mexico and Panama. High sequence divergences and an absence of gene flow indicate complete separation of all populations studied. Our results suggest ongoing speciation processes within the genus *Megaloprepus* probably driven by ongoing fragmentation of their forest habitats. Genetic distances at the species level suggest that the *Megaloprepus caerulatus* is not a single species rather than a group of at least three species. Our data illustrate the impact of tropical rainforest fragmentation on genetic isolation of a habitat specialized species and demonstrate how important it is to evaluate genetic diversities of indicator species. Together with general monitoring data the knowledge about conservation genetic parameters allow to propose refined conservation decisions in tropical forests." 10248. Fincke, O.M. (2011): Excess offspring as a maternal strategy: constraints in the shared nursery of a giant damselfly. *Behavioral Ecology* 22(3): 543-551. (in English) ["Maternal reproductive strategies should optimize the quality and quantity of surviving offspring. In *Megaloprepus caerulatus*, a damselfly that exhibits male-biased size dimorphism, larval siblicide, and a disproportionate fitness advantage from large sons, mothers lay many more eggs in water-filled tree holes than can survive to emergence. Using field experiments, I tested the siblicide advantage of excess offspring (i.e., faster development and/or larger survivors) in small and large holes and 2 alternative functions of excess offspring (predator satiation and insurance against nonpredator mortality). In small pots, the sole siblicidal survivors emerged larger than noncannibals but no sooner. However, doubling or even quadrupling a modest clutch of 25 failed to produce larger offspring. In large tubs, the size advantage that survivors gained from siblicide was constrained by a trade-off between offspring size and number. A clutch of 20 produced half as many but larger offspring than one of 100. When multiple females contributed eggs to a large nursery,

size of survivors was independent of the mother's clutch size. Finally, large clutches failed to satiate dragonfly predators, and although 25 neonates were better than 2 as insurance against nonpredator mortality, a clutch of 50 provided no additional benefit. In natural and experimental holes, survivorship was female biased, suggesting that sons suffered greater mortality than daughters. Because mothers seemed unable to adaptively bias offspring sex ratio, excess offspring may compensate for the lower survivorship of sons, particularly in large nurseries where males garner a disproportionate size advantage relative to females." 10249. Florencio, M.; Diaz-Paniagua, C.; Serrano, S.; Bilton, D.T. (2011): Spatio-temporal nested patterns in macroinvertebrate assemblages across a pond network with a wide hydroperiod range. *Oecologia* 166(2): 469-483. (in English) ["Nestedness has been widely used to measure the structure of biological communities and occurs when species-poor sites contain subsets of species-rich ones. Here, we examine nested patterns across the macroinvertebrate assemblages of 91 ponds in Doñana National Park, Spain, and explore temporal variation of nestedness and species richness in 19 temporary ponds over 2 years with differing rainfall. Macroinvertebrate assemblages were significantly nested; both pond spatial arrangement and environmental variation being important in driving nested patterns. Despite the nested structure observed, a number of taxa and ponds deviate from this pattern (termed idiosyncratic), by occurring more frequently than expected in species-poor sites, or having assemblages dominated by species largely absent from species-rich sites. Aquatic adults of winged insects, capable of dispersal, were more highly nested than non-dispersing taxa and life-history stages. Idiosyncratic taxa were found in ponds spanning a wide range of hydroperiods, although nestedness was higher in more permanent waterbodies. Monthly sampling demonstrated a gradual increase of species richness and nestedness from pond filling to April-May, when the most temporary ponds started to dry. Although the degree of nestedness of individual pond assemblages varied from month to month, the overall degree of nestedness in the two study years was practically identical despite marked differences in hydroperiod. Our results suggest that differential colonization and environmental variation are key processes driving the nested structure of Doñana ponds, that macroinvertebrate assemblages change in a predictable manner each year in response to cycles of pond wetting and drying, and that connectivity and environmental variability maintain biodiversity in pond networks." (Authors) Larvae of *Lestes virens* are largely restricted to long hydroperiod sites, and some *Sympetrum* dragonfly larvae occurred preferentially in ponds with short and intermediate hydroperiods.] Address: Florencio, Margarita, Doñana Biological Station-CSIC, P.O. 10250. Gall, B.G.; Stokes, A.N.; French, S.S.; Schlepforst, E.A.; Brodie, E.D.; Brodie, E.D. (2011): Tetrodotoxin levels in larval and metamorphosed newts (*Taricha granulosa*) and palatability to predatory dragonflies. *Toxicon* 57(7-8): 978-983. (in English) ["Some populations of the newt *Taricha granulosa* possess extremely high concentrations of the neurotoxin tetro-

dotoxin (TTX). Tetrodotoxin is present in adult newts and their eggs, but has been assumed to be absent from the larval stage. We tested larval and metamorphosed juveniles for the presence of TTX and evaluated the palatability of these developmental stages to predatory dragonfly nymphs. All developmental stages retained substantial quantities of TTX and almost all individuals were unpalatable to dragonfly nymphs. Tetrodotoxin quantity varied greatly among individuals. When adjusted for mass, TTX concentrations declined steadily through metamorphosis. Several juveniles were palatable to dragonflies and these individuals had significantly lower TTX levels than unpalatable juveniles. These results suggest that despite previous assumptions, substantial quantities of TTX, originally deposited in the embryo, are retained by the developing larvae and metamorphosed juveniles and this quantity is enough to make them unpalatable to some potential predators." 10251. Gassmann, D.; Richards (2011): Odonata (damselflies and dragonflies) of the Nakanai Mountains, East New Britain proving, Papua New Guinea RAP. Rapid Biological Assessments of the Nakanai Mountains and the upper Strickland Basin: surveying the biodiversity of Papua New Guinea's sublime karst environments 60: 61-69. (in English) ["Odonatological results of a biodiversity assessment ... in April 2009 are presented. Thirty-two species of Odonata were collected at three different elevations (200-1,700 m) in the Nakanai Mountains and, to a minor extent, on the coastal fringe of Jacquinot Bay. Ten species are recorded from New Britain island for the first time. An undescribed species of *Pseudagrion* Selys and a species or subspecies of *Tetrathemis* Brauer new to science were found. Eleven odonate taxa appear to be endemic to the island and some species were only found at particular elevations suggesting that more odonate species await discovery on the island. Due to the karst topography of the Nakanai Mountains, surface water that is essential for the development of odonate larvae is very scarce in the region. Natural forest cover is crucial for the survival of forest-dwelling habitat specialists, particularly those occupying the limited above-ground aquatic habitats that do exist. The designation of a World Heritage Area in the Nakanai Mountains will be an important first step to protect New Britain's unique aquatic invertebrate fauna from extinction." 10253. Gossum, H. van; Bots, J.; Heusden, J. van; Hammers, M.; Huyghe, K.; Morehouse, N.I. (2011): Reflectance spectra and mating patterns support intraspecific mimicry in the colour polymorphic damselfly *Ischnura elegans*. *Evol. Ecol.* 25: 139-154. (in English) ["Coexistence of female colour morphs in animal popula-

tions is often considered the result of sexual conflict, where polymorphic females benefit from reduced male sexual harassment. Mate-searching males easily detect suitable partners when only one type of female is present, but become challenged when multiple female morphs coexist, which may result in frequency-dependent mate preferences. Intriguingly, in damselflies, one female morph often closely resembles the conspecific male in body coloration, which has led to hypotheses regarding intra-specific male-mimicry. However, few studies have quantitatively evaluated the correspondence between colour reflectance spectra from males and male-like females, relying instead on qualitative visual assessments of coloration. Using colour analyses of reflectance spectra, we compared characteristics of the body coloration of ontogenetic male and female colour morphs of the damselfly *Ischnura elegans*. In addition, we evaluated whether males appear to (1) discriminate between immature and mature female colour morphs, and (2) whether male-like females experience reduced male mating attention and low mating frequencies as predicted from male-mimicry. Spectral reflectance data show that immature female morphs differ substantially in coloration from mature individuals. Mating frequencies were much lower for immature than mature female morphs. For the male-like female morph, measures of colour were statistically indistinguishable from that of both immature and mature conspecific males. Mating frequencies of male-like females were lower than those of other mature female morphs under field and experimental conditions. Together, our results indicate that males may use the observed spectral differences in mate choice decisions. Furthermore, male-like females may be regarded as functional mimics that have reduced attractiveness and lowered rates of sexual harassment by mate-searching males." 10254. Grant, P.B.C.; Samway, M.J.; Simaika, J.P. (2011): Threats to dragonflies on land islands can be as great as those on oceanic islands. *Biological Conservation* 144(3): 1145-1151. (in English) ["We ask whether oceanic islands and equivalent-sized continental blocks, which we call here 'land islands', are similar or not in their species richness, number of range-restricted species, and in number of threatened species. We used sites in southern Africa and islands in the Western Indian Ocean. We chose dragonflies as they are taxonomically tractable, well surveyed, and provide a range of characteristics from narrow-range endemics to widely-spread and vagile opportunists. We then selected as many oceanic islands as possible where there were sufficient data to make comparisons with land islands of a similar area in African savanna, grassland and mountains rich in endemic species. Generalized Linear Mixed Models were used to analyse the overall, range-restricted and threatened species richness for all islands (both oceanic and land) and then for the two types of island separately. Species richness increased with island size, with oceanic and land island size relationships being similar. Land islands overall had significantly more range-restricted species. Species on land islands were as threatened as those on oceanic islands. However, the land islands of the Western Cape were under a higher level of threat than oceanic islands of comparative size. The large islands of Madagascar and Sri Lanka were outliers with very high levels of threat. Trans-

lated into conservation, the results illustrate that over-generalizations about island faunas being more threatened than continental ones are not necessarily valid. While not wishing to draw attention away from the urgent conservation action needed on many tropical islands, we argue that comparisons of oceanic versus land islands detract from the more urgent task of local conservation action based on the special needs of any particular area, whether land or oceanic. It is more meaningful to establish how threats operate and how to mitigate them on small populations rather than focusing purely on any particular island type per se." 10255. Grant, P.B.C.; Samway, M.J. (2011): Micro-hotspot determination and buffer zone value for Odonata in a globally significant biosphere reserve. *Biological Conservation* 144(2): 772-781. (in English) ["Reserves are frequently constrained in design and size by various financial, social or political factors. Maintenance of existing reserves must therefore rely on strategic management practices, and prioritization of conservation activities within them. Identification of global and regional hotspots have been effective for prioritizing conservation activities. Yet, identification of micro-hotspots, or overlapping areas of endemic and rare species that are under threat at the landscape scale, have largely been ignored. From a reserve management point of view, knowledge of critical micro-hotspots within a reserve, are focal points for directing cost effective, conservation initiatives, especially removal of invasive alien plants which are a major threat to biodiversity. Using diversity patterns of dragonfly assemblages, many endemic and threatened, within a biosphere reserve located in the core of a global biodiversity hotspot, we investigated the concept of micro-hotspots. As biosphere reserves contain zones with varying degrees of anthropogenic impact, we also investigated the value of buffer and transition zones for complementing the dragonfly fauna of the reserve core. We found a distinct micro-hotspot within the protected core zone which shows concordance for both endemism and species richness. We conclude that focused conservation actions to remove invasive alien plants within this micro-hotspot would help insure its continued integrity. Furthermore, while there is greater habitat degradation within the buffer and transition zones, they support many additional species, but not those necessarily endemic or threatened. The complementary value of buffer and transition zones therefore lies in increasing habitat heterogeneity and species richness of the whole reserve." (Authors)] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

10258. Harabiš, F.; Dolný, A. (2011): The effect of ecological determinants on the dispersal abilities of central European dragonflies (Odonata). *Odonatologica* 40(1): 17-26. (in English) ["Individual species dispersal ability deserves special attention mainly because of negative impact of human induced changes on freshwater ecosystems. This study is focused on Central European dragonflies, because there is a high concentration of very experienced odonatologists in this region. It is more difficult to estimate dispersal ability of distant taxa than closely related species. This study supports the widespread awareness of limited dispersal abilities of habitat generalists. Although there are a variety of life-history groups between both suborders, the majority of species with limited dispersal abilities are from the suborder Zygoptera. Mediterranean elements, often referred to as those expanding due to global warming, embody higher dispersal abilities than Siberian elements. Lentic species may benefit from the stable conditions of standing waters in comparison to lotic ones, although this preference is not so strong according to authors' analysis." 10260. Huang, C.-C.; Lin, S.-C. (2011): Lineage-specific late Pleistocene expansion of an endemic subtropical gossamer-wing damselfly, *Euphaea formosa*, in Taiwan. *BMC Evolutionary Biology* 2011, 11:94: (in English) ["Background: Pleistocene glacial oscillations have significantly affected the historical population dynamics of temperate taxa. However, the general effects of recent climatic changes on the evolutionary history and

genetic structure of extant subtropical species remain poorly understood. In the present study, phylogeographic and historical demographic analyses based on mitochondrial and nuclear DNA sequences were used. The aim was to investigate whether Pleistocene climatic cycles, paleo-drainages or mountain vicariance of Taiwan shaped the evolutionary diversification of a subtropical gossamer-wing damselfly, *Euphaea formosa*. Results: *E. formosa* populations originated in the middle Pleistocene period (0.3 Mya) and consisted of two evolutionarily independent lineages. It is likely that they derived from the Pleistocene paleo-drainages of northern and southern Minjiang, or alternatively by divergence within Taiwan. The ancestral North-central lineage colonized northwestern Taiwan first and maintained a slowly growing population throughout much of the early to middle Pleistocene period. The ancestral widespread lineage reached central-southern Taiwan and experienced a spatial and demographic expansion into eastern Taiwan. This expansion began approximately 30,000 years ago in the Holocene interglacial period. The ancestral southern expansion into eastern Taiwan indicates that the central mountain range (CMR) formed a barrier to east-west expansion. However, *E. formosa* populations in the three major biogeographic regions (East, South, and North-Central) exhibit no significant genetic partitions, suggesting that river drainages and mountains did not form strong geographical barriers against gene flow among extant populations. Conclusions: The present study implies that the antiquity of *E. formosa*'s colonization is associated with its high dispersal ability and larval tolerance to the late Pleistocene dry grasslands. The effect of 3 late Pleistocene climatic changes on the subtropical damselfly's historical demography is lineage-specific, depending predominantly on its colonization history and geography. It is proposed that the Riss and Würm glaciations in the late Pleistocene period had a greater impact on the evolutionary diversification of subtropical insular species than the last glacial maximum (LGM)." 10261. Kadoya, T.; Akasaka, M.; Aoki, T.; Takamura, N. (2011): A proposal of framework to obtain an integrated biodiversity indicator for agricultural ponds incorporating the simultaneous effects of multiple pressures. *Ecological Indicators* 11(5): 1396-1402. (in English) ["One of the promising approaches to monitoring biodiversity is assessing the status of pressures driving the biodiversity state. To achieve this, we need to identify the principal pressures that cause simultaneous biodiversity loss across taxonomic groups and clarify how multiple pressures act synergistically or at least simultaneously to decrease biodiversity in the focal ecosystem. Here, we used a series of 64 ponds as a case study and we developed a framework for an integrated biodiversity indicator that took into consideration the estimated relative importance of multiple pressures. The indicator is defined as a function of the pressure(s) and is parameterized to explain a number of individual indicators of biodiversity, such as richness, abundance, and functional diversity of focal taxa. We selected aquatic macrophytes, Odonata, and benthic macroinvertebrates as the focal taxa. In addition, we focused on three types of pressure: eutrophication (represented by total phosphorus, total nitrogen, suspended solids, chlorophyll a, and density of cyanobacteria of pond water), habitat de-

struction (land-use type around the pond and pond bank protection), and invasive alien species (abundance of bluegill, largemouth bass, red swamp crayfish, and American bullfrog). We then evaluated the relationships among direct pressures and the individual biodiversity indicators and used a hierarchical Bayesian approach to calculate the integrated biodiversity indicator. Using this framework, we demonstrated that eutrophication had greater effects on the state of biodiversity of the agricultural ponds than did habitat destruction or the presence of invasive alien species. We also showed that the integrated indicator could well explain the behaviours of several individual biodiversity indicators, including total richness, endangered species richness, and functional diversity of focal taxa. These results demonstrate the advantages of the framework in providing a more practical method for assessing biodiversity, and quantifying the relative importance of the major threats to biodiversity to prioritize strategies in conservation planning and policy making." 10262. Kerbiriou, C.; Bargain, B.; Le Viol, I.; Pavoine, S. (2011): Diet and fuelling of the globally threatened aquatic warbler at autumn migration stopover as compared with two congeners. *Animal Conservation* 14(3): 261-270. (in English) ["The effective conservation of aquatic warbler *Acrocephalus paludicola*, one of the most threatened western Palaearctic migratory passerines, requires good knowledge of its ecological needs at stopover sites. In particular, identifying its diet, which controls the accumulation of fat reserves during migration, facilitates the selection and management of adequately protected areas. Further key information includes the relationship between prey species abundance and habitats of aquatic warbler on stopover. We performed standardized mist netting in the Audierne marshes (western France) during 12 years, which resulted in the capture of 1200 aquatic warblers, and provided measurements for mass gain and the collection of faeces to infer the birds' diet. Invertebrate sampling was carried out in the three main Audierne marsh habitats (reed bed, fen mire and meadow). In order to go beyond prey digestibility bias, we also studied two closely related *Acrocephalus* species, present at migration stopover sites during the same period. We found that the diet composition of aquatic warbler observed at migration stopover sites is based on large-sized prey (Odonata, Orthoptera, Lepidoptera). Like sedge warblers, aquatic warblers put on weight during migration stopovers (daily mass gain=0.38 g). This increase in weight suggests that the aquatic warblers might have adopted a strategy for long-distance migration with few stopovers only. Owing to great differences in diet, conservation management for the threatened aquatic warbler at stopover sites should not rely on existing knowledge about sedge and reed warblers. Similarities in the diet of aquatic warbler between nesting areas and migration stopover areas and the relationship between habitat and prey abundance suggest that fen mires play an important role in the quality of the foraging habitat at stopover sites." 10263. Kloskowski, J. (2011): Impact of common carp *Cyprinus carpio* on aquatic communities: direct trophic

effects versus habitat deterioration. *Fundamental and Applied Limnology / Archiv für Hydrobiologie* 178(3): 245-255. (in English) ["*C. carpio*, a worldwide introduced benthivorous fish, has been implicated in the degradation of native environments through initiation of a shift to a phytoplankton-dominated turbid state, which is associated with dramatic biodiversity loss. This study combined surveys of ponds containing either low total biomass of small-sized carp or high densities of large-sized carp with an enclosure/exclosure experiment, in order to quantify the direct (trophic) and indirect (via habitat deterioration) impacts of carp on pond communities. High-density ponds supported substantially lower biodiversity and were more turbid than low-density ponds. The subsequent field experiment examined the effects of carp presence/absence and of clear-water versus moderately turbid conditions mediated by carp on the survival to metamorphosis of larval anurans *Pelobates fuscus* and *Hyla arborea*, on Zygotera and Anisoptera densities, and on the biomass of submerged macrophytes. The presence of enclosed one-year old carp resulted in the complete elimination of larval anurans and the absence of Odonata. The effects of the habitat conditions were not significant, apart from better survival of *P. fuscus* in the moderately turbid carp enclosures than in clear water. Submerged plants were more abundant in clear-water than in turbid treatments, with a negligible effect of enclosures/exclosures. These results suggest that carp predation and related effects may be primarily responsible for animal diversity loss in invaded communities, as they may act prior to, or independent of, the ecosystem switch to a turbid phase." (Authors)] Address: Kloskowski, J., Dept of Nature Conservation, Institute of Biology, M. Curie-Skłodowska University, Akademicka 19, 20-033 Lublin, Poland. E-mail: januszkl@poczta.umcs.lublin.pl

10265. Konopko, D. (2011): New locality of the Pygmy Damselfly *Nehalennia speciosa* (Charpentier, 1840) (Odonata: Coenagrionidae) in the Tricity Landscape Park. *Odonatrix* 7(1): 24-27. (in Polish, with English summary) ["*N. speciosa* inhabits mainly small natural water bodies with the area less than 1 ha, great amount of mud sedge *Carex limosa* and slender sedge *C. lasiocarpa* as well as submerged vegetation. In Poland, 75 sites of this species have been discovered so far of which 44 are regarded as contemporary. In the Tricity Landscape Park, the Pygmy Damselfly was discovered for the first time in July 2006 at the site about 1,1 km NE away from Kamień in the commune of Szemud (Konopko 2007). The next site was discovered in July 2009, in a peat bog bordered from NE with Zawiat Lake situated in the vicinity of Bieszkowice, in the commune of Wejherowo. The central point of the peat bog is a dystrophic water body with the Sphagnum moss mat separated from the lake by 90 meter-width belt of *Vaccinio uliginosi*-*Pinetum sylvestris* Kleist 1929 bog woodland. *N. speciosa* are present in *Carex limosa* swamp. The population is small; the highest number of individuals was 70. During earlier studies this species was not found in the peat bog. The colonization of this site was probably made before our eyes. Except for *N. speciosa*,

32 dragonfly species were observed in the peat bog in which four of them are under protection: *Aeshna subarctica*, *Leucorrhinia albifrons*, *L. caudalis* and *L. pectoralis*. In the future, in the area of the peat bog, the forming of the nature reserve called „Bieszkowickie Moczary” is planned, however, nowadays the steps for establishing the second refuge for the *N. speciosa* in the area of the Tricity Landscape Park are taken." 10266. Kovalenko, K.E.; Dibble, E.D. (2011): Effects of invasive macrophyte on trophic diversity and position of secondary consumers. *Hydrobiologia* 663(1): 167-173. (in English) ["Invasive species are one of the widespread stressors of aquatic ecosystems. Several studies document food web effects of invasive fish, but little information is available on the effects of invasive macrophytes. We studied differences in food chain length as well as trophic position and trophic diversity of fish and odonates in lakes dominated by native plants or invasive Eurasian watermilfoil. Trophic position and food chain length were determined using baseline-adjusted $\delta^{15}\text{N}$ isotope signatures. Trophic diversity, or isotope niche width, was estimated from convex hull area analysis. Results show that trophic position of secondary consumers was not affected by the invasive macrophyte, whereas trophic diversity was greater in watermilfoil-dominated lakes. The direction of isotopic niche expansion was different in fish and odonates, suggesting potential decoupling in predator-prey interactions. This study shows that dominant non-native macrophytes may cause significant changes in food web structure of invaded ecosystems. Trophic diversity may be a more sensitive indicator of environmental stress than trophic position and has the potential to be used for assessment of invasive species impacts and restoration success." 10267. Koyama, T.; Takano, H.; Yokoyama, T. (2011): Micropores in the Vitelline Layer of the Eggs of the Dragonfly *Oligoaeshna pryeri*: A Preliminary Observation from the Viewpoint of Oxygen Uptake. *Advances in experimental medicine and biology* 915: 307-310. (in English) ["In dragonfly eggs, oxygen diffusing in, and carbon dioxide diffusing out, encounter barriers in the shell. According to Tullett and Board, in avian eggs the most important of these barriers results from the geometry of the pores through the shells. As in birds, dragonfly egg shells consist of three layers: the exochorion, endochorion and the innermost vitelline membrane. Trueman has described pores and fine anchorlike structures in the endochorion but the vitelline membrane does not seem to have been studied. In the present work we have used scanning electron microscopy to examine the vitelline membrane in hatching eggs of *Oligoaeshna pryeri*. We have assumed that the numerous openings seen on the micrographs are pores through the membrane. Results are expressed as means \pm SD. The pore diameter, pore area and number per μm^2 of the vitelline membrane were 74.7 ± 61.3 nm, 4380 ± 3555 nm² and 4.16 ± 1.3 pores/ μm^2 (4.16×10^8 pores/cm²), respectively. The total pore area was calculated to be 18,222 nm²/ μm^2 . In avian egg shells pore density depends on the weight of the egg. Results given by Tullett and Board suggest that an egg weighing 1 g may have a pore density of 300 pores/cm², which is

much lower than the present result for dragonflies. It seems likely that the difference reflects the fact that in *Oligoaeshna pryeri* the eggs are immersed in water." (Authors)] Address: Koyama, T., Hokkaido University, Sapporo, Japan. E-mail: tomkoyamajp@yahoo.co.jp.

10268. Lampo, C.; Riservato, E.; Lencioni, V. (2011): Contributo alla conoscenza dell'odonatofauna della Val di Ledro (Trentino). *Studi Trent. Sci. Nat.* 88: 53-59. (in Italian, with English summary) ["In 2009-2010 the odonatofauna from two lakes, Ampola and Ledro (southern Trentino, NE-Italy) was studied. Larvae, exuviae and adults were collected. In all, 21 species were identified, all of them already known for the Trentino Province but only three already found in the study area. The occurrence in Trentino of two species, *Somatochlora flavomaculata* and *Aeshna isosceles*, is confirmed after 30 years. As expected, a higher species richness was recorded in Lake Ampola, being a protected site since 1990thies: 16 species of which 9 with evidence of reproduction. Only 9 species (of which 5 reproductive, with modified phenology) were observed at Lake Ledro, impacted by water abstraction with consequent high level fluctuations." 10270. Lima Silveira, T.C.; Rodrigues, G.G.; Coelho de Souza, G.P.; Würdig, N.L. (2011): Effects of cutting disturbance in *Schoenoplectus californicus* (C.A. Mey.) Soják on the benthic macroinvertebrates. *Acta Scientiarum. Biological Sciences*, Maringá 33(1): 31-39. (in English, with Portuguese summary) ["Lagoons are considered protected areas because these systems play a key ecological role. However, the extraction of macrophyte *Schoenoplectus californicus* is held for manufacture of handicrafts, being an alternative income for riverbank communities. This study evaluated the impact of *S. californicus* experimental cutting on benthic macroinvertebrates through a field experiment. Macroinvertebrates were sampled at 1, 12, 26 and 60 days after the macrophyte cutting in demarked plots (1 m²), as well at control plots. The families number was not statistically different (ANOVA, $p > 0.05$), but the total density of invertebrates, and the density of *Ceratopogonidae* were significant (ANOVA, $p < 0.05$) for interaction between sampling date and treatment. A Principal Components Analysis identified that the level of the water column was the variable that most influenced the variation between the samples gathered in the experiment. We concluded that the cutting of *S. californicus*, in this area, as the intensity of the cut held, did not affect considerably the aquatic macroinvertebrates. The results

suggest that the small-scale extractivism in these regions carries little effect because the fauna of adjacent areas probably can quickly colonize the disturbed areas. ... Because only the fauna associated with sediment have been assessed in this study, some taxa more active or rare, were not sampled in larger quantities, among them Odonata, Ephemeroptera and Hyallellidae (Table 1). The sampler used (corer) is more effective in collecting taxa with little mobility, i.e. most of detritivores." 10271. Mac Nally, R.; Wallis, E.; Lake, P.S. (2011): Geometry of biodiversity patterning: assemblages of benthic macroinvertebrates at tributary confluences. *Aquatic ecology* 45(1): 43-54. (in English) ["We assessed whether tributaries in upland catchments (=watersheds) affected assemblages of benthic macroinvertebrates in mainstems, as has been reported in northern hemisphere systems. Eight confluences of small to medium streams (stream orders 1–4, 2.2–10.8 m wide) were studied in the Acheron River basin in Victoria, Australia. For each confluence, two transects were sampled at each of five zones relative to the confluence: two zones upstream in the mainstem, one zone upstream in the tributary, one zone at the confluence and one zone downstream in the mainstem. Surveys were conducted in both high-flow and lowflow conditions. In mainstems, there was no change in macroinvertebrate density, taxonomic richness or functional feeding group composition downstream relative to upstream of the confluences. While tributaries statistically had distinctive benthic macroinvertebrate assemblages compared to mainstems, these distinctions were small. In low flows, densities in tributaries were substantially lower than in mainstems, but densities during high flows were more similar (albeit only about one-third as high as in low flow) in tributaries and mainstems. An inverse pattern was evident for taxonomic richness, where richness in tributaries and mainstems was similar in low flows but was greater in mainstems than in tributaries in high flows. We found little evidence of tributary effects in macroinvertebrate assemblages in this basin, which is at odds with some previous results from other continents. To explain this divergence, we suggest a conceptual model outlining factors that control variation in effects of tributaries on assemblages of benthic macroinvertebrates in mainstems." (Authors) The "Supporting information" to this paper includes a list of taxa recorded in the Acheron River catchment and including "Synthemistidae" and "Telephlebiidae".] Address: Mac Nally, R., Australian Centre for Biodiversity, School of Biological Sciences, Monash University, Melbourne 3800, Australia. 10274. Medlock, J.M.; Vaux, A.G.C. (2011): Assessing the possible implications of wetland expansion and management on mosquitoes in Britain. *European Mosquito Bulletin* 29: 38-65. (in English) ["The expansion of existing wetlands, their creation from arable land, and the creation of new saltmarsh to alleviate coastal erosion and flooding are important UK issues as the environment sector adapts to the possible impacts of climate change and continues to meet its goals in providing increased wetland habitat for wildlife, and an outdoor space for human 'well-being'. Concerns have been raised over the potential impacts that such initiatives might have on mosquitoes and the possible future transmission of infectious diseases. This paper aims to firstly review wetland management and design strategies used in North America and Australia in relation to managing mosquitoes in wetlands, and secondly specifically discuss possible mitigating strategies for the key British mosquito species of freshwater wetland habitats in order to guide future research in this field. Developing this evidence-base is a crucial element in preparing for the emergence of mosquito-borne disease in the UK and in aiding policy makers in their assessments of the risks and impacts associated with wetland expansion on mosquito nuisance and disease risk. It is important to ensure that biodiversity gain and habitat restoration can advance without inadvertently elevating the risks from disease vectors." (Authors) Passing references to Odonata as predators of mosquitoes are made.] Address: Medlock, J.M., Medical Entomology & Zoonoses Ecology Group, Microbial Risk Assessment, Emergency Response Department, Health Protection Agency, Porton Down, Salisbury, Wiltshire SP4 0JG, UK. katchewan. In: *Arthropods of Canadian Grasslands (Volume 2): Inhabitants of a Changing Landscape*. Edited by K. D. Floate. Biological Survey of Canada. ISBN 978-0-9689321-5-5: 119-157. (in English, with French summary) ["The diversity of aquatic insects in the Saskatchewan River system in Saskatchewan is high. This reflects the postglacial recruitment of species from as far away as the Colorado River system and Eurasia, but also the diverse nature of the waterway itself. Clear, cool waters flow over a variety of rubble, gravel, and sand substrates and harbour habitats of submerged branches, logs, and growing vegetation. Of the more than 1,000 species of aquatic and semi-aquatic insects that inhabit waters on the grasslands of the Canadian prairie, at least half occur in streams and rivers. This chapter provides an overview of the latter species, with an emphasis on mayflies (Ephemeroptera), stoneflies (Plecoptera), caddisflies (Trichoptera), and non-biting midges (Chironomidae) and only brief mention of other insect species. Aquatic insects often represent a large biomass with great biodiversity in pristine prairie rivers. This is still the case for some areas of the Saskatchewan River, which shows minimal damage and appears to be in its near original state. Elsewhere, however, dams, sewage, and agricultural runoff have degraded aquatic habitats over large expanses. Laws protecting flowing waters in Canada are weak, and large areas of these waters require detailed study to increase our understanding of the biodiversity and ecological roles of aquatic insects." (Authors) Odonata are treated at pages 150-152.] Address: Miyazaki, R., Department of Biology, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N 5E2

10277. Muzon, J.; Lozano, F. (2011): Description of the final instar larva of *Progomphus joergenseni* Ris (Ephemeroptera: Gomphidae). *Zootaxa* 2762: 56-60. (in English) ["The final instar larva of *P. joergenseni* is described and illustrated for the first time based on specimens collected in Río Negro Province, northern Patagonia, Argentina. Right mandibular molar crest shows an extreme reduction in the number of teeth with no intermediates between teeth a and b. Antennal, leg and paraprocts morphology suggest a close relationship with the species included in the *Pygmaeus* group, but *P. joergenseni* differs from them because of its larger size and longer anal pyramid." 10278. Nagel, L.; Zanuttig, M.; Forbes, M.R. (2011): Escape of parasitic water mites from dragonfly predators attacking their damselfly hosts. *Canadian Journal of Zoology* 89(1): 213-218. (in English, with French summary) ["Many parasites are transmitted trophically, whereas others can either succumb to, or escape from, the predators of their hosts. We examined the extent to which larval arrenurid water mites (*Arrenurus planus* Marshall, 1908 and *Arrenurus pollictus* Marshall, 1910) parasitizing *Lestes forcipatus* and *L. disjunctus* escape from predatory libellulid dragonflies that are consuming their hosts. We hypothesized that the brightly coloured mites would be avoided by feeding dragonflies. However, all partially engorged *A. pollictus* mites were eaten while their host was being consumed in staged predation trials. In contrast, half of the fully engorged mites detached and therefore escaped consumption. Trials with *A. planus* mites showed that they detached more readily than their congeners, which may be due to se-

lection on those temporary pond mites to survive desiccation stress following detachment. The effect of dragonfly predation on transitioning of mites from parasitic larvae to their free-living aquatic stages therefore depends on the degree of engorgement and the mite species." 10280. Nelson, S.M. (2011): Response of stream macroinvertebrate assemblages to erosion control structures in a wastewater dominated urban stream in the southwestern U.S. *Hydrobiologia* 663: 51-69. (in English) ["Effects of stream erosion control structures on aquatic macroinvertebrates were studied (2000–2009) in a wastewater dominated drainage (Wash) in Las Vegas, Nevada. Mainstem sites with and without structures, wastewater treatment plant outfalls, a reference site above treatment plant inputs, and tributary sites were sampled. Ordination suggested hydrology and channel characteristics (current velocity, stream depth, and width), and water quality (conductivity) were primary factors in organizing macroinvertebrate communities, with some variables altered at structures. Treatment plant inputs changed hydrology (increased flows), water chemistry (conductivity decreased below treatment plants), and temperature. Assemblages differed between site types, with midges and damselflies important at tributary sites and Fallceon mayflies and Smicridea caddisflies common at erosion control structures. Locally unique communities developed at structures which also may have facilitated exotic species invasions. Analyses showed that taxa richness increased over time at these sites and differed significantly from richness at sites without structures. Structures appeared important in retaining organic matter and, among mainstem sites, coarse particulate organic matter was highest, but variable, at structures and at wetlands above the structures. Erosion control structures, coupled with warm effluent, high baseflows, and altered water quality resulted in development of a macroinvertebrate community that did not trend towards reference or tributary sites. In this case, ecological communities at structures used for river restoration were not on a continuum between disturbed and reference sites. Goal setting of community responses at these structures would have required insight beyond the simple use of reference site attributes." (Author) Odonata are treated at the family

level.] Address: Nelson, S.M., Technical Service Center, Bureau of Reclamation, Denver Federal Center, Bldg. 56, Rm. 2010, P.O. Box 25007 (86-68220), Denver, CO 80225, USA. E-mail: snelson@usbr.gov

10281. Ngiam, R.W.J.; Sun, S.W.; Sek, J.Y. (2011): An update on *Heliogomphus cf. retroflexus* Ris, 1912 with notes on *Microgomphus chelifera* Selys, 1858 in Singapore (Odonata: Anisoptera: Gomphidae). *Nature in Singapore* 4: 95-99. (in English) ["Ngiam (2010) published a paper describing two gomphid larvae collected from the Central Catchment Nature Reserve which had been reared unsuccessfully. The two larvae were believed to be from the genus *Heliogomphus*, and based on their antennal morphology, Ngiam discussed the possibility that the larvae could be *Heliogomphus cf. retroflexus*. However the two larvae were not reared to adulthood and *Heliogomphus retroflexus* adults have never been recorded locally. Singapore is also well outside the known distribution range of *Heliogomphus retroflexus* and no other *Heliogomphus* species other than *Heliogomphus kelantanensis* Laidlaw, 1902 has been recorded in Singapore (Tang et al., 2010). Thus the exact identity of the two mysterious gomphid larvae remains unsolved. Recently more larvae similar to those collected by Ngiam (2010) were collected and two individuals were reared to adulthood. The identity of the larva is finally revealed to be *Microgomphus chelifera* Selys, 1858. In this paper, larvae from the genus *Heliogomphus* and *Microgomphus* are discussed. In addition, the successful rearing of *Microgomphus chelifera* larvae provides an update on its local status." 10282. Nóbrega, C.C.; De Marco Jr. P. (2011): Unprotecting the rare species: a niche-based gap analysis for odonates in a core Cerrado area. *Diversity and Distributions* 17(3): 491-505. ["Aim: We evaluated Odonata distribution data and predicted the compositional resemblance based on niche-based species distribution models to analyse the following questions: (1) How is estimated species richness distributed, and how can it be preserved under the actual network of conservation units (a gap analysis approach)? (2) How is the estimated odonate beta diversity distributed, and is there a better distribution of conservation units (a priority setting approach)? (3) Is the probability of being under protection a function of the potential species range size? and (4) Will the current conservation network proposals protect odonate taxa? Location: Central Brazil in a core Cerrado area. Methods: We generated odonate species distribution predictions based on MaxEnt and maps derived from estimated species richness, beta diversity and gap analysis for all species predicted to occur in the study area. Then, we compared these maps with current conservation units, land-use patterns and proposals for the establishment of conservation units. Results: Raw odonate species records provided limited utility for setting conservation priorities without the use of niche-based models. However, area under the receiver operating curve (AUC) values were characterized by substantial variation that was related to the number of records. No current conservation units overlapped the areas with higher predicted richness and beta diversity, and in general, conservation units were not preserving restricted/rare species. There was a direct linear correlation between species range size and the

proportion of its range protected in the current network of conservation units. Finally, we identified three areas with high odonate beta diversity where conservationist actions should be implemented. Main conclusions: Current conservation units and future suggested areas do not overlap regions with high conservation values for odonates. Conservation units protect species at random, and the level of protection has a direct relationship with species range size; thus, wide-range species are expected to be more protected than restricted or threatened species." 10284. Ojha, N.; Clausnitzer, V.; Suhling, F.; Schaab, G. (2011): Adding a distribution modelling tool for conservationists of the African Odonata database. In: Niekisch, M. & B. Streit (Eds.): Status and future of tropical biodiversity. Conference of the Society for Tropical Ecology, Gesellschaft für Tropenökologie e.V. - gtö, Goethe University, 21 - 24 February 2011, Frankfurt a. M., Programme & Abstracts: 163. (in English) [Verbatim: "Species distribution models have often been employed to find the potential habitat range. Making use of the unique African Odonata database which covers over 800 species, we present a logistic-regression based modelling tool for predicting their potential distribution. Thus, the scientifically collected database has the potential to be useful for conservation related applications; as determining the species potential distribution range is one of them. E.g. the potential distribution range can aid in the assessment of IUCN's threat status. Odonata serve as good indicator species for conservation and environmental monitoring and planning for various reasons: they are easy to monitor, the taxonomy is straight forward, they inhabit aquatic (larvae) and terrestrial (adults) habitats, and they are top predators. Here we present the example of modelling, currently based on presence-only data, of two Odonata species in tropical Africa categorised as vulnerable in the IUCN red list of threatened species. The tool applies the maximum likelihood method based on the expectation-maximisation approach. In order to develop a tool in particular useful to conservationists, emphasis is given mainly to a) functions to ensure proper harmonisation of raster and vector datasets, b) a user-friendly graphical user interface, and c) a comprehensive help system. *Coryphagrion grandis*, mainly residing in the coastal areas of Kenya and Tanzania and *Pseudagrion bicoerulans*, mainly found in the montane areas of Kenya, Uganda and Tanzania have been threatened by wood extraction (deforestation), agriculture and water pollution. Therefore, the variables used for modelling are surrogates of a) climate (like 6 bioclimatic variables), b) habitat (land-co-

ver, elevation), c) resources (vegetation index, distance to water) and d) potential anthropogenic impact (population density). These example species show the model's usefulness in e.g. identifying areas in need of conservation for these species in East-Africa. An assessment of the sensitivity of the variables in regard to the predicted habitat ranges can help to project relative impacts caused by the various variables." 10286. Ordóñez, C.; Loughheed, V.L.; Gardea-Torresdey, J.L.; Bain, L.J. (2011): Impact of Metals on Macroinvertebrate Assemblages in the Forgotten Stretch of the Rio Grande. *Arch. Environ. Contam. Toxicol.* 60: 426-436. (in English) ["The objective of this study was to examine how changes in the benthic macroinvertebrate community structure and a variety of abiotic variables, such as conductivity and sediment metal concentrations, are modified along the Forgotten River stretch of the Rio Grande. This stretch receives industrial effluent, raw sewage, and agricultural return flow from the El Paso (TX, USA)—Ciudad Juárez (CHI, Mexico) metroplex and then flows relatively undisturbed for 320 km before its next significant input. The high degree of use, followed by the 320-km undisturbed stretch, makes the Forgotten River a unique study site to examine downstream attenuation of contaminants and other abiotic variables to determine their potential effects on macroinvertebrates. Five different sites along the Forgotten Stretch were sampled over a 2-year period. Metal concentrations were low throughout the stretch and were predominantly correlated to percent sediment organic matter rather than explained spatially. Several sensitive invertebrate species, such as Leptophlebiidae, increased in relative abundance downstream, whereas the percentage of tolerant invertebrates decreased. Nonmetric multidimensional scaling separated the macroinvertebrate communities upstream from those downstream, with the more sensitive species being found predominantly downstream and more tolerant taxa associated upstream. Additionally, there was a distinct seasonal gradient to the community. The most important drivers of the community assemblage appear to be distance downstream and seasonality, as well as water conductivity and concentrations of sediment cadmium, which was the only metal that exceeded protective criteria. This study did not provide evidence of the downstream attenuation of heavy metals in the sedi-

ments in the Forgotten Stretch; however, downstream changes in macroinvertebrates toward more sensitive taxa suggests that other, unmeasured contaminants might be affecting biological communities in this isolated stretch of an international waterway." 10289. Outomuro, D.; Ocharana, F.J. (2011): Wing pigmentation in Calopteryx damselflies: a role in thermoregulation? Biological Journal of the Linnean Society 103(1): 36-44. (in English) ["Body melanization may show adaptive variation related to thermoregulation ability, and it is to be expected that the degree of melanization will change among populations or closely related species across environmental gradients of solar radiation and/or environmental temperature. Some melanized secondary sexual traits may also play a role in sexual selection, leading to interpopulation variation, which would not be predicted by thermoregulation pressures alone. We studied the relationships between the interpopulation variation in wing pigmentation level (i.e. melanized secondary sexual trait) of two closely related species of Calopteryx damselfly, and both solar radiation and maximum environmental temperature estimates. Wing pigmentation differs between these species, is gender specific and is used in species' discrimination. Only *C. virgo meridionalis* males showed a significant negative partial correlation between wing pigmentation degree and temperature. However, *C. virgo meridionalis* females showed a positive significant partial correlation between wing pigmentation degree and solar radiation. Wing pigmentation in *C. xanthostoma* males was not related to solar radiation or temperature. Thus, thermoregulation pressures poorly explained the observed variations in wing pigmentation between populations, although they might have an adaptive significance at the species' level. As wing pigmentation showed important latitudinal variation, several other selection pressures which might act on melanized traits are briefly discussed." 10290. Patterson, R.J.; Smokorowski, K.E. (2011): Assessing the benefit of flow constraints on the drifting invertebrate community of a regulated river. River research and applications 27: 99-112. (in English) [Ontario, Canada; "The downstream effects of hydroelectric dam operations on the abundance and diversity of the

macroinvertebrate drift community of a regulated river were compared to that of an unregulated river, longitudinally and across three seasons. The regulated river operated under minimum flow and ramping rate (rate of change of flow) restrictions resulting in a 'modified peaking' regime, which means the facility could still peak, but at a slower rate and may not reach maximum turbine flows in the short time typically required to respond to market energy demand. The unregulated river had no dams or other water control structures. There was a trend of increasing abundance and diversity with distance from the dam on the regulated river, with no discernable trend along the unregulated river. While feeding guild proportions did not vary along the unregulated river, within the regulated river feeding guild proportions changed longitudinally as scrapers and collector gatherers increased, and filterers and predators decreased with distance downstream. The regulated river had similar or higher abundance across all seasons, with lower diversity in the spring. Seasonal average discharge was found to be lowest in summer on both rivers, with the regulated river benefiting from a minimum flow to help maintain higher abundance and diversity. Overall, our examination of the drifting invertebrate community on a regulated river support that operational constraints associated with modified peaking regimes helped mitigate the typical negative effects associated with river regulation." 10292. Pérez-Santigosa, N.; Florencio, M.; Hidalgo-Vila, J.; Díaz-Paniagua, C. (2011): Does the exotic invader turtle, *Trachemys scripta elegans*, compete for food with coexisting native turtles? Amphibia-Reptilia 32(2): 167-175. (in English) ["Nowadays, established populations of exotic turtles, *Trachemys scripta elegans*, coexist with native turtles in the wild in southern Spain. We analysed the diet of this exotic species and compared it with the diet of the two native species (*Mauremys leprosa* and *Emys orbicularis*) in two ponds. The exotic turtle is an opportunistic omnivore. In one of our study ponds where exotic invasive crayfish were very abundant, adult and juvenile exotic turtles fed mainly on this prey. In the other study pond, juveniles fed mainly on animal matter and adults ate similar proportions of plants and animals. Na-

tive turtles also ingested mainly crayfish in the first study pond, but *M. leprosa* were mainly herbivorous in the second pond. We did not detect strong differences among the diets of the three species. While native species significantly differ in their diets, the exotic turtles did not differ from some groups of native ones. Exotic turtles had the widest range of food, overlapping the food spectra of different age groups of the two native species in both localities. Comparing with previous reports on native turtles diet of the same area, our results did not reveal changes in the diet which could be associated to interactions with exotic turtles, but the observed shift to a higher proportion of animals in the diet in one of the ponds were mainly due to the high abundance of exotic crayfish." (Authors) Odonata contributed significantly to the diet of all turtle species.] Address: Díaz-Paniagua, Carmen, Estación Biológica de Doñana (CSIC), P.O. 10294. Rantala, M.J.; Honkavaara, J.; Dunn, D.W.; Suhonen, J. (2011): Predation selects for increased immune function in male damselflies, *Calopteryx splendens*. *Proc. R. Soc. B.* 278(1709): 1231-1238. (in English) ["Predation selects for numerous traits in many animal species, with sick or parasitized prey often being at high risk. When challenged by parasites and pathogens, prey with poor immune functions are thus likely to be at a selective disadvantage. We tested the hypothesis that predation by birds selects for increased immune function in a wild population of male damselflies *Calopteryx splendens*, while controlling for a trait known to be under selection by bird predation, dark wing-spots. We found that selection on both immune function and wing-spot size was significantly positive, and that selection on either trait was independent of selection on the other. We found no evidence of nonlinear quadratic or correlational selection. In contrast to previous studies, we found no phenotypic correlation between immune function and wing-spot size. There was also no difference in immune response between territorial and non-territorial males. Our study suggests that predation may be an important agent of selection on the immune systems of prey, and because the selection we detected was directional, has the potential to cause phenotypic change in populations." 10295. Remsburg, A.J. (2011): Relative influence of prior life stages and habitat variables on dragonfly (Odonata: Gomphidae) densities among lake sites. *Diversity* 3(2): 200-216. (in English) ["Many aquatic species have discrete life stages, making it important to understand relative influences of the different habitats occupied within those populations. Although population demographics in one stage can carry over to spatially separated life stages, most studies of habitat associations have been restricted to a single life stage. Among Gomphidae, recruitment via adult oviposition establishes initial population sizes of the aquatic larvae. However, spatial variability in larval survivorship could obscure the relationship between adult and larval densities. This study uses surveys conducted during 2005 and 2006 of Gomphidae larval, emergence, and adult stages from 22 lake sites in northern Wisconsin, USA, to investigate (1) whether the Gomphidae density of each life stage correlated spatially with that of the preceding life stage and (2) what habitat factors help explain variation in densities at each life stage. Results indicated that adult densities from the previous season helped predict densities of early-instar larvae. This finding suggests that oviposition site selection controlled the local larval distribution more than larval survivorship or movement. Late-instar larval densities helped predict densities of emerging Gomphidae later the same season, suggesting that variation in survivorship of final-instar larvae among sites is small relative to the variation in larval recruitment. This study demonstrates that locations with higher densities of odonates in the water also have higher densities of odonates on land. In addition to the densities of Gomphidae in previous life stages, water clarity helped predict larval densities, and riparian wetland vegetation helped predict emergent dragonfly densities." 10296. Rival, D.; Schönweitz, D.; Tropea, C. (2011): Vortex interaction of tandem pitching and plunging plates: a two-dimensional model of hovering dragonfly-like flight. *Bioinspiration & Biomimetics* 6(1) 016008: (in English) ["The force evolution and associated vortex dynamics on a nominal two-dimensional tandem pitching and plunging configuration inspired by hovering dragonfly-like flight have been investigated experimentally using time-resolved particle image velocimetry. The aerodynamic forces acting on the flat plates have been determined using a classic control-volume approach, i.e. a momentum balance. It was found that only the tandem phasing of $\alpha = 90^\circ$ was capable of generating similar levels of thrust when compared to the single-plate reference case. For this tandem configuration, however, a much more constant thrust generation was developed over the cycle. Further examination showed that the force and vortex development on the fore-plate was unaffected by the tandem configuration and that nearly all variations in performance could be attributed to the vortex interaction on the hind-plate. By calculating the trajectory and strength of the hind-plate's trailing-edge vortex, the chain-like vortex interaction mechanism responsible for improved performance at $\alpha = 90^\circ$ could be identified. The underlying result from this study suggests that the dominant vortex interaction in dragonfly flight is two dimensional and that the spanwise flow

generated by root-flapping kinematics is not entirely necessary for efficient propulsion but potentially due to evolutionary restrictions in nature." (Authors)] Address: Rival, D., Institute of Fluid Mechanics and Aerodynamics, Technische Universität Darmstadt, Germany. E-mail: derival@ucalgary.ca

10297. Roberts, N.W.; Porter, M.L.; Cronin, T.W. (2011): The molecular basis of mechanisms underlying polarization vision. *Phil. Trans. R. Soc. B* 366(1565): 627-637. (in English) ["The underlying mechanisms of polarization sensitivity (PS) have long remained elusive. For rhabdomic photoreceptors, questions remain over the high levels of PS measured experimentally. In ciliary photoreceptors, and specifically cones, little direct evidence supports any type of mechanism. In order to promote a greater interest in these fundamental aspects of polarization vision, we examined a varied collection of studies linking membrane biochemistry, protein-protein interactions, molecular ordering and membrane phase behaviour. While initially these studies may seem unrelated to polarization vision, a common narrative emerges. A surprising amount of evidence exists demonstrating the importance of protein-protein interactions in both rhabdomic and ciliary photoreceptors, indicating the possible long-range ordering of the opsin protein for increased PS. Moreover, we extend this direction by considering how such protein paracrystalline organization arises in all cell types from controlled membrane phase behaviour and propose a universal pathway for PS to occur in both rhabdomic and cone photoreceptors." (Authors) *Hemiodulia tau* is presented as ultraviolet-sensitive, blue-sensitive and green-sensitive. According a personal information given by the author, at present the development of polarization vision in odonates from larval stages through to adult is studied.] Address: Roberts, N.W., School of Biological Sciences, Univ. of Bristol, Woodland Road, Bristol BS8 1UG, UK. (2011): Dragonfly cyclovirus, a novel single-stranded DNA virus discovered in dragonflies (Odonata: Anisoptera). *Journal of General Virology* 92: 1302-1308. (in English) ["We describe Dragonfly cyclovirus (DfCyV), a new species of ssDNA virus discovered using viral metagenomics in dragonflies (Libellulidae family) from the Kingdom of Tonga (Tongatapu and Vava'u islands). Metagenomic sequences of DfCyV were similar to viruses of the recently proposed Cyclovirus genus within the Circoviridae family. Specific PCR resulted in the recovery of twenty-one DfCyV genomes from three dragonfly species (*Pantala flavescens*, *Tholymis tillarga*, and *Diplacodes bipunctata*). The 1741 nucleotide DfCyV genomes share >95% nucleotide identity and are classified into eleven subtypes representing a single strain. The DfCyV genomes share 48-63% genome-wide nucleotide identity to cycloviruses identified in human faecal samples. Recombination analysis revealed three recombinant DfCyV genomes suggesting that recombination plays an important role in cyclovirus evolution. To our knowledge this is the first report of a circular ssDNA virus identified in insects, and the data may help elucidate evolutionary links among novel Circoviridae recently identified in animals and environmental samples." 10300. Samways, M.J.; Pryke, J.S.; Simaika, J.P. (2011): Threats to dragonflies on land islands can be as great as those on oceanic islands. *Biological Conservation* 144(3): 1145-1151. (in English) ["We ask whether oceanic islands and equivalent-sized continental blocks, which we call here 'land islands', are similar or not in their species richness, number of range-restricted species, and in number of threatened species. We used sites in southern Africa and islands in the Western Indian Ocean. We chose dragonflies as they are taxonomically tractable, well surveyed, and provide a range of characteristics from narrow-range endemics to widely-spread and vagile opportunists. We then selected as many oceanic islands as possible where there were sufficient data to make comparisons with land islands of a similar area in African savanna, grassland and mountains rich in endemic species. Generalized Linear Mixed Models were used to analyse the overall, range-restricted and threatened species richness for all islands (both oceanic and land) and then for the two types of island separately. Species richness increased with island size, with oceanic and land island size relationships being similar. Land islands overall had significantly more range-restricted species. Species on land islands were as threatened as those on oceanic islands. However, the land islands of the Western Cape were under a higher level of threat than oceanic islands of comparative size. The large islands of Madagascar and Sri Lanka were outliers with very high levels of threat. Translated into conservation, the results illustrate that over-generalizations about island faunas being more threatened than continental ones are not necessarily valid. While not wishing to draw attention away from the urgent conservation action needed on many tropical islands, we argue that comparisons of oceanic versus land islands detract from the more urgent task of local conservation action based on the special needs of any particular area, whether land or oceanic. It is more meaningful to establish how threats operate and how to mitigate them on small populations rather than focusing purely on any particular island type per se." 10303. Sesterhenn, T.M. (2011): Effects of predators and injury over different time scales in the damselfly *Ischnura posita* (Odonata: Coenagrionidae). *Annals of the Entomological Society of America* 104(2): 358-363. (in English) ["Sublethal appendage injury or loss has been shown to alter many behaviors of animals, including foraging and predation avoidance. But most studies of this phenomenon to date have been short-term in scope, and longer term studies may produce different results as seen in some studies on predator effects. Larval damselflies routinely autotomize their caudal lamellae and encounter predators, making them ideal for comparisons of short-term and longer term effects of appendage loss and predator exposure. In this study, I examined activity and foraging of larval *I. posita*, testing for effects of lamella loss and predator cues both in the short term (1 h) and the longer term (8 d). I predicted that both predators and injury would decrease activity and foraging for a short time and that these effects would diminish over time. Results indicated that only the most severe injuries affected foraging, delaying first prey capture when no predator was present; but injury did not affect total prey caught. In the 1-h experiment, damselflies had lower activity in the presence of predator cues, with no effect of injury, whereas the 8-day experiment showed no effect of predator cues on activity. I did not find a major effect of injury or predator cues on activity or foraging of larval damselflies; no effects were detectable over the entire 8-d study. I conclude that the ecological implications of such injuries in nature may often be negligible." 10306. Stoks, R.; De Block, M. (2011): Rapid growth reduces cold resistance: Evidence from latitudinal variation in growth rate, cold resistance and stress proteins. *PLoS ONE* 6(2): e16935. doi:10.1371/journal.pone.0016935: 6 pp. (in English) ["Background: Physiological costs of rapid growth may contribute to the observation that organisms typically grow at submaximal rates. Although, it has been hypothesized that faster growing individuals would do worse in dealing with suboptimal temperatures, this type of cost has never been explored empirically. Furthermore, the mechanistic basis of the physiological costs of rapid growth is largely unexplored. Methodology/Principal Finding: Larvae of the damselfly *Ischnura elegans* from two univoltine northern and two multivoltine southern populations were reared at three temperatures and after emergence given a cold shock. Cold resistance, measured by chill coma recovery times in the adult stage, was lower in the southern populations. The faster larval growth rates in the southern populations contributed to this latitudinal pattern in cold resistance. In accordance with their assumed role in cold resistance, Hsp70 levels were lower in the southern populations, and faster growing larvae had lower Hsp70 levels. Yet, individual variation in Hsp70 levels did not explain variation in cold resistance. Conclusions/Significance: We provide evidence for a novel cost of rapid growth: reduced cold resistance. Our results indicate that the reduced cold resistance in southern populations of animals that change voltinism along the latitudinal gradient may not entirely be explained by thermal selection per se but also by the costs of time constraint-induced higher growth rates. This also illustrates that stressors imposed in the larval stage may carry over and shape fitness in the adult stage and highlights the importance of physiological costs in the evolution of life-histories at macro-scales." 10307. Sychra, J.; Adamek, Z. (2011): The impact of sediment removal on the aquatic macroinvertebrate assemblage in a fishpond littoral zone. *J. Limnol.* 70(1): 129-138. (in English) [Bottom sediment removal, a widely used technique in restoration management of standing water bodies, has a strong influence on communities of aquatic organisms. As most information on the impact of sediment removal on the aquatic environment comes from studies on lakes, the aim of this study was to describe macroinvertebrate assemblage

succession in a fishpond (Štěpánek fishpond, Bohemian-Moravian highlands, Czech Republic) littoral zone following restoration by sediment removal during the winter of 2003/2004. Semi-quantitative hand net sampling was undertaken one year before (2003) and in each of the following five years (2004–2008) after sediment removal. A significant decrease in both abundance (approx. 90% of individuals) and diversity (approx. 30% of taxa) of macroinvertebrates was detected immediately after pond restoration. The values gradually increased over subsequent years, reaching comparable abundance and diversity three years after sediment removal. A significant shift was recorded in the taxonomic and functional composition of the macroinvertebrate assemblage after sediment removal. Mayfly larvae were the dominant invertebrates before restoration, while chironomid larvae and oligochaetes dominated after sediment removal. Phytophilous taxa, grazers and scrapers, and swimming or diving invertebrates were common in 2003, whilst open-water taxa preferring mud and other mostly inorganic microhabitats, gatherers/collectors, and burrowing/boring invertebrates were relatively common after sediment removal. In 2008, the assemblage reverted towards the situation before sediment removal, probably connected with a lower water level and accelerated macrophyte bed succession. Principal Component Analysis on the species data confirmed the differences in invertebrate taxonomic structure among sampling years. Succession of the fishpond invertebrate assemblage in the years following sediment removal was mainly influenced by fish farming practice and local conditions, i.e. the presence of macrophyte beds, mesohabitat changes following restoration, and the presence of other water bodies in the surroundings." (Authors) Odonata taxa reported are: *Platycnemis pennipes*, *Coenagrion* sp., *Ischnura elegans*, *Ischnura* sp., and *Libellula depressa*.] Address: Sychra, J., Dept of Botany and Zoology, Faculty of Science, Masaryk Univ., Kotlářská 2, 611 37 Brno, Czech Republic. 10308. Takahashi, Y.; Watanabe, M. (2011): Male mate choice based on ontogenetic colour changes of females in the damselfly *Ischnura senegalensis*. *Journal of Ethology* 29(2): 293-299. (in English) ["While male mate choice behaviour has been reported in many taxa, little is known about its plasticity and evolutionary consequences. In *I. senegalensis*, females exhibit colour dimorphism (gynomorph and andromorph). The body colour of gynomorphs changed ontogenetically in accordance with sexual maturation, while little change occurred in andromorphs. To test the male mate choice between sexually immature and mature females of both morphs, binary choice experiments were conducted. Virgin males that were reared separately from females after emergence did not show significant preference between sexually immature and mature females for both morphs, indicating that virgin males were unable to discriminate female reproductive status. On the other hand, males that had experienced copulation with gynomorphs preferred sexually mature gynomorphs to sexually immature ones. However, males that had experienced copulation with andromorphs could not discriminate between sexually immature and mature andromorphs, probably due to the absence of significant ontogenetic change in their thoracic colour. Therefore, female body colour is an important cue for males in discriminating between sexual maturation stages. Learned mate discrimination depending on copulation experien-

ce might help males to detect potential mates effectively and avoid sexually unreceptive immature female. We finally discuss the adaptive significance of the ontogenetic colour change in females." 10309. Todd, B.D.; Bergeron, C.M.; Hepner, M.J.; Burke, J.N.; Hopkins, W.A. (2011): Does maternal exposure to an environmental stressor affect offspring response to predators? *Oecologia* 166(1): 283-290. ["There is growing recognition of the ways in which maternal effects can influence offspring size, physiological performance, and survival. Additionally, environmental contaminants increasingly act as stressors in maternal environments, possibly leading to maternal effects on subsequent offspring. Thus, it is important to determine whether contaminants and other stressors can contribute to maternal effects, particularly under varied ecological conditions that encompass the range under which offspring develop. We used aquatic mesocosms to determine whether maternal effects of mercury (Hg) exposure shape offspring phenotype in the American toad (*Bufo americanus*) in the presence or absence of larval predators (dragonfly naiads). We found significant maternal effects of Hg exposure and significant effects of predators on several offspring traits, but there was little evidence that maternal effects altered offspring interactions with predators. Offspring from Hg-exposed mothers were 18% smaller than those of reference mothers. Offspring reared with predators were 23% smaller at metamorphosis than those reared without predators. There was also evidence of reduced larval survival when larvae were reared with predators, but this was independent of maternal effects. Additionally, 5 times more larvae had spinal malformations when reared without predators, suggesting selective predation of malformed larvae by predators. Lastly, we found a significant negative correlation between offspring survival and algal density in mesocosms, indicating a role for top-down effects of predators on periphyton communities. Our results demonstrate that maternal exposure to an environmental stressor can induce phenotypic responses in offspring in a direction similar to that produced by direct exposure of offspring to predators." 10313. Wiesenborn, W.D. (2011): Nitrogen Contents in Riparian Arthropods is most dependent on allometry and order. Florida Entomologist 94(1): 71-80. (in English, with Spanish summary) ["I investigated the contributions of body mass, order, family, and trophic level to nitrogen (N) content in riparian spiders and insects collected near the Colorado River in western Arizona. Most variation (97.2%) in N mass among arthropods was associated with the allometric effects of body mass. Nitrogen mass increased exponentially as body dry-mass increased. Significant variation (20.7%) in N mass adjusted for body mass was explained by arthropod order. Adjusted N mass was highest in Orthoptera, Hymenoptera, Araneae, and Odonata and lowest in Coleoptera. Classifying arthropods by family compared with order did not explain significantly more variation (22.1%) in N content. Herbivore, predator, and detritivore trophic-levels across orders explained little variation (4.3%) in N mass adjusted for body mass. Within orders, N content differed only among trophic levels of Diptera. Adjusted N mass was highest in predaceous flies, intermediate in detritivorous flies, and lowest in phytophagous flies. Nitrogen content in riparian spiders and insects is most dependent on allometry and order and least dependent on trophic level. I suggest the effects of allometry and order are due to exoskeleton thickness and composition. Foraging by vertebrate predators, such as insectivorous birds, may be affected by variation in N content among riparian arthropods." (2011): Seasonal changes in body size, sexual size dimorphism and sex ratio in relation to mating system in an adult odonate community. Evolutionary Ecology 25(1): 59-75. (in English) [Study area: 27 lakes of the Columbia National Wildlife Refuge (USA) in 1997, which occur in the centre of the Columbia Basin in eastern Washington State (46°55' N, 119°15' W; USA. "Seasonal environments impose developmental time constraints on insects which can be reflected in body size and sex ratio. By tracking these two aspects in recently emerged adults of 10 species of an odonate community in a number of lakes, we investigated whether (a) body size in both sexes

decreased as the flight season progressed and whether this led to seasonal changes in sexual size dimorphism (SSD); (b) SSD patterns were related to mating systems; (c) biases in sex ratio could be explained by mortality rates associated with the largest sex (e.g. in species with male-biased SSD, a female-biased sex ratio; in species with female-biased SSD, a male-biased sex ratio). Our results indicated that adults in most species, but not all, tend to reach a smaller body size as the season progressed. However, the opposite pattern was found in a few species. Predictions about the relation between SSD and mating systems were confirmed: a female-biased SSD in nonterritorial species and monomorphism for territorial species. However, predictions of biases in sex ratio according to SSD were not met in all species. Interestingly, changes in body size and SSD along the season were lake-specific in two species in which these patterns could be examined. These results, although partially supportive of environmental and sexual selection patterns acting on size and sex ratio as documented in other odonate species, indicate that we are still far from understanding seasonal constraints in these animals." (Authors) 14 species (*Aeshna californica*, *A. multicolor*, *Anax junius*, *Erythemis collocata*, *Libellula forensis*, *Pachydiplax longipennis*, *Sympetrum costiferum*, *S. occidentale*, *Enallagma boreale*, *E. carunculatum*, *Ischnura cervula*, *I. perparva*, *Lestes congener*, *Tramea lacerata*) were caught, but only 10 species used for the analysis, as the small sample size of the remaining four prevented statistical analysis.] Address: Córdoba-Aguilar, A., Depto de Ecol. 10317. Croyle, B.T. (1997): Population and community ecology of stream macroinvertebrates: the role of disturbance. M.Sc. thesis, Zoology, Texas Tech University, Lubbock: VII + 98 pp. (in English) [Texas, USA. "Quantifying factors that influence the abundance, distribution, or diversity of species within communities is a major focus of ecology and conservation biology. As concerns for the preservation and maintenance of worldwide biodiversity increase, identifying and understanding these factors becomes a critical endeavour. This goal should not be limited to large preserves of endangered habitat such as Yellowstone National Park or the plains of Africa. Indeed, knowledge gained from addressing such topics in small, accessible localities is of interest in its own right, and may prove useful when dealing with endangered habitats. Streams play vital roles in terrestrial ecosystems, as a source of water, in cycling nutrients, and as habitat for many organisms during part or all of their life cycles. This study assesses factors that affect the community structure of streams (i.e. the distribution, abundance, and diversity of aquatic macroinvertebrates)." (in Dutch) ["*C. ornatum* is a rare damselfly in Europe with an intriguing outpost north of Osnabrück, 90 kilometers from the Dutch border (Germany). *C. ornatum* is present here in very small streams with extensive *Berula erecta* vegetation. The species is in serious decline and is currently reproducing in moderate numbers (tens of individuals) at only one location. The main reasons for the decline of *C. ornatum* in central Europe are the cold winter of 1995 / 1996 when many localities became deep frozen, the lack of management practice, or too intensive management, habitat destruction, dessication and eutrofication. This article discusses the possible occurrence of this species in The Netherlands. Although suitable habitat is locally present and the dispersal capacities of *C. ornatum* seems to be rather well developed, climatic conditions and the lack of a large source population appear to be limiting factors. For the moment, it is not likely that *C. ornatum* can be recorded in The Netherlands." (Authors)] Address: Ketelaar, P., p/a De Vlinderstichting, Postbus 506, NL-6700 AM Wageningen, The Netherlands. 10330. Aberlenc, H.-P.; Lentenois, P. (2003): Les insectes du bois de Païolive. In: Holthof, J.F. & Schnetzler, J. (Eds), *De Saint-Eugène en Païolive, Montmélian et les Vans, La Fontaine de Siloé et Saint-Eugène en Païolive*. 320 pp: 55-72. (in French) [Departement Ardeche, France. The Bois de Païolive is a forest situated at the eastern fringe of the Cevennen. It grows on a karstic plateau south of the river Chassezac within the administrative area of the villages Les Vans, Banne and Berriasset-Casteljau. A total of 38 Odonata species is listed, in-

cluding *Coenagrion mercuriale*, *Oxygastra curtisi*, and *Macromia splendens*. This species protected by the European law are briefly commented. Supplemental data to the regional fauna are updated in Aberlenc (2008) and Aberlenc (2011: www.aberlentomo.fr/1listeinsectespaoliolive29jan2011.doc) Address: Aberlenc, H.P., CIRAD, UMR CBGP, TA A-55/L, 34398 Montpellier cedex 5, France

10331. Bass, D. (2003): A survey of freshwater macroinvertebrates in Tobago. *Living World - Journal of the Trinidad and Tobago Field Naturalists' Club*, 2003: 64-69. (in English) ["A survey of macroinvertebrates inhabiting the freshwater environments of Tobago was made during April, May, and June of 1996. This collection yielded 61 species, bringing the total number of freshwater macroinvertebrate taxa known from Tobago to 112. Dominant taxa included a few species of gastropods, decapod crustaceans, ephemeropterans, odonates, hemipterans, and coleopterans. Species richness was usually greatest in streams having cobble substrates and flowing through undisturbed forested land. Generally this macroinvertebrate fauna is sparse when compared to that of continents, most likely due to the relatively small size of Tobago and to a much lesser extent, human disturbance of freshwater environments in some areas of the island. Further studies are likely to find additional species that were previously unknown to occur on Tobago, some of which may be endemic to the island." (Author) The following taxa are listed: *Argia* sp., *Dythemis* sp., *Erythemis vesicula*? *Ischnura ramburii*, *Micrathyrta* sp.] Address: Bass, D., Biology Dept, Univ. of Central Oklahoma, Edmond, Oklahoma, USA 73034. E-mail: Dbass@ucok.edu

(in English) ["Many external characters of this species are closely allied to those of *S. pryleri* (Martin, 1909) from the mainland of Japan, not to *S. niisatoi* (Karube, 1998) from northern Vietnam." (Author)] Address: Kawashima, I., Nagasawa 1-50-9, Yokosuka-shi, Kanagawa, 239-0842 Japan

10340. Kojo, T. (2003): On the nocturnal roosting in *Orthetrum albistylum speciosum*. *Tombo* 45(1/4): 36-38. (in Japanese, with English summary) ["The author observed three cases of nocturnal roosting by males of *O. albistylum speciosum* during middle and late August, 2001, in a condominium garden in a suburban area of Saitama Prefecture, Kanto District, Japan. The observations on all cases were made from the moment they touched the branches of low trees in the late afternoon to the moment of flight in the early morning. Roosting time was about 12 hours on average. They hung vertically on the branch with their wings spread and their dorsum to the west. After the dark, they became insensitive and never moved at any time during their roost. Just before flying off, they appeared sometimes to warm up by clipping wings and bobbing abdomen." (Author)] Address: not transliterated into English

10341. Kojo, T. (2003): *Sympetrum infuscatum* changes posture in the nocturnal roosting. *Tombo* 46: 23-28. (in Japanese, with English summary) ["The author observed the nocturnal roosting posture, *S. infuscatum* during the period from Aug. to Sept. 2001 and again in Aug. to Sept. 2002 in a condominium garden in a suburban area of Saitama Prefecture, Kanto District, Japan. In this report, I describe the changes in the roosting posture using photographs. One of the typical characteristics of *S. infuscatum* is that adults change posture during a period of nocturnal roosting. More precisely, although they hang horizontally during the beginning of the nocturnal roosting period, they gradually change posture to a vertical direction during the middle of the night and then change posture again to a horizontal position before flying off in the early morning. This is a remarkable difference from *Or-*

thetrum albistylum speciosum which does not change posture during nocturnal roosting." (Author)] Address: not stated in English transliteration

10342. Marine, N. (2003): Triple connection of *Orthetrum albistylum speciosum* (Uhler). Tombo 46: 34. (in bilingual in Japanese and English) [20-VII-1997; Nakamura City, Kochi Prefecture, Japan.] Address: not stated in English transliteration

10343. Miyagawa, T. (2003): A new record of *Trithemis aurora* from Kumamoto pref., Kyushu. Tombo 45: 39. (in Japanese, with English summary) [male and female specimens of *T. aurora* were found on September 12, 2002. This is the first record from the Kumamoto Prefecture, Kyushu, Japan.] Address: not transliterated into English

10344. Müller, O. (2003): Interaktion zwischen invasiven Amphipoden und Gomphidenlarven. Libellennachrichten 8/9: 10. [Only one Odonata specimen has been established in the diet of fifty-seven specimens of *L. ocellatus*. No species name provided.] Address: Vrcibradic, D., Se-

tor de Ecologia, Instituto de Biologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, 20550-011, Rio de Janeiro, RJ, Brasil. E-mail: da-vor@centroin.com.br

10349. Van Swaay, C.A.M.; Groenendijk, D.; Ketelaar, R. (2003): Monitoring butterflies and dragonflies in The Netherlands in 2002. Rapport VS2003.005, De Vlinderstichting, Wageningen: 31 pp. (in Dutch, with English summary) ["In 2002 dragonflies were counted every fortnight between May and September at 306 sites. The average number of dragonflies per transect were higher than previous years (table 2; figure 9). Like other years *Enallagma cyathigerum* was the most common species with almost 80000 individuals. For the first time indices are presented for a number of species (chapter 8). An alarming decreasing trend was detected for *Leucorrhinia pectoralis*. Another Red List species, *Lestes virens*, shows a positive trend. A translation for the Dutch vernacular names is given in chapter 10." (Authors)] Address: Groenendijk, D., De Vlinderstichting, Postbus 506, NL 6700 AM Wageningen, The Netherlands. E-mail: dick.groenendijk@vlinderstichting.nl

10350. Watanabe, K. (2003): A brief observation on the oviposition of *Tetracanthagyna plagiata* in West Malaysia. Tombo 46: 30. (in English) [Verbatim: "Species of *Tetracanthagyna* are known to oviposit in moss-covered branches 5 m or more above streams in thick forest (Corbet 1999). During my odonatological survey in west Malaysia in May, 2002, I had an opportunity to observe egg-laying behaviour by a female *T. plagiata*. The female, sitting in oviposition posture, was found on a decayed wood in a lowland jungle, at an altitude of 30 m, 20 km north of Kota Tinggi, Johor at 9:10 a.m. on May 5. Up until the time the insect was captured by me for a voucher, she continued to lay eggs into the decayed wood, about 150 cm above the water surface of a river. The surface of the wood was not covered with moss, a different situation from that observed by Corbet (1999). As the place of oviposition was above the water, it is likely that the hatched larvae drop down into the river water." (Author)] Address: Watanabe, K., 145-1, Maesato, Ishigaki, 907-0002 Japan

10351. Watcharee, L. (2003): The diet and feeding factors of the Wrinkle-lipped Free-tailed Bat (*Tadarida plicata*) at Khao-Chong-Pran, Ratchaburi Province. Master of Science (Forestry) thesis, Major Field: Forest Biology, Department of Forest Biology, The Pattaya School. University College of Agriculture Pattaya: 90 pp. (in Thai, with English summary) [Thailand; Odonata contributed with 6% to the diet of *T. plicata*] Address: not stated

2004

10352. Cowell, B.C.; Remley, A.H.; Lynch, D.M. (2004): Seasonal changes in the distribution and abundance of benthic invertebrates in six headwater streams in central Florida. *Hydrobiologia* 522(1-3): 99-115. (in English) ["Seasonal variations in invertebrate assemblages at two sites (upstream and downstream) on six central Florida headwater streams were compared by sampling at quarterly intervals with core and dip net samplers. Two of the streams were reclaimed following phosphate mining (app. 6 yr prior to this study), two received runoff from mined lands, and two were disturbed by agriculture and/or residential developments. Physical and chemical characteristics of the reclaimed streams differed markedly from those of the non-reclaimed streams; principal differences

between the streams were in current velocity, percent organic matter (POM), Mn, conductivity and alkalinity. Annual mean densities of meiofauna and smaller macrofauna for the 12 stream sites ranged from 20 896 to 175 212 m² and the mean for all sites was 56 492 m². The reclaimed streams and one of the streams influenced by agriculture had annual means of less than 40 000 m², 3- to 5-fold lower than the other streams. Fall and winter core densities were 2.4-fold greater than those for spring or summer when drought and low dissolved oxygen prevailed. Meiofauna comprised 68.91% of the core sample invertebrates in reclaimed streams but only 43.62% in the non-reclaimed streams; principal functional groups were: gathering collectors - 61.5%, predators - 19.3% and filtering collectors - 15%. The taxonomic composition of the reclaimed streams was predominated by crustaceans (60.71%) while chironomids and annelids were more abundant (71.92%) in the non-reclaimed streams. Dip net sampling added 21 larger macrofauna species (Odonata, Hemiptera and Coleoptera) to our list of taxa, producing a total of 209 species. Species richness and diversity (H and N₂) indices were lower in the reclaimed streams, but evenness was more variable. The Czekanowski-Dice-Sørensen similarity index showed that the reclaimed stream sites were quite similar to each other, but differed markedly from the other stream types; there was large variation both within and between seasons. For central Florida headwater streams, drought appears to have a larger influence on invertebrates than the type of land use, however this relationship should be confirmed using streams of similar hydrology." (Authors) The following Odonata taxa have been collected: *Anax junius*, *Boyeria vinosa*, *Gynacantha nervosa*, *Brachymesia gravida*, *Pachydiplax longipennis*, *Hagenius brevistylus*, *Argia* sp., *Calopteryx maculata*, and *Enallagma* sp.] Address: Cowell, B., Dept Biol., Univ. S. Florida, Tampa, FL, 33620, USA. E-mail: cowell@chuma1.cas.usf.edu

10353. Eda, S. (2004): Two cases of interspecific tandem formation between different genera. Tombo 47: 52. (in English, with Japanese summary) [(1) Tandem between male of *Stylurus oculatus* and female of *Anisogomphus maacki*, September 18, 2003, at Miya-gawa river in Suwa city and (2) tandem between male of *Anax parthenope julius* and female of *Aeshna nigroflava*, September 16, 2004 at Ebinoko-ike pond in Shiojiri city, Japan.] Address: Eda, S., 3-4-25 Sawamura, Matsumoto, Nagano 390-0877, Japan. E-mail: SND 02767@nifty.com

10354. Grosser, N.; Schmidt, P. (2004): Die Tier- und Pflanzenarten nach Anhang IV der Fauna-Flora-Habitatrichtlinien im Land Sachsen-Anhalt. Naturschutz im Land Sachsen-Anhalt 41 (Sonderheft): 1-142. (in German) [The legally protected species in Sachsen-Anhalt (Germany) are treated in a monographic style. Information for each species including *Aeshna viridis*, *Stylurus flavipes*, and *Leucorrhinia albifrons* is presented and is dealing with its threat category and conservation status in Germany and Sachsen-Anhalt, biology and ecology, biogeographic distribution, regional distribution. Brief description of the taxon and regional threats and protection measures are presented as well. The profiles are prepared by Rosemarie Steglich and Joachim Müller.] Address: Steglich, Rosmarie, Zollstr. 1/128, 39114 Magdeburg, Germany. E-mail: roeseli@mdcc-fun.de

10355. Hampe, A. (2004): Comunidades de libélulas (Odonata) en el río Barbate (Cádiz): relictos glaciales y colonizadores orientales. Revista de la Sociedad Gaditana de Historia Natural 4: 205-215. [Odonate communities of

the Barbate river: glacial relicts and oriental colonizers.) The odonates of the upper and middle reach of the Río Barbate (Alcalá de los Gazules, Cádiz, Spain) were surveyed, and their flight phenology, larval development and biogeographic origin were compared. Faunistic similarity was very low. No species reproduced at both upper and middle reach. More species were recorded at the middle reach (19 vs 12). The flight phenologies showed similar patterns, although species abundances grew remarkably through the summer at the middle reach but not at the upper reach. Semivoltine species occurred only at the upper reach whereas species with two or more generations per year formed an important fraction of 77 % at the middle reach. These were mostly Libellulidae that have probably colonized southern Spain from the eastern Mediterranean Basin after the Pleistocene glaciations. In contrast, the species of the high tracks have most probably been present in the area during longer times and are (at least) glacial relicts." (Author)] Address: Hampe, A., UMR 'Biodiversité, Gènes & Communautés' (INRA), 69, Route d'Arcachon, F-33612 Cestas Cedex - France. E-mail: arndt.hampe@pierroton.inra.fr

10356. Kawashima, I.; Yoshida, M. (2004): External morphology of the last instar larvae (exuviae) of hybrids between *Sympetrum maculatum* Oguma and *S. darwinianum* (Selys) (Libellulidae). Tombo 47: 37-40. (in Japanese, with English summary) ["The external morphology of the last instar larvae (exuviae) of hybrid individuals between male *Sympetrum maculatum* Oguma, 1915 and female *S. darwinianum* (Selys, 1883) are described and illustrated. Hybrid exuviae showed the intermediate state of parent species in the external characters and almost could not be distinguished from each other. However, the lateral abdominal spines are long and slender, and more resemble those of *S. maculatum*, but are only slightly different distinguished from *S. darwinianum*. Moreover, the hybrids were clearly larger than each of the parent individuals." (Authors)] Address: not transliterated into English

10357. Lawton, J.H. (2004): Japan prize commemorative lecture: Biodiversity, conservation and sustainability. Notes Rec. R. Soc. Lond. 58(3): 321-333. (in English) [John H. Lawton, who stated his scientific career 1969 with a Ph.D. thesis at the University of Durham, UK, on "Studies on the ecological energetics of damselfly larvae (Odonata; Zygoptera)", was awarded the 2004 Japan Prize for 'Observational, experimental and theoretical achievements for the scientific understanding and conservation of biodiversity'. In this framework he gave a lecture on 21 April 2004, in Tokyo, Japan, on the occasion of the 20th Anniversary of the Japan Prize. This lecture focuses on bracken ecology, and includes no references to Odonata.] Address: Lawton, J.H., Natural Environment Research Council, Polaris House, Swindon SN2 1EU, UK and Centre for Population Biology, Imperial College, Silwood Park, Ascot SL5 7PY, UK

10358. Naraoka, H. (2004): Fluctuations of the daily activity and the reproductive behaviour of *Mortonagrion selenion* (Ris). Tombo 47: 53-57. (in Japanese, with English summary) ["The adult behaviour of *M. selenion* was examined in a period between 2000 and 2004, at a rice field in Kuroishi-City, Aomori Pref. Japan. Adults appeared from the middle of June to early August with a peak from late June to middle July. The mate-searching flights of males and copulations commenced at nearly 4:00 am or around sunrise and ended about 8:00 am. After that, males spent their time perched during almost every hour of the day. Copulation is divided into 3 stages.

Stage I was very longer when the male's abdomen was pumping ($x=2\text{ h }23\text{ m }20\text{ s} \pm 37\text{ m }34\text{ s}$, $n=13$). Stage II with intermittent pumping and Stage III with no pumping were short, $1\text{ m }57\text{ s} (\pm 31.8\text{ s})$ and $19.8\text{ s} (.5.5\text{ s})$ in mean, respectively. The total duration of copulation was negatively correlated ($P<0.01$) with the time of day (Fig. 2). The male may guard female during pre-oviposition from rival males." The habitat is characterised by a high diversity and high abundances of species.] Address: Brunken, G., Kalklage 1, 37077 Göttingen, Germany

10363. Murphy, G.W.; Newcomb, T.J.; Orth, D.J.; Reeser, S.J. (2005): Food habits of selected fish species in the Shenandoah River Basin, Virginia. *Proceedings of the Annual Conference of the Southeastern Association of Fish and Wildlife Agencies* 59: 325-335. (in English) ["Food habits of redbreast sunfish (*Lepomis auritus*), smallmouth bass (*Micropterus dolomieu*), and white sucker (*Catostomus commersoni*) populations in the Shenandoah River Basin, Virginia, were assessed during 2002 to identify dietary pathways and patterns potentially affecting mercury uptake. Aquatic insects (71% to 83%) were the principal food item of redbreast sunfish, while small-

mouth bass mainly consumed aquatic insects (32% to 48%), crayfish (19% to 31%), and fish (22% to 29%). Principal food items of white sucker included aquatic insects (20% to 26%) and detritus (66% to 70%). Dipterans, ephemeropterans, and trichopterans were the main taxa of aquatic insects consumed by all species." (Authors) The contribution of Odonata to the diet of the fish species is quite limited.] Address: Murphy, G.W., Delaware Division of Fish and Wildlife, 4876 Hay Point Landing Road, Smyrna, DE 19977, USA

10364. Resende, D.C. (2005): *Libellulidae* (Anisoptera: Odonata) phylogeny and body size and thermoregulation effects on behavioural evolution. Tese. Universidade Federal de Viçosa: VII + 93 pp. (in Portuguese, with English summary) ["Adult males of *Libellulidae* (Anisoptera: Odonata) are classified as perchers or fliers as a function of the time spent in flight. Insect thermoregulation depends on body length and may restrict behaviour. The family *Libellulidae* (Anisoptera: Odonata) had its monophyly corroborated by several phylogenetic hypothesis. I proposed here a phylogenetic hypothesis for *Libellulidae* using morphologic characters, including 33 Brazilian genera and four genera from other regions. Using this phylogeny, I tested if flight ability depends on body length, expecting that larger species control better the body temperature. I also tested if species that spent more time in flight have an increase in their hind wing anal area or an increase in their abdomen surface as adaptations to thermoregulation. Three *Corduliidae* species were used to polarize the characters in the phylogeny and branch support was estimated by Bootstrap. Species behaviour was obtained from an Odonata data bank and I was used a phylogenetic autocorrelation to exclude phylogenetic dependence of species. *Macrothemis*, *Miathyria*, *Tremea*, *Oligoclada*, *Rhodopygia*, *Erythemis*, *Brachymesia*, *Uracis*, *Perithemis*, *Diastatops*, *Zenithoptera*, *Nephepeltia* and *Elasmothemis* genera had their monophyly corroborated. *Palpopleurinae* is a paraphyletic group and *Brachydiplacinae*, *Leucorrhininae*, *Trithemistinae*, *Libellulinae*, *Sympettrinae* and *Tremeinae* were polyphyletic groups. Morphometry and behavioural measures showed high phylogenetic dependence. Flying time was dependent on species body weight. There was no relationship between hind wing anal area or abdomen surface and species flying time. However, total wing area increased with species body length, suggesting a possible natural selection leading to passive fly in larger species. There was a reduction in body length during *Libellulidae* evolution. It is possible that basal species, with large bodies and solar radiation dependence, are more restricted to open areas and that occupation of shadow environments caused a directional body length reduction. Decreasing of body length may have affected geographic distribution and diversification rates, affecting the conservation strategies to this group." 10365. Yanoviak, S.P.; Fincke, O.M. (2005): Sampling methods for water-filled tree holes and their artificial analogues. In: Leather, S.R. (Ed.): *Insect Sampling in Forest Ecosystems*: 168-185. (in English) [Conclusions: "Although there is a growing number of studies documenting the insect fauna of water filled tree holes around the world (Kitching 2000, Yanoviak 2001a), current knowledge remains overwhelmingly biased towards potential

disease vectors. Despite considerable interest in the ecology of this system, few studies have addressed the importance of microbial diversity and ecology in tree holes (e.g. Walker & Merritt 1988; Walker et al. 1991). Decomposer microbes (bacteria and fungi) form a critical link between the nutrient base (e.g. leaf litter) and secondary consumers (e.g. mosquito larvae) in tree holes (Fish E.; Carpenter 1982). Various other microorganisms, such as microcrustaceans, rotifers, and protozoans, also occur in tree holes (Kitcing 2000, Yanoviak 2001a), and may function as prey or competitors with the macrofauna. Microbial ecology has been largely overlooked in tropical tree holes, and several basic questions remain to be answered for this system in general. For example, what regulates microbial diversity and productivity in tree holes? How does the composition of detritus affect decomposer assemblages? Does microbial diversity influence macroorganism diversity or productivity? Are microbial assemblages more species-rich in tropical tree holes? The ecology of microorganisms has been examined in other phytotelmata (e.g. Addicott 1974, Cochran-Stafira & von Ende 1998, Carrias et al. 2001), and these studies exemplify the kinds of investigations that are needed in tree holes. Likewise, few studies have addressed the ecological importance of inorganic nutrients (e.g. nitrogen and phosphorus) in tree holes (e.g. Carpenter 1982; Walker et al. 1991). Microbial and nutrient dynamics have been described for many large freshwater systems, and some of the techniques commonly used by stream and lake ecologists to quantify these parameters could be transferred to tree holes. In summary, water-filled tree holes are tractable habitats for ecological and behavioural studies; sampling their insect fauna is a relatively simple process, and the use of artificial holes is an inexpensive way to increase sample size and control multiple factors for experiments. The extent to which inferences from tree hole data have a more general application for freshwater systems remains to be seen. Nevertheless, given their important ecological role, these aquatic microhabitats merit much more attention than they have received, especially in tropical forests." 10368. Brady, V.J.; Bradley J.C.; Gathman, J.P.; Burton, T.M. (2006): Does facilitation of faunal recruitment benefit ecosystem restoration? An experimental study of invertebrate assemblages in wetland mesocosms. Restoration Ecology 10(4): 617-626. (in English) ["We used wetland mesocosms (1) to experimentally assess whether inoculating a restored wetland site with vegetation/sediment plugs from a natural wetland would alter the development of invertebrate communities relative to unaided controls and (2) to determine if stocking of a poor invertebrate colonizer could further modify community development beyond that due to simple inoculation. After filling mesocosms with soil from a drained and cultivated former wetland and restoring comparable hydrology, mesocosms were randomly assigned to one of three treatments: control (a reference for unaided community development), inoculated (received three vegetation/sediment cores from a natural wetland), and stocked + inoculated (received three cores and were stocked with a poorly dispersing invertebrate group—gastropods). All mesocosms were placed 100 m from a natural wetland and allowed to colonize for 82 days. Facilitation of invertebrate colonization led to communities in inoculated and stocked + inoculated treatments that contrasted strongly with those in the unaided control treatment. Control mesocosms had the highest taxa richness but the lowest diversity due to high densities and dominance of Tanytarsini (Diptera: Chironomidae). Community structure in inoculated and stocked + inoculated mesocosms was more similar to that of a nearby natural wetland, with abundance more evenly distributed among taxa, leading to diversity that was higher than in the control treatment. Inoculated and stocked + inoculated communities were dominated by non-aerial invertebrates, whereas control mesocosms were dominated by aerial invertebrates. These results suggest that facilitation of invertebrate recruitment does indeed alter invertebrate community development and that facilitation may lead to a more natural community structure in less time under conditions simulating wetland restoration." (Authors) Taxa collected from wetland mesocosms and a nearby natural wetland included *Aeshniidae*, *Orthemis sp.*, and *Coenagrionidae*.] Address: Brady, Valerie, Natural Resources Research Institute, University of Minnesota Duluth, 5013 Miller Trunk Highway, Duluth, MN 55804, USA.

10369. Chandra, G.; Chatterjee, S.N.; Ghosh, A. (2006): Role of dragonfly (*Brachytron pratense*) nymph as bio-control agent of larval mosquitoes. Bul. Penel. Kesehatan 34(4): 147-151. (in English) ["The failure of traditional vector control operations through chemical insecticides renewed interest in biological control method. In the present study Dragonfly (*Brachytron pratense*) nymph has been proved to be a strong biocontrol agent of *Anopheles subpictus* larvae in the laboratory condition. Average daily larval feeding rate of *B. pratense* nymph decreased when the search area was increased. Feeding rate increased when prey density was increased. In the field conditions also, *B. pratense* played very effective role as predator of different species of larval mosquitoes." Please note: *B. pratense* is not a member of Indian dragonfly fauna.]

10372. Stav, G.; Kotler, B.P.; Blaustein, L. (2006): Direct and indirect effects of dragonfly (*Anax imperator*) nymphs on green toad (*Bufo viridis*) tadpoles. *Hydrobiologia* 579 (1): 85-93. (in English) ["We conducted an artificial pond experiment to assess the direct and indirect effects of predation on *Bufo viridis* tadpoles. We ran three treatments: free *Anax* (unrestrained predatory dragonfly nymph *Anax imperator*), caged *Anax* (non-consumptive effects), and control (no *Anax*). *Anax* showed both strong consumptive and non-consumptive effects on *Bufo* tadpoles. Free *Anax* eliminated all of the tadpoles within six days. Tadpoles preferred the shady side of the ponds. Caged *Anax* caused tadpoles to increase their spatial preferences. Tadpoles avoided the center of the pond, and in the presence of the caged predator, they were found in the center even less. Tadpoles also showed a strong preference for crowding together, and in the presence of a caged *Anax*, they tended to crowd more. Moreover, *Bufo* metamorphosed earlier and at a larger size in the caged *Anax* ponds, possibly by providing extra food resources due to the extra organic matter excreted by the predators." (in Dutch, with English summary) ["In Limburg, *Cordulegaster boltonii* is known to occur in the Haeselaarsbroek and Meinweg nature reserves. At Meinweg, which houses the largest population in the Netherlands, the species occurs along the Boschbeek, Roode

beek and Nartheciumbeek brooks. Recently, specimens have also been observed along the Venbeek brook, probably representing the fourth subpopulation of *C. boltonii* at the Meinweg reserve." (Author)] Address: Geraeds, R.P.G., Bergstraat 70, 6131 AW Sittard, The Netherlands

10376. Hermans, J.T. (2007): De Gewone bronlibel in de Meinweg [The Golden-ringed dragonfly at the Meinweg National Park]. *Natuurhistorisch Maandblad* 96(6): 165-169. (in Dutch, with English summary) ["*Cordulegaster boltonii* has always been a rare species in the Netherlands, whose main area of distribution in the country is restricted to the province of Limburg. The population of *C. boltonii* at the 'De Meinweg' National Park is the largest in the Netherlands. At the Meinweg area, the species has three sub-populations along the Bosbeek, Nartheciumbeek and Venbeek brooks. The sub-population along the Venbeek brook is the result of recent colonisation. The habitats in which the species occurs at the Meinweg National Park are shallow streams, which are characterised by their small size, the presence of organic litter as a biotope for the larvae and the fact that they are fed from local springs producing oxygenous groundwater with a low mineral content and a constant low temperature. In 2006, several individuals were marked with different colours to investigate possible exchanges between the sub-populations, but no such exchanges could be confirmed. *Calopteryx virgo* and *Orthetrum coerulescens* are the most characteristic accompanying dragonfly species at the Meinweg. One of the main threats to the presence of *C. boltonii* at this nature reserve is that the streams where they breed run dry during periods of drought." (Author)] Address: Hermans, J.T., Hertestraat 21, 6067 ER Linne, The Netherlands.

10377. New, T.R. (2007): The *Hemiphlebia* damselfly, *Hemiphlebia mirabilis* Selys (Odonata, Zygoptera) as a flagship species for aquatic insect conservation in south-eastern Australia. *The Victorian Naturalist* 124(4): 269-272. (in English) ["The endemic *H. mirabilis* has been a focus of conservation attention since its rediscovery in Victoria was publicised in the mid 1980s. It was listed under the state's Flora and Fauna Guarantee Act (FFG) in 1991. Discovery of additional colonies has indicated that *Hemiphlebia* is far more widespread than earlier supposed, and continued study indicates that it is variously secure or vulnerable in different places – rather than 'endangered', as previously thought. The history of study of the species is summarised briefly, and its values in promoting awareness of insect conservation as a 'flagship species' in southern Australia are discussed." 10382. Sahuquillo, M.; Poquet, J.M.; Rueda, J.; Miracle, M.R. (2007): Macroinvertebrate communities in sediment and plants in coastal Mediterranean water bodies (Central Iberian Peninsula). *Ann. Limnol. - Int. J. Lim.* 43(2): 117-130. ["Sediment and plant-associated macroinvertebrates were sampled in six shallow water bodies along the central part of the coast of Mediterranean Spain. The size of ponds, salinity and hydroperiod were highly variable. Seventy-one taxa were recorded, some of them were endemic or uncommon species, evidencing the important contribution of these ponds to biodiversity. Crustaceans and gastropods of biogeographical interest were found in the most primeval site. Correspondence analysis showed that macroinvertebrate assemblages responded to environmental variables such as salinity, temporality and eutrophication. The brackish water fauna was dominated by crustaceans, while *Oligochaeta* and insect larvae were abundant in freshwater conditions. *Oligochaeta* were abundant at localities with high trophic level, whereas localities with semi-permanent waters were dominated by chironomids. The density of macroinvertebrates was clearly related with trophic state but we did not find significant relationships between density and salinity or water permanence. For plant associated samples our results showed negative relationships between species richness and temporality or salinity, contrary to sediment samples, where the *Oligochaeta/Chironomidae* ratio in sediments and the percentage of sensitive taxa (Ephemeroptera, Odonata, Trichoptera) were useful indices, and were dependent on pond typology. This study emphasizes the broad ecological variety of ponds found in these wetlands and their importance for biodiversity. Some ponds act as permanent biodiversity reservoirs in

fluctuant marshes with seasonal dryness, calling for more attention on their ecological relevance for management strategies." (Authors) Odonata taxa are mentioned as follows: *Sympetrum fonscolombii*, *Ischnura elegans*, *Pyrhosoma nymphula*, *Coenagrionidae*, *Libellulidae*, *Corduliidae*, *Lestidae*.] Address: Sahuquillo, M., Departament de Microbiologia i Ecologia, Facultat de Biologia, Universitat de València, E-46100 Burjassot, València, Spain

10385. Stange, G.; Schmeling, F.; Berry, R.; Lenz, G.; (2007): The temporal resolution of flight attitude control in dragonflies and locusts: Lessons for the design of flapping-wing MAVs. Australian National University Canberra. Research School of Biological Sciences. Contract Number: FA48690610059; Report Number: A038474: 16 pp. (in English) ["In order to identify stability constraints in flapping-winged MAVs, within the context of longitudinal stabilization of flight attitude, the question is examined whether insects are capable of controlling flight attitude at the temporal resolution of a single wing beat. It is found that the phenomenon of phase locking between a periodic light flash and the wingbeat of insects is suitable for the examination of the time resolution with which vision contributes to stabilization. In tethered locusts, flying in a wind tunnel with a wingbeat frequency of 22 Hz, phase locking can be readily obtained by a periodic stimulus of UV light. It is suggested that the effect is a by-product of the animal continuously trying to apply corrections. Therefore, in the closed-loop situation of free flight, frequency components of the visual input at or above wing beat rate are also present and must contribute to stability control. The response is mediated by the median ocellus. In dragonflies, with a wingbeat frequency of 50 Hz, the effect is not observed. This suggests that organisms or MAV of the size and wingbeat rate of locusts require active damping by visual inputs, whereas the same is not necessary in smaller systems." 10387. George, B.M.; Batzer, D. (2008): Spatial and temporal variations of mercury levels in Okefenokee invertebrates: Southeast Georgia. *Environmental Pollution* 152: 484-490. (in English) [USA; "Accumulation of mercury in wetland ecosystems has raised concerns about impacts on wetland food webs. This study measured concentrations of mercury in invertebrates of the Okefenokee Swamp in Georgia, focusing on levels in amphipods, odonates, and crayfish. We collected and analyzed total mercury levels in these invertebrates from 32 sampling stations across commonly occurring sub-habitats. Sampling was conducted in December, May, and August over a two-year period. The highest levels of mercury were detected in amphipods, with total mercury levels often in excess of 20 ppm. Bioaccumulation pathways of mercury in invertebrates of the Okefenokee are probably complex; despite being larger and higher in the food chain, levels in odonates and crayfish were much lower than in amphipods. Mercury levels in invertebrates varied temporally with the highest levels detected in May. There was a lack of spatial variation in mercury levels which is consistent with aerial deposition of mercury." (Authors)] Address: George, B.M., School of Science and Technology, Georgia Gwinnett College, 1000 University Center Lane, Lawrenceville, GA 30043, USA. E-mail address: bgeorge@ggc.usg.edu

10402. Kronenbitter, J. (2009): Laichhabitatwahl des Kleinen Granatauges (*Erythromma viridulum*) (Zygoptera: Coenagrionidae). *Der Einfluss verschiedener Habitatparameter*. Diplomarbeit. Bayerische Julius-Maximilians-Universität Würzburg: 201 pp. (in German, with English

summary) ["Human-induced climate change has caused distributional shifts of many species of Odonata in Europe within the last few decades. Among them, *E. viridulum*, a naturally holo-mediterranean distributed species is today found in many parts of Germany. Within just a decade the number of locations it has been identified in Bavaria has increased nearly tenfold. According to a number of authors, besides the influence of climate change, this increase in its distribution can also be explained by its having been previously overlooked. This is due to the fact that individuals of this species are commonly found far from the vicinity of water bodies. Until now, a systematic survey of *E. viridulum* has been hindered by the fact that no studies which allow quantitative statements about the habitat requirements of the species exist. The method of statistical habitat modelling I used in this study provides the opportunity of identifying and quantifying the relevant habitat factors which determine the presence of a species at a habitat. The data acquisition was undertaken in the area around Würzburg and Haßfurt in the North of Bavaria, Germany. I surveyed 92 standing water bodies for the presence of *E. viridulum* and recorded various potentially relevant parameters. The forecast values of the habitat models I created on the basis of this data proved to be a good representation of the likelihood of the presence of this species. The occurrence probability increased with the low isolation of a water body, a large expanse of open water surface without any swamp plants, a low degree of shading and the presence of immersed leaf vegetation, especially large stands and plants with an extremely fine-branched leaf structure. Relationships between preferred parameter values and the biology of the species are discussed. To identify suitable breeding sites, damselflies need to discriminate between different values of the relevant habitat parameters and polarotaxis plays a major role in this. At artificial ponds I undertook experimental measurements over different light regimes of the reflection-polarisation patterns of the water surface, of different ground colours and of immersion leaf vegetation at several depths. I showed the possibility of distinguishing between different parameter values on the basis of very few characteristics of the reflection-polarisation patterns. For damselflies this suggests the advantage of being able to select a preferred breeding site from a distance simply on the basis of visual information." (Author)] Address: Kronenbitter, Jenja, Schwabenstr. 21., D-76646 Bruchsal, Germany

10403. Lingane, P.J. (2009): The design and fabrication of a micro mechanical dragonfly. Senior Thesis. Project Report. Submitted March 19, 2009: 51 pp, app. (in English) ["The goal this project was to create a scaled model of a flapping wing aerial vehicle. The design was initially based on a remote controlled model available at many toy stores. This model was in the form of a dragonfly but about four times the size in each dimension. My project was to scale this down, ideally to the size of a real dragonfly. This however was difficult, and a half scaled prototype (twice life size) was constructed instead. Scaling was done using dimensionless fluid parameters such as the Reynolds and Strouhal numbers which effectively related the various properties of each model. Testing and modification of the prototype were carried out, and in the process an analytical model was made to model the dynamics. Although still not flying, the prototype will hopefully soon be ready for testing against the theory. In the future, more testing will be completed, and minor modifications made to get the scaled prototype flying. All of this is part of a larger goal to miniaturize a flapping flying ro-

bot of which this project is only a part." (Author)] Address: Lingane, P.J., Department of Mechanical Engineering, Union College, Schenectady, NY, USA

10404. Mey, E. (2009): Beobachtungen an Libellen (Insecta, Odonata) in Thüringen, insbesondere in der Umgebung von Rudolstadt. Rudolstädter naturhistorische Schriften 15: 39-98. (in German, with English summary) [Germany; "The scientific study of dragonflies and damselflies in Thüringen goes back to the first half of the 18th century, is connected with the rise of natural history cabinets, and had its hesitant beginnings in the pre-Linné era in (e.g.) the work of the Nordhausen natural theologian F. C. Lesser. For the first concrete data between 1773 and 1818 we have to thank A. C. Kühn and A. J. G. K. Batsch, but above all J. M. Bechstein and G. L. Scharfenberg. All available historical records up to the middle of the 20th century are here collected together according to their faunistic aspects and annotated. At least nine Odonata eruptions from various regions of Thüringen are known from the last 250 years or more: 1746, 1806, 1816, 1822, 1839, 1853, 1857, 1881, and 1917. They concern population explosions of a single species each time: *Libellula depressa* (twice) and *L. quadrimaculata* (five times). The original accounts are documented here. No Odonata eruptions have been recorded in Thüringen for more than 90 years. Between the end of the 18th century and about 1950, 47 species of Odonata were recorded in Thüringen. However, during this period of more than 150 years faunistic interest in dragonflies and damselflies was only sporadic. Between 1952 and the present day, reports of 17 further species have been published, bringing the total number of Odonata species recorded in Thüringen to 64. From 1984 to 2008 an attempt was made to record the entire Odonata species spectrum occurring in and around Rudolstadt (eastern Thüringen). The material consists of around 2000 data points. It deals with parts of the following natural landscapes: the central Thüringer Wald (Forest), the high Thüringen shale hills, the Schwarzsaale-Sornitz region, the Ilm-Saale-Ohrdruf shell limestone plateau, the Paulinzella bunter sandstone woodland area, the Saale sandstone plateau, and the central Saale Valley. Within this region, 48 Odonata species have been recorded, including some older valuable specimens in the Natural History Museum in Rudolstadt (*Cordulegaster bidentata*, *Gomphus vulgatissimus*, *Onychogomphus forcipatus*, and *Leucorrhinia rubicunda*). In addition, some observations on the life style of *Cordulegaster boltonii* made by the author are given. Contrarily to other reports, there are no confirmed records of *Somatochlora arctica* from Thüringen." 10407. Schilling, E.G.; Loftin, C.S.; Hury, A.D. (2009): Macroinvertebrates as indicators of fish absence in naturally fishless lakes. *Freshwater biology* 54: 181-202. ["1. Little is known about native communities in naturally fishless lakes in eastern North America, a region where fish stocking has led to a decline in these habitats. (2.) Our study objectives were to: (i) characterise and compare macroinvertebrate communities in fishless lakes found in two biophysical regions of Maine (USA): kettle lakes in the eastern lowlands and foothills and headwater lakes in the central and western mountains; (ii) identify unique attributes of fishless lake macroinvertebrate communities compared to lakes with fish and (iii) develop a method to efficiently identify fishless lakes when thorough fish surveys are not possible. (3.) We quantified macroinvertebrate community structure in the two physiographic fishless lake types (n = 8 kettle lakes; n = 8 headwater lakes) with submerged light traps and sweep nets. We also compared fishless lake macroinvertebrate communities to those in fish-containing lakes (n = 18) of similar size, location and maximum depth. We used nonmetric multi-dimensional scaling to assess differences in community structure and t-tests for taxon-specific comparisons between lakes. (4.) Few differences in macroinvertebrate communities between the two physiographic fishless lake types were apparent. Fishless and fish-containing lakes had numerous differences in macroinvertebrate community structure, abundance, taxonomic composition and species richness. Fish presence or absence was a stronger determinant of community structure in our study than differences in physical conditions relating to lake origin and physiography. (5.) Communities in fishless lakes were more speciose and abundant than in fish-containing lakes, especially taxa that are large, active and free-swimming. Families differing in abundance and taxonomic composition included Notonectidae, Corixidae, Gyridae, Dytiscidae, Aeshnidae, Libellulidae and Chaoboridae. (6.) We identified six taxa unique to fishless lakes that are robust indicators of fish absence: *Graphoderus liberus*, *Hesperocorixa* spp., *Dineutus* spp., *Chaoborus americanus*, *Notonecta insulata* and *Callicorixa* spp. These taxa are collected most effectively with submerged light traps. (7.) Naturally fishless lakes warrant conservation, because they provide habitat for a unique suite of organisms that thrive in the absence of fish predation. ... A total of 46 Hemiptera, Coleoptera, Odonata and Chaoborus taxa were identified from submerged light trap and littoral sweeps, with eight taxa abundant in most fishless lakes. The total number of captured macroinvertebrates and total species richness, as well as richness at the family level, did not differ between fishless kettle lakes and fishless headwater lakes. No taxa collected in littoral sweeps showed significant differences in abundance or per cent occurrence between fishless kettle lakes and fishless headwater lakes. The total number of macroinvertebrates captured in submerged light traps was greater in fishless lakes than fish-containing lakes, with greater abundances of Hemiptera, Coleoptera and Odonata in fishless lakes. Odonates associated with fishless lakes were Aeshnidae, Libellulidae and Coenagrionidae, with *Aeshna eremita* and *Leucorrhinia glacialis* more abundant, as well as present in more lakes lacking

fish. Seven species were unique but not widespread among fishless lakes, including *Leucorrhinia patricia* in two lakes. Four species were unique to fish-containing lakes, *Enallagma geminatum* and *E. carunculatum*, *Lesites vigilax* and the haliplid *Haliplus connexus*. None of these was widespread, each occurring in two fish-containing lakes." 10410. Srivastava, S.K.; Babu, N.; Pandey, H. (2009): Traditional insect bioprospecting – as human food and medicine. *Indian Journal of Traditional Knowledge* 8(4): 485-494. (in English) ["The wisdom that indigenous people have regarding bioprospecting is embedded in their belief system and their culture. Food insects play an important role in the new insect focus. Ants, bees, termites, caterpillars, water bugs, beetle larvae, flies, crickets, katydids, cicadas, and dragonfly nymphs are among a long list of edible insects that provide nutrition for the people of Asia, Australia, Africa, South America, the Middle East, and the Far East. Insects represent an important food source for a wide variety of other animal species. By weight, termites, grasshoppers, caterpillars, weevils, houseflies and spiders are better sources of protein than beef, chicken, pork or lamb. The traditional healers use insects as medicine. Chemicals produced by insects against self defense can be used for antibacterial and anticancer drugs. The nutritional and economic value of edible insects is often neglected and we should further encourage their collection and commercialization, given the benefits to the environment and human health. It is an interesting concept, managing pest insects by developing them into a sought after delicacy." Boletín de la Real Sociedad Española de Historia Natural. Sección biológica 103: 131-144. (in Spanish, with English summary) ["Benthic macroinvertebrate communities of the Arba river basin (Aragon, NE Spain) have been studied with the aim of evaluating its ecological status. In the summer of 2001 two samplings campaigns were carried out with a Surber net, coincident with the season of lower flow. Community structure was studied by means of taxa richness and diversity, equitability and dominance indices. Water quality was evaluated by taxa number of Ephemeroptera, Plecoptera and Trichoptera (EPT groups), IASPT and IBMWP indices, using this last one to classify the ecological status of the sampled reaches. In the upper reaches the superficial water is reduced to isolated pools; nevertheless they maintain diverse communities with high values in the IBMWP. There were differences among tributaries due to the diverse degree of anthropic disturbance that they support, being more serious in the downstream part of the basin. Temporality and anthropic disturbance explain the composition of the benthic macroinvertebrate communities in these Mediterranean rivers." (Authors) The taxa list includes 'Aeshnidae' and 'Gomphidae'.] Address: Torralba Burrial, A., Departamento de Biología de Organismos y Sistemas, Universidad de Oviedo, E-33071 Oviedo, Spain. 10416. Anderson, C.N.; Grether, G.F. (2010): Character displacement in the fighting colours of *Hetaerina* damselflies. Proc. R. Soc. B 277(1700): 3669-3675. (in English) ["Aggression between species is a seldom-considered but potentially widespread mechanism of character displacement in secondary sexual characters. Based on previous research showing that similarity in wing coloration directly influences interspecific territorial aggression in *Hetaerina* damselflies, we predicted that wing coloration would show a pattern of character displacement (divergence in sympatry). A geographical survey of four *Hetaerina* damselfly species in Mexico and Texas showed evidence for character displacement in both species pairs that regularly occurs sympatrically. *Hetaerina titia*, a species that typically has large black wing spots and small red wing spots, shifted to having even larger black spots and smaller red wing spots at sites where a congener with large red wing spots is numerically dominant (*H. americana* or *H. occisa*). *H. americana* showed the reverse pattern, shifting towards larger red wing spots where *H. titia* is numerically dominant. This pattern is consistent with the process of agonistic character displacement, but the ontogenetic basis of the shift remains to be demonstrated." 10426. Davis, J.M.; Rosemond, A.M.; Eggert, S.L.; Cross, W.F.; Wallace, J.B. (2010): Nutrient enrichment differentially affects body sizes of primary consumers and predators in a detritus-based stream. *Limnol. Oceanogr.* 55(6): 2305-2316. (in English) ["We assessed how a 5-yr nutrient enrichment affected the responses of different size classes of primary consumers and predators in a detritus-based headwater stream. We hypothesized that alterations in detritus availability because of enrichment would decrease the abundance and biomass of large-bodied consumers. In contrast, we found that 2 yr of enrichment increased the biomass and abundance of all consumers regardless of body size. Furthermore, during the fourth and fifth year of enrichment, the abundance and biomass of large-bodied primary consumers continued to increase, while small-bodied primary consumers returned to pretreatment levels. The size structure of a dominant primary consumer (*Pycnopsyche* spp.) also shifted during the 5-yr enrichment: its average and maximum individual body size increased in the treatment stream compared with the reference stream. Positive en-

richment effects also occurred on small-bodied predators, but not on large-bodied predators. Thus, enrichment increased prey body size, but these positive effects on large prey did not propagate up to higher trophic levels to affect large predators. Because consumer body size can be an important species-specific trait determining population dynamics and ecosystem processes, these observed shifts in consumer size distributions suggest a potentially important pathway for global increases in nutrient enrichment to alter stream structure and function...The predator community was dominated by app. 20 taxa of invertebrate (e.g., Beloneuria [Plecoptera], Ceratopogonidae [Diptera], Cordulegaster, Hexatoma [Diptera], and Lanthus)." 10427. Dow, R.A. (2010): A review of the *Teinobasis* of Sundaland, with the description of *Teinobasis cryptica* sp. nov. from Malaysia (Odonata: Coenagrionidae). *International Journal of Odonatology* 13(2): 205-230, pl. II. (in English) ["*Teinobasis cryptica* sp. nov. (holotype male: Borneo, Sarawak, Bahagian Samarahan, Kota Samarahan, old UNIMAS campus, disturbed peat swamp forest, 25 ii 2008, RMNH) from Malaysia is described from both sexes and compared with other *Teinobasis* species known to occur in Malaysia. The members of the genus known from Sundaland are reviewed. Records of *T. ruficollis* from Borneo are clarified. New records of other Bornean species are listed. The females of *T. laidlawi*, *T. rajah* and *T. ruficollis* are described for the first time. Keys are given to both sexes of all named species from the genus known from peninsular Malaysia, Singapore and the Greater Sunda Islands and the species are placed provisionally into two groups: the *laidlawi*-group and *ruficollis*-group. The former group also includes *T. rubricauda* from the Palawan region of the Philippines, which may be a junior synonym of *T. laidlawi*." (Author)] Address: Rory A. Dow, Netherlands Centre for Biodiversity Naturalis, P.O. Box 9517, 2300 RA Leiden, The Netherlands. E-mail: rory.dow230@yahoo.co.uk

10428. Dozark, K.G. (2010): Sediment effects on aquatic macroinvertebrates in a prairie pothole, Oak Lake, in eastern South Dakota. Dissertation, South Dakota State University: 90 pp. (in English) ["The Clean Water Act aims to maintain the physical, chemical, and biological integrity of the nation's waters. Sedimentation is a major pollutant to world, national, and state waterbodies. The developments of Total Maximum Daily Loads (TMDLs) are required to improve water quality problems through the use of Best Management Practices (BMPs). Sedimentation can be detrimental to aquatic ecosystems by reducing feeding ability, smothering habitat, clogging respiratory apparatuses, and increasing scouring and abrasion to exoskeletons of aquatic organisms. This study examined the influence of regional sediment loads on aquatic macroinvertebrate communities in the littoral zone of a prairie pothole lake, Oak Lake. Ten emergent macrophyte bed and ten rocky shoreline locations were treated with varying levels of soil to simulate regional sediment loads of 25 tons/km², 250 tons/km², 2,500 tons/km² and 25,000 tons/km². Five plots were treated and sampled at each of ten locations during the summers of 2005 and 2006. Invertebrates were subsampled, identified to the lowest practical taxonomic level, and classified into habitat and feeding guilds. A total of 129 invertebrate taxa were identified throughout the experiment. Macrophyte beds contained an average of 23 genera and rocky

shores contained an average of 18 genera. Sedimentation significantly decreased the percentages of collector-gatherers and sprawlers in both habitats. Percentages of gliders, swimmers, and scrapers increased with the addition of sediment in both habitats. Macrophyte beds exhibited an increase in Ephemeroptera, Trichoptera, and Odonata richness following sedimentation. The percentage of sprawlers in rocky shorelines was significantly decreased due to sedimentation. These relationships were log linear. Oligochaeta, *Caenis latipennis*, Endochironomus and Coenagrionidae abundances were reduced following treatment in macrophyte beds. In rocky habitats abundances of Oligochaeta, water mites, and *Hyalella azteca* increased following treatment. However, *C. latipennis* and *Hydra* abundances decreased. Overall, macroinvertebrate communities changed little following sedimentation. Other studies suggest that macroinvertebrate communities in the Prairie Pothole region are tolerant to environmental disturbances and changes. Non-anthropogenic factors, such as lake morphology, may be more influential to macroinvertebrate communities than anthropogenic factors, such as human development along lake shorelines. Future studies should examine possible macroinvertebrate threshold levels with higher sediment loads than were used in this study." (Author)] Address: not stated

10429. Dudarev, A.N. (2010): Strekozy (Insecta, Odonata) verkhovo bolota „El'nya" [Dragonflies (Insecta, Odonata) of the high peat bog „El'nya"]. *Vesnik Vitebskaya dzerzhavnaga universiteta* 2010(2): 80-84. (in Russian) [Belarus; 20 Odonata species have been found in the bog of El'nya, Belarus. Dominant species are *Lestes sponsa*, *Sympetrum flaveolum* and *Enallagma cyathigerum*. Noteworthy species are also *Coenagrion hastulatum*, *C. pulchellum*, *Somatochlora flavomaculata*, *Leucorrhinia albifrons*, *L. rubicunda*, and *L. dubia*.] Address: Dudarev, A.N., UO Vitebsk State Univ., PM Masherau, Belarus

10430. Geraeds, R.P.G. (2010): Habitat and development of larvae of the Club-tailed dragonfly in the river Roer. *Natuurhistorisch Maandblad* 99(11): 249-255. (in Dutch, with English summary) ["The locations and timing of emergence of in the river Roer (in the Dutch province of Limburg) have been thoroughly investigated in recent years. It is assumed that the dragonflies generally emerge close to their larval habitat. Since surveys of actual larval habitats in the Netherlands have been very rare, four transects of the Roer were checked for the presence of larvae of the Clubtailed dragonfly (*Gomphus vulgatissimus*) during 2006-2009. The goal was to discover what type of substrate the larvae prefer, and if the places where the dragonflies emerge are situated close to the actual larval habitats, as well as to find out how long larval development along the river Roer takes. The survey of larvae was carried out in four transects (Muytert, Melicker Ohé, Zwarte Berg and Roermond). The larvae were caught with a hand brailer which is normally used for fish and amphibian surveys. For each of the larvae caught, I noted the type of substrate in which it was caught and its distance to the riverbank, measured the width of its head and determined its sex. Larvae of the Clubtailed dragonfly develop in 14 stages (F13 to F0), and the stage of development can be identified by measuring the width of the head. The last hibernation before emergence always takes place in the final stage of development (F0). The larvae do not grow during hibernation, i.e. from October to May. Each transect was investigated eight times during the 2006-2009 period, and 615 larvae of *G. vulgatissimus*

simus were caught. Most were caught at the Melicker Ohé transect (245), while only four larvae were caught at the Roermond transect. Most larvae were found within a 1 m distance of the riverbank, and almost 50% even within 0.50 m from the bank. The largest distance from the bank at which larvae were caught was 5 m. Most larvae were found in mixed substrates, dominated by a combination of silt and detritus. Only a few larvae were found in substrates dominated only by silt, detritus, sand or gravel. The widths of the larval heads ranged from 1.3 to 6.5 mm. According to Müller (1995) and Kern (1999), this means that the larvae were in the last seven developmental stages (F6 to F0). Most of the larvae were in the final stage (F0). Surveys during hibernation yielded only larvae in the last six stages (F5 till F0). The distribution of developmental stages of larvae caught during hibernation shows that most of the larvae of the population in the River Roer develop over a period of three years, which means that most of the larvae hibernate successively in stages F4, F2 and F0." 10433. Han, J.-s.; Chang, J.W.; Kang, I.-m.; Kim, S.-t. (2010): Flow visualization and force measurement of an insect wing based on dragonfly hovering. 28th AIAA Applied Aerodynamics Conference, 28 June - 1 July 2010, Chicago, Illinois: (in English) ["Flow visualization and aerodynamic force measurements were conducted in order to investigate the flow phenomena around the wing of a hovering dragonfly. Two pairs of 4-bar linkage mechanisms were installed in a flapping model and driven by a stepping motor. The fore- and hindwing have a phase difference angle of 180°. The stroke amplitude, pitch angle and incidence angle of the model were 75°, 0-90° and 60°, respectively. A wing beat frequency of 0.087 was chosen, and the corresponding Reynolds number was 2.0×10³ based on the forewing. Each wing generated LEV at the start of downstroke and the LEV was developed and maintained on the upper surface of the wing. Aerodynamic forces were also generated in the downstroke motion in all cases. When the wings stroke together, the LEV on the hindwing was deformed by the

forewing, and the forces on the hindwing are lower than in the hindwing only cases. These results indicate that the wing-wing interaction have a negative effect on the generation of aerodynamic forces." 10437. Joniak, T. (2010): Benthic fauna of humic lakes of Drawieński National Park – history of research and state of knowledge. In: Joniak, T. (Ed.), *Functioning and protection of marsh ecosystems. Vol 3. Benthic fauna of Polish national parks.* Department of Water Protection Faculty of Biology A. Mickiewicz University, Poznań: 40-46. (in Polish, with English summary) ["The work present the history of research and state of knowledge of macrozoobenthos of humic lakes in Drawieński National Park, Poland. The specific feature of humic lakes is the presence of dissolved, mainly humic organic matter. The process of lake humification is connected with the inflow of organic substances cause significant changes in the water environment as well as the formation of a specific association of hydrobionts. The increase in the concentration of humic acids in lake waters leads to changes in the abiotic features of the environment, such as high water colour, decline in the thickness of the trophogenic zone, pH decrease (<6.5), limitation of the bioavailability of biogenic compounds. In these conditions some groups of benthic fauna are not found (for example Crustacea, Mollusca), and species diversity and number are reduced." (Author) The following Odonata species are mentioned: *Cordulia aenea*, *Enallagma cyathigerum* and *Ischnura elegans*.] Address: Joniak, T., Adam Mickiewicz University of Poznań, Faculty of Biology, Department of Water Protection, Umultowska str. 89, 61-614 Poznań, Poland. 10439. Kery, M.; Gardner, B.; Monnerat, C. (2010): Predicting species distributions from checklist data using site-occupancy models. *Journal of Biogeography* 37(10): 1851-1862. (in English) ["Aim (1) To increase awareness of the challenges induced by imperfect detection, which is a fundamental issue in species distribution modelling; (2) to emphasize the value of replicate observations for species distribution modelling; and (3) to show how 'cheap' checklist data in faunal/floral databases may be used for the rigorous modelling of distributions by site-occupancy models. Location: Switzerland. Methods: We used checklist data collected by volunteers during 1999 and 2000 to analyse the distribution of *Aeshna cyanea*, a common dragonfly in Switzerland. We used data from repeated visits to 1-ha pixels to derive 'detection histories' and apply site-occupancy models to estimate the 'true' species distribution, i.e. corrected for imperfect detection. We modelled blue hawker distribution as a function of elevation and year and its detection probability of elevation, year and season. Results: The best model contained cubic polynomial elevation effects for distribution and quadratic effects of elevation and season for detectability. We compared the site-occupancy model with a conventional distribution model based on a generalized linear model, which assumes perfect detectability ($p = 1$). The conventional distribution map looked very different from the distribution map obtained using site-occupancy models that accounted for the imperfect detection. The conventional model underestimated the species distribution by 60%, and the slope parameters of the occurrence–elevation relationship were also underestimated when assuming $p = 1$. Elevation was not only an im-

portant predictor of blue hawker occurrence, but also of the detection probability, with a bell-shaped relationship. Furthermore, detectability increased over the season. The average detection probability was estimated at only 0.19 per survey. Main conclusions: Conventional species distribution models do not model species distributions per se but rather the apparent distribution, i.e. an unknown proportion of species distributions. That unknown proportion is equivalent to detectability. Imperfect detection in conventional species distribution models yields underestimates of the extent of distributions and covariate effects that are biased towards zero. In addition, patterns in detectability will erroneously be ascribed to species distributions. In contrast, site-occupancy models applied to replicated detection/non-detection data offer a powerful framework for making inferences about species distributions corrected for imperfect detection. The use of 'cheap' checklist data greatly enhances the scope of applications of this useful class of models." (Authors)] Address: Kéry, M., Swiss Ornithological Institute, 6204 Sempach, Switzerland. 10443. Kück, P.; Meusemann, K.; Dambach, J.; Thormann, B.; Reumont, B.M. von; Wägele, J.W.; Misof, B. (2010): Parametric and non-parametric masking of randomness in sequence alignments can be improved and leads to better resolved trees. *Frontiers in Zoology* 2010, 7: 12 pp. (in English) ["Methods of alignment masking, which refers to the technique of excluding alignment blocks prior to tree reconstructions, have been successful in improving the signal-to-noise ratio in sequence alignments. However, the lack of formally well-defined methods to identify randomness in sequence alignments has prevented a routine application of alignment masking. Here, the effects on tree reconstructions of the most commonly used profiling method (GBLOCKS), which uses a predefined set of rules in combination with alignment masking, are compared with a new profiling approach (ALISCORE) based on Monte Carlo resampling within a sliding window, using different data sets and alignment methods. While the GBLOCKS approach excludes variable sections above a certain threshold which choice is left arbitrary, the ALISCORE algorithm is free of a priori rating of parameter space and therefore more objective. ALISCORE was successfully extended to amino acids using a proportional model and empirical substitution matrices to score randomness in multiple sequence

alignments. A complex bootstrap resampling leads to an even distribution of scores of randomly similar sequences to assess randomness of the observed sequence similarity. Testing performance on real data, both masking methods, GBLOCKS and ALISCOPE, helped to improve tree resolution. The sliding window approach was less sensitive to different alignments of identical data sets and performed equally well on all data sets. Concurrently, ALISCOPE is capable of dealing with different substitution patterns and heterogeneous base composition. ALISCOPE and the most relaxed GBLOCKS gap parameter setting performed best on all data sets. Correspondingly, Neighbour-Net analyses showed the most decrease in conflict. Alignment masking improves signal-to-noise ratio in multiple sequence alignments prior to phylogenetic reconstruction. Given the robust performance of alignment profiling, alignment masking should routinely be used to improve tree reconstructions. Parametric methods of alignment profiling can be easily extended to more complex likelihood based models of sequence evolution which opens the possibility of further improvements." 10446. Levy, D.E.; Seifert, A. (2010): Parameter study of simplified dragonfly airfoil geometry at Reynolds number of 6000. *J. Theor. Biol.* 266(4): 691-702. (in English) ["Aerodynamic study of a simplified Dragonfly airfoil in gliding flight at Reynolds numbers below 10,000 is motivated by both pure scientific interest and technological applications. At these Reynolds numbers, the natural insect flight could provide inspiration for technology development of Micro UAV's and more. Insect wings are typically characterized by corrugated airfoils. The present study follows a fundamental flow physics study (Levy and Seifert, 2009), that revealed the importance of flow separation

from the first corrugation, the roll-up of the separated shear layer to discrete vortices and their role in promoting flow reattachment to the aft arc, as the leading mechanism enabling high-lift, low drag performance of the Dragonfly gliding flight. This paper describes the effect of systematic airfoil geometry variations on the aerodynamic properties of a simplified Dragonfly airfoil at Reynolds number of 6000. The parameter study includes a detailed analysis of small variations of the nominal geometry, such as corrugation placement or height, rear arc and trailing edge shape. Numerical simulations using the 2D laminar Navier-Stokes equations revealed that the flow accelerating over the first corrugation slope is followed by an unsteady pressure recovery, combined with vortex shedding. The latter allows the reattachment of the flow over the rear arc. Also, the drag values are directly linked to the vortices' magnitude. This parametric study shows that geometric variations which reduce the vortices' amplitude, as reduction of the rear cavity depth or the reduction of the rear arc and trailing edge curvature, will reduce the drag values. Other changes will extend the flow reattachment over the rear arc for a larger mean lift coefficients range; such as the negative deflection of the forward flat plate. These changes consequently reduce the drag values at higher mean lift coefficients. The detailed geometry study enabled the definition of a corrugated airfoil geometry with enhanced aerodynamic properties, such as range and endurance factors, as compared to the nominal airfoil studied in the literature." (Authors)] Address: Levy, D.E., School of Mechanical Engineering, Faculty of Engineering, Tel-Aviv Univ., Tel Aviv, Israel

10447. Malikova, E.I. (2010): Zoogeographically interesting dragonfly (Odonata) records from the Upper Amur region. *Eurasian Entomological Journal* 9(2): 291-294. (in Russian, with English summary) ["New records of 10 species are reported. *Lestes temporalis*, *Paracercion calamorum*, *Anax parthenope julius* and *Sinictinogomphus clavatus* are recorded for the first time from the region. The W Palaearctic *Orthetrum cancellatum*, reported from Upper Amur (Blagoveshchensk, Amurskaya Oblast, Russia), probably migrated from Chinese Inner Mongolia, following a mass migration of the beet webworm (*Loxostege sticticalis*) in 2008." 10448. Michalczyk, W.; Buczyński, P. (2010): The second recent locality of *Coenagrion ornatum* (Odonata: Coenagrionidae) in the southeastern Poland. *Odonatrix* 6(1): 15-21. (in Polish, with English summary) ["*Coenagrion ornatum* is a critically endangered species in Poland. It has been known from 24 localities so far, of which only one is preserved till now - in Śniatycze situated east of Zamosc (south-eastern Poland). The authors give and discuss a new species locality situated west-north-west of Zamość, ca. 40 km from Śniatycze, in the village of Średnie Duże (50°50'32"N, 23°01'15"E, UTM: FB43). The species inhabits the River Rakówka. The discovery was made on 13 July, thus the estimating of population number is uncertain, however, it can be at least equally numerous as the population in Śniatycze which is regarded as large and stable. New data moves the boundary of the current range of *C. ornatum* in Poland a bit to the north. The presence of the species in south-eastern Poland is probably associated with its occurrence in western Ukraine, where it was recorded at ca. 20 localities. Although many of them are historical ones, there is also fresh data from the Shatsk Lake District (Chokalo,

Werwes 2009). *Rakówka* seems to be untypical as a habitat of *C. ornatum* due to high values of river section and flow velocity. However, the calculated parameters of flow turned out to be similar to these from the other localities of this species. The discussed locality is seriously endangered due to its localization in the centre of a village - the small river is fragmented into many stretches with different type of using. *C. ornatum* has been observed on the stretch of the total length of ca 200 m, however, the numbers were different. In places with the least favourable conditions (with the bottom of concrete and removed vegetation) the species was absent. Passive and active protection of this locality is a must." 10450. Muehlbauer, J.D.; Doyle, M.W.; Bernhardt, E.S. (2010): Macroinvertebrate community responses to a dewatering disturbance gradient in a restored stream. *Hydrol. Earth Syst. Sci. Discuss.* 7: 9599-9630. (in English) [Timberlake mitigation site, Carolina, USA. "Dewatering disturbances are common in aquatic systems and represent a relatively untapped field of disturbance ecology, yet studying dewatering events along gradients in non-dichotomous (i.e., wet/dry) terms is often difficult. Because many stream restorations can essentially be perceived as planned hydrologic manipulations, such systems can make ideal test-cases for understanding processes of hydrological disturbance. In this study we used an experimental drawdown in a 440 ha stream / wetland restoration site to assess aquatic macroinvertebrate community responses to dewatering and subsequent rewetting. The geomorphic nature of the site and the design of the restoration allowed dewatering to occur predictably along a gradient and decoupled the hydrologic response from any geomorphic (i.e., habitat heterogeneity) effects. In the absence of such heterogeneous habitat refugia, reach-scale wetted perimeter and depth conditions exerted a strong control on community structure. The community exhibited an incremental response to dewatering severity over the course of this disturbance, which was made manifest not as a change in community means but as an increase in community variability, or dispersion, at each site. The dewatering also affected inter-species abundance and distributional pat-

terns, as dewatering and rewetting promoted alternate species groups with divergent habitat tolerances. Finally, our results indicate that rapid rewetting – analogous to a hurricane breaking a summer drought – may represent a recovery process rather than an additional disturbance and that such processes, even in newly restored systems, may be rapid." (Authors) The supplementary material contains the taxa lists identified to the genus level (*Anax*, *Enallagma*, *Ischnura*, *Erythemis*, *Miathyria*, *Pachydiplax*.)] Address: Muehlbauer, J.D., Curriculum for the Environment and Ecology, Univ. of North Carolina, Chapel Hill, NC, USA. 10454. Relyea, R.A.; Edwards, K. (2010): What doesn't kill you makes you sluggish: How sublethal pesticides alter predator-prey interactions. *Copeia* 2010(4): 558-567. (in English) ["Pesticides commonly occur in ecological communities at relatively low concentrations, leading to growing interest in determining the sublethal effects of pesticides. Such effects should affect individuals and, in turn, alter interspecific interactions. We sought to determine how sublethal concentrations (0.1 and 1.0 mg/L) of two common pesticides (carbaryl and malathion) affected predator and prey behaviour as well as subsequent predation rates. We conducted a series of experiments using three species of larval amphibians (Gray Treefrogs, *Hyla versicolor*; Green Frogs, *Rana clamitans*; and American Bullfrogs, *R. catesbeiana*) and three species of their predators (larval dragonflies, *Anax junius*; adult water bugs, *Belostoma flumineum*; and adult Red-spotted Newts, *Notophthalmus viridescens*). We found that the pesticides frequently reduced the activity of all three tadpole species. For the two invertebrate predators (*Anax* and *Belostoma*), the pesticides were lethal, precluding us from examining sublethal effects on predator-prey inter-

actions. However, newt survival was high and the addition of the pesticides reduced the predation rates of newts in one of the three tadpole species. There were no effects of the pesticides on the striking frequency of the newts or on their prey capture efficiency. Thus, the mechanism underlying the pesticide-induced reduction in predation rates remains unclear. What is clear is that sublethal concentrations of pesticides have the potential to alter prey behavior and species interactions and thereby alter the composition of ecological communities." 10459. Simard, G. (2010): *Flying Dragons*. Editions Alatus. ISBN: 978-2-9526011-5-3: 144 pp. (in English) ["Flying Dragons rule supreme over the world of insects. High-speed manoeuvres, instant changes of direction, hovering, reverse flight, dragonflies can do almost anything on the wing. The photographs of Ghislain SIMARD

open a fresh window into a world where aerial motions are too fast to be observed by human eyes. The photographer's lens offers a journey through miniature landscapes around ponds, canals, streams, rivers and peat bogs. The chapters are arranged to show the diversity of behaviour that these spectacular insects enjoy. Frail Damselflies are unpredictable, Broad-bodied Chasers always return to the same roost, Keeled Skimmers mate in flight, Common Darters play with their reflections in the water while the Emperor flaunts its aerial prowess. The briskness of dragonflies' actions turns the photography of their flight into an almost impossible task. To shoot such actions, high-speed equipment dedicated to flying insects is required. Some tools have even been designed specifically to arrest dragonflies in flight. The final section of the book details this working method for wildlife photographers." (Publisher) Coffee table book] Address: not stated

10460. Singh, H.; Gusain, O.P.; Gusain, M.P. (2010): Benthic insect-substratum relationship along an altitudinal gradient in a Himalayan stream, India. *International Journal of Ecology and Environmental Sciences* 36(4): 215-231. (in English) ["Takoli Gad is a small spring-fed tributary of the River Alaknanda (a tributary of River Ganga) in Tehri district of Uttarakhand (India). Insect-substratum relationship was studied at five sampling sites representing an altitudinal gradient in Takoli Gad during January 2000 to February 2002. The swift flowing stream is largely dominated by pebbles and boulders (>32 nun). In general, the substrate composition ranged from coarse sand ($\phi = 0$) to small pebbles ($\phi = -4$). The benthic fauna comprised of 34 genera belonging to 09 orders and 25 families of insects. It included mostly the nymphs and larvae of Ephemeroptera, Plecoptera, Trichoptera, Coleoptera, Lepidoptera, Odonata, Neuroptera, Diptera and Hemiptera. The total benthic density was maximum during winter III (3408.0 ind. m^{-2}) at downstream site, and minimum during monsoon I (283.0 ind. m^{-2}) in the middle stretch. The Simpson Index of Diversity (D) for substrate heterogeneity was low for headwater region of the stream. The Index of Representation (IR) revealed that the heterogeneous substratum was the preferred habitat of most of the taxa during the winter. The distribution of the benthic insects varied slightly along the longitudinal gradient. Many genera were seasonally absent in different sections of the stream. Seasonal variation in the density of benthic insects was correlated with the change in the substrate composition, notably during the rainy season when the mean grain size changes to cobbles ($Md = 8$). A relatively stable substrate composition during winter together with low to moderate current velocity (0.4-0.6 $m\ s^{-1}$) and shallow water depth (0.14-0.20 m) along with abundant detritus favours a rich and diverse insect community. Further, clustering method also shows the substratum during winter to be preferred by majority of the taxa." (Authors) Odonata taxa are *Hagenius!* and *Ophiogomphus*.] Address: Singh, T., Freshwater Biology Unit, Department of Zoology, HNB Garhwal University, Srinagar-Garhwal 246174, Uttarakhand, India

10461. Skevington, J.H.; Beatty, C.D.; Van Gossom, H.; Donnelly, T.W.; Sherratt, T.N.; Rashed, A.; Kelso, S. (2010): Molecular phylogenetics of *Nesobasis* and *Melanesobasis* (Odonata: Coenagrionidae): exploring the evolution of a large insular insect radiation. *Cladistics* 26: 224-225. (in English) [Verbatim: "In 1990 Nick Donnelly revised a large part of the Fijian damselfly fauna. An unusual anomaly was discovered—some species appeared to be heavily female biased. In an effort to better under-

stand this phenomenon, we decided to create a phylogenetic hypothesis for the two large, near-endemic, Fijian genera, *Nesobasis* and *Melanesobasis*. These putative sister taxa had never been studied phylogenetically; however, Donnelly postulated the existence of several species groups and some sister species relationships based on a few characters. We refute the concept that *Nesobasis* and *Melanesobasis* are sister taxa and provide quantitative evidence supporting most of Donnelly's perceptions about relationships within *Nesobasis*. Two mitochondrial genes (COI and 12S) and one nuclear gene complex (ITS1 and ITS2, and ribosomal 5.8S rDNA) were sequenced for 45 taxa in our analysis. This represents most of the extant species of *Nesobasis* and *Melanesobasis* and all of the numerous undescribed species. Female-biased species were found in more than one lineage. Results and analytical methods will be discussed and ecological traits will be explored in light of our phylogenetic hypothesis." (2010): Preliminary estimation of population total abundance of *Leucorrhinia caudalis* and *L. pectoralis* in "Zdręczno Lake" nature reserve (Tuchola Forest, Poland). *Odonatrix* 6(1): 9-14. (in Polish, with English summary) ["A study upon the total abundance of *Leucorrhinia caudalis* and *L. pectoralis* was performed at the beginning of June 2008 in the nature reserve „Zdręczno Lake”, Tuchola Forest, Poland. The abundance estimation was based upon the number of exuviae collected within the reserve, among the reed and shore vegetation, also in some distance from the shore. Altogether 76 samples were gathered, each composed of exuviae collected from the area of 1m². In total 101 exuviae of *L. caudalis* (mean density: 1.33 ind/m², density range: 0-7 ind/m², SD=1.32) and 176 exuviae of *L. pectoralis* (mean density: 2.32 ind/m², density range: 0-7 ind/m², SD=1.68) were found. Based on aerial photographs the total area of habitat available for *Leucorrhinia* larvae in Zdręczno Lake was estimated to be from 12,179 m² (1.2 ha) to 65,969 m² (6.6 ha). Concluding, the total population abundance in the reserve was calculated as 16,198 - 97,739 individuals for *L. caudalis* and 28,255 - 153,048 individuals for *L. pectoralis*." 10467. Watson, G.S.; Watson, J.A.; Hu, S.; Brown, C.L.; Cribb, B.W.; Myhra, S. (2010): Micro and nanostructures found on insect wings – designs for minimising adhesion and friction. *International Journal of Nanomanufacturing* 5(1/2): 112-128. (in English) ["Adhesion and friction have been measured on insect wings where contamination (water and/or contaminating particles) can potentially have a detrimental effect on their flight capabilities or daily functioning. Adhesion forces as low as 2 nN were recorded in air for particles with radii of 10-15 nm, and 20 nN for particles of 31 nm radius. The effective coefficients of friction were in the range of 0.01 to 0.10. The low adhesion and frictional values demonstrate that only very low out-of-plane and in-plane forces are required to

remove contaminants of nanometre and micron dimensions from the cuticle membranes. Many of the surfaces demonstrate superhydrophobic properties and will not only reduce the effects of contact with surfaces but also promote a self-cleaning function for removing foreign bodies. It has also been demonstrated that surface structures and properties can be duplicated on polymer surfaces by using the wing membrane as a 'natural template'. (Authors) *Rhyothemis phyllis chloe* is among the insects studied.] Address: Watson, G.S., School of Pharmacy and Molecular Sciences, James Cook University, Townsville, QLD 4811, Australia

10468. Wellenreuther, M.; Sánchez-Guillén, R.A.; Cordero, A.; Hansson, B. 10477. Acorn, J.H. (2011): Sand hill arthropods in Canadian grasslands. In: *Arthropods of Canadian Grasslands (Volume 2): Inhabitants of a Changing Landscape*. Edited by K. D. Floate. Biological Survey of Canada: 25-43. (in English) ["Sand hill environments in the Canadian grasslands can be classified as sandstone outcrops, upland dunes, sand features associated with water, non-human disturbances, anthropogenic disturbances, beach dunes, or sandbars. Insects and other arthropods use these environments for burrow construction, access to sand-associated host plants, open ground predation and scavenging, thermoregulation, and locomotion in a quiet substrate. The arthropod faunas of sand hills in the Canadian grasslands are diverse, include organisms that are specific to sand hills, and include a number of rare or endemic taxa. Dune stabilization is cause for conservation concern, whereas the threat of global warming may reverse the stabilizing trend and create larger areas of open drifting sand. .. Various Anisoptera are often found perched on open ground, including non-vegetated sand, from which they fly up in pursuit of prey and potential mates (Dunkle 2000). Typical open-ground species include *Ophiogomphus severus* and *Stylurus intricatus*, as well as species in the genus *Sympetrum*. Most other anisopterans prefer to perch in vegetation, as do species of Zygoptera. However, on sand hill sites near water, various damselflies (e.g., *Enallagma* spp., *Coenagrion* spp., *Lestes* spp.) will forage in the relatively open vegetation on and around open sand patches." 10481. Anderson, C.N.; Grether, G.F. (2011): Multiple routes to reduced interspecific territorial fighting in *Hetaerina* damselflies. *Behavioral Ecology* 22(3): 534-534. (in English) ["Interspecific territoriality may be adaptive if territories contain depletable resources that are valuable to both species, but it can also arise as a maladaptive by-product of intraspecific territoriality. In the latter scenario, sympatric species ought to diverge in ways that reduce interspecific fighting. We studied 4 *Hetaerina* damselfly species that can be found in sympatry in North America. Prior work showed that sympatric populations have diverged from each other in wing coloration and competitor recognition in 2 of the 4 sympatric species pairs (*H. titia* / *H. occisa*, *H. titia*/*H. americana*). Here, we show that sympatric populations of these 2 species pairs overlap completely in habitat use, and yet, interspecific territorial fights occur much less frequently than intraspecific fights. Experimentally manipulating the wing coloration of male *H. occisa* and *H. americana* to more closely resemble *H. titia* increased the rate of interspecific fights, which provides direct evidence that divergence in wing coloration is partly responsible for the low rate of interspecific fights. We found that interspecific fighting is also reduced in the other 2 species pairs (*H. occisa* / *H. cruentata*, *H. americana* / *H. cruentata*), even though prior work showed that heterospecific territory intruders are attacked just as aggressively as conspecific territory intruders. In these cases, however, the sympatric species differ sufficiently in habitat use to reduce the interspecific encounter rate and thereby account for the reduced rate of interspecific fighting. Thus, interspecific fighting is reduced relative to intraspecific fighting in all 4 species pairs, albeit through different mechanisms.] Address: Anderson, C.N., Department of Ecology and Evolutionary Biology, University of California, Los Angeles, 621 Charles E. 10482. Andrew, R.J.; Thaokar, N.; Dhamani, A.A. (2011): Oviposition and details of egg shell fine structure in *Ceragrion coromandelianum* (Fabricius) (Zygoptera: Coenagrionidae). *Odonatologica* 40(3): 169-178. (in English) ["In central India, floating leaves of *Nymphaea nouchali* form a perfect site for landing and oviposition for *C. coromandelianum*. Experiments with *N. nouchali* leaves suggest that oviposition occurs preferentially within distinct region of the leaf lamina. Oviposition is maximal in the lateral region of the lamina (LRL) which was the most popular site over the whole period of observation and

least in the petiolar region (PRL) while at the basal and apical regions (BRL & ARL) the total number of oviposition are similar to each other and intermediate between the lateral and petiolar regions. There is a direct correlation between the position of leaf lamina region used for oviposition and the day of oviposition. There is also a direct association between the day of the bouts of oviposition and the position of the leaf lamina region used for oviposition. In *C. coromandelianum*, visual and tactile cues play an important role in leaf lamina preference. It is not the toughness of the leaf lamina (thickness of the epidermis) but its submergence which is an important decisive factor for oviposition. 1 Scanning electron microscopic examination of the egg reveals that it is elongate and cylindrical with a pointed anterior and rounded posterior end. The egg chorion is composed of an outer, thin, lightly corrugated exochorion and an inner, thick, smooth, non-porous endochorion. The anterior end is surrounded by 5 micropylar orifices. Each orifice is semicircular and continues as a long horizontal streak on the endochorion and concludes at a bifid terminal point. This forms the entry point of the micropylar chute which penetrates the endochorion. The vitelline envelope below the endochorion is thin and smooth." 10485. Aweng-Eh, R.; Ismid, S.; Maketab, M. (2011): Effects of land use on benthic macroinvertebrate assemblages at three rivers in Endau catchment area, Kluang, Johor, Malaysia. *Journal of Applied Sciences in Environmental Sanitation* 6(2): 97-103. (in English) ["Study was conducted for six times from November 2008 to June 2010 to determine the effect of land use on benthic macroinvertebrate assemblages in Mengkibol, Madek and Dengar rivers. Eight stations were selected which two stations from each river except Dengar which has two sampling reach comprised of four stations. A 500 meter reach of the stream was selected for each sampling site. One sampling reach comprises of two sampling stations where one station is located at the upper reach, while the other station is situated at the lower reach. Surber Net measuring 500 micron mesh size combined with a rectangular quadrat of 30 cm x 30 cm (0.09 m²) was used to

sample macroinvertebrates. The results showed that undisturbed river has complete sensitive taxa namely Ephemeroptera, Plecoptera and Trichoptera (EPT). Meanwhile, there were only two sensitive taxa namely Ephemeroptera and Trichoptera were found in the river which flows through palm oil plantation. Similar scenario was found in the river which flows through logging area where there were also two sensitive taxa namely Ephemeroptera and Trichoptera found in this river. In addition, the results obtained for urban river was the other way round where there was an absent of all three sensitive taxa (EPT) in the river which flows through urban area. Most of the macroinvertebrate taxa that were found in this station are pollution resistant taxa comprised Diptera, Odonata, Mesogastropoda, Basommatophora, Hirudinea and Haptotaxida. The results can be use as a biological indicator for river water quality assessment." (Authors) Records of Odonata are as follows: Forest (Un-disturbed): none; Agriculture (Palm Oil): "Arigomphus, Hagenius, Dromogomphus, Gomphaeschna, Somatochlora"; Logging: Arigomphus, Dromogomphus; Urban (Kluang Town): Ophiogomphus, Helocordulia. - 10490.** Beganyi, S.R.; Batzer, D.P. (2011): Wildfire induced changes in aquatic invertebrate communities and mercury bioaccumulation in the Okefenokee Swamp. *Hydrobiologia* 669(1): 237-247. (in English) ["Fire is an important natural disturbance in the Okefenokee Swamp. From April–June 2007, wildfire burned 75% of the wetland area. With the existence of extensive pre-fire data sets on community structure and total mercury of invertebrates, the fire presented an opportunity to assess impacts of wildfire on invertebrates. Post-fire collection of samples occurred in September, December, and May, 2007–2009. Sample sites included 13 burned and 8 non-burned (reference) sites. Comparisons of data among pre-fire, post-fire reference, and post-fire burned sites revealed that the major difference between pre-fire communities and post-fire communities was a decrease in the number of water mites. We also found a decrease in mercury concentrations in amphipods, odonates, and crayfish post-fire. The differences between pre-fire and post-fire samples may be confounded by drought conditions during the baseline study. NMDS ordinations and ANOSIM tests suggested that habitat was an important factor; communities in burned cypress differed from reference cypress. Unexpectedly, burned sites had lower mercury concentrations in odonates and crayfish, with variation again being greatest in cypress stands. These findings and others suggest mercury levels do not follow a predictable pattern but can vary with pre-fire concentrations, variation in water levels, and burn intensity. We found that wildfire in the Okefenokee had little impact on invertebrates in prairies and scrub-shrub thickets, but can affect indicator organisms (Oecetis, Ischnura, and Sigara) in cypress stands. Our study suggests that vegetation type and burn intensity may have impacts on the invertebrate communities and mercury concentrations of organisms." - 10496.** Bouton, N.; Iserbyt, A.; van Gossum, H. (2011): Thermal plasticity in life-history traits in the polymorphic blue-tailed damselfly, *Ischnura elegans*: No differences between female morphs. *Journal of Insect Science* 11 (112): 11 pp. (in English) ["Female polymorphism is observed in various animal species, but is particularly common in damselflies. The maintenance of this polymorphism has traditionally been explained from frequency and density dependent sexual conflict, however, the role of abiotic factors has recently attracted more interest. Here, the role of ambient temperature in shaping life-history was investigated for the three female morphs of *I. elegans*. Eggs were obtained from the three mature female morphs for two populations in the Netherlands. Using a split-brood design, eggs of both populations were divided between a cold and a warm treatment group in the laboratory, and egg survival and hatching time were measured. Significant thermal plasticity was found in both hatching time and egg survival between both temperature treatments. However, individuals born to mothers belonging to different colour morphs did not differ in their response to temperature treatment. Independent of colour morph, clear differences in both life-history traits between the populations were found, suggesting local adaptation. Specifically, individuals from one population hatched faster but had lower egg survival in both thermal regimes. The selection force establishing fast hatching could be (facultative) bivoltinism in one of the populations compared to univoltinism in the other. This would be in line with the more southern (and more coastal) location of the presumed bivoltine population and the inverse relation between voltinism and latitude known from earlier studies. However, other natural selection forces, e.g. deterioration of the aquatic habitat, may also drive fast hatching." 10497. Brasil, M.A.; Freitas Horta, G. de.; Fraxe Neto, H.J.; Barros, T.O.; Colli, G.R. (2011): Feeding ecology of *Acanthochelys spixii* (Testudines, Chelidae) in the Cerrado of Central Brazil. *Chelonian Conservation and Biology* 10(1): 91-101. ["We studied the diet of *Acanthochelys spixii* in a wild population in the Cerrado of central Brazil for 19 months, investigating ontogenetic, sexual, and inter-individual variation. The diet consisted mainly of nymphs of Odonata, although other insects, amphibians, and plant material were also present. We observed no ontogenetic shifts in diet composition (e.g., no shift from carnivorous juveniles to herbivorous adults), which can be related to the high abundance of prey at the study site. There was no association between prey size and turtle carapace length, with larger animals still taking small prey. Dietary niche overlap was high, and there was no difference in niche breadth between sexes. However, differences in diet composition suggested differential habitat use, with males using more the periphery and females using more the center of ponds. Diet composition varied more among males than among females, which can result from higher diversity of prey at the pond margins, higher movement rates, or larger home range of males. The high frequency of empty stomachs (41%) reflected life-history characteristics of turtles (e.g., low metabolism, ectothermy, late sexual maturity, and great longevity). The importance of prey categories sensitive to pollution in the diet of *A. spixii* highlights the integrity of the study sites and the vulnerability of these populations to the rapid degradation of Cerrado biome." (2011): Insects associated to *Alpinia purpurata* (Vieill.) K. Schum. (Zingiberaceae) in Maceió and Rio Largo, AL, Brazil. *Revista Caatinga* 24(1): 1-8. (in Portuguese, with English summary) ["Due the fast growing in flowers and ornamental plants production and their high export potential, it is important to identify the insects species associated with *Alpinia purpurata* (Vieill.) K. Schum crops and to establish their role in this agroecosystem/production system The insects were collected from *A. purpurata* cv. Pink Ginger and Red Ginger plants cultivated in two farms with different agroecological characteristics, located in two recognized tropical flower production areas/regions, Maceió and Rio Largo cities/localities, Alagoas state, during one year. They were identified and its frequency analyzed according with a numerical scale. According to the results was collected 790 insects of which 69 were identified to specific level, belonging to 59 families of 9 ordens. Results showed Hymenoptera individuals as the most frequent, mainly predator ants and/or associated with phytophagous insects (sucking), besides natural enemies, followed by Hemiptera and Lepidoptera orders, which involved recognized agricultural pests. Insects belonging to the order Odonata ("Coenagrionidae, Libellulidae") and Orthoptera were found less frequently." 10499. Broyer, J.; Curtet, L. (2011): The influence of fish farming intensification on taxonomic richness and biomass density of macrophyte-dwelling invertebrates in French fishponds. *Knowledge and Management of Aquatic Eco-*

systems (2011) 400, 10: 12 pp. (in English, with French summary) ["Fishponds are man-made ecosystems where fish farming may strongly interfere with biodiversity. Intensified practices could be suspected to have a negative impact on animal and plant communities. We investigated the hypothesis that, in French fishponds, taxonomic richness and biomass density of macrophyte-dwelling macro-invertebrates could be influenced by fish stock density and pond fertilization. With a sample of 95 water bodies from three of the most important fishpond regions, studied in 2000, 2001 or 2002, we compared a series of models in which macrophyte cover (in three classes), emergent shore vegetation (in % of pond area) and invertebrate biomass in pond sediment were also considered. Among explanatory variables, macrophyte and helophyte abundance were included in the best models explaining variation in invertebrate taxonomic richness and in biomass density. Taxonomic richness was lower when abundance of both macrophytes and emergent shore vegetation was low (< 10% and < 7.5%, respectively). Biomass density was higher when macrophyte cover was >= 10% provided that emergent vegetation was abundant (>=7.5%). We conclude that fish farming intensification in French fishponds may affect aquatic invertebrate communities, mainly through its impact on the development of aquatic vegetation." (Authors) Odonata are treated at the family level.] Address: Broyer, Joel, Office National de la Chasse et de la Faune Sauvage, Direction des études et de la recherche, 01330 Birieux, France. 10504. Chetelat, J.; Amyot, M.; Garcia, E. (2011): Habitat-specific bioaccumulation of methylmercury in invertebrates of small mid-latitude lakes in North America. *Environmental Pollution* 159(1): 10-17. (in English) ["We examined habitat-specific bioaccumulation of methylmercury (MeHg) in aquatic food webs by comparing concentrations in pelagic zooplankton to those in littoral macroinvertebrates from 52 midlatitude lakes in North America. Invertebrate MeHg concentrations were primarily correlated with water pH, and after controlling for this influence, pelagic zooplankton had significantly higher MeHg concentrations than littoral primary consumers but lower MeHg than littoral secondary consumers. Littoral primary consumers and pelagic zooplankton are two dominant prey for fish, and greater MeHg in zooplankton is likely sufficient to increase bioaccumulation in pelagic feeders. Intensive sampling of 8 lakes indicated that habitat-specific bioaccumulation in invertebrates (of similar trophic level) may result from spatial variation in aqueous MeHg concentration or from more efficient uptake of aqueous MeHg into the pelagic food web. Our findings demonstrate that littoralepelagic differences in MeHg bioaccumulation are widespread in small mid-latitude lakes." (Authors) Greater MeHg in Odonata compared to all other invertebrates was probably due to their higher trophic

level.] Address: Chételat, J. Groupe de recherche interuniversitaire en limnologie, Département de sciences biologiques, Université de Montréal, Montréal, Québec H3C 3J7, Canada

10505. Cicek, K. (2011): Food composition of Uludag frog, *Rana macrocnemis* Boulenger, 1885 in Uludag (Bursa, Turkey). *Acta Herpetologica* 6(1): 87-99. (in English) ["Feeding habit and food preferences of *R. macrocnemis* were studied in 2006 and 2007 in Uludag (Bursa, Turkey). Stomach contents of 165 (87 males, 58 females, 20 juveniles) individuals were analyzed and a total of 2,129 prey items were determined. It was found that the species fed mainly on a variety of invertebrates and especially on insects (96.5%). The most frequently consumed prey items were Coleoptera (62.8%), Diptera (14.4%), and Hymenoptera (9.8%). There was no significant sex- and age-dependent difference in the feeding regime. It appears that the species is feeding less in the breeding period and more in the post-breeding period. It was also evident that there was an increase in the consumption of Coleoptera depending on the elevation." (Author) Odonata contributed with ca 8% to the insect diet.] Address: Çiçek, K., Ege University, Faculty of Science, Biology Department, Zoology Section, 35100, Bornova, Izmir, Turkey. 10506. Conn, A.T.; Ling, C.S.; Burgess, S.C. (2011): Biomimetic Analysis of Insect Wing Kinematics for Flapping MAVs. *International Journal of Micro Air Vehicles* 3(1): 1-11. (in English) ["Despite significant interest for over a decade in developing micro air vehicles (MAVs) that mimic the flight performance exhibited by insects, no design has achieved this challenge. This has principally been due to limitations in actuation devices, which have resulted in constrained flapping motions that require conventional rudder and aileron control surfaces. Recent advances in "artificial muscle" actuation technologies mean that reproducing the complex wing kinematics of insects with sufficient power density for MAV flight has become feasible. Consequently, there is a need to analyse the wing kinematics of insects and how they are modulated for controlled, manoeuvrable flight. It is also important to understand how wing kinematics affect the unsteady aerodynamic mechanisms that crucially augment lift and thrust force production. In this paper a biomimetic analysis of insect wing kinematics based on established biological literature is presented, that aims to aid the development of agile and controllable flapping MAVs." (Authors) References to Odonata are made] Address: Conn, A.T., Dept of Mechanical Engineering, Univ of Bristol, Bristol, U.K.

10507. Conniff, K.L.; van der Poorten, N.E.; Gunasingha, S. 10508. Contreras-Garduno, J.; Cordoba-Aguilar, A.; Martinez-Becerril, R.I. (2011): The relationship between male wing pigmentation and condition in *Erythrodiplax funerea* (Hagen) (Anisoptera: Libellulidae). *Odonatologica* 40(2):

89-94. (in English) ["Theory predicts that sexual traits ought to be related to physiological indicators of condition. In Zygoptera, for example, wing pigmentation expression (i.e. a sexual trait) correlates positively with male immune response, fat reserves and muscle mass. Here, it is for the first time investigated for anisopteran, whether such relationships hold in male *E. funerea*. Males in territorial activity, were collected and challenged to induce a melanization-based immune response. Male wing pigmentation was then correlated with melanin, fat reserves and muscle mass. Unlike previous results in Zygoptera, pigmentation was negatively related with immune response but no significant relation was found with fat and muscle mass. Furthermore, immune response showed no relationship with fat content or muscle mass. Possibly, the extremely high levels of male aggression observed in this species may have caused males to make an unusually high allocation of resources to wing pigmentation which may have impaired immune response." 10510. Corbi, J.J.; Froehlich, C.G.; Trivinho Strixino, S.; dos Santos, A. (2011): Evaluating the use of predatory insects as bioindicators of metals contamination due to sugarcane cultivation in neotropical streams. Environ Monit. Assess. 177(1-4): 545-554. (in English) ["Streams located in areas of sugarcane cultivation receive high concentrations of metal ions from soils of the adjacent areas causing accumulation of metals in the aquatic sediment. This impact results in environmental problems and leads to bioaccumulation of metal ions in aquatic organisms. In the present study, metal concentrations in different predatory insects were studied in streams near sugarcane cultivation and compared to reference sites. Possible utilisation of predatory insects as bioindicators of metal contamination due to sugarcane cultivation from 13 neotropical streams was evaluated. Ion concentrations of Al, Cd, Cr, Cu, Zn, Fe, and Mn in adult Belostomatidae (Hemiptera) and in larvae of Libellulidae (Odonata) were analysed. Nine streams are located in areas with sugarcane cultivation, without riparian vegetation (classified as impacted area) and four streams were located in forested areas (reference sites). Metal concentrations in insects were higher near sugarcane cultivations than in control sites. Cluster analysis, complemented by an ANOSIM test, clearly showed that these insect groups are good potential bioindicators of metal contamination in streams located in areas with sugarcane cultivation and can be

used in monitoring programmes. We also conclude that Libellulidae appeared to accumulate higher concentrations of metals than Belostomatidae." (Authors)] Address: Corbi, J.J., Depto de Biologia, Faculdade de Filosofia Ciências e Letras, Universidade de São Paulo-USP, CEP: 14040-900, Ribeirão Preto, SP, Brazil, julianocorbi@yahoo.com.br

(in Dutch, with English summary) ["During a first visit to the nature reserve De Weerribben (Overijssel, the Netherlands) on 9 May 2009, a female *B. pratense* was observed during a successful kill. Its prey turned out to be a *L. quadrimaculata* which was caught in flight. After having eaten the eyes and weak parts of the head, the female *B. pratense*

flew off. A second visit to the same locality on 20 May 2011 resulted in the observation of a male *B. pratense* which caught a *C. aenea*. Some time later a second male was seen attacking another *C. aenea*. The thorax of the latter was partly eaten by *B. pratense*. After one minute the male *Brachytron* flew away, leaving behind the still living male of *C. aenea*. To our knowledge, these are the first published reports of hunting behaviour by *B. pratense* on other dragonflies." (Authors)] Address: Muusse, T., Billitonstraat 19, 3312SB Dordrecht, The Netherlands. E-mail: theomuusse@chello.nl

10515. Demayo, C.G.; Harun, S.A.; Torres, M.A.J. (2011): Procrustes analysis of wing shape divergence among sibling species of *Neurothemis* dragonflies. *Australian Journal of Basic and Applied Sciences* 5(6): 748-759. (in English) ["This study was conducted to determine wing shape divergence in several species of *Neurothemis* dragonflies collected from Northern Mindanao, Philippines. These includes the species *N. terminata terminata* (Ris, 1911), *N. fluctuans* (Fabricius, 1793), *N. ramburii ramburii* (Kaup & Brauer, 1866). The identification of these species are sometimes difficult as the males of these species have similarities in their colored wings ranging from red to brown. For the females, *N. terminata terminata* also show extensive female-limited polymorphism expressed as intra-specific color variations. Since the quantitative description, analysis and interpretation of shape and shape variation in biology have become a fundamental area of research; the geometric method of morphometrics was used in this study aimed at comparing the shapes themselves. In this methodology, the generalized least square fitting analysis done via procrustes superimposition of landmarks from the fore- and hind wings was used. The landmark data were converted to shape residuals via Procrustes-fitting and is comprised of three steps: (1) translation to a common centroid, (2) rotation to a common centroid size and (3) rotation to minimize sum of squared differences between landmark sets. To illustrate ordination of the shapes' consensus, the consensus shape data (mean shape) of the separate populations was measured by a relative warp ordinations plot using tpsRelw 1.36. Results of the relative warp analysis showed significant variation among the *Neurothemis* species. The first extracted relative warp showed differences in the shape of the pterostigma and disparity in the distance between the distal end of the radial planate supplement and the distal margin of the wings bounded by the end points of the intercalary vein and the radial branch. Differences in the shape of the pterostigma were also observed and accounting for the variations in the shapes of the hind wing. Distance matrices were also constructed for the four data sets: left and right fore-wing; left and right hind wing. Results of the comparison via correlation analyses of the four matrices of distances among the species are indicative of the significant contribution of the shape of the fore-wing as compared to the hind wing in discriminating among species. The results of the present study clearly show the importance of geometric morphometric analysis and the utility of wing morphology in the taxonomy and discrimination of sibling species of *Neurothemis*." (Authors) Reagan Villanueva wrote on 02.08. 2011: The species they labelled as *N. fluctuans* is actually a small *N. ramburii*.] Address: Demayo, C.G., Dept of Biological Sciences, College of Science and Mathematics, MSU-Iligan Institute of Technology, Iligan City, Philippines. 10517. Dominguez-Granda, L.; Lock, K.; Goethals, P.L.M. (2011): Application of classification trees to determine biological and chemical indicators for river assessment: case study in the Chaguana watershed (Ecuador). *Journal of Hydroinformatics* 13(3): 489-499. (in English) ["Benthic macroinvertebrates were sampled in the Chaguana river basin in SW Ecuador in March (wet season) and September (dry season) of 2005 and 2006. Aquatic insects dominated the macrobenthos, with Trichoptera, Diptera, Ephemeroptera, Hemiptera and Odonata being the orders with the highest diversity and Ephemeroptera and Diptera being most abundant. No systematic differences in richness and abundance were observed between dry and wet seasons, which is in agreement with the literature. It is concluded that, in the neotropics, macroinvertebrates can probably be sampled for water quality assessments during the whole year: however, sampling soon after spates should be avoided. Using multivariate analysis, stations could be clustered into three groups based on their macroinvertebrate community composition: sites with low, intermediate and high human impact. Classification trees indicated that stations with low human impact had low conductivities, while stations with high conductivities were characterised as highly impacted if the dissolved oxygen concentration was low and intermediately impacted if the dissolved oxygen concentration was high. Classification trees also indicated that Leptophlebiidae (Ephemeroptera) were characteristic for sites with low impact; in sites with intermediate impact, this family was absent but Hydropsychidae (Trichoptera) were present; when both families were absent, impact was high." 10522. Ferraz Luiz, T.; Roquetti Velludo, M.; Carvalho Peret, A.; Luiz Rodrigues, J.; Moldenhauer Peret, A. (2011): Diet, reproduction and population structure of the introduced Amazonian fish *Cichla piquiti* (Perciformes: Cichlidae) in the Cachoeira Dourada reservoir (Paranaíba River, central Brazil). *Rev. Biol. Trop.* 59(2): 727-741. (in English) ["The Blue Peacock Bass (*Cichla piquiti*), native to the Tocantins-Araguaia river basin of the Amazon system, was introduced into the basin of the Paranaíba River, Paraná River system. Cachoeira Dourada reservoir is one of a series of dams on the Paranaíba River in central Brazil, where this fish has become established. A study of its feeding spectrum, combined with information about its reproductive characteristics and population structure, would enable the current state of this species in the reservoir to be assessed and might provide useful data for the management of other species native to this habitat. This study showed that the peacock bass has no predators or natural competitors in the reservoir and that

reproduces continuously, with high reproductive rates, and has a smaller median length at first maturity (L50) than other species of *Cichla*. Its successful establishment in habitats strongly affected by human activity should cause changes in the whole structure of the local fish communities. Nonetheless, in this reservoir, there appears to be some sharing of the functions of this species with native carnivorous fish, a situation that may be sustained by the presence of a wide variety of foraging fish." (Authors) Odonata were found in 0,81% of the stomachs of *C. piquiti*.] Address: Ferraz Luiz, Tatiane, Population Dynamics Laboratory, Department of Hydrobiology, Federal University of São Carlos (UFSCar) Washington Luís Highway (SP-310), km 235. 10523. Fulan, J.A.; Raimundo, R.; Figueiredo, D.; Correia, M. (2011): Abundance and diversity of dragonflies four years after the construction of a reservoir. *Limnetica* 29(2): 279-286. (in English, with Portuguese summary) [Southern Portugal, 38°08'N, 7°35'E. "Few studies have investigated the impacts of river impoundments on reservoir constructions. Reservoir construction deeply changes dragonflies' habitat structures, especially in relation to shoreline vegetation. This study investigated the effects of the impoundment of the Guadiana River and its tributaries on dragonflies four years after the construction of a reservoir. A total of 17 dragonfly species (11 Zygoptera and ten Anisoptera), representing six families, were recorded in 21 sites in the years 1999 and 2003. *Aeshna mixta*, *Coenagrion caeruleum*, *C. scitulum*, *Sympetrum foscolum*, *S. meridionale* and *S. striolatum* were sampled just before the impoundment took place, and *Anax parthenope*, *Onychogomphus forcipatus*, *Orthetrum coerulescens*, *Trithemis annulata*, *Platycnemis acutipennis* and *P. latipes* were recorded only after the construction of the reservoir. We concluded that the construction of the Alqueva Reservoir four years earlier did not change the dragonfly species richness, possibly because of species overlap, but that the species composition was modified. Changes in marginal vegetation may have been important to new species compositions." (Authors)] Address: Fulan, J.A., Unive Federal do Amazonas (UFAM). CEP: 69800-000, Humaitá, AM, Brasil. (2011): A profundidade como fator determinante na variação anual da densidade dos macroinvertebrados associados à *Salvinia auriculata* Aublet. *Revista Brasileira de Biociências* 9(2): 214-219. (in Portuguese, with English summary) ["(The depth as a factor in determining annual change density of macroinvertebrates associated with *Salvinia auriculata* Aublet). The aim of this work was to study the effects of water annual variation of Paranapanema River and others variables on macroinvertebrates that lives in macrophytes roots, from March 2006 to February 2007. The sampled was realized with a hand-net (mesh size: 0.25 mm) and 0.07 m² circle area. We measured air and water temperature, depth, dissolved oxygen, pH, K25 and suspended matter. The normality was tested and a Canonical Correspondence Analysis (CCA) was realized. Telebasis showed high density in period studied. There was a high variation in depth: 6.07 m in April 2006 to 1.83 m in November 2007. The CCA showed that Culicidae, Ephemeroptera, Ostracoda, Calopterygidae, Coryphaeschna and Cyanallagma were significative correlated with the depth. We concluded that the effect of the depth on larvae Odonata can not have been direct, but indirect by the effect in your substrate as aquatic plant." (Au-

thors)] Address: Fulan, J.A., Universidade Federal do Amazonas (UFAM). CEP: 69800-000, Humaitá, AM, Brasil. E-mail: joaofulan@ig.com.br

(2011): Survival and growth of the caddisfly *Limnephilus flavastellus* after predation on toxic eggs of the Rough-skinned Newt (*Taricha granulosa*). *Can. J. Zool.* 89: 483-489. (in English) ["*T. granulosa* possesses a powerful neurotoxin, tetrodotoxin, in the skin that is secondarily deposited in the ova. Although assumed to serve an antipredator function in the eggs, empirical evidence of the toxin's role in preventing egg predation is lacking. In this study, we characterized the aquatic macroinvertebrate community at a location sympatric with extremely toxic newts and estimated the abundance of caddisflies. We tested aquatic macroinvertebrates sympatric with toxic newts for their capacity to consume the toxic eggs, and examined the propensity of egg predation and its effect on growth of the only known predator of newt eggs, caddisfly larvae. Limnephilid caddisfly larvae were the only invertebrate observed to consume substantial quantities of toxic newt eggs. Survival and growth of *L. flavastellus* continued when larvae consumed toxic eggs and did not differ from *L. flavastellus* that also had access to an alternative food source (detritus). *L. flavastellus* that had access to eggs + detritus consumed a similar number of eggs compared with those provided with eggs only. These results, combined with the abundance of caddisflies, suggest that caddisflies are important predators of eggs of *T. granulosa*." (Authors) Macroinvertebrates collected at Soap Creek ponds and tested for their propensity to consume toxic eggs of *T. granulosa* included Odonata. Eggs were offered to Libellulidae (n specimens=11), Aeshnidae (n=1) and Coenagrionidae (n=6). In any case the offered eggs were consumed.] Address: Gall, B.G., Dept of Biology, Utah State University, 5305 Old Main Hill, Logan, UT 84322, USA. E-mail: brian.gall@usu.edu

(2011): Identification of realistic worst case aquatic macroinvertebrate species for prospective risk assessment using the trait concept. *Environmental Science and Pollution Research* 18(8): 1316-1323. ["Approaches in environmental risk assessment for pesticides are becoming more and more realistic. Thereby, risk assessment has to be protective in a way that no long-lasting (adverse) effects on populations will occur in the environment. Since this imperative includes species generally showing high population vulnerability due to their life history traits, prospective risk assessment should be based on realistic worst cases. Based on life history traits, the purpose of the current study was to verify whether a worst case combination of low potential for intrinsic recovery and low ability for recolonisation can be found in the field. Methods: Combinations of traits related to dispersal ability and reproduction of macroinvertebrates were investigated using monitoring data from edge of field water bodies in Germany. The relative distribution of traits was analyzed across different agricultural regions and across sites of different potential for exposure to pesticides. Species were sorted in a tiered approach in order to gain a list of realistic worst case species. Results: Life history traits were found equally distributed across different regions. Thereby, dispersal ability and voltinism were not randomly combined. Within the data analysed, low dispersal ability was found to be exclusive to semivoltine taxa. Owing to their appearance in reference sites, poor dispersal ability and a long time reproduction, three species were considered potentially worst case. Conclusions: The trait approach was found to be suitable in comparing trait distributions within different regions and in compiling a list of critical taxa for consideration in environmental risk assessment." (Authors) The paper includes a few passing notes on voltinism and dispersal of Odonata.] Address: Gergs, A., Institute for Environmental Research, RWTH Aachen University, Aachen. Germany. (2011): Infection effects on feeding and territorial behaviour in a predatory insect in the wild. *Animal Behaviour* 81(6): 1185-1194. (in English) ["Sick animals may change their feeding behaviour to compensate for infections. However, there is little information regarding whether infection affects (1) feeding behaviour of predators, (2) feeding behaviour using an experimental approach in the wild, (3) other costly behaviours and/or (4) physiological components of condition. We experimentally infected males of the predatory damselfly *Hetaerina americana* in a field experiment. We hypothesized that infection would reduce feeding behaviour. We further predicted a reduction in territorial activity, an increase in immune response (measured by the activity of phenoloxidase, PO) and a reduction of fat reserves and flight-associated muscle mass (two traits usually traded off with immune ability and territorial behaviour). We also infected males in a laboratory experiment that controlled for food supply and territorial activity, and measured the same physiological characters. Immune challenges in the field experiment unexpectedly increased feeding rate but did not change territorial activities. Muscle mass was reduced in the field but not in the laboratory, probably because of differences in the presence of energetically expensive territorial activities. In the laboratory, starvation and infection reduced PO activity and fat stores but did not affect muscle mass. Thus, our field and laboratory results support the idea that increased feeding compensates for infections in predators." (2011): Range limits, large-scale biogeographic variation, and localized evolutionary dynamics in a polymorphic damselfly. *Biological Journal of the Linnean Society* 102: 775-785. (in English) ["Studies of heritable colour polymorphisms allow investigators to track the genetic dynamics of natural populations. By comparing polymorphic populations over large geographic areas and across generations, issues about both morph stability and evolutionary dynamics can be addressed, increasing our understanding of the potential mechanisms maintaining genetic polymorphisms. In the present study, we investigated population morph frequencies in a sex-limited heritable colour polymorphic damselfly (*Ischnura elegans*), with three discrete female morphs. We compared the frequencies of these three female morphs in 120 different populations from ten European countries at differing latitudes and longitudes. There were pronounced differences in morph frequencies both across the entire European biogeographic range, as well as at a smaller scale within regions. We also found considerable between-population variation at the local scale within regions, particularly at the edges of the range of this species. We discuss these findings in the context of recent models of adaptive population divergence along the range of a species. This polymorphism is thus highly dynamic, with stable morph frequencies at the core of the species range but fluctuating morph dynamics at the range limits. We finish with a discussion of how local interactions and climatic factors can be expected to have a strong influence on the biogeographic patterns in this species and other sexually se-

lected polymorphisms." (Authors)] Address: Gosden, T.P., School of Biological Sciences, Univ. of Queensland, St Lucia 4072 QLD, Australia. E-mail: t.gosden@uq.edu.au

10533. Grant, P.B.C.; Samways, M.J. (2011): Micro-hotspot determination and buffer zone value for Odonata in a globally significant biosphere reserve. *Biological Conservation* 144(2): 772-781. (in English) ["Reserves are frequently constrained in design and size by various financial, social or political factors. Maintenance of existing reserves must therefore rely on strategic management practices, and prioritization of conservation activities within them. Identification of global and regional hotspots have been effective for prioritizing conservation activities. Yet, identification of micro-hotspots, or overlapping areas of endemic and rare species that are under threat at the landscape scale, have largely been ignored. From a reserve management point of view, knowledge of critical micro-hotspots within a reserve, are focal points for directing cost effective, conservation initiatives, especially removal of invasive alien plants which are a major threat to biodiversity. Using diversity patterns of dragonfly assemblages, many endemic and threatened, within a biosphere reserve located in the core of a global biodiversity hotspot, we investigated the concept of micro-hotspots. As biosphere reserves contain zones with varying degrees of anthropogenic impact, we also investigated the value of buffer and transition zones for complementing the dragonfly fauna of the reserve core. We found a distinct micro-hotspot within the protected core zone which shows concordance for both endemism and species richness. We conclude that focused conservation actions to remove invasive alien plants within this micro-hotspot would help insure its continued integrity. Furthermore, while there is greater habitat degradation within the buffer and transition zones, they support many additional species, but not those necessarily endemic or threatened. The complementary value of buffer and transition zones therefore lies in increasing habitat heterogeneity and species richness of the whole reserve." 61-71. (in English) ["Perceived growth in the adventure recreation sport of canyoning in the Greater Blue Mountains World Heritage Area (Australia) has raised concerns with park management that such activity is resulting in unsustainable visitor impacts to canyon ecosystems. Three levels of trampling intensity were applied within an upland section of a canyon stream to assess the impact of trampling on benthic macroinvertebrate communities. After an initial detrimental effect from trampling, there was a rapid recovery of the macroinvertebrate community. Recovery occurred within one day of trampling ceasing, and overall community composition was similar among treatments after 15 days. However, by day 15 the untrampled sites showed a substantial decrease in animal abundance. This indicated that adjacent habitat contributed greatly to the recolonisation of animals into trampled areas." 10536. Haritonov, A.; Popova, O. (2011): Spatial displacement of Odonata in south-west Siberia. *International Journal of Odonatology* 14(1): 1-10. (in English) ["A brief account is presented of mass dragonfly migrations observed previously in Russia and West Siberia in particular. A mass migration in *Libellula quadrimaculata* is described in detail. It occurred on 1 July 1981 in the south-western part of the West Siberian Plain in the valley of the Ishym River. From 1968 to 2008 we studied population dynamics, spatial distribution and displacement in dragonflies in the West Siberian forest-steppe. Detailed research was conducted at the biological station of the Russian Academy of Sciences near the Chany Lake. Mass migrations in *L. quadrimaculata* and some *Leucorhinia* spp. followed situations with an extremely high population density and local mass aggregations and occurred with a period of c.10 years, correlated with fluctuation of water level in the region, mainly in the south. It is suggested that dragonfly migration not only optimizes their population size but increases the rate of transport of chemical elements and organic matter to dry land from eutrophic water bodies, which increases the importance of dragonflies to ecosystems at large." (Authors)] Address: Haritonov, A.YU.; Laboratory of Insect Ecology, Biological Institute of the Siberian Branch of the Academy of Sciences, Frunze str. 11, RUS-630091 Novosibirsk, Russia. 10537. Haritonov, A.Yu.; Popova, O.N. (2011): [Dragonfly (Odonata) migration in the south west Siberian plain]. *Zoologicheskii zhurnal* 90(3): 302-310. (in Russian) ["Brief information on mass dragonfly migrations observed previously in Russia, and in Western Siberia in particular, is presented. From 1969 to 2009, the authors studied the dynamics of dragonfly population, their spatial distribution and displacements in the West-Siberian forest-steppe. The main studies were conducted in the Chany Lake basin (the Biological Station of the Institute of Animal Systematics and Ecology, Siberian Division, Russian Academy of Sciences). The spatial redistribution of dragonflies is regarded as a balance of homing and wandering activities. Homing results in a relative stability of local dragonfly populations and communities. Wandering is a result of dispersal of dragonflies from their emergence sites and colonization of new habitats that is especially important due to the short time of existing the larval biotopes - shallow water bodies. The formation of more or less constant

migration routes is a peculiar variant of wandering activities. Mass exodus from native habitats at excessive growth of the population density takes special place in dragonfly migrations. Exodus flight leads to death of all or most individuals not only. In addition, it optimizes not only the number of dragonfly populations, but also intensifies the removal of chemical elements and organic matter from eutrophic water bodies. An original generalized classification of special displacement of dragonflies is proposed." (Authors)] Address: Haritonov, A.YU.; Laboratory of Insect Ecology, Biological Institute of the Siberian Branch of the Academy of Sciences, Frunze str. 11, RUS-630091 Novosibirsk, Russia. 10538. Hasumi, M.; Hongorzul, T.; Terbish, K. (2011): Animal species diversity at a land-water ecotone in Mongolia. *Limnology* 12(1): 37-45. (in English) [The biodiversity of wetland ecosystems has received scant attention in Mongolia. We measured amphibian and macroinvertebrate species diversity at a complicated land-water ecotone of a pond within a wetland complex in Shaamar during July 2005. From our study area (0.5-ha grassland and an adjacent pond), we sampled 4,926 animals including 1 mammal, 4 amphibian, and 26 aquatic macroinvertebrate (>2 mm) species with a biomass of 4,444 g. Among these, a backswimmer (*Notonectidae* sp. 1) was a dominant species, representing 65% of the total number of animals collected (3,209) and 22% of the mass (999 g). Our study area was small but contained 4 amphibian species (*Hyla japonica*, *Rana amurensis*, *Bufo raddei*, and *Salamandrella keyserlingii*) in a mixed community with Shannon Diversity Index (H') of 1.678 and Pielou's Evenness Index (J') of 1.211. No larvae or tadpoles of any amphibian species were found in the pond, indicating their early metamorphosis. H' and J' with 26 macroinvertebrate species were estimated to be 1.828 and 0.561, respectively. This suggests that low macroinvertebrate species diversity relative to high species richness is due to low evenness resulting from considerable numbers of a backswimmer. In 6 sites sampled in the pond, mean water pH revealed high alkalinity (range 9.01–10.45). The presence of our taxa in a highly alkaline environment indicates that they may be alkaliphilic." (Authors) The paper includes records of "Aeshnidae sp., Libellulidae sp. 1, Libellulidae sp. 2, *Cercion* sp.".] Address: Hasumi, M., Biological Institute, Faculty of Science, Niigata University, Niigata 950-2181, Japan. 10539. Henry, J.R. (2011): A comparative study of dragonfly flight in variable oxygen atmospheres. M.Sc. thesis, Arizona State University: V + 39 pp. ["One hypothesis for the small size of insects relative to vertebrates, and the existence of giant fossil insects, is that atmospheric oxygen levels have constrained body sizes because oxygen delivery would be unable to match the needs of metabolically active tissues in larger insects. This study tested whether oxygen delivery becomes more challenging for larger insects by measuring the oxygen-sensitivity of flight metabolic rates and behaviour during hovering for 11 different species of dragonflies that range in mass by an order of magnitude (*Aeshna multicolor*, *Anax junius*, *Libellula comanche*, *L. luctuosa*, *L. saturata*, *Macrodiplox balteata*, *Pachydiplax longipennis*, *Pantala flavescens*, *P. hymenaea*, *Tramea lacerata*, *T. onusta*). Animals were flown in 7 different oxygen concentrations ranging from 30% to 2.5% to assess the sensitivity of their behaviour and flight metabolic rates to oxygen. I also assessed the oxygen-sensitivity of flight in low-density air (nitrogen re-

placed with helium), to increase the metabolic demands of hovering flight. Lowered atmosphere densities did induce higher metabolic rates. Flight behaviours but not flight metabolic rates were highly oxygen-sensitive. A significant interaction between oxygen and mass was found for total flight time, with larger dragonflies varying flight time more in response to atmospheric oxygen. This study provides some support for the hypothesis that larger insects are more challenged in oxygen delivery, as predicted by the oxygen limitation hypothesis for insect gigantism in the Paleozoic." 10541. Honkanen, M. (2011): Perspectives on variation in species richness: area, energy and habitat heterogeneity. *Jyväskylä Studies in Biological and Environmental Science* 219: 46 pp. (in English) ["Species richness (i.e. number of species) tends to differ from one area to another. Two major patterns observed in the nature are 1) species-area relationship which states that larger areas contain usually larger species richness, and 2) species-energy relationship which postulates that the amount of energy encompassed in the area determines species richness. Even though both of these relationships may result from multiple mechanisms, which may be also intertwined, for instance through heterogeneity of habitats, they are not often studied simultaneously. In addition to broaden our theoretic knowledge understanding the mechanisms that produce species richness could help us to protect biodiversity. I studied the effects of area, energy, and habitat heterogeneity on species richness and related adjacent mechanisms in three taxa. My results showed that bird species richness was determined mainly by total energy (measured as tree volume and growth) in an area through its effects on the number of individuals. Bird species richness was further limited by the density of energy and its spatial dispersion, most likely because increased habitat heterogeneity benefits specialists. Also aquatic macrophyte species richness was determined by a multiple of factors and one of them was potential productivity (a measure of energy). Whilst potential productivity increased species richness, species turnover showed a unimodal relationship with it. Thus, potential productivity may decrease the regional species diversity as the species turnover between lakes may be reduced. Finally, Odonata species richness was determined by habitat heterogeneity (measured as aquatic macrophyte species

density), and the relationship was shaped by just a handful of common species. My results help to build up the theoretic knowledge about the mechanisms behind species richness patterns and have important implications for species conservation." 10542. Horn, M.Y.; Rodrigues, K.A.; Anzotegui, L.M. (2011): Primeras evidencias de interacción insecto-planta en el Neógeno del noroeste de la Argentina. *Rev. bras. paleontol.* 14(1): 87-92. (in Portuguese, with English summary) ["This study provides the first evidence for plant-insect associations from fossil leaf impressions of the San José and Palo Pintado formations, dated as middle and upper Miocene age, from northwestern Argentina. The size, shape and arrangement of leaf damage on several plant hosts consists of various chew marks made by mandibulate insects occurring along the leaf blades of *Malvaciphyllum quenquiadensis* Anzotegui and *Cristalli* (Malvaceae), hole feeding along the leaf edge of *Nectandra saltensis* Anzotegui (Lauraceae), mines within the internal tissues of *M. quenquiadensis*, and oviposition scars in *Cedrela* sp. (Meliaceae). Based on specific, identifiable features of the plant damage, the likely producers responsible for this damage include external foliage feeders such as Orthoptera, Phasmoptera and Coleoptera; leaf miners from the Lepidoptera but possibly Hymenoptera and Diptera; and ovipositing insects representing the Odonata. Many of these insect groups were previously known from earlier Paleogene deposits of Argentina, and similar ovipositional damage has been documented from the early Eocene of Rio Negro and middle Eocene of Chubut in Patagonia, indicating geochronological continuity and occurrence in marsh and open woodland plant communities under warm and seasonal climatic conditions." 10544. Infante-Rodriguez, D.A.; Novelo-Gutierrez, R.; Mercado, G.; Williams, T. (2011): Spinosad toxicity to *Simulium* spp. larvae and associated aquatic biota in a coffee-growing region of Veracruz State, Mexico. *Journal of Medical Entomology* 48(3): 570-576. (in English) ["Spinosad is a naturally derived insecticide that has shown potential as a mosquito larvicide. To determine the activity of spinosad against blackflies, late-instar larvae from a community comprising *Simulium tritatum* (63.6%) and seven other species, including three known vectors of onchocerciasis in Mexico (*S. metallicum*, *S. ochraceum*, and *S. callidum*), were subjected to concentration-mortality laboratory bioassays following World Health Organization guidelines. Cephalic capsule measurements confirmed the relatively homogeneous distribution of experimental larvae. The 50% lethal concentration of spinosad was estimated at 1.48 ppm spinosad (95% confidence interval: 1.07-2.33) for a 10-min exposure period, whereas

larvae treated with 0.05 ppm of the organophosphate temephos experienced 61% mortality. Immature aquatic insects were identified to genus and tested for their susceptibility to spinosad in the laboratory. After exposure to 12 ppm spinosad for 10 min, ephemeropterans, odonates, trichopterans, and hemipterans did not experience significantly increased mortality over that of untreated controls, whereas a significant increase in mortality was observed in spinosad-treated Plecoptera (P 0.001). Tilapia and trout fry exposed to 12 ppm spinosad for 10 min did not experience increased mortality at 24-h postexposure over that of the controls. We conclude that spinosad is less toxic than temephos to these blackfly species, but is likely to have a low impact on nontarget members of the aquatic community." 10547. Janananda, B.G. (2011): Characterization of changes in Megalagrion opsin genes to detect signatures of selection. Open Access Theses. Paper 259: Master of Science thesis, Department of Biology (Arts and Sciences), University of Miami. 59 pp. (in English) ["Megalagrion damselflies have radiated into new breeding habitats in-

dependently at least six times in the Hawaiian archipelago, and have evolved bright body coloration numerous times. We hypothesize that these radiations are correlated with specific changes in the opsin proteins. We isolated and characterized two opsin genes from nine different Megalagrion species. The opsin phylogeny is consistent with the phylogeny based on breeding habitat preference of Megalagrion species supporting the correlation between the evolutionary changes of vision and habitat shifts. dN/dS ratios of opsin sequences show that these genes are evolving under purifying selection, though some sites of the opsin genes might be evolving under positive selection. Two terrestrial-breeding Megalagrion species show higher rates of opsin gene evolution that are correlated with a rapid transformation in their breeding habitats from aquatic to terrestrial. These results support the hypothesis that opsin gene evolution has played a role in Megalagrion radiation in Hawaii." (Author)] Address: E-mail: bhagya@bio.miami.edu

10550. Kalnins, M.; Bernard, R.; Mikelson, I. (2011): Protected aquatic insects of Latvia – *Nehalennia speciosa* (CHARPENTIER, 1840) (Odonata: Coenagrionidae). *Latvijas entomologs* 50: 41-54. (in English) ["*N. speciosa* "is protected by the Regulations of the Cabinet of Ministers of Latvia. Published and all known unpublished data have been used to present and analyse its distribution, population size, habitat selection and conservation status. The distribution of *N. speciosa* has been mapped using a basic grid of 5x5 km squares in the Baltic grid system. In total, *N. speciosa* has been recorded from 36 squares and 38 localities occurring sparsely or in small concentrations over a large part of the country apart from its western territories. The majority of the recent localities are situated in northeastern and southeastern Latvia. The known pattern of the species' distribution partly results from the abundance and density of appropriate habitats and possibly a climatic influence. However, this also may be a consequence of an insufficient and uneven odonatalogical exploration of the country. The majority of the species' populations seem to be small. *N. speciosa* has mostly been recorded in primary habitats in Latvia, such as complexes of lakes with *Sphagnum* fens, transition mires and bogs, with a diverse, not only small, size of water body. *N. speciosa* inhabits spatially restricted fragments of these habitats, i.e. a transition-mire zone bordering the open water table or fen and boggy patches with a higher water level, both habitats overgrown with a specific vegetation predominated by narrow-leaved sedges. Post-excavation peaty pools in degraded raised bogs with natural regeneration play a major role among rare secondary habitats of the species. The flight season of the *N. speciosa* in Latvia ranges mainly from mid June to late July. The conservation status of the species in Latvia is described and conservation measures are suggested." 10552. Khan, F.R.; Irving, J.R.; Bury, N.R.; Hogstrand, C. (2011): Differential tolerance of two *Gammarus pulex* populations transplanted from different metallogenic regions to a polymetal gradient. *Aquatic Toxicology* 102(1-2): 95-103. (in English) ["The River Hayle, Cornwall, UK exhibits pronounced Cu and Zn concentration gradients which were used to compare the metal handling abilities of two populations of *Gammarus pulex* (Crustacea: Amphipoda). One population was native to the Hayle region (Drym) and presumably has been historically impacted

by elevated Cu and Zn levels, whilst naïve gammarids were collected from the River Cray, Kent, UK. Both populations were subject to a 32 day in situ exposure at four R. Hayle sites (Drym, Godolphin, Relubbus and St. Erth). Mortality (LT50), Cu and Zn accumulation and sub-cellular distribution, and oxidative stress (malondialdehyde production) increased with the expected Cu and Zn bioavailabilities at the four sites (i.e. Godolphin > Relubbus > St. Erth > Drym). The naïve population experienced greater metal induced effects in terms of Cu and Zn accumulation, oxidative stress responses and lower LT50s. Analysis of Cu and Zn sub-cellular distribution, however, revealed no significant differences in metal handling. In both populations each metal was localised predominantly to the sub-cellular fraction containing metal bound to metallothionein-like proteins (MTLP) or that holding both metal-rich granules (MRG) and exoskeleton, MTLP and MRG binding being indicative of metal detoxification. However, a greater capacity for detoxified metal storage is not a mechanism implicated in the perceived tolerance of the historically impacted gammarids. Instead our results suggest that the historically impacted population was adapted for lower uptake of Cu and Zn leading to lower bioaccumulation, stress response and ultimately mortality. These results demonstrate not only the usefulness of the in situ methodology, but also that differences in population exposure history can cause significant differences in metal responses during exposure at higher concentrations." (Authors) Larvae of *Cordulegaster boltonii* settled at one of the five studied sections the river. Hydrochemical parameters at the section Relubbus of River Hayle are: heavy metals in dissolved water: Cu: 10.7 ± 0.9 Zn: 664.5 ± 43.9 ; heavy metals in sediment: Cu: 1279.6 ± 17.6 Zn: 479.2 ± 68.0 ; Total hardness: 96.6 ± 2.1 ; pH: 6.68 ± 0.03 ; Conductivity: 69.6 ± 0.1] Address: Khan, F.R., Nutritional Sciences Division, King's College London, Franklin-Wilkins Building, 150 Stamford Street, London SE1 9NH, UK.

(2011): Taxonomic uncertainty of a highly endangered brook damselfly, *Copera tokyoensis* Asahina, 1948 (Odonata: Platycnemididae), revealed by the mitochondrial gene genealogy. *Conservation Genetics* 12(3): 845-849. (in English) ["In the Japanese main islands, two brook damselfly species are sympatrically distributed. One is highly endangered damselfly, *Copera tokyoensis*, Asahina, 1948, and the other is a congeneric common species, *C. annulata* (Selys, 1863). Mitochondrial gene genealogy reconstructed by the maximum likelihood method showed that they are not reciprocally monophyletic. These two congeneric species might have experienced mitochondrial introgres-

sions possibly through hybridizations. The effect of hybridization against endangered species is generally poorly understood. Taxonomic uncertainty might also explain this situation because extremely dispersed pattern of the haplotype network could not be appeared by once or twice hybridization. Three closely located populations of *C. tokyoensis* in the Kanto district showed significant population differentiation. It might suggest the low dispersal tendency of this endangered species." 10556. Knijf, G. de; Flenker, U.; Vanappelghem, C.; Mancini, C.O.; Kalkman, V.J.; Demolder, H. (2011): The status of two boreo-alpine species, *Somatochlora alpestris* and *S. arctica*, in Romania and their vulnerability to the impact of climate change (Odonata: Corduliidae). *International Journal of Odonatology* 14(2): 111-126. (in English) ["It is expected that climate change will have a great impact on many species and habitats. This will be greater if populations are found at the edge of their range or are isolated, and could lead to regional extinction. Here we investigate the possible impact on two boreo-alpine dragonfly species, *Somatochlora alpestris* and *S. arctica*, at their range margins. Both species were unknown for most parts of south-eastern Europe. In 2007 we found 15 localities for *S. alpestris* and two for *S. arctica* in the Carpathian Mountains of Romania. Both species are there confined to mountain peat bogs. All localities are situated between 1300 m and 2100 m altitude, with the majority restricted to a small range between 1600 m and 1800 m. Based on the factor altitude we predict a hypothetical distribution map for *S. alpestris*. The underlying models exclusively rely on the ultimate factor "altitude" and explain more than 60% of the deviance. In addition, we assessed the impact of climate change for two scenarios: a 1.5°C temperature increase and a 3°C increase. The first resulted in altitudinal range shifts of +200 m and in a distributional shrinkage of 40%, the latter corresponds to an upward range shift of 600 m and a loss of 90% of the area. Habitat specialists, especially those at their margins of distribution, are hardly able to keep pace with climate change. It seems unlikely that mountain peat bogs will develop at rates comparable to those of current climate change. This may effect regional extinctions of boreo-alpine species." 10560. Kouamé, M.K.; Dietoa, M.Y.; Edia, E.O.; Da Costa, S.K.; Ouattara, A.; Gourène, G. (2011): Macroinvertebrate communities associated with macrophyte habitats in a tropical man-made lake (Lake Taabo, Côte d'Ivoire). *Knowledge and Management of Aquatic Ecosystems* 400, 03: 18 pp. (in English, with French summary) ["An ecological study was done on Lake Taabo with the main objective of characterising macroinvertebrate communities associated with the microhabitats created mainly by *Eichhornia crassipes* and other littoral native macrophytes. We sampled organisms in patches of those aquatic macrophytes. Also, some abiotic variables (temperature, transparency, turbidity, pH, TDS, conductivity, dissolved oxygen, NH, NO, NO₂, PO and SiO) were measured. Overall, forty-three taxa of macroinvertebrates were identified. Ten of them were exclusively associated with water hyacinth while five were only associated with littoral macrophytes. Macroinvertebrate taxa with some of the highest family richness were Gastropoda, Coleoptera, He-

teroptera, Odonata and Diptera. The taxon with highest density in both microhabitats was Chironomidae. Although higher values of taxonomic richness (Rs), the Shannon index (H') and evenness (J) were obtained with the water hyacinth habitat, significant differences between the two microhabitats were not observed. Canonical Correspondence Analysis revealed that samples of *E. crassipes* collected in the dry season were characterised by Gastropoda and Odonata, as well as higher values of transparency and ammonia-nitrogen. Baetidae, Hydrophilidae, Chironomidae, Ceratopogonidae, Coenagrionidae, Naucoridae and Ostracoda were most abundant in both *E. crassipes* and littoral macrophyte habitats during the rainy season. This season was characterised by higher levels of nitrates and conductivity." (Author) Taxa are treated at the family level.] Address: Kouamé, M.K., Laboratoire d'Environnement et de Biologie Aquatique (LEBA), UFR – Sciences et Gestion de l'Environnement, Université d'Abobo-Adjamé, Abidjan, Côte d'Ivoire. 10561. Křoupalová, V.; Bojková, J.; Schenková, J.; Pařil, P.; Horsák, M. (2011): Small-scale distribution of aquatic macroinvertebrates in two spring fens with different groundwater chemistry. *International Review of Hydrobiology* 96(3): 235-256. (in English) ["We examined responses of macroinvertebrate assemblages to environmental and temporal variations along spring source-spring brook transects in two fen habitats, sharply differing in groundwater chemistry, and compared the patterns among individual taxonomical groups. We hypothesised a different importance of environmental heterogeneity and seasonal changes primarily linked to strong tufa precipitation, which causes stronger environmental filtering in the calcareous fen. In concordance, we observed that assemblages of the more homogenous calcareous fen primarily changed over time, due to seasonal shifts in source availability and favourable conditions. Their spatial distribution was determined by the amount of CPOM, tufa crusts and temperature variation, but a substantial part of the assemblage exhibited spatial uniformity (Plecoptera, Clitellata, and especially Trichoptera and Diptera). The assemblages of the more heterogeneous Sphagnum-fen were primarily driven by water pH and substrate and the season was a notably weaker predictor. We found that different macroinvertebrate groups can display various responses to the measured variables shaping the overall pattern obtained based on the whole community. Further, greater environmental heterogeneity can result in temporally stable species distribution patterns even at very small spatial scales within a single site." (Authors) The study includes data on *Aeshna cyanea*, *Cordulegaster boltonii*, and *Pyrrosoma nymphula*.] Address: Kroupalová, Vendula, Department of Botany and Zoology, Faculty of Science, Masaryk University, Kotlářská 2, CZ-61137 Brno, Czech Republic. 10562. Kuitunen, K.; Gorb, S.N. (2011): Effects of cuticle structure and crystalline wax coverage on the coloration in young and old males of *Calopteryx splendens* and *Calopteryx virgo*. *Zoology* 114(3): 129-139. (in English) ["Male secondary sexual characters, such as colour patterns, are often investigated at the macroscale level. However, micro- and nanoscale levels of morphological investigations may reveal functional features responsible for a particular coloration, thus providing more information, e.g., about the condition dependence of male sexual characters. The aim of this paper was to investigate cuticle colour and its structure in males of two con-

generic damselfly species, *Calopteryx splendens* and *Calopteryx virgo*, and reveal possible colour changes with age. According to spectrometer measurements, *C. splendens* males were bluer and had a greater saturation of blue in their abdomen than *C. virgo* males, which were, in turn, greener and had more green saturation. Although the two species differed in the number of structural layers and the spacing of the layers, it seems that intactness of the wax crystals covering the epicuticle was most often the morphological trait which was related to the colour parameters measured from males' cuticles. The effect of the crystalline wax coverage on cuticle colour was also confirmed by removing the wax using chloroform: after the treatment, the hue was bluer, the cuticle had a greater brightness and greater blue saturation, but less green saturation. Age differences influencing the colour and structure of the cuticle were also observed: older males had more blue and green saturation and had more intact wax coverage than did younger males. Although multilayer reflection should be responsible for the iridescent colour of males, our results suggest that wax coverage plays an important role in the colour tuning of the male cuticle. This may have a considerable signal function, indicating the males' viability to competing males or to females." 10565. Lambret, P.H.; Stoquert, A. (2011): Diel pattern of activity of *Lestes macrostigma* at a breeding site (Odonata: Lestidae). *International Journal of Odonatology* 14(2): 175-191. (in English) ["Monitoring methods always recommend gathering data during the maximal activity of adults. Hence monitoring the threatened *Lestes macrostigma* requires knowledge of its activity pattern. Dragonfly "activity" is ambiguous and its intensity can be assessed in different ways, including by the threshold of response to a predator stimulus, i.e. "awareness". We studied the daily pattern of activity of *L. macrostigma* at the breeding site by monitoring the frequencies of behaviours, especially those of different flights, flight duration and speed, and awareness. We also assessed the abundance together with the probability to detect the species. The pattern of behaviour was characterized by reproduction but also feeding and roosting. Flight activity was more intense in early morning for males, around midday for pairs, and in the evening for males and females. Flight speed was highest around midday. These patterns were related to ambient temperatures and to a trade-off between the needs to mate and to feed. Awareness was almost constant all day long, suggesting new insights on daily activity variations in the Odonata, especially when perching. Slight differences between males and females indicated opposite trends. The pattern of abundance was singularly trimodal. This abundance depends on the true presence at the breeding site and to a probability of detection. The timing of monitoring is therefore not to be related to the activity per se, but to the abundance of adults. We recommend gathering data on *L. macrostigma* during early morning." 10570. Leggett, R.; Kirchoff, B.K. (2011): Image use in field guides and identification keys: review and recommendations. *AoB PLANTS* 2011 plr004 doi:10.1093/aob-pla/plr004: 37 pp. (in English) ["Background and aims: Although illustrations have played an important role in identification keys and guides since the 18th century, their use has varied widely. Some keys lack all illustrations, while others are heavily illustrated. Even within illustrated guides, the way in which images are used varies considerably. Here, we review image use in paper and electronic guides, and establish a set of best practices for image use in illustrated keys and guides. Scope: Our review covers image use in both paper and electronic guides, though we only briefly cover apps for mobile devices. With this one exception, we cover the full range of guides, from those that consist only of species descriptions with no keys, to lavishly illustrated technical keys. Emphasis is placed on how images are used, not on the operation of the guides and key, which has been reviewed by others. We only deal with operation when it impacts image use. Main points: Few illustrated keys or guides use images in optimal ways. Most include too few images to show taxonomic variation or variation in characters and character states. The use of multiple images allows easier taxon identification and facilitates the understanding of characters. Most images are usually not standardized, making comparison between images difficult. Although some electronic guides allow images to be enlarged, many do not. Conclusions: The best keys and guides use standardized images, displayed at sizes that are easy to see and arranged in a standardized manner so that similar images can be compared across species. Illustrated keys and glossaries should contain multiple images for each character state so that the user can judge variation in the state. Photographic backgrounds should not distract from the subject and, where possible, should be of a standard colour. When used, drawings should be prepared by professional botanical illustrators, and clearly labelled. Electronic keys and guides should allow images to be enlarged so that their details can be seen. [...] Fig. 5 Facing pages from *Damselflies of Chicagoland* (Garrison 2010) showing the use of marginal coloured bands (Table 1: Best Practice 2) to indicate seasonal appearance (left margin of left page), species group (lower right corner of right page) and size (upper right corner of right page). The solid rectangle in the size band indicates the minimum body length. The solid and hashed bands, taken together, indicate the maximum length." 10572. Letsch, H.O.; Kjer, K.M. (2011): Potential pitfalls of modelling ribosomal RNA data in phylogenetic tree reconstruction: Evidence from case studies in the Metazoa. *BMC Evolutionary Biology* 2011, 11:146: 12 pp. (in Eng-

lish) ["Background: Failure to account for covariation patterns in helical regions of ribosomal RNA (rRNA) genes has the potential to misdirect the estimation of the phylogenetic signal of the data. Furthermore, the extremes of length variation among taxa, combined with regional substitution rate variation can mislead the alignment of rRNA sequences and thus distort subsequent tree reconstructions. However, recent developments in phylogenetic methodology now allow a comprehensive integration of secondary structures in alignment and tree reconstruction analyses based on rRNA sequences, which has been shown to correct some of these problems. Here, we explore the potentials of RNA substitution models and the interactions of specific model setups with the inherent pattern of covariation in rRNA stems and substitution rate variation among loop regions. Results: We found an explicit impact of RNA substitution models on tree reconstruction analyses. The application of specific RNA models in tree reconstructions is hampered by interaction between the appropriate modelling of covarying sites in stem regions, and excessive homoplasy in some loop regions. RNA models often failed to recover reasonable trees when single-stranded regions are excessively homoplastic, because these regions contribute a greater proportion of the data when covarying sites are essentially downweighted. In this context, the RNA6A model outperformed all other models, including the more parametrized RNA7 and RNA16 models. Conclusions: Our results depict a trade-off between increased accuracy in estimation of interdependencies in helical regions with the risk of magnifying positions lacking phylogenetic signal. We can therefore conclude that caution is warranted when applying rRNA covariation models, and suggest that loop regions be independently screened for phylogenetic signal, and eliminated when they are indistinguishable from random noise. In addition to covariation and homoplasy, other factors, like non-stationarity of substitution rates and base compositional heterogeneity, can disrupt the signal of ribosomal RNA data. All these factors dictate sophisticated estimation of evolutionary pattern in rRNA data, just as other molecular data require similarly complicated (but different) corrections." mary) ["A seasonal survey of water quality and benthic macroinvertebrates was conducted for a mountain lake Chia-Lo and three mountain ponds, Che-Tui, Hao-Mai, and Wei-Tan, in the northeastern Taiwan, 2002 to 2003. A total of 14,719 specimens of benthic macroinvertebrates were collected. They were consisted of 22 taxa, of that seven taxa belonged to Odonata, six taxa to Diptera, three taxa to Tricoptera, two taxa to each of Hemiptera and Coleoptera, and a taxon to each of Oligochaeta and Ephemeroptera. *Notonecta saramao* and *Sympetrum speciosum taiwanum* were found to be the endemic species. Relationships between the water quality and the benthic macroinvertebrate assemblages were assessed with the coinertia analysis. The results showed that turbidity and ammonia were related to water saprobity, and pH and total hardness to water acidification. They were the most important water quality variables that explained the formation and distributional pattern of macroinvertebrate assemblages in the mountain ponds. Oligochaeta was recommended as a bio-indicator for the water saprobity, and *Dicrotendipes* sp. and *Cloeon* sp. for water acidification." (Authors) The following odonate taxa have been sampled: *Ceragrion fallax fallax*, *Lestes cyaneus*, *Aeshna petalura taiyal*, *Anax nigrofasciatus*, *Sympetrum speciosum taiwanum*, *Orthetrum japonicum internum*, and *O. melania*.] Address: Shieh, S.-H., Dept of Ecology, Providence University, Taichung, Taiwan. 10576. Lorenzo-Carballa, M.O.; Beatty, C.D.; Haitlinger, R.; Valdecasas, A.G.; Utzeri, C.; Vieira, V.; Cordero-Rivera, A. (2011): Larval aquatic and terrestrial mites infesting parthenogenetic *Ischnura hastata* (Odonata: Coenagrionidae) from the Azores islands. *Experimental and Applied Acarology* 54(3): 225-241. (in English) ["We report here the prevalence of parasitism by water mites (*Arrenurus* sp.) and terrestrial mites (*Leptus killingtoni*) on parthenogenetic *I. hastata* from the Azores islands. *L. killingtoni* was only found on the island of Pico, and the prevalence of infestation was highly variable among the different ponds studied, ranging from 0 to 41%. *L. killingtoni* was observed on three of the four odonate species from the archipelago: *I. hastata*, *I. pumilio*, and *Sympetrum fonscolombii*, all of them new hosts for this species. Aquatic mites have been found parasitizing *I. hastata* females on the island of São Miguel. The prevalence of mite parasitism by *Arrenurus* sp. on *I. hastata* was very low, ranging from 12% (2003) to 1% (2008), and in most

of the studied ponds, no mites were found attached to females. Although *I. hastata* coexists with a sexual congener species in the Azores (*I. pumilio*), they are syntopic in only a small fraction of ponds. Therefore, a comparison between *I. hastata* and *I. pumilio* was insufficient to test the predictions of the Red Queen Hypothesis, and further research on parasitism rates in both species needs to be done. In any case, the low prevalence of mite parasitism found in the Azores, coupled with the fact that most of the populations in the archipelago are almost free from competitors and predators, could explain the persistence of these *I. hastata* parthenogenetic populations, despite their low levels of genetic variation." 10577. Lotfy, N.M.; Hassanein, M.A.; Abdel-Gawad, F.K.; El-Taweel, G.E.; Bassem, S.M. (2011): Detection of *Salmonella* spp in aquatic Insects, fish and water by MPN-PCR. *World Journal of Fish and Marine Sciences* 3(1): 58-66. (in English) ["Salmonellosis had become an increasing problem in industrialized countries during the last few decades. The natural habitat of *Salmonella* spp. is the gastrointestinal tract of mammals, birds and reptiles. Therefore, *Salmonella* species may reach aquatic environments through faecal contamination and it has been isolated from freshwater fish culture ponds in many countries. This accounts for the occasional detection of *Salmonella* from fish and fishery products. The present study focused on the use of some aquatic insects and fish as bioindicators for transmission of *Salmonella* in the River Nile, Egypt. Six hundred and seventy *Salmonella* isolates were isolated from aquatic insects, fish and water during the year 2009/2010. Seven hundred and ten random isolates of typical colonies of salmonellae were determined by MPN method and then confirmed by PCR and nested PCR. Five hundred and fourteen isolates were *Salmonella* spp. +ve when tested by PCR from which only 144 isolates were +ve when tested by the nested PCR assay. Results also indicated that PCR and the nested PCR assay are rapid and simple assays for sensitive and specific identification of *Salmonella* spp. in water, fish and aquatic insects. It could be concluded that aquatic insects and fish could act as bioindicators of zoonotic diseases. [...] In the control point in the main stream of River Nile before branches 55 isolates were tested for the presence of *Salmonellae*; 78% were *Salmonellae* spp. +ve from which 25.6% were +ve when tested by Nested PCR." (Authors) This sample point resulted also in records of *Enallagma* (*Azuragrion*) *vansomereni*.] Address: Fagr Abdel-Gawad, Department of Water Pollution, National Research Center, Dokki, Giza, Postal code 12622, Egypt. (2011): Ovipositor morphology and egg laying behaviour in the dragonfly *Lestes macrostigma* (Zygoptera: Lestidae). *International Journal of Odonatology* 14(1): 69-82. (in English) ["*L. macrostigma* is a stenotopic dragonfly species of Western Palaearctic distribution that has high conservation status almost throughout its range. It inhabits mainly brackish water with a typical plant species, sea club-rush *Bolboschoenus maritimus*. Due to the absence of special investigations, the nature of this insect-plant association is not clearly understood, but it was supposed that *L. macrostigma* prefers egg laying in *B. maritimus*. In this paper we describe the ovipositor morphology and the egg laying behaviour of *L. macrostigma* in detail. The cutting ovipositor reveals several morphological peculiarities recorded previously in other lestids. The internal surface of the valves reveals rich microsculpture. Numerous single and clustered sensilla of different shape are found on the valves and styli and are probably involved in oviposition-plant recognition by females and/or in production of an egg clutch. Oviposition is carried out in stems of *B. maritimus* and *Juncus maritimus*. An egg clutch consists of a row of single eggs deposited in line along the long axis of a plant. Results are discussed in the light of possible morphological and behavioural adaptation to oviposition

into specific plant substrates." (Authors)] Address: Lambret, P.H., Marais du Vigueirat, 13104 Mas-Thibert, France. E-mail: philambret@hotmail.com

10583. McPeck, M.A.; Symes, L.B.; Zong, D.M.; McPeck, C.L. (2011): Species recognition and patterns of population variation in the reproductive structures of a damselfly genus. *Evolution* 65(2): 419-428. (in English) ["The selection pressures imposed by mate choice for species identity should impose strong stabilizing selection on traits that confer species identity to mates. Thus, we expect that such traits should show nonoverlapping distributions among closely related species, but show little to no variance among populations within a species. We tested these predictions by comparing levels of population differentiation in the sizes and shapes of male cerci (i.e., the clasper structures used for species identity during mating) of six *Enallagma* damselfly species. Cerci shapes were nonoverlapping among *Enallagma* species, and five of six *Enallagma* species showed no population variation across their entire species ranges. In contrast, cerci sizes overlapped among species and varied substantially among populations within species. These results, taken with previous studies, suggest that cerci shape is a primary feature used in species recognition used to discriminate conspecific from heterospecifics during mating." 10587. Moreno Pallares, M.I. (2011): Distribución espacio-temporal de náyades de odonatos en los humedales La Vaca y Santa María del Lago, Bogotá, Colombia. M.Sc. thesis. Departamento de Biología, Facultad de Ciencias, Universidad Nacional de Colombia, Sede Bogotá: (in Spanish, with English summary) ["We evaluated the spatial and temporal variation of communities of dragonflies naiads and the association to the habitat rehabilitation status in wetlands la Vaca and Santa María del Lago. There were carried out four samples in each wetland during a year. Using standard techniques for collecting macroinvertebrates, in stations at the entry, exit and water mirrors of the wetlands. We found a gradient in the distribution of the abundance of nymphs observed in both wetlands, where naiads community had the most of number of individuals in the spatial sampling stations that are located at larger distances from the dumping sites. Comparing the composition between wetlands, heterogeneity was found in both wetland communities through assessment of beta diversity. The gradient in the distribution of the abundance of naiads observed in both gradients in both wetlands is more suited to a species response in terms of tolerance to environmental variables. The two wetlands showed aggregate variable decreased to the water outlets in the concentrations of solids, BOD₅, COD, nitrogen, phenols, SAAM, nutrients in the microbiological factors, which matched the increase of

naiads in points distant from the dumping. The spatial distribution of Odonata in terms of biotic and abiotic parameters showed that the composition of nymphs can provide information on the ecological conditions of the system it inhabits." (Author)] Address: not stated

10588. Moya, N.; Domínguez, E.; Goitia, E.; Oberdorff, T. (2011): Desarrollo de un índice multimétrico basado en macroinvertebrados acuáticos para evaluar la integridad biológica en ríos de los valles interandinos de Bolivia. *Ecología Austral* 21: 135-147. (in Spanish, with English summary) ["We developed a multimetric index that could discriminate natural from anthropogenic variability in 91 sites (63 reference sites and 28 disturbed sites) fairly evenly distributed across the upper Grande River Basin (Bolivia). To do so, we examined 12 candidate metrics for their potential to indicate degradation and reflecting different aspects of macroinvertebrate assemblage structure and function. Initially, using the reference sites, we developed statistical models describing the response of the different metrics to the natural environmental variability. In a second step, using sites experiencing three types of anthropogenic disturbances (i.e., agriculture, urban and mining activities), we quantified the deviation in the response of each metric model between reference and disturbed conditions. From the initial 12 metrics, we retained only 5 metrics in the final index (total richness, total abundance, richness of Ephemeroptera, Plecoptera and Trichoptera (EPT), percentage of EPT abundance and percentage of scrapers abundance). These metrics were the most effective ones in responding to anthropogenic disturbances. Our final index performed well in discriminating between reference and disturbed sites, giving a significant negative linear response to a gradient of physical and chemical anthropogenic disturbances. This index can be used as a monitoring tool to evaluate the biological integrity and aquatic biodiversity of the Bolivian inter-Andean valleys streams." (Authors) "Odonata" are treated at the family level: "Coenagrionidae, Aeshnidae, Corydalidae, Arctiidae"] Address: Moya, N., UMR BOREA, IRD 207, Unidad de Limnología y Recursos Acuáticos (ULRA), Universidad Mayor de San Simón, Cochabamba, Bolivia. 10589. Murakami, T.; Hodoki, Y. (2011): Comparison of population density and species composition of aquatic insect between the upstream and downstream reaches of a flood control dam without impoundment; a case study of the Masuda-gawa Dam in Shimane Prefecture, Japan. *Kaname Osamu* 57: 75-79. (in Japanese, with English summary) ["We compared the population density and species composition of aquatic insect communities up- and downstream of two types of dams to evaluate the effects of rivercrossing construction on benthic invertebrates. One is the Masuda-gawa Dam, a so called "dry dam" or "uncontrolled dam" because its invariably open gates are set at the bottom of the construction to maintain river continuity, and the other is the Sasaura Dam with a reservoir behind the construction: Both are located on the Masuda River System, Shimane Prefecture. Population densities and species compositions upstream the two dams did not show large difference, and were dominated by several insect species belonging to Heptageniidae (Ephemeroptera). In the downstream reaches of both dams, however, the population density of two net-spinning caddis flies (Hydropsychidae, Trichoptera), which are frequently found in high densities in Japanese dammed rivers, was higher than the up-stream reaches; by 50-fold in the case of Sasaura Dam and by 7-fold in the Masuda-

gawa Dam. The difference in the density increment of net-spinning caddis flies between the two dams may indicate that dry dam poses less influence on lotic environment." (Authors) In the case of the taxon "Gomphidae" at Masuda-gawa Dam the ratio between up- and downstream density was 0,4 (96 : 37), and at Sasakura Dam 1,1 (43 : 48).] Address: not transliterated into English

10590. Murphy, J.F.; Nagorskaya, L.L.; Smith, J.T. (2011): Aquatic macroinvertebrate communities in lakes exposed to Chernobyl-derived ionising radiation. *Journal of Environmental Radioactivity* 102(7): 688-694. (in English) ["Littoral (lake shore) macroinvertebrate communities were studied in eight natural lakes affected by fallout from the Chernobyl accident. The lakes spanned a range in ¹³⁷Cs contamination from 100 -15500 kBq m² and estimated external dose rates ranged from 0.13 - 30.7 nGy h⁻¹. General linear models were used to assess whether abundance of individuals, taxon richness, Berger-Parker dominance and Shannon-Wiener diversity varied across the lakes. Step-wise multiple regressions were used to relate variation in total abundance, taxon richness, Berger-Parker dominance, Shannon-Wiener diversity, taxon richness within major groups of macroinvertebrates and abundance of the more common individual taxa to the measured environmental characteristics (conductivity, pH, total hardness and phosphate; lake area, lake maximum depth and total external dose) of the lakes. No evidence was found in this study that the ecological status of lake communities has been influenced by radioactive contamination from the Chernobyl accident. Indeed, the most contaminated lake, Glubokoye, contained the highest richness of aquatic invertebrates. Taxon richness in the eight study lakes varied from 22 (Svyatskoe #7) to 42 (Glubokoye) which spans a range typical for uncontaminated lakes in the region. Since ⁹⁰Sr is readily-absorbed by Mollusca, estimated dose rates to this group exceeded those for other invertebrate groups in two lakes (Perstok and Glubokoye). However this study found no association between mollusc diversity or abundance of individual snail species and variation between lakes in the external radiation dose. Indeed Glubokoye, the lake most contaminated by ⁹⁰Sr, had the highest richness of freshwater snails per sample (an average of 8.9 taxa per sample)." (Authors) The study includes the following Odonata species: *Coenagrion armatum*, *C. hastulatum*, *Aeshna viridis*, *A. cyanea*.] Address: Smith, J.T., School of Earth & Environmental Sciences, University of Portsmouth, Burnaby Bldg, Burnaby Road, Portsmouth PO1 3QL, UK. 10591. Nagy, H.B.; László, Z.; Köver, S.; Szállassy, N.; Dévai, G. (2011): Population size effects on the behaviour of *Libellula fulva* (Odonata: Libellulidae) males, a five year study. *North-western journal of zoology* 7(1): 39-46. (in English) ["We tested the hypothesis that population density alters male territorial and mating behaviour of dragonflies. We predicted that males at higher densities fight more and mate less. During five years we studied two *Libellula fulva* populations along two small lowland creeks in East Hungary. Using mark-resight method we marked a total number of 1454 dragonfly males. Our results show that on the two study sites there were different population densities. At higher population densities the number of matings per male decreased, but population size had no effect on the frequency of intraspecific fights. However, the long run study showed remarkable difference from the outcome of partial analyzes which underlines the importance of studies overtaken through several years."

10593. Nelson, B.; Ronayne, C.; Thompson, R. (2011): Ireland Red List No.6: Damselflies & Dragonflies (Odonata). National Parks and Wildlife Service, Department of the Environment, Heritage and Local Government, Dublin, Ireland: 27 pp. (in English) ["Based on almost 32,000 records for Ireland, the 24 species of resident Odonata are evaluated for their conservation status using International Union for the Conservation of Nature (IUCN) criteria (IUCN, 2001, 2003). Four (17%) of the Irish species are assessed as threatened, and one species as near threatened. The populations of all five species need to be thoroughly surveyed and monitoring programmes for each initiated. Causes of the decline in each species need to be determined, existing and possible threats identified, and protective measures introduced. The remaining species are all assessed as least concern. The Irish odonate fauna is a limited one, reflecting the recent geological history of the island; its location off the western edge of the European continent; the climate, and the range of habitats present. Despite this, the fauna is not without interest and in particular when compared to that of Great Britain. The most interesting species of the Irish fauna is *Coenagrion lunulatum* which is mainly a northern Eurasian species that is absent from Great Britain. The Irish population of *Lestes dryas* is also of interest because of its association with the turloughs of the western limestone. Three of the threatened odonates, *Somatochlora arctica*, *Cordulia aenea* and *C. lunulatum*, are found in low nutrient status wetlands and the change brought about by enrichment of these habitats is regarded as the primary threat to these species. The decline of these should act as a warning of the negative trend in the state of these wetlands which are a distinctive feature of many Irish counties. These three are also predominantly northern species and the Irish populations lie at the southern edge of their ranges. In the long term the impact of climate change may be significant. Climate change may actually benefit the remaining threatened species, *Ischnura pumilio*, and the near threatened *L. dryas*, but the immediate threat to these species is habitat loss. Both these damselflies are dependent on specific hydrological conditions which are easily damaged and altered." (Authors)] Address: Thompson, R., 8 Weaver's Court, Banbridge, Co. Predator type and predator experience trade-offs in relation to tadpole mortality rates. *Journal of Zoology* 284(2): 144-150. (in English) ["Cryptic behavior and unpalatability are common defensive strategies that occur in different taxonomic groups, but the effectiveness of these defensive strategies is context dependent, varying with predator type and co-occurring species. We tested this assumption by measuring the mortality rates of *Eupemphix nattereri* (cryptic behavior) and *Rhinella schneideri* (unpalatable) tadpoles in association with the predatory fish *Oreochromis niloticus* (vertebrate) and the dragonfly larvae of *Aeshna* sp. (invertebrate). We designed a second experiment to evaluate whether fish predators are capable of learning to avoid unpalatable prey once they have encountered it. Our results showed that fish preyed selectively on palatable tadpoles, avoiding unpalatable tadpoles and that the odonate larvae were more efficient in preying on the more active unpalatable tadpoles and less efficient in capturing those tadpoles that presented cryptic behaviors. Additionally, our data suggest that the antipredator traits of tadpoles can interact with each other, with cryptic tadpoles showing lesser mortality when co-occurring with unpalatable tadpoles and odonate predators. Unpalatable tadpoles also increase the mortality of cryptic tadpoles in the presence of experienced fish predators. These prey traits interact in modifying the prey preference of the predator, which constitutes a prey-induced trait-mediated interaction (TMI). This type of TMI is dependent on the system complexity (number of predator and prey species interactions) and could define food web properties, such as the role of predators and the number of competitor species in the system." 10596. Nordström, K.; Bolzon, D.M.; O'Carroll, D.C. (2011): Spatial facilitation by a high-performance dragonfly target-detecting neuron. *Biology Letters* 7(4): 588-592. (in English) ["Many animals visualize and track small moving targets at long distances—be they prey, approaching predators or conspecifics. Insects are an excellent model system for investigating the neural mechanisms that have evolved for this challenging task. Specialized small target motion detector (STMD) neurons in the optic lobes of the insect brain respond strongly even when the target size is below the resolution limit of the eye. Many STMDs also respond robustly to small targets against complex stationary or moving backgrounds. We hypothesized that this requires a complex mechanism to avoid breakthrough responses by background features, and yet to adequately amplify the weak signal of tiny targets. We compared responses of dragonfly STMD neurons to small targets that begin moving within the receptive field with responses to targets that approach the same location along longer trajectories. We find that responses along longer trajectories are strongly facilitated by a mechanism that builds up slowly over several hundred milliseconds. This allows the neurons to give sustained responses to continuous target motion, thus providing a possible explanation for their extraordinary sensitivity." (Authors)] Address: Nordström, Karin,

(2011): Composition of aquatic invertebrates associated with macrophytes in Lake Tonle Sap, Cambodia. *Limnology* 12(2): 137-144. (in English) ["Faunal composition of aquatic invertebrate communities associated with submerged parts of several species of macrophytes were studied in different areas in littoral Lake Tonle Sap in Cambodia, with special reference to those in root systems (interrhizon) of a free-floating water hyacinth (*Eichhornia crassipes*). Nine phyla of invertebrates were collected, of which oligochaetes, shrimps and *Limnoperna* mussels were abundant along with meiobenthic crustaceans. The macrophyte-associated invertebrates in Lake Tonle Sap might be unique in having abundant sessile animals, such as sponges, bryozoans and *Limnoperna* mussels. The *Limnoperna* mussels attached to macrophytes were more abundant in offshore and inundated forest than in secluded vegetational stands toward the shoreline. It suggests that water movement can be an important factor determining the distribution and abundance of the sessile animals by controlling larval dispersions and might be associated with the hydrological characteristic of the lake, i.e., the lake opens to the large Mekong River with drastic seasonal changes in water level." 10603. Pan, B.-z.; Wang, Z.-Y.; He, X.-B. (2011): Studies on assemblage characteristics of macrozoobenthos in the West River. *Acta hydrobiologica Sinica* 35(5): 1-6. (in Chinese, with English summary) ["To conserve and manage the West River, field investigations of macrozoobenthos were conducted in November 2009 (at low water level) and May 2010 (at high water level). Altogether 70 taxa of macrozoobenthos belonging to 30 families and 59 genera were identified (including *Lamelligomphus* sp., *Leptogomphus* sp., *Megalogomphus* sp.). ... The average density and biomass of total macrozoobenthos were 140 ind/m² and 0.23 g dry weight/m², respectively. Macrozoobenthic density peaked in the cobbles, while biomass reached the maximum in the bedrock. Detrended Correspondence Analysis (DCA) revealed that substrate played an important role in structuring macrozoobenthic assemblages. The higher substrate stability was more favorable to survival of benthic animals. Macrozoobenthic assemblages in soft sediment were characterized by dominance of collector-gatherers (mainly Tubificidae and Chironominae), while macrozoobenthos in stone substrates were dominated by scrapers (e.g. *Semilucospora* spp.) or collector-filterers (e.g. *Limnoperna lacustris*). In recent years, channel regulation projects have

led to reduction of habitat quality and habitat loss, which will have a negative impact on survival of benthic animals." (Authors)] Address: Pan, B.-z., State Key Laboratory of Hydroscience and Engineering, Tsinghua University, Beijing 100084, China

10605. Parry, G.S.; Burton, S.; Cox, B.; Forman, D.W. (2011): Diet of coastal foraging Eurasian otters (*Lutra lutra* L.) in Pembrokeshire south-west Wales. *European Journal of Wildlife Research* 57(3): 485-494. (in English) ["The importance of the marine environment to Eurasian otters is currently poorly understood. Wales is one of the few countries where coastal activity has been recorded and an increase in marine otter sightings could indicate remarkable developments within Welsh populations. The trophic niche of coastal otter populations around Pembrokeshire was investigated over a 12-month period. Marine activity was more widespread than previously thought and marine prey formed the largest component of otter diet, although, otters also consumed freshwater and terrestrial prey throughout the year. Otter diet was very diverse compared to other European coastal populations and a spring contraction in trophic niche width coincided with the estimated timing of breeding activity. Seasonal variation in prey composition was predominantly due to differences in the consumption of alternate prey types. In areas where wetlands are fragmented and populations of freshwater fish are declining, the marine environment may become an increasingly important habitat for otters. It is necessary to define the historical importance of coastal populations to otter conservation. Coastal areas are often subject to pressure from human activities, so the impact of disturbance needs to be assessed. Importantly, there is no verified otter survey method for coastal areas, so the use of marine habitat is likely to be underestimated." (Authors) Odonata contributed with 0,2% of relative frequency of occurrence to the otter diet on the Pembrokeshire coast between July 2007–June 2008.] Address: Forman, D.W., Dept of Pure and Applied Ecology, Conservation Ecology Research Team, School of the Environment and Society, Swansea Univ., Singleton Park, Swansea SA2 8PP. 10607. Payne, J.L.; McClain, C.R.; Boyer, A.G.; Brown, J.H.; Finnegan, S.; Kowalewski, M.; Krause, R.A.; Lyons,

S.K.; McShea, D.W.; Novack-Gottshall, P.M.; Smith, F.A.; Spaeth, P.; Stempien, J.A.; Wang, S.C. (2011): The evolutionary consequences of oxygenic photosynthesis: a body size perspective. *Photosynth. Res.* 107: 37-57. (in English) ["The high concentration of molecular oxygen in Earth's atmosphere is arguably the most conspicuous and geologically important signature of life. Earth's early atmosphere lacked oxygen; accumulation began after the evolution of oxygenic photosynthesis in cyanobacteria around 3.0–2.5 billion years ago (Gya). Concentrations of oxygen have since varied, first reaching near-modern values *600 million years ago (Mya). These fluctuations have been hypothesized to constrain many biological patterns, among them the evolution of body size. Here, we review the state of knowledge relating oxygen availability to body size. Laboratory studies increasingly illuminate the mechanisms by which organisms can adapt physiologically to the variation in oxygen availability, but the extent to which these findings can be extrapolated to evolutionary timescales remains poorly understood. Experiments confirm that animal size is limited by experimental hypoxia, but show that plant vegetative growth is enhanced due to reduced photorespiration at lower O₂:CO₂. Field studies of size distributions across extant higher taxa and individual species in the modern provide qualitative support for a correlation between animal and protist size and oxygen availability, but few allow prediction of maximum or mean size from oxygen concentrations in unstudied regions. There is qualitative support for a link between oxygen availability and body size from the fossil record of protists and animals, but there have been few quantitative analyses confirming or refuting this impression. As oxygen transport limits the thickness or volume-to-surface area ratio — rather than mass or volume — predictions of maximum possible size cannot be constructed simply from metabolic rate and oxygen availability. Thus, it remains difficult to confirm that the largest representatives of fossil or living taxa are limited by oxygen transport rather than other factors. Despite the challenges of integrating findings from experiments on model organisms, comparative observations across living species, and fossil specimens spanning millions to billions of years, numerous tractable avenues of research could greatly improve quantitative constraints on the role of oxygen in the macroevolutionary history of organismal size. [...] Despite widespread awareness of Late Paleozoic gigantism, there have been few attempts to determine whether organisms the size of Carboniferous giants would be prohibited at present-day oxygen levels or whether the magnitude of temporal variation in maximum size within the relevant taxa has been of the magnitude predicted by modeled changes in pO₂. Okajima (2008) (*Lethaia* 41(4): 423-430) was the first to examine the link between insect size and oxygen concentration quantitatively through the Phanerozoic, using newly compiled data on the sizes of fossil dragonflies. She found that the variation in maximum size of dragonflies through time has been much greater than predicted by variation in atmospheric oxygen concentrations, assuming respiration via diffusion through tracheae, and assuming that the sizes of Carboniferous dragonflies represent an oxygen-limited maximum size. If oxygen limited maximum body size in the Carboniferous, it has not consistently done so during other periods. Alternatively, if oxygen is limiting in the modern, then anatomical or physiological differences must exist between the Protodonata and Odonata to explain the inability of the Odonata to achieve similarly large sizes. The latter interpretation is suggested by the fact that all of the largest Paleozoic specimens belong to the Protodonata;

Paleozoic members of the Odonata exhibit sizes comparable to the largest in the Mesozoic and Cenozoic. Alternatively, the simplifying assumption of oxygen diffusion through tracheae may be inaccurate; there is emerging evidence for active tracheal breathing in insects (Socha et al. 2008; Westneat et al. 2003). Okajima (2008) proposed still another alternative: although variation in oxygen may have contributed to size evolution, maximum size of Mesozoic and Cenozoic dragonflies was limited by ecological competition with flying vertebrates. A further possibility, not examined by Okajima (2008), is that the trend in maximum size of fossils is poorly correlated with the true evolutionary pattern. Temporal variation in the quality of the insect fossil record (Labandiera 2005; Smith and Cook 2001) makes it difficult to determine the extent to which variation in maximum size in the fossil record reflects biological reality versus variation in the quality of available material. For example, the Carboniferous contains an unusually extensive record of the coastal marsh environments that may be most likely to house large insects." 10610. Perez-Gutierrez, L.A.; Montes-Fontalvo, J.M. (2011): Rediscovery of *Mesagrion leucorrhinum* (Zygoptera: Megapodagrionidae): a "formal" description of female and ultimate stadium of larva with notes on habits. *International Journal of Odonatology* 14(1): 91-100. (in Eng-

lish) ["Adult female and ultimate stadium larva of *Mesagrion leucorrhinum* are formally described and illustrated based on material from three locations in Antioquia, Meta and Cundinamarca Departments, Colombia. The species is sexually dimorphic. The female is distinguishable from other related genera by a pair of notches in the prothoracic anterior lobe and shares with *Heteropodagrion* and *Dimeragrion* females a yellowish, scarcely sclerotized region dorsally between the posterior margin of S7 and anterior border of S8. The larva is very similar to *Heteropodagrion*. Differences for separating them are: the pro-, meso- and metathoracic supracoxal processes are less prominent in *Mesagrion*, and the length of the terminal filament of the middle gill is notably longer in *Mesagrion*. The specimens were also compared with other related genera. Observations on habits are added." 10614. Rajabi, H.; Moghadami, M.; Darvizeh, A. (2011): Investigation of microstructure, natural frequencies and vibration modes of dragonfly wing. *Journal of Bionic Engineering* 8(2): 165-173. (in English) ["Investigation on the microstructural and morphological aspects of dragonfly wings was carried out using scanning electron micro-

scope. Then, based on this study and the previous reports, a precise three-dimensional numerical model was developed and natural frequencies and vibration modes of dragonfly forewing were determined by finite element method. The results shown that dragonfly wings are made of a series of adaptive materials, which form a very complex composite structure. This bio-composite fabrication has some unique features and potential benefits. Furthermore, the numerical results show that the first natural frequency of dragonfly wings is about 168 Hz and bending is the predominant deformation mode in this stage. The accuracy of the present analysis is verified by comparison of calculated results with experimental data. This paper may be helpful for micro aerial vehicle design concerning dynamic response." 10616. Reels, G.T. (2011): Emergence patterns and adult flight season of Anisoptera at a managed wetland site in Hong Kong, southern China. *International Journal of Odonatology* 14(1): 33-48. (in English) ["Anisoptera emergence in the seasonal tropics was monitored at a 35-ha managed wetland site in Hong Kong from February 2004 to November 2007. Exuviae records of 18 species from multiple emergence screens, exuviae traps and transect surveys were combined. The presence of adults during this period was also monitored. The study site comprised a mosaic of ponds separated by narrow bunds. Exuviae of larvae living amongst dense submerged vegetation, and adults of crepuscular species, were probably underrecorded. Anisoptera emergence was strongly seasonal in all four years, commencing in March, with EM50 – the point at which 50% of the annual population has emerged, expressed as number of days since the start of emergence – falling between April and June, for most species; but emergence also showed considerable inter-year variation, particularly after EM50. Emergence of three species continued into December in at least one year. Extended emergence periods were generally ascribed to multivoltinism associated with unregulated life cycles, presumably facultative in the case of tropical-temperate species. The migrant *Pantala flavescens* showed no clear seasonality in emergence patterns. Composite species emergence periods over the four years ranged from two to 11 months, with no clear difference between tropical and tropical-temperate species. No species were

univoltine. Adult flying seasons usually commenced in March or April, and in eight species continued until at least November, although it is unlikely that any adults survived to the following spring. Five species were on the wing for six months or less. There was considerable phenological variation among species, with life histories commonly intermediate between those of equatorial and higher latitude species." 10617. Reeves, M.K.; Perdue, M.; Blakemore, G.D.; Rinnella, D.J.; Holyoak, M. (2011): Twice as easy to catch? A toxicant and a predator cue cause additive reductions in larval amphibian activity. *Ecosphere* 2(6) art 72: 20 pp. (in English) ["Toxicants may harm predators or prey differentially, hindering clear determination of multiple stressor effects on predation dynamics in polluted aquatic systems. We built on a prior field study in which we demonstrated that a chemical contaminant, copper (Cu) and odonate predators were correlated with more frequent observations of skeletal abnormalities in Alaskan wood frog (*Rana sylvatica*) tadpoles. Our prior study established a multiple stressor effect linked to an important environmental phenomenon (malformed amphibians) but did not provide clear mechanisms that might guide management. We here investigated behavioral mechanisms because of their potential to produce large changes in predation dynamics, and because in published studies low concentrations of Cu produced behavioral changes in predator-detection in fish. Surprisingly, low but environmentally relevant concentrations of Cu (5 µg/L) combined with chemical cues from a predator (*Aeshna sitchensis*) to produce large changes in the behavior of larval amphibians. Experiments demonstrated that a low concentration of Cu did not inhibit the ability of wood frog tadpoles to detect chemical cues of predators by olfactory means, but produced strong behavioral effects, causing tadpoles to reduce activity and alter microhabitat use. These results occurred with Cu at an exposure level lower than any we could find reported as toxic to amphibians in the literature. When Cu and predator cues were administered together, the activity reduction was additive and stronger at earlier life stages. We suggest that Cu intoxication would be disadvantageous to larval amphibian prey with prolonged exposure to predators during development, and we present field data from 2010 that support this assertion. Our study demonstrates the need to use sensitive behavioral assays and to investigate multiple stressor mechanisms to understand how multiple threats combine to affect organisms in nature." 10618. Riedel, I.R.; Marinoni, R.C.; Martins-Opohs, N. (2011): Spatio-temporal trends of insect communities in southern Brazil. *Journal of Entomology*, 2008: 1897-1902. (in English) ["In this study, insect seasonality using Malaise traps at eight stations was investigated from abundance collections taken between August 1986 and July 1988 in four climatic regions and one transitional region of Paraná State, Southern Brazil. Temperature and humidity were also measured to represent environmental conditions at the eight stations One station was located in the coastal region, one in the coastal mountain range, one in the first and third plateaus and three stations were located in the second plateau. All insects were counted

aiKl identified to order. Randomization-based techniques were used to assess insect abundance variation by season for the nine most abundant taxa. An Analysis of Similarity (ANOSIM) using stations and seasons as factors and a non-metric multidimensional scaling (NMDS) to assess the 2-D projection of station along axes of abundance were used to assess insect community dissimilarities. A Mantels test assessed correlations between the abundance similarity matrix and the matrix for the environmental factors. Of the most common orders, the most abundant was Diptera, followed by Hymenoptera, Lepidoptera, Collembola, Homoptera, Coleoptera, Psocoptera, Orthoptera and Hemiptera. Insect orders were generally most abundant during the spring and summer, but least abundant during the winter. Following ANOSIM analysis, station location and season best explained variations in abundance. The NMDS analysis found that the coastal station differed most from all the other stations. Humidity was positively correlated with insect abundance." (Authors) Taxa including Odonata are treated at the order level.] Address: Riedel, I.R., Gulf Coast Research Laboratory, University of Southern Mississippi, 703 E. 10619. Robson, B.J.; Chester, E.T.; Austin, M. (2011): Why life history information matters: drought refuges and macroinvertebrate persistence in non-perennial streams subject to a drier climate. *Marine and Freshwater Research* 62(7): 801-810. (in English) ["In some arid, semi-arid or Mediterranean climate regions, increased water extraction combined with climate change will prolong periods of drought in non-perennial streams, but the effects on macroinvertebrate populations are poorly understood. Drought refuges allow species to survive drying but their use depends on species' traits, and refuge availability depends on landscape structure. This review evaluates the utility of existing ecological concepts for predicting the role of drought refuges for sustaining biodiversity in non-perennial streams. We also suggest traits that may determine invertebrate species' resistance or resilience to prolonged drying. Parts of the likely responses by populations to increased stream drying are described by existing ecological concepts, such as the biological traits of species and their interaction with the habitat template, barriers to dispersal and metapopulation dynamics, the use of drought refuges, habitat fragmentation and population and landscape genetics. However, the limited knowledge of invertebrate life histories in non-perennial streams restricts our ability to use these concepts in a predictive manner. In particular, reach or pool occupancy by species cannot be accurately predicted, but such predictions are necessary for evaluating potential management actions such as the use of environmental flows to sustain drought refuges during dry periods." (Authors) The paper includes several references to Odonata.] Address: Robson, Belinda, School of Environmental Sciences, Murdoch University, 90 South Street, Murdoch, WA 6150, Australia. 10622. Rosset, V.; Oertli, B. (2011): Freshwater biodiversity under climate warming pressure: Identifying the winners and losers in temperate standing waterbodies. *Biological Conservation* 144(9): 2311-2319. (in English) ["Climate warming is affecting the biodiversity all around the world, resulting in the expansion or contraction of the geographical range of species, and leading to colonisation (winners) and extinction (losers) events in ecosystems. It is crucial for the conservation of biodiversity to identify these potential winners and losers. We focus here on small standing waterbodies in Switzerland and on five taxonomic groups: vascular plants, snails, beetles, dragonflies and amphibians. We first assessed the sensitivity of each species to climate warming through their thermal preferences, using current altitudinal and latitudinal distribution, as a surrogate for temperature. We then evaluated the resilience of species to perturbations through five ecological and biogeographical criteria applicable to the perturbation "warming": dispersal ability, degree of habitat specialisation, geographical extent in the study area, future trend in geographical extent, and future trend of habitat availability for species. Potential winners and losers of a warming climate could be quantified through their thermal preferences. The proportion of potential losers ranged from zero species for snails to 33% of the regional species pool for dragonflies. The set of potential winners was much larger, ranging from 53% for amphibians to 61% for dragonflies. A multimetric index combining the five resilience criteria enabled the further prioritisation of the species along a gradient of extinction risk. This potential threat from climate warming is not reflected by the current Red Lists of dragonflies and amphibians, suggesting that conservation management could gain from a complementary label indicating the degree of sensitivity to warming. Highlights: › Climate warming will lead to colonisation (winners) and extinction (losers) events. › We quantified the potential winners and losers in Swiss small standing waterbodies. › The proportion of losers was smaller than the proportion of winners. › A resilience index further prioritizes the species along an extinction risk gradient. › The potential threat from climate warming is not reflected by the current Red Lists." 10623. Ruzzante, D.E.; Walde, S.J.; Macchi, P.J.; Alonso, M.; Barriga, J.P. (2011): Phylogeography and phenotypic diversification in the Patagonian fish *Percichthys trucha*: the roles of Quaternary glacial cycles and natural selection. *Biological Journal of the Linnean Society* 103: 514-529. (in English) ["Current patterns of genetic and morphological diversity are the product of historical climatic and geomorphological events, and of contemporary selection processes acting upon this diversity. Here we examine the phylogeographic and phenotypic patterns of diversity within *Percichthys trucha*, a widely distributed Patagonian fish species complex that inhabits Andean and steppe freshwater environments. Molecular analysis (mtDNA control region) of 21 populations distributed throughout its latitudinal range revealed little evidence of phylogeographic structure and no evidence of species-level genetic divergence east of the Andes. The complex, however, exhibits high levels of intra- and interpopulation phenotypic variation. Patterns of among-population divergence in morphology were most easily explained by differences in predation pressure among populations; dorsal fin spines (commonly a defensive characteristic) were longer in environments with greater densities of potentially piscivorous fish. Trophic characters were highly variable within populations, suggesting an important role for resources in generating within-population morphological variation. The very shallow levels of divergence shown by the molecular data most likely reflect the historical mixing of populations as a result of the climatic and landscape changes that affected Patagonia throughout the Quaternary. The phenotypic divergences, in contrast, are probably the result of differing contemporary selection regimes acting on currently disjoint populations. [...] The two diet items with the highest loading on PC1 are Odonata and Chironomid larvae and pupae [...] Some of the variation in diet could be associated with variation in morphology: for instance, populations that relied heavily on Odonata tended to have relatively short gill rakers and jaws compared with those that did not feed on Odonata. We do not know the nature of any links between diet and trophic morphology for *Percichthys*: adult morphology is almost certainly influenced by the diet of early developmental stages, and diet can also be affected by predation regime." 10624. Rychła, A.; Benndorf, J.; Buczyński, P. (2011): Impact of pH and conductivity on species richness and community structure of dragonflies (Odonata) in small mining lakes. *Fundamental and Applied Limnology / Archiv für Hydrobiologie* 179(1): 41-50. ["Although acidification in freshwaters reduces the richness of aquatic species in general, dragonflies are less affected. However, detailed knowledge regarding the effects of very acidic (pH < 4.0) and highly conductive (> 700 $\mu\text{S cm}^{-1}$) water on dragonfly species richness and composition is still scarce. To assess this, 19 anthropogenically influenced waters with a wide range of pH (2.64 - 6.81) and conductivity (113 - 2620 $\mu\text{S cm}^{-1}$) were investigated in the Muskau Arch area (western Poland, eastern Germany). Of the 41 dragonfly species found, 31 were autochthonous. Both total (St) and autochthonous (Sa) species richness correlated positively with pH and negatively with conductivity. How-

ever, the correlations for autochthonous species were strongly influenced by the samples from the extremely acidic (pH 2.64 - 2.86) and most ion-rich (conductivity > 1200 $\mu\text{S cm}^{-1}$) waters, where no species developed. The Sa values from acidic waters with slightly higher pH values (between 3.0 and 4.0) did not differ significantly from those found in neutral waters. Nevertheless, species preferring acidic or neutral conditions, respectively, were clearly separated, showing a direct or indirect effect of pH on the community structure in the area. We thus conclude that only pH values below 3.0 and conductivity above 1200 $\mu\text{S cm}^{-1}$ have a detrimental effect on dragonflies. Other acidic waters are suitable habitats for specialists, which do not develop in neutral waters. Thus, moderate acidification enhances the dragonfly species richness of a region like the Muskau Arch area." 10626. Samways, M.J.; Sharratt, N.J.; Simaika, J.P. (2011): Effect of alien riparian vegetation and its removal on a highly endemic river macroinvertebrate community. *Biological Invasions* 13(6): 1305-1324. (in English) ["Invasive alien trees along river banks can reduce indigenous biodiversity, while their removal can restore it. We assessed here family- and species level responses of river benthic macroinvertebrate assemblages to three riparian vegetation types (natural, alien trees, cleared of alien trees) in the Cape Floristic Region biodiversity hotspot. High species beta diversity of this highly endemic fauna meant that between-river, as well as seasonal effects, dominated assemblage patterns. SASS5, a qualitative, rapid bioassessment technique, based on the sensitivity of the families present, was used as a measure of river health and, indirectly, of water quality. SASS indicated a decline in water quality conditions after alien clearing, a likely response to the greater insolation and apparent erosion of cleared banks, resulting in elevated temperatures and suspended solids and lowered oxygen levels. Overall, cleared and natural sites were more similar to each other than to alien sites, suggesting some post-clearing recovery. However, many sensitive, endemic taxa survived in alieninvaded sites, and more than in the natural sites. These endemic species made use of shady, cool, high oxygen levels under the alien tree canopy. However, endemics declined in overall abundance in sites cleared of aliens, being replaced by more tolerant, widespread taxa. Clearance of the alien trees opened up the rivers to sunny conditions, which had a major impact on community composition. Vegetation types, oxygen levels and river width were important environmental variables affecting these macroinvertebrate responses. Re-establishment of invertebrate biodiversity matched that of indigenous vegetation, with the most sensitive endemic taxa only recovering after establishment of bushy

indigenous and shade-producing fynbos. Therefore, for biodiversity conservation objectives to be achieved, it is essential that indigenous plants are maintained and encouraged during and after clearing to ensure the recovery of endemic and sensitive taxa." (Authors) All taxa are identified on the species level and include Ephemeroptera, trichoptera, Odonata, and Plecoptera.] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. 10627. Sánchez-Guillén, R.A.; Wellenreuther, M.; Cordero-Rivera, A.; Hansson, B. (2011): Introgression and rapid species turnover in sympatric damselflies. *BMC Evolutionary Biology* 11:210. (in English) ["Background: Studying contemporary hybridization increases our understanding of introgression, adaptation and, ultimately, speciation. The sister species *Ichnura elegans* and *I. graellsii* are ecologically, morphologically and genetically similar and hybridize. Recently, *I. elegans* has colonized northern Spain, creating a broad sympatric region with *I. graellsii*. Here, we review the distribution of both species in Iberia and evaluate the degree of introgression of *I. graellsii* into *I. elegans* using six microsatellite markers (442 individuals from 26 populations) and five mitochondrial genes in sympatric and allopatric localities. Furthermore, we quantify the effect of hybridization on the frequencies of the genetically controlled colour polymorphism in females of both species. Results: In a principal component analysis of the microsatellite data, the first two principal components summarised almost half (41%) of the total genetic variation. The first axis revealed a clear separation of *I. graellsii* and *I. elegans* populations, while the second axis separated *I. elegans* populations. Admixture analyses showed extensive hybridization and introgression in *I. elegans* populations, consistent with *I. elegans* backcrosses and occasional F1-hybrids, suggesting hybridization is on-going. More specifically, approximately 58% of the 166 Spanish *I. elegans* individuals were assigned to the *I. elegans* backcross category, whereas not a single of those individuals was assigned to the backcross with *I. graellsii*. The mitochondrial genes held little genetic variation, and the most common haplotype was shared by the two species. Conclusions: The results suggest rapid species turnover in sympatric regions in favour of *I. elegans*, corroborating previous findings that *I. graellsii* suffers a mating disadvantage in sympatry with *I. elegans*. Examination of morph frequency dynamics indicates that hybridization is likely to have important implications for the maintenance of multiple female morphs, in particular during the initial period of hybridization." 10632. Schröter, A. (2011): Review of the distribution of *Somatochlora sahlbergi* (Odonata: Corduliidae). *International Dragonfly Fund - Report* 41: 1-27. (in English) ["Based on data collected from literature, museum collections, national databases and personal communications, an up-to-date map of the worldwide distribution of *Somatochlora sahlbergi* is presented. A new hypothesis is presented indicating that occurrences are at least regionally correlated with *palsa mires*. Two examples of larval habitats in Europe are illustrated and described, including the

first observation of reproduction in Norway and the first record of co-occurrence with Zygoptera in Europe. The exuvia of *S. sahlbergi* is illustrated and distinguishing features briefly discussed." (Author)] Address: Schröter, A., Rasenweg 10, D-37130 Gleichen, Germany. E-mail: asmustim@gmx.de

10633. Shah, R.D.T.; Shah, D.N.; Neseemann, H. (2011): Development of a macroinvertebrate-based Nepal Lake Biotic Index (NLBI): an applied method for assessing the ecological quality of lakes and reservoirs in Nepal. *Int. J. Hydrology Science and Technology* 1(1/2): 125-146. (in English) ["In Nepal, the impairment status of lakes and reservoirs has generally been measured and classified based on nutrient concentrations and physico-chemical parameters, typically with no direct measurement of biological communities. In response to the recent focus on the bioassessment of lakes and reservoirs, the macroinvertebrate-based Nepal Lake Biotic Index (NLBI) has been developed. Benthic samples were collected from reference and impaired lakes during 2006 and 2009 from two ecological zones: Terai-Siwaliks and Mid-Hills. We used a tolerance score based on a ten-point scoring system ranging from very pollution sensitive to very pollution tolerant taxa to calculate the NLBI. In reference to the transformation scale, the calculated NLBI describes the lake water quality as high, good, fair, poor and bad. Candidate metrics of richness measures and tolerance measures discriminated well between the reference and impaired lakes (Mann-Whitney U test, $p < 0.01$). The relationships between the biological metrics and the environmental variables were also established with the lake water quality class (LWQC). Further, the validation of the NLBI performance was done by assessing nine lakes/reservoirs from both the zones. Thus, the index presented here provides an effective method to measure the ecological condition of lakes and reservoirs in Nepal." (Authors) Taxa - including Odonata - are treated at the order level.] Address: Shah, R.D.T., Hindu Kush Himalayan Benthological Society, Bhaktapur, P.O. Box 20791, Sundhara, Kathmandu, Nepal. E-mail: ramdevishah@hkhbenso.org

10634. Sharma, K.K.; Chowdhary, S. (2011): Macroinvertebrate assemblages as biological indicators of pollution in a Central Himalayan River, Tawi (J&K). *International Journal of Biodiversity and Conservation* 3(5): 167-174. (in English) [Jammu and Kashmir, India; "Benthic macroinvertebrate assemblages at sub-tropical River of Jamu, River Tawi, corresponding to different catchment land uses, were assessed in 2008 to 2009 as indicators of water quality. The relative diversity, species richness, dominance, evenness indices, physico-chemical parameters and percentage of Annelida + Arthropoda + Mollusca (AAM) individuals were determined. Significant spatio-temporal variation was observed in relative diversity, with Diptera dominating the study area instead of Annelida, Odonata, Ephemeroptera, Hemiptera and Gastropoda. Significant relationships were recorded between physico-chemical parameters [...] and the occurrence of specific genera. Significant changes in macroinvertebrate assemblages were primarily due to changes in water quality. As elsewhere, macroinvertebrate communities proved to be good indicators of water quality and should be used as bioindicators in long-term monitoring of this river." (Authors) The taxa list includes "Ophiogomphus sps., Perithemis sps., Progomphus sps." probably identified by use of "Pennak, R.W. (1978). Fresh water invertebrates of United States."] Address: Sharma, K.K., Dept of Zoology,

University of Jammu-180006, Jammu and Kashmir, India. E-mail: prof.ksharma@gmail.com

10636. Shoukry, N.M.; Morsy, T.A. (2011): Arthropod borne diseases at Toshka, Upper Egypt. *World Journal of Zoology* 6(2): 126-133. (in English) ["The Egyptian Government plan to move in 25 years from an inhabited area of 6-25% of the total Nile land area to a larger one to compensate the huge increase of Egyptian populations. The decision was recently made to begin a development project at Toshka, on the western bank of the River Nile, Upper Egypt. Toshka depression is more or less close to Wadi Halfa of Sudan. Therefore, it was necessary to develop of Toshka on the west bank of the River Nile. Consequently, two specialized teams, one is national and the other is from WHO, were interested to study the health risk impact of the project on the vector-borne diseases and pests and to plan recommendations for prevention and feasible control of these diseases. The present study was initiated during spring of 2007 & 2008, as spot light survey, on wild rodents and the arthropods having medical and/or veterinary importance. Whilst *Psammomyes obesus* Cretzschmar, 1828 was the only recognized rodent, the following arthropods were identified: the scorpion, *Buthus quinquestriatus* Hanté en E., the insects, *Cephus tabidus* (F.), *Ischnura senegalensis* (Rambur, 1842), *Mantis religiosa* Linnaeus, 1758 and *Tabanus taeniola* Palisot de Beauvois, *Culicoides riethi* Kieffer, *Anopheles sergenti* Theobald and *Phlebotomus papatasi* (Scopoli). The medical, veterinary and agriculture importance of each species have been discussed and feasible control measures were suggested." (Authors) In contrast to this statement any medical, veterinary or agricultural importance of *I. senegalensis* is not discussed.] Address: Morsy, T.A., Dept of Parasitology, Faculty of Medicine, Ain Shams University, Cairo, 11566, Egypt. 10637. Silva, F.L.; Oliveira, H.R.N.; Escarpinati, S.C.; Fonseca-Gessner, A.A.; Paula, M.C. (2011): Colonization of leaf litter of two aquatic macrophytes, *Mayaca fluviatilis*, *Aublet* and *Salvinia auriculata*, *Aublet* by aquatic macroinvertebrates in a tropical reservoir. *Ambi-Água, Taubaté* 6(1): 30-39. (in English, with Portuguese summary) ["Decomposition and colonization of *S. auriculata* and *M. fluviatilis* by macroinvertebrates were analyzed during 40 days to determine whether differences existed on colonization by aquatic macroinvertebrates of two macrophytes with distinct habits (submerged versus fluctuant). Leaf litter of *S. auriculata* and *M. fluviatilis* were incubated in 24 litter bags (12 of each species), in a small reservoir surrounded by a cerrado fragment with low level of anthropic impact. After 10, 20, 30 and 40 days, the litter bags were removed and aquatic macroinvertebrates community was analyzed. 220 macroinvertebrates were associated with *S. auriculata* and 261 were associated with *M. fluviatilis*, identified in 24 taxa. Both macrophyte species were colonized mainly by macroinvertebrate predators. *Ablabesmyia* with predator and collector food mechanisms was present in all sampling. The data showed an expressive increase of abundance during the process of decomposi-

tion and a decrease at the end of the experiment, in both macrophytes. Cluster analysis permitted inference that the colonization of the leaf litter by macroinvertebrates was determined by incubation time of leaf litter not by the habit of macrophytes (submerged or fluctuant)." (Authors) A single specimen of "Lestidae" was found among leaf litter of *M. fluviatilis* on the tenth and twentieth days.] Address: da Silva, F.L., Univde Federal de São Carlos - UFSCar, Depart. de Hidrobiologia, Laboratório de Entomologia Aquática, Brasil. 10638. Soluk, D.A.; Zercher, D.S.; Worthington, A.M. (2011): Influence of roadways on patterns of mortality and flight behavior of adult dragonflies near wetland areas. *Biological Conservation* 144(5): 1638-1643. (in English) ["The relatively low population size and long adult lifespan of dragonflies (Odonata, Anisoptera) makes them one of the few non-vertebrate groups likely to be impacted by direct roadway mortality. We studied adult dragonfly mortality and behaviour associated with roadways for a number of species. Daily mortality rates for dragonflies were estimated from standardized surveys along predetermined lengths of roads. Relative abundance and flight behaviour around and across roadways, a potentially important mortality factor, was determined from timed roadside observations. Observed flight behaviour provided no evidence that roads act as significant barriers to dispersal for adult dragonflies. Estimated mean number killed ranged from 2 to 35 dragonflies/km/day. Species varied greatly in their susceptibility to motor vehicles. Two species (*Plathemis lydia* and *Libellula luctuosa*) made up more than 70% of the dead dragonflies collected, but only represented 14% and 31% of live dragonflies observed, respectively. The relatively low flight heights of these two species over roads (typically under 2 m) may explain their susceptibility; however, another common species (*Tamea lacerata*) also exhibited low flight height but did not experience high mortality, possibly because of its increased flight agility. Large numbers of adult dragonflies were killed over the entire flight season by motor vehicle collisions, exhibiting the need for assessing the long-term impact of roadway mortality on dragonfly population dynamics." (Authors)] Address: Zercher, Deanna, The Nature Conservancy, 11304 North Prairie Road, Lewistown, IL 61542, USA. E-mail: dzercher@tnc.org

10639. Spyra, A. (2011): Autochthonic and allochthonic plant detritus as zoobenthos habitat in anthropogenic woodland ponds. *Oceanological and Hydrobiological Studies* 40(1): 27-35. (in English) ["Regardless of origin, all water bodies situated inside forests form a unique habitat for many freshwater animals due to the allochthonous detritus covering the bottom, composed mostly of leaves from waterside trees. For many years these woodland ponds have been considered to be advantageous to regional biodiversity. Investigations were carried out in eight anthropogenic woodland ponds, formed as a consequence of coal mining activities, situated in forest complexes in Upper Silesia (Southern Poland), to evaluate the impact of allochthonic and autochthonic plant detritus on the formation of zoobenthic communities, together with insolation intensity. In sites covered by a layer of allochthonic plant matter, zoobenthos were more abundant compared to places covered by autochthonic detritus. The density of zoobenthos in sun-exposed sites was two to three times greater than in shaded sites." (Author) Taxa - including Coenagrionidae, Aeschnidae, Libellulidae - are treated at the family level.] Address: Spyra, Aneta, Dept of Hydrobiology Faculty of Biology and Environmental Pro-

tection, The University of Silesia, ul. Bankowa 9, 40-007 Katowice, Poland. E-mail: aneta.spyra@us.edu.pl

10640. Staniczek, A.H.; Bechly, G.; Godunko, R.J. (2011): Coxoplectoptera, a new fossil order of Palaeoptera (Arthropoda: Insecta), with comments on the phylogeny of the stem group of mayflies (Ephemeroptera). *Insect Systematics & Evolution* 42(2): 101-138. (in English) ["*Mickoleitia longimanus* gen. et sp.n. is described from the Lower Cretaceous limestone of the Crato Formation in Brazil. It is attributed to a new family Mickoleitiidae and a new fossil insect order Coxoplectoptera within the palaeopterous Ephemera, based on the presence of an elongated costal brace. This fossil insect exhibits a very peculiar combination of derived characters like specialized forelegs with strongly elongated, free coxae, single-clawed pretarsus, and distinctly skewed pterothorax as in dragonflies. On the other hand, several plesiomorphies are present that exclude this taxon from modern Ephemeroptera, namely large hind wings with widened anal area and numerous cross veins that separate the elongate costal brace from the costal margin. Fossil larvae described by Willmann as larval *Cretereismatidae* are herein attributed to Mickoleitiidae fam. n., based on the shared presence of broad hind wing buds with distinctly broadened anal area, wing bud venation similar to the adult holotype, and subchelate forelegs with elongate free coxae. These larvae are also highly autapomorphic in the structure of their abdominal gills and laterally flattened body with vertically oval section that is unique within Ephemera. On the other hand they possess plesiomorphic lateral wing pads with pronounced articulation like Palaeozoic pterygote larvae, while wing pads in modern insects are always secondarily fused to the tergum. A similar fossil larva from the Jurassic of Transbaikals was earlier described as *Mesogenesia petersae* and classified within modern mayflies. It is herein attributed to Mickoleitiidae fam.n. Coxoplectoptera are recognized as putative sister group of modern Ephemeroptera based on the shared presence of only 7 pairs of abdominal gills, while Permoplectoptera still have retained 9 pairs of gills. The phylogenetic reclassification of the mayfly stem group by Willmann is critically discussed and modified." (Authors) Phylogenetic relationships to dragonflies are discussed.] Address: Bechly, G., Staatliches Museum für Naturkunde, Abt. Paläontologie, Rosenstein 1, D-70191 Stuttgart, Germany. 10641. Strobbe, F.; McPeck, M.A.; De Block, M.; Stoks, R. (2011): Fish predation selects for reduced foraging activity. *Behavioral Ecology and Sociobiology* 65(2): 241-247. (in English) ["Despite the importance of foraging activity for the growth/predation risk trade-off, studies that demonstrated predator-induced survival selection on foraging activity under semi-natural conditions are relatively rare. Here, we tested for fish-induced selection for reduced foraging activity in two larval *Enallagma* damselflies using a field enclosure experiment. Fish imposed considerable mortality in both damselfly species and survival selection on foraging activity could be detected in *Enallagma geminatum*. We did not detect selection in *E. hageni*, probably because this species already was not eating very much in the absence of fish compared to *E. geminatum*. Both species responded strongly to the presence of predators by reducing their foraging activity. The documented survival selection on foraging activity was detected despite the already low activity levels in fish lake prey species and despite strong predator-induced plasticity in this trait." 10643. Suhail, M.A.; Arshad, M.; Arif, J.; Gogi, M.D. (2011): Conservation of beneficial insects for sustainable agriculture. In: H. Gökçekuç et al. (eds.): *Survival and Sustainability, Environmental Earth Sciences, Part 9*. Springer-Verlag Berlin Heidelberg: 1463-1468. (in English) ["Insects are the most diverse group of organisms and are 3/4th of all described forms of life. Potentially they are highly indicative of environmental change through close adaptation to their environment. Migratory insect species are at the verge of extinction owing to increasing trend in global warming. Insect fauna also represent the majority of links in the community food chain and they likely have the largest biomass of the terrestrial animals. While the positive values of the insect fauna is remarkably more than that of their negative values. They act as pollinators and bio-control agents in the agro-ecosystem and have better impact for the development of sustainable agriculture. Thus, knowledge about them is fundamental to study the environment. One to three million insect species are identified worldwide while 2,000 from Pakistan. Out of which more than 954 species from 10 orders are identified/explored by the "Insect Biodiversity and Biosystematics Lab", Department of Agri-Entomology, University of Agriculture, Faisalabad, Pakistan. Of the described species in the order Orthoptera (Grasshoppers, Crickets, 279), Odonata (Dragonflies, 130), Lepidoptera (Moths and Butterflies, 82), Diptera (Syrphids, Fruitflies, Clypterate species 187), Homoptera (Aphids, Whiteflies, 65), Thysanoptera (Thrips, 52), Neuroptera (Antlion, Chrysopids, 42), Dictyoptera (Mantids, 32), Hemiptera (Reduviid & Anthocorid Bugs, 11) and Hymenoptera (Braconids, 17). The abundance of bee forage plants throughout the year determines the growth of honey bee colonies and hence the productivity of bee farming. Pakistan is endowed with more than 700 plant species. Out of which entomophilous crops cover 7.3 million hectares of land and forest more than 10 million hectares which can support 0.4–0.5 million honey bee colonies. Despite fairly abundant floral sources and quite suitable climatic conditions for keeping bees in the country, honey production (1000 tonnes) from 3,00,000 colonies is much below to its exploitable potential. All of this work has been completed by students M.Sc/Ph.D theses research and many students are working on different groups of insect fauna and their biodiversity. Eleven species of scarabid beetles (Coleoptera) have been identified recently on molecular level by DNA characterization. Many other identified species specimens, are placed in the departmental insectarium, which are not mentioned in this report." 10645. Szkokan-Emilson, E.J.; Wesolek, B.E.; Gunn, J.M. (2011): Terrestrial organic matter as subsidies that aid in the recovery of macroinvertebrates in industrially-damaged lakes. *Ecological Applications* 21: 2082-2093. (in English) ["The importance of allochthonous carbon to the productivity of stream ecosystems in temperate ecozones is well understood, but this relationship is less established in oligotrophic lakes. The nearshore littoral zones, at the interface of terrestrial and aquatic systems, are areas where the influence of terrestrial subsidies is likely greatest. We investigated the response of nearshore communities to variation in the quantity and composition of allochthonous materials, determined the landscape characteristics that regulate the variation of this subsidy, and explored the potential for terrestrial restoration practices to influence the export of organic matter to lakes. Stepwise multiple regressions revealed that diversity of nearshore macroinvertebrate families increased with the amount of fine particulate organic matter (FPOM) captured in sediment traps. The quantity of FPOM (g) increased with forest cover, and the relative amount of FPOM (percentage of total particulate material) in the traps increased with surface area of wetland in the catchments. These models suggest that terrestrially derived subsidies are important in smelter-impacted watersheds, and that the restoration of forests and wetlands will speed the return of nearshore consumer community diversity in industrially damaged lakes." (Authors) Predators include (at the family level) Aeshnidae, Coenagrionidae, Corduliidae, and Libellulidae.] Address: Szkokan-Emilson, E.J., Cooperative Freshwater Ecology Unit, Biology Dept, Laurentian Univ., 935 Ramsey Lake Road, Sudbury, Ontario P3E 2C6 Canada. 10646. Takhelmayum, K.; Gupta, S. (2011): Distribution of aquatic insects in phumdis (floating island) of Loktak Lake, Manipur, northeastern India. *Journal of Threatened Taxa* 3(6): 1856-1861. (in English) ["A study was made on the temporal fluctuations of distribution of aquatic insects around Phumdi Live (PL), Phumdi Mixed (PM) and Phumdi Dry (PD) areas of Loktak Lake. Phumdis are a heterogeneous mass of soil, vegetation and organic matter. The study revealed the presence of predators, and the absence of herbivores and detritivores in both PL and PM, the PD area was totally devoid of insects. Although both the habitats supported the same predator groups hemiptera and odonata, diversity and density in terms of family and species were higher in PL than in PM. Temporal fluctuations revealed that the Shannon-Weiner's Diversity Index values were highest in June for both PL (0.726) and PM (0.47). In both the sites the highest density was recorded in February. The relative abundance of hemiptera was higher than that of odonata in most of the months in PL. Phumdi Mixed was represented by one species of hemiptera only, in the month of February and dominated by odonates otherwise. Community composi-

tion of Odonata larvae did not show any difference between the two habitats. Although the study revealed low diversity and density of insects in both sites, the PL community provided a better habitat to aquatic insects than that of PM. These are of value as fish food and in turn for fish production." 10652. Tschanz, B.; Hegglin, D.; Gloor, S.; Bontadina, F. (2011): Hunters and non-hunters: skewed predation rate by domestic cats in a rural village. *Eur. J. Wildl. Res.* 57: 597-602. (in English) [Finstersee (70 households, 0.25 km², 47°10'N 8°37'E), Switzerland; "Domestic cats *Felis catus*, as companion animals provided with supplemental food, are not limited by the availability of wild prey and locally occur at extraordinary high densities. There is growing concern about the potential impact of large cat numbers on native prey populations. In the present study, we quantified the minimum number of animals killed in a rural village in Switzerland by asking owners (1) to estimate the predation rate in advance and (2) to record prey animals returned home by their pets. The frequency distribution of the numbers of prey items was markedly skewed: 16% of the cats accounted for 75% of prey, irrespective of sex, age or breed. A large fraction of owners considerably overestimated their cat's predation, indicating that surveying predation rates by means of a questionnaire alone is not sufficient. The observed average rate of predation within 48 days in spring was 2.29 prey items/cat/month (N=32 cats); major prey types were rodents (76.1%) and birds (11.1%). The absolute number of prey items taken per area is striking and indicates that cat predation represents an important factor in ecosystems. Its role may be momentous in intensively fragmented urban habitats, where cat densities are especially high." (Authors) 25 of the prey items accounted to insects and included four Odonata specimens.] Address: Bontadina, F., SWILD, Urban Ecology and Wildlife Research, Wuhstr. 12, 8003, Zürich, Switzerland. 10655. Uieda, V.S.; Pinto, T.L.F. (2011): Feeding selectivity of ichthyofauna in a tropical stream: space-time variations in trophic plasticity. *Community Ecology* 12(1): 31-39. (in English) ["In studies on the partitioning of resources, one issue which has been largely neglected is the change in feeding habits based on the availability of food in the environment, an aspect which is dealt with here with regard to the ichthyofauna of a tropical stream. Feeding preference was analyzed for eight species of fish which consumed high percentages of aquatic insects, based on a collection of fish and invertebrates during both the dry season (June 2006) and the wet season (December 2006) and in two different stretches of the stream, one of which shaded by gallery forest ("closed area") and the other just bordered by herbaceous vegetation ("open area"). Based on a quantitative analysis of the composition of the benthic fauna and the diet of the ichthyofauna, the electivity index was calculated in order to assess potential alterations in the feeding preferences in line with seasonal and spatial modifications to the structure of the habitat and the supply of food. The analysis of the abundance of aquatic insects in the environment showed a predominance of Ephemeroptera in all situations analyzed (areas and seasons), with this insect group being the food item preferred by the majority of fish. However, space-time variations were observed in prey selection by the ichthyofauna. The analysis of supply, consumption and preference demonstrated somewhat varied situations for the majority of species, with both high and low selectivity for items consumed in low and high percentages, with the preferred item varying both spatially and seasonally. The sole exception to this was *Phalloceros harpagos*, choosing Diptera-Chironomidae in all the situations analyzed." (Authors) Odonata are represented at the family level by Aeshnidae, Calopterygidae, Coenagrionidae, and Corduliidae] Address: Uieda, V.S., UNESP — Univ Estadual Paulista Department of Zoology C.P. 510 18618-970 Botucatu, SP Brazil. 10656. van Damme, K.; Banfield, L. (2011): Past and present human impacts on the biodiversity of Socotra Island (Yemen): implications for future conservation. *Zoology in the Middle East, Supplementum* 3: 31-88. (in English) ["The Socotra Archipelago (Yemen) is globally recognized for its outstanding biodiversity and endemism, designated on this basis a UNESCO World Heritage Site in 2008. The island underwent long geological and political isolation, ensuring preservation of unique ecosystems until the start of the new millennium. Now, Socotra Island is undergoing rapid development, out of balance with conservation. Major causes for biodiversity loss in other global insular ecosystems such as habitat fragmentation and degradation, pollution, invasive species and the impact of tourism, are becoming pressing issues that deserve close attention. Unsustainable resource use, the loss of traditional land management and illegal trade in biota are worrying phenomena that further increase the pressures on Socotra's ecosystems. We provide the first comprehensive review of potential human impacts on Socotra before the 21st century, an updated discussion of some of the principal threats to its biodiversity in recent

times, discussing local examples within a historical context of known extinction processes on islands, and underline the importance of traditional knowledge in the protection of Socotran ecosystems." (Authors) The paper includes references to the local extinction of *Rhyothemis semihyalina* (Odonata) in the Hadiboh Plain.] Address: Van Damme, K., Department of Biology, Ghent University, K. L. Ledeganckstr. 35, 9000 Ghent, Belgium. E-mail: kay.vandamme@gmail.com.

10657. Van Duzor, R.G. (2011): Community structure and secondary production of aquatic macroinvertebrates in coastal wetland ponds of the west copper river Delta, Alaska, following tectonic uplift. M.Sc. thesis, Dept Biology, Loyola University Chicago: 75 pp. (in English) ["The Great Alaska Earthquake of 1964 (magnitude 9.2) greatly altered the coastal landscape in southcentral Alaska and had particularly dramatic effects on the Copper River Delta (CRD), an ecologically and economically important area within the Chugach National Forest. The earthquake caused tectonic uplift (up to 3.5m) of the CRD coastal tidal marsh and transformed it into a perched freshwater marsh. Copper River Delta ponds, which are crucial habitat to a myriad of migrating songbirds, shorebirds, and waterfowl, are of particular interest to wildlife managers in the CRD and along the Pacific coasts of North, Central and South America. This study was conducted to characterize the general ecology of CRD ponds, with particular focus on aquatic insect communities. Twelve ponds in two geomorphologic zones were studied to compare physicochemical characteristics, aquatic insect community structure and annual secondary production. Six ponds were in the Uplifted Marsh (UM), which was formed as a result of the tectonic uplift, and six ponds were in the Outwash Plain (OP), an area that was present before the earthquake and was relatively unaffected by tectonic activity. Uplifted Marsh and OP ponds were similar with respect to basic physicochemical parameters. *Callicorixa vulnerata* (Uhler 1861) (Hemiptera: Corixidae) was the numerically dominant non-dipteran taxon in 11 of the 12 study ponds and represented 30-81% of all non-dipterans collected. Densities of the numerically dominant predators, *Aeshna* spp. and *Enallagma* spp. were higher in OP ponds (<1-20/m²) compared to UM ponds (<1-4/m²), and production was 5X higher in OP than in UM ponds (507 vs. 97 mg AFDM/m² /yr). In contrast, secondary production of aquatic insect primary consumers such as *Agrypnia* spp. (Trichoptera: Phryganeidae) and *Nemotaulius hostilis* (Hagen 1873) (Trichoptera: Limnephilidae), although found in relatively low densities (<1-3.3/m²), was almost 10X higher in UM ponds than in OP ponds (246 vs. 30 mg AFDM/m² /yr). Overall, annual secondary production of non-dipterans was greater in UM ponds than in OP ponds (3091 vs. 2205 mg AFDM/m² /yr). Results from this study indicate distinct differences in aquatic insect community structure, secondary production, and functional feeding group composition in UM and OP ponds. Creation of the UM ecosystem by tectonic disturbance increased the availability of suitable habitats for aquatic insects, particularly primary consumers, e.g., Trichoptera, and omnivores, e.g., *C. vulnerata*, which subsequently colonized UM ponds to take advantage of the newly abundant primary food resources (aquatic vegetation). In comparison, more mature OP ponds supported higher densities of aquatic insect predators, particularly Odonata, while supporting lower densities of Trichoptera and *C. vulnerata*." 10658. van Hardenbroek, M.; Heiri, O.; Wilhelm, M.F.; Lotter, A.F. (2011): How representative are subfossil assemblages of Chironomidae and common benthic invertebrates for the living fauna of Lake De Waay, the Netherlands? *Aquatic Science* 73: 247-259. (in English) ["The distribution of benthic invertebrates and their subfossil remains was examined within the basin of De Waay, a dimictic, eutrophic lake in the Netherlands. We focused on Chironomidae, but also report the abundances of 11 invertebrate groups that potentially produce chitinous remains that are preserved in the fossil record, although their remains could only be identified at a coarser taxonomic resolution. Most living invertebrates sampled in different seasons were constrained to the littoral zone, with the exception of a few taxa (*Ceratopogonidae*, *Chaoborus flavicans*, and *Chironomus*) that are adapted to low oxygen conditions in the seasonally anoxic profundal zone. In contrast, assemblages of invertebrate remains in lake surface sediments were similar in the entire lake basin, suggesting that considerable numbers of invertebrate remains are transported and redeposited off-shore in Lake De Waay, due to its steep bathymetry. These results indicate that a single sediment sample obtained from the centre of this lake contains subfossil invertebrate remains originating from the entire lake basin. In Lake De Waay, the majority of taxa found in the living assemblages were identified as remains in lake surface sediments, at least for the Chironomidae that could be identified at a similar taxonomic level in living and subfossil assemblages. [...] Our results indicate that subfossil assemblages in surface sediment samples provide spatially integrated and representative samples of the living assemblage. However, a combined approach examining both the living benthic invertebrate fauna and invertebrate remains in lake surface sediments will potentially give a more complete and detailed overview of benthic invertebrates in a lake ecosystem than an approach based exclusively on one of these groups." (Author) *Aeshna mixta* and *Ischnura elegans* were representatives of the living assemblage, "Odonata" of the subfossil.] Address: van Hardenbroek, M., Laboratory of Palaeobotany & Palynology, Institute of Environmental Biology, Palaeoecology, Utrecht University, Budapestlaan 4, 3584 CD Utrecht, The Netherlands. 10661. Vilenica, M.; Micetić Stanković, V.; Franković, M. (2011): Dragonfly fauna (Insecta, Odonata) in the Turo-polje region (Croatia). *Natura Croatica* 20(1): 141-158. (in English, with Croatian summary) ["This study presents the results of dragonfly fauna research in the Turo-polje region of Croatia. Faunal analyses were conducted in the period from 1986–2009, with some interruptions, while an ecological analysis (composition of dragonflies ac-

ording to habitat characteristics such as vegetation structure, air temperature, cloudiness) was conducted in the period 2007–2009. Faunal and ecological analyses were carried out at seventeen and nine localities, respectively. A total of 35 dragonfly species was recorded, indicating high species richness in comparison to the total number of 67 species known in Croatia. Zoogeographic analysis of the recorded dragonfly species showed the domination of the Holo-Mediterranean element which indicates complex glaciation and interglaciation processes during the geological past in Europe, when the Croatian territory served as a refugium. The results show that the distribution and abundance of dragonflies are indicative of habitat characteristics (vegetal structure, cloudiness and air temperature). Dragonflies prefer mosaic habitats (diverse vegetation structure) with average air temperatures ranging from 26–28°C and sunny weather. Since this research was conducted in only a part of the whole Turo-polje region, and only adult specimens were sampled, further research should be focused on the life cycles of dragonflies and their distribution throughout the entire Turo-polje region." - 10668.** Weinländer, M.; Füreder, L. (2011): Crayfish as trophic agents: Effect of *Austropotamobius torrentium* on zoobenthos structure and function in small forest streams. *Knowledge and Management of Aquatic Ecosystems* (2011) 401, 22: 15 pp. (in English, with French summary) [Austria; "Crayfish are among the largest and most threatened invertebrates in freshwater habitats. Due to their size, behaviour and feeding activity they may affect structure and function of aquatic ecosystems and their organisms. Despite their importance in many freshwaters and available information on their ecology for several species little is known about the European crayfish *A. torrentium*. In order to evaluate the potential effects of indigenous crayfish presence on the structural and functional composition of the zoobenthic community, we measured population size and densities of three *A. torrentium* populations and compared macroinvertebrate assemblages and physicochemical parameters in three streams with and three without crayfish. The experimental setup considered crayfish effects at a large scale in defined reaches of pristine headwaters in association with the whole benthic fauna under natural conditions. Presence of *A. torrentium* significantly affected zoobenthic abundance, diversity and the relative proportions of functional feeding groups. In crayfish streams, especially Trichoptera and collector gatherers were more abundant and diverse, while sites without crayfish had significantly higher abundances and diversities of shredders and wood feeders. Our study provided strong evidence that the presence of the indigenous crayfish *A. torrentium* had important effects on the trophic cascades of headwater stream communities." (2011): Environmental and climatic determinants of molecular diversity and genetic population structure in a coenagrionid damselfly. *PLoS ONE* 6(6): e20440. doi:10.1371/journal.pone.0020440: 16 pp. (in English) ["Identifying environmental factors that structure intraspecific genetic diversity is of interest for both habitat preservation and biodiversity conservation. Recent advances in statistical and geographical genetics make it possible to investigate how environmental factors affect geographic organisation and population structure of molecular genetic diversity within species. Here we present a study on a common and wide ranging insect, the blue tailed damselfly *Ischnura elegans*, which has been the target of many ecological and evolutionary studies. We addressed the following questions: (i) Is the population structure affected by longitudinal or latitudinal gradients? (ii) Do geographic boundaries limit gene flow? (iii) Does geographic distance affect connectivity and is there a signature of past bottlenecks? (iv) Is there evidence of a recent range expansion and (v) what is the effect of geography and climatic factors on population structure? We found low to moderate genetic sub-structuring between populations (mean $F_{ST} = 0.06$, $D_{est} = 0.12$), and an effect of longitude, but not latitude, on genetic diversity. No significant effects of geographic boundaries (e.g. water bodies) were found. F_{ST} - and D_{est} -values increased with geographic distance; however, there was no evidence for recent bottlenecks. Finally, we did not detect any molecular signatures of range expansions or an effect of geographic suitability, although local precipitation had a strong effect on genetic differentiation. The population structure of this small insect has probably been shaped by ecological factors that are correlated with longitudinal gradients, geographic distances, and local precipitation. The relatively weak global population structure and high degree of genetic variation within populations suggest that *I. elegans* has high dispersal ability, which is consistent with this species being an effective and early coloniser of new habitats." (2011): UV-excited fluorescence on riparian insects except Hymenoptera is associated with nitrogen content. *Psyche* Volume 2011, Article ID 875250: 6 pp. (in English) ["I photographed ultraviolet-excited fluorescence of external resilin on insects in 7 orders, 17 families, and 18 genera collected from shrubs and trees alongside the Colorado River in western Arizona, USA. The localized blue-fluorescence characteristic of resilin was emitted by a variety of structures including sutures and wing articulations on Odonata and Diptera and

membranous wings, compound eyes, or ocelli on Hemiptera, Neuroptera, and Hymenoptera. Different widespread, but blotchy, light-blue fluorescence was observed on cuticles of immature Orthoptera and adult Hemiptera. Insects in Hymenoptera and Coleoptera fluoresced least. Ranked amounts of fluorescence, relative to body area, were positively correlated with ranked nitrogen contents (%N of body dry-mass) of insects in genera excluding Hymenoptera. Nitrogen concentrations in insect exoskeletons appear to increase as abundances of resilin and other fluorescent, elastic proteins increase. These structural compounds may be an important nitrogen source for insectivorous vertebrates." [Figure 3 shows the blue fluorescence in UV light on ventrolateral and dorsal views of the thorax of *Pachydiplax longipennis*.] "Most fluorescence ... was produced by translucent white cuticle attached to the axillary and humeral plates below the base of each front and hind wing. The articulations above the wings similarly fluoresced blue. Broad bands of whitish cuticle ventrally joining the thorax and abdomen also fluoresced. Narrow bands of fluorescence were detected between the front coxa and trochanter, at the bases of the middle and hind coxae, and at the margins of the abdominal sternum." 10681. Zilihona, I.; Heinonen, J.; Nummelin, M. (1998): Arthropod diversity and abundance along the Kihansi gorge (Kihansi River) in the southern Udzungwa Mountains, Tanzania. Journal of East African Natural History 87: 233-240. (in English) ["Arthropod diversity and abundance at the order level was investigated along the Kihansi Gorge in the southern Udzungwa Mountains between June and August 1997 by using sweep netting, timed Lepidoptera counts, malaise-traps, solar powered lighttraps, baited pitfall-traps, sticky-traps and baited butterfly traps. The study was undertaken to predict the possible effects of damming the Kihansi River above the fierce waterfall in the gorge. The gorge was divided into four micro-habitats, two of which are affected by

waterfall spray (open spray, forest spray), and two of which were not affected directly by the waterfall (forest and riverine sites). The highest arthropod diversity was found in the forest spray, whereas the open spray contained the least. The forest spray area harboured the rarest arthropod orders. Arthropods are most abundant in the riverine site where 31 % of all sampled arthropods were recorded. The forest spray channel, forest site and open spray channel follow with 28%, 23 % and 18 % of the sample respectively. It is suggested that the Mhalala Stream should be diverted to the gorge to replace the dammed Kihansi River. This would maintain at least partially the extraordinary micro-climate of the gorge and possibly retain the specialised arthropod community." (Authors) A single zygopteran specimen (no species details) was found.] Address: Zilihona, I., Tanzania Forestry Research Institute, Silvicultural Research Centre, P.O. Box 95, Lushoto, Tanzania

10683. Kefford, B.J. (2000): The effect of saline water disposal: implications for monitoring programs and management. Environmental Monitoring and Assessment 63: 313-327. (in English) ["In an effort to combat rising groundwater tables and expanding saline lakes, saline water has been disposed of into the aquatic environment, despite there being little information as to the environmental effects. Monitoring of the effect of saline lake water disposal on aquatic macroinvertebrates and water quality was conducted in the Barwon River, south west Victoria, Australia, in association with toxicity tests.

The disposal of saline lake water was associated with changes in macroinvertebrate community structure. Contrary to expectations, increases in electrical conductivity (a measure of salinity) was not the only water quality parameter associated with saline water disposal. An experiment was conducted where the toxicity of saline lake water was compared to that of a prepared solution of the same electrical conductivity. Toxicity was greater in the saline lake water than the prepared solution. The results suggest that saline water disposal is impacting on macroinvertebrate fauna but electrical conductivity is not the only factor responsible. These results have consequences for both management of aquatic resources and for monitoring programs which are discussed." (Author) Odonata (*Nososticta*, *Austrolestes annulosus* and *Ischnura heterostrieta*) were reported with an increase in abundance.] Address: Kefford, B.J., Dept of Biotechnology and Environmental Biology, RMIT University, PO Box 71, Bundoora, 3083, Victoria, Australia. 2003

10694. Boulton, A.J. (2003): Parallels and contrasts in the effects of drought on stream macroinvertebrate assemblages. *Freshwater Biology* 48(7): 1173-1185. (in English) [(1) It is axiomatic that unusually long dry periods (droughts) adversely affect aquatic biota. Recovery after drought is rapid by macroinvertebrates that possess strategies to survive drying or are highly mobile but other taxa take longer to recolonise depending on the timing, intensity, and duration of the dry phase. (2) Although drought acts as a sustained 'ramp' disturbance, impacts may be disproportionately severe when certain critical thresholds are exceeded. For example, ecological changes may be gradual while a riffle dries but cessation of flow causes abrupt loss of a specific habitat, alteration of physicochemical conditions in pools downstream, and fragmentation of the river ecosystem. Many ecological responses to drought within these habitats apparently depend on the timing and rapidity of hydrological transitions across these thresholds, exhibiting a 'stepped' response alternating between gradual change while a threshold is approached followed by a swift transition when a habitat disappears or is fragmented. (3) In two Australian intermittent streams, drought conditions eliminated or decimated several groups of macroinvertebrates, including atyid shrimps, stoneflies and free-living caddisflies. These taxa persisted during the early stages of the drought but did not recruit successfully the following year, despite a return to higher-than-baseflow conditions. This 'lag effect' in response to drought emphasises the value of long-term survey data. Although changes in faunal composition were inconsistent among sites, marked shifts in taxa richness, abundance and trophic organisation after the riffle habitat dried provide evidence for a stepped response. (4) Responses by macroinvertebrate assemblages to droughts of differing severity in English chalk streams were variable. The prolonged 1988-92 drought had a greater impact than shorter droughts in the early 1970s but recovery over the next 3 years was swift. Effects of the 1995 summer drought were buffered by sustained groundwater discharge from the previous winter. These droughts tended to reduce available riverine habitats, especially via siltation, but few taxa were eliminated because they could recolonise from perennial sections of the chalk streams. (5) In the contrasting environments

of the intermittent streams studied in England and Australia, there are parallels in the rapid rates of recolonisation. However, recruitment by taxa that lack desiccation-resistant stages or have limited mobility is delayed. Currently, long-term data on these systems may be insufficient to indicate persistent effects of droughts or predict the impacts of excessive surface or groundwater abstraction or the increased frequency and duration of droughts expected with global climate change." (Author) The paper includes a reference to Odonata.] Address: Boulton, A.J., Ecosystem Management, University of New England, Armidale, NSW, 2351, Australia. E-mail: abouton@metz.une.edu.au

2004

10695. Alling, V.; Andersson, P.; Fridriksson, G.; Rubio Lind, C. (2004): Oskarshamn site investigation. Biomass production of Common reed (*Phragmites australis*), infauna, epiphytes, sessile epifauna and mobile epifauna. Common reed biotopes in Oskarshamn's model area. Svensk Kärnbränslehantering AB, Swedish Nuclear Fuel and Waste Management Co, Box 5864, SE-102 40 Stockholm, Sweden: 19 pp + app.. (in English) ["The aim of the study was to determine and estimate the total amount of Common reed biomass, *Phragmites australis*, both standing crop and the rhizome biomass, in SKB's regional modelling area in Simpevarp, Oskarshamn. The biomasses of infauna and mobile epifauna are determined as well as the carbon content in the sediment. The grand mean value for reed biomass in the Oskarshamn area is 1,254.3 g/m². Mean value for reed rhizome biomass in the same area is 3,705.6 g/m². The result from the standing crop biomass measurement corresponds with earlier studies of reed biomass, but the mean biomass value for the rhizome was almost the double. Two of the infauna taxa, Diptera and Gastropoda, were found in all of the five sites where Gastropoda represented the greatest biomass and Diptera the highest abundance. Epiphytes, such as macro algae, could not be detected on any reed straws. The mobile epifauna sampling did result in a relative high number of different taxa. Gastropoda and Anisoptera were the taxa that showed the highest biomass value with a relatively low abundance number. Taxa showing the reversed relation between biomass and abundance were Isopoda and possibly Diptera. Carbon content of the sediment, sampled in the edge of the reed stands was approx 11% with high variation between the sites." (Authors)] Address: Svensk Kärnbränslehantering AB, Swedish Nuclear Fuel and Waste Management Co, Box 5864, SE-102 40 Stockholm, Sweden

10696. Arab, A.; Lek, S.; Lounaci, A.; Park, Y.S. (2004): Spatial and temporal patterns of benthic invertebrate communities in an intermittent river (North Africa). *Ann. Limnol. - Int. J. Lim.* 40(4): 317-327. (in English) ["The spatial and temporal distribution patterns of benthic macroinvertebrates were studied in an intermittent river in Algeria (Chelif wadi, North Africa), by using the self-organizing map (SOM), an unsupervised artificial neural network. The samples were collected monthly at 8 sampling sites (630 to 20 m above sea level) and community variation was analysed in space and time. Overall, the study sites showed a very poor macroinvertebrate fauna: more than 60% of samples contained less than 11 species, and 99% had less than 30 species.

Furthermore, most species displayed very low abundance: 66% of the species were represented by less than 20 individuals (abundance). Among the identified taxa, Chironomidae was the dominant taxon at all sampling sites except at the most upstream site (630 m a.s.l.) where it was replaced by Coleoptera. Concerning monthly changes, the species richness was very low in August and October. Through the learning process of the SOM, samples were classified into four clusters by the SOM, and the classification was mainly related to the location of the sampling sites. Benthic macroinvertebrates were divided into four classes, which revealed the influence of pollution on their longitudinal distribution in this stream. According to the distribution gradients of the environmental variables on the SOM map, their influence on the classification of the sampling sites could be assessed effectively." (Authors) The following taxa - based on larval identification - are listed: *Erythronema lindenii*, *Platynemis acutipennis*, *Coenagrion armatum*, *Stylurus flavipes*, *Gomphus pulchellus*, *Libellula depressa*, *Libellula quadrimaculata*, *Somatochlora arctica*, *Libellula fulva*, and *Gomphus vulgatissimus*.] Address: Park, Y.S., Laboratoire Dynamique de la Biodiversité (LADYBIO), UMR 5172, CNRS - Université Paul Sabatier, 118 route de Narbonne, 31062 Toulouse cedex 4, France. E-mail: park@cict.fr

10697. Matsubara, K. (2004): Daily activity and reproductive behaviors of *Calopteryx atrata* Selys (Zygoptera: Calopterygidae). *Tombo* 47: 47-52. (in Japanese, with English summary) ["The daily activity and reproductive behaviours of a territorial damselfly *C. atrata* were investigated at the upper Tafuse River in Saga-shi, Saga Prefecture, Northern Kyushu. The average number of active males did not notably change from early morning to late afternoon, and almost all active males were territorial. Although the average number of active females was always less than that of active males, the female numbers increased from 10:00 am to 17:00 pm, when reproductive behaviour was frequently observed, and fell abruptly in the late afternoon when females flew to roosting sites for the night. A territorial male established a territory containing one or more oviposition sites and several perching sites. The territorial and mating behaviours of *C. atrata* males were frequently observed from early morning and their frequency peaked around noon, thereafter decreasing until late afternoon. On the other hand, feeding flights were observed less frequently in the daytime but their frequency increased abruptly during the late afternoon, when the territorial and mating behaviours of males were less. Territorial males defended against intruding conspecific males by aerial displays. They normally chased intruders out of their territories with brief pursuit flights. On the other hand, escalated combats sometimes occurred between territorial males and intruders. During these combats, flight speed increased, involving back-and-forth chasing and circling or spiralling by both males, lasting much longer (up to an hour or more) over other oviposition sites. When a territorial male found a female approaching an oviposition site within his territory, he began a pair-forming display and courtship flight. After copulation, the males performed a non-forming display and courtship flight. After copulation, the male performed a non-contact guarding behaviour for the ovipositing female inside his territory. During her oviposition, he chased approaching males out of his territory." 10701. Gunzburger, M.S.; Travis, J. (2005): Critical literature review of the evidence for unpalatability of amphibian eggs and larvae. *Journal of Herpetology* 39(4): 547-571. (in English) ["We examined 142 papers, which contained 603 separate predator-prey trials, to investigate whether unpalatability is an important defense against predation for amphibian eggs and larvae. Although unpalatability is often cited as an antipredator defense, it was rarely demonstrated that 89% of the trials that we reviewed found prey to be palatable. The most extensively studied taxa, the genera *Bufo* and *Rana*, were diagnosed unpalatable at rates comparable to all other taxa. Diagnoses of unpalatability were not always consistent for a prey species across different predators and were influenced by experimental method. Despite these limitations and our conservative definition of unpalatability, several patterns emerged. First, across all taxonomic groups, eggs and hatchlings were unpalatable more often than mobile larval stages. Second, species that breed in temporary ponds were more likely to be palatable to fish predators than those that breed in permanent habitats. Third, fish and caudates were more likely to find amphibian prey unpalatable than insect

predators. We conclude that unpalatability is rare, but when it occurs, it is a property of an ensemble (predator, prey, and alternative prey) and a life-history stage in a particular circumstance but is not a species-specific attribute. We suggest methods of experimentation that could strengthen future research on the palatability of amphibian eggs and larvae. [...] The most common predators used in trials were salamander adults and larvae, which found prey unpalatable in 15 of 123 trials. Other predators finding prey unpalatable in some trials were aquatic insects (odonate naiads, coleopterans, heteropterans, and others), snakes (*Thamnophis* spp.), tadpoles, snails, mammals, and turtles. Vertebrate predators (fish and salamander adults and larvae) were twice as likely to find prey unpalatable than insect predators (Odonata, Hemiptera, and Coleoptera; $\chi^2 = 5.16$, $P = 0.023$). (Authors)] Address: Gunzburger, Margaret, United States Geological Survey, Florida Integrated Science Center, 7920NW71st Street, Gainesville, Florida 32653-3701, USA. 10702. Kazantzidis, S.; Goutner, V. (2005): The diet of nestlings of three Ardeidae species (Aves, Ciconiiformes) in the Axios Delta, Greece. *Belg. J. Zool.* 135(2): 165-170. (in English) ["The diets of the little egret (*Egretta garzetta*), the night heron (*Nycticorax nycticorax*) and the squacco heron (*Ardeola ralloides*) were studied by analyzing nestling regurgitations collected during five breeding seasons (1988-1990 and 1994-1995) at a heronry in the Axios Delta (Northern Greece). In total, 267 regurgitations from little egrets, 247 from night herons and 19 from squacco herons (only in 1995) were collected and analyzed. Each prey item was identified to the lowest possible taxon. The dry mass of each prey taxon was also estimated from oven-dried prey specimens collected in the field. Little egret: At least 58 different taxa were identified among 5,108 prey items (1,499 g dry mass). By number, fish were the most important prey category (39.6%), followed by insects (32.1%) and amphibians (24.9%) (Fig.1). From a total of 22 fish species identified, *Aphanius fasciatus*, *Gambusia affinis* and *Gasterosteus aculeatus* represented 85.5% of all items. Of at least 27 species of insects, the majority were larvae of Odonata, Dytiscidae and Hydrophilidae (94.3% of all insect larvae). Among imagoes, *Gryllotalpa gryllotalpa* and *Zygoptera* spp. (Odonata) prevailed, making up 72.2% of all items." (Authors) Approximately 90% less Odonata contributed to the diet of Night herons and Squacco herons.] Address: Kazantzidis, S., Forest Research Institute, National Agricultural Research Foundation, GR-57006 Vassilika, Thessaloniki, Greece. 10707. Borisov, S.N. (2006): Dragonfly night breeding (Odonata) in temperate latitudes western Asia. *Siberian Journal of Ecology* 13(4): 449-455. (in Russian, with English summary) ["The night emergence was established for 30 species and subspecies of dragonflies in temperate latitudes of West Asia. This phenomenon is most characteristic of the plains in Middle Asia, where 20 species with night transformation are known; for a half of them, it is obligate. In southern mountains and in West Siberia, the night emergence was observed for seven taxons. The adaptive value of dragonfly issue and flying away from water reservoirs during the dark period lies in avoidance of extremely high day temperature, dryness and insolation, on the one hand, and

preying on the other." (Author) Results and discussion consider the following species *Anormogomphus kirtschchenkoi*, *Lindenia tetraphylla*, *Sympecma gobica*, *S. fusca*, *S. paedisca*, *Coenagrion armatum*, *Ophiogomphus reductus*, *Stylurus flavipes*, *Anax ephippiger*, *Lestes macrostigma*, *Anax imperator*, *A. parthenope*, *Aeshna grandis*, *A. crenata*, *A. mixta*, *A. affinis*, *Crocothemis servilia*, *C. erythraea*, *Sympetrum vulgatum vulgatum*, *S. vulgatum decoloratum*, *S. flaveolum*, *S. striolatum*, *S. fonscolombii*, *S. meridionale*, *S. arenicolor*, *Orthetrum sabina*, *O. brunneum*, *O. albistylum*, *Selysiothemis nigra*, and *Pantala flavescens*.] Address: Borisov, S., Institute of Systematics and Ecology of Animals, Russian Academy of Sciences, Siberian Branch, Frunze str. 11, Novosibirsk 630091 Russia. E-mail: borisov-s-n@yandex.ru

10708. Bowman, N. (2006): Reports from Coastal Stations - 2005: Eccles-on-sea, Norfolk. *Atropos* 27: 70-71. (in English) ["It was also a quiet year for Odonata with even the resident population of *Erythromma viridulum* present in depressingly low numbers. However, some fresh primary migrants were noted, particularly on 29 August when 80 were counted, including some 30 pairs in tandem." (Author)] Address: not stated

10709. Canedo, C.; Garcia, J.P.; Fernandes, R.; Pomal, J.P. (2006): Diet of *Pipa carvalhoi* (Amphibia, Pipidae) is not influenced by female parental care. *Herpetological Review* 37(1): 44-45. (in English) [Odonata larvae contributed between 0 – 0.2% to the diet, while chironomid larvae were consumed exclusively to near 100%.] Address: Canedo, C., Departamento de Vertebrados, Museu Nacional/UFRJ, Quinta da Boa Vista, 20940-040 Rio de Janeiro, RJ, Brazil. E-mail: canedo@mn.ufrj.br

10710. Clancy, S. (2006): Reports from Coastal Stations - 2005: Dungeness area, Kent. *Atropos* 27: 60-62. (in English) ["Odonata records of interest in the area included at least nine different male *Anax parthenope* in the Dungeness area as follows: two at Cooke's Lake on 22 June, two at the Water Tower pits on 23 June with one still there on 24th, one at the Water Tower Pits on 3 July, one on Lade Pit on 17 July, one at Hooker's Pits on 20 July, one at the Long Pits on 1 August, and one at New Diggings on 25 and 27 August. In contrast, there were only three records of single male *Sympetrum fonscolombii* on the RSPB Reserve during the season, these occurring on 23 June and 3 /11 July." (Author)] Address: not stated

10711. Deans, M. (2006): Reports from Coastal Stations - 2005: Bawdsey Peninsula, Suffolk. *Atropos* 27: 68-69. [*Sympetrum striolatum* at artificial light on 17-VIII, 22-IX, and 7-X-2006.] Address: not stated

10712. Dewick, S. (2006): Reports from Coastal Stations - 2005: Curry Farm, Bradwell-on-sea, Essex. *Atropos* 27: 66-67. (in English) ["Little significant recording of Odonata was attempted in 2005, but it is worth noting that Common Darter *Sympetrum striolatum* once again continued to be seen in numbers very late in the year, the last being seen on 22 November (three). Night-time immigration appears to have been very limited, the only records of this species in the light-trap being singles on 25 & 31 July, 16 & 29 August and 3, 20, 21 & 27 September, two being noted on 11 September. A single Migrant Hawker *A. mixta* was also recorded at light on 15 August." (Author)] Address: Dewick, S.; Curry Farm, Bradwell-on-Sea, Southminster, Essex, CM0 7NL, UK

10713. Harvey, R. (2006): Reports from Coastal Stations - 2005: Minsmere RSPB Reserve, Suffolk. *Atropos* 27: 69-70. (in English) ["It was an excellent year for *Aeshna isosceles* with records on 20 dates from 2 June to 20 July. This compares with sightings on ten dates from 9 June to 10 July in 2004. The peak count was five on 26 June. A female observed ovipositing on the levels on 17 July was the first definite proof of breeding on the reserve. In contrast there were no records of *Erythromma viridulum* at the regular locations." (Author)] Address: not stated

10714. Hunter, I. (2006): Reports from Coastal Stations - 2005: Elms Farm, Icklesham, East Sussex. *Atropos* 27: 59-60. (in English) [*Erythromma viridulum* in high abundances is reported.] Address: not stated

10715. Jarman, N. (2006): Reports from Coastal Stations - 2005: Kingsdown Beach, Kent. *Atropos* 27: 62-63. (in English) [UK; *Erythromma viridulum*] Address: not stated

10716. Knill-Jones, S. (2006): Reports from Coastal Stations - 2005: Isle of Wight. *Atropos* 27: 56-57. (in English) [UK; records of *Erythromma viridulum*, *Brachytron pratense*, and *Sympetrum flaveolum* are reported.] Address: Tunmore, M., 36 Tinker Lane, Meltham, Huddersfield, West Yorkshire HD7 3ES, UK. E-mail: atropos@atroposed.freereserve.co.uk

10717. Kovács, T.; Kovács, T. sr (2006): Records of larval Ephemeroptera, Odonata and Plecoptera from the upper part of the Hungarian section of Ipoly River, with notes on aquatic Heteroptera and Coleoptera. *Folia Historico-Naturalia Musei Matraensis* 30: 159-165. (in Hungarian, with English summary) [Records of *Calopteryx splendens*, *C. virgo*, *Erythromma najas*, *E. viridulum*, *Ischnura elegans pontica*, *Stylurus flavipes*, *Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Onychogomphus forcipatus*, and *Somatochlora metallica* are presented] Address: Kovács, T., Mátra Museum. H-3200 Gyöngyös, Kossuth Lajos u. 40., Hungaria. E-mail: koati@t-online.hu

10718. Lambrechts, J.; Knijf, G. de (2006): Dragonflies in the Høge Kempen National Park. *LIKONA* 2005: 50-57. (in Dutch, with English summary) [50 Odonata species are documented for the Park; it which is considered an odonate hotspot in Flanders (Belgium). The odonate fauna is reviewed with species presented mostly with their vernacular names. Special emphasize is given to *Coenagrion hastulatum*, *Cordulegaster boltonii*, *Somatochlora arctica* and *S. flavomaculata*.] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. E-mail: geert.deknijf@inbo.be

10719. Lyons, R. (2006): Dan Hull gets county record. *Proof sheet* 14(2): 1. (in English) [*Libellula saturata*, 18-IX-2006, at Shore Acres, Coos County, Oregon, USA.] Address: c/o Proof Sheet, Oregon Coast Photographers' Association INC., P.O. Box 5646, Charleston, OR 97420, USA

10720. Martin, J. (2006): Lebendnachweise der Kleinen Flussmuschel (*Unio crassus* PHILLIPSSON, 1788) im Rahmen einer Molluskenbergung am Komplexbauwerk Wehr und Schleuse Kossenblatt. *Naturschutz und Landschaftspflege in Brandenburg* 15(1): 13-16. (in German) [In the framework of a study in *Unio crassus* in Brandenburg, Germany, also records of larval *Aeshna*

sp., *Gomphus vulgatissimus*, and *Somatochlora metallica* were made.] Address: Martin, J., Kopernikusstr. 34, 14482 Potsdam, Germany

10721. Morgan, L. (2006): Reports from Coastal Stations - 2005: Skomer Island NNR, Pembrokeshire. *Atropos* 27: 74-75. (in English) ["A total of seven species of Odonata was recorded in 2005. *Enallagma cyathigerum* and *Ischnura elegans*, both breeding species, were recorded in their highest annual numbers with a daily maximum of 30 and 50 respectively on 27 June. A single *Orthetrum cancellatum* on 10 July was a new record for the Island — this species may become a more regular Island visitor in future years with its breeding range now expanded to include Pembrokeshire. A single *Libellula depressa* on 19 June was the first record of this species since 2000." (Author)] Address: not stated

10722. Odin, N. (2006): Reports from Coastal Stations - 2005: Landguard Bird Observatory, Suffolk. *Atropos* 27: 67. (in English) [UK; *Sympetrum striolatum*, *Coenagrion puella*] Address: not stated

10723. Parr, A.J. (2006): Dragonflies at Light: an appeal for information. *Atropos* 27: 87. (in English) ["Although dragonflies are normally day-flying, some records of nocturnal activity are not unknown. Typically such records refer to individuals caught in MV moth traps, or attracted to streetlights and other types of light. It is planned to take a closer look at such records in a future issue of *Atropos*. While there is some literature available, a lot of information must also exist only in field notebooks. I would be pleased to hear from anyone who has any information relating to Odonata at light. This might involve either dragonflies or damselflies, and while the analysis will have a strong UK bias, information from abroad would also be gratefully received. Please send information to me at the address below or to the *Atropos* editorial address." (Author)] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK. E-mail: Adrian.parr@bbsrc.ac.uk

10724. Parr, A.J. (2006): Migrant dragonflies in 2005 including recent decisions and comments by the Odonata Record Committee. *Atropos* 27: 33-38. (in English) [UK; the following species are involved: *Lestes barbarus*, *Pyrrhosoma nymphula*, *Erythromma viridulum*, *Aeshna mixta*, *Anax imperator*, *A. parthenope*, *Libellula depressa*, *L. fulva*, *Orthetrum cancellatum*, *Sympetrum striolatum*, *S. fonscolombii*, *S. flaveolum*, *S. sanguineum*, *S. danae*] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK. E-mail: Adrian.parr@bbsrc.ac.uk

10725. Scott, D.A. (2006): Reports from Coastal Stations - 2005: Dursey Island, Co. Cork. *Atropos* 27: 75- [Ireland; *Sympetrum striolatum*] Address: not stated

10726. Scott, M.A.; Scott, W.J.; Scott, T.R. (2006): Reports from coastal stations - 2005: Longstone Heritage Centre, St Mary's, Isles of Scilly. *Atropos* 27: 47-49. (in English) ["Five species of Odonata were recorded. The highlight was *Anax parthenope* seen and photographed on 25 September, this being the first for the Isles of Scilly. Also new for the site was *Pyrrhosoma nymphula* on 9 June (possibly another first for the Islands). *Ischnura elegans* were present during June/July and several larvae were found on 10 June. Only three singles each of *Sympetrum striolatum* and *Aeshna mixta*

were seen in August/ September." (Authors)] Address: not stated

10727. Solly, F. (2006): Reports from Coastal Stations - 2005: Isle of Thanet. *Atropos* 27: 64-65. (in English) ["Dragonfly recording was limited to the Kingsgate area, a lack of standing water reducing the potential. However, a good range of species for the site was recorded in the spring/early summer period. A *Brachytron pratense* on 15 May was only the third area record, whilst single *Libellula quadrimaculata* on 1 June and *Orthetrum cancellatum* on 7 June were the second Thanet records. This season's only *Anax imperator* was noted on 28 May, and *Libellula depressa* occurred on four dates between 28 May and 22 June. Damselfly records are always unusual on Thanet so records of up to three *Coenagrion pulchellum* on three dates between 26 May & 2 June, *Coenagrion puella* on 6 June, single *Ischnura elegans* on 17 & 30 June, and *Enallagma cyathigerum* on 17 June were well above average. *Sympetrum striolatum* was recorded from 1 July but remained scarce until 30 were seen on 2 August, after which it was present on most days until late October. The year's first record of *Aeshna mixta* involved 20 on 1 August, this species occurring most days after this until mid-October." (Author)] Address: not stated

10728. Spence, B. (2006): Reports from Coastal Stations - 2005: Spurn Point, east Yorkshire. *Atropos* 27: 72-73. (in English) [UK; "The season started off quite well for Odonata with very good numbers of *Libellula quadrimaculata*, *Orthetrum cancellatum* and *Anax imperator* in late June. However, after this numbers dropped considerably and the rest of the season produced very much below average numbers for all species. The only records of note were single *Sympetrum fonscolombii* on 22 & 27 June and 5 & 10 July." (Author)] Address: not stated

10729. Troake, P. (2006): Reports from Coastal Stations - 2005: Gibraltar Point, Lincolnshire. *Atropos* 27: 71-72. (in English) [UK; *Sympetrum fonscolombii*; *Lestes sponsa*] Address: not stated

10730. Tunmore, M. (2006): Reports from Coastal Stations - 2005 : Lizard Peninsula, Cornwall. *Atropos* 27: 49-51. (in English) ["It was generally a poor year for Odonata, one highlight being a *Ceriagrion tenellum* seen near Predannack on 17 July. Records of single *Aeshna mixta* at light on 10 September and Common Darter *Sympetrum striolatum* on 24 September were suggestive of immigration, but it was one of the worst recent years for *S. fonscolombii* with five seen on Goonhilly Downs on 9 July, two near Predannack on 10 July, followed by two at Windmill Farm on 17 July and one there on 10 August." (Author)] Address: Tunmore, M., 36 Tinker Lane, Meltham, Huddersfield, West Yorkshire HD7 3ES, UK. E-mail: atropos@atroposed.free-serve.co.uk

2007

10731. Bouwman, J.; Bakker, S.; de Boer, P.; van Hijum, E.; Hylkema, G. (2007): Beheerplan De Wylde-merk 2008-2012. Rapport VS2007.034, De Vlinderstichting, Wageningen: 15 pp. (in Dutch) [In 2007, De Wylde-merk was established as the first dragonfly sanctuary of the Netherlands. A management plan was prepared for the site. A total of 10 different pools or reed-

beds are identified as as suitable habitat for dragonflies. Conservation measures that must be taken to improve the habitat function are suggested.] Address: De Vliinderstichting, Postbus 506, 6700 AM Wageningen, The Netherlands

10732. Faucheux, M. (2007): Sensilla and cuticular structures in the marval caudal appendages of *Erythromma lindenii* (SÉLYS, 1840), (Odonata: Zygoptera: Coenagrionidae). *Entomology Bulletin* 77: 113-120. (in English, with French summary) ["The cuticular structures and the sensilla on the larval caudal appendages (caudal lamellae) of *E. lindenii* have been studied using scanning electron microscope. Four types of sensilla are visible on the external face of the two lateral lamellae and both faces of median lamella. The aporous sensilla filiformia are vibroreceptors which detect a predatory or hostile presence. The aporous sensilla campaniformia are proprioceptors which may play the role of osmoreceptors here. An olfactory function is presumed for the multiporous sensilla coeloconica and a tactile function for the aporous spatula-shaped sensilla chaetica. The sensilla filiformia and the sensilla campaniformia have already been described on the caudal lamellae of Odonata. The sensilla coeloconica and the spatula-shaped sensilla chaetica are observed for the first time on these appendages." (Author)] Address: Faucheux, M.J., Laboratoire d'Endocrinologie des Insectes Sociaux, Université de Nantes, 2 rue de la Houssinière, B.P. 92208, F-44322 Nantes Cedex 03, France. E-mail: faucheux.michel@free.fr

10733. Faucheux, M. (2007): Multiporous and aporous sensilla on the larval antennae of the relict dragonfly *Epiophlebia superstes* (SÉLYS, 1889) (Odonata, Anisozygoptera: Epiophlebiidae). *Entomology Bulletin* 77: 121-128. (in English, with French summary) ["The larval antennal sensilla of the relict dragonfly, *E. superstes* have been studied by means of scanning electron microscope. Five types of sensilla are present: curved aporous sensilla chaetica, aporous sensilla filiformia, multiporous sensilla coeloconica, sensilla ampullacea and sensilla basiconica. A tactile function is attributed to the curved sensilla chaetica, a chemoreceptive function to the sensilla ampullacea and sensilla basiconica, a chemoreceptive or hygroreceptive function to the sensilla coeloconica, a vibroreceptive function to the sensilla filiformia. *Epiophlebia*, which lives in the turbulent waters of mountain streams, differs from the other larvae of Zygoptera and Anisoptera, whose habitat is calm water, by the reduced number of sensilla filiformia. *Libellula depressa*, a previously studied anisopteran species, and *Epiophlebia* (Anisozygoptera) both possess sensilla coeloconica. The presence of sensilla coeloconica is common both to the antennae of the final-stadium larva of *Epiophlebia* and of adult Odonats." (Author)] Address: Faucheux, M.J., Laboratoire d'Endocrinologie des Insectes Sociaux, Université de Nantes, 2 rue de la Houssinière, B.P. 92208, F-44322 Nantes Cedex 03, France. 10734. Holuša, O.; Jeziorski, P. (2007): Collection of dragonflies (Insecta: Odonata) in the Ostravian Museum (Czech Republic). *Práce a Stud. Muz. Beskyd (Přir. Vědy)* 19: 143-150. (in Czech, with English summary) [The collections of the Ostravian Museum, Ostrava town harbour 718 specimens in 39 species. "The material was collected mainly in the northern Moravia and Silesia (Czech Republic), but also in Bohemia, Slovakia and Croatia, Macedonia, Hungaria during the years 1920-

1982. Besides rather common dragonfly species in the whole territory of the Czech Republic, the collection also includes several scarce and rare ones, such as *Coerulescens*, *Orthetrum albistylum*, *O. coerulescens*, and *Sympetrum depressiusculum*." (Authors)] Address: Holuša, O., Bruzovská 420, 738 01 Frýdek - Místek, Czech Republic. E-mail: holusao@ email.cz

10735. Martins, F.A.; Del Claro, K. (2007): Distribuição espacial e abundância de *Oxyagrion microstigma* (Odonata: Coenagrionidae) em uma área de Cerrado. *Anais do VIII Congresso de Ecologia do Brasil*, 23 a 28 de Setembro de 2007, Caxambu - MG: 1-2. (in Portuguese) [The territorial behaviour of *O. microstigma* is briefly described and further work in this species is suggested.] Address: Martins, F.A., Universidade Federal de Uberlândia, Instituto de Biologia, Laboratório de Ecologia Comportamental e Interações, Rua Ceará, s/nº Bloco 2D - Campus Umuarama, 38400902, Uberlândia, MG - Brasil - Caixa Postal: 593

10736. Naraoka, N.; Iakahashi, K. (2007): The landing from the water and the terrestrial period before emergence of the final instar larvae of *Epiophlebia superstes* Selys (Anisozygoptera: Epiophlebiidae). *Tombo* 49: 15-21. (in Japanese, with English summary) ["The exiting of the final instar larvae of *Epiophlebia superstes* from water to terrestrial hiding sites before emergence was investigated in the spring of 2005 and 2006, at a mountain stream (width: 2-3 m, water depth: 20-60 cm, altitude: 520-550 m) in Nurukawa-mura, Hirakawa-shi, Aomori prefecture, Japan. The number of larvae walking on the snow (snow depth: 3-4 m) was counted during the period from 3 to 29 April. Over 14 days during 2005 and 2006, we found 193 and 188 larvae on the snow, respectively. Most of the larvae climbed and crawled westward (90.3%) on the snow cover from the mountain stream in the morning, while some larvae climbed and crawled eastward (25.8%) or changed their course to the east from the west as the sun moved from the east to the south (ca. 10 : 30). The larvae moved to land without snow cover 13-36 m away from the stream, and hid under fallen leaves. It took 1.5-4.5 hours to move from the stream to the hiding sites. When hiding sites were not available, the larvae continued walking on the snow for 5-6 hours travelling as far as 40-60 m from the stream. Exiting from the water was observed from 8:00 to 15:00 h with a peak between 10:00-11:00 h, and were mostly in the morning (67.7%) rather than in the afternoon (33.3%). The number of exits from the water was also influenced by weather conditions: 33 + 11 (s.d.) (n=5) on fine days, 24+11(s. d.) (n=7) on fine-cloudy days and 4±2 (s. d.) (n=5) on cloudy days. Walking velocities of the larvae on slope (0-80) and on vertical surfaces (90°C) on the snow were 8-66 (n=89) and 15.3 ±5. 2 (s. d.) (n=23) cm/minute, respectively. The larvae moved faster at higher ambient temperature. The body temperature of larvae varied between 3.5 and 15.5°C, with a mean of 7±3.8°C (s. d.) (n=17 Fig. 5), which correlated with the ambient temperature. We could not observe any adult emergence in May or early July, the time that is supposed to be the emergence period for this species in the study area (Naraoka, 2004). Some larvae were collected in mid and late April and were brought to the lower altitudes (16 m) to observe their emergence periods. The larvae collected in mid April emerged 30.2 ±1.3 (s. d.) days (n=5) after exiting the water but those collected in late April emerged 24.0 ± 1.2 (s. d.) days (n=5) after leaving the water. Also,

some exiting larvae were collected in late April, and were kept in containers in the study area. They emerged 29.3 ± 1.3 (s. d.) days (n=4) after departing the stream (Tabl. 2). We concluded that the final instar larvae of *E. superstes* leave the water area before their emergence during April, and their terrestrial period of life is 25-35 days." (Authors)] Address: Naraoka, H., 36-71, Aza-Motoizumi, Fukunoda, Itayanagi-cho, Kita-gun, Aomori Prefecture, 038-3661, Japan

10737. Nishiura, N. (2007): Records of *Sympetrum fonscolombii* and *S. uniforme* in Osaka Prefecture. Tombo 49: 27-29. (in Japanese, with English summary) [A male of the migrating species, *S. fonscolombii* was collected for the first time from Osaka Prefecture, Japan (20-XI-2005), and two males of the "Red listed" species *S. uniforme* were captured at the same place and at the same day. Therefore, "it would be plausible to guess that the insects arrived at the capture sites riding in the same wind."] Address: not stated in English

10743. Balian, E.V.; Segers, H.; Leveque, C.; Martens, K. (2008): The Freshwater Animal Diversity Assessment: an overview of the results. *Hydrobiologia* 595: 627-637. (in English) ["We present a summary of the results included in the different treatments in this volume. The diversity and distribution of vertebrates, insects, crustaceans, molluscs and a suite of minor phyla is compared and commented upon. Whereas the available data on vertebrates and some emblematic invertebrate groups such as Odonata (n = 5,680 species) allow for a credible assessment, data are deficient for many other groups. This is owing to knowledge gaps, both in geographical coverage of available data and/or lack of taxonomic information. These gaps need to be addressed urgently, either by liberating data from inaccessible repositories or by fostering taxonomic research. A similar effort is required to compile environmental and ecological information in order to enable cross-linking and analysis of these complementary data sets. Only in this way will it be possible to analyse information on freshwater biodiversity for sustainable management and conservation of the world's freshwater resources." (Authors)] Address: Balian, Estelle, Freshwater Laboratory, Royal Belgian Institute of Natural Sciences, Vautierstraat 29 B-1000, Brussels, Belgium. E-mail: Estelle.Balian@naturalsciences.be

10744. Belova, Y.N. (2008): Chapter 2. Order Odonata. In: Belova, Y.N.; Dolganova, M.N.; Kolesova, N.S.; Shabunov, A.A.; Filonenko, I.V.: Diversity of insects of the Vologda region. Vologda: Center of operative printing "Kopernik". 368 pp. ISBN 978-5-87822-369-0: 16-25. (in Russian, with English summary) [This study on the fauna of the Vologda region, Russia includes 33

Odonata species. These are treated on pages 16-25. Records and habitat preferences are documented. Most records result from 2003-2005 study period.

10745. Cannings, R.A. (2008): Dunes, dragonflies and dikdiks: a short trip to Namibia and South Africa. *Boreus* 28(1): 32-34. (in English) [Brief report from a trip in April and May 2007 to southern Africa. It includes some notes on the WDA congress in Namibia.] Address: Cannings, R.A., Royal British Columbia Museum, 675 Belleville Street Victoria, British Columbia V8W 9W2. Canada. E-mail: rcannings@royalbcmuseum.bc.ca

10746. Domek, P.; Joniak, T.; Piotrowicz, R. (2008): Spatial and seasonal variation of macrozoobenthos in disharmonic lakes of the Drawa National Park. In: R. Goldyn, P. Klimaszyk, N. Kuczyńska-Kippen & R. Piotrowicz (eds): The Functioning and Protection of Water Ecosystems. Department of Water Protection, Faculty of Biology, Adam Mickiewicz University, Poznań 2008: 39-44. (in English) ["The spatial and seasonal variation in species composition, density and biomass of macrozoobenthos in three disharmonic lakes of the Drawa National Park in the profundal zone and in the peatbog zone were compared. Investigations in all the lakes indicated higher values of all parameters in spring than in autumn. The profundal zone was dominated by Diptera, while the littoral zone was dominated by Ephemeroptera. The total biomass of organisms in the profundal zone was much higher than in the peatbog zone. The greatest biomass of a single species was noted in the oligohumic lake, 16 698 mg·m⁻² for *Chaoborus flavicans* (Meig.) (Diptera: Chaoboridae). The peatbog zone was a better habitat for macroinvertebrates than the profundal zone. A great influence on the deep-water biocoenosis of benthic fauna was exerted by the quality of the bottom sediments." (Authors) Odonata taxa recorded are: *Aeshna* sp., *Cordulia aenea*, *Enallagma cyathigerum*, *Gomphus vulgatissimus*, and *Ischnura elegans*.] Address: Domek, P., Dept of Water Protection, Fac. Biology, Adam Mickiewicz Univ., Umultowska 89, 61-614 Poznań, Poland. E-mail: domekp@amu.edu.pl

10747. Eagles-Smith, C.A.; Suchanek, T.H.; Colwell, A.E.; Anderson, N.L. (2008): Mercury trophic transfer in a eutrophic lake: The importance of habitat-specific foraging. *Ecological Applications* 18(8) Supplement, 2008: A196-A212. (in English) ["Mercury (Hg) trophic transfer and bioaccumulation in fish from a mineimpacted eutrophic lake were examined in relation to foraging habitat, trophic position, and size. Diet analysis indicated that there were clear ontogenetic shifts in foraging habitats and trophic position. Pelagic diet decreased and benthic diet increased with increasing fish length in bluegill, black crappie, inland silverside, and largemouth bass, whereas there was no shift for prickly sculpin or threadfin shad. Stable carbon isotope values ($\delta^{13}C$) were inversely related to the proportion of pelagic prey items in the diet, but there was no clear relationship with benthic foraging. There were distinct differences between pelagic and benthic prey basal $\delta^{13}C$ values, with a range of approximately 28‰ in pelagic zooplankton to approximately 20‰ in benthic caddisflies. Profundal prey such as chironomid larvae had intermediate $\delta^{13}C$ values of approximately 24‰, reflecting the influence of pelagic detrital subsidies and suppressing the propagation of the benthic carbon isotope signal up the food chain. Fish total mercury (TotHg) concentrations varied with habitat-specific foraging, trophic position,

and size; however, the relationships differed among species and ages. When controlling for the effects of species, length, and trophic position, TotHg and $\delta^{13}\text{C}$ were positively correlated, indicating that Hg trophic transfer is linked to benthic foraging. When examined on a species-specific basis, TotHg was positively correlated with $\delta^{13}\text{C}$ only for bluegill, largemouth bass, and threadfin shad. However, diet-based multiple regression analyses suggested that TotHg also increased with benthic foraging for inland silverside and black crappie. In both species, benthic prey items were dominated by chironomid larvae, explaining the discrepancy with $\delta^{13}\text{C}$. These results illustrate the importance of foraging habitat to Hg bioaccumulation and indicate that pelagic carbon can strongly subsidize the basal energy sources of benthic organisms." (Authors) Diet items of the studied fishes include Odonata.] Address: Eagles-Smith, C., US Geological Survey, Western Ecological Research Center, Davis Field Station, One Shields Avenue, Davis, California 95616 USA. E-mail: ceagles-smith@usgs.gov

10748. Jackson, J.I.; Boutle, R. (2008): Ecological functions within a sustainable urban drainage system. 11th International Conference on Urban Drainage, Edinburgh, Scotland, UK, 2008: 10 pp. (in English) ["Sustainable Urban Drainage Systems (SUDS) are regarded as engineering solutions to urban storm water control and flood risk. Additional benefits from SUDS in the built environment include sediment entrapment and remediation of water quality from urban runoff through the use of retention/detention systems. Biodiversity value of SUDS is alluded to but few studies have evaluated conservation potential or monitored ecological processes that may occur within them." (Authors) Biodiversity (including Odonata) was studied at the family level.] Address: Jackson, Janet, School of Applied Scienc., Park Campus, Boughton Green Road, Northampton, NN2 7AL, UK. E-mail: janet.jackson@northampton.ac.uk

10749. Kuczyńska-Kippen, N. (2008): Spatial distribution of zooplankton communities between the Sphagnum mat and open water in a dystrophic lake. Polish Journal of Ecology 56(1): 57-64. (in English) ["Composition and dynamics of zooplankton (Rotifera, Crustacea) communities were studied in a dystrophic lake (Drawieński National Park, northern Poland). This lake is a typical mid-forest lake of a small area (ca. 0.65 ha) but relatively deep ($Z_{\text{max}} = 6.8\text{m}$) and covered with a peat (Sphagnum sp.) mat. The study was made in the shallow part of the lake ($Z = 0.5\text{m}$). Zooplankton was collected twice in August 2004, in triplicate subsamples, taken from three stations (1. under the peat mat, 2. the transitional zone between the peat mat and open water area and 3. open water zone) from two different sites within the same lake." (Author) The following Odonata taxa are listed: *Cordulia aenea*, *Enallagma cyathigerum*, *Ischnura elegans*, *Pyrrhosoma nymphula*, and *Leucorhinia* sp."] Address: Kuczyńska-Kippen, Natalia, Dept of Water Protection, Institute of Environmental Biology, Adam Mickiewicz University, Umultowska 89, 61-614 Poznań, Poland. E-mail: kippen@hot.pl

10750. Lee, E.-H.; Jang, H.-K.; Paik, M.-Y.; Yoon, J.; Kim, J.G.; Bae, Y.J. (2008): A preliminary study on a restoration of habitats for *Nannophya pygmaea* Rambur (Odonata: Libellulidae). Kor. J. Env. Eco. 22(1): 35-42. (in Korean, with English summary) ["This study was conducted to provide basic information that can be used to restore habitats of *N. pygmaea*. *N. pygmaea* is

an endangered species of wildlife fauna in Korea and its habitats are distributed very scarcely in Korea. Ten wetland sites throughout Korea, where *N. pygmaea* inhabited were investigated from June 2006 to August 2007. Investigation was made on landscape properties, habitat sizes, vegetation types, water environments, and water sources. *N. pygmaea* was generally found in the abandoned paddy fields surrounded by mountains. The habitats ranged from 113.4 m² to 1,153.1 m² in area, and were mostly dominated by *Juncus effusus* and *Persicaria thunbergii*. The water level was 2.6-7.3 cm, and the water temperature ranged from 16°C to 27.8°C. The elevation of the habitats ranged from 139 to 243 m a.s.l., which was mostly lower than that of other high mountain wetland habitats. In conclusion, the habitats of *N. pygmaea* can be restored at wetlands, which have similar condition with field habitat such as abandoned paddy fields in the beginning stage of oligotrophy. Because *N. pygmaea* is sensitive to microtopography and other surrounding environments, the approach to restore the habitats for *N. pygmaea* should consider those microhabitat conditions shown in this study." (Authors)] Address: Lee, Eun-Heui, Division of Environmental Life Sciences, Seoul Women's Univ., Korea.

10751. Légaré, S.; Labonté, P.; Champoux, L. (2008): Impacts des précipitations acides sur la faune benthique des lacs québécois. Naturaliste Canadien 132 (2): 67-74. (in French, with English summary) ["Despite significant reductions in emissions observed in Canada and the United States for three decades, acid rain still represent one of the most serious threats to ecosystems in eastern Canada. The Canadian Wildlife Service has set up a monitoring network to document the current impacts and long-term acid deposition on aquatic fauna. Between 2001 and 2003, the animal communities of 33 lakes in southern Quebec have been inventoried. The results show that the acidity of water affects benthic invertebrates by reducing their abundance and the number of taxa present. Some families of amphipods, gastropods and mayflies appear particularly vulnerable to acidification and have good potential as bio-indicator for monitoring on the long term. An increase in the number of taxa was observed from east to west of the study area. Other chemical, physical, biological and geographical influence community composition and should be considered." (Authors) Canonical Correspondance Analyses also included at the family level Gomphidae and Corduliidae] Address: Légaré, S. E-mail: Stephane.legare@ec.gc.ca

10752. Ott, J. (2008): Libellen als Indikatoren der Klimaänderung – Ergebnisse aus Deutschland und Konsequenzen für den Naturschutz. Insecta 11: 75-89. (in German) [The author reviews his recent (1988-2008) research on Odonata as indicators of climatic change in Germany and on implications of the latter for nature conservation. Emphasis is given to *Crocothemis erythraea*.] Address: Ott, J., Friedhofstr. 28, D-67705 Trippstadt, Germany. E-mail: L.U.P.O.GmbH@t-online.de

10753. Subramanian, K.A.; Samir, A.; Ramachandra, T.V. (2008): Odonates as indicators of riparian ecosystem function-A case study from south western Karnataka. Fraseria (N.S.) 7: 83-95. (in English) ["The influence of riparian land use on the diversity and distribution were investigated by sampling 113 localities covering 4 districts in south-western Karnataka, India. A total of 55 species in 12 families were recorded. Streams, rivers and lakes had higher diversity than marshes and

sea coast. However, lakes had low endemism than streams and rivers. Streams flowing through evergreen forests had higher diversity and endemism. Human impacted riparian zones such as paddy fields had relatively lower species richness. However, streams flowing through forestry plantations had higher diversity than other natural riparian zones such as dry deciduous, moist deciduous and semi evergreen forests. Myristica swamps-a relict evergreen forest marsh had low diversity and high endemism. Odonate communities of lentic ecosystems, and human impacted streams and rivers were characterized by widespread generalist species. Endemics and habitat specialists were restricted to streams and rivers with undisturbed riparian zone. The study documents possible odonate community change due to human impact: The influence of riparian landuse change on odonate community is also discussed." (Authors)] Address: Subramanian, K.A., Zoological Survey of India, Western Regional Station, Pune-411 044 Maharashtra, India. E-mail: subbuka.zsi@gmail.com

10754. Ware, J.L. (2008): Molecular and morphological systematics of Libelluloidea (Odonata: Anisoptera) and Dictyoptera. Dissertation, Graduate School-New Brunswick Rutgers, The State University of New Jersey: III + 260 pp. (in English) ["Libelluloidea are highly successful dragonflies with unique behaviour and life histories. The systematics of Libelluloidea (Odonata: Anisoptera) has historically been in conflict, with little agreement about the number of families that are comprised in this large, heterogeneous group. For my PhD thesis, I have assembled the most comprehensive molecular and morphological libelluloid dataset to date, in an attempt to revise and simplify libelluloid taxonomy, and to answer questions about the evolutionary history of the group. I ran Bayesian and parsimony analyses to recover phylogenetic hypotheses with which I explore the success of Libelluloidea. Divergence estimation, a method by which nodes of a tree are dated, was first explored under different evolutionary models for a subset of libelluloid taxa in order to determine whether treatment of hydrogen-bonded ribosomal nucleotides affected the age of divergence estimates. Using methodology based on these results, I was able to estimate divergence dates and diversification rates for the first large-scale dating analysis of dragonflies. On a smaller scale, I also completed a study of *Syncordulia*, a vulnerable genus of endemic South African libelluloid dragonflies whose systematics was not yet confirmed. Additional studies of phylogenetic methodology were undertaken in my thesis work for another large and heterogeneous group, the Dictyoptera (Mantodea, Blattodea and Isoptera). In this study, the effect of outgroup selection was determined using a broad, comprehensive taxon set for which we had both molecular and morphological data. These results suggest that the evolution of sociality, on which much of the recent discussion in dictyopteran systematics has focused, cannot be reliably determined when different outgroups recover dramatically conflicting topologies." (Author)] Address: Ware, Jessica L., Rutgers, The State University of New Jersey, Cook College, 93 Lipman Drive, New Brunswick, New Jersey 08901, USA. E-mail: jware@amnh.org

10773. Altamiranda-S., M.; Perez-G., L.A.; Gutierrez-M., L.C. (2010): Composition and microhabitat preference of Odonata larvae (insecta) in the San Juan de Tocagua swamp (Atlántico, Colombia). *Caldasia* 32(2): 399-410. (in Spanish, with English summary) ["We evaluated the response of the assembly of Odonata larvae to the available substrates on the shoreline of the Swamp San Juan de Tocagua, Atlántico, Colombia. We sampled the habitats from September 2006 to March 2007 to estimate diversity, richness and abundance of larval odonates. We also measured physical

and chemical parameters of the water body. The species showed a broad occupancy of the substrate, with greater cover and permanence on the floating macrophytes and the muddy bottom. The species of the bottom of the swamp were not associated with a particular type of texture. The measured physicochemical factors were not associated with the diversity, richness and abundance of the larvae in the system, suggesting that the variation in the values of these parameters does not explain the response of the assembly during the study." (Authors) The following taxa are involved into the study: *Ischnura ramburii*, *Telebasis* sp., *T. salva*, *T. filiola*, *Triacanthagyna septima*, *Coryphaeschna adnexa*, *Dythemis sterilis*, *Erythemis plebeja*, *E. attala*, *Erythrodiplax umbrata*, *E. fervida*, *Miathyria simplex*, *Perithemis mooma*, and *Tramea onusta*.] Address: Altamiranda-S., M., Universidad Nacional de Colombia sede Medellín, Apartado 3840, Medellín, Colombia. E-mail: maltamiranda@gmail.com.

10774. Balzan, M.V. (2010): An integrative ecological approach towards insect conservation in a Mediterranean agricultural landscape: The case of Insect (Odonata) fauna in the Maltese Islands. 40th Anniversary Conference. Gesellschaft für Ökologie. Book of Abstracts August 30th to September 03rd, 2010: 364. (in English) [Verbatim: An integrative ecological approach to the assessment of conservation of insect groups within highly modified Mediterranean agricultural landscapes is proposed. A hierarchical multiscale analysis was carried out and investigated how habitat characteristics at multiple scales, ranging from the immediate habitat structure to the local agricultural landscape characteristics, influence a target group (Insecta: Odonata) distributions. Multivariate statistical procedures were used to analyse the relationship between Odonata assemblage patterns and environmental variables. Moreover, stakeholders were considered as an inherent part of the landscape, and consequently local ecological knowledge together with stakeholders' perception of insect conservation was carried out. Results from this study suggest that Odonata populations are influenced by habitat characteristics at multiple scales, ranging from the physical properties and characteristic vegetation to landscape composition and diversity. Concurrently, this study identified farmers' perception of insects in agricultural landscapes, their conservation, cause of decline of 'beneficial' species, and persistent pest problems arising from resource management actions. Grounded in these findings, an iterative and integrative ecosystem-based management approach is proposed for the conservation of insect species in the agricultural landscapes.] Address: Balzan, M.V., Malta College of Arts, Science and Technology

10775. Bazova, N.V.; Bazov, A.V. (2010): Ecology of odonate larvae (Odonata) in the Selenga river. Eurasian Entomological Journal 9(2): 285-289. (in Russian, with English summary) [Between 1987-2005, data on the occurrence, abundance and biomass of *Ophiogomphus* sp. larvae in the channel part of the Selenga (from its outlet on Lake Baikal to the Mongolian border), are analysed, based on 2316 quantitative samples, taken from 25 vertical sections from beneath the ice (December and March). Habitat parameters were noted to a depth of 1-2 m, with a low stream velocity (0.0-0.4 m/s). During the under-the-ice period, larvae move to the deeper parts of the channel because of the significant fall of water level and the increasing of the ice thickness near

the bank (up to 2 m). This is considered as a normal behaviour in *Ophiogomphus* sp.] Address: Bazova, N.V., Institute of General and Experimental Biology, ul. Sakhyanovoy 6, Ulan-Ude, 670042 Russia

The resident *Erythromma viridulum* population seemed at a very low ebb until numbers of presumed immigrants appeared in mid-August." (Author) see also Harvey & Higott (2009)] Address: not stated

10777. Brucet, S.M.; Boix, D.; Quintana, X.D.; Jensen, E.; Nathansen, L.W.; Trochine, C.; Meerhoff, M.; Gascon, S.; Jeppesena (2010): Factors influencing zooplankton size structure at contrasting temperatures in coastal shallow lakes: Implications for effects of climate change. Limnol. Oceanogr. 55(4): 1697-1711. (in English) ["We assessed the importance of temperature, salinity, and predation for the size structure of zooplankton and provided insight into the future ecological structure and function of shallow lakes in a warmer climate. Artificial plants were introduced in eight comparable coastal shallow brackish lakes located at two contrasting temperatures: cold-temperate and Mediterranean climate region. Zooplankton, fish, and macroinvertebrates were sampled within the plants and at open-water habitats. The fish communities of these brackish lakes were characterized by small-sized individuals, highly associated with submerged plants. Overall, higher densities of small planktivorous fish were recorded in the Mediterranean compared to the cold-temperate region, likely reflecting temperature-related differences as have been observed in freshwater lakes. Our results suggest that fish predation is the major control of zooplankton size structure in brackish lakes, since fish density was related to a decrease in mean body size and density of zooplankton and this was reflected in a unimodal shaped biomass-size spectrum with dominance of small sizes and low size diversity. Salinity might play a more indirect role by shaping zooplankton communities toward more salt-tolerant species. In a global-warming perspective, these results suggest that changes in the trophic structure of shallow lakes in temperate regions might be expected as a result of the warmer temperatures and the potentially associated increases in salinity. The decrease in the density of large-bodied zooplankton might reduce the grazing on phytoplankton and thus the chances of maintaining the clear water state in these ecosystems." (Authors) Macroinvertebrate predators of zooplankton sampled include coenagrionid larvae and *Ischnura elegans*.] Address: Brucet, Sandra, National Environmental Research Institute, Dept of Freshwater Ecology, Aarhus University, Silkeborg, Denmark. It introduces the regional natural history, maps all records and presents threats to each Odonata species. The study is arranged in a monographic style

with photographs to each species.] Address: Kern, D., Taxusweg 2, D-27232 Sulingen, Germany

10797. Knill-Jones, S. (2010): Reports from Coastal Station - 2009: Isle of Wight, Hampshire. *Atropos* 39: 45-47. (in English) [*Cordulia aenea*, *Brachytron pratense* and *Sympetrum fonscolombii* were brought on record.] Address: not stated

10798. Latha, C.; Thanga, V.S.G. (2010): Choice of bio-indicator species for estuaries of south Kerala: An approach based on macroinvertebrate. *The Ecoscan* 4(4): 285-289. (in English) ["Spatial and temporal patterns of macroinvertebrate community structure were used to assess the water quality of two estuaries in south Kerala viz., Kadinamkulam and Veli. A total of 14,660 individuals representing 24 taxa and 3 phyla viz., Mollusca, Arthropoda and Annelida were collected from the sampling sites. The dominance of taxa varied with seasons as well as sites. Species abundance was highest at V2 followed by K. Species richness, abundance and diversity were found to be lowest in site K2. Diversity index ranged from 0.27 to 2.33. At V1, there was no significant difference ($p > 0.05$), K1 was found to be significantly different from K2 and V2; K2 was significantly different from sites K3 and V3; K3 differed significantly from V2 ($p < 0.05$); V3 was significantly different from V2 ($p < 0.01$). Kadinamkulam was found to be highly polluted than Veli considering the richness and abundance of macroinvertebrates in the estuaries. The indicator species chosen for Kadinamkulam was Culicidae and Chironomidae; whereas they were Peracaridae and Planorbidae for Veli. [...] Corduliidae, Aeshnidae, Coenagrionidae were present only in V1 and V2." (Authors)] Address: Latha, C., Department of Zoology, M. S. M College, Kayamkulam, University of Kerala - 690 502, India. 10804. Orr, A.G.; Kalkman, V.J. (2010): *Arrhenocnemis parvibullis* sp. nov. (Odonata: Platycnemididae), a new calicnemiine damselfly from Papua New Guinea, with a description of the female of *A. amphidactylis* Lieftinck, 1949. *Australian Entomologist* 37(4): 137-146. (in English) ["*Arrhenocnemis parvibullis* (Odonata: Platycnemididae), from the Muller Range of Papua New Guinea is described and its habits and habitat discussed. It represents the third species of this distinctive genus, known from just 16 specimens. The recently discovered female of *A. amphidactylis* is described for the first time." (Authors)] Address: Orr, B., Griffith School of Environment, Griffith University, Nathan, Qld. 4111, Australia

10805. Parr, A. (2010): Migrant dragonflies in 2009, including recent decisions and comments by the Odonata Records Committee. *Atropos* 39: 26-33. (in English) ["The 2009 season saw major arrivals of *Sympetrum fonscolombii* during the late spring and summer, and a significant hot weather movement of many migratory/dispersive species during a short period around the end of June/early July. Other significant finds included the discovery of singleton *Lestes barbarus* at three sites on the East Anglian coast during August. The highlight of the year was, however, the discovery of large numbers of *Lestes viridis* in southeast Suffolk, under circumstances strongly suggestive of the presence of a recently-established breeding population." (Author) A total of 18 Odonata species is documented and discussed.] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK. E-mail: Adrian.parr@bbsrc.ac.uk

10806. Paulson, D.A. (2010): Review: GARRISON, R. W., VON ELLENRIEDER, N., AND LOUTON, J. A. 2010. *Damselfly Genera of the New World, an Illustrated and Annotated Key to the Zygoptera*. The Johns Hopkins University Press, 490 pp., 2586 figs., 108 maps. ISBN 978-0-8018-9670-5. Hardback, \$84.37 (amazon.com). *Florida Entomologist* 93(4): 666. (in English) [Verbatim: "This book follows by four years its companion volume on the Anisoptera of the New World by the same authors (Garrison et al. 2006, reviewed in *Florida Entomologist* 90: 290-291). Although about the same number of genera (124 Anisoptera, 118 Zygoptera) are treated in the two books, the dragonflies are treated in 368 pages with 1626 figures, the damselflies in 490 pages with 2586 figures. This points out the considerably greater degree of work and detail the authors put into the second volume. In addition, while preparing to write and writing this volume, the first two authors have become the pre-eminent odonate taxonomists of the New World tropics, publishing no fewer than 17 papers (since 2000) to clarify the taxonomy of numerous

groups, some of them large. Before this, the largest family, Coenagrionidae, was a taxonomic quagmire, and now a fair modicum of order has emerged from the chaos. How else to build a key to genera that actually works? This book easily lives up to the expectations promised by the dragonfly volume, including comprehensive, extremely well illustrated keys; detailed morphological descriptions of each genus; and brief descriptions of natural history wherever known. The writing is clear, but its conciseness fails to convey how much work at the microscope must have gone into the keys and descriptions. And most of us will be unable to imagine the amount of time that went into producing the figures. They are meticulous and superb, by the standards of any scientific illustrator. They are lavishly provided, often more than one species in a genus. I am constantly engaged by the morphological diversity of damselflies that one can see under magnification, and this book shows it all. Many of them were used before, in their recently published papers, but the majority appear uniquely in this book. Having worked with the authors on several genera, I can add that they are impeccably accurate. The three-dimensional rendering of medio-dorsal views of terminal appendages is so much more helpful than the old standard of dorsal and lateral views that one wonders why the excellent illustrators of a century ago didn't come up with it. There are a lot more photos in this book than in the dragonfly book, 81 vs. 24, and the beauty and variety of New World damselflies are shown off to the fullest. All the families are represented, and there was a real effort made to get all the genera. Many have not been photographed. Everything about this volume invites the term "comprehensive." The maps of generic ranges are of great value to the biogeographer and might be used to point out poorly surveyed regions. The long list of references provides access to the taxonomic and biological literature of all New World damselflies, and to that all-important opportunity to identify specimens to species. The list that attributes a locality to every figure is a nice touch. If there are mistakes in the volume, I did not find them with my level of scrutiny. The very timely Appendix lists additions and corrections to the Anisoptera volume, and such a list will doubtless be generated for this volume in a few years. Like Philip Corbet's grand book on Odonata (Corbet 1999), the two superb volumes from these authors are perfectly placed to show us what still needs to be done: 1) databasing and georeferencing existing collections to give an even clearer picture of regional biodiversity; 2) many more surveys and much more collecting over neotropical regions that are still poorly known; 3) modern taxonomic revisions of genera that have not yet received that treatment; and 4) sets of keys to species, especially regional keys such as those by Lencioni (2005, 2006). Finally, regional photo-illustrated field guides to all species!" Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dpaulson@ups.edu

10807. Rozner, G.; Lökkös, A.; Ferincz, A. (2010): Preliminary studies on the distribution of Large Golden Ringed Dragonfly (*Cordulegaster heros* Theischinger, 1979) and Golden Ringed Dragonfly (*Cordulegaster bidentata* Selys, 1843) in the Kőszeg-mountains. *Folia Historico-Naturalia Musei Matraensis* 34: 37-40. (in English) ["In former studies the occurrence of *C. bidentata* was reported from the Kőszeg Mountainins, Bakony Mountains and Northern Mountains, *C. heros* was found in the Mecsek, the Sopron Mountains, the Örség and nowa-

days it has been observed in the Zselic Hills. In the years 2008 and 2010 our examinations confirmed the occurrence of *C. heros* also in several waterflows of Kőszeg Mountains." These findings enlarge the known regional range of distribution of *C. heros*, and evidence the co-occurrence of the two species in Hungary.] Address: Rozner, G., Managership of Balaton-felvidéki National Park, H-8229 Csopak, Kossuth u. 16, Hungary

10815. van Dijk, T. (2010): Effects of neonicotinoid pesticide pollution of Dutch surface water on non-target species abundance. MSc Thesis, Sustainable Development, Track Land use, Environment and Biodiversity (SD: LEB), Utrecht University: 75 pp. (in English) ["Conclusions: Neonicotinoid pesticides are applied in the largest amounts where potatoes, horticultural products and chicory are grown. In these areas, which are mainly found in the Dutch provinces of Zuid-Holland, Noord-Holland, Zeeland and Groningen, imidacloprid can be found in the surface water in concentrations often far exceeding the MTR norm of formerly 13 ng/l and presently 67 ng/l. Neonicotinoid pesticides work by inhibiting nerve impulses in susceptible species, particularly insects, which leads to their demise and, at lower concentrations, several sublethal effects including reduced learning and signalling, and starvation of the individual or colony. The effects of neonicotinoid pesticides on many non-target species have been reported in scientific literature – in this study, toxicity data from previous research were listed for 44 different species. Flying insects quite consistently appeared to be the most vulnerable to neonicotinoids, and therefore species abundance of three orders of flying insects was combined with imidacloprid concentrations in the Dutch surface water, to see whether any correlation between these properties existed. Six other orders, of aquatic insects and crustaceans, were also included in this analysis. Species abundance for the flying insect order Diptera tends to decrease with increasing imidacloprid concentration. This was shown by all three different methods of analysis used: classification by number of times the MTR norm, classification by groups with equal n, and visualisation of data in scatter plots. All methods yielded significant results for Diptera. The order Hydracarina showed an opposite effect, as abundances were higher at high imidacloprid concentrations. Results for the other orders were often more ambiguous. However, after a square root transformation had been applied to the data, the significance of the finding that Coleoptera, Amphipoda and Odonata are negatively influenced by the presence of imidacloprid was shown to be at a 93, 89 and 87% confidence level, respectively. Also, the scatter plots of transformed data for all orders showed declining trend lines for separate species and sometimes for all species together, and these were significant for Diptera and all species of Amphipoda together, and had a relatively high level of significance for a species of Trichoptera and most species of Heteroptera. This indicates that if the amount of data available had permitted

analysing separate species, more significant differences might well have been found, as the presence of insensitive species may have distorted results for the entire order. If analysis of separate species had been possible, the hypothesis drafted for this study might have been confirmed unequivocally. As is, the hypothesis has been confirmed for Diptera, and, less strongly, for Coleoptera, Amphipoda, Heteroptera and Odonata. It was invalidated for Hydracarina, and for the other orders results were ambiguous." (Author)] Address: not stated

10821. Abdel-Gawad, F.K.; Hassanein, M.A.; Lofty, N.M.; Bassem, S.M. (2011): Evaluation of DNA damage in fish and aquatic insects induced by environmental pollutants in River Nile. World Applied Sciences Journal 14(7): 1085-1090. (in English) ["The development of comet assay for aquatic organisms is of particular relevance in light of the importance of fisheries testing for environmental pollutants. Various tests in organisms have been utilized for the detection and identification of toxic substances in the air, water and soil. In the present study, the comet assay was applied on fish and aquatic insects to conduct an environmental assessment of River Nile. The collected samples from the mixed point of waste water represented the highest degree of DNA damage concerning damage stages and comet% followed by the mixed point of agriculture drain when compared with samples collected from control site. Results of DNA damage by one way ANOVA analysis of tail moment of fish and aquatic insects collected from this study demonstrates the potential application of the comet assay to different aquatic sites were not significantly different from samples collected from control site ($P=0.08$). While when analyzing other comet parameters (comet% and tail length) samples were significantly different ($P=0.04$). The results suggested a genotoxicity of the aquatic environment at River Nile and that the comet assay in fish and aquatic insects provided adequate sensitivity to be utilized as a tool in the monitoring of water pollution and environmental risk assessment." (Authors) The study includes *Enallagma (Azuragrion) vansomeri*.] Address: Fagr Abdel-Gawad, Dept of Water Pollution, National Research Cen-

ter, Dokki, Giza, Postal code 12622, Egypt. E-mail: fagr-abdlgawad@gmail.com

10822. Ahani, M. (2011): Environmental assessment of downstream water from Latian Dam using benthics as a biological index. International Conference on Chemical, Environmental and Biological Sciences (ICCEBS'2011): 302-307. (in English) [Iran; "This paper reports the results of a study on the environmental assessment of the downstream water using benthics as a biological index of water quality in Jajrood River. The research was carried out at four sampling sites of a downstream section of Latian Dam in the fall-winter and spring seasons. Using the Hilsenhoff Biotic Index to assess water quality at the sampling sites, the monthly and seasonal flow water changes were investigated in the Jajrood catchment for a period of 30 years. Statistical investigations indicate that spring is the wettest season in the Jajrood catchment, and the result of a paired t-test indicates that the seasonal differences of all benthic families except Rhyacophilidae is significant. According to the Hilsenhoff Biotic Index results, the water quality downstream of Latian Dam was average at three sampling sites, and the water quality was only good at site 2. The dominant benthic families were Chironomidae and Caenidae. In this study, the presence of pollution-tolerant families in the sampling sites indicates that these sites are ecologically unhealthy and that the flow water at the downstream section of Latian Dam differs considerably from the environmental flow water requirements of aquatic ecosystems during the fall-winter and spring seasons." (Author) Odonata (Platycnemidae, Coenagrionidae) are only represented in spring in low abundances.] Address: Ahani, M., Department of Environment planning and management, Faculty of Environment, Tehran University, Tehran, Iran. Email: Monireh Ahani@yahoo.com

10823. Akin, S.; Sahin, C.; Verep, B.; Turan, D.; Mutlu Gözler, A.; Bozkurt, A.; Çelik, K.; Çetin, E.; Aracı, A.; Sargın, Y (2011): Feeding habits of introduced European perch (*Perca fluviatilis*) in an impounded large river system in Turkey. African Journal of Agricultural Research 6(18): 4293-4307. (in Akin, S., Faculty of Agriculture, Department of Fisheries and Aquatic Sciences, Gaziosmanpasa University 60240 Tokat, Turkey. E-mail: senol.akin@gop.edu.tr) ["The feeding habits of perch were documented by analyzing gut contents of more than 3300 specimens collected seasonally at nine stations located along the impounded large river in Turkey. Perch largely preferred fish (36%), insects (54%), other crustaceans (16%) and daphnia (13%). Spatial analysis showed that perch substantially preferred fish in the river section above the dam lakes and insects, crustacean and fish in the river section below the dam lake and in dam lakes. The perch at every size seemed to prefer fish with the highest and lowest percentage obtained for 0 to 80 and 141 to 200 mm. Insects and crustaceans were important for 81 to 140 mm and 0 to 120 mm length, respectively. Crustaceans were important in June, November and July. Insects and fish except for June 2009 constituted an important portion of the diets during every sampling month. The perch showed a piscivory feeding habit, a result obtained by trophic level calculated by stomach contents (3.87) and stable isotope (3.91) methods. Trophic level change little during the ontogeny with relatively higher value obtained for the larger length. The perch inhabiting in the river section above the dam lakes had the highest trophic level compared to the other sites. Diet breadth of perch was

lower and higher for larger and middle length (101 to 140 mm), respectively. The diet breadth was higher in dam lakes, indicating opportunistic feeding habits in lakes. Being the most abundant fish species in the study system and showing predatory feeding habits suggested that perch may have an effect on local fish assemblage and itself through predation." (Authors) The diet includes very few Odonata specimens.] Address: not stated

10824. Amaya Vallejo, V.; Novelo-Gutierrez, R. (2011): The larva of *Palaemnema mutans* Calvert, 1931 (Odonata: Platystictidae). Zootaxa 3049: 59-63. (in English, with Spanish summary) ["The larva of *P. mutans* is described, illustrated, and compared with larvae of the genus described to date. *P. mutans* differs from the other species in having a shorter body length, a larger number of teeth in the internal molar lobe of the left mandible and shorter caudal lamellae, as well as an apical filament proportionally longer than in any other species. The hypopharynx is described for the first time for the genus. This is the first record of *P. mutans* for Colombia." 10825. Ammerschlaeger, J.; Hübner, T.; Kiel, E.-F. (2011): Maßnahmen zur Anpassung an den Klimawandel in NRW. Möglichkeiten, die Auswirkungen des Klimawandels auf Arten und Lebensräume abzuschwächen. Natur in NRW 4/11: 11-14. (in German) [Measures to deaden climatic effects on the regional fauna are discussed. Dragonflies most serious susceptible by the effects and therefore of concern are *Somatoclora arctica*, *S. flavomaculata*, *Thecagaster bidentata*, *Aeshna subarctica elisabethae*, *Leucorrhinia dubia*, *L. rubicunda*, *Coenagrion lunulatum*, and *C. hastulatum*.] Address: Hübner, T., LANUV, Leibnitzstr. 10, 45659 Recklinghausen, Germany. E-mail: thomas.huebnerlanu.nrw.de

10826. Andrew, R.J.; Thakkar, N.; Dhamani, A.A. (2011): Eggshell ultrastructure of the damselfly *Ceragrion coromandelianum* (Zygoptera: Coenagrionidae). National Seminar on Biodiversity and Intangible Natural Heritage on 28th September, 2011. Organised by National Museum of Natural History Zoological Survey of India, Tansen Marg, New Delhi (MoEF, Govt. of India), M-Block, New Alipore, Kolkata (MoEF, Govt. of India) on September 28th, 2011: 23. (in English) [Verbatim: Scanning electron microscopic examination of the egg of *C. coromandelianum* reveals that it is elongate and cylindrical with a pointed anterior and rounded posterior end. The egg chorion is composed of an outer, thin, lightly corrugated exochorion and an inner, thick, smooth, non-porous endochorion. The anterior end is circumscribed by five micropylar orifices. Each orifice is semicircular and continues as a long horizontal streak on the endochorion and concludes at a bifid terminal point. This forms the entry point of the micropylar chute which penetrated the endochorion. The vitelline envelope lodged below the endochorion is thin and smooth.] Address: Dhamani, A.A., Nevjabai Hitkarini College, Brahmapuri, Dist.- Chandrapur (MS), India

10827. Andrew, R.J. (2011): Diversity in the egg shell ultrastructure of dragonflies (Insecta: Odonata). National Seminar on Biodiversity and Intangible Natural Heritage on 28th September, 2011. Organised by National Museum of Natural History Zoological Survey of India,

Tansen Marg, New Delhi (MoEF, Govt. of India), M-Block, New Alipore, Kolkata (MoEF, Govt. of India) on September 28th, 2011: 24-25. (in English) [Verbatim: The present report describes the ultrastructural diversity of the egg shell of five odonates exhibiting different mode of oviposition and fertilization. The dragonflies lay eggs in and around water bodies because of their amphibiotic nature. The type of water body and substrate used for oviposition has a profound influence on the ultrastructural modifications of the eggshell. The eggshell is divided into an external chorion and an inner vitelline envelope. The chorion is further differentiated into an outer exochorion and an inner endochorion. Both the layers of the chorion exhibit ultrastructural radial and regional complexities. Scanning electron microscopic investigations reveal that the radial complexity is customized in accordance with the mode of oviposition whereas the regional complexity is modified for effective fertilization and complements the fertilization pore of the vagina. The functional significance of the egg chorion is described, classified and discussed in the light of recent literature.] Address: Andrew, R.J., Shri Dnyanesh Mahavidyalaya, Navargaon, Dist. Chandrapur- 441 223, (MS), India

10828. Angert, A.L.; Crozier, G.G.; Rissler, L.J.; Gilman, S.E.; Tewksbury, J.J.; Chunco, A.J. (2011): Do species traits predict recent shifts at expanding range edges. *Ecology Letters* 14: 677-689. (in English) ["Although some organisms have moved to higher elevations and latitudes in response to recent climate change, there is little consensus regarding the capacity of different species to track rapid climate change via range shifts. Understanding species abilities to shift ranges has important implications for assessing extinction risk and predicting future community structure. At an expanding front, colonization rates are determined jointly by rates of reproduction and dispersal. In addition, establishment of viable populations requires that individuals find suitable resources in novel habitats. Thus, species with greater dispersal ability, reproductive rate and ecological generalization should be more likely to expand into new regions under climate change. Here, we assess current evidence for the relationship between leading-edge range shifts and species traits. We found expected relationships for several datasets, including diet breadth in North American Passeriformes and egg-laying habitat in British Odonata. However, models generally had low explanatory power. Thus, even statistically and biologically meaningful relationships are unlikely to be of predictive utility for conservation and management. Trait-based range shift forecasts face several challenges, including quantifying relevant natural history variation across large numbers of species and coupling these data with extrinsic factors such as habitat fragmentation and availability. [...] British Odonata: Lm analyses of Odonata range shifts yielded low to moderate explanatory power ($R^2 = 0.10-0.24$; Table 3). Egg habitat, which is associated with clutch size, had a marginally significant positive effect in most top-ranked models and was the variable with highest relative importance (Table 3), but confidence intervals surrounding the model-averaged regression coefficient for egg habitat contained zero (Fig. 1c). In phylogenetically corrected analyses, egg habitat became a statistically significant predictor variable (Fig. 2c; Table 3). Specifically, exophytic species (large clutches laid on water or land) shifted 0.83 standard deviations (65.69 km) further north, on average, than endophytic species (small clut-

ches laid in plants)."] Address: Angert, Amy, Department of Biology and Graduate Degree Program in Ecology, Colorado State University, Fort Collins, CO 80523, USA. E-mail: amy.angert@colostate.edu

10829. Appel, E.; Gorb, S.N. (2011): Resilin-bearing wing vein joints in the dragonfly *Epiophlebia superstes*. *Bioinspiration & Biomimetics* 6(4) 046006 doi: 10.1088/1748-3182/6/4/046006: 11 pp. (in English) ["In this study, we compared the dorsal and ventral patterns of three vein joint types and three types of resilin patches in the wings of the dragonfly *E. superstes*. The joint types were classified according to their general structure and the resilin patch types according to their arrangement at joints and in the adjacent wing membrane. Resilin patches are found in both dorsal and ventral pleat valleys of the corrugated wings of *E. superstes*, which results in different patterns of resilin distribution on the dorsal and ventral sides of the wing. In addition to its probable function in conferring flexibility to stressed joints, resilin may also have a damping function. Our results suggest that resilin patches in the leading edge may be loaded in compression, whereas in the trailing area, they may be involved in angle widening and thus loaded in tension. Possible adaptations to the deformability of different areas of the wing, e.g. during the process of camber formation, are discussed."] Address: Gorb, S.N., Functional Morphology and Biomechanics, Zoological Institute, Christian-Albrecht University of Kiel, 24098 Kiel, Germany. E-mail: sgorb@zoologie.uni-kiel.de

10830. Appel, E.; Gorb, S.N. (2011): Resilin in dragonfly wings. Abstracts - DGaaE-Entomologentagung 21.-24.3.2011 Berlin: 27. (in English) ["Resilin is well known for its rubber-like properties, including long-range (visco-) elasticity, ability to store kinetic energy, absorb shocks, and enhance flexibility of cuticular structures. In insect flight systems it has already been described in vein joints, veins, folding lines, transitions between veins and wing membrane, as well as in wing hinges and elastic muscle tendons in various species, including Coleoptera and Dermaptera. In contrast to wings of neopteran insects, where resilin plays a crucial role in wing folding, examinations on the distribution of resilin in wings of Odonata is especially important for understanding wing mechanics during flight, because the rather stiff corrugated wings of representatives of this order cannot be folded. Previously, only wings of the damselfly *Enallagma cyathigerum* Charp. (Coenagrionidae) have been studied (Gorb, 1999). In the present study we combined (1) fluorescence microscopy, (2) scanning electron microscopy, and (3) simple mechanical tests to elucidate the distribution of resilin patches in wings of the basal anisozygopteran species, *Epiophlebia superstes* Selys (Epiophlebiidae). Resilin patches are mainly located in wing vein joints situated in pleat valleys, thus their distribution distinctly differs between the dorsal and ventral wing sides. Our morphological results complement data from previous experimental studies (Wootton & Newman, 1986; Kim et al., 2009) to suggest that resilin is involved in either compression or tension, depending on the location in either narrow pleats at the leading edge (compression) or shallower pleats at the trailing area (allowing the angle widening). This morphological basis enables rather stiff, ultralight, and corrugated wings to bear deformations, e.g. during camber formation, without material damage or fatigue, thus enabling the strong lift production Odonata are

known for." (Authors)] Address: Appel, Esther, Dept of Functional Morphology and Biomechanics, Zoological Institute, Christian Albrechts University, Kiel, Germany, estherappel@gmx.de

10831. Asimea, O.A.; Zakka, U. (2011): The effect of petroleum waste on insect occurrence, speciation and distribution at the Brass Terminal in Niger delta area of Nigeria. *Journal of Emerging Trends in Engineering and Applied Sciences* 2(5): 782-786. (in English) ["Species occurrence and distribution of insects was investigated around Brass oil terminal where petroleum waste was constantly released into the Brass river through a man made canal. Random soil samples were collected from various locations distributed between Brass community and the oil terminal. At each sampling location, the soil samples were analysed for physico-chemical parameters using standard methods. Insects were collected using sweep net and traps. Electrical conductivity, pH and nutrient parameters of soil were within acceptable limits, microclimatic conditions like ambient temperature and relative humidity were within permissible range. Twenty-eight species of insects representing 23 families in 9 orders was recorded at Okpoma community that recorded 28.49 mg/kg THC and 12.85 mg/kg TPH. Twenty five insect species representing 17 families in 8 orders were recorded at the tank farm that had 51.09 mg/kg and 40.69 mg/kg TPH and only 5 species representing 4 families were encountered along the banks of effluent canal that had a value of 1261.41 mg/kg and 935.85 mg/kg TPH. Species common in hydrocarbon contaminated environment were *Camponotus sericeus*, *Crioceris latipennis* (Chrysomelidae), *Gryllus pennsylvanicus*, and *Allonemobius fasciatus* (Gryllidae). These species were able to tolerate hydrocarbon impacted environment. The aim of this investigation is to identify insect species that thrive in petroleum waste polluted environment and to explore their use as bio indicators of petroleum hydrocarbon pollution." (Authors) *Agriocnemis pygmaea*, *A. femina*, *Umma longistigma*, and *Orthetrum abbotti* are listed in the appendix to the paper.] Address: Zakka, U., Department of Crop and Soil Science, Faculty of Agriculture, University of Port Harcourt, Nigeria

10835. Bakare, S.S.; Andrew, R.J. (2011): The genital ducts of the male dragonfly *Anax guttatus* (Anisoptera: Aeshnidae). National Seminar on Biodiversity and Intangible Natural Heritage on 28th September, 2011. Organised by National Museum of Natural History Zoological Survey of India, Tansen Marg, New Delhi (MoEF, Govt. of India), M-Block, New Alipore, Kolkata (MoEF, Govt. of India) on September 28th, 2011: 23-24. (in English) [Verbatim: Light and transmission electron microscopic (TEM) studies reveal marked variations in the ultra structure of the male genital duct as it terminates into the sperm sac. TEM studies show two types of cells, the brush border cells with short motile irregular microvilli and the smooth border cells in the wall of vasa deferentia. Moreover, the seminal vesicles contain only the cells with brush border. Large number of electron dense granules and cell-coat particles accumulate in the lumen of vasa deferentia. A dense layer of globules mostly mucoproteins aggregate around the hyaline cap of the sperm bundles in the vasa deferentia. The chemical composition varies in the seminal fluid of vasa deferentia, seminal vesicles and sperm sac. Changes occur in the seminal fluid as it moves down successively through the vas deferens, seminal vesicle and ultimately in the sperm sac. The seminal fluid is stored and condensed in the sperm sac. Histochemical studies demonstrate chemical composition of the seminal fluid as a mixture of protein, carbohydrate and lipid. Presence of dense quantity of DNA and RNA in the nuclei and cytoplasm of the epithelial cells and mercury bromophenol blue stained granular material suggests that the central canal, vasa deferentia and seminal vesicles are well-equipped with the cellular machinery required for protein synthesis. Histochemical tests demonstrate, in addition, large amount of mucopolysaccharides and lipids. SDS-PAGE of seminal fluid reveals 7 and 12 protein bands in the vasa deferentia and seminal vesicles, respectively.] Address: Andrew, R.J., Shri Dnyanesh Mahavidyalaya, Navargaon, Dist. Chandrapur- 441 223, (MS), India

10836. Barrios, M.; Wolff, M. (2011): Initial study of arthropods succession and pig carrion decomposition in two freshwater ecosystems in the Colombian Andes. *Forensic Science International* 212(1-3): 164-172. (in English) ["Entomological succession and trophic roles of arthropods associated with different stages of carcass decomposition were studied to estimate the post-mortem submersion interval in two freshwater ecosystems in the Colombian Andes, at an altitude of 2614 m. Pig carcasses were employed as models placed 68 m apart, one in a stream (lotic) and another in an artificial lake (lentic). Decomposition time to skeletal remains was 74 days in the lake and 80 days in the stream. Six phases of decomposition were established: submerged fresh, early floating, floating decay, bloated deterioration, floating remains and sunken remains. A total of 18,832 organisms associated with the carcasses were

collected: 11,487 in the lake (four orders, 19 families and 33 species) and 7345 in the stream (eight orders, 15 families and 25 species). Organisms were classified in the following ecological categories: shredders, collectors, predators, necrophagous, sarcosaprophagous and opportunists. Physical and chemical properties of the habitats, such as water temperature, CO₂ and conductivity, varied according to rainfall. In the lake, shredders (Coleoptera: Tropisternus sp. and Berosus sp.) and collectors (Diptera: Chironomus sp.) were found to be associated with submerged phases. Predators (Odonata) were only present during the first phases. Coleoptera (Dytiscidae) were found during floating decay and bloated deterioration stages. In the stream, shredders (Hyalella sp.) and collectors (Simulium sp.) were found during all stages, whereas the predator Oxelytrum discolle was found exclusively during the floating stages, during which body temperature increased in a fashion similar to active decay in terrestrial environments." (Authors)] Address: Wolff, Marta, Grupo de Entomología Universidad de Antioquia, Medellín, Colombia. E-mail: mariabape@gmail.com

10837. Baudermann, S.; Martens, A. (2011): Ortstreue und tagesrhythmischer Ortswechsel der Larven von Cordulegaster bidentata in Quellrinnensalen (Odonata: Cordulegastridae). Libellula 30(3/4): 133-144. (in German, with English summary) ["C. bidentata colonizes spring runnels with minimal water depth. The significance of small depressions as microhabitats and the activity patterns of the larvae in such border zones are not well known. In August and September 2010, respectively, in two spring runnels in the Kocher valley near Künzelsau, Baden-Württemberg, Germany, the daily movement of the larvae has been investigated. Tin cans, serving as artificial pools, were buried at the bottom of the very shallow water in an area of 4 m² at both localities. Prepared with removable plastic containers inserted in the tin frame, the presence of larvae was recorded every 12 h for ten days. The artificial pools were regularly colonized by C. bidentata larvae after a short time. Immigration and emigration took place during night as well as during daytime, with a significant preference for the nighttime." (Authors)] Address: Baudermann, Sandra, Eichholzweg 3, 74653 Künzelsau, Germany. E-mail: sbaudermann@yahoo.de

10838. Bedjanič, M. (2011): Coenagrion hastulatum (Charpentier, 1825), new for the dragonfly fauna of Bosnia and Herzegovina (Odonata: Coenagrionidae). Natura Sloveniae 13(2): 31-36. (in English, with Slovenian summary) ["At the high-altitude Donje Bare and Gornje Bare Lakes in the surroundings of Tjentište village, Zelengora Mts., Sutjeska National Park, SE Bosnia and Herzegovina, Coenagrion hastulatum was recorded on 26 June 2011. The occurrence of the species on the southern border of its European range is outlined and discussed. Faunistic records on a total of 22 species observed at 11 localities in the southeastern part of the country between 26 and 29 June 2011 are appended." 10839. Benigno, G. (2011): Invertebrate drift in neighboring perennial and seasonal tributaries of the Sacramento River. Master of Science thesis, Biological Sciences California State University, Chico: IX + 33 pp. (in English) ["While seasonal floodplains are known to provide abundant food and important rearing habitat for na-

tive and anadromous fish in California, the value of other types of seasonally aquatic habitats is less well understood. The use of seasonally flowing tributaries of the Sacramento River as non-natal rearing habitat for salmonids and as spawning areas for native fish has been previously documented. In order to evaluate food availability in Sacramento River tributaries, I compared invertebrate drift in a seasonal tributary with a neighbouring perennial tributary through the duration of seasonal tributary flow, from November 2005 through June 2006. I compared drift density, taxonomic diversity, and community composition between the two tributary types. Overall drift abundance was greater in seasonal tributary samples. Taxonomic richness in the seasonal tributary was comparable to the perennial tributary, although community composition was different between the two tributary types. Specifically, chironomid larvae and small crustaceans were abundant in seasonal tributary drift, while terrestrial invertebrates were the primary component of perennial tributary drift. The results illustrate that seasonally flowing tributaries can provide greater prey availability to fish that use these habitats compared with perennial tributaries." (Author) The taxa list includes a few Odonata.] Address: Benigno, Gina, Biology Department, California State Univ., Chico, CSU Chico, Holt Hall, Chico, CA 95927, USA

10841. Borisov, S.N. (2011): Migrant dragonflies in Middle Asia. 2. Sympetrum fonscolombii (Selys, 1840) (Odonata, Libellulidae). Eurasian Entomological Journal 10(4): 415-421. (in Russian, with English summary) ["Data on the distribution, phenology and migrations of Sympetrum fonscolombii in Middle Asia are presented. The first spring-time generation is represented by immigrant specimens from the southern part of the range. Pre-imaginal development lasts about 2 months. Development of two generations during summer and autumn is probable. In autumn the dragonflies migrate in a southerly direction. 2008–2010 migrations were studied in the Chok-Pak mountain range in Western Tien-Shan Mountains (N42.53°, E70.60°) by «Rybachinsky-type» by means of ornithological traps. Migrations lasted from the end of August until October. The intensity of migrations increased with the onset of cold air masses. Sequential expansion of different generations is probably characteristic, being an adaptive strategy of S. fonscolombii aimed at maximising the use environmental resources both spatially and temporally." (Author)] Address: Borisov, S.N., Institute of Systematics and Ecology of Animals, Russian Academy of Sciences, Siberian Branch, Frunze str. 11, Novosibirsk 630091 Russia. E-mail: borisov-s-n@yandex.ru

10842. Bosch, J.G. van 't, (2011): Rare dragonflies in the Netherlands in 2002, 2003, 2004 and 2005, CWNO-reports 4. Brachytron 14(1): 40-48. (in Dutch, with English summary) ["This is the fourth report of the Dutch Committee for records of rare odonates (CWNO). In this report, records from the period 2002-2005 are reviewed. Acceptability is judged independently by each of the committee members, based on the documentation available (e.g. descriptions, drawings, pictures or collected material). Only accepted records are reviewed.

wed. Of each accepted record the Province, nearby city, location, date, number, gender and observers are given. In most cases only the first record is given; subsequent records of the same individual or population are accepted on the basis of the first record and are not reviewed. From this record on, observations marked with an asterisk *, are regarded as a 'known location'. New records from a known location will not be reviewed in future. The three categories of species that are considered by the CWNO are described. The third category is a new one: only proof and indication of reproduction are currently considered for *Anax parthenope* and *Aeshna affinis*. Species that are no longer considered by the CWNO are *Crocothemis erythraea* (after 2003) and *Orthetrum coerulescens* (after 2006). Records of these species in 2002-2005 are not reviewed in this article. 2002 – A new population of *Sympetrum depressiusculum* was discovered near Budel (Noord-Brabant/ Limburg). Several new populations of *Somatochlora flavomaculata* were found. 2003 – The most spectacular discovery in 2003 was the first observation for The Netherlands of *Coenagrion scitulum* near Tegelen (Limburg). Subsequent searches did not result in additional observations. The fourth ever observation (fifth individual) of *Anax ephippiger* for the Netherlands was at Schiermonnikoog (Friesland). The fourth population of *Somatochlora arctica* was discovered at Vragenderveen (Gelderland). 2004 – The most memorable in 2004 was the third ever observation for The Netherlands of *Sympetrum meridionale*, at Cadzand-bad (Zeeland) 2005 – The most spectacular event in this four-year period was without doubt the discovery of a population of *Leucorrhinia albifrons* near Oldeberkoop (Friesland). The previous observation was a single male in 1994 at nearby Appelscha. The fourth ever observation of *S. meridionale* was at Berghem (Noord-Brabant). The fifth population of *Somatochlora arctica* and the first population for Overijssel was discovered at Landgoed Twickel." (Author) Records of the followingspecies are presented in some details: *Cordulegaster boltonii*, *Leucorrhinia albifrons*, *L. pectoralis*, *Coenagrion armatum*, *C. scitulum*, *C. hastulatum*, *Calopteryx virgo*, *Sympecma paedisca*, *Aeshna affinis*, *A. subarctica elisabethae*, *Anax parthenope*, *A. ephippiger*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia*, *Somatochlora arctica*, *S. flavomaculata*, *Crocothemis erythraea*, *Orthetrum brunneum*, *O. coerulescens*, *Sympetrum depressiusculum*, *S. meridionale*] Address: Bosch, J.G. van 't, Newtonplein 62, 2562 JX Den Haag. E-mail: cwno@brachytron.nl

10843. Brandt, K.; Buchwald, R. (2011): Die Bedeutung von Kompensationsgewässern für die Libellenfauna der Stadt Oldenburg (Odonata). *Libellula* 30(3/4): 111-132. (in German, with English summary) ["As only very few natural standing waters still exist, compensation ponds have a potentially high value for the aquatic fauna and flora in the city of Oldenburg (Lower Saxony, Germany). In order to analyse their value for the odonate fauna a study of 17 ponds in Oldenburg was carried out in 2009. Altogether 28 species of Odonata were recorded and 21 species were regarded as potentially or definitely autochthonous at one or some pond(s). These 28 species amount to 39 % of the total odonate fauna of the region Weser-Ems. The total odonate fauna of the standing water bodies of Oldenburg comprises 32 species. Therefore, 66 % of its potential fauna was recorded at the 17 compensation ponds. We found a wide range of 0-19 species of Odonata at one pond. Both the open water surface and the period in which a pond

dries up in the summer months are decisive for odonate diversity. Furthermore, some influence of the trophic level on the species diversity could be recognized. Among others, *Coenagrion puella*, *Ischnura elegans*, *Pyrrhosoma nymphula* and *Libellula quadrimaculata* were the species with the highest frequency, all being widespread and euryoecious. In addition, rather rare and stenoecious species were found at single ponds. We summarize that some compensation ponds in the city of Oldenburg are species-rich and have a high value for the dragonfly fauna of the region; the same is true for the total species diversity of all studied ponds for the Odonata diversity of Oldenburg. With this study other authors' results regarding compensation ponds and/or urban waters are discussed and modifications suggested, but in essence they are confirmed." (Authors)] Address: Brandt, Kirsten, Kaiser-Friedrich-Str. 15, 53113 Bonn, Germany. E-mail: Kirsten.Brandt@gmx.net

10844. Brochard, C.; van der Ploeg, E. (2011): Looking for the best spot: how far will *Cordulegaster insignis* walk? *Brachytron* 14(1): 64-66. (in Dutch, with English summary) ["In this short portrait, some of the habitat preferences, larval ecology and emerging behaviour of *Cordulegaster insignis* are discussed. During a search for larval skins in Mugla province, Turkey, 70 exuviae were found during three visits. They were mainly found in trees, at an altitude varying from a few cm to 8 m from the ground. The maximum distance from the nearest water was 30 meters." (Authors)] Address: Brochard, C., Marsstraat 77, 9742 EL Groningen, The Netherlands

10845. Brockhaus, T. (2011): Informationen zum Projekt der Libellenfauna Deutschlands. *Libellennachrichten* 26: 5-7. (in German) [The author reports on the current status of the book on the German Odonata-fauna.] Address: Brockhaus, T., An der Morgensonne 5, D-09387 Jahnsdorf, Germany. E-mail: T.Brockhaus@t-online.de

10846. Buckland-Nicks, A. (2011): Mercury bioaccumulation in dragonflies (Odonata: Anisoptera) from two lakes in Kejimikujik National Park, Nova Scotia. In: Atlantic Division of the Canadian Association of Geographers. Programm and Abstracts 23th Annual Meeting and Conference October 14th - 16th, 2011 Mount Allison University, Sackville, NB: 8. (in English) [Verbatim: Anisoptera are important vectors for mercury in aquatic and terrestrial food chains. Dragonfly naiads, adults, and exuviae were collected from two acidic lakes in Kejimikujik National Park, Nova Scotia (Canada) in order to compare mercury bioaccumulation patterns between their life stages and body sections. Samples were dried, digested, and analyzed for methylmercury (MeHg), divalent mercury (Hg(II)), and total mercury (THg) using gas chromatography-atomic fluorescence spectroscopy (AFS). MeHg concentrations in naiad and adult dragonflies were comparable to fish, at 234 ± 113 ng g⁻¹ d.w. (n=64) and 232 ± 68 µg g⁻¹ d.w. (n=28), respectively. There was no significant difference between naiad and adult MeHg concentrations (p>0.05). Mean MeHg concentration in exuviae (6 ± 4 ng g⁻¹ d.w.; n=32) was 50-fold lower than naiads and adults, however Hg(II) concentrations were not significantly different. Emerging adults had between 1.5 and 3-fold higher Hg(II) than naiads and adults but similar MeHg. Within the naiad population, MeHg and THg increased with age and weight, with a large increase in variation. The oldest

and heaviest naiads had both the lowest and highest MeHg. Bioaccumulation patterns of Hg(II) in dragonfly life stages may indicate MeHg detoxification mechanisms. However, the adults still have a high potential for transferring substantial amounts of MeHg to terrestrial predators.] Address: Buckland-Nicks, Amy, Department of Earth and Environmental Science, Acadia University, Wolfville, NS, USA. 10849. Butkas, K.J.; Vadeboncoeur, Y.; Vander Zanden, M.J. (2011): Estimating benthic invertebrate production in lakes: a comparison of methods and scaling from individual taxa to the whole-lake level. *Aquatic Sciences - Research Across Boundaries* 73(1): 153-169. (in English) [Sparkling Lake, Wisconsin, USA. "Studies of aquatic invertebrate production have been primarily conducted at the level of individual taxa or populations. Advancing our understanding of the functioning and energy flow in aquatic ecosystems necessitates scaling-up to community and whole-lake levels, as well as integrating across benthic and pelagic habitats and across multiple trophic levels. In this paper, we compare a suite of non-cohort based methods for estimating benthic invertebrate production at subpopulation, habitat, and whole-lake levels for Sparkling Lake, WI, USA. Estimates of the overall mean benthic invertebrate production (i.e. whole-lake level) ranged from 1.9 to 5.0 g DM m⁻² y⁻¹, depending on the method. Production estimates varied widely among depths and habitats, and there was general qualitative agreement among methods with regards to differences in production among habitats. However, there were also consistent and systematic differences among methods. The size-frequency method gave the highest, while the regression model of Banse and Mosher (*Ecol Monogr* 50:355-379, 1980) gave the lowest production estimates. The regression model of Plan-

te & Downing (*Can J Fish Aquat Sci* 46:1489-1498, 1989) had the lowest average coefficients of variation at habitat (CV = 0.17) and whole-lake (CV = 0.08) levels. At the habitat level, variance in production estimates decreased with sampling effort, with little improvement after 10-15 samples. Our study shows how different production estimates can be generated from the same field data, though aggregating estimates up to the whole-lake level does produce an averaging effect that tends to reduce variance." (Authors) Odonata taxa - with the exception of *Hagenius brevistylus* - are treated at the family level.] Address: Vander Zanden, M.J., Center for Limnology, Univ. of Wisconsin-Madison, 680 N. 10855. Chester, E.T.; Robson, B.J. (2011): Drought refuges, spatial scale and recolonisation by invertebrates in non-perennial streams. *Freshwater Biology* 56(10): 2094-2104. (in English) ["1. If resistance traits drive recolonisation after drought, then drought refuges should contribute strongly to assemblage composition within streams. If resilience traits drive recolonisation, macroinvertebrates emerging from refuges may disperse widely, colonising many streams. To determine whether the contribution of drought refuges to macroinvertebrate recolonisation in non-perennial streams was mostly local (within stream) or broader scale (across streams), we measured the association between the composition of invertebrate assemblages in different types of in-stream drought refuge and the assemblage composition of streams when flow resumed. 2. We sampled 16 streams of varying hydrological regime on the western side of the Victoria Range in the Grampians National Park, Victoria, Australia. Drought refuges (perennial pools, dry sediment, damp sediment, seeps, patches of leaf litter, beneath stones) were identified and sampled during autumn. Most taxa were found in perennial pools; few taxa were found aestivating beneath stones or having desiccation-resistant stages in dry sediment. Perennial pools and perennially flowing reaches were the refuges that harboured the greatest diversity of macroinvertebrate taxa. 3. Streams were sampled again during spring. Assemblage composition of non-perennial reaches in spring was unrelated to composition in nearby refuges in the previous autumn. In contrast, assemblage composition in perennial reaches during spring was strongly correlated with composition during autumn. Therefore, drought refuges did not directly influence assemblage composition locally within non-perennial streams. Rather, both perennially flowing reaches and perennial pools acted as drought refuges across the broader landscape. Resilience traits are likely to drive recolonisation in these streams. 4. Monitoring of drought refuges in a particular stream will therefore not predict species composition when flow resumes. Drought refuges are likely to sustain biodiversity over larger spatial scales such as groups of streams or whole drainage networks. Consequently, stream networks will need to be managed as entities rather than as single waterways and the focus of drought refuge protection should be on perennial pools and reaches." 10856. Cicek, K.; Ayaz, D. (2011): Food composition of the European pond turtle (*Emys orbicularis*) in Lake Sülüklü (Western Anatolia, Turkey). *Journal of Freshwater Ecology* 26(4): 571-578. (in English) ["We examined the seasonal changes in the food composition of *E. orbicularis* in Lake Sülüklü (Manisa, Turkey) during spring and summer 2010. The stomach contents of 110 (40 males, 62 females, eight juveniles) *E. orbicularis* individuals were analyzed, and 461 prey items were found. Gastropods (2.2%), earthworms (0.4%), insects (67.2%), fishes (6.9%), amphibians (15.0%), and plant material (8.2%) constituted the food of the species. Food consisted primarily of insects and other invertebrates during the breeding season and of vertebrate and plant material (especially seeds and roots) during the post-breeding season. Based on these results, the European pond turtle is a generalist opportunistic omnivore whose diet is most strongly influenced by prey availability ... Terrestrial prey items (adult Odonata, Anisobalidae, Cicadidae, adult Hymenoptera, Formicidae, Cerambycidae, Staphylinidae, Muscidae, and Culicidae) constituted only 8.7% of the stomach contents." 10857. Cordoba-Aguilar, A.; Gonzalez-Tokman D.M. (2011): Male harassment and female energetics in the territorial damselfly *Hetaerina americana* (Fabricius) (Zygoptera: Calopterygidae). *Odonatologica* 40(1): 1-15. (in English) ["The possible energetic costs due to male harassment in *H. americana* females were explored by investigating: (a) changes in thoracic and abdominal fat during / adulthood, (b) the fat budget after each of the 2 matings that females engage in during 2 seasons of varying male harassment, (c) the fat imbalance due to male harassment in the thorax (where fat is used mainly for flying) and abdomen (where fat is used to produce eggs), (d) whether re-mating takes longer when harassment is high compared to when harassment is low, and (e) the feeding rate after each mating in both seasons to see whether female balance the energetic resources they spend. Females gained fat resources after emergence but lost fat when they became old. Fat decreased more in the 'high harassment' season than in the 'low harassment' season; in the former, fat was reduced more intensively after a second mating. Thoracic fat decreased to a lower level after the second mating in the 'high harassment' season compared with the 'low harassment' season. When harassment was high, re-mating took longer than when harassment was low. Feeding was similar between seasons. These results suggest substantial energetic costs for females due to male harassment." 10858. Cortes, L.; Almeida, M.C.; Pinto, N.S.; De Marco, P. (2011): Fogo em Veredas: Avaliação de Impactos sobre Comunidades de Odonata (Insecta). *Biodiversidade Brasileira* 1(2): 128-145. (in Portuguese, with English summary) ["The marshes are open areas of Cerrado (Brazilian savannas), which play an essential role in protecting water sources. Moreover, the marshes are also considered of great importance to direct use of rural people living in the Cerrado. These

conflicts of use of the marshes are now a major challenge for biodiversity conservation. This study aimed to test the effect of fire on the richness and composition of Odonata (dragonflies) in burned and unburned marshes within the Estação Ecológica Serra Geral do Tocantins (EESGT). Species richness was estimated for each of the sampled marshes through non-parametric method of first order Jackknife. The analysis of indicator species was made by IndVal. The similarity in community composition of Odonata were obtained through the index of Chao. In total we sampled 33 species of Odonata, distributed among five families. No species of Odonata were associated specifically with burned or unburned environments. The marshes burned recently showed a greater similarity in community composition of Odonata than unburned marshes and the same pattern is evident when considering only the suborder Zygoptera. This work with Odonata communities has shown that there is impact of fire on species composition of the suborder Zygoptera which has less ability to disperse. This reinforces the idea that the fire is known to be one of the main threats to protected areas of the Cerrado and a threat to the biodiversity of EESGT marshes. If decisions of fire management are taken, it is crucial that it come together with research monitoring marshes in EESGT." 10860. Crespo, J.G. (2011): A review of chemosensation and related behavior in aquatic insects. *Journal of Insect Science* 11(62): 1-39. (in English, with Spanish summary) ["Insects that are secondarily adapted to aquatic environments are able to sense odors from a diverse array of sources. The antenna of these insects, as in all insects, is the main chemosensory structure and its input to the brain allows for integration of sensory information that ultimately ends in behavioural responses. Only a fraction of the aquatic insect orders have been studied with respect to their sensory biology and most of the work has centred either on the description of the different types of sensilla, or on the behaviour of the insect as a whole. In this paper, the literature is exhaustively reviewed and ways in which antennal morphology, brain structure, and associated behaviour can advance better understanding of the neurobiology involved in processing of chemosensory information are

discussed. Moreover, the importance of studying such group of insects is stated, and at the same time it is shown that many interesting questions regarding olfactory processing can be addressed by looking into the changes that aquatic insects undergo when leaving their aquatic environment." 10863. Davis, R.B.; Nicholson, D.B.; Saunders, E.L.; Mayhew, P.J. (2011): Fossil gaps inferred from phylogenies alter the apparent nature of diversification in dragonflies and their relatives. *BMC Evolutionary Biology* 2011, 11:252 doi:10.1186/1471-2148-11-252: (in English) ["Background: The fossil record has suggested that clade growth may differ in marine and terrestrial taxa, supporting equilibrium models in the former and expansionist models in the latter. However, incomplete sampling may bias findings based on fossil data alone. To attempt to correct for such bias, we assemble phylogenetic supertrees on one of the oldest clades of insects, the Odonatoidea (dragonflies, damselflies and their extinct relatives), using MRP and MRC. We use the trees to determine when, and in what clades, changes in taxonomic richness have occurred. We then test whether equilibrium or expansionist models are supported by fossil data alone, and whether findings differ when phylogenetic information is used to infer gaps in the fossil record. Results: There is broad agreement in family-level relationships between both supertrees, though with some uncertainty along the backbone of the tree regarding dragonflies (Anisoptera). "Anisozygoptera" are shown to be paraphyletic when fossil information is taken into account. In both trees, decreases in net diversification are associated with species-poor extant families (Neopetalidae, Hemiphlebiidae), and an upshift is associated with Calopterygidae + Polythoridae. When ghost ranges are inferred from the fossil record, many families are shown to have much earlier origination dates. In a phylogenetic context, the number of family-level lineages is shown to be up to twice as high as the fossil record alone suggests through the Cretaceous and Cenozoic, and a logistic increase in richness is detected in contrast to an exponential increase indicated by fossils alone. Conclusions: Our analysis supports the notion that taxa, which appear to have diversified exponentially using fossil data, may in fact have diversified more logistically. This in turn suggests that one of the major apparent differences between the marine and terrestrial fossil record may simply be an artifact of incomplete sampling. Our results also support previous notions that adult colouration plays an important role in odonate radiation, and that Anisozygoptera should be grouped in a single inclusive taxon with Anisoptera,

separate from Zygoptera." (Authors)] Address: Davis, R.B., Dept Biol., Univ. of York, York, YO10 5YW, UK. E-mail: davis@ut.ee

10869. Donoughe, S.; Crall, J.D.; Merz, R.A.; Combes, S.A. (2011): Resilin in dragonfly and damselfly wings and its implications for wing flexibility. *Journal of Morphology* 272(12): 1409-1421. (in English) ["Although there is mounting evidence that passive mechanical dynamics of insect wings play an integral role in insect flight, our understanding of the structural details underlying insect wing flexibility remains incomplete. Here, we use comparative morphological and mechanical techniques to illuminate the function and diversity of two mechanisms within Odonata wings presumed to affect dynamic wing deformations: flexible resilin vein-joints and cuticular spikes. Mechanical tests show that joints with more resilin have lower rotational stiffness and deform more in response to a load applied to an intact wing. Morphological studies of 12 species of Odonata (*Calopteryx augustipennis*, *Lestes rectangularis*, *Ischnura verticalis*, *I. posita*, *Enallagma divagans*, *Aeshna verticalis*, *Aeshna constricta*, *Sympetrum vicinum*, *S. rubicundulum*, *Erythemis simplicicollis*, *Somatochlora tenebrosa*, *Epitheca cynosura*) reveal that resilin joints and cuticular spikes are widespread taxonomically, yet both traits display a striking degree of morphological and functional diversity that follows taxonomically distinct patterns. Interestingly, damselfly wings (suborder Zygoptera) are mainly characterized by vein-joints that are double-sided (containing resilin both dorsally and ventrally), whereas dragonfly wings (suborder Epiprocta) are largely characterized by single-sided vein-joints (containing resilin either ventrally or dorsally, but not both). The functional significance and diversity of resilin joints and cuticular spikes could yield insight into the evolutionary relationship between form and function of wings, as well as revealing basic principles of insect wing mechanical design." 10873. Edwards, G.M. (2011): The functional morphology and ecology of jet propulsion swimming in larval dragonflies under predation from suction-feeding fish. Ms.Thesis, Integrative Biology, University of Guelph, Ontario, Canada: 82 pp + VI app. (in English) ["A functional understanding of how phenotypic traits may affect growth, reproduction and survival is necessary to understand their ecological and evolutionary consequences. Larval anisopteran dragonflies swim using jet propulsion, likely controlled by abdominal traits and perhaps to escape fish predators. I investigated whether abdominal morphology explains swimming performance and if either explains the distribution of larvae among ponds that vary in predation risk. I recorded and measured the swimming performance of dragonflies responding to simulated attack and tested relationships with abdominal traits expected to influence jet thrust force generation. Variation in swimming performance was explained by abdomen dry weight, ventral surface area, and abdominal segment 10 width across genera as hypothesized. High-performance dragonflies were more likely to occur in ponds containing predatory fish. This is the first investigation of the morphology responsible for jet propulsion, and the relationship between swimming performance and larval dragonfly ecology." (Author)] Address: not stated

10874. Eggens, G.; Bouwman, J.H. (2011): From salty polder to dragonfly jewel. *Brachytron* 14(1): 3-13. (in Dutch, with English summary) [The Netherlands; "The relatively recent origin of the Dutch Province of Flevoland enables us to obtain new insights into the colonisation of 'new' land by dragonflies. After a slow start many species seem to have found Flevoland. Especially the species of lowland peat-marshes seem to have profited from the new water surfaces available there. Rare species such as *Leucorrhinia pectoralis* and *Libellula fulva* already reproduce here and species such as *Aeshna viridis* and *Somatochlora flavomaculata* are likely to make an appearance soon. Fen species and species of running water also have colonised Flevoland successfully. In view of all recent and planned nature developments, the future of dragonflies in Flevoland looks very bright." 10875. Fairweather, A.D.; McAlpine, D.F. (2011): History and status of the Natural History Society of New Brunswick entomology collection: 1897-1931. *J. Acad. Entomol. Soc.* 7: 14-19. (in English, with French summary) ["The Natural History Society of New Brunswick (NHSNB; 1862-1932) played a key role in the creation of the New Brunswick Museum (NBM), transferring its insect collection to the NBM upon the museum's opening in 1932. Here we review the history of the NHSNB insect collection, amassed mainly between 1897 and 1910, and report on the collectors involved and the experts and institutions sourced for specimen exchange and assistance with insect identification. The NHSNB entomology collection provides an important historical perspective on the early development of entomological research in Atlantic Canada and illustrates the wide-ranging scientific contacts established by one entomologist working in the Maritimes in the late 19th and early 20th centuries. William McIntosh, the principal collector, established contacts with various well-known amateur and professional entomologists across Canada and in the northeastern United States, gaining identification assistance in particular from specialists associated with the U.S. National Museum-U.S. Department of Agriculture. An inventory of the extant NHSNB insect specimens shows that 7,248 of an estimated 19,467 specimens present in 1914 remain, principally Lepidoptera, Coleoptera, Hymenoptera and Diptera. Despite losses, specimen records of scientific significance remain. About 30% of the 142 odonate species currently known from the Maritimes and southeastern Quebec are first documented on the basis of NHSNB specimens collected from 1898—1900, a 1906 specimen of *Eumorpha labruscae* (Lepidoptera: Sphingidae) remains the only one from Canada, and beetles that document the first occurrence of adventives help to establish timelines for the introduction of non-native Coleoptera to the Maritimes." 10878. Ferreira, N.; Feijó, C.; Giorgi, A.; Leggieri, L. (2011): Effects of macrophyte heterogeneity and food availability on structural parameters of the macroinvertebrate community in a Pampean stream. *Hydrobiologia* 664(1): 199-211. (in English) ["Environmental heterogeneity in natural ecosystems influences several parameters at the population and community levels. In freshwater ecosystems, habitat heterogeneity can be provided by macrophyte species with different structural shapes. Previous studies suggest that aquatic plants with more complex architectures will support higher number, biomass, and taxon richness of macroinvertebrates than plants with simpler shape. We investigated the influence of macrophyte structural heterogeneity (quantified by fractal dimension) and food availability (represented by epiphytic biomass) on several parameters (number of individuals, biomass, body size distribution, taxon richness, and diversity) of the macroinvertebrate community in a Pampean stream. Four submerged macrophyte species (*Egeria densa*, *Elodea ernstae*, *Ceratophyllum demersum*, and *Stuckenia striata*) and associated macroinvertebrates were sampled in late spring, summer, and autumn. Plants were photographed and fractal dimension was estimated from the images by the box-counting method. Fractal dimension was independent of plant surface area per unit of macrophyte biomass and differed significantly among species. Mean fractal dimension varied between 1.29 and 1.62, and increased following the sequence *E. densa* -> *S. striata* -> *E. ernstae* -> *C. demersum*. Macrophyte species with higher fractal dimension supported a greater abundance of macroinvertebrates, especially those of small body size (500–1,000 µm); but fractal dimension was unrelated to macroinvertebrate biomass, richness, and diversity. However, overall animal biomass was significantly associated to the epiphytic abundance. Consequently, macrophyte heterogeneity influences macroinvertebrate density and body size distribution, while animal biomass depends on epiphytic food resources provided by plants. ... Other groups such as Odonata (8%) ... were also present." (Authors) "] Address: Ferreira, N., Leggieri Instituto de Ecología y Desarrollo Sustentables (INEDES) and Departamento de Ciencias Básicas, Univ. 10883. Fulan, J.A.; Henry, R.; Souza Davanso, R.C. (2011): Effects of daily changes in environmental factors on the abundance and richness of Odonata. *Acta Limnologica Brasiliensia* 23(1): 23-29. (in English, with Portuguese summary) ["Aim: The aim of this work was to investigate the effects of daily changes in surface water abiotic factors on the abundance of Odonata larvae and the genus richness in a lateral lake isolated from a tropical river during the nycthemeral cycle in dry and wet seasons; Methods: Macrophytes were sampled on a single day at 6-hours intervals for 24 hours (at 12:00 AM, 6:00 AM, 12:00 PM and 6:00 PM) in dry and wet periods. At each site, abiotic factors were measured as follows: air temperature, surface water temperature, dissolved oxygen, pH, and electric conductivity. Canonical correspondence analysis (CCA) of abiotic and biological data and sampling periods was made using CANOCO program; Results: A total of 249 and 265 Odonata larvae from six genera (*Acanthagrion*, *Cyanalagma*, *Telebasis*, *Erythemis*, *Erythrodiplax* and *Tauriphila*) were sampled in association with macrophytes in wet and dry seasons, respectively. *Telebasis* presented the highest frequency of occurrence and was collected in all nycthemeral cycle sampling periods in both seasons. The highest abundance of dragonflies was recorded at 6:00 AM and 12:00 AM in wet and dry seasons, respectively. Anoxia was detected in wet sea-

son during the entire nycthemeral cycle, while in the dry season, the highest variability in oxygen content was observed during sunlight. Canonical correspondence analysis showed that the abundances of Telebasis and Erythemis were positively related to water electrical conductivity, temperature, and depth, while for Acanthagrion and Tauriphila, abundance showed a positive relationship to water oxygen and pH. The variability of the abundance of Odonata due to surface water temperature, dissolved oxygen, electrical conductivity, pH, and depth during the daily cycle was therefore evidenced; Conclusions: We suggested that the better sampling period Odonata larvae must be carried in the morning, since that we recorded the highest densities of both wet and dry stations at that hour. We point out that our data must to be examined with caution because the low sampling effort and the reduced taxonomic resolution." 10886. Geraeds, R.P.G.; Haese, U. (2011): Rheophile Libellen in einigen grenzüberschreitenden Wasserläufen im deutsch-niederländischen Naturpark Maas-Schwalm-Nette. Natuurhistorisch Maandblad 100(10): 199-204. (in German, with English summary) ["A few brooks and rivers that cross the German-Dutch border in the Maas-Swalm-Nette nature park are of special value regarding rheophilic dragonflies, and the distribution of some of these species in the Netherlands is mainly – or even completely – restricted to a few of these streams. As a result, the Dutch parts of the brooks and rivers have been closely investigated. Since the distribution of most of these species in the German parts of these streams was unknown, however, surveys in 2009 and 2010 recorded rheophilic dragonflies in the Swalm, Roer, Rode Beek and Kitschbach streams in the border region. Species that were surveyed included *Calopteryx splendens*, *C. virgo*, *Cordulegaster boltonii*, *Gomphus flavipes*, *G. vulgatissimus*, *Ophiogomphus cecilia* and *Onychogomphus forcipatus*. *C. splendens* is the most common species in the area; it occurs in all streams on both sides of the border. The *C. virgo* is rare and was found only along the Rode Beek brook, in the

German as well as Dutch parts. *C. boltonii* appears to be plentiful along the Rode Beek. In 2010, it was also found upstream of the Dalheimer Mühle in Germany, its first record in Germany. In 2007, two larvae were caught in the Dutch part of the river Swalm, near the border. The species was also occasionally spotted along the German part of the Swalm in the past. A few exuviae were found there in 2010, making it clear that there is also a population in Germany. The presence of *G. flavipes* is restricted to the Dutch part of the river Roer, where the species mainly inhabits the downstream parts. Only one specimen was spotted in the study area, near Vlodrop, in 2010. *G. vulgatissimus* is a widespread species along the running waters we investigated. It occurs on both sides of the Dutch-German border along the Swalm, Roer and Kitschbach. This species was first spotted along the German part of the Roer in 2009. *O. cecilia* was known to live along the Dutch parts of the rivers Swalm and Roer, and the German Kitschbach brook. In 2009 and 2010, the species was also found along the German parts of the Swalm and Roer, though it was not spotted along the Kitschbach in these years. *O. forcipatus* very rarely appears in the study area. This species was spotted only twice in the past: along the Roer in 2000 and along the Rode Beek in 2008. The Roer harbours a small population downstream of the study area. The animal that was seen along the Rode Beek brook was probably a drifter from the Roer population." (Authors)] Address: Haese, U., Am Gut Bau 28, 52072 Aachen, Germany

10887. Giugliano, L.; Terzani, F. (2011): The dragonflies of the retrodunal wetlands in the Migliarino, San Rossore, Massaciuccoli Regional Park (Odonata). Boll. soc. entomol. ital. 143(1): 3-13. (in Italian, with English summary) ["The biodiversity of the Regional Park of Migliarino, San Rossore and Massaciuccoli has been the subject of monitoring studies since a long time. The scope of this study is to fill the knowledge gap about the Odonata inhabiting the park, as at the present time there is no specific knowledge about the Odonata community located in the retrodunal ponds of park. Past surveys, although undertaken only sporadically, have produced a census of 29 species and samples have been collected – 28 in adult phase, 13 in larval phase and 11 like exuviae. The results of this study evidenced many interesting issues in terms of conservation, with several aspects which encourage further research." - 10892.** Guillermo-Ferreira, R.; Del-Claro, K. (2011): Oviposition site selection in *Oxyagrion microstigma* Selys, 1876 (Odonata: Coenagrionidae) is related to aquatic vegetation structure. *International Journal of Odonatology* 14(3): 275-279. (in English) ["Oviposition site selection is crucial in the life history of odonates since females must find a suitable habitat to enhance larval survival and development. Males perch at these sites to get access to females to mate. Here we studied how different types of vegetation influence site selection of the damselfly *O. microstigma* in a Neotropical savanna pond. We identified and quantified the aquatic plants on the study site and investigated the relationship between plant species density, male site fidelity and female oviposition. The results showed that male density increased with higher densities of the Cyperaceae *Eleocharis* sp. but with lower densities of the Pontederiaceae, *Pontederia parviflora*. The number of males was also positively correlated with the number of ovipositing females and the duration of oviposition bouts. The females were found ovipositing on sites with *Eleocharis* sp., which was used as an oviposition substrate. We suggest that the species composition of aquatic vegetation in the environment, as well as the distribution and abundance of plants, can be a major determinant factor of damselfly habitat selection." - 10896.** Hermans, J.; Sennert, G. (2011): Die Libellenfauna des Naturparks Maas-Schwalm-Nette. *Naturhistorisch Maandblad* 100(10): 216-225. (in German, with English summary) ["The dragonfly fauna of the Maas-Schwalm-Nette nature park is extremely rich, with 57 species found in this region between 1980 and 2010. One of the most important reasons for this large number of species is the diversity of biotopes and habitats. The area includes many types of water body: stagnant and running waters, nutrient-poor to nutrient-rich waters with several transitional stages in between, waters fed by percolating groundwater and water bodies in various stages of vegetation development. Other reasons for the presence and settlement of so many species include improved water quality, targeted habitat management of fens and pools involving the development and restoration of biotopes and habitats, and changing climate conditions. The article briefly summarises de-

velopments in the distribution patterns of some species. Examples of species whose populations and distribution patterns have stabilized include *Coenagrion lunulatum*, *Aeshna juncea*, *Leucorrhinia rubicunda* and *L. dubia*. Some species, such as *Sympecma fusca*, *Somatoclora flavomaculata* and *Aeshna isosceles*, have benefited from the current climate change and extended their area of distribution. The rise in average annual temperatures has allowed some Mediterranean dragonfly species to extend their distribution northward and establish viable populations in several locations. Examples of such species are *Crocothemis erythraea* and *Orthetrum brunneum*. *O. coerulescens* is a dragonfly that took advantage of the restoration of some habitats in heath and moorland biotopes, where new small streams were created." 10900. Hopkins, G.R.; Gall, B.G.; Brodie, D.E. (2011): Ontogenetic shift in efficacy of antipredator mechanisms in a top aquatic predator, *Anax junius* (Odonata: Aeshnidae). *Ethology* 117(12): 1093-1100. (in English) ["The ability of prey to escape predation often lies in the occurrence and efficacy of their predator avoidance and antipredator behaviours, which are often coupled with specialized morphology. How the use and efficacy of these behaviours change throughout ontogeny may be indicative of the vulnerability and ecological roles these animals experience throughout their lives. We examined the antipredator behaviour of a large dragonfly nymph, *Anax junius*, from a historically fishless pond where these animals have traditionally been classified as top predators. These dragonfly nymphs displayed a series of distinct aggressive antipredator behaviours

when grasped that involved stabbing with lateral and posterior spines and seizing with labial hooks. Larger (older) nymphs displayed these aggressive behaviours significantly more than smaller (younger) animals in simulated predation trials. During encounters with live larval salamander predators (*Ambystoma tigrinum*), all large nymphs, but only 12.5% of small nymphs successfully escaped predation attempts by the amphibians through the use of antipredator behaviour. Large nymphs were also significantly more active than smaller nymphs in the presence of salamander larvae. Despite often being considered top predators in fishless ponds, our study demonstrates that their true role is more complex, depending on ontogeny and body size, and that effective antipredator behaviour is likely necessary for survival in these systems." 10902. Ilvonen, S.; Ilvonen, J.J.; Kaunisto, K.M.; Krams, I.; Suhonen, J. (2011): Can infection by eugregarine parasites mediate species coexistence in *Calopteryx damselflies*? *Ecological Entomology* 36(5): 582-587. (in English) ["1. Parasitism may be an important factor determining the coexistence of closely related species. Although host-parasite interactions can affect the ecology and distribution of the host species, virtually nothing is known about how other interspecific interactions affecting the host, such as competition or predation, relate to the parasite burden of the host. 2. We studied parasite-mediated competition between two closely related *Calopteryx damselflies*, *C. virgo* L. and *C. splendens* Harris. We investigated a total of 31 populations, including 18 allopatric and 13 sympatric populations. We measured the occurrence of gut parasites, eugregarines. 3. We found that the prevalence of gregarines was higher in *C. virgo* than in *C. splendens*. On average, more than half of the *C. virgo* individuals were infected by eugregarines both in allopatric and sympatric populations. However, hardly any allopatric *C. splendens* populations had gregarines, but most of sympatric populations had infected individuals. 4. According to our results, co-existence of the host species affects the likelihood of the subordinate species showing higher levels of parasitism. Interspecific aggression, lower species genetic heterozygosity, and the difference in host species immunity are proposed as possible explanations for greater parasite burdens in the inferior species at sympatric sites." 10903. Iserbyt, A.; van Gossom, H. (2011): Show your true colour: cues for male mate preference in an intra-specific mimicry system. *Ecological Entomology* 36(5):

544-548. (in English) ["1. Polymorphism limited to the female sex occurs in a variety of animal species and has been shown to be an attractive model system for examining general questions in signal detection theory. 2. When observed in damselflies, typically one female morph is an example of sexual dimorphism, whereas the other is considered as a functional malemimic that resembles the male's phenotype in several traits. 3. While several studies focused on male harassment and subsequent cost/benefit trade-offs in female morphs, it remains understudied at the proximate level, which precise cues are relevant to mate-searching males for discriminating among potential mates. 4. In the present study, we scored male mate preference to natural and manipulated phenotypes in the polymorphic damselfly *Nehalennia irene* Hagen. 5. In contrast to expectation, male preference did not change when colour was manipulated and male preference remained consistently for andromorph > male > gynomorph across treatments. 6. This suggests that cues other than body coloration primarily affect male mate preference in the present study system." 10909. Juen, L.; De Marco, P. (2011): Odonate biodiversity in terra-firme forest streamlets in Central Amazonia: on the relative effects of neutral and niche drivers at small geographical extents. *Insect Conservation and Diversity* 4: 265-274. (in English) ["1. The Amazon region is formed primarily by a dense network of acid and nutrient-poor streamlets. The stability of environmental conditions coupled with spatial constraints to dispersal turns these streamlets into an interesting arena to compare neutral and niche drivers for community organisation. Here, we evaluated the relative importance of local environmental conditions and regional dispersal limitation to determine beta-diversity and distributional patterns of species richness of the adult Odonata assemblage present in the Adolpho Ducke Forest Reserve (Manaus, Amazon) river basins. 2. Samples were taken in 24 streamlets distributed in four river sub-basins (pairwise distances up to 10 km) during the rainy season. The samples consisted of visual surveys for adult individuals of Odonata present in 100 m transects along each streamlet; each transect was divided into 20 segments of 5 m. 3. A total of 17 species were observed and 23 (± 4.8) were estimated using a jackknife procedure. Four sub-basins were statistically similar based on species richness and beta-diversity. Distance among the streamlets had a low predictive power for species richness, while beta-diversity patterns were mainly explained by local environmental variables (channel width and depth). The low values of the beta-diversity index may be attributed to the high similarity of the environment, which presented little variation in abiotic conditions. 4. Low dispersal constraints and environmental stability are the primary explanations for low beta-diversity at this spatial extension. Nevertheless, the importance of local environmental variables to determine beta-diversity suggests its inclusion as criteria for setting conservation priorities for this group." 10911. Kalkman, V.J.; Theischinger, G.; Richards, S.J. (2011): Dragonflies and Damselflies of the Muller

Range, Papua New Guinea. In: Richards, S.J. and Gamui, B.G. (editors). 2011. Rapid Biological Assessments of the Nakanai Mountains and the upper Strickland Basin: surveying the biodiversity of Papua New Guinea's sublime karst environments. RAP Bulletin of Biological Assessment 60. Conservation International. Arlington, VA: 175-181. (in English) ["We conducted a survey of dragonflies at three elevations in the Muller Range of centralwestern Papua New Guinea (PNG) from 4-25 September 2009. Thirty-six species were documented, of which 31 were found only at the lowland site. Diversity at Camp 1 (Gugusu; ~500 m) was similar to that documented from the limited number of other sites studied in the central mountain range, and the dragonfly community conformed with a number of patterns previously observed at low elevations in the central ranges: (1) Higher level taxonomic diversity (number of families) is high in proportion to the number of species; (2) the majority of species are dependent on running water; (3) most of the species associated with running water are endemic to New Guinea while most species occupying standing water habitats are more widespread and often also occur outside New Guinea. At least six species new to science were found at Gugusu reinforcing the view that many species of dragonflies still await discovery in New Guinea. This is probably especially so for the southern slopes of the central mountain range in PNG because this area remains relatively unexplored. Diversity was extremely low at Camp 2 (Sawetau; 1,600-2,000 m; 1 species) and Camp 3 Apalu Reke; 2,875 m; 4 species). The karst area at camp 2 is largely devoid of aquatic habitats and hence has a very poor dragonfly fauna. Camp 3 was above the altitudinal limit of all but a few species. However the discovery of the presumed larvae of *Papuagrion* at Camp 3 constitutes the first record of larvae of this genus. Its life-style (aboreal and semi-terrestrial) is unique among dragonflies and warrants more research. We also report on a small collection of dragonflies assembled during the 2008 RAP survey at Tualapa near Wanakipa Village in the upper Strickland River catchment on the northern edge of the Muller Range. Opportunistic collecting at elevations between 845-1,422 m around Tualapa Camp documented 18 species of dragonflies including only the second records of the poorly known *Hylaeargia magnifica* and the recently described *Argiolestes verrucatus*." 10913. Karraker, N.E. (2011): Are toad tadpoles unpalatable: evidence from the behaviour of a predatory dragonfly in South China. *Amphibia-Reptilia* 32(3): 413-418. (in English) ["Predators are important determinants of amphibian community structure in aquatic habitats, and larval odonates can be significant predators of amphibian larvae. Despite their toxicity as adults, the palatability of bufonid eggs and tadpoles to vertebrate and invertebrate predators remains widely debated. I tested the palatability of hatchling tadpoles of the Asian common toad (*Bufo melanostictus*) and four other amphibians in Hong Kong to larvae of the dragonfly *Pantala flavescens*. Attempted predation of *Bufo melanostictus* hatchling tadpoles by *P. flavescens* resulted in 100% mortality of hatchlings, but none were consumed. All other amphibians were palatable to *P. flavescens*. Development of toxins may not protect early-stage bufonids from invertebrate predators that detect prey by visual cues and then make a debilitating strike. These findings present the first report of unpalatability of bufonid tadpoles to an invertebrate predator and provide evidence that unpalatability of early stage bufonids to odonates may decrease through ontogeny." 10914. Keller, D.; Brodbeck, S.; Flöss, I.; Vonwil, G.; Holderegger, R. (2011): Ausbreitung und Besiedlungsgeschichte der Zierlichen Moosjungfer *Leucorrhinia caudalis* in der Schweiz (Odonata: Libellulidae). *ENTOMO HELVETICA* 4: 139-152. (in German, with English and French summaries) ["*Leucorrhinia caudalis* is considered a threatened dragonfly species in Central Europe. In Switzerland, the species was formerly widespread in the lowlands, but only a single known population was left in the 1980s. However, a spread has been observed in the 1990s, where close-by ponds at a distance of 0.5–7 km have been colonised. Additionally, two new populations at distances of 30 km and 50 km were discovered in the 2000s. In the present study, a combination of a mark-resight study with genetic methods was applied to investigate current migration and genetic footprints of colonisation history in Switzerland. Both the mark-resight and the genetic study showed that *L. caudalis* is a sedentary species that migrates only rarely, seldom exceeding distances of 5 km. The genetic results reflected the recent colonisation history in Switzerland. The oldest and largest population was genetically the most variable and acted as source for recent colonisations. The close-by but only recently founded populations also showed high genetic variability, implicating that close ponds are relatively easily colonised and establish well if functional connectivity is ensured." 10915. Kerst, C. (2011): Pins to envelopes. *Bulletin of the Oregon Entomological Society* Fall 2011: 5. (in English) [Verbatim: The Oregon State University Arthropod Collection has a number of cabinet drawers of pinned Odonate specimens. Pinned specimens require considerable cabinet space for storage, and specimens are less secure from damage by pests. The modern method of storing Odonata specimens is to place them in polypropylene envelopes after processing. The data for each specimen is printed on a 3 × 5 card and placed inside the envelope. I have begun the process of mov-

ing the pinned specimens into envelopes. This is a time-consuming procedure involving relaxing specimens in a moist air-tight environment. After relaxing, the specimens are removed from pins, positioned, and placed in an acetate envelope along with labels. After air drying, the specimen data are entered into a spreadsheet from which the 3 × 5 cards are printed. The original data labels are glued to the cards along with a bar code and placed in the poly envelopes along with the specimen. The end of the poly envelopes is folded over and taped closed. Specimens are well protected in these envelopes and hopefully will be useful for another hundred years. Data for specimens are also then available in the collection's database. There are a few interesting specimens that I have come across to date. A specimen of *Gomphus lynnae* from Rome, Oregon was collected in 1952. This species was described by Dennis Paulson in 1983. There is a specimen of *Aeshna palmata* collected by P. P. Calvert on 22 July 1896, and a specimen of *Rhionaeschna californica* labeled J. G. Needham from 5 July of the same year. Both specimens are from Olympia, Washington. It's a delight to come across specimens collected by these pioneering odontologists.] Address: not stated

10916. Kerst, C.; Gordon, S. (2011): *Dragonflies and Damselflies of Oregon. A Field Guide.* Oregon State University Press. 304 pp. (in English) ["Growing interest in watching and identifying dragonflies and damselflies has sharpened the need for an authoritative resource like *Dragonflies and Damselflies of Oregon*, a definitive field guide devoted solely to dragonflies and damselflies found in the state. Cary Kerst and Steve Gordon include information on identification, as well as biology and behaviour, using common terms useful to the novice and experienced enthusiast alike. The book features stun-

ning colour photographs of male and female of all species currently known in Oregon, along with helpful illustrations and charts with important identification characteristics. *Dragonflies and Damselflies of Oregon* presents the life cycle and larval habits of dragonflies and damselflies, along with photographs of the larvae of families. The Oregon range for each species is mapped, and the size range of adults is provided in text and illustration. The book also includes a description of the best sites in Oregon to observe these amazing insects, a useful tool for viewing uncommon species in spectacular settings." (Publisher)

10917. Kolshorn, P. (2011): *Kleinvieh & Co: Libellen.* *Naturspiegel* 83: 26. (in German) [Regional data of *Leucorrhinia pectoralis* and *Anax parthenope* from De Wittsee/Nettetal and *Elmpter Schwalmbruch/Niederkrüchen*, Nordrhein-Westfalen, Germany are documented.] Address: not stated

10918. Kosterin, O.E.; Zaika, V.V. (2011): *Fauna of dragonflies and damselflies (Odonata) of Tuva.* *Amurian zoological journal* III(3): 210-245. (in Russian, with English summary) ["The known odonate fauna of Tuva in Siberia, Russia, is documented. It includes 47 species. In the southern Ubsu-Nur depression 29 species were recorded (2 just there); in the Central Tuvinian depression 34 species (6 just there) and in the Todzha depression 32 species (9 just there). The fauna of the more humid taigaous region of Todzha contains lacks 7 species found elsewhere in Tuva. In spite of Todzha's position in the north-east, its fauna shows a more western character and includes a population of *Calopteryx splendens* with a high proportion of two morphs of an-drochromic females and a male morph with wings coloured to the tips. Todzha is inhabited by *Enallagma c. cyathigerum* with a variably melanised abdomen, while in the Central Tuvinian and Ubsu-Nur depressions, *E. c. risi* occurs. In Turan and the Upper Kaa-Khem basin, intergradation between both taxa takes place. In Todzha, *Somatochlora exuberata* and *S. metallica abocanica* are sympatric without intermediate forms and with habitat segregation, thus proving their status as separate species. Todzha is inhabited by *Ophiogomphus obscurus* while the rest of Tuva harbours *O. spinicornis*. The status of vicariant western/eastern pairs of taxa in the genus *Leucorrhinia*: *dubia/orientalis* and *rubicunda/intermedia*, is discussed in detail." (2011): The impact of forest management on litter-dwelling invertebrates: a subtropical-temperate contrast. *Biodivers. Conserv.* 20: 2133-2147. (in English) [In Brazil, the study was conducted in the Sao Francisco de Paula National Forest, Rio Grande do Sul State, Brazil. In Germany, the study was conducted in the area of Hainich-Dün, a range of hills in the North-West of Thuringia. "Land use intensification in forests is a main driver of global biodiversity loss. Although historical state of land use differs between subtropical and temperate zones, gradients of land-use intensities similarly range from unmanaged to very intensively managed forests. Irrespective of similar land use forces in both climate zones, comparative studies on land use effects are still rare. Such studies are, however, promising in discovering more general impacts and geographical specifics of land use intensification. We studied litter-dwelling invertebrates along a gradient of increasing land use intensity in subtropical forests in Southern Brazil and temperate forests in Central Europe using similar sampling designs. Effects of land use intensity on the entire community were analyzed on the level of orders and feeding guilds. In both climate zones a similar number of individuals were caught when standardized to 100 pitfall trap days, but taxa richness was higher in the subtropics. Moreover, community composition differed between both climate zones. In both regions, land use intensity did not affect taxa richness, but invertebrate abundance was affected in opposite ways; while increasing land use intensity resulted in a decrease of invertebrate abundance in the subtropics, an increase was observed in the temperate zone and this was mostly consistent regarding different feeding guilds. Management practices should take into account that the effect of land use intensity on biodiversity can differ drastically among climatic regions." (2011): Molecular and functional characterisation of resilin across three insect orders. *Insect Biochemistry and Molecular Biology* 41(11): 881-890. (in English) ["Resilin is an important elastomeric protein of insects, with roles in the storage and release of energy during a variety of different functional categories including flight and jumping. To date, resilin genes and protein function have been characterised only in a small number of flying insects, despite their importance in fleas and other jumping insects. Microscopy and immunostaining studies of resilin in flea demonstrate the presence of resilin pads in the pleural arch at the top of the hind legs, a region responsible for the flea's jumping ability. A degenerate primer approach was used to amplify resilin gene transcripts from total RNA isolated from flea (*Ctenocephalides felis*), buffalo fly (*Haematobia irritans exigua*) and dragonfly (*Aeshna* sp.) pharate adults, and full-length transcripts were successfully isolated. Two isoforms (A and B) were amplified from each of flea and buffalo fly, and isoform B only in dragonfly. Flea and buffalo fly isoform B transcripts were expressed in an *Escherichia coli* expression system, yielding soluble recombinant proteins Cf-resB and Hi-resB respectively. Protein structure and mechanical properties of each protein before and after crosslinking were assessed. This study shows that resilin gene and protein sequences are broadly conserved and that crosslinked recombinant resilin proteins share similar mechanical properties from flying to jumping insects. A combined use of degenerate primers and polyclonal sera will likely facilitate characterisation of resilin genes from other insect and invertebrate orders." 10936. Martínez-Coronel, M.; Pérez-Gutiérrez, M. (2011): Composición de la dieta de *Craugastor lineatus* (Anura: Craugastoridae) de Chiapas, México. *Acta Zoológica Mexicana* (n. s.) 27(2): 215-230. (in Spanish, with English summary) ["The ontogenetic and seasonal changes in the diet of *C. lineatus* were described. We obtained 121 prey items from 54 stomachs by dissection, prey and prey parts were counted and identified to ordinal level. Twenty two food categories were identified. Frogs consumed mainly Aranae, Chilopoda, Coleoptera, Hymenoptera, Isopoda, Orthoptera, and plants, although the representation of each category varied ontogenetically and temporally. The maximum length of the prey items was positively correlated with frog body size; meanwhile, the number of prey items was negatively correlated with frog body size. Juveniles consumed more Coleoptera and Isopoda, while adults captured more Aranae, Orthoptera and Chilopoda. Sixteen items were consumed in wet season, with Diptera, Isopoda, Lepidoptera and Acari as exclusive. During the dry season were ingested 18 items, with Phasmatoidea, Odonata, Psocoptera, Diplopoda and Pseudoscorpionida as exclusive." 10937. Matushkina, N.A.; Klass, K.-D. (2011): Morphology of female external genitalia in *Phenes raptor* (Odonata: Petaluridae). *International Journal of Odonatology* 14(3): 199-215. (in English) ["The exoskeleton of the female genitalic region in *Phenes raptor* is described based on light microscopy and scanning electron microscopy. It is shown that in this species the pattern of sclerites, articulations, processes, and apodemes is overall the same as in other ovipositor-bearing Odonata, i.e. Zygoptera, the anisozygopteran *Epiophlebia*, and the anisopteran Aeshnidae. However, many morphological details differ among all these taxa. Fifty-four characters

were scored for *P. raptor* in order to be included in a previously compiled dataset for phylogenetic analysis of ovipositor-bearing Odonata. These characters include only few specific similarities between *P. raptor* and either Aeshnidae or *Epiophlebia*. Instead, *P. raptor* shows a number of features that are unique among ovipositor-bearing Odonata. Absence of serration on the ovipositor in *P. raptor* and reduction of the interlocking mechanism connecting the two first valves medially is probably correlated with the endosubstratic egg-laying of the female. The ovipositor bears numerous sensilla of different shape, which probably detect suitable places for oviposition." 10938. McCauley, S.J.; Rowe, L.; Fortin, M.J. (2011): The deadly effects of "nonlethal" predators. *Ecology* 92: 2043-2048. (in English) ["Nonconsumptive predator effects are widespread and include plasticity as well as general stress responses. Caged predators are often used to estimate nonconsumptive effects, and numerous studies have focused on the larval stages of animals with complex life cycles. However, few of these studies test whether nonconsumptive predator effects, including stress responses, are exclusively sublethal. Nor have they assessed whether these effects extend beyond the larval stage, affecting success during stressful life-history transitions such as metamorphosis. We conducted experiments with larvae of *Leucorrhinia intacta* that exhibits predator-induced plasticity to assess whether the mere presence of predators affects larval survivorship, metamorphosis, and adult body size. Larvae exposed to caged predators with no ability to attack them had higher levels of mortality. In the second experiment, larvae reared with caged predators had higher rates of metamorphic failure, but there was no effect on adult body size. Our results suggest that stress responses induced by exposure to predator cues increase the vulnerability of prey to other mortality factors, and that mere exposure to predators can result in significant increases in mortality." 10939. Menetrey, N.; Oertli, B.; Lachavanne, J.-B. (2011): The CIEPT: A macroinvertebrate-based multimeric index for assessing the ecological quality of Swiss lowland ponds. *Ecological Indicators* 11(2): 590-600. (in English) ["Since ponds are limnologically different from rivers and lakes, and as there is a lack of specific methods to assess their ecological quality, we developed a method to assist managers in routine biomonitoring of ponds. For this work, a total of 36 lowland permanent ponds were selected from an existing dataset of 134 Swiss ponds that were classified along a gradient from reference to degraded sites. Site degradation was characterised by seven variables indicative of pond ecological condition: (i) one descriptor of plant communities (macrophyte species richness); (ii) one descriptor of trophic state (total phosphorus and total nitrogen (PN)), and (iii) five anthropogenic stressors linked to land use (percentage of semi-natural areas within a 50-m radius of the site, connectivity with other wetlands within 1 km, percentage of agricultural activities and pastures in the pond catchment, and dominant land use in terms of surface area). A total of 55 potential

macroinvertebrate and amphibian metrics were tested to assess their relationship to site degradation. The metrics were based on taxonomic richness (total and selected macroinvertebrate groups), intolerance of degradation, conservation values, and biological/ecological traits. The selection of the metrics to be integrated into the index followed a stepwise procedure. To be selected, a metric had to fulfil four criteria. It must have: (1) a significant relationship with at least one of the seven indicators of pond ecological condition; (2) the ability to discriminate between reference and degraded sites; (3) a relative scope of impairment inferior to 1 (low inherent variability of a metric); (4) no redundancy with other metrics used in the index. To produce the index, 18 combinations of selected metrics were tested. The final index (CIEPT) was built using three metrics: genera richness of Coleoptera (C), macroinvertebrate family richness (I), and Ephemeroptera, Plecoptera and Trichoptera (EPT) family richness. The CIEPT responded significantly to pond ecological condition and was tested successfully with an external dataset to confirm suitability. The CIEPT index could be a useful and relatively low cost tool to assist site managers in assessing the ecological quality of ponds." (Authors) Taxa (including Odonata) are treated at the order level.] Address: Menetrey, Nathalie, Laboratory of Ecology and Aquatic Biology, University of Geneva, Ch. des Clochettes 18, 1206 Geneva, Switzerland

10942. Millán, A.; Velasco, J.; Gutiérrez-Cánovas, C.; Arribas, P.; Picazo, F.; Sánchez-Fernández, D.; Abellán, P. (2011): Mediterranean saline streams in southeast Spain: What do we know? *Journal of Arid Environments* 75(12): 1352-1359. (in English) ["Many Mediterranean streams in arid and semiarid areas are naturally saline systems due to the presence of evaporitic rocks of Miocene or Triassic origin. Despite the fact that these aquatic ecosystems are rare in Europe, they are common in southeast of Spain. The environmental constraints of these semiarid saline streams are imposed by both geological and climatic conditions. This paper is a compilation and summary of the principal results obtained from various studies on semiarid saline streams in the Iberian southeast. Available data for these typical environments in the region covers diverse issues such as those regarding their physical and chemical features,

typology, biodiversity, community structure and ecosystem functioning, as well as different ecological and evolutionary aspects of their biota (e.g. ecophysiological responses, life cycles and phylogeography). Issues concerning the conservation of these habitats, such as the main human uses, impacts, threats and their management are also summarised. Finally, topics in need of further research are provided. The current knowledge of saline streams in southeastern Spain highlights the physical and ecological singularity of these environments, and their high conservation value. Saline streams are particularly interesting due to their halotolerant/halophilic biota and high number of rare and endemic species. ... Odonata (*Aeshnidae*, *Libellulidae* and *Coenagrionidae*) [...] are scarce with most inhabiting hyposaline streams (Mellado et al., 2008)." (Authors) (Mellado, A., Suárez, M.L., Vidal-Abarca, M.R., 2008. Biological traits of stream macroinvertebrates from a semiarid catchment: patterns along complex environmental gradients. *Freshwater Biology* 53: 1-21.)] Address: Millán, A., Depto de Ecología e Hidrología, Facultad de Biología, Univ. de Murcia, Campus de Espinardo, 30100 Murcia, Spain. 10943. Mlynarek, J.J.; Bert, D.G.; Peralta-Vázquez, G.H.; James, J.A.; Forbes, M.R. (2011): Relationships between gregarine infection in damselflies, wetland type, and landscape characteristics. *The Canadian Entomologist* 143(5): 460-469. (in English) ["Although human-modified landscapes are characterized by the loss of natural habitats, new habitats also can be created and exploited by many species. The importance of landscape change to invertebrate associations (particularly host-parasite associations) is understudied. Our objective was to determine whether prevalence and intensity of gregarine parasitism in *Ischnura verticalis* differed between 17 artificial and 7 natural wetlands in landscapes that varied in amount of forest and wetland cover and road density determined at spatial extents of 500m and 1km from each wetland. Wetlands were located in and around Ottawa, Ontario, and Gatineau, Quebec, Canada. Wetland type did not account for significant variation in principal components based on forest and wetland cover and road density at either spatial extent. Gregarine prevalence was higher in damselflies collected from natural wetlands than in those collected from artificial wetlands and was positively associated with increasing forest cover. In contrast, gregarine intensity was inversely related to road density. Our results suggest that parasitism of damselflies by gregarines is associated with wetland type and landscape characteristics, although the mechanisms producing such relationships are unknown." (Authors)] Address: Mlynarek, Julia, Dept Biol., Carleton Univ., 1125 Colonel By Drive Ottawa, ON Canada K1S 5B6. E-mail: jmlynare@connect.carleton.ca

10944. Monnerat, C.; Hoess, R. (2011): Libellen aus Jordanien, dem Westjordanland und dem Libanon, gesammelt von Johann Friedrich Klapperich zwischen 1956 und 1969 (Odonata). *Libellula* 30(1/2): 77-88. (in German, with English and French summaries) ["This collection of J.F. Klapperich (1913-1987) is deposited in the Natural History Museum of Geneva, Switzerland. It consists of 224 specimens representing 21 species, all labelled with date and locality. This material, collected by Klapperich during several voyages, is of great historical importance. It gives information on an otherwise almost neglected period between older studies and

more recent investigations in Jordan that began in the 1980s. Looking back, this material represents the earliest record for Jordan for twelve species. Special emphasis is put on *Crocothemis sanguinolenta*, *Diplacodes lefebvrei*, *Onychogomphus lefebvrei*, *Orthetrum trinacria* and *Pantala flavescens*." (Authors)] Address: Monnerat, C. 10947. Nagel, L.; Mlynarek, J.J.; Forbes, M.R. (2011): Immune response to nylon filaments in two damselfly species that differ in their resistance to ectoparasitic mites. *Ecological Entomology* 36(6): 736-743. (in English) ["1. Insects commonly resist parasites using melanotic encapsulation. Many studies measuring immune response use the amount of melanin deposited on an artificial object that has been inserted into the animal as a proxy of the amount of resistance that the host is capable of mounting to natural parasites. 2. The relevance of this methodology to immune response in natural insect populations needs further study. Here, we examined two temperate damselfly species to elucidate the relationships among damselfly size, natural resistance to mites, and the immune response mounted by the same damselflies against nylon filaments. 3. The damselfly species that had high rates of melanotic encapsulation of mites in nature deposited more melanin on the nylon inserts than the species with low rates of natural resistance. 4. In females of this species, those that had resisted mites naturally melanised the nylon filament more aggressively than those that did not resist mites. 5. Our results show some support for the use of nylon filaments to assess natural patterns of immune response in these damselflies, but also suggest that cau-

tion should be used in interpreting the responses." (Authors)] Address: Forbes, M.R., Dept of Biology, Carleton University, 587 Tory Building, 1125 Colonel By Drive, Ottawa, ON K1S 5B6, Canada. E-mail: mforbes@ccs.carleton.ca

10951. Obolewski, K.; Gotkiewicz, W.; Strzelczak, A.; Osadowski, Z.; Astel, A.M. (2011): Influence of anthropogenic transformations of river bed on plant and macrozoobenthos communities. *Environmental monitoring and assessment* 173(1-4): 747-763. (in English) ["This study describes the influence of urban area on plant communities and benthic invertebrates inhabiting the Slupia River (northern Poland). Ten plant communities and 37 macrozoobenthos taxa (including "Aeshnidae" and *Lestes viridis*) were determined during four seasonal samplings at 25 sampling sites (October 2005 and January, April, and August 2006). The obtained data set was statistically evaluated in order to reveal the influence of anthropogenic transformations on the investigated communities against the background of other abiotic factors. Multivariate regression tree (MRT) method was used for vegetation, while for benthic fauna, both MRT and artificial neural network (ANN) methods were applied. The following explanatory variables were used: season, water temperature, and salinity; location of a sampling site; degree of human impact on the riverbed; microhabitat; and substrate type. MRT analyses showed significant differences in plant community structure depending on the location of a sampling site, indicating the influence of anthropogenic pressure, while macrozoobenthos composition differed significantly only between seasons. The overall ANN

model proved the importance of type and location of a sampling site for the approximation of benthic fauna density. Additionally, influence of the explanatory variables on the consecutive macrozoobenthos taxa was analyzed on the basis of separate ANN." 10954. Orłowski, G.; Karg J.; Czarnicka J (2011): Frugivory and size variation of animal prey in Black Redstart *Phoenicurus ochruros* during summer and autumn in south-western Poland. *Ornis fennica* 88: 161-171. (in English) [Analyses of faeces of the Black Redstart *Phoenicurus ochruros* from the countryside of south-western Poland revealed a significant increase in the proportion of plant items (mainly berries of *Sambucus nigra* / *racemosa*) between July and October; for animal prey items an inverse trend was found. During summer-autumn, no significant trends in the mass of all animal prey were found. The most numerous animal prey were three genera of ants (*Lasius*, *Formica* and *Myrmica*; 44.1% by number of all animal prey). Large numbers of undamaged seeds of several species of shrubs in the analyzed faeces, including non-native species, indicate that the Black Redstart is a potential disperser of woody plants in rural landscapes of Europe." (Authors) The diet also includes an unidentified Libellulidae.] Address: Orłowski, G., Institute for Agricultural and Forest Environment, Polish Academy of Sciences, Bukowska 19, 60-809 Poznań, Poland. 10955. Ouden, A. den; Roosmalen, J. van (2011): Favorite hibernating spots of *Sympetma fusca*. *Brachytron* 14(1): 28-39. (in Dutch, with English summary) ["In the period between 2006 and 2011, hibernating *S. fusca* have been studied at several sites in the Dutch provinces of Noord-Brabant, Limburg, Gelderland and Noord-Holland. Observations have been made on habitat preference and weather-driven behaviour of the species in winter. Furthermore, experience on the best search strategy was gained. Most hibernating damselflies of the inland populations were found in bushes of *Calluna vulgaris* or, less often, tussocks of *Molinia caerulea*. Most hibernating damselflies of the coastal dunes population were found on branches of *Salix repens*. All locations had a southward exposure in common, offering sunny conditions. They were all shielded from the wind by surrounding forest edges. The damselflies were most easily found during bleak weather con-

ditions, when they are unable to turn away from the observer. The light-colored thorax and globular eyes are the features easiest to spot. During cold periods the damselflies choose lower positions in the vegetation compared to warmer periods. During snowfall they are often completely buried. Survival has been reported after night temperatures down to -18 °C. The results of this study show many similarities with previous studies on hibernating *S. paedisca*, although the latter species has been found to hibernate on locations much further away from suitable reproduction waters. Further study is required to obtain more information on hibernating *Sympetma* species and might help to explain the changing distribution patterns of these species in The Netherlands." (Authors)] Address: Ouden, A. den, Dr. Kanterslaan 166, 5361 NK Grave, The Netherlands. E-mail: andeno@planet.nl

10956. Palacino-Rodriguez, F. (2011): Taxonomía y filogenia del género *Erythemis* Hagen, 1861 (Odonata: Libellulidae). Universidad Nacional de Colombia, Facultad de Ciencias, Departamento de Biología Sede, Bogotá: 141 pp. (in Spanish, with English summary) ["*Erythemis* Hagen, 1861 (Odonata: Libellulidae) is a genus comprised of ten species distributed in the Nearctic and the Neotropics. Currently, the taxonomy of the group is based on characters of the thorax, hind femur, genitalia and wings. However, it is possible to confuse species groups as *Erythemis attala* - *E. plebeja* and *E. credula*, a situation that is repeated in *E. haematogastra* - *E. carmelita* - *E. mithroides* and *E. simplicicollis* - *E. collocata* and *E. vesiculosa*. The problems for the species made it necessary to revise the characters currently working and propose other to help recognize the variability within species, between species and propose to define phylogenetic relationships within the group. The characters were examined in specimens from five entomological collections in the country and two overseas, after examination, were assessed with multivariate approaches such as discriminant analysis and Principal Component Analysis. For phylogenetic analysis we used parsimony method, including as outgroup species of related genera *Sympetrum*, *Libellula*, *Perithemis*, *Rhodopygia*, *Pantala*, *Miathyria* and *Brachymesia*. For the basic tree search heuristic method was used with the software under the package Nona Winclada softwares. Dichotomous keys were developed, and diagnosis for males and females of the species and developed a hypothesis about the phylogenetic relationships within the group. The most reliable morphometric characters for separating the species are related to the wings and coloration. The characters of colour are highly variable and present overlap between some species, but in other cases, help to differentiate them. The review of a female close to *E. attala* and a male close to *E. mithroides* show that their characteristics apart from the rest of the species the genre, but more samples need to be included in the analysis to establish it as a new species. The complexity and ambiguity of some characters proposed in the literature led to his careful review to re-code and assess their taxonomic value, finding that this information is useful in separating species of the genus. Of the 109 characters are only nine peer reviewed, finding that *Erythemis* is not a natural group as a recodification of the character associated with the posterior femoral structure showed that it is shared by *Rhodopygia* and *Erythemis* genus, and *Libellula* and *Perithemis*. According to these results, it is necessary to explore a greater number of characters of the genitalia and care-

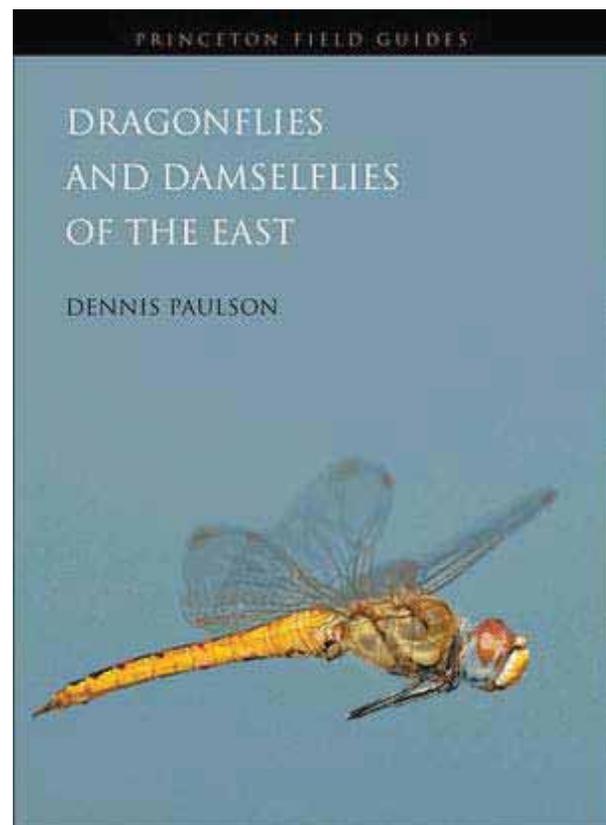

fully review the length and width ratio of hind femur to assess if the thickened condition presents this structure helps to resolve conflicts. It is also necessary to reassess the largest possible number of characters and other outgroups species, in order to find homologous characters to help resolve relationships within this genus and other genera of Libellulidae." 10957. Palatitz, P.; Fehervari, P.; Soltsz.; Kotyman, L.; Neidert, D.; Harnos, A. (2011): Exploratory analyses of foraging habitat selection of the Red-footed falcon (*Falco vespertinus*). *Acta Zoologica Academiae Scientiarum Hungaricae* 57(3): 255-268. ["The foraging habitat selection of *F. vespertinus* was investigated in a characteristic Hungarian habitat between 2006–2008. Potentially available habitat types were assessed within a 10 km² study site with remote sensing technologies. Altogether 18 adult birds were equipped with tail-mount VHF radio-tags and individually followed until visual contact to record location and foraging behaviour. Foraging areas were assessed with 100% Minimum Convex Polygons (MCP), global Manly's selectivity measures were used to detect population level habitat preference, and the eigenanalysis of selection ratios was carried out to partition the variability in individual habitat preference. We found large individual variability in the extent of foraging areas. Females had significantly smaller foraging areas compared to males, while males at the largest colony had significantly larger foraging areas compared to males of the smaller colonies. Global Manly's selectivity measures showed that birds significantly avoided intertilled crops, water surface" (in spite the fact that Odonata strongly contribute to the diet of this falcon species) ", woods and artificial surfaces. The eigenanalysis of selection ratios partitioned individual habitat selection rates into two distinct groups; the first using grasslands and alfalfa while the second group of birds preferring grasslands and cereals. Positive habitat preference towards arable habitat types, indicate that species specific conservation efforts of this declining raptor should also focus on agricultural land use practices." 10960. Pavitt, A. (2011): The Future of British Odonata. Determining temporal range dynamics from distribution patterns and dispersal. M.Sc. thesis, Imperial College London, Silwood Park: 7 + 69 pp. (in English) ["Temporal range dynamics (range shift and change index), dispersal morphometrics (wing length, wing aspect ratio, and thoracic volume), and distribution pattern (residual D) were investigated in British Odonata. Initial analyses discounted range shift from this study due to the absence of evidence that the data were showing directional shift rather than non-directional expansion. A significant proportion of change index (Teller et al. 2002) was described by combining the three dispersal traits and residual D. Species with increasing range size were those with long, broad wings, large thoracic volumes and a more aggregated distribution. This morphology is found in the anisopteran (dragonflies) suborder, which showed a substantially greater increase in occupancy than the smaller and weaker zygopteran (damselflies). In a preliminary investigation into the extant representativeness of museum collections, there was found to be no differences in wing length with recently caught, wet specimens." - 10963.** Persson, S. (2011): Is the dragonfly composition changing in Central Sweden? Examensarbete/ Bachelor's thesis; Högskolan i Halmstad • Box 823 • 301 18 Halmstad: 15 pp. (in English) ["The dragonfly communities in Sweden may be affected in many ways. Loss of habitats, habitat alteration or even environmental toxins might have a negative impact on the communities. A new threat to the communities and to the species in general is climate change. In this study I examined whether the dragonfly composition had changed in an area in central Sweden between 1997 and 2010. I did a nestedness matrix to see if the dragonfly composition (only using partivoltine species) was more or less nested in 2010 than it was in 1997, i.e. if there was more unexpected species recorded in the area. I also looked at the surrounding of the lakes and whether the species were considered to be generalist species or specialist species. I found that the dragonfly composition had changed during these 13 years and that the composition was more nested in 1997 than in 2010, i.e. there was more unexpected species in the 2010 survey. I also recorded seven new species for the area and that six species had disappeared. Six species had gone from being generalists to being specialists. The surroundings had not changed significantly and I thus see climate change as a possible explanation to these changes." 10977. Reis, E.F.; Pinto, N.S.; Carvalho, F.G.; Juen, L. (2011): Environmental integrity effect on fluctuating asymmetry in *Erythrodiplax basalis* (Libellulidae: Odonata) (Kirby). *EntomoBrasilis* 4(3): 103-107. (in Portuguese, with English summary) ["Constituted by simple and cheaply techniques, measures of changes in ontogenetic development are good biomonitoring tools. One of these techniques commonly used is the Fluctuating Asymmetry (FA). In this study, we explore the effects of riparian vegetation removal on the levels of FA on hind wings traits of *E. basalis*. The results showed that traits present normal distribution and zero mean, which allows us to assume that observe levels of asymmetry are FA. It was also evident that FA indexes are not correlated to the wing length, and present low levels of measurement error. There is no significantly evidence of increase in the FA levels in degraded areas in comparison with preserved areas for the measured variables (wing length, wing width on the nodus level, distance between triangle and nodus and distance between anal loop and nodus). The hypothesis that individuals collected in altered areas present higher levels of FA in wing traits was not corroborated. This may result from the fact that *E. basalis* is a species with good dispersal capability, and the specimens sampled in disturbed areas may have developed elsewhere and were only using the areas as a point of foraging and therefore was not detected AF. Another factor that corroborates this prediction is the fact that other studies using

Zygoptera species that have lower dispersal ability, significant levels of physical activities has been detected." (Authors)] Address: Ferreira dos Reis, Eva, Pontifícia Universidade Católica de Goiás, Brazil. E-mail: evadosreis@hotmail.com.

10978. Ribeiro Loiolal, G.; De Marco, P. (2011): Behavioral ecology of Heteragrion consors Hagen (Odonata, Megapodagrionidae): a shade-seek Atlantic forest damselfly. *Revista Brasileira de Entomologia* 55(3): 373-380. (in English, with Portuguese summary) ["The intensity of the inter- and intra-sexual selection can affect male behavioural traits as territorial fidelity and aggressiveness allowing the existence of different strategies. However, its differential success could be affected by environmental – as the diel variation in temperature – and physiological constrains – as the variation in thermoregulatory abilities. In this context, we present a behavioural analysis of *H. consors* trying to characterize its mating system, diel activity pattern, temporal budget, territoriality and reproductive biology. These data were obtained based on field observations using the focal individual method and mark-recapture techniques in 120 m of a shaded Atlantic Forest stream in Brazil. The males of this species were territorial, varying in its local fidelity, while the females appear sporadically. Males were perched in the majority of the time, but were also observed in cleaning movements, longitudinal abdominal flexion, wing flexion and sperm transfer during perch. The males presented a perched thermoregulatory behaviour related to an exothermic regulation. Foraging and agonistic interactions were rare, but dominate the other behavioural activities. Abdominal movements associated to long lasting copula pointed to the existence of sperm competition in this species. Males performed contact post-copulatory guarding of the females. These observations pointed to a non-resource mating system for this species." 10979. Riva-Murray, K.; Chasar, L.C.; Bradley, P.M.; Burns, D.A.; Brigham, M.E.; Smith, M.J.; Abrahamsen, T.A. (2011): Spatial patterns of mercury in macroinvertebrates and fishes from streams of two contrasting forested landscapes in the eastern United States. *Ecotoxicology* 20(7): 1530-1542. (in English) ["Controls on mercury bioaccumulation in lotic ecosystems are not well understood. During 2007–2009, we studied mercury and stable isotope spatial patterns of macroinvertebrates and fishes from two medium-sized (80 km²) forested basins in contrasting settings. Samples were collected seasonally from multiple sites across the Fishing Brook basin (FBNY), in New York's Adirondack Mountains, and the McTier Creek basin (MCSC), in South Carolina's Coastal Plain. Mean methylmercury (MeHg) concentrations within macroinvertebrate feeding groups, and mean total mercury (THg) concentrations within most fish feeding groups were similar between the two regions. However, mean THg concentrations in game fish and forage fish, overall, were much lower in FBNY (1300 and 590 ng/g dw, respectively) than in MCSC (2300 and 780 ng/g dw, respectively), due to lower trophic positions of these groups from FBNY (means 3.3 and 2.7, respectively) than MCSC (means 3.7 and 3.3, respectively). Much larger spatial variation in to-

pography and water chemistry across FBNY contributed to greater spatial variation in biotic Hg and positive correlations with dissolved MeHg and organic carbon in streamwater. Hydrologic transport distance (HTD) was negatively correlated with biotic Hg across FBNY, and was a better predictor than wetland density. The small range of landscape conditions across MCSC resulted in no consistent spatial patterns, and no discernable correspondence with local-scale environmental factors. This study demonstrates the importance of local-scale environmental factors to mercury bioaccumulation in topographically heterogeneous landscapes, and provides evidence that food-chain length can be an important predictor of broad-scale differences in Hg bioaccumulation among streams." 10988. Sang, A.; Teder, T. (2011): Dragonflies cause spatial and temporal heterogeneity in habitat quality for butterflies. *Insect Conservation and Diversity* 4: 257-264. (in English) ["1. Mortality caused by natural enemies is an essential but largely overlooked aspect of habitat quality for herbivorous insects. Quantitative data on mortality sources and their spatiotemporal variation are especially scarce for adult insects. 2. Here we report the results of an extensive field study aimed to quantify spatial and seasonal variation in dragonfly predation on adult butterflies in their natural habitats in temperate calcareous grasslands. We rely on direct observations of actual predation events during standardised transect walks. 3. Dragonflies were found to exert high mortality in butterflies. Their impact on butterflies was dependent on predator abundance, which strongly varied among habitat patches and during the season. This suggests that dragonflies can generate substantial spatiotemporal heterogeneity in habitat quality for butterflies in terms of survival. 4. Obtaining prior knowledge of where and when predators are abundant, and avoiding such sites for butterfly conservation, could considerably improve the efficiency of butterfly conservation practices." (Authors)] Address: Sang, Anu, Dept of Zoology, Institute of Ecology and Earth Sciences, Univ. of Tartu, Vanemuise 46, 51014 Tartu, Estonia. E-mail: anu.sang@ut.ee

10989. Santolamazza, S.; Baquero, E.; Cordero-Rivera, A. (2011): Incidence of *Anagrus obscurus* (Hymenoptera: Mymaridae) egg parasitism on *Calopteryx haemorrhoidalis* and *Platycnemis pennipes* (Odonata: Calopterygidae: Platycnemididae) in Italy. *Entomological Science* 14(3): 366-369. (in English) ["Very little is known about the incidence of egg parasitoids in odonates, perhaps because Odonata eggs are well protected by stems or leaves, sometimes below water. In Central Italy (Pontecorvo, Frosinone Province) two damselflies, *Calopteryx haemorrhoidalis* and *Platycnemis pennipes*, occur in high densities. In August 2007 we collected 30 stems of the aquatic plant *Potamogeton* sp. used as substrate for oviposition and incubated eggs in the laboratory. Most stems (24 for *C. haemorrhoidalis* and 23 for *P. pennipes*) contained Odonata eggs. Parasitoids emerged from 12 stems, with a mean parasitism of 2% for *C. haemorrhoidalis* and 6% for *P. pennipes*, and a maximum of 14% and 50%, respectively. Furthermore, we observed egg-laying of 19 females of *C. haemorrhoidalis* and 11 of *P. pennipes*, and marked the stems where oviposition was observed. Clutches remained in the river for five days and were then collected and incubated. Parasitoids emerged from 11 of 30 stems, with an average parasitism of 8% for *C. haemorrhoidalis* and 3% for *P. pennipes* (maximums of 50% and 29%, respectively). All parasitoids belonged to the family Mymaridae, and were identified as *Anagrus* (*Anagrus*) *obscurus* Förster, 1861, sensu Soyka, 1955. This is the first time that this species is described as an egg parasitoid of odonates, and that the egg parasitoid of *C. haemorrhoidalis* and *P. pennipes* is identified. Our data suggest that egg parasitism might be a significant selective factor for both odonates in the studied locality, affecting female oviposition behaviour." 10991. Schlotmann, F. (2011): Die Entwicklung der Libellenfauna (Insecta: Odonata) des Soonwaldes (Rheinland-Pfalz) im Lauf von drei Jahrzehnten - eine Analyse ökologischer Faktoren. *Fauna und Flora in Rheinland-Pfalz* 12(1): 241-265. (in German, with English summary) ["Due to the dominance of oligo- and dystrophic ponds the community of damselfly and dragonflies in the Soonwald forest is characterized by moorland species. According to different current publications these species are decreasing in many parts of Europe. This can best be explained by increasing competition of ubiquitous species that are expanding their ranges into the specific bog habitats as an effect of the man made climate change. Stemming against this trend in the Soonwald forest the species of the peatbog habitats have yet managed to keep their populations while competitors like *Anax imperator*, *Libellula depressa* und *Sympetrum striolatum* have started to colonise the ponds of the area. A significant increase of Mediterranean species couldn't be proved yet, but first tendencies could be found: The darters *Sympetrum sanguineum* and *S. striolatum* have started to crowd out the genus' species of the Eurosiberian element which are *S. danae*, *S. flaveolum* and *S. vulgatum*. In general many population trends on the local scale go in line with the trends that have been described on a Western European scale. These are the increases of *Calopteryx virgo*, *Lestes virens*, *A. imperator*, *Cordulia aenea* and *S. sanguineum* as well as the decreases of *Enallagma cyathigerum* and *Leucorrhinia rubicunda*. The only ecological parameter that seemed to have significantly influenced the composition of the species community within the three decades was drought resistance. Species that winter in the egg stage had been increasing significantly. This mirrors the progressing problem of pond desiccation in the Soonwald forest which is caused by forestry (drainage and melioration), abstraction of drinking water (sinking of the ground water table) and subtle changes in the precipitation regime driven by the man made climate change. These are also the main challenges for conservation efforts in other peatlands in western and central Europe." (Author)] Address: Schlotmann, F., Weserstr. 11, D-55296 Harxheim, Germany. 10995. Sharma, G.; Dhadeech, S.N. (2011): Comparative studies on the reproductive behaviour of damselfly, *Neurobasis chinensis chinensis* (Linnaeus) at Ravi river, Chamba (H. P.) and of dragonfly, *Orthetrum sabina sabina* (Drury) at Kailana lake, Jodhpur (Rajasthan). National Seminar on Biodiversity and Intangible Natural Heritage on 28th September, 2011. Organised by National Museum of Natural History Zoological Survey of India, Tansen Marg, New Delhi (MoEF, Govt. of India), M-Block, New Alipore, Kolkata (MoEF, Govt. of India) on September 28th, 2011: 64-65. (in English) [Verbatim: The reproductive behaviour of *N. chinensis* was studied three times around Ravi river, Chamba, Himachal Pradesh during September-October, 2007. Courtship is well marked and male demonstrate a circular territory with a radius of about 2-4 m, guarded or defended by the resident male from the intruding conspecific males by wing opening or abdomen raising. As female entered into the territory, the male started following her and got success to bind in tandem link, catching hold her prothorax by its anal appendages. The before wheel tandem lasted for 3-5 minutes. After that the female tried to interlock its vulvar region with the secondary copulatory apparatus of male to form the spectacular courtship wheel. The courtship wheel lasts for about 4-6 minutes and is performed of perching on vegetation or stone near water body. After finding suitable oviposition spot, the male releases the grip on female prothorax. The after wheel tandem lasted for 5-7 minutes. Oviposition is endophytic among the aquatic vegetation. The female went down underwater till their thorax wings and head above water using her ovipositor to grip the oviposited vegetation. This underwater oviposition continued for 6-8 minutes. During oviposition the male hovers in air around female to defend her from intruding intra- or interspecific males. The duration of reproductive behaviour of *N. chinensis* lasts for 18-26 minutes. The repro-

ductive behaviour of *O. sabina* was studied five times in Kailana lake, Jodhpur, Rajasthan, India during January, 2008 to July, 2008. Courtship is well marked and male demonstrate a circular territory with a radius of about 1-3 meters, guarded or defended by the resident male from the intruding conspecific males. As female entered into the territory, the male started following her and got success to bind in tandem link, catching hold her prothorax by its anal appendages. Before wheel tandem lasted for 5-12 seconds. After that the female tried to interlock its vulvar region with the secondary copulatory apparatus of male to form the copulatory wheel. The courtship wheel lasts for about 4-9 minutes and is performed of perching on vegetation or boundary wall of water body. After completion of copulation, the male release the grip on female prothorax, hovers around and guarded female from the intruding conspecific males during oviposition. Oviposition is exophytic, the eggs are laid by dripping the tip of the abdomen several times in water and lasts for 2-4 minutes. The duration of reproductive behaviour lasts for 10-15 minutes. The study reveals that there is variation in reproductive behaviours of both the species in all the stages.] Address: Sharma, G., Zoological Survey of India, Desert Regional Centre, Jhalamand, Pali Road, Jodhpur-342 005, Rajasthan, India. 10997. Sherratt, T.N.; Hassall, C.; Laird, R.A.; Thompson, D.J.; Cordero-Rivera, A. (2011): A comparative analysis of senescence in adult damselflies and dragonflies (Odonata). *Journal of Evolutionary Biology* 24 (4): 810-822. (in English) ["Any population whose members are subject to extrinsic mortality should exhibit an increase in mortality with age. Nevertheless, the prevailing opinion is that populations of adult damselflies and dragonflies do not exhibit such senescence. Here,

we challenge this contention by fitting a range of demographic models to the data on which these earlier conclusions were based. We show that a model with an exponential increase in age-related mortality (Gompertz) generally provides a more parsimonious fit than alternative models including age-independent mortality, indicating that many odonates do indeed senesce. Controlling for phylogeny, a comparison of the daily mortality of 35 odonate species indicates that although male and female mortalities are positively correlated, mortality tends to be higher in males of those species that exhibit territoriality. Hence, we show for the first time that territoriality may impose a survivorship cost on males, once the underlying phylogenetic relationships are accounted for." 11000. Stanton, D.J.; Allcock, J.A. (2011): Habitat characteristics and odonate communities at selected sites used by *Mortonagrion hirosei* Asahina (Zygoptera: Coenagrionidae) in Hong Kong. *Journal of Threatened Taxa* 3(12): 2242-2252. (in English, with Chinese abstract) ["*M. hirosei*, a Near Threatened species, is recorded from several isolated sites across its entire range in eastern Asia. Previous research has indicated a strong affinity for brackish wetlands, including reedbeds and marshes, where potential predation or competition by other odonates is reduced. Results from surveys conducted in Hong Kong during 2009-2011 provide information on the habitat at a number of sites occupied

by *M. hirosei* and report on the presence of populations in mangrove and mangrove-mosaic habitats as well as brackish marsh, often in association with a diversity of other odonates. Information is also provided on two previously unreported sites in Hong Kong. These new findings indicate that the species uses a greater diversity of habitats than the odonate-poor *Phragmites* reedbeds in which it has been well-studied in Japan, and consequently may be more widespread than previously supposed. Given that coastal habitats are threatened throughout its range, it is hoped this broader understanding of the species' habitat requirements will encourage others to explore other coastal sites and to aid in its conservation." 11002. Steele, D.B.; Siepielski, A.M.; McPeck, M.A. (2011): Sexual selection and temporal phenotypic variation in a damselfly population. *Journal of Evolutionary Biology* 24(7): 1517-1532. (in English) ["Temporal variation in selection can be generated by temporal variation in either the fitness surface or phenotypic distributions around a static fitness surface, or both concurrently. Here, we use within- and between-generation sampling of fitness surfaces and phenotypic distributions over 2 years to investigate the causes of temporal variation in the form of sexual selection on body size in the damselfly *Enallagma aspersum*. Within a year, when the average female body size differed substantially from the average male body size, male body size experienced directional selection. In contrast, when male and female size distributions overlapped, male body size experienced stabilizing selection when variances in body size were large, but no appreciable selection when the variances in body size were small. The causes of temporal variation in the form of selection can only be inferred by accounting for changes in both the fitness surface and changes in the distribution of phenotypes." 11004. Suriano, M.T.; Fonseca-Gessner, A.A.; Roque, F.O.; Froehlich, C.G. (2011): Choice of macroinvertebrate metrics to evaluate stream conditions in Atlantic Forest, Brazil. *Environ. Monit. Assess.* 175: 87-101. (in English) ["The development of biomonitoring programs based on the macroinvertebrate community requires the understanding of species distribution patterns, as well as of the responses of the community to anthropogenic stressors. In this study, 49 metrics were tested as potential means of assessing the condition of 29 first- and second-order streams located in areas of differing types of land use in São Paulo State, Brazil. Of the sampled streams, 15 were in well-preserved regions in the Atlantic Forest, 5 were among sugarcane cultivations, 5 were in areas of pasture, and 4 were among eucalyptus plantations. The metrics were assessed against the following criteria: (1) predictable response to the impact of human activity; (2) high taxonomic resolution, and (3) operational and theoretical simplicity. We found that 18 metrics were correlated with the environmental and spatial predictors used, and seven of these satisfied the selection criteria and are thus candidates for inclusion in a multimetric system to assess low order streams in São Paulo State. These metrics are family richness; Ephemeroptera, Plecoptera and Trichoptera (EPT) richness; proportion of Megaloptera and Hirudinea; proportion of EPT; Shannon diversity index for genus; and adapted Biological Monitoring Work Party biotic index." (Authors) The basal analysis included "Odonata".] Address: Suriano, Marcia Thais, Laboratório de Entomologia Aquática. FFCLRP, Universidade de São Paulo, Ribeirão Preto, São Paulo, Brazil. 11006. Teixeira da Silva, E.; Ribeiro Filho, O.P.; Neves Feio, R. (2011): Predation of native anurans by invasive bullfrogs in southeastern Brazil: Spatial variation and effect of microhabitat use by prey. *South American Journal of Herpetology* 6(1): 1-10. (in English, with Portuguese summary) ["Invasive predators are one of the causes of population declines of anurans around the world. The American Bullfrog (*Lithobates catesbeianus*) stands out among these predators. Based on field observations and stomach content analysis, predation on native anurans by invasive Bullfrogs was investigated in two localities of Southeastern Brazil. The spatial variation in predation and similarity in microhabitat use by native species and Bullfrogs were also determined. Anurans of the families Bufonidae, Hylidae, Leiuperidae and Microhylidae were found among Bullfrog prey. The species preyed upon had medium to high similarity with Bullfrogs regarding microhabitat use. Anurans had high relative importance in the diet of adult Bullfrogs from the site where natural vegetation is preserved. Thus, the

possible negative impact of predation by Bullfrogs can be more significant on anuran species which use microhabitats similar to those used by the invasive frogs. This impact may also be higher in preserved sites, increasing the necessity of monitoring and controlling the spread of this invasive species to natural areas. However, as factors other than predation are known to contribute toward negative impacts, further studies are required to clarify the status of invasive Bullfrogs in Brazil." (Authors) Diet also included Odonata larvae and imagines.] Address: Teixeira da Silva, E., Centro de Estudos em Biologia, Instituto Superior de Educação, Centro Universitário de Caratinga, Rua Niterói 230, CEP 35300-345, Caratinga, MG, Brasil. 11008. Teske, A. (2011): Herbstlebensräume von *Sympetma paedisca* (BRAUER, 1877) und *S. fusca* (VANDER LINDEN, 1820) im Bereich Thülsfelder Talsperre (LK Cloppenburg). *Drosera* 2010: 149-158. (in German, with English summary) ["From 2009 until 2011, the occurrence, autumn habitats, and behaviour of *S. paedisca* and *S. fusca* were studied in the north-west of Lower Saxony, Germany. At the beginning of autumn 2010, one large occurrence of *S. paedisca* and two smaller ones were recorded in the area of the Thülsfelder Talsperre. *S. fusca* was found exclusively in the area of the large occurrence of *S. paedisca*. The sites are microclimatically favoured open forest areas with withered grass, *Calluna vulgaris*, withered *Tanacetum vulgare* and piles of dead wood. Whether these sites are only late summer habitats respectively autumn or winter habitats remains to be clarified. As no further occurrence of *S. paedisca* was confirmed the population and suitable habitats in the area of the Thülsfelder Talsperre have a high nature conservation value. Possible reasons of endangering and measures to protect *Sympetma*-species are discussed as well as appropriate methods to find out late summer and autumn habitats." (Author)] Address: Teske, Ariane, AG Terrestrische Ökologie, Institut für Biologie und Umweltwissenschaften (IBU), Fakultät V, Universität Oldenburg, 26111 Oldenburg, Germany. 11016. Watanabe, M.; Suda, D.; Iwasaki, H. (2011): The number of eggs developed in the ovaries of the dragonfly *Sympetrum infuscatum* (Selys) in relation to daily food intake in forest gaps (Anisoptera: Libellulidae). *Odonatologica* 40(4): 317-325. (in English) ["Daily food intake of *S. infuscatum* was estimated using the quantity of faeces produced. Dry weight of faeces excreted during 24 h after capture was measured for each sex of both sexually immature and mature stages. The grain-like faeces (faecal pellets) contained many fragments of cuticle of prey insects. In the laboratory, there was a relationship between the amount of daily faeces excreted and the quantity of daily food intake. Although both sexes excreted a similar amount of faeces in the immature stages, mature females had greater faecal weight than males, suggesting that females fed on more prey than males. The estimated daily dry weight of prey insects was about 17.7 mg in females. The relationship between the number of mature eggs in the ovaries and the quantity of food intake indicated that about 8 days were needed to accumulate enough mature eggs in the ovaries to lay in rice paddy fields. The duration of the mature stage in // was one and a half months, hence the number of visits to rice paddy fields must be 6, confirming the importance of food intake during visits to the forest gaps between bouts of oviposition." 11030. Prejs, A.; Koperski, P.; Prejs, K. (1997): Food-web manipulation in a small, eutrophic Lake Wirbel, Poland: the effect of replacement of key predators on epiphytic fauna. *Hydrobiologia* 342: 377-381. (in English) ["The effect of fish removal on the invertebrate fauna associated with *Stratiotes aloides* was studied in a shallow, eutrophic lake. The biomass of invertebrate predators was approximately 2.5 times higher in the invertebrate dominated year (1992) than in the fish-dominated year (1991), while the density of non-predatory invertebrates in 1991 was ca half that in the invertebrate-dominated year. The decrease was due to a sharp fall in the density of epiphytic chironomids, with the density of plant-mining chironomids being far less affected. Marked declines in the density of non-predatory invertebrates in the invertebrate-dominated year were most probably caused by invertebrate predators. Once freed from suppression induced by fish, invertebrate predators were able to control the density of epiphytic prey more effectively than fish. ... In summer 1991, prior to fish removal, the total biomass of predators was estimated at 15 g f.w m² of which fish accounted for 90%. In summer 1992, after rotenone treatment, the total biomass of predators was 10 g f.w. m², of which approximately 90% was made up by invertebrates. The increase in the biomass of invertebrate predators in 1992 resulted from sharp rises in the biomass of Odonata larvae, Heteroptera and Argyroneta aquatica, which were particularly distinct in late spring (June), early summer (July) (Heteroptera and *A. aquatica*) and summer (July–September) (Odonata). In the case of Odonata biomass and density, the significance of differences between 1991 and 1992 was confirmed by Student's test (biomass: P = 0.01, density: P = 0.003)." 11031. Sabine, M.E.J. (1998): Macroinvertebrate communities of different-aged beaver ponds. Master of Science thesis, University of New Brunswick: 81 pp. (in English) ["Previous studies of waterfowl utilization of beaver ponds for breeding and brood-rearing have found higher waterfowl use of new beaver ponds (c 5

years old) than old beaver ponds. These studies have concluded, based on waterfowl use only, that new beaver ponds are more productive for waterfowl than old beaver ponds. I tested the hypothesis that productivity in beaver ponds, in terms of macroinvertebrates and water quality, declined with beaver pond succession. In 1993 and 1994, fifteen and nine beaver ponds, respectively, of three different age groups (new, mid-aged, old) were sampled for invertebrates and water quality to quantify differences among age groups. No significant differences ($p < 0.05$) were found in invertebrates or water quality among different age classes. Significant differences were found in most measures over the different sampling periods, with invertebrates being higher in the earlier sampling periods, while nutrients were higher in the later sampling periods. The former is most likely due to a peak in insect emergence early in the summer, while the latter is probably a result of a water level drop between periods. Highly significant differences were also noted for most measures among individual ponds, and this pond variability probably masked any patterns of different age classes. Nutrients and invertebrates were relatively low throughout the study area, which may also have hidden any true differences in age classes of beaver ponds. Because of the low productivity in the study site, beaver pond management for waterfowl would not be feasible or cost-effective in this area." 11034. Amakye, J.S. (1999): Effect of Temephos 20EC on non-target saxicolous fauna of a tropical African Island river at first treatment. *West African journal of applied ecology* 7: 109-121. (in English) ["River Musola on Bioko Island in the Republic of Equatorial Guinea was treated with temephos 20EC, a Simutium larvicide, in March 1999 under a pilot experiment to eradicate *Simulium damnosum* s.l. from that island. The mean density of the saxicolous macroinvertebrates prior to temephos treatment of the river was $5.946.7 \pm 2,065.7$ individuals m^2 . The density of macroinvertebrates observed 24 h after treatment with temephos was $4.062.2 \pm 2,588.0$ individuals m^2 , indicating 31.7% reduction in the density of the population. There was 100% reduction in density of Odonata, Hydroptilidae, Ecnomidae, Leptoceridae and Tanyptodinae in the post treatment samples. Baetidae and Orthocladiinae were affected significantly by temephos ($P \leq 0.1$). Whereas impact of temephos on *Cheumatopsyche digitata* (Trichoptera: Hydropsychidae) was marginal (-16.7%), there was complete loss of *C. falcifera* (100%) from the river, following treatment with the larvicide, indicating differential response to the larvicide by these sympatric species. In general, 'Filtering Collectors' (73%) dominated the saxicolous biocoenosis prior to treatment with temephos. However, no 'Grazers' or 'Scrapcrs' were present in the saxicolous community of the section of the river studied during the pretreatment period. The 100% reduction in density observed for many taxa in the biocoenosis, in the immediate post treatment period was attributed to the low discharge of the river and the low population densities of the various taxa observed at the time of the experiment, as well as the extremely heterogeneous nature of the river bottom. It is proposed that the gallery forests be maintained to aid conservation of the faunistic diversity of the river." 11040. Futahashi, R. (2001): A new record of *Sympetrum maculatum* from Shizuoka Prefecture. *Tombo* 43: 38-39. (in Japanese, with English summary) [A male of *S. maculatum* was a new record for Shizuoka Prefecture. This is an unusual migratory record because of the following facts: the locality, Enshu-hama (Hamamatsu), is more than 70 kilometers away from the nearest habitats known at present; no other sighting has thus been recorded there despite the investigations carried out by many odonatologists; the captured individual was found just after a typhoon and no plant translocation from other habitats has been recorded in the area.] Address: Futahashi, R., Fujiwara Lab., Univ. Tokyo, Biosci. Bldg 501, Kashiwa, Chiba, 377-8562, Japan

11041. Futahashi, R.; Futahashi, H.; Araki, Y. (2001): Recent findings concerning Odonata in Hokuriku district. *Tombo* 43: 31-36. (in Japanese, with English summary) [Japan; "*Lyriothemis pachygastra* was recorded for the first time from Toyama Prefecture. *Sympetrum s. speciosum* was newly recorded from the Noto peninsula. Exuviae and larvae of *Aeshna mixta soneharai* were recorded from Toyama Prefecture, Hokuriku district for the first time. Four migratory species, *Anax guttatus*, *Sympetrum cordulegaster*, *S. depressiusculum* and *Trapezostigma virginia* were recorded at several sites in Toyama and Ishikawa Prefecture. Some males that seemed to be hybrids between *Anax n. nigrofasciatus* and *Anax parthenope julius* were recorded at several sites in Toyama Prefecture. Some adults of *Aeschnophlebia longistigma*, which usually disappear by the end of August were recorded in September. Recent records of the following 5 sharply decreased species in this area were reported: *Gynacantha japonica*, *Asiagomphus pryleri*, *Gomphus postocularis*, *Somatochlora clavata*, *Sympetrum maculatum*. Distributional records of Odonata in the Hokuriku district were reported including

several species rare in this area: *Cercion sexlineatum*, *Sympetma paedisca*, *Aeshnophlebia anisoptera*, *Davidius moiwanus taruu*, *Stylogomphus suzuku*, *Sympetrum striolatum imitoides*." (Authors)] Address: Futahashi, R., Fujiwara Lab., Univ. Tokyo, Biosci. Bldg 501, Kashiwa, Chiba, 377-8562, Japan

11042. Kano, K. (2001): A cleaning behavior of *Davidius moiwanus moiwanus* (Okumura) after oviposition. Tombo 43: 57-58. (in Japanese, with English summary) ["A cleaning movement of a female of *D. m. moiwanus* was observed at a small stream at the Shiga Heights, Nagano Prefecture, Japan, on July 20, 2000. The female, after oviposition, moved onto a mugwort leaf near the waters edge with some eggs attached to her abdominal tip. She repeatedly rubbed her abdominal tip by bending her abdomen against the underside of the leaf and scraped off the eggs into the water. This behaviour lasted for 30 seconds. As the eggs are not very sticky, the behaviour should be regarded as a selfcleaning rather than epiphytic oviposition, which has been reported in *Malgassophlebia*, *Tetrathemis* and *Micrathyria*." 11052. Brooker, J.S. (2002): *Enallagma civile* (Odonata: Coenagrionidae) life history and production in a west Texas playa. Master of Science (Biology), University of North Texas: 46 pp. (in English) ["This study was conducted to describe the life history of *E. civile* and the other Odonates that inhabit playa habitats in the Southern High Plains of Texas. It was learned that *E. civile* has a low secondary production estimate of 66.8 mg/m². It was also determined that this species had a developmental time of approximately 21 days in a playa setting. Another important fact was that *E. civile* was the earliest colonizer of all of the Odonate species studied. It was recorded in the playa at least one week earlier than all of the other Odonates. Odonate populations in the playa continued to increase in size throughout the study. Some populations grew more quickly than others. For instance, *Lestes disjunctus*, had the population that grew the slowest. Its average population estimate per m² changed from 0 to approximately 3 in an eight-week time period. On the opposite end of the spectrum, *E. civile*, had an average population estimate per m² which increased in size from 2 to approximately 670 naiads in the same eight-week time period. When the playa began to lose water and thus dwindled in size, the Odonate populations all had significant decreases in size. The naiads either became prey for another organism, emerged or died due to lack of water or lack of food. None of the species in this study were able to continue increases in their population sizes during this time. The period after this drought is what is unique. Some of the species continued to have numbers that dwindled, while others maintained relatively similar amounts of naiads. One species, *Anax junius*, actually had a population explosion after the drought when the playa began to refill close to the beginning of September. During the course of this study, much was learned about the niches that Odonates occupy in a playa. The populations of some prominent dragonfly species were studied and their quantities were estimated for different periods during one season. Sizes of head capsules were studied in an effort to determine the development of Odonate populations over a period of time. In addition, field sampling showed high points in population sizes and trends in growth. Research was conducted of the life histories of Odonates and a lot of information was gained about the productivity of dragonflies. This study was a valuable proponent to the collection of information available about playa habitats." (Author)] Address: Jennifer Suzanne Booker, not further details

11054. Jeschke, J.M. (2002): Funktionelle Reaktionen von Konsumenten: die SSS Gleichung und ihre Anwendung. Dissertation, Fakultät für Biologie, Ludwig-Maximilians-Universität München: 192 pp. [Chapter 5 of the thesis "Correlates and Consequences of Predator Confusion" uses Odonata in laboratory experiments: "When confronted by a swarm of their prey, many predators

become confused and are thus less successful in their attacks. It is unknown how widespread this confusion effect is and largely unknown which predator or prey traits facilitate or impede it. We therefore performed corresponding experiments in the predator-prey systems *Aeshna cyanea* (Odonata) – *Daphnia magna* (Crustacea), *Libellula depressa* (Odonata) – *D. magna*, *Chaoborus obscuripes* (Diptera) - *Daphnia obtusa*, and *Triturus alpestris* (Alpine newt) – *D. obtusa*. We combine our results with literature data and find that predators have become confused in 70% of the 20 predator-prey systems studied to date. Tactile predators appear to be generally susceptible, whereas visual predators seem susceptible only if their prey is highly agile. This difference arguably results from the superiority of the latter in singling out individual prey. To allow a better understanding of the ecological, ethological, and evolutionary consequences of predator confusion, we examine its effects on functional responses. We theoretically and empirically show that the widespread assumption confusion would let a functional response become dome-shaped is not necessarily true. The response can alternatively remain qualitatively unchanged and is affected only in a quantitative way. Thus, a non-dome-shaped response is no indication for the absence of predator confusion." (Author) Additional reading: Jeschke, J.M.; Tollrian, R. (2005): Effects of predator confusion on functional responses. *Oikos* 111: 547-555; Jeschke, J.M.; Tollrian, R.
