

Odonatological Abstract Service (OAS)

alle Ausgaben in einem pdf – all editions compiled in one pdf!

Wichtiger Hinweis – bitte beachten!

Von 1998 bis 2016 wertete Martin Schorr – unterstützt durch verschiedene Kollegen – zahllose odonatologische Publikationen (einschließlich "grauer Literatur", also unveröffentlichte Berichte, wissenschaftliche Abschlussarbeiten etc.) aus und stellte diese als Zitate, in den meisten Fällen mit Zusammenfassung, in Form des "ODONATOLOGICAL ABSTRACT SERVICE" (OAS) als Veröffentlichung des INTERNATIONAL DRAGONFLY FUND e.V. (IDF) in Kooperation mit der WORLDWIDE DRAGONFLY ASSOCIATION (WDA) zusammen. Nachdem mit der Doppelnummer 45/46 die letzte Ausgabe erschienen ist, stellt der IDF nun alle OAS in einem pdf zusammengefasst gratis zum Herunterladen zur Verfügung. Durch Suche nach Stichworten kann diese Datei sehr komfortabel für Literaturrecherchen genutzt werden.

Wenn Sie mit Hilfe von OAS odonatologische Literatur recherchieren, bitten wir Sie darum, dieses in Ihren eigenen Berichten oder Publikationen zu vermerken. Dieses kann beispielsweise in der Danksagung in folgender oder ähnlicher Form geschehen:

"Bei der Literaturrecherche wurde der Odonatological Abstract Service (OAS) des INTERNATIONAL DRAGONFLY FUND e.V. (IDF) herangezogen. Dieser steht im Internet unter www.dragonflyfund.org zum Herunterladen zur Verfügung."

Der IDF ist ein gemeinnütziger Verein, dessen Ziel die Förderung von Projekten zur Erforschung und zum Schutz der Libellen unserer Erde und ihrer Lebensräume ist.

Spenden, die in Projekte des IDF fließen werden (siehe [IDF-Reports](#)) sind daher äußerst willkommen. Spendenquittungen können ausgestellt werden.

International Dragonfly Fund e.V.

Important information – please take notice!

From 1998 to 2016, Martin Schorr – supported by several colleagues – acquired and analysed countless odonatological papers (including "grey literature", i.e. unpublished reports, thesis papers etc.) and compiled them as citations, in most cases with abstracts, as "ODONATOLOGICAL ABSTRACT SERVICE" (OAS), a publication of INTERNATIONAL DRAGONFLY FUND e.V. (IDF) in cooperation with WORLDWIDE DRAGONFLY ASSOCIATION (WDA).

OAS edition 45/46 (May 2016) was the final one and OAS is discontinued. Now IDF offers a free compilation of all OAS editions. It offers great opportunities for odonatological literature research.

If you use OAS for your literature research, we ask you to credit this in your own reports or papers. **This can be done**, for instance, in the acknowledgements by stating something like this:

"Odonatological Abstract Service of the INTERNATIONAL DRAGONFLY FUND e.V. (IDF) has been a useful tool for literature research. It can be downloaded under the following link: www.dragonflyfund.org."

IDF is a registered non-profit association. Its aim is to support projects dedicated to the exploration and protection of the dragonflies of our world and their habitats.

Donations for projects funded by IDF (see [IDF-Reports](#)) are highly welcome. Contribution receipts can be submitted.

Odonatological Abstract Service

published by the INTERNATIONAL DRAGONFLY FUND (IDF) in cooperation with the WORLDWIDE DRAGONFLY ASSOCIATION (WDA)

Editors:

Dr. Martin Lindeboom, Wolfstr. 6, D-72119 Ammerbuch, Germany. Tel. ++49 (0) 7073 5262; e-mail: Lindeboom@aol.com and Martin Schorr, Waldfrieden 25, D-54314 Zerf, Germany. Tel. ++49(0)6587 1025; e-mail: FOEATrier@aol.com

The ©ODONATOLOGICAL ABSTRACT SERVICE is a supplement to AGRION, the Newsletter of the Worldwide Dragonfly Association.

Anadu, D.I.; Anaso, H.U. and O.N.D. Onyeka 1996: Acute toxicity of the insect larvicide Abate (Temephos) on the fish *Tilapia melanopleura* and the dragonfly larvae *Neurocordulia virginensis*. *Journal of Environmental Science and Health, Part B: Pesticides, Food, Contaminants and Agricultural Wastes* 31(6): 1363-1375

[*"Acute bioassay tests on the toxic effects of the insect larvicide Abate(R) (temephos) on the mouth brooder cichlid fish Tilapia melanopleura and the dragonfly larvae (Odonata) Neurocordulia virginensis were conducted in static non renewal toxicity test set ups. ...The dragonfly larvae were 15 times more susceptible to the larvicide than the tilapia. ... The estimated 'safe' concentration of the pesticide to the fish was 3.0 mg/L and 0.2 mg/L for insect larvae. These figures are far above the concentrations approved for use in the control of mosquito larvae (0.0004-0.01 mg/L)."*]

Anholt, B.R.; Skelly, D.K. and E.E. Werner 1996: Factors modifying antipredator behavior in larval toads. *Herpetologica* 52(3): 301-313

[*"This study examines the behavioral responses of larvae of the American toad, Bufo americanus, to the presence of an invertebrate predator, larvae of the dragonfly Anax junius. ... Toad larvae did avoid predators, but the level of avoidance could not be shown to vary with predator density, food availability, or body size."*]

Arikawa, K.; Ozaki, K.; Tsuda, T.; Kitamoto, J. and Y. Mishina 1996: Two visual pigment opsins, one expressed in the dorsal region and another in the dorsal and the ventral regions, of the compound eye of a dragonfly, *Sympetrum frequens* (vol 1, pg 33, 1995). *Invertebrate neuroscience* 2(3): 209 (Correction/Addition)

Bayerisches Landesamt für Wasserwirtschaft (Hrsg.) (1996): *Ökologische Typisierung der aquatischen Makrofauna. Informationsberichte des bayerischen Landesamtes für Wasserwirtschaft* 4/96: 543 pp. DM 49,- + p. u. p.

 Snyder, S.D. and J. Janovy 1996: Behavioral basis of second intermediate host specificity among four species of *Haematoloechus* (Digenea: Haematoloecidae). *Journal of Parasitology* 82(1): 94-99
 ["Cercarial behavior patterns were examined in 4 species of frog lung flukes (*Haematoloechus* spp.). ...Cercariae of *H. longiplexus* attached to experimental hosts in approximately the same numbers as *H. complexus*, but *H. longiplexus* penetrated only damselfly naiads, and only at the base of the zygopteran caudal gills. Cercariae of *H. complexus*, a second intermediate host generalist, were able to penetrate and enter several arthropod species at the intersegmental membranes. ..."]

 Wagner, T.; Neinhuis, C. and W. Barthlott 1996: Wettability and contaminability of insect wings as a function of their surface sculptures. *Acta Zoologica (Stockholm)* 77(3): 213-225
 ["The wing surfaces of 97 insect species from virtually all relevant major groups were examined by high resolution scanning-electron-microscopy, in order to identify the relationships between the wing microstructures, their wettability with water and their behaviour under the influence of contamination. ... Some insects with very unwettable wings show a highly significant "self-cleaning" effect under the influence of rain or dew. Detailed analysis revealed that there is a correlation between the wettability and the "SM Index" (quotient of wing surface/body mass)(0.67) with values ranging from 2.42 to 57.0. Furthermore, there is a correlation between the "self-cleaning" effect and the SM Index, meaning that taxa with a high SM Index. e.g. "large-winged" Ephemeroptera, Odonata, Planipennia, and many Lepidoptera, have very unwettable wings and show high particle removal due to dripping water drops."]

 Wetzel, E.J. and G.W. Esch 1996: Influence of odonate intermediate host ecology on the infection dynamics of *Halipegus* spp., *Haematoloechus longiplexus*, and *Haematoloechus complexus* (Trematoda: Digenea). *Journal of the Helminthological Society of Washington* 63(1): 1-7
 ["The prevalences and relative densities of *Halipegus* spp., *Haematoloechus longiplexus*, and *Haematoloechus complexus* metacercarial infections in anisopteran (dragonfly) and zygopteran (damselfly) odonate intermediate hosts were examined."]

[“In June and July 1992 and June and August 1996, numerous "freshwater prawns" *Palaemonetes varians* were recorded in three brackish-water lakes at Grimstad, ... This is the first reliable record of the species in Norway, at least for many decades. The remaining fauna consisted of both limnic and marine animals, and included rare species like *Brachytron pratense* (Odonata) and *Gyrinus caspius* (Coleoptera).”]

Ferreras-Romero, M. 1997: The life history of *Boyeria irene* (Fonscolombe, 1838) (Odonata: Aeshnidae) in the Sierra Morena Mountains (southern Spain). Hydrobiologia 345(2-3): 109-116
[“The life history of *Boyeria irene* is inferred from size-frequency analyses of sweep-net samples taken during five years in a permanent stream in the Sierra Morena Mountains. There the species is apparently mainly semivoltine, although a few larvae require three years to complete development.”]

Fincke, O.M. 1997: Conflict resolution in the odonata: implications for understanding female mating patterns and female choice. Biological Journal of the Linnean Society 60(2): 201-220
[“With reference to the Odonata, a taxon in which mating requires cooperation of the female, the active role that females play in mating decisions is often ignored, leading to the premature conclusion that male coercion of Females is common. A critical review of the outcome of sexual conflict among odonates leads me to alternative explanations of female mating patterns that need to be refuted before concluding that males coerce matings.”]

Fincke, O.M.; Yanoviak, S.P. and R.D. Hanschu 1997: Predation by odonates depresses mosquito abundance in water-filled tree holes in Panama. Oecologia 112(2): 244-253
[“In the lowland moist forest of Barro Colorado Island, Panama, larvae of four common species of odonates, a mosquito, and a tadpole are the major predators in water-filled tree holes. Mosquito larvae are their most common prey. Holes colonized naturally by predators and prey had lower densities of mosquitoes if odonates were present than if they were absent. Using artificial tree holes placed in the field, we tested the effects of odonates on their mosquito prey while controlling for the quantity and species of predator, hole volume, and nutrient input. In large and small holes with low nutrient input, odonates depressed the number of mosquitoes pre-

sent and the number that survived to pupation. Increasing nutrient input (and consequently, mosquito abundance) to abnormally high levels dampened the effect of predation when odonates were relatively small."

Fitzhugh G.H. and J.H. Mardsen 1997: Maturation changes in troponin T expression, Ca²⁺-sensitivity and twitch contraction kinetics in dragonfly flight muscle. *Journal of Experimental Biology* 200 (10): 1473-1482

["Maximum lift production and the thermal sensitivity of lift production increase dramatically during adult maturation of *Libellula pulchella* dragonflies. Here, we report that the mechanistic basis for this transition appears to involve a developmental change in protein expression, which alters the Ca²⁺-sensitivity of muscle activation and twitch contraction kinetics."]

["Several hypotheses concerning factors that favour coexistence of female morphs in damselflies (Zygoptera: Odonata) invoke differential attraction to (or harassment of) female morphs from mate-searching males. We designed experiments to determine whether males were differentially attracted to either of two discrete female morphs in a damselfly, *Nehalennia irene* (Hagen)."]

Gorb, S.N. 1997: Porous channels in the cuticle of the head-arrester system in dragon/damselflies (Insecta: Odonata). *Microscopy Research and Technique* 37(5-6): 583-591

["The ultrastructure of the porous channels (PC) of the postcervical sclerite (SPC), which provides additional head fixation to the neck in adult odonates, was studied using TEM and high resolution SEM microscopy. ... The porous channel system of the odonate arrester is interpreted as a device transporting adhesive excretions from the epidermal cells to the cuticular surface."]

Goutner, V. and R.W. Furness 1997: Mercury in feathers of little egret *Egretta garzetta* and night heron *Nycticorax nycticorax* chicks and in their prey in the Axios delta, Greece. *Archives of Environmental Contamination and Toxicology* 32(2): 211-216

["Mercury concentrations were measured in feathers of little egret and night heron chicks and in their prey in the Aries Delta, Greece. ... Diets differed considerably between the two species due to use of different foraging habitats and this seems responsible for different mercury contents of feathers. Mercury concentrations in the pumpkinseed sunfish *Lepomis gibbosus*, goldfish *Carrasius auratus*, and in dragonfly Odonata larvae were the highest among the prey categories. ... Night heron chick feathers, freshwater fish and dragonfly larvae could be used to monitor mercury contamination in this region, but use of bird feathers alone could give misleading results if changes in diet occurred."]

[*"...In the Calopterygidae and Chlorocyphidae this development (of territorial behaviour patterns) implies synchronization between males and females for mating. These behavioural strategies seem to mirror an evolutionary trend - at least in Zygoptera - which is in accordance with the morpho-phylogenesis. ... To ensure optimal reproductive success, males guard females during egg-laying, hence, egg-laying with male coupled to female in tandem position is the most secure proceeding. This behaviour may lead to non-contact guarding, a pattern generally found in the Calopterygidae and Chlorocyphidae, and a few territorial species of Anisoptera. The ancestral Lestes-Sympecma-Type seems to have developed independently in Zygoptera and Anisoptera: thus, this type must be seen as analogous; it does not allow a cladogenetic interpretation..."*]

sons to the century before: The legacy of R. C. L. Perkins and Fauna Hawaiiensis as the basis for a long-term ecological monitoring program. Pacific Science 51(4): 490-504.

[*"As one means of assessing the impact of the past 100 yr of development and biological alteration in Hawai'i, the damselfly (Odonata: Coenagrionidae) and carabid beetle (Coleoptera: Carabidae) collections of R. C. L. Perkins made in the 1890s are compared with similar collections made one century later during the 1990s. Two islands that have experienced very different histories of development are compared: O'ahu and Moloka'i. Of eight native damselfly species originally inhabiting O'ahu, one has been extirpated from the island, another is now reduced to a single population, and three more are at risk. Of the eight species originally found on Moloka'i, by contrast, there is only one species that has not been rediscovered, although there is reasonable probability that it has simply eluded capture because of inherent rarity, whereas the remaining species retain large and stable populations. ..."*]

51. **Rolff, J. (1997):** Better hosts dive: Detachment of ectoparasitic water mites (Hydrachnellae: Arrenuridae) from damselflies (Odonata: Coenagrionidae). *Journal of Insect Behavior* 10(6): 819-827.

["In this paper I present experimental data for the detachment rate of water mite larvae (*Arrenurus cuspidator*) from different host species, *Coenagrion hastulatum* and *C. puella*, in relation to the host's oviposition behavior. *C. hastulatum* oviposits submerged, whereas *C. puella* oviposits at the water surface and aggregates with conspecifics. It was found that mite larvae detach at a significantly higher ratio from hosts with submerged oviposition. Experimental tests showed that this is not a species-specific effect. It is caused mainly by the oviposition behavior. The results are discussed in the light of different oviposition systems in damselflies."]

60. **Van Buskirk, J., McCollum, S.A. & E.E. Werner (1997):** Natural selection for environmentally induced phenotypes in tadpoles. *Evolution* 51(6): 1983-1992.

["... We measured selection in the presence of predators by exposing groups of 10 *Pseudacris triseriata* tadpoles to *Anax* in overnight predation trials and regressing the average phenotype of survivors against the number of tadpoles killed. ... In the presence of *Anax*, tadpoles with shallow and narrow body, deep tail fin, and wide tail muscle survived best. In the absence of free predators, tadpoles with narrow tail muscle grew significantly faster, and those with shallow tail fin and deep body grew somewhat faster. ... These results suggest that phenotypic plasticity in some morphological traits, such as tail depth and tail muscle width, has evolved under intermittent selection by dragonflies. Other traits that undergo selection by dragonflies, such as body morphology, appear developmentally rigid, perhaps because of historically strong opposing selection in nature or other constraints."]

75. **Bowen, K.L., Kaushik, N.K., & A.M. Gordon (1998):** Macroinvertebrate communities and biofilm chlorophyll on woody debris in two Canadian oligotrophic lakes. *Arch. Hydrobiol.* 141(3): 257-281.

[Submerged coarse woody debris may be a valuable contributor of littoral invertebrate production in the two Algonquin lakes, especially for those taxa which require high levels of dissolved oxygen and do not survive in loose detritus. Upon submerged, fresh woody debris was rapidly colonized by biofilm algae and invertebrates, particularly early instar chironomids. Although influenced by the emergence of dault insects, invertebrate density tended to increase over the one year duration of the experiment. Naturally occurring coarse woody debris, which was usually more decayed and lacked bark and small twigs, generally supported a smaller but more diverse invertebrate community. Invertebrate densities and taxa richness on both introduced and natural substrates tended to be greater on complex surfaces. Density of Odonata was very low: 0,01 and 0,11% (introduced substrates) and 0,15 and 0,41% (natural substrates) of the total biomass of macrobenthos. This represents only 1 or 2-5 individuals. Reference is made on *Cordulia*, *Neurocordulia*, *Aeshna* and *Boyeria* on the genus level, and on *Coenagrionidae*.]

82. **Cordero, A.; Carbone, S.S. & C. Utzeri (1998):** Mating opportunities and mating costs are reduced in androchrome female damselflies, *Ischnura elegans* (Odonata). *Animal Behaviour* 55(1): 185-197.

[Female colour polymorphism is a perplexing characteristic of many damselfly species. In *Ischnura elegans* three female phenotypes occur, one of which has the same blue coloration as the male (androchromes) whilst the others are inconspicuous brown gynochromes (*infuscans* and *infuscans-obsoleta* morphs). By marking a natural population near Rome, Italy, we found that all female phenotypes have similar survivorship, but they differ in mating frequency. Androchromes represented 55% of females but were involved in 43% of matings, whereas *infuscans* females represented 27% of females and 40% of matings and the *infuscans-obsoleta* phenotype 18% of females and 17% of matings. Old androchromes stored significantly less sperm in their spermatheca than old gynochromes, suggesting that they had mated less often. ... Our results indicate that androchrome females mate less often than gynochromes, which could be a means of avoiding unnecessary and costly matings, but some androchrome females failed to reproduce (mate or oviposit) probably because they were unable to mate at all.]

83. **d'Aguilar, J. & J.-L. Dommaget (1998):** Guide des libellules d'Europe et d'Afrique du nord. Delachaux et Niestlé. Lausanne. ISBN 2-603-00566-9. 463 pp.

[This book is the new and totally revised edition of the well known field guide from 1985. 20 plates present information on habitats, ecology or ethology, and 28 plates with figures and photos of most of the European species will help to identify most of the European or North-African Odonata. Compared with the 1985 edition, some of these plates are new, e.g. the plates with photographs of most of the European and North-African species or subspecies of the family Cordulegastridae. All species, including the species non figured, are described in detail, but not keyed. This remains a serious disadvantage of the book. Without consulting of the original figures and descriptions some of the species, e.g. in the genus *Cordulegaster*, identification will be extremely difficult. The quality of some of the plates, e.g. plate 2 with the *Lestidae* is not adequate in some species, as no details are to be recognized. In some of the plates colours are too intensive, and will mislead people not common with European Odonata (e.g. plate 21). Even compared with the first edition the printing quality of plates differs considerably: in some cases contrast is so intensive that details of coloration disappear (e.g. plate 18). The distribution maps are new; they contain a lot of interesting information, even on the distribution of most of the subspecies. Also new is a key of the European Odonata larvae or exuviae on genus level (prepared in cooperation with H. Heidemann, Bruchsal). This book is a supplement to Askew's "The Dragonflies of Europe" which will remain the standard book on European Odonata. Despite the abstractor's critical remarks the "Guide des libellules ..." is a very good tool to study European Odonata, and should not be missing in any odonatological library. (M. Sch.)]

100. **Koperski, P. (1998):** Predator-prey interactions between larval damselflies and mining larvae of *Glyptotendipes gripekoveni* (Chironomidae): reduction in feeding activity as an induced defence. *Freshwater biology* 39: 317-324.
 ["feeding methods and intensity of predation by larvae of *Erythromma najas* on *G. gripekoveni* were examined in artificial habitats... The experiments assessed the influence of chemical stimuli from the predator, light and the concentration of suspended food on the feeding activity of *G. grip.* inside and outside of the mine. *E. najas* preyed upon *G. grip.* as the latter grazed outside mines. When the food concentration for the chironomid was high, it significantly reduced both filtering activity and activity outside mines in response to the kairomone produced by *E. najas*. Feeding activity did not change when food was scarce... The predator can detect and catch mining prey in either the light (visually) or dark (mechanically). This may explain the lack of diel periodicity in the chemically induced differences in prey activity. Reduced feeding activity of the mining larvae in the chemically simulated presence of a larval damselfly can be explained as an induced antipredator behaviour ..."]

[Mark McPeck regards *E. vernale* and *E. cyathigerum* as two distinct species. "My working hypothesis for the boreale/cyathigerum/vernale relationships are as follows: (1) Sometime very recently (probably <<350 000 year ago if the molecular clock is right), a lineage of an *Enallagma* species in the fish lake habitat was established in a dragonfly lake. This founder population quickly adapted to living with dragonfly predators instead of fish predators... This was the progenitor species of boreale, cyathigerum and vernale. (2) A subsequent speciation event occurred to give rise to boreale and cyathigerum somewhere in the northeastern part of North America (this is from considering the biogeography of species along with our phylogeny) (3) then another speciation event associated with a habitat shift from dragonfly lakes back into fish lakes occurred in the cyathigerum lineage to form *E. vernale*." Mark McPeck reports on a project of Jenifer Mitchell, who compared the larval morphology and behaviour of boreale and vernale. Both species are indistinguishable in the size and shape of caudal lamellae, abdomen and labium. However, they are very different in behaviour.]

121. **Painter, D. (1998):** Effects of ditch management patterns on Odonata at Wicken Fen, Cambridgeshire, UK. *Biol. Conservation* 84: 189-195.

[Patterns of adult and larval Odonata distribution in relation to ditch management cycles were studied... Newley excavated sites with little shading from bankside vegetation are favoured by territorial males and ovipositing females; densely reeded sites are rarely used by adults. However, ditches with abundant submerged and floating macrophytic growth support more larvae than newley excavated or deeply shaded sites with poor plant development. Rotational clearance of ditches allows good displays of adult Odonata and breeding success to be achieved simultaneously on a reserve. Management implications for the conservation of Odonata are discussed.] (Personal note of M. Sch.: It is quite astonishing to see that e.g. the extensive German literature on effects of ditch management on Odonata has been ignored totally in the discussion.)

[Can fish abundance influence benthic macroinvertebrate numbers, biomasses and species composition? Two lakes with similar physical and chemical characteristics in south-central Ontario (Canada) but contrasting fish communities were studied from June to August 1992. Ranger Lake was dominated by piscivorous bass and had low populations of small-bodied planktivore-benthivores (e.g. yellow perch, golden shiners). Mouse Lake had no obligate piscivores and very large populations of small-bodied planktivore-benthivores. The two lakes had similar populations of large-bodied, benthivorous white suckers. Comparison of depth-stratified samples of benthic macroinvertebrates collected monthly suggested that in the

shallow water zone (<1 depth) Ranger Lake supported significantly higher benthic densities, biomasses, and taxon richness. In these shallow water zones, consumption of benthic invertebrates by fish, revealed that the small-bodied planktivore-benthivores in Mouse Lake exerted more than twice as much predation pressure on the benthos as they did in the lake with fish. In the deeper water (>1m depth) there were no between-lake differences in the macroinvertebrate communities." Prey consumption by white suckers (generally distributed in >1m depth) was similar in the two lakes. The authors conclude that high rates of prey consumption by the small-bodied planktivores-benthivores could have accounted for the lower inshore biomasses found in Mouse Lake. 13 Odonata are listed on the species (*Gomphus exilis*, *Hagenius brevistylus*, *Celithemis eponina*, *Didymops transversa*, *Basiaeschna janata*, *Libellula julia*, *Pachydiplax longipennis* and *Cordulia shurtelffi*) or genus level (*Ischnura*, *Somatochlora*, *Cordulia*, *Leucorrhinia*, *Sympetrum*). Odonata are analyzed on the order level with reference to their density, biomass, wet weight, and preference as fish diet.]

149. **Bechly, G. (1997):** New fossil odonates from the Upper Triassic of Italy with a redescription of *Italophlebia gervasuttii* Whalley, and a reclassification of triassic dragonflies. *Riv. Mus. civ. Nat. "E. Caffi" Bergamo* 19: 31-70. (in English with Italian summary).

["The odonate fauna of the Upper Triassic of Bergamo is revised. *Italomyrmeleon bergomensis* gen. et spec. nov. is described as first Protomyrmeleontidae from the Triassic of Europe. A tiny fossil odonate which belongs to a new genus and species is described but not named because it is a poorly preserved specimen. *Italophlebia gervasuttii* is redescribed and a new species of the same genus, *Italophlebia paganoniae* spec. nov., is described. The phylogenetic position of *Italophlebia* is discussed and the genus is shown to be one of the oldest known stem-group representatives of Anisoptera, and is therefore transferred from Zygoptera - Hemiphlebioidea to "Anisozygoptera" - Isophlebioptera. Within Isophlebioptera a new clade Parazygoptera is proposed and a phylogenetic system of its subgroups is introduced. *Italophlebiidae* is regarded as junior subjective synonym of *Triassothemistini* stat. nov., and *Progonophlebiidae* is regarded as junior subjective synonym of *Mesophlebiinae*. *Triassoneuridae* is regarded as junior subjective synonym of *Triassoletidae*, and *Oreopteridae* is regarded as junior sub-

jective synonym of *Asiopteridae*. A new genus *Pseudotriassothemis* gen. nov. (type genus of *Pseudotriassothemistinae* subfam. nov.) is erected for the three Japanese Triassic species "*Triassoneura*" *okafujii*, "*Triassothemis nipponensis*" and "*Triassothemis*" *minensis*. *Afrotriassothemis* subgen. nov. is proposed as new subgenus in *Triassothemis* for the two South African Triassic species *T. heidia* and *T. regularis*, that were previously classified in the genus *Triassoneura*. "*Triassoneura*" *primitiva* is transferred from *Triassoneuridae* to *Archizygoptera* - *Batkeniidae* in a new genus *Paratriassoneura* gen. nov.. "*Sogdopteron*" *legibile* is transferred from *Asiopteridae* to *Triassoletini*. *Sogjutella mollis* is transferred from *Asiopteridae* to *Cyclothemistidae*. *Sphenophlebia*, *Mesoepiophlebia* and *Ensphingophlebia* are transferred from *Euthemistidae* and *Epiophlebiidae* to a new family *Sphenophlebiidae* fam. nov. which is regarded as most basal group of *Parazygoptera*. *Proeuthemis pritykinae* is preliminarily transferred from *Euthemistidae* to the new family *Sphenophlebiidae* too, although it might also be the sister-group of *Asiopteridae*. "*Sphenophlebia*" *pommerana* is transferred to the genus *Turanopteron* in *Asiopteridae*. *Triadotypus guillaumei* is recognised as junior subjective synonym of *Reisia gelasii* and *Reisia nana* spec. nov. is described from the Triassic of France. Consequently *Triadotypus sogdianus* is changed to *Reisia sogdianus* comb. nov.. *Reisia* (= *Triadotypus*) and *Triassologus* are both transferred from "*Protodonata*" to *Triadophlebioptera*, so that there are no Triassic protodonates known any longer. *Thuringopteryx gimmi* is transferred from "*Protodonata*" to *Palaeodictyoptera*, as the first known Triassic representative of this group.]"

["Maximum lift production and the thermal sensitivity of lift production increase dramatically during adult maturation of *Libellula pulchella* dragonflies. Here, we report that the mechanistic basis for this transition appears to involve a developmental change in protein expression, which alters the Ca^{2+} -sensitivity of muscle activation and twitch contraction kinetics. The alternatively spliced Ca^{2+} regulatory protein troponin T (TnT) undergoes an isoform shift during adult maturation. Skinned (demembrated) fibers of mature flight muscle are up to 13 times more sensitive to activation by Ca^{2+} than skinned fibers from teneral (newly emerged adult) flight muscle, and their Ca^{2+} -sensitivity is more strongly affected by temperature. Intact muscle from mature individuals has a shorter time to peak tension and longer time to half-relaxation during twitch contractions, which is consistent with a greater Ca^{2+} -sensitivity of mature muscle. Because it becomes activated more quickly and relaxes more slowly, mature flight muscle is able to generate, with each twitch, more force per unit area than teneral muscle; this difference in force becomes greater at high temperatures. There do not appear to be any age-related differences in actomyosin crossbridge properties, since teneral and mature flight muscles do not differ in shortening velocity, tetanic tension or instantaneous power output during isotonic contraction. Thus, variation in TnT expression appears to affect the temperature-dependent Ca^{2+} -sensitivity of muscle activation, which in turn affects the kinetics and force production of the twitch contractions used by dragonflies during flight. This cascade of effects suggests that maturational changes in the expression of TnT isoforms may be a key determinant of overall muscle and organismal performance." (Authors)]

184. **Holusa, O. (1997):** The dragonflies (Odonata) of the broad surroundings of Lednice in Moravia. Sbornik Prirodovedneho klubu v Uh. Hradisti 2: 93-108. (in Czech with English summary).

[In the broad surroundings of Lednice on Moravia (Czech Republic. Moravia, geomorphological unit Dolnomoravsky úval, elevation 152-168 m above sea level) 30 species of dragonflies were found, i.e. 41 % of the number of species on the check list according to Teyrovský (1977) for the former Czechoslovakia. Some species were found for the first time: *Aeshna grandis*, *Anax parthenope*, *Somatochlora metallica*, *Orthetrum albistylum*, *Crocothemis erythraea*. The total number of species established in the surroundings of Lednice is 34. According to the zoogeographical characteristics the species diversity is represented by: Holopalaeartic (7 species, i.e. 20,59 %), European-Siberian (7 species, i.e. 20,59 %) and Holomediterranean (7 species, i.e. 20,59 %) elements. 6 European-Mediterranean species form 17,65 %, Holarctic. European and Mediterranean-Afrotropical species occur rarely, each of this group has up to 2 species (i.e. 5,88 %). 1 species represents the Afrotropical-Mediterranean group (i.e. 2,94 %). On this territory stagnicolous species are dominant (76,47 %), reophilous species are represented by 2 species (i.e. 5,88 %) and among erythroecious species 6 species (i.e. 17,65 %) can be found. The superiority of stagnicolous species is a consequence of the character of the investigated territory, the number of reophilic biotopes is limited, therefore the number of reophilous species will not increase in the future. The most diverse localities according to the author's records are small ponds and remain of oxbows of the river Dyje without dense trees vegetation on the shore, which are not very deep and with a thick water vegetation. The highest number of species was found on Pouzdrany pond (together 17 species), Allah I. pond and near pools at Podivín. Few species occurred on big ponds with Typha, Phragmites vegetation zone on shallow places. The difference in the number of species between the author's and Perutik's (1955) records on these ponds is probably the consequence of stagnation of the water column and water vegetation on shallow places. At the time of the research the water reached to the basin of the vertical shore and there were not any shallow places with other water vegetation suitable for the occurrence of dragonflies. Most of species have permanent populations in

this territory, but some species which migrate from the south - *Hemianax ephippiger* and *Crocothemis erythraea*. *H. ephippiger* can reproduce here (PERUTIK 1955). The existence of permanent populations of *C. erythraea* is possible. The species diversity of the surroundings of Lednice is relatively stable as is evident from the comparison of the author's and Perutik's (PERUTIK 1955) records (tab. 2). The absence of some species of the genera *Sympetma* and *Lestes* is probably caused by the low population density of these species. The situation with new species is similar - *Aeshna grandis*, *Somatochlora metallica*. More specimens of *Anax parthenope* were found only in one locality where a permanent population of this species is supposed. So far no research on dragonflies was carried out in this locality and that might be the reason of missing records. *Orthetrum albistylum* was probably penetrated into this territory not long ago, according to the first record by WERNEROVÁ (1958) of its occurrence in Moravia from the lower part of the river Morava. *C. erythraea* specimens were considered migratory." (Author)]

185. **Holusa, O.** (1997): The occurrence of dragonfly *Aeshna subarctica* Walker, 1908 (Odonata: Aeshnidae) in the Hrubý Jeseník Mts. (Czech Republic). *Cas. Slez. Muz. Opava (A)*. 46: 287-288. (in Czech with English summary).

[Altogether 5 males, 1 female and 2 exuviae of *Aeshna subarctica* Walker, 1908 were collected by the author on 8. IX. 1997 at peaty lake Malé mechové jezírko on the moorland Rejvíz (745 m above sea level, Hrubý Jeseník Mrs., north-western Silesia in Czech Republic). One oviposition in *Eriophorum* sp. along the margin of the lake and frequent hunting by *Aeshna subarctica* of tandems of *Sympetrum*-species were observed. There is only one old record of a male in August 1956 in the Rejvíz peat-bog (Teyrovský & Perutik 1958). Thus Rejvíz is the only known locality of *Aeshna subarctica* within the territory of Moravia and Silesia." Note in prove: *A. subarctica* Walker does not occur in (Central) Europe; *A. subarctica* elisabethae Djakonov, 1922 is the correct name for western Palearctic populations. (M. Sch.)]

Address: Holusa, O., Muzeum Beskyd, prirodovedné oddelení, Zámecké náměstí 1264, CZ-738 01 Frydek-Místek.

187. **Lombardo, P.** (1997): Predation by *Enallagma* nymphs (Odonata, Zygoptera) under different conditions of spatial heterogeneity. *Hydrobiologia* 356: 1-9. (in English).

["Odonate nymphs are sometimes associated with complex leaf macrophytes. Because of their wide prey spectrum, colonization of spatially heterogeneous macrophyte habitats may be due to a higher predation suc-

cess in such a habitat rather than to the presence of particular prey species. Odonate (*Enallagma* sp.) nymph predation success was tested under conditions of high (complex leaf *Ceratophyllum demersum* L. leaf packs) and low (simple leaf *Potamogeton illinoensis* Morong leaf packs) spatial heterogeneity. Prey species included two pulmonate gastropods, an amphipod, and a turbellarian that were common in the natural habitat of *Enallagma*. *Enallagma* significantly reduced the amphipod and the turbellarian populations and the prey assemblage as a whole, but did not have any statistically significant impact on the snail populations, which increased their absolute and relative abundance in the presence of the odonate. Numerical losses by *Enallagma* predation (if any) were not related to macrophyte architecture, suggesting that prey vulnerability to *Enallagma* predation is species-specific rather than habitat-determined. *Enallagma*'s preferential distribution in spatially heterogeneous macrophyte habitats, when occurring, may be due to other factors such as a refuge from fish predation and/or a generally greater prey availability and diversity in complex leaf than in simple leaf macrophyte habitats." ["Assessment of biotic communities in running water at diversion-type hydropower plant sites (main emphasis: benthic macroinvertebrates): The biotic community in watercourses is governed by extremely complex interactions between numerous factors. An insufficient flow of water along the river bed of a diversion-type hydropower plant thus has a noticeable effect on the ecology of the river courses concerned. In order to represent the effects of a reduced discharge in the residual flow reaches of hydropower plants, existing relationships between the benthic macroinvertebrates present in a watercourse and the abiotic factors were investigated. The present paper arose from the research project "Residual flow" at the Technische Universität München (Chair of Hydraulic Structures and Water Resources under Dr.-Ing. Theodor Strobl). Extensive investigations of biological, hydraulic, morphological, chemical and physical parameters were carried out at 20 hydroelectric power-plant sites on 10 Bavarian rivers (design capacity of the plants: < 1300 kW). The studies were carried out at representative cross-sections of residual flow reaches and also of virtually unaffected reference reaches. To record the maximum impact, the samplings were carried out during summer weather and at existing discharge levels. The benthic organisms were collected in a quantitative and qualitative manner by means of a Surber-sampler. For the purpose of describing the flow behaviour, flow velocities were measured using a micro-flowmeter with a vane diameter of 9,7 mm, and using FST hemispheres. A horizontoscope was employed to determine the exposition of the water courses to solar radiation during the course of the day (reference point: 21st June). In order to take account of different radiation intensities at different times of the day, the measurements were weighted and processed to the parameter "effective irradiation EI". The total taxa count of the benthic macroinvertebrates ($Taxa_{ges}$) was split (ac-

cording to their dependence on water flow-rate) into the classes R (rheotypical: $Taxa_{rheo}$), L- (limno-typical; $Taxa_{lim}$) and U (ubiquitous or unknown preference; $Taxa_{au}$). From these, the parameters $Taxa_{rheo \geq 2}$ and $Taxa_{lim \geq 2}$ were derived which indicate the taxa counts without coincidental collection. The results indicate that the impacts of different discharge levels are far better represented by analyzing cross-sections of the watercourse than by individual sampling areas. For the purpose of describing the near-bed flow characteristics, the hydraulic flowmeter proved to be more suitable than the FST hemispheres. The correlations between the near-bed flow conditions and various parameters of the benthic macroinvertebrates (total and specific density of organisms, diversity, evenness, turnover of species, rhithron feeding-type index) showed very different levels of significance. In many cases these parameters were affected by further factors (mostly by the food situation and the extent of debris transport). The rhithron feeding-type index (RETI) was improved by a modified $RETI_m$. The parameters $Taxa_{ges}$ and $Taxa_{rheo \geq 2}$ also showed variable correlations with the near-bed flow conditions. The saprobic index (= measure of organic pollution) and the limnotypical variety of species ($Taxa_{lim}$ and $Taxa_{lim \geq 2}$) were not found to be suitable methods for describing the ecological impacts of power plants. At all rivers studied, the rheotypical variety of species ($Taxa_{rheo}$, concerning cross-sections) proved to be a meaningful parameter to quantify the ecological effects of different discharge levels. The value of $Taxa_{rheo}$ increases with rising near-bed velocities up to a saturation value, which was attained at mean near-bed velocities (v_{sohl} of 0,15 to 0,30 m/s). As the relationships between $Taxa_{rheo}$ and v_{sohl} are mainly determined by the discharge level, these correlations were taken as the basis for a model for determining the ecologically-required minimum discharge level. With the aid of the newly-developed MEFI-model (Munich ecological flow investigations), the individual situations at the different power plant sites can be taken into account. The results indicate that the rheotypical variety of species is limited by the residual discharge level; the limnotypical variety, however, is affected by the high-water events. Studies of fish biology, the ecosystems of gravel banks and the situation in winter round off this thesis. The statements of this report are mainly valid for upper and middle reaches of mountain and low mountain rivers. Further studies are needed to examine whether these results can be extrapolated to other types of stretches of water." (Author)]

["The order Odonata is represented in Patagonia by at least 35 species, almost 50% of which are endemics. Based on its distribution they can be divided into two groups: subantarctic and widespread neotropical. Patagonia exhibits two main biomes: temperate forest, which shows the highest diversity and species richness, and the large shrub steppe. The steppe displays remarkable levels of species richness at two localities, Choele Choel and Somuncurá plateau, which presumably represent an ecotonal zone and a relict of pre-quaternary subtropical biota respectively. The Andean mountains do not seem to represent an effective geographic barrier for Odonata; however these mountains strongly influence precipitation patterns which, in turn, affect the distribution of Odonata." ["The local circulation method was applied to the free forward flight of the damselfly *Ceriagrion melanurum* Selys. The kinematic data used in the calculations were obtained by analyzing video-taped images of damselflies in free flight in a transparent container. The inclination of the

stroke plane was smaller and the flapping amplitude was larger than those of dragonflies reported in other studies on odonate flight. However, the phase shift between the fore- and hindwings agreed with none of the previously reported patterns for damselflies: the forewings lead the hindwings by approximately a quarter-period. The calculated forces were within the expected range of error. The muscle-mass-specific power was between 40 and 80 W kg⁻¹. The vorticity distribution of trailing and shed vortices in the wake was also analyzed. Strong trailing vortices were observed at the wing tips, whereas shed vortices were concentrated near the wing root as the stroke switched direction." (Authors)]

212. **Thapa, V.K. (1997):** An inventory of Nepal's insects. Volume I (Protura-Odonata). IUCN Nepal Biodiversity Publication Series 1: 98 pp. (in English).

[The Odonata are dealt with on pages 67-88. The aim of the book is "to generate proper knowledge and infor-

mation on insects in order to enable the government and people of Nepal to provide protection to Nepalese insects". "This work is aimed to provide a comprehensive record of insects occurring in Nepal". 17 insect orders are treated as commented checklists, the latter mainly based on published records. The data are organized as follows: name of species, localities in Nepal and surrounding countries, altitudinal distribution, abundance in Nepal, flight season. The chapter closes with selected references on Nepalese dragonflies, but the list of references lacks e.g. in the very important publication of 'Vick, G.S. (1989): List of the dragonflies from Nepal with a summary of their altitudinal distribution (Odonata). Opusc. zool. flumin. 43:1-21'. It is also very regrettable that some of the newly described species of Nepal as *Macromia sombui* Vick, 1988 are missing in the checklist. Altogether V.K. Thapa considers 147 species autochthonous in Nepal while Vick lists 172 species for Nepal; Clausnitzer & Wesche added another three species to this list (Opusc. zool. flumin. 147, 1996). There is also a remarkable discrepancy between the two lists. Of course everybody interested in Nepalese Odonata should use the publication of G.S. Vick as fundament of odonatological research. (M. Sch.)]

216. **Wakeling, J.M.; Ellington, C.P. (1997):** Dragonfly flight. 1. Gliding flight and steady state aerodynamic forces. J. exp. biol. 200(3): 543-556. (in English).

["The free gliding flight of the dragonfly *Sympetrum sanguineum* was filmed in a large flight enclosure. Reconstruction of the glide paths showed the flights to involve accelerations. Where the acceleration could be considered constant, the lift and drag forces acting on the dragonfly were calculated. The maximum lift coefficient (C_L) recorded from these glides was 0.93; however, this is not necessarily the maximum possible from the wings. Lift and drag forces were additionally measured from isolated

wings and bodies of *S. sanguineum* and the damselfly *Calopteryx splendens* in a steady air flow at Reynolds numbers of 700-2400 for the wings and 2500-15 000 for the bodies. The maximum lift coefficients ($C_{L, max}$) were 1.07 for *S. sanguineum* and 1.15 for *C. splendens*, which are greater than those recorded for all other insects except the locust. The drag coefficient at zero angle of attack ranged between 0.07 and 0.14, being little more than the *Blassius* value predicted for flat plates. Dragonfly wings thus show exceptional steady-state aerodynamic properties in comparison with the wings of other insects. A resolved-flow model was tested on the body drag data. The parasite drag is significantly affected by viscous forces normal to the longitudinal body axis. The linear dependence of drag on velocity must thus be included in models to predict the parasite drag on dragonflies at non-zero body angles." (Authors)]

217. **Wakeling, J.M.; Ellington, C.P. (1997):** Dragonfly flight. 2. Velocities, accelerations and kinematics of flapping flight. *J. exp. biol.* 200(3): 557-582. (in English).
["The free flapping flight of the dragonfly *Sympetrum sanguineum* and the damselfly *Calopteryx splendens* was filmed in a large flight enclosure at 3000 frames s⁻¹. The wingtip kinematics are described for these flights. Despite the two species being similar in size, the damselfly flew with wingbeat frequencies half those of the dragonfly. The damselfly could perform a clap and fling, and the proximity to which the wings approached each other during this manoeuvre correlated with the total force produced during the wingstroke. The dragonfly beat its wings with a set inclination of the stroke planes with respect to the longitudinal body axis; the damselfly, in contrast, showed a greater variation in this angle. Both species aligned their stroke planes to be nearly normal to the direction of the resultant force, the thrust. In order to achieve this, the dragonfly body alignment correlated with the direction of thrust. However, the damselfly body alignment was independent of the thrust direction. Velocities and accelerations were greater for the dragonfly than for the damselfly. However, non-dimensional velocities and accelerations normalised by the wingbeat periods were greater for the damselfly." (Authors)]

218. **Wakeling, J.M.; Ellington, C.P. (1997):** Dragonfly flight. 3. Lift and power requirements. *J. exp. biol.* 200(3): 583-600. (in English).
["A mean lift coefficient quasi-steady analysis has been applied to the free flight of the dragonfly *Sympetrum sanguineum* and the damselfly *Calopteryx splendens*. The analysis accommodated the yaw and accelerations involved in free flight. For any given velocity or resultant aerodynamic force (thrust), the damselfly mean lift coefficient was higher than that for the dragonfly because of its clap and fling. For both species, the maximum mean lift coefficient C_L was higher than the steady $C_{L, max}$. Both species aligned their stroke planes to be nearly normal to the thrust, a strategy that reduces the C_L required for flight and which is different from the previously published hovering and slow dragonfly flights with stroke planes steeply inclined to the horizontal. Owing to the relatively low costs of accelerating the wing, the aerodynamic power required for flight represents the mechanical power output from the muscles. The maximum muscle mass-specific power was estimated at 156 and 166Wkg⁻¹ for *S.*

sanguineum and *C. splendens*, respectively. Measurements of heat production immediately after flight resulted in mechanical efficiency estimates of 13 % and 9 % for *S. sanguineum* and *C. splendens* muscles, respectively." (Authors)]

225. **Andres, J.A.; Cordero, A. (1998):** Effects of water mites on the damselfly *Ceriagrion tenellum*. *Ecological Entomology* 23(2): 103-109. (in English).
[1. Water mite parasitism is expected to have an important effect on damselfly survivorship and reproductive success, because mites drain considerable amounts of body fluids from their hosts. This study tests the effect of water mite parasitism in a marked population of the damselfly *Ceriagrion tenellum* during 1995 (individuals marked as mature adults) and 1996 (individuals marked as teneral). ... 5. These results indicate that water mite parasitism does not reduce damselfly survivorship, but it could reduce male mating success in some circumstances. Further long-term studies are needed, especially in populations with a lower incidence of parasitism.]

228. **Arnquist, G.; Johansson, F. (1998):** Ontogenetic reaction norms of predator-induced defensive morphology in dragonfly larvae. *Ecology* 79(6): 1847-1858. (in English).
["The study of phenotypic plasticity, one of the most important mechanisms of phenotypic adaptation, is by tradition focused on differences in ontogenetically static phenotypic expression in different environments. Ontogenetic reaction norms, in contrast, describe how phenotypes unfold during growth in different environments. We studied the ontogenetic reaction norms of the morphological shape of a series of defensive abdominal spines in dragonfly larvae, both in the laboratory and in a number of natural populations. In a laboratory rearing experiment, we demonstrated that these spines grew more solid and elongated when waterborne environmental cues of fish predators were present: this is evidence of phenotypic plasticity in defensive spine morphology. The ontogenetic reaction norms of defensive spines were also found to differ in natural populations with and without fish. A detailed analysis of the growth trajectories showed that this differentiation
- was primarily due to ontogenetic acceleration in environments with fish, leading to relatively exaggerated spine shape in these environments. However, while the ontogenetic trajectories of shape in some spines diverged at the onset of ontogeny in the two environments, those of others remained parallel until a given phase of ontogeny. Hence, the timing of the developmental divergence of these phenotypically integrated traits differed, suggesting differences in the underlying regulatory mechanisms. Our results illustrate that a conceptual integration of environmental and ontogenetic approaches to the study of phenotypic differentiation can significantly promote our understanding of the ecology and evolution of adaptive phenotypic plasticity." 233. Bechly, G.; Nel, A.; Martínez-Delclòs, X.; Fleck, G. (1998): Four new dragonflies from the Upper Jurassic of Germany and the Lower Cretaceous of Mongolia (Anisoptera: Hemeroscopidae, Sonidae, and Proterogomphidae fam. nov.). *Odonatologica* 27(2): 149-187. (in English).

["*Prohemeroscopus jurassicus* gen. et sp. nov. and *P. kuehnepfeli* sp. nov. are described as first Hemeroscopidae from the Upper Jurassic of Germany (Solnhofen Lithographic Limestone). The monophyly of Hemeroscopidae is discussed and preliminarily advocated. The Mesozoic Hemeroscopidae are recognized as potential stem-group representatives of extant Chlorogomphoidea within Anisoptera - Cavilabiata. The status of the alleged hemeroscopid larvae is discussed and they are preliminarily transferred as new (unnamed) species to Sonidae. The family Sonidae is restricted to the referring larvae. The adult fossil dragonflies from the Lower Cretaceous of Mongolia that were previously attributed to *Sona nectes* (Sonidae) are ... classified as a new taxon, *Proterogomphus krauseorum* gen. et sp. nov. (Proterogomphidae fam. nov.) within the monophylum Gomphides, as sister-group of Hageniidae. A new species, *Proterogomphus renatae* sp. nov. is described from the Upper Jurassic of Germany. [...] A numerical cladistic analysis of Anisoptera could neither convincingly resolve the phylogenetic relationships within Hemeroscopidae, nor the phylogenetic positions of Gomphides and Proterogomphidae fam. nov., because of their lack of wing venational apomorphies, but otherwise confirmed the phylogenetic reclassification of dragonflies by BECHLY (1996, *Pelalura* [Special Vol.] 2: 342-402)." 234. Bechly, G. (1998): New fossil damselflies from Baltic amber with description of a new species, a redescription of *Litheuphaea carpenteri* Fraser, and a discussion on the phylogeny of Epallagidae (Zygoptera: Caloptera). *International Journal of Odonatology* 1(1): 33-63. (in English).

["*Litheuphaea ludwigi* sp. n. is described as first representative of Epallagidae from Baltic amber. The holotype of *Litheuphaea carpenteri* Fraser, 1955 is redescribed, the phylogenetic position of all fossil Epallagidae is discussed, and a new phylogenetic classification is proposed. The authorship of Selys (1853) for the family-group name Euphaeidae is rejected, since the "legion Euphaea" proposed by Selys is neither a noun in the nominative plural, nor ending in a latinized suffix. Consequently, the correct family name must be Epallagidae Needham, 1903, since Euphaeidae were first established by Jacobson & Bianchi (1905) and thus have to be considered as a junior subjective synonym. Similarly, all the other "legions" proposed by Selys are rejected as available family-group taxa, so that the next available family-group name has to be used, e.g. *Heliocharitidae* Tillyard & Fraser,

1939 instead of *Dicteriadidae* Montgomery, 1959 (nec Selys, 1853). *Parazacallitinae* Nel, 1988 is considered as junior subjective synonym of *Eodichromatinae* Cockerell, 1923 which is regarded as an extinct subfamily of Epallagidae, comprising the sister-tribes *Litheuphaeini* Bechly, 1996 and *Eodichromatini* stat. nov. for the sister-genera *Eodichroma* Cockerell, 1923 and *Parazacallites* Nel, 1988. *Zacallitidae* Cockerell, 1928 is restored as a distinct family and preliminarily regarded as the sister-group of Epallagidae. A unique fossil odonate is briefly described, which represents a damselfly in Baltic amber that is just emerging from the exuvia (probably *Platystictidae* or *Megapodagrionidae*). An annotated new catalogue of all known odonates in amber is provided, including 46 specimens from Lebanon, Dominican, Baltic and Saxonian amber, of which 3 specimens are adult Anisoptera and 5 specimens are exuviae. A lectotype for *Plutyenemis? antiqua* (Pictet & Hagen, 1856) is designated and illustrated." (Author)]

[The possible functions of the tail-tip display in male *Calopteryx*: "Suggested functions of the "tail-tip" or "water" display in males of the European species of *Calopteryx* are discussed, using literature data on various species and own observations on *C. haemorrhoidalis*. Courting males show the light-coloured ventral side of the last

three abdominal segments ... in a conspicuous way by curling up the tip of the abdomen and spreading the dark-coloured wings as a contrasting background while hovering just above or floating on the water surface. This display is shown in the centre of the territory, both during initial courtship and after copulation. As a signal to the female, the display might indicate both the ownership and location of an oviposition site as well as its quality... Moreover, it might give some indication of the quality of the male. In the present paper, it is argued that indication of the exact oviposition site appears to be the most important among these possible functions."]

[This paper presents an environmental evaluation of the Krugle Bagno peatbog (the Leczynsko-Włodawskie Lake District, buffer-zone of the Poleski National Park) on the grounds of selected elements of its fauna. The topographical, hydrological and floristic preliminary descriptions are also provided. Collected 121 species represent the following higher taxa: Aranei, Chilopoda, Insecta (Odonata; Orthoptera; Heteroptera aquatica; Coleoptera: Hydrophiloidea, Dytiscidae, Haliplidae, Gyrinidae, Staphylinidae, Scarabaeidae, Chrysomelidae, Curculionidae; Lepidoptera), Pisces, Amphibia and Reptilia. The studies focused on Odonata and Staphylinidae. The recorded taxa are divided according to their environmental preferences. Particular attention was paid to (specific) indicator species for the examined biotope: tyrphobionts, tyrphophiles (Heteroptera aquatica, Odonata, Coleoptera aquatica), sphagnophilous stenotopic species (Staphylinidae). Their significant predominance in respect of number of species and individuals collected (among Odonata - 39.3% of all species. 56.4% of all larvae and exuviae; among Staphylinidae - about 75% of all individuals collected) attests to high environmental quality of the peatbog. It is connected with high and stable water-level. Such a situation is favourable for the existence of many rare species, which are sensitive to overdrying of environment, as well as instability of water-level and humidity. Due to this situation, species rare in Poland occur here, such as: *Nehalennia speciosa*, *Aeshna subarctica* (Odonata), *Acylophorus wagenschieberi* (57% of all rove beetles collected) and *Atanygnathus terminalis* (Staphylinidae). Out of recorded taxa, 8 are protected by law, among them noteworthy is the lake minnow (Morocco percunus). Regarding the above data, it has been suggested that Krugle Bagno should be protected as a partial reserve. It is also proposed to use good account of the obtained data as a point of reference in evaluation of the state of the natural environment of other lowland peatbogs in south-eastern Poland." (Authors). 28 Odonata species are listed; of special Central European faunistic interest are in addition to the above mentioned species *Coenagrion armatum*, *Sympecma paedisca*, *Leucorrhinia albifrons*, and *L. pectoralis*.]

[A long-term study [sic!] (08.05 - 14.11.1995) was performed on the fate and effects of hexachlorobenzene (HCB) in aquatic mesocosms. Discontinuous dosing of the sparingly soluble test substance up to the limit of its water solubility (5 µg/l at 20°C) did not cause any significant effects on the aquatic communities. From this point of view, a quality objective of 5 µg/l is considered to maintain the structures and functions of aquatic communities on a long-term scale." (Author) The experimental ponds are located on the properties of the Bayer AG plant in Leverkusen, Germany. Dragonflies considered not be affected by HCB were the common *Sympetrum striolatum* and *Libellula* sp., the only species occurring in the experimental ponds.]

["Although benthic stream macroinvertebrates have been widely used in bio-monitoring, further developments towards more general biomonitoring tools are timely. Therefore, we compared traditional ways of biomonitoring such as diversity, biotic indices and community structure with a new approach using biological traits such as reproduction, life duration, and feeding habits. These approaches were applied to a typical biomonitoring scenario, i.e. for two sites being upstream and downstream of the effluent from a waste water treatment plant. Physico-chemical variables did not discriminate between upstream and downstream site. Among eight tested biological indices, only Margalefs and Shannon's index and the French Biotic Index "indice biologique global normalise" (IBGN) significantly separated the upstream from the downstream site. However, biomonitoring through these three indices depended significantly on the sampling effort, which was not the case for the community structure or biological traits. Community structure in terms of taxa abundances separated the upstream from the downstream site (17.9 % of discrimination). Biological traits weighted by taxa abundances better separated the upstream from the downstream site (23.1 % of discrimination). The biological traits showed that the functional structure at the upstream site was characteristic for organisms using the strategy of resilience in more variable but less adverse environments. In contrast, the functional structure observed at the downstream site was characteristic for organisms using the strategy of resistance in less variable but more adverse environments. Thus, the functional approach to indicate pollution effects in streams through biological traits may provide a tool for future stream management which is robust, general and based on current concepts of ecological theory." (Authors) Odonata recorded in the River Chalaronne

["The behaviour of this rainforest dragonfly was studied in the Kakamega Forest, West Kenya. Seven different activities were distinguished: perching, sun-flights, patrolling, inspection, interspecific, intra-specific, and sexual flights. Two-act sequences of these behaviours were analysed and quantified to determine significant transition probabilities. Sun-flights into the tree canopies were the most common flight activity and followed any other behaviour significantly more often than expected. Coming back from a sun-flight, the males preferentially perched or patrolled; after patrolling males typically perched. Most of the time the males spent perching in their territory (32% of total time in territory). Proposed functions of these territorial behavioural activities in *Notiothemis roberisi* are deduced from these results."]

270. **Czachorowski, S.; Buczynski, P. (1998):** Preliminary evaluation of the specificity of aquatic insects of Polesie based on dragonflies (Odonata) and caddis flies (Trichoptera). *Tezisy dokladov. Mezhdunarodnoy nauchnoy konferentsii. "Souremennye proylemy izucheniya, ispol'zovani' i okhrany prirodnykh kompleksov polesya". Sektsiya 3: Sokhranie landshchaftnogo i biologicheskogo razanoobraziya poles'ya.* 22-25 September 1998, Minsk, Respublika Belarus'. Belszns. Minsk: 204. (in English).

[Polesie is an extremely interesting region in Europe because of its unique water and wetlands habitats. Among areas in Eastern Europe, it has one of the highest numbers of wetlands. Specificity of aquatic fauna originating from various geographical regions probably occurs there and is likely the meeting of fauna from Siberia and Eastern Europe with west-European fauna, as well as northern and southern elements. Extensive drainage in recent years has caused great changes in swamp and water habitats and has probably affected the distribution of insects. The effect on aquatic insects is interesting. Additionally, it is significant that peat-bog habitats are deteriorating in western and central Europe, causing fauna living in these habitats to approach extinction. Polesie is probably the last sizable place where these species occur and where they may be protected. The aquatic insects of Polesie, a region occurring partially in Poland, Belarus and the Ukraine, are very poorly known. There are only a few data about caddis flies from Polish and Belarusian Polesie, and no information from the Ukrainian part of the region. Dragonflies are known only from the Polish and Ukrainian part of Polesie. Odonata and Trichoptera were collected in Lublin Polesie (western Polesie) in lakes, pools, rivers, ponds and ditches. Trichoptera were collected in three places of Polesie in Belarus: in the vicinity of Brzesc, the vicinity of Olmany (mid-Polesie) and in the Chernobyl region. Fifty-one species of caddis flies are known in the region, including 36 in Poland and 23 in Belarus. The total number of Trichoptera of Polesie will prob-

ably be about 70-100. Twenty-seven species were found in lakes, nine in peat-bog ponds, 13 in ditches, 14 in old river beds and 16 in rivers. Fifty-eight species of Odonata (79% of the species occurring in Poland) were found in the Polish part of Polesie. and 31 in Ukrainian part. These species probably also occur in all of Polesie. The species *Gomphus flavipes*, *Orthetrum coerulescens* and *Sympetrum striolatum* also occur in Polesie. Twenty-nine species of dragon flies were caught in rivers, 35 in ditches, 41 in dystrophic lakes, 35 in eutrophic lakes, and 49 in peatbogs. In Polesie, fauna typical for swampy and peat-bog habitats is very common. Some of the interesting species occurring there are rare or rare in Europe. Polesie may be a very important area for the protection of these species. It is very interesting that river fauna is relatively poor. Earlier investigations of aquatic insects in the Biebrza River, which has acidic and dystrophic waters from adjacent swamps and peat-bogs in the Biebrza Valley, have also shown very poor fauna. So. it is also a possibility that rivers in Polesie have specific and poor aquatic-insect fauna. This possibility strongly needs to be checked by field investigations. Many species that are rare in Europe (tyrphobionts and tyrphophilous) occur in Polesie, but these species are in danger of extinction. The specific and unique insect fauna of Polesie strongly need active protection, may be through the creation of a national park or euroregion. Aquatic insects are very poorly known and more investigations are needed. We are currently looking for interesting parts from Belarus and the Ukraine for common field investigations (expeditions) and for scientific co-operation. (Verbatim)]

["The Amazonian Campina is a woodland with emergent trees of about 10 m found in patches in the Amazonian rain forest. It usually has open areas with a white sand soil directly exposed to sun, and shaded areas with a more dense vegetation. I sampled the dragonfly assemblage in this system counting every dragonfly at pre-determined points, at 5 min intervals, between 7:00 and 18:00 h. *Erythrodiplax lativittata*, *Miathyria marcella* and *Erythemis vesiculosa* were the most abundant spp. The frequency data by point revealed an association of *E. lativittata* (percher) with shaded habitats, and *M. marcella* and *E. vesiculosa* (fliers) with open habitats. The characteristics of thermoregulation of fliers and perchers seem to explain this microhabitat selection. Due to high productivity and density of small insects, the Campina is probably an excellent habitat for foraging. It is suggested that in these foraging habitats the spatial species arrangement is mostly determined by behavioural-physiological traits, which may help to explain the community faunal composition." (Author) study area: Suframa-INPA reserve, Brazil; 15 Libellulidae and 1 Corduliidae were observed; mean front wing size of 11 species is given; figure with mean perch or flight height]

279. **De Marmels, J. (1998):** A five year survey of an odonate community inhabiting a north Venezuelan mountain stream. *Odonatologica* 27(2): 189-199. (in English).
["Monthly counts of adult Odonata were carried out along a transect following a forested mountain stream, "Quebrada Pasaquire". 17 of the 41 spp. recorded were considered for evaluation. The average monthly abundance curve of spp. such as *Euthore fasciata* Sel., *Archilestes grandis* (Ramb.), *Philogenia cassandra* Sel., *Progomphus abbreviatus* Belle, *Brechmorhoga rapax* Calv. and *Libellula herculea* Karsch matches the climogram of the study area, e.g. these spp. are markedly seasonal with high adult abundances in the wet season, and low numbers in the dry season. On the other hand the presence of adult *Hetaerina capitalis* Sel. and *H. cruentata* (Ramb.) did not seem to be correlated with season. *Macrothemis pseudimitans* Calv. and *Micrathyria venezuelae* De Marmels appeared to be more common in the dryer months, but their population sizes were always low. Based upon the data of this survey it can be stated that the odon. community studied has a persistent structure, relatively low variabilities of population densities, and is stable. The evidence includes persistence of the dominant taxa over at least 5 generations, typical standard deviations of the logarithm of population sizes, as well as high and significant year-to-year rank concordance. *Cannaphila vibex* (Hag.) and *Progomphus abbreviatus* became more common during this survey, while *Andaeschna rufipes* (Ris) shifted towards local extinction. However, 5 yr may not be sufficient to show such trends to be irreversible: in almost all species at least one trend reversal occurred during the survey. Some of the potential ecological mechanisms underlying the constancy and stability of this odonate community are discussed and it is suggested that abiotic factors, such as periodical floods in this lotic habitat, may be of some concern." 291. **Dole-Olivier, M.-J. (1998):** Surface water-groundwater exchanges in three dimensions on a backwater of the Rhône River. *Freshwater biology* 40: 93-109. (in English).
["1. Hydrological exchange between the surface stream and the hyporheic zone is well documented in the main channel of rivers, especially at the reach scale. Hydrological processes of advection/convection occur at different scales, and in secondary channels of large rivers little is known about these exchanges in the hyporheic zone on a broad scale (i.e. kilometres). This work studied exchanges of water and biota in a secondary channel on a large scale (4 km), using a three-dimensional framework. 2. The exchanges of water were described using physicochemical indicators of surface and groundwaters. Samples of water and biota were taken in three dimensions: (i) vertically from benthic (i.e. 0.20 m below the surface of the substratum) to hyporheic (0.50 m) and deep interstitial (1.0 m) zones; (ii) laterally from the right to the left bank (i.e. right, middle and left positions); and (iii) longitudinally from upstream to downstream (seven stations regularly distributed along the channel). 3. The physicochemical indicators clearly revealed hydrological heterogeneity in the longitudinal and vertical dimensions, whereas lateral variability was not significant. 4. Spatial distribution of biota exhibited strong longitudinal variations that were not gradual as predicted by an upstream/downstream continuum, but patchy and discontinuous. No significant differences were found between the three positions across the channel. 5. Analyses, of both physicochemical and faunal data sets produced matched ordination of samples and stations, indicating that interstitial-surface flow relationships appear to be an important governing factor in the distribution of interstitial biota at this broad scale. 6. Results are discussed in relation to the hypothetical three-dimensional models of the hyporheic zone in rivers. Contrasting with other observations on the

main channel (where advection/convection patterns are dominated by morphological changes of the river-bed morphology), it is proposed that water exchanges in backwaters are more likely to be related to local modifications of stream-bed porosity." (Author) "Coenagrionidae (young stages)" were used in the faunal analysis.]

Address: Dole-Oliver, M.-J., Freshwater and River Ecology Unit, Université Claude Bernard Lyon, 1-43 Bd du 11 Novembre 1918, F-69622 Villeurbanne cedex, France.

292. **Dommanget, J.-L. (1998):** Analyse et commentaire relatifs au "Catalogue des libellulidées des environs de Besançon" de M. Léandre Pidancet (1856). *Martinia* 14 (1): 31-36. (in French with English summary).

[The author analyzes and comments on the difficulties to work with old odonatological papers. In the example used, the publication of Pidancet (1856) is documented as annex: Some of the taxa occurring at that time in the Département Doubs, France were not still described, and the odonatological "must" of that time Selys-Longchamps & Hagen's "Revue des Odonates ou Libellules d'Europe" (1850) and Charpentier's "Libellulidae europaeae. Descriptae ac depictae" (1840) were unknown to resp. not used by Pidancet. Dommanget presents a very useful checklist for checking old publications in relation to verify them and make them comparable to modern papers. Two new taxa were introduced by Pidancet to science. Dommanget considers *Aeshna justii* Pidancet (1856), a synonym unknown to most of the odontists incl. Bridges, for *Aeshna juncea* (Linnaeus, 1758). The identity of the likewise obscure *Libellula bruandi* Pidancet (1856), probable a *Orthetrum* (*coerulescens?*), remains unsolved.]

314. **Eversham, B.C.; Cooper, J.M. (1998):** Dragonfly species-richness and temperature: National patterns and latitude trends in Britain. *Odonatologica* 27(3): 307-316. (in English).

["The pattern of Odonata species-richness in Britain is mapped at 10 km resolution. This is strongly correlated with mean air temperatures. The relationship with seasonal and monthly mean temperatures is explored: summer temperatures are better predictors, of overall dragonfly richness than are winter temperatures. However, there appears to be some latitude variation in the relationship. Thus, in northern Britain, increasing Odonata richness is correlated with increasing summer temperatures for non-boreal species, and with decreasing winter temperatures for predominantly-boreal species; physiological adaptations of individual species are proposed as a possible explanation."]

Address: Eversham, B.C., Biological Records Centre, NERC Institute of Terrestrial Ecology, Monks Wood, Abbots Ripton, Huntingdon, Cambs PE17 2LS, United Kingdom.

315. **Faton, J.-M. (1998):** Les libellules (Odonata) de la Réserve naturelle des Ramières du Val de Drôme. *Inventaire et suivi des peuplements. Sympetrum* 11: 35-45. (in French).

[commented checklist of 36 Odonata known to occur in the Natural Biological Reserve of Val de Ramières, France]

Address: Faton, J.-M., Réserve Naturelle des Ramières, Maison des Ramières, F-26400 Alex, France.

[checklist of the Odonata of 17 localities in the Département Hautes-Alpes, France, 2 males of *C. caerulescens* were discovered at an altitude of 1070m]

Address: Faton, J.-M., Réserve Naturelle des Ramières, Maison des Ramières, F-26400 Alex, France.

317. **Finck, P. (1998):** Der Einfluß von Probenahmezeitpunkt und -häufigkeit auf die Erfassung der Makroinver-

tebraten in Mittelgebirgsbächen. *Lauterbornia* 34: 245-254. (in German with English summary).

[The influence of sample timing and frequency on the recording of the macroinvertebrates in mountain brooks: The extent of recording of macroinvertebrates was studied in two brooks in the Eifel mountains in Northrhine-Westfalia, Germany, with timing and frequency of sampling varying. Additionally, the dominance structures of the biocoenosis indicating different habitat requirements were analysed. Recommendations are given for a minimum standard to guarantee the relevance and validity of the results for physical planning: not less than 4 samples per annum, obligatory in March, May, June, and September. *Calopteryx virgo* and *C. splendens* are recorded for the watercourses of Ahbach and Klausenbach.]

Address: Finck, P., Bundesamt für Naturschutz, Abt. Biotopschutz und Landschaftsökologie, Konstantinstr. 110, D-53179 Bonn, Germany.

318. **Fliedner, H. (1998):** Johann Franz Christian Heyer (1777-1864) und sein Beitrag zur Kenntnis der Libellen. 1. Teil. *Libellula* 17(1/2): 71-90. (in German with summaries in Latin and English).

["Recently, letters have turned up which Heyer, a low rank town officer of the city of Lüneburg, Germany, wrote to H.A. Hagen. Based on those letters a chapter of history of odonatology will be presented concerning that period in which more than half of the European Odonata taxa was described. Trading extensively with insects amateur entomologist, Heyer came into contact with many important entomologists. He discovered 4 species of Zygoptera; he gave reliable information about the regional odonate fauna of Lüneburg to scientists; due to his connections to certain scientists he was able to contribute to the enodation of the intricat synonymy of dragonflies; furthermore, he observed the behaviour of some species of dragonflies. The results of his observations were published by Hagen. The paper is completed by some notes on Heyers trade with insects."]

Address: Fliedner, H., Louis-Seegelken Str., D-28717 Bremen, Germany.

319. **Förster, S. (1998):** Oviposition high above water in *Micrathyrta dictynna* Ris (Anisoptera: Libellulidae). *Odonatologica* 27(3): 365-369. (in English).

[A female of *Micrathyrta dictynna* was observed to attach eggs onto the underside of a leaf hanging more than 2 m above the water level of a small rainforest stream in Costa Rica (La Selva Biological Station, Puerto Viejo de Sarapiquí). "It was found that the eggs usually remain in this position until the larvae hatch. This type of oviposition, the first recorded in a member of the subfamily Brachydiplactinae, is similar to that of some Old World Tetratheminae and it is suggested to be a case of convergence due to similar environmental conditions. Its adaptive significance is discussed briefly." The author takes the minimizing of predation risk by fishes for the relevant factor for the reproductive strategy of *M. dictynna*. "This hypothesis is supported by the occurrence of many small fishes in the stream which were observed to react quickly to all objects dropping onto the water surface. Under this high potential predatory pressure the multi-layered egg mass of *M. dictynna* could be advantageous because of different developmental stages of the eggs and their different hatching times."]

323. **Gerken, R. (1998):** Reproduktionsnachweis der Grünen Keiljungfer (*Ophiogomphus cecilia* Fourcroy 1785) am Unterlauf der Aller. *Beiträge zur Naturkunde Niedersachsens* 51: 155-157. (in German).

[report on the occurrence of *O. cecilia* in the River Aller (Administration district Verden, Lower Saxony, Germany); exuviae were found in 1992 and 1996]

Address: Gerken, R., Birkenweg 4, D-38678 Clausthal-Zellerfeld, Germany.

324. **Gibbins, C.N.; Moxon, J.B. (1998):** *Calopteryx splendens* (Harris) at edge of range sites in North-East England. *J. Br. Dragonfly Soc.* 14(2): 33-45. (in English).

[A survey of adult *Calopteryx splendens* (Harris) in the middle section of the River Wear, County Durham, UK was undertaken over the summers of 1994-96. The species was found in one new 10km square in the county and the survey confirmed its regular presence in another two. Flows in the Wear are regulated by inter-basin water transfers and pumped minewater releases, both of which result in considerable short-term flow change. Several sites occupied by *C. splendens* were also found to suffer water quality problems associated with sewage treatment works and contamination from minewaters. *C. splendens* may be more widespread in Durham than previously

thought and there is increasing evidence that it is present on many suitably slow-flowing rivers in north-east England. However, the species' presence at some sites on the Wear with relatively poor water quality and variable daily flow patterns remains puzzling. Detailed results are presented to water quality (physico-chemical characteristics, metals and nutrients) and sediment contamination, and its effects on *C. splendens*.]

327. **Gorb, S.N. (1998):** Visual cues in mate recognition by males of the damselfly, *Coenagrion puella* (L) (Odonata: Coenagrionidae). *Journal of Insect Behavior* 11(1): 73-92. (in English).

[*Coenagrion puella* males search actively for mates and are not aggressive to other males. To study the role of visual cues in male-female discrimination, four types of models were used: (1) bodies of intact insects, (2) models of painted males, (3) models of male-female chimeras, and (4) models of female body parts. Abdomen coloration pattern and presence of wings were the most important cues for sexual recognition by males. Step-by-step elimination of male coloration pattern leads to an increase in the tandem response rate. ... The results indicate that *C. puella* males can distinguish males from females visually by morphological structures and coloration pattern. This study was financially supported by the International Dragonfly Fund.]

349. **Ishizawa, N. (1998)**: Thermoregulation in *Sympetrum frequens* (Selys) with notes on other *Sympetrum* species (Anisoptera: Libellulidae). *Odonatologica* 27(3): 317-334. (in English).

[Thermoregulation in *S. frequens* was investigated throughout its adult life, from emergence to reproduction. Data were analyzed by the least squares method. Body temperature was highly correlated to ambient temperature in the sun in the teneral stage and as the life stage advanced the correlation of body temperature to ambient temperature was lowered. Sexual differences were confirmed on thermoregulation; in the male the correlation decreased, whereas, in the female it decreased less. Males have lower body temperatures at high ambient temperatures than the females, and when ambient temperatures were low at the reproductive period in autumn, they maintained high body temperatures. The sexual difference of body temperatures ranged 2.5-3.4°C. This seems to be due to the sexual difference in body size. Females have smaller thorax and are likely to be influenced by ambient temperature. Because of the small thorax, females seem to be tolerant of high ambient temperature. High body temperature in ovipositing males were not caused by metabolic heat production at the tandem flight, but by the elevation of it during copulation. At low ambient tem-

peratures males were seen warming up at the last stage of copulation. Body temperature in non-contact ovipositing females approximated to that of ovipositing males in tandem and the duration of the former was shorter than that of the latter. *S. frequens*, in spite of small size and disadvantage for warm-up, is a periodic endotherm." Additional data are presented for *S. darwinianum*, *S. parvulum*, *S. eroticum*, *S. infuscatum*, and *Anotogaster sieboldii*.]

Address: Ischizawa, N., Yamaguchi 1644-15, Tokorozawa, Saitama 359-1145, Japan.

350. **Jacobsen, D.; Encalada, A. (1998):** The macroinvertebrate fauna of Ecuadorian highland streams in the wet and dry season. *Arch. Hydrobiol.* 142(1): 53-70. (in English).

[examination of the community structure and functional feeding groups of the macroinvertebrate fauna; "The abiotic environment of the streams was highly unstable with great variability in discharge during the wet season, but relatively constant during the short dry season. Overall, the number of individuals and species were significantly higher in the dry season than in the wet season. In all streams the composition of the fauna differed markedly between the two seasons, but no consistent change in the community structure and proportions of functional feeding groups was found ... Collector-browsers were the most numerous organisms while filterers, predators and shredders were much less important. Maximum stream temperature was the single environmental parameter that best explained the variability in community structure among the streams ... The instability of these tropical Andes streams is probably the main feature structuring the invertebrate fauna. The streams may be alternating between a stochastic community structure during the wet season and early successional stages dominated by organisms with a fast growth and high colonisation capacity during the dry season." 'Aeshnidae' are reported for 3 streams.]

Address: Jacobson, D.; Freshwater Biological Laboratory, University of Copenhagen, 51 Helsingorsgade, DK-3400 Hillerød, Denmark.

351. **Jarzembowski, E.A.; Martinez Delclos X.; Bechly, G.; Nel, A.; Coram R.; Escullie, F. (1998):** The Mesozoic non-calopterygoid Zygoptera: description of new genera and species from the Lower Cretaceous of England and Brazil and their phylogenetic significance (Odonata, Zygoptera, Coenagrionoidea, Hemiphlebioidea, Lestoidea). *Cretaceous Research* 19 (3-4): 403-444. (in English).

[The earliest fossils which belong to the Coenagrionoidea (or Hemiphlebioidea), *Parahemiphlebia cretacea* gen. nov., sp. nov., and *P. allendaviesi* sp. nov., from the Lower Cretaceous of Brazil and southern England respectively, have non-petiolated wings. Consequently, a long wing petiolation may result from evolutionary convergence between different superfamilies of Zygoptera: Calopterygoidea, Lestoidea, Coenagrionoidea and (to a lesser degree) ... The phylogenetic position of the Lower Cretaceous genus *Cretacoenagrion* Jarzembowski 1990 from the Wealden of the Weald is discussed and several new genera and species of Wealden Zygoptera are described from southern England, viz. *Cretarchistigma greenwoodi* gen. nov., sp. nov. (questionably placed in the subfamily Euarchistigmatinae), *Cretahemiphlebia rossi* gen. nov., sp. nov. (family undetermined) and *Cretalestes martinae* gen. nov., sp. nov. (lestoid?)]

Address: Jarzembowski, E.A., Maidstone Museum and Art Gallery, Maidstone ME14 1IH, Kent, England.

352. **Jennions, M.D. (1998):** Tibial coloration, fluctuating asymmetry and female choice behaviour in the damselfly *Platycypha caligata*. *Animal Behaviour* 55(6): 1517-1528. (in English).

[The territorial damselfly *Platycypha caligata* (Odonata: Chlorocyphidae) has a courtship behaviour where males wave the white anterior surface of all six laterally enlarged tibiae at females. I experimentally altered this white tibial surface using black paint to determine the effect on male behaviour of a 25% reduction in area, or an increase in asymmetry between the left and right side of the body. I collected behavioural data on courtship, mating and fighting for males already holding territories. Neither a reduction in the area nor an increase in asymmetry of tibial whiteness affected male mating rate, courtship rate or fighting behaviour. ... However, the natural area of tibial whiteness was significantly positively related to both mean male mating rate and copulation duration for territorial males. This result suggests that a phenotypic correlate of area of tibial whiteness, probably body size, is sexually selected through female choice among males that already hold territories.]

[Striking similarities in the proventriculi (gizzards) of Lepismatidae (*Zygentoma*), Blattellidae (Dictyoptera), and nymphal Corduliidae (Odonata) permit the reconstruction of the ground-plan of Dicondylia: Six major plicae, each with a large denticle-bearing sclerite anteriorly and a smaller pulvillus posteriorly, are present in a hexaradial arrangement. ... Within Odonata, Corduliidae are closest to the ground-plan, but the unpaired plicae are reduced. In the derived condition the proventriculus of Odonata has a tetradial symmetry with the bilateral symmetry lost. ... This study gives also insights into the evolution of symmetry relations and reveals some unusual aspects of serial homology. Many homoplasies were found in the evolution of the proventriculus of Dictyoptera and Odonata.]

365. **Koperski, P. (1998):** Feeding in epiphytic, carnivorous insects: resource partitioning and the avoidance of intraguild predation. *Arch. Hydrobiol.* 142(4): 467-483. (in English).
["The gut contents of larval *Enallagma cyathigerum* (Zygoptera: Odonata), *Cymus flavidus* (Polycentropodidae: Trichoptera) and *Ablabesmyia monilis* (Tanyptodinae: Chironomidae) feeding in nature and in experimental aquaria, were analysed. The diet of *C. flavidus* overlapped greater with the diet of *A. monilis* than with the diet of *E. cyathigerum*. Feeding intensity and diet composition in *C. flavidus* and *A. monilis* were different in experimental aquaria with and without *E. cyathigerum*. Weights of their food and mean weights of their prey were lower in the presence of the latter when compared with the control, while the number of prey items was not. The proportions of active prey items in diets of *C. flavidus* and *A. monilis* were higher in the presence of *E. cyathigerum* but the numbers of such prey items were higher in the diet of *C. flavidus* only. These differences are probably caused by reduced predator mobility during feeding, not by a behavioural response from prey. Induced changes in feeding activity are considered an effect of a behavioural defence mechanism reducing the risk of intraguild predation." (Author) Study site: Lake Ros in northern Poland]

380. Mauersberger, R. (1998): Naturschutzprojekt Uckermärkische Seen, Brandenburg. *Natur und Landschaft* 73(7/8): 320-326. (in German with English summary).

["The central feature of the nature conservation project 'Uckermärkische Seen' in NE Germany is a glacially formed landscape containing many lakes, bogs and swamps of various types and several endangered Europe species of plants and animals ... The strategy of the project is to purchase areas which include ecosystems and habitats of national importance or these regions which have a bearing on it. One of the main problems for the project has been that state-owned properties have been sold to private persons or corporations in the eastern part of Germany with no regard for state-controlled and financed nature conservation projects." Among the most noteworthy Odonata of the region are *Nehalennia speciosa*, *Aeshna viridis*, *Gomphus vulgatissimus*, *Leucorrhinia pectoralis*, *L. albifrons* and *L. caudalis*.]

["Body temperature regulation and behavioral responses to temperature variation in the field were investigated in *Sympetrum vicinum*, a common North American libellulid that is most abundant as a mature adult in autumn. Because of its late flight season, this species is faced regularly with cooler environmental temperatures than most dragonflies investigated heretofore. By virtue of postural adjustments and perch selection, individuals are able to maintain both thoracic and head temperatures within a relatively narrow range even at ambient temperature as low as 10 °C. Physiological adaptations, including relatively low minimum temperature for effective flight and relatively rapid digestive function at low temperature, also enhance their ability to cope with cool conditions. Copulation and tandem oviposition and mate guarding interfere with the ability to regulate body temperature, although oviposition was observed at air temperature as low as 14°C." 389. **Mielewcyk, S. (1998):** Materials to the knowledge of the water entomofauna (Odonata, Heteroptera, Coleoptera) of the fishponds near Siedlce as the proposed nature reserve "Rybakówka". *Rocznik naukowy Polskiego towarzystwa ochrony przyrody "Salamandra"* 2: 109-118. (in Polish with English summary).

[The studies were carried out in the late spring and early autumn of 1997 in the fish ponds "Rybakówka" bordering the Siedlce town (eastern Poland). 15 species of Odonata, 15 of Heteroptera, and 30 of Coleoptera (water A-dephaga and Hydrophilidae) were recorded. A numerous occurrence of *Sympetma braueri* and larvae of *Orthetrum albistylum* is a characteristic feature of odonate fauna of these ponds. For *Orthetrum albistylum* is the northernmost locality in Europe. Predominating species among Coleoptera - *Haliphus flavicollis* and *Laccophilus hyalinus* show cleanness of water and a low degree of eutrophy. From a quantitative point of view, entomofauna is fairly poor because it stays under feeding pressure from fish and water birds. Besides, because shore waters are densely overgrown with *Typha angustifolia* and *Phragmites communis*, unfavourable conditions for water insects are created. However, despite these elements, fauna of these ponds is interesting and needs further studies. The richness of flora and avifauna as well as species composition of water insects under study are the main arguments for postulating, a setting, up of a floristic-faunistic reserve of didactic nature." 429. **Reinhardt, K. (1998):** Reproductive behaviour of *Leucorrhinia albifrons* (Burmeister) in a non-territorial situation (Anisoptera: Libellulidae). *Odonatologica* 27(2): 201-211. (in English).

["The reproductive behaviour in a high-density situation of the sp. was investigated in northern Poland in 1993 and 1995. Because of their high density, males were non-territorial. After a very brief tandem flight copulations took place either on the ground or in the surrounding pine trees and lasted, on average, 640 s. Afterwards the male guarded the female while she was on post-copulatory rest (PCR). During PCR [...] the male bent his abdomen tip up to the basal segments after a mean time of 81 s. This behaviour was interpreted as intra-male sperm translocation. Oviposition took place over open water. During the time of mating, from 10:00 h to about 17:00 CEST, almost none of the observed ovipositions was completed undisturbed. Outside this time, half of the ovipositions observed were completed undisturbed. The latter lasted 34 s, in which the female had an average frequency of 0.6 to 1.9 dips per s. Eleven hand-held ovipositions revealed a mean egg number of 327 eggs per female and a mean egg flow rate of 4.6 eggs s⁻¹. It is concluded that the mating system of *L. albifrons* is best described as a combination of resource limitation and female control. Some known effects of high male density on the reproductive behaviour of the Libellulidae are discussed." (Author)]

["Dragonfly communities were surveyed at 24 sites in 2 adjacent study regions, during the summer of 1994. In each of the 2 regions, 12 sites were grouped into 3 different study areas based on forest status. Forest status was determined by stand age and time since last logging disturbance, resulting in study areas defined as old-growth forest, mature second-growth forest, or recently clear-cut areas. Study sites within each forest-status study area included stream, pond, lake, and bog/swamp habitats. Recently-cleared forest areas exhibited the lowest species number and species diversity, while the greatest species number and diversity were found in the old-growth study areas. These differences were correlated with different vegetation structure variables characteristic of each forest-status study area. Furthermore, Beta-diversity, indicating changes in species composition across the forest-status gradient in each study area, was greater between the sites adjacent to the smallest old-growth forest "habitat island". These findings may be of importance in understanding dragonfly response to forest disturbance in the northern Minnesota landscape mosaic."]

[To understand the relationship between copulation duration and sperm precedence in *I. senegalensis*, which mate for several hours, laboratory experiments and field observation were conducted. By irradiated male techniques, P2 value (sperm precedence of the last male to mate) was measured. P2 value was almost 100 % until 2 days after copulations regardless of the copulation duration. The interval between copulations in a female was about 2.3 days in the field. It is suggested that the last male to mate gains advantages in sperm precedence regardless of the copulation duration in the field. And complete sperm mixing (the point when the P2 value was 50 %) occurred 6 days after copulation." (Author)]

["1. The assemblage of suspension-feeding microcrustaceans in lakes changes along a habitat gradient from nearshore to offshore. This gradient of microcrustaceans was explored in relation to differences in macrophytes and the associated changes in water chemistry, food resources and types of predators. 2. Some microcrustacean species were littoral or limnetic specialists, while others changed their distribution along this horizontal habitat gradient on a diel or seasonal basis. Distribution patterns were similar in a lake and a pond which differed in extent of macrophyte habitat. 3. There was a large shift in the composition of sestonic food, indicating heterotrophic seston nearshore and more autotrophic seston offshore. Sit-and-wait predators of microcrustaceans (e.g. *Enallagma* spp.) dominated nearshore and cruising predators (e.g. *Leptodora kindtii* Focke) were more common offshore. 4. A reciprocal transplant experiment revealed that littoral specialists could survive equally well when fed littoral or limnetic seston, while limnetic specialists performed poorly when fed littoral seston. Food resources may be important in determining where some microcrustacean species live along this horizontal habitat gradient." (Authors). Other invertebrate predators in low numbers include dragonfly larvae (Libellulidae) and damselfly larvae (*Lestes* spp.). The study site was Lower Crooked lake in south-west Michigan, US.]

["The habitat and the territorial and reproductive behaviours of this [...] euphaeid damselfly are described. It breeds in narrow shady streams in lowland forest in northern Borneo. Territories are defended vigorously against conspecific males. Some flights take the form of head to head contests during which the combatants can fly high into the forest canopy. Males show considerable site tenacity and return day after day to the same small section of stream. Females climb underwater down protruding branches to oviposit into decaying twigs or leaves. Males remain perched above the oviposition site during the early part of the oviposition bout, but increasingly towards the end, return regularly to their preferred territorial perches." 485. **Watanabe, M.; Taguchi, M.; Ohsawa, N. (1998)**: Population structure of the damselfly *Calopteryx japonica* Selys in an isolated small habitat in a cool temperate zone of Japan (Zygoptera: Calopterygidae). *Odonatologica* 27(2): 213-324. (in English).

["The population structure was studied in a small stream in a cool temperate zone of Japan in 1989 and 1990. using a mark-release-recapture method. The estimated daily number of males was 500 (1989) and 150 (1990), while that of females was 450 (1989) and 100 (1990). The operational sex ratio in each year was probably unity. The daily estimate number of immigrants in each year was ca. 10% of the population, and the daily survival rate was more than 80%. Therefore, the populations in both years were considered to be closed. The distribution of each individual perching was surveyed. The perching site of the damselfly depended upon the sunlit area on the bank of the stream. Accordingly, they concentrated on the west bank during the morning, and the east bank during the afternoon. However, along the bank the perching sites of males was shown to be a regular distribution, due to territorial behaviour. There were many small insects that could be prey for the damselflies along the stream and the edge of the paddy fields nearby. Dipteran insects were dominant the potential prey in this habitat. Since the habitat of the damselfly is surrounded by paddy fields and lakes, the maintenance of the population probably depends on the abundance of substrate for oviposition and the larval habitat." 491. **Wildermuth, H. (1998):** Terrestrial and aquatic mating territories in *Somatochlora flavomaculata* (Vander Linden) (Anisoptera: Corduliidae). *Odonatologica* 27(2): 225-237. (in English).

["In search of receptive females, the males of many cordulid species patrol over open water. Additionally, some species exhibit localized patrol flights also over terrestrial sites. In open fen habitats, *Somatochlora flavomaculata* may be an extreme case in this respect, as it conspicuously patrols often away from water. In consideration of its possible function, the terrestrial patrol flights were investigated in a descriptive and experimental field study and compared with those at aquatic sites. Typically, the males patrolled close to vertical structures such as trees and bushes or over footpaths in glades of reedbeds. No relevant differences between the patrol flights at aquatic and terrestrial localities were found. Both types of flight

were territorial in function as conspecific males were vigorously driven away. It is speculated that the males establish territories away from ponds because the occurrence of females is unpredictable, the preferred oviposition sites (shallow and largely overgrown puddles) being scattered over large areas. Hence, the best strategy for males for intercepting mates would be to patrol near vertical structures serving as landmarks and guidelines for arriving females." (Author) Further information is given e.g. to "flight altitude", "flight velocity", "feeding during patrol flights", "reactions towards flying non-prey objects", "conspecific encounters", and "sperm vesicle contents".] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. e-mail: wildermuth@swissonline.ch.

492. **Wildermuth, H. (1998):** Verlängerte Flugzeiten von *Somatochlora flavomaculata* (Vander Linden) und *S. arctica* (Zetterstedt): Folge ungewöhnlicher Wetterverhältnisse? (Anisoptera: Corduliidae). *Libellula* 17(1/2): 45-58. (in German).

["A systematic field study near Zürich (Switzerland) showed that in 1997 the flight periods of either spp. ended in the first decade of October, thus lasting ca 3 weeks longer than usual. The findings are based on more than 200 data for a period from August to October in *S. flavomaculata* and a single record of *S. arctica* in early October respectively. The extension of the flight periods are connected with the special weather conditions from spring to autumn of the year: wet and few sunshine in June and July; dry, sunny and warm late summer and autumn." Fig 2 demonstrates flight periods of *S. flavomaculata* and *S. arctica* according to general literature and regional or local faunistic studies from regions comparably close situated to Wildermuth's study area. Some remarks on longevity of *S. flavomaculata* are made.]

[*A. mixta* was surveyed in the former brown coal mining area at Berzdorf, southern Saxonia, Germany in 1996 and 1997. "During July and early August, the specimens were observed only on sunny SW or SE exposed pathways and meadows in reforested areas. The places ("mid-summer habitats") were at least 400 m away from the ponds where they later mated and reproduced. Mid-summer habitats are rather small areas (e.g. 15 x 400 m) in which large numbers of specimens aggregated (up to 250) without interspecific aggression, whereas interspecific reactions with *Aeshna cyanea* were observed. At this time *A. mixta* could not be found at its later reproduction sites. All specimens showed a premature colouration and

the groups consisted of both sexes in rather aequivalent proportion.... From mid-August until the end of the life span of the imaginal phase *A. mixta* was found in these localities only in low numbers, few significant lower and rested on vegetation closer to the ground (mainly < 2 m). At this time ... the vast majority of the specimens was observed at open ponds either without or with only few trees in their periphery ("reproduction habitat"). About 80% of the specimens observed at these sites were males..." (Authors)]

[In 1993-1994, larvae and imagines of Odonata were collected in 10 branches of the river Danube. Odonata larvae were also collected during the hydrobiological research of the Morava river basin in 1990-1993. Following the method of hierarchical classification, based on the presence of dragonfly species at selected localities, we distinguished the characteristic biotopes, as follows: 1) lentic biotopes renewed and newly formed, with undercurrents and rippling inhabited by rheophilous dragonflies, *Calopteryx splendens*, *Platycnemis pennipes* and the pioneer species, *Anax imperator*; 2) drying, unstable, eutrophic biotopes are inhabited by the coenosis *Lestes-Sympetrum* sp.; 3) original stagnant waters inhabited by the coenosis *Orthetrum-Libellula depressa* and *Erythromma-Anax imperator*; 4) original localities with larger areas inhabited by the coenosis *Lestes-Sympetrum-Aeshna* sp.; 5) lotic biotopes of the river Rudava with the coenosis *Cordulegaster-Ophiogomphus cecilia*, comprising the rare species, *Ophiogomphus cecilia*." [“An attractive, well organised and nicely produced field guide [...] Out of the 142 (known Taiwanese spp., 90 are treated here. - In the introductory chapters (pp. 12-59), the adult morphology is briefly outlined, but the main emphasis is given to the ecology and behaviour (pp. 18-55). A simple pictorial key is introducing the reader to the concise species narratives, which constitute the main part of the book (pp. 60-243). These are richly illustrated with col. field phot. (adults & larvae). The family (species) coverage is as follows: Calopterygidae (4 spp.), Chlorocyphidae (2), Euphaeidae (2), Synlestidae (1), Lestidae (1), Megapodagrionidae (1), Platyneuridae (4), Protoneuridae (1), Coenagrionidae (10), Cordulegastridae (3), Gomphidae (12), Aeshnidae (10), Corduliidae (2) and Libellulidae (37). A chapter on dragonfly conservation is added. [...] Two minor errors should be corrected: the bottom phot. on p. 130 shows a *Chlorogomphus brevistigma* rather than *C. risi* and, according to the information from the second Author, the phot. on p. 159 is probably referable to an undescribed *Oligoaeschna* sp.. (OA 11559).]

520. **Laister, G. (1997)**: Leitbild-Libellen, Donau-Traun-Krems-Auen. *Naturk. Jahrbuch Stadt Linz* 42/43: 181-196. (in German, with English summary).

[on the basis of old maps (Franziscäisches Kataster, 1826), the potential dragonfly fauna of the floodplains of the river system of Donau, Traun and Krems is reconstructed. The recent dragonfly fauna is compared with an assumed dragonfly fauna for unregulated rivers in the past century. The missing of species is explained by the absence of special habitats or the loss of special structures of vegetation (zonation). Abstracters note: This is a very remarkable publication with reference to dragonfly conservation, and building up guidelines for habitat development focussing on landscape ecology. A very similar attempt was exemplified for the River Mosel, Rhineland-Palatinate, and prepared by M. Schorr in 1996 for the German Bundesanstalt für Gewässerun-

de, Koblenz: Schorr, M. (1996): Flußauenlibellen der Mosel und ihre Indikatorfunktion. Teil I: Aut- und Etho-ökologie ausgewählter Arten. 522. **Norling, U.; Sahlén, G. (1997):** Odonata, Dragonflies and Damselflies. In: Nilsson, A. (Ed.): Aquatic insects of North Europe, a taxonomic handbook. Vol. 2. Apollo Books. Stenstrup: 13-65. (in English).
[detailed keys to the Skandinavian larvae and imagos of Odonata with original black and white illustrations; introductory chapter with information on life cycles and phenology, habitats, trophic relationships within the food chain, state of knowledge of Odonata, morphology (eggs, larvae, adults, methods (collecting, rearing, and preparation and conservation for / in collections). Most of the illustrations are made by Ulf Norling (larvae) and Göran Sahlén (imagos) from Skandinavian material. This is a very interesting aspect of this key: due to geographic variation in the morphology of some species, some of the keys to larvae or exuviae (e.g. Heidemann/Seidenbusch) in some cases do not match the material to be identified because the illustrations are based on specimens from regions far away from the actual collecting side. This is - in my opinion - the best reason to use the book resp. the publication of Norling/Sahlen if you have to deal with Skandinavian Odonata: It works with autochthonous Skandinavian specimens, and it provides illustrations of species as *Somatochlora sahlbergi* or *Aeshna ossiliensis* you will hardly find in any other book of such quality. (M. Schorr)]

["The species composition of the damselfly assemblage and the life history patterns of two *Coenagrionidae* (*Ischnura elegans* and *Cercion lindenii*) were investigated along the urban tract of a river (Tiber, Roma, Italy) characterized by increasing organic pollution. The assemblage was dominated by generalist species, usually recorded in lentic habitats, rather than by typical riverine species and the proportion of the latter decrease at the most polluted sites. At the end of winter, the mean size and instar distribution were different between the sampling sites showing that the life history of both species examined were influenced by a degradation of the environmental quality. A longer reproductive period, absence of diapause, and tolerance of low oxygen concentration appear to be key factors that allow generalist species *I. elegans* and *C. lindenii* to predominate at the polluted sites." ["*L. barbarus* (Odonata: Zygoptera) completes its life cycle in Belgium. Formerly, this species was thought to wander from Southern France to Belgium every year. For three consecutive years small populations were present at Merchtem and Wilrijk. The species was found ovipositing in *Juncus effusus*. During a larval survey in June 1996 several ultimate and penultimate instars were found at both sites. These observations raise the number of Lestidae reproducing successfully in Belgium to five. Although *Lestes* larvae seem unable to coexist with fish, our results show that coexistence with newts is possible. A limiting factor in the larval distribution of *L. barbarus* may be competition with *L. sponsa*. The emergence pattern suggests a latitudinal temporal gradient in emergence, as in *L. sponsa* where emergence begins earlier in warmer southern areas." (Authors)]

["We studied the mating system of the emerald damselfly *Lestes sponsa*. All males showed intense contact mate guarding by holding the female in tandem during the entire oviposition period. Our findings support the predictions made by Alcock (1994) about the occurrence of intense mate guarding: (1) a high female receptivity after copulation, (2) a high male capacity to resist takeovers, (3) sperm precedence, (4) a high operational sex ratio, (5) a high male density, (6) high access by rivals to mated females, (7) low energy expenditure, (8) a low risk of guarding, and (9) a short interval between copula and oviposition. This indicates a positive cost-benefit balance for this behavior, at least in males. A comparison within the genus *Lestes* suggests that the male-biased sex ratios and the ease with which mated females are detected have been strong selection pressures in the evolution of intense contact mate guarding." 532. **Anholt, B.R.; Werner, E.E. (1998):** Predictable changes in predation mortality as a consequence of changes in food availability and predation risk. *Evolutionary Ecology* 12(6): 729-738.

[Theory predicts that animals will have lower activity levels when either the risk of predation is high or the availability of resources in the environment is high. If en-

counter rates with predators are proportional to activity level, then we might expect predation mortality to be affected by resource availability and predator density independent of the number of effective predators. In a factorial experiment, we tested whether predation mortality of larval wood frogs, *Rana sylvatica*, caused by a single larval dragonfly, *Anax junius*, was affected by the presence of additional caged predators and elevated resource levels. Observations were consistent with predictions. The survival rate of the tadpoles increased when additional caged predators were present and when additional resources were provided. ...]

["Dietary analyses of juvenile Lake Sturgeon in a resource-poor habitat showed them to be a general predator. Cladocera dominated numerically the prey taxa, but were recorded in only four of the individual sturgeon examined and therefore excluded from stomach content analyses. Mayfly larvae (Ephemeroptera), primarily *Hexagenia*, were numerically the next most abundant (34% of all prey items) and the most widely taken (75% of all sturgeon) of the 10 prey categories. Others were Odonata, Annelida, Mollusca, Diptera and Trichoptera, each at 5-8% of all prey items. ..."]

543. **Bedjanic, M. (1998)**: Poskus analize favne kacijh pastirjev Sri Lanke (Insecta: Odonata). *Diplomska Naloga*: 90 pp. (in Slovene, with English summary).
["An attempt of the analysis of the dragonfly fauna of Sri Lanka (Insecta: Odonata)": M.s. thesis. "In the introduction an overview of research into odonate fauna of Sri Lanka is presented. All published information on each particular dragonfly taxon are systematically gathered in the Synopsis of the odonate fauna of Sri Lanka and a list of 115 species and subspecies which occur on the island is compiled. The results of the author's research of dragonfly fauna of Sri Lanka in January and February 1995 are also presented. Altogether 52 taxa, 17 endemic ones, were recorded at 22 localities between 15.I.1995 and 08.II.1995. Of special interest are the records of *Elatoneura bigemmata*, with first description of the female, and of *Epopthalmia vittata cyanocephala*, with description of the larval skin. For all dragonfly species listed for the island phenology of occurrence of adult animals is presented and a comparison to the author's research is made. Zoogeographical analysis of the odonate fauna of Sri Lanka shows similarity with that of South India, however 53 or 46,5% of taxa are confined to the island. An overview and analysis of the present knowledge on the odonate fauna of Sri Lanka show that it is still very incomplete. The odonate fauna of Sri Lanka is endangered and the main reasons for this are given. In addition, the significance of dragonflies for Sri Lanka biodiversity is discussed."]

(Author). M. Bedjanic made available an extended German summary resp. comments to different chapters or tabs. With the help of this, there is no problem to study and understand the thesis in its central aspects.]

["Benthic aquatic insects were collected from rocky nearshore areas (<1 m deep) of 17 lakes near Sudbury, Ontario, with a pH range of 4.7-7.3 and a size range of less than 10 ha to over 10,000 ha. ... Declines in abundances of several taxa of Ephemeroptera at pH below 5.5 were attributable to acid toxicity, while increases in the abundances of Odonata and Diptera at pH below 5.5 were associated with the absence of fish predators and other indirect effects of acidity. The communities of

two experimentally neutralized lakes restructured rapidly within 5 years, approaching but not achieving community structures typical of our near-neutral survey lakes. Neutralization led to recolonization or increased abundance of the acid-sensitive mayfly, *Stenacron interpunctatum*, and the dragonfly, *Boyeria grafiana*; [...] Consistent with results for the survey lakes, declines in the abundances of the dragonflies *Aeshna interrupta*, *Aeshna eremita*, and *Leucorrhinia glacialis* in the neutralized lakes were associated with reintroductions of *Salvelinus fontinalis* (aurora trout) and increased fish predation pressure, ..."]

566. **Catling, P.M.; Brownell, V.R. (1998):** Migratory concentrations of dragonflies on the north shore of Lake Ontario, and northward extension of migratory species. *Argia* 10(4): 19-22. (in English).

["Aggregations of several thousand dragonflies within an area of 5 acres have been noted at several sites along the north shore of Lake Ontario in late August and early September. The larger species of dragonflies in these aggregations are usually in the late teneral or early adult stage and the aggregations are believed to be a result of an arrested movement in a southerly direction, and are thus migratory. In 1998 at Sandbanks Provincial Park, eastern Lake Ontario, *Anax junius* was the most abundant species but other species including *Tramea lacerata*, *Pantala flavescens*, and *P. hymenaea* were also recorded. Tandem pairs of *Sympetrum vicinum* were also observed moving in a southerly direction. *Tramea lacerata* has been reported north of the Carolinian zone only once, and observations by the authors of 12 individuals at the northeastern end of Lake Ontario indicate the possibility of a recent expansion of range northward. Both a gradual warming trend and the unusually warm spring and summer of 1998 may have been contributing factors. Northward expansion of migratory species may make migratory stopover areas along Lake Ontario increasingly important for dragonflies." (Authors)]

567. **Chessman, B.C.; McEvoy, P.K. (1998):** Towards diagnostic biotic indices for river macroinvertebrates. *Hydrobiologia* 364(2): 169-182. (in English).

["The construction of biotic indices that use macroinvertebrates to assess pollution and other anthropogenic disturbances of rivers and streams often requires that each taxon be assigned a number indicating its level of sensitivity. ... Gastropod molluscs (family Thiaridae) were tolerant of dam effects but sensitive to sewage and metals, whereas coenagrionid damselfly nymphs, elmids beetles and ostracods were most tolerant of sewage. Corydalid alderfly larvae, leptophlebiid mayfly nymphs, lepid damselfly nymphs, libellulid dragonfly nymphs and scirtid beetle larvae were most tolerant of metals. [...] We conclude that the approach has merit but requires considerable further development and testing, as well as consideration of the levels of specificity and di-

agnostic strength that are appropriate or achievable." (Author)]

568. **Corbet, P.S.; Hoess, R. (1998):** Sex ratio of Odonata at emergence. *International Journal of Odonatology* 1(2): 99-118. (in English).

["Final-instar exuviae left at the emergence site by Odonata can provide information of high quality for measuring sex ratio, especially of Anisoptera. Criteria are listed according to which counts of such exuviae are acceptable for this purpose. Records of sex ratio of Odonata, published and unpublished, are critically reviewed, and 194 that meet the listed criteria are presented and analysed. Variability of sex ratio differs widely among taxa but is less in large (N >299) than in small (N = 100-199) collections. Large collections indicate that the proportion of males is greater in Zygoptera than in Anisoptera (respectively 65 and 21% of records featuring >50% males). Because the sex-determination mechanism in Odonata predicts a sex ratio of unity in the zygote, variability and imbalance of sex ratio detected at emergence can plausibly be attributed to differential mortality of eggs and/or larvae and therefore, probably, to differential predation on larvae. The effect, if any, of sex ratio at emergence on reproductive potential of the adult population is unlikely to be significant, except perhaps when, rarely, the number of females is unusually low, thus reducing the size of the next generation." ["In damselflies, the arrester system is responsible for an additional attachment of the head to the neck. It consists of a pair of mobile postcervical sclerites (SPC) covered by microtrichia. In their lateral position, SPCs can fixate the head on fields of microtrichia on the back surface of the head. The intact surface of microtrichia of die SPC is usually covered by a lipid-containing secretion. The present study provides ultrastructural data on the secretory epidermis and pore channels adapted to transport the secretion to the cuticle surface. ... It seems that the secretion reaches the epicuticle through terminal channels and diffuses through the epicuticle without any channel structures.]

["Insect flight metabolism is completely aerobic, and insect resting metabolism is quite insensitive to atmospheric oxygen level, suggesting a large safety margin in the capacity of the tracheal system to deliver oxygen during flight. We tested the sensitivity of flight initiation and metabolism to atmospheric oxygen level in the libellulid dragonfly *Erythemis (Mesothemis) simplicicollis* using flow-through respirometric measurements of the rate of CO₂ emission (VCO₂). ... These are the first data to show oxygen-limitation of flight metabolism in a free-flying insect. A low safety margin for oxygen delivery during dragonfly flight is consistent with a previous hypothesis that atmospheric hyperoxia facilitated gigantism in Paleozoic protodonates." (Author)]

den en in the toekomst. *Natuurhistorisch Maandblad* 87: 194-201. (in Dutch, with English summary).

["Moorland management at "De Hamert" National Park: The role of fauna in past, present and future: "In the mid-1980s, very high nitrogen depositions had led to the disappearance of 255 of the original 300 hectares of heath vegetation. Of the remaining 45 hectares, only 12 had vital heath. The remaining area had become overgrown by Wavy hair-grass, Purple moor-grass and Bramble. In the mid-1980s, large parts of the area's topsoil were mechanically removed in order to restore the heath vegetation. In addition, the area was fairly intensively grazed by sheep, goats, cattle and horses. As a result, the heath coverage has grown considerably. The importance of moorland as a biotope is mainly due to its rich fauna. De Hamert has always housed large numbers of species specifically associated with moorland biotopes. Unfortunately, the large-scale management measures at De Hamert have not restored the habitat of the typical moorland fauna; in fact, the fauna seems to have deteriorated in many places. The reason is that much of the structural variation in the vegetation cover, which is a key aspect of the habitat, has been lost. The article discusses a number of prominent moorland species to illustrate the importance of the fauna in moorland management. On the basis of biotope preference, the moorland fauna can be classified into a number of groups. A few representatives of each group are discussed (Sand lizard, *Lacerta agilis*; Small red damselfly, *Ceriongia tenellum*; Moorfrog, *Rana arvalis*; Silver-studded blue, *Plebejus argus*; Nightjar, *Caprimulgus europaeus*), indicating the management measures which would preserve and develop the habitat for the fauna. Finally, the article discusses some moorland management options which could restore the lost structural variation to the vegetation at De Hamert; these include extensive grazing, small-scale management and expanding and linking the isolated moorland patches." 608. **Jacobsen, D. (1998):** The effect of organic pollution on the macroinvertebrate fauna of Ecuadorian highland streams. *Arch. Hydrobiol.* 143(2): 179-195. (in English).

["The effect of organic pollution on macroinvertebrate communities was studied in five small streams located at 2600 to 3100 meters above sea level in the Andes of Ecuador. Sampling of invertebrates and measurements of physico-chemical parameters were performed at the end of the rainy season and at the end of the dry season at upstream unpolluted sites and at adjacent downstream polluted sites. At all upstream sites, more taxa were collected in the dry season, while at the polluted downstream sites, more taxa were collected in the wet season. Also values of two biotic indices (BMWP and ASPT) tended to increase at the upstream sites and decrease at the downstream sites in the dry season. Thus, the effect of organic pollution was most pronounced during the dry season. In addition, both biotic indices were highly correlated to minimum oxygen satu-

ration and phosphate concentration in the dry season, while correlations were much weaker in the wet season. Overall, the shift in faunal composition with organic pollution resembled that described from temperate streams at higher latitudes. However, the main shift in the tropical highland fauna occurred abruptly at about 80 % oxygen air saturation, but because of the low partial pressure of oxygen at an altitude of 3000 meters, this corresponds to no more than 56 % of the oxygen partial pressure of air saturated water at sea level. I propose that tropical highland streams are more sensitive to further lowering of oxygen levels through organic pollution than their temperate counterparts." (Author). "Aeshnidae" are listed for two localities.]

["This article gives a review of the status of the Odonatofauna in Flanders based on data collected by the Odonata Working Group 'Gomphus'. The review has been written in the framework of the 'Nature Report' drawn up by the Institute of Nature Conservation by order of the Flemish government. First data sources are given and the method described used to identify hot spots (5x5 km squares rich in species). The next chapter deals with species richness and historical changes in distribution status. For the various Flemish ecoregions a summary is given of total species number and number of Red List Species. In the Campine ecoregion all Flemish species (58) are present, as well as all Red List species (29). On the other hand, the Dune and Polder regions count the lowest number of species (res. 23 and 25) and possess only one Red List species. An analysis of Red List species hot spots shows that with the exception of the Damvallei near Gent, the most important hotspots can be found in the Campine ecoregion. Characteristic species for each ecoregion are described in detail. Legal conservation of dragonflies and the international value of certain species are dealt with. Finally, characteristic species of three important biotopes (running water, oligotrophic fens and mesotrophic waterbodies) are described and the various causes of changes in the Odonatofauna discussed."] (Authors)]

[Life history analyses, behavioural and population ecology as a basis for conservation: the necessity of long-term studies: Some examples are presented that demonstrate the necessity of long-term studies for behavioural and population ecology as well as analyses of life histories to make up reliable foundations for conser-

vation. The following propositions are illustrated: • Long-term studies may avoid misinterpretations of phenomena in the field of evolutionary ecology. (Example: *Bufo bufo*, Amphibia) • Long-term studies may avoid underestimation of reproductive flexibility as well as plasticity in habitat selection, and may preclude misjudgement of habitat quality. (Examples *Bufo bufo*, Amphibia; *Acrocephalus scirpaceus*, Aves) • Conservation measures run the risk of being inefficient or even counter-productive unless based on a sound comprehension of species' life history and population ecology - which normally requires long term studies (especially in perennial species). (Example: *Bufo bufo*, Amphibia) • Only continuous long-term monitoring allows of separating fluctuations from real trends. • Monitoring in intervals of several years often is misleading. • Long-term studies help to identify stock size determinants as well as the influence of phenological factors on stock development. • Long-term data sets may be reminiscent of experiments. • Short-term knowledge of an area may cause false estimations of its conservation potential. (Examples: *Rana dalmatica*, *Hyla arborea*, Amphibia; *Sympetrum flaveolum*, Odonata; 'Vegetation') (Author)] Address: Kuhn, J., Max-Planck-Institut für Verhaltensphysiologie, Abt. Wickler, D-82319 Seewiesen, Germany

623. **Kuhn, K.; Burbach, K. (1998):** Libellen in Bayern. 333 pp. Ulmer. Stuttgart. ISBN 3-8001-3495-0.

This is really a well organized and extremely informative book on the dragonflies of Bavaria, Germany. Introductory information is given on natural history situation, and the history of dragonfly research in Bavaria. The main topic of the book is the publication of the results of the Bavarian species mapping programme, started in the late 80's (92000 records from 14500 localities). These results are presented in a monographic way: Colour photographs of each species, distribution and status, habitat and habits, distribution maps (Europe, Bavaria), altitudinal distribution, and phenology.

In Chapter 7, 20 different habitat types characterised from the are odonatological point of view. For each of these habitats the main regional resp. geographic distribution in Bavaria is outlined, the Odonata characteristic of these habitats are listed, black and white drawings illustrate characteristic features of the habitat and the microhabitats of key species, the main threats are analysed, and measures for species conservation are proposed.

In Chapter 8, 13 ecoregions ('Naturräume') are odonatologically characterised. The reader will find comparisons between older and new data on the odonate fauna of these ecoregions, and the development of their odonate fauna in this century.

Chapter 9 outlines the possibilities for the conservation of Odonata in Bavaria, including legal, and the variety of Bavarian action programmes for habitat and species conservation. These actions programmes are assessed for dragonfly conservation purposes, and action plans for threatened Odonata in Bavaria are outlined.

The book ends with general information on dragonfly research from the conservationist's point of view, and with a remarkably comprehensive bibliography on odonatological literature in Bavaria.

For people not familiar with the German language it might be a disadvantage that the entire text is written in German. But there is a way to solve this problem: This

excellent book on Bavarian Odonata could give the reason to fresh up or even to learn German.

I consider the book of Klaus Kuhn and Klaus Burbach, and their numerous contributors (!) the most informative book on German Odonata, especially in the conservationist's point of view, you can purchase at present. It also is an excellent example how to present a regional dragonfly fauna in book form.

Please note a small mistake on page 110: The colour photograph depicts *Gomphus simillimus* (not *G. pulchellus*), a species not found in Bavaria. (M. Schorr)

624. **Laurent, S. (1998):** Chronologie du peuplement odonatologique d'une ripisylve du Rhône. *Martinia* 14(3): 79-84. (in French, with English summary).

[survey of Odonata north of Arles (Département Bouches-du-Rhône, France); 17 species were recorded; their diversity was compared using different indexes as Shannon and Menhinick]

626. **Lefort, F.; Catling, P.M. (1998):** A survey of damselfly adults at urban and non-urban strams at Ottawa, Ontario. *Argia* 10(4): 17-19. (in English).

["Sixteen species of adult damselflies were recorded at 23 stream sites, but only 9 were found at 3 or more sites. The most frequent species were *Enallagma exsulans* and *Ischnura verticalis*. Numbers of species and numbers of individuals were significantly less at streams inside the city than at streams outside, which are probably less polluted, suggesting that the numbers of species and individuals may prove useful in assessing water quality. Species with over 75% of their sites, and over 95% of their numbers on non-urban streams, including *Argia moesta*, *Calopteryx aequabilis*, *Enallagma antennatum*, and *E. exsulans*, may serve as useful specific indicators of good water quality. The relatively rare species, *Chromagrion conditum*, may also prove to be a useful indicator of good water quality."] (Authors)]

[The post-copulatory behaviour of Calopteryx splendens females was studied under field and laboratory conditions. After termination of copulation females usually perch and bend the abdomen so that its apex touches the ground (post-copulatory posture). The post-copulatory posture is a consequence of sperm removal by males. Male and female microstructures (spines and scales) interact to move previous sperm from the female sperm storage organs to the outside during copulation stage I, after which moved sperm is located on the ovipositor. After termination of copulation females require an average of 45 seconds to brush off this sperm (N=21). The post-copulatory behaviour of females may also allow males to chase rival males before the females start to oviposit (prevention of disturbances). The present study shows no evidence of cryptic female choice in *C. splendens*." (Author)]

[The relative influence of riparian vegetation and geomorphology on trophic structure was examined at three streams in adjacent catchments of the French Massif Central mountains. The study sites differed mainly by the degree of anthropogenic alteration of riparian and watershed vegetation, and by valley geomorphology. Fishes, benthic macroinvertebrates (grouped into functional feeding groups), macrophytes and periphyton were sampled seasonally between July 1991 and April 1992. At the riffle-pool (10 m) scale, instream morpho-

logical units appear to control the spatial partitioning of trophic resources and their consumers. [...] At the reach-segment scale (10 to 100 m), valley morphology was the primary factor controlling the stream ecosystem, but anthropogenic alteration of riparian vegetation seems to override geomorphological controls on the trophic structure. [...] Overall, the results emphasize the importance of riparian vegetation on the trophic structure of streams, especially when anthropogenic alteration of riparian vegetation is severe. We conclude that there is a need to better integrate riparian vegetation into European stream management practices in order to maintain the vitality of these systems over the long-term." (Authors). "Calopterygidae" and "Cordulegasteridae" are listed in tab. 2.]

[“Benthic macroinvertebrates and epilithic diatoms were surveyed in six forest spring brooks of Saxonia-Anhalt and Saxonia (eastern Germany). The aquatic communities changed from acid-sensitive to acid-tolerant along a gradient of acidity within the sampling area. The acidity states of the brooks were assessed by indicator species and pH values measured weekly. Waters close to industrial emitters showed lower acidity states than those farther from them. The different assessment methods used tended to yield corresponding results. In some cases, however, the results were not congruent, particularly when macroinvertebrates were used. Possible modifications of acidity-indication evaluation systems are discussed which may lead to improved assessments.” (Author). 6 species of Odonata are listed. *Cordulegaster boltonii* is the most dominant species and represented at most localities independent of pH average.]

647. **Pilon, J.-G.; Lagace, D. (1998):** Les Odonates du Québec. Entomofaune du Québec Inc., 637, Boulevard Talbot, Suite 108, Chicoutimi, Québec G7H 6A4 CANADA: 367 pp. (in French).

[LES ODONATES DU QUÉBEC by Jean-Guy Pilon and Denise Lagace, reviewed by Nick Donnelly: Verbatim, taken from *Argia* 10(4): 31-32: "This long awaited book fills a substantial gap in our knowledge of the odonate fauna of northeastern North America. It makes available the extensive collecting results and careful studies (including extensive larval studies) of Jean-Guy Pilon, who has been studying Odonates for several decades from his base in Montreal and his many students. This book is in French and attempts, in the words of the authors, to make the subject available to a large francophone audience of "beginning naturalists and amateurs". The book fills a large need, because the excellent book by Fr. Adrien Robert (*Les Libellules du Québec*, 1963) has been sadly unavailable for many years. The book begins a recapitulation of the history of Odonata study in Québec (which began with Abbé Léon Provancher in the late 1800's). A discussion of species which should be sought in Quebec is especially useful; all too often regional guides omit this essential information. There is a discussion of Odonata biology, morphology, and conservation. The main part of the first half of the book is an extensively illustrated key to adult odonates, which follows the useful earlier format of Robert's book rather closely. Neither book, unfortunately, keys or even illustrates the larval forms. Because a large number of the "beginning naturalists" may be associated with fresh-water studies related to problems of conservation of streams and other wetlands, this seems an unfortunate omission. The second half of the book begins with a discussion of Odonata habitats in Québec, arranging them into biologic zones. The main part of this half is a recapitulation of the distribution for each species. Happily there are dot maps for each species, because the long text references (a locality and a bibliographic reference is included for each and every occurrence!) are very exhausting to follow. The dot map scheme is wisely not based on political subdivisions of the Province, which are irregular in shape and quite variable in size, but by arranging them in blocks of about 27 km in the north-south direction, and 37 km in the east-west direction. This is a very sensible scheme which makes the distribution very clear at a glance. The dot maps merit careful inspection. I was very interested to find that there are more than twice as many blocks in which *Somatochlora franklini* occurs, for example, than for *Libellula luctuosa*. And nearly as many for *Somatochlora brevicincta* and *Aeshna septentrionalis*. All readers will be impressed also by the very sparse dots for the entire northern three quarters of the province. This is a very difficult province to survey, and Pilon and his students deserve high praise for their results. One departure from Robert's book is the absence of any discussion of habitat for individual species. There is also no discussion of taxonomic problems, although these are hinted at in the key by assigning some taxa to "formes" pending further revisionary study. The book will be an important work for all northeastern Odonata workers to include in their libraries. Even a glance at the extensive locality information that this book makes available will impress even the most devoted worker with the major effort that Pilon and his many students have devoted to finding and understanding Odonata in this province. I expect that this book will reach its intended audience, and that there will be a resurgence of interest among younger

people in eastern Canada. It certainly stands as a monument to Pilon's vast labors."]

656. **Samraoui, B.; Bouzid, S.; Boulahbal, R.; Corbet, P.S. (1998):** Postponed reproductive maturation in upland refuges maintains life-cycle continuity during the hot, dry season in Algerian dragonflies (Anisoptera). International Journal of Odonatology 1(2): 118-135. (in English).

["Anisoptera were monitored or sampled regularly at lowland and nearby upland sites in northeastern Algeria during 1992 and 1993. After emerging in lowlands at about sea level in May and June, adults disappeared from lowlands and were then soon encountered in nearby hills at ca 500-1000 m a.s.l. where they aestivated in woodland for about three and a half months (Sympetrum meridionale) or more than four months (Aeshna mixta, Sympetrum striolatum). During aestivation adults foraged, gradually changed colour and achieved reproductive maturity. Aestivation ended with the onset of heavy rain in late September or early October when mature adults reappeared at lowland sites where they promptly exhibited reproductive behaviour. Although no adults marked in lowlands were recaptured in uplands, the inference that individual adults made two-way flights between lowlands and uplands is compelling. Postponed reproductive maturation in upland refuges maintains continuity of the life cycle in habitats inimical to survival of the aquatic stages during the protracted hot, dry season. This type of life cycle can be expected to occur in populations of European Odonata near the southern limit of their geographic distribution where they encounter a Mediterranean climate. The implications of such a life cycle for habitat conservation are discussed." (Authors)]

657. **Samu, S. (1998):** Zur Populations- und Verhaltensökologie von Coenagrion lunulatum (Charpentier) (Zygoptera: Coenagrionidae). Libellula 17(3/4): 173-193. (in German with English summary).

["On the population and behavioural ecology of Coenagrion lunulatum (Charpentier) (Zygoptera: Coenagrionidae) - At a small field-pond close to Schwerin, NE Germany, the emergence period started on 5-V-1995 and lasted 35 days. The EM50 of 11 days was quite low

but the emergence curve shows two approximately similar sized peaks. So, C. lunulatum can not be described as a typical spring species, because the emergence curve missed the typical course of a mass emergence. - Exuviae were found on an average of 5.2 cm above waterlevel. Most of the individuals emerged in shallow areas with a water depth between 6 to 25 cm. - The reproductive period lasted 23 days, though the main flight period with high numbers of adult damselflies covered only 9 days. The maturation period was estimated to be 9-10 days. The average adult life-span was 8.3 days. - For oviposition the tandem pair submerged for a mean of 13.03 min. Oviposition above the waterlevel was not observed. The tandem pairs did not aggregate." (Author)]

658. **Samways, M.J.; Osborn, R. (1998):** Divergence in a transoceanic circumtropical dragonfly on a remote island. Journal of Biogeography 25 (5): 935-946. (in English).

["One terrestrial invertebrate that naturally spans the globe and travels vast distances is the dragonfly Pantala flavescens (Fabricius) (Odonata: Libellulidae). [...] The variation and differences in morphology and behaviour of an African continental (Pietermaritzburg, South Africa) and a remote island population (Easter Island) of P. flavescens was investigated to determine whether the island population was panmictic with the migrant population, or whether it was a founder population. [...] The fact that P. flavescens is the only species of dragonfly on Easter Island, and the great distance of the island from any mainland, suggests infrequent arrival of migrants arriving on the island, with resultant reduced genetic variation. The morphological and behavioural differences between the two populations suggests divergence is occurring."]

["Data are given on the morphometry, substrata of the littoral zone, water quality, vegetation and benthic macroinvertebrate assemblages of Oak Mere ... In 1994, vegetation was confined to a sparse marginal zone containing very few individuals of macroinvertebrates with a community structure characterised by high diversity and maximum equitability. By 1996, this marginal zone had increased in area and a new submerged vegetation zone had developed. The new and substantial macroinvertebrate assemblages of these two 1996 zones were closely similar in species composition, species richness, diversity and equitability. In both sampling years the macroinvertebrate assemblages of a niche provided by the undersides of stones remained similar in all respects. The development of marginal and submerged vegetation zones, providing niches for macroinvertebrates, is attributed to a stable water level between the two sampling years." (Authors). Coenagrion puella was sampled in 1996 both in the marginal and submerged vegetation.]

["Damselfly larvae can autotomize their caudal lamellae to escape predation. Costs of caudal lamellae autotomy were investigated by directly manipulating lamellae condition of *Lestes sponsa* in laboratory experiments. Larvae without lamellae had higher predation mortality in the presence of *Notonecta*. Both lamellae loss and larval density increased the probability of being cannibalized. The results suggest that the increased vulnerability after lamellae loss resulted from a reduced escape performance. Larvae were less mobile after lamellae loss or in the presence of a predator, but the decrease was no longer significant when both factors were combined. This indicates that larvae compensate for the increased predation risk with a fixed response. Both lamellae loss and predator presence reduced hunting success, but the decrease after lamellae loss was only significant in the absence of a predator. The fitness consequences of these effects for both the larval and adult stages are discussed. In general, the data strongly suggest that

lamellae autotomy plays a role in population regulation of damselflies." (Author)]

686. **Andrews, S.J. (1999):** Observations on the use of Yellow Flag (*Iris pseudacorus*) as a support for emerging zygopteran larvae. *Journal of the British Dragonfly Society* 15(1): 12-17. (in English).

["A total of 60 exuviae of *E. cyathigerum* was examined, 34 during 1996. It is noteworthy that a small but significant number of larvae appeared to bypass the irises and emerge on other vegetation including the nettles

behind the mud/shingle bank. These alternative supports for emergence appeared to be used more often during the early part of the emergence period (data not shown). [...] The average height climbed by larvae in this study for emergence was 42cm (range 10-100cm). Together with additional data collected during the emergence periods for 1994 and 1996, it can be seen that most larvae climb at least two-thirds of the total height of the Iris for emergence but not necessarily right up to the very top (Fig. 1). [...] As a general observation, the average width of any single iris leaf does not vary considerably throughout most of its length, the overall width tending to increase with increasing length (age) of the leaf. The average leaf width at the position of emergence was 14mm (range 5 to 25mm). [...] An equal number of exuviae were recovered from both sides of the Iris leaves. 41 % of larvae chose a position whereby both sets of legs could clasp both edges of the leaf whilst 53 % chose an alternative position utilizing the mid-rib vein as an alternative to one of the leaf edges (Table 2)."] (Author) study site: Wraysburg, UK

695. **Che Salmah, M.R.; Hassan, S.T.S.; Ali, A.; Abu Hassan, A. (1999):** Life history of *Neurothemis tullia* (Drury) in a tropical rainfed rice field (Anisoptera: Libellulidae). *Odonatologica* 28(1): 1-11. (in English).

[The study was performed from June 1993 through April 1995 in a rainfed rice field of Bandar Baru District in Kedah, Peninsular Malaysia. "Larval growth was more uniform during early instars. Increasing variations of growth were obvious during the later instars, especially in the final instar. [...] Larval development was asynchronous and a maximum of 8 larval instars was found on one sampling occasion. 4 emergences were observed in 1994, in March, May, July and October. In general emergence was relatively synchronized. The E50 values were achieved within the first 38%, 9% and 16% of the total duration of emergences 2, 3, and 4 respective-

ly. A relatively short life cycle, continual breeding and oviposition, synchronous emergence and immediate reproduction after a dry period ensure survival of *N. tullia* in the unpredictable rainfed rice ecosystem." (Authors)]

696. **Chippindale, P.T.; Dave, V.K.; Whitmore, D.H.; Robinson, J.V. (1999):** Phylogenetic relationships of North American damselflies of the genus *Ischnura* (Odonata: Zygoptera: Coenagrionidae) based on sequences of three mitochondrial genes. *Molecular Phylogenetics and Evolution* 11(1): 110-121. (in English).

["Relationships of North American damselflies of the genus *Ischnura* (Odonata: Zygoptera: Coenagrionidae) were investigated using a total of 1205 bp from portions of three mitochondrial genes: cytochrome b, cytochrome oxidase II, and 12S ribosomal DNA. Parsimony and neighbour joining analyses reveal a monophyletic group consisting of *I. damula*, *I. demorsa*, *I. perparva*, *I. posita posita*, *I. posita atezca*, *I. verticalis*, and probably *I. denticollis*, likely reflecting a recent radiation in North America. *Ischnura kelicotti*, *I. barberi*, *I. prognata*, *I. hastata*, *I. ramburri*, and *I. capreola* appear to represent much earlier divergences in the group. Many previous hypotheses of relationships among North American species of *Ischnura* are not supported by the molecular-based analyses. However, there is agreement in many respects between the results of the molecular phylogenetic analyses and the morphologically based conclusions of Kennedy (1919, 'The Phylogeny of the Zygoptera', Ph.D. Dissertation, Cornell University, Ithaca)."] (Authors)]

["The dragonfly fauna of an isolated pond in Merchtem (Vlaams-Brabant). We report on the monitoring of dragonflies of a newly excavated, isolated pool for amphibians at Merchtem. The pool is situated in an agricultural landscape, and rather small and shallow. During the first year, six species were seen at the pool. Over the first four years, a total of 13 species has been observed. Compared to the adjacent 10 x 10 km squares, this is a reasonable number. Striking is the absence of local populations of *Lestes sponsa* and *L. viridis* despite their occurrence in nearby squares and the suitability of the habitat. Interesting is the yearly occurrence of a local population of *L. barbarus* (the first proof of successful reproduction for Belgium) and occasional sightings of *L. dryas* and *Aeshna affinis*. Despite the absence of any populations of species listed in the Red List of Flanders, the observations show the importance of such pools for local odonata richness." (Authors)]

["Secondary production of insects in a Hong Kong stream was measured over two years when the intensity of monsoonal rains (influencing stream discharge) showed marked inter-year variation. Data for 19 species (Ephemeroptera, Odonata Trichoptera and Coleoptera) revealed considerable variation in production between years by some species. A hypothesis that these fluctuations reflected microhabitat occupancy was tested and supported by the data. Production by rheophilic species living in coarse substrates increased during the year with higher stream discharge while that of species living in depositional habitats declined. The opposite trend was observed during the year with low rainfall. Despite variation in annual production of individual species, where data were available for an entire functional feeding group (e.g. filter-feeders), production estimates were rather constant between years." (Author). Secondary production of: *Euphaea decorata* was relatively consistent between the years 1977-1978 and 1978-1979.]

(1999):** The life cycle of *Onychogomphus uncatatus* (Charpentier, 1840) (Odonata: Gomphidae) in the Sierra Morena Mountains (southern Spain): an example of protracted larval development in the Mediterranean basin. *Arch. Hydrobiol.* 144(2): 215-228. (in English).

["The life cycle of the dragonfly *Onychogomphus uncatatus* was studied for three consecutive years, mainly by systematic sampling of larvae, in a permanent upland stream in southern Spain, towards the southern part of this species' range. During larval development a hatching cohort divides into 'fast' and 'slow' components which respectively complete development in two and three years and correspond in their mode of seasonal regulation to summer and spring species (sensu CORBET 1954). In these respects the life cycle resembles closely that of certain other Odonata near the northern limit of their distribution in the United Kingdom and Sweden. Advanced metamorphosis (in the last larval instar) and emergence were confined to spring and summer respectively, but unusually low autumn temperatures correlated with the appearance in autumn, rather than in winter or spring, of intrastadial changes foreshadowing metamorphosis." ["A successful reproduction of the Red-veined Darter (*Sympetrum fonscolombei* Selys, 1840) in Walloon Region (Southern Belgium). This note account for the observation of a minimum of four males and two females of *Sympetrum fonscolombei*, all tenerals, at the end of September 1998, near a pond in Southern Belgium, in Gaume. It is the first reported case of successful reproduction of this southern species in Walloon Region. These recently emerged adults had descended probably from the development of eggs laid by migrants during spring 1998. Observations of that species seem more and more regular in Southern Belgium, from 1993 (at least) till now. Since that date, indeed, several data were recorded each year, relating sometimes to little groups (up to about twenty individuals) and egg-laying has sometimes been observed. Occasional effective reproduction was therefore expected." (Authors)]

["The arrester or fixation system of the head in adult Odonata is unique among arthropods. This system involves the organs of two body segments: the head and the neck. It consists of a skeleton-muscle apparatus that sets the arrester parts in motion. The parts comprise formations covered with complicated microstructures-fields of microtrichia on the rear surface of the head and post-cervical sclerites of the neck. The arrester immobilizes the head during feeding or when the dragonfly is in tandem flight. Thus, it may serve as an adaptation to save the head from violent mechanical disturbance and to stabilize gaze in a variety of behavioural situations. This study shows the evolutionary trend of the arrester in the order Odonata by using scanning electron microscopy and measurements of arrester structures in 227 species from 26 odonate families. The arrester design occurring in the Epiophlebiidae, Gomphidae, Neopetaliidae, Petaluridae and Chlorogomphinae is suggested to be the basic one. Two convergent pathways of head-arrester evolution among Zygoptera and Anisoptera are proposed. The possible functional significance of the arrester system is discussed." (Author)]

["Damselflies are suitable subjects for examination of a variety of biological questions, but most research has been carried out in the field. Several questions are hard to test because of the uncontrolled conditions inherent in field studies. This can be circumvented by studying

populations in semi-natural outdoor insectaries. We assessed the suitability of such insectaries by comparing the survival and adult behaviour of *Ischnura elegans* (Vander Linden) in insectaries and in the field. Our results showed that damselflies behaved differently under experimental conditions. Nevertheless, outdoor insectaries can be regarded as a valuable tool to elucidate questions concerning life history traits since they offer the possibility to eliminate predation, emi- and immigration and hidden life." western Australia. *Freshwater biology* 41: 299-316. (in English).

["1. The northern half of Western Australia is a large, sparsely populated area with a climate that ranges from monsoonal in the Kimberley to arid in the Gascoyne and Pilbara regions. The aquatic invertebrate fauna is poorly known. 2. Fifty-one sites located on 14 river systems were sampled three times between August 1994 and October 1995. A total of 90 taxa, most identified to family level, were collected. The fauna was dominated by insects, which constituted 74% of the total number of taxa collected. 3. Major habitats at each site were sampled separately and sites with more habitats tended to have a richer fauna. All habitats showed significant differences in taxonomic richness between regions. Family richness decreased with increasing latitude, being highest in the Kimberley region and lowest in the Gascoyne. 4. Despite the differences in taxon richness between regions, community composition of the aquatic invertebrate fauna at the family level did not differ greatly. Four major groups of sites were identified by cluster analysis, based on the invertebrate families present at each site, but differences between groups were small. 5. Significant temporal variation in taxon richness was found in channel habitat but not the three other habitats sampled (riffle, macrophyte, pool-rocks). Community composition in channel habitat varied temporally among groups of sites identified by cluster analysis but the pattern was not consistent." (Authors) The Odonata (8 families) are listed for the sampled 51 river sites in appendix 1.]

739. **Lüderitz, V.; Hentschel, P. (1999):** Umgestaltung des Landeskulturgrabens bei Dessau. Ein Beispiel für den Umgang mit anthropogenen Fließgewässern. *Naturschutz und Landschaftsplanung* 31(1): 18-23. (in German with English summary).
["Recultivation of the 'Landeskulturgraben' in Dessau as an example of the treatment of anthropogenic water bodies. The 'Landeskulturgraben' is a small canal in the Biosphere Reserve 'Mittlere Elbe', the ecology of which had been severely disturbed. In 1994 the canal bed structures were ecologically enhanced by different measures. By creating meanders, stillwater coves, course widenings, separated ponds and shallow banks the eco-morphological grade increased from 4.5 to 2.5. Water quality improved from class II-III (critically loaded) in

1994 to class II (moderately loaded) in 1995/1996. The number of macroinvertebrate species increased from 38 to 85. the number of water and amphibic plant species grew by 27." (Authors). 13 species of Odonata are listed: 4 species in 1993, and 13 in 1996/97. Most of the (regional) typical Odonata of ditches could be recorded, a good indication of the success of the measures.]

740. **Marchant, R.; Hirst, A.; Norris, R.; Metzeling, L. (1999):** Classification of macroinvertebrate communities across drainage basins in Victoria, Australia: consequences of sampling on a broad spatial scale for predictive modelling. *Freshwater biology* 41: 253-268. (in English).
["Spatial scale may influence the interpretation of environmental gradients that underlie classification and ordination analyses of lotic macroinvertebrate communities. This could have important consequences for the spatial scale over which predictive models derived from these multivariate analyses can be applied. 2. Macroinvertebrate community data (identified to genus or species) from edge and main-channel habitats were obtained for sites on rivers from 25 of the 29 drainage basins in Victoria. Trends in community similarity were analysed by carrying out separate multivariate analyses on data from the edge habitats (199 sites) and the main-channel habitats (163 sites). 3. Hierarchical classification (UPGMA) showed that the edge data could be placed into 11 site groups and the main-channel data into 12 site groups. 4. Ordination analysis (hybrid multidimensional scaling) showed no sharp disjunctions between site groups in either habitat; overlap was frequent. Correlation of the ordination patterns with environmental variables showed that edge communities varied, longitudinally within a drainage basin and from the east to the west of Victoria. These two trends were superimposed on one another to form a single gradient on the ordination. The taxon richness of edge communities was also related to the species richness of macrophytes at a site. Main-channel communities also displayed a longitudinal and a geographic gradient, but these two gradients were uncorrelated on the ordination. 5. Community similarity only weakly reflected geographic proximity in either habitat. A preliminary subdivision of Victoria into a series of biogeographic regions did not match the pattern of distribution of site groups for the edge habitat, illustrating the difficulties of applying to lotic communities a priori regionalizations based on terrestrial features of the landscape. 6. The longitudinal gradients in the two data sets were commonly observed in data gathered at smaller spatial scales in Victoria. The other gradients (geographic, macrophyte), however, were either not consistently repeated or not evident at smaller spatial scales. At small spatial scales (i.e. within a single drainage basin) gradients were related to variables that varied over restricted ranges, e.g. mean particle size of the substratum. 7. Species richness was very variable when plotted against river slope or distance of site from source; both of these are measures of position on the longitudinal gradients. In contrast to suggestions in the literature, species richness did not show a unimodal trend on these gradients, or any other trend. 8. Environmental gradients (apart from longitudinal gradients) that underlie predictive models of macroinvertebrate distribution are reflections of the spatial

scale on which the model has been constructed and cannot be extrapolated to different scales. Models must be suited to the spatial scale over which predictions are required." (Authors). At the species level *Ischnura heterosticta* was classified as edge taxon, and *Austroaeschna pulchra* and *Notoaeschna sagittata* als main-channel taxa.]

["Dragonfly census in Flanders: the first results of a pilot project in the "Kalmthoutse Heide" (Antwerp) in 1998. In order to follow and evaluate the long-term evolution of the odonatofauna in Flanders, a monitoring scheme is necessary. In Flanders, such a project has not yet started, but it has been decided to start a pilot project at several sites, e.g. in the 'Kalmthoutse Heide' (province of Antwerp). The first results are given here. Seven fens have been visited regularly during the flying season. The same transect has been followed and adults and exuviae have been counted over a strip of 3 meters wide. A total of 24 species have been detected, 6 of them 'Red List' species: *Coenagrion lunulatum*, *Cordulia aenea*, *Leucorrhinia dubia*, *Lestes virens*, *Ceragrion tenellum*, and *Aeshna juncea*. For next year, it has been proposed to count two transects of 5 fens each instead of one transect of 7 fens." (Author)]

["1. Water-filled ditches are an important ecological feature of lowland Britain. Originally dug to facilitate wetland drainage, ditches often provide refuges for aquatic flora and fauna of high conservation value. 2. The ditches, ponds and major waterways of a traditionally managed undrained fen and the ditches of a previously drained cattle-grazed fen meadow were sampled at Wicken Fen National Nature Reserve for Coleoptera, Mollusca and Odonata, and for physical, chemical and biological variables. 3. Multivariate analysis showed a clear division between ditches on the two fens, and between larger and smaller waterbodies. 4. Individual ditches possessed distinctive faunas. Ditch age and bank profile were important factors influencing faunal species composition. 5. Invertebrate distributions were shown to be significantly correlated with macrophyte distribution. 6. Waterbodies were ranked in terms of their species quality, using a point-scoring system; there was no cor-

relation between rankings for the three invertebrate groups; only ditch age and detritus levels were correlated with species quality score (for Coleoptera). 7. Ditch management recommendations are discussed in the light of these results." (Author); 14 odonate taxa are listed]

750. **Parr, A. (1999):** Late season records of Emperor Dragonfly *Anax imperator*. *Atropos* 6: 33-34. (in English).

[in 1998 in the UK, *A. imperator* was on the wing late in September and early in October, and fresh exuviae were found in September. "The autumn records described above, and in particular the fresh exuviae found in September, clearly do not fit this pattern (of *A. imperator* as a 'spring species'). It is possible that some individuals encounter conditions which overcome their diapause and allow an autumn emergence. A more likely explanation is that autumn Emperors are the progeny of immigrants from Mediterranean Europe or North Africa, where the species may be adapted to conditions which favour more rapid development, or where no larval diapause is necessary. The Green Darner *Anax junius*, which is the commonest *Anax* species in North America, is known to have a migrant form which produces an autumn generation of adults from eggs laid by migrants in early summer (Trottier 1971), and perhaps immigrant Emperors can also follow this strategy. It is of interest that the September exuviae of the Emperor that have been found in recent years have all come from areas where Red-veined Darter *Sympetrum fonscolombei* were also breeding at the time. This supports the immigrant hypothesis, and may give some hints as to the possible origins of any incoming spring adults. It is of course possible that some of the autumn Emperors may themselves be primary immigrants." (Author)]

["On 1 October 1998, my husband and I observed the homeochromic female Green Darner *Anax junius* on Tresco, Isles of Scilly, for a period of 40-45 minutes. It was discovered the previous day and had remained perched in the same position since discovery. Notes taken at the time describe an interesting sequence of events. My initial observations describe an insect with

pale blue either side of the brown central line on the abdomen. The impression of a pale grey-blue and dull dragonfly was disappointing as I had seen [a colour picture in the periodical; M. Sch.] *Atropos* and was expecting something more spectacular! Notes on a later sketch indicate brown eyes, leaf green thorax, brown wing-base and blue-green on the abdomen as opposed to the pale grey-blue noted earlier. There were blue/green spots on the last segments above the anal appendages. In the last few seconds before it flew, the blue suddenly became a brighter turquoise colour, contrasting with the chocolate-brown central line. With a flash of metallic blue/green it was gone. The impression was that earlier colour changes had been subtle as the day became warmer, and the final changes were very sudden and marked. We watched the insect for a long time and if I hadn't been watching the whole time, I would have been adamant that there were two insects." (Verbatim)]

765. **Samways, M. (1999):** Diversity and conservation status of South African dragonflies (Odonata). *Odonatologica* 28(1): 13-62. (in English).

["To date, 155 spp. have been recorded in South Africa; 29 spp. (18.7%) are endemic. *Metacnemis angusta* and *Paragomphus dicksoni* are only known from female specimens and are of doubtful taxonomic status. *Chlorolestes apricans*, *C. draconica*, *Ecchlorolestes nylephtha*, *E. peringueyi*, *Metacnemis valida*, *Pseudagrion inopinatum*, *P. unsingaziense*, *Enallagma polychromaticum*, *Ceratogomphus triceraticus*, *Syncordulia gracilis*, *S. venator*, *Orthetrum rubens* and *Urothemis luciana* are ecologically threatened. *Chlorolestes apricans* and *U. luciana* are of particular concern. *C. apricans*, whose populations have declined in recent years, appears not to occur in any protected area. [...] Not all anthropogenic disturbance is harmful to Odonata. Small dams play an important role in geographically increasing the overall density of many lentic spp. Similarly, the aquatic weed *Pistia* enhances local species richness in the Krüger National Park. Most major human disturbances however, are harmful to population levels. Exotic tree plantations within 30m of the river's edge reduce species richness. The rainbow trout is implicated in causing range retraction of the very rare and threatened *E. peringueyi*, while removal of natural forest in the southern Cape has eliminated populations of the equally rare *E. nylephtha*. Cattle grazing, resulting in bank vegetation destruction, and black wattle infestations along Eastern Cape river banks have had a major adverse impact on *C. apricans*. These factors are synergistic with lowered water levels in causing population fragmentation. [...] Presence of rare species in nature reserves does not necessarily guarantee their survival." (Author)]

766. **Sawabe, K.; Higashi, K.; Kanda, K.; Nagase, K. (1999):** Genetic variability and differentiation in isozymes in *Mnais damselflies* of Fukuoka in Japan (Zygoptera: Calopterygidae). *Odonatologica* 28(1): 63-78. (in English).

["To analyze the genetic differences, *M. pruinosa* and *M. nawai* were collected in 2 localities of Fukuoka Pref. Kyushu, Japan. In the Hisayama area, 2 forms of *M. pruinosa* males occur, viz. orange winged f. *esakii* and clear winged f. *strigata*, and one female form with clear wings f. *sieboldi*. In the Kami-ishigama area, *M. pruinosa* and *M. nawai* both occur and the forms of *M. pruinosa* also f. *esakii*, f. *strigata* and f. *sieboldi*. 2 forms of *M. nawai* males are also found, the orange winged f. *nawai* and the pale-orange winged f. *sahoi*, and one female form with pale-orange wings f. female *-nawai*. The genetic differences among the samples collected in the areas were assessed by electrophoretic analysis. 21 protein loci of 10 proteins were analyzed by 5 % polyacrylamide gel electrophoresis; 2 of the 21 loci were monomorphic. [...] Conclusion: (1) For the male strains, two polymorphic forms of *M. pruinosa*, f. *esakii* and f. *strigata*, and also two forms of *M. nawai*, f. *nawai* and f. *sahoi*, belong to single species, respectively. (2) The males of *M. pruinosa* and *M. nawai* belong to separate species. (3) All the females are genetically close to each other, though they include those of two different species, *M. pruinosa* and *M. nawai*." (Authors)]

 ["Swimming is the most important escape mechanism in leetid damselflies. The effect of lamellae autotomy and sexual size dimorphism on startle-response performance was studied experimentally in larvae of the leetid damselfly *Lestes sponsa*. In contrast with the prediction of McNeill (1960) that lamellae loss would not affect swimming speed in fast swimmers such as *Lestes* larvae, swimming performance decreased in a quadratic way with the removal of subsequent lamellae. Lamellae autotomy therefore will considerably reduce the probability of escape from a predator. Larger larvae swim faster than smaller ones of the same instar. This may contribute to a higher survival of larger larvae compared with smaller ones when confronted with both conspecific and heterospecific predators. Despite larvae showing sexual size dimorphism, with females being larger, no difference in swimming speed between the sexes was found." (Author)]

775. **Suhling, F. (1999):** Effects of fish on the micro-distribution of different larval size groups of *Onychogomphus uncatus* (Odonata: Gomphidae). *Arch. Hydrobiol.* 144(2): 229-244.

["Four types of field experiments were carried out in order to study the effects of fish predation on different size groups of burrowing larval dragonflies *Onychogomphus uncatatus* (CHARP.). (1) The effects of the bottom feeding fish *Barbatula* (*Nemacheilus*) *barbatula* (L.) on three size groups of *O. uncatatus* in three types of substrate: sand, gravel and stones, were recorded using field enclosure cages. The densities of small sized larvae inhabiting cages with stones and gravel were reduced in the presence of fish compared with fish-free controls. No effects due to fish presence were found in larger larvae. (2) The colonisation of sand, gravel and stones in the field by different size groups of *O. uncatatus* was studied using frames filled with substrates. Substrate as well as size specific effects were found. The low density of small larvae in coarse substrates is interpreted mainly as a direct effect of predation by *B. barbatula* which exclusively colonised these substrates. (3) To test the effect of exclusion of all fish on colonisation of *O. uncatatus*, frames filled with stones were exposed in a running water and half of these were protected by cages. The densities of very small and medium sized larvae in the protected substrates were higher than in those without cages. (4) In cages with a wide mesh size, which allowed a free exchange of dragonfly larvae and *B. barbatula* but prevented predation by large fish, the density of small larvae of *O. uncatatus* was reduced. *B. barbatula* were found exclusively inside the cages. It is suggested that predation by *B. barbatula* using the cages as a shelter against predation by large fish was responsible for this reduction." (Author)]

Pacific Science 51 (4): 395-412. (in English). ["A phylogeny of the 22 species currently recognized in the genus *Megalagrion*, endemic to the Hawaiian Islands, is presented based on an analysis of 23 morphological and ecological characters. After the exclusion of *M. williamsoni*, known from only a single male, and inclusion of subspecies within their nominate taxa, a single resolved tree of length 85 was obtained; this tree has a consistency index of 0.56 and a retention index of 0.72. Based on this phylogeny, it appears that the major clades within *Megalagrion* differentiated on Kaua'i or an antecedent high island. These clades subsequently colonized the younger islands in the chain in an independent and sequential fashion. The phylogeny also implies an ecological progression from ancestral breeding sites in ponds or slow stream pools to breeding on seeps, with the latter habitat having given rise on one hand to a clade of species breeding in phytotelmata or terrestrially, and on the other hand to a clade breeding in rushing midstream waters. The latter ecological progression also indicates a transformation series in larval gill structure from foliate to saccate and eventually to lanceolate. Most species of current conservation concern are shown to be clustered in particular clades, indicating an inherent phylogenetic vulnerability of certain taxon clusters to novel ecological perturbations; the additional species at risk not present in the above clades are endemics confined to the island of O'ahu and have declined because of their geographic provenance." (Author)] Address: Polhemus, D.A., Department of Entomology, MRC 105, National Museum of Natural History, Smithsonian Institution, Washington, D.C.20560, USA

805. **Bechly, G. (1998):** A revision of the fossil dragonfly genus *Urogomphus*, with description of a new species (Insecta: Odonata: Pananisoptera: Aeschniidae). Stuttgarter Beiträge zur Naturkunde Ser. B., 270: 1-47. (in English, with German summary). ["The dragonfly genus *Urogomphus* from the Upper Jurassic of Germany is revised and its position in Aeschniidae is confirmed. *Urogomphus giganteus* and *U. eximius* are redescribed, and a lectotype for *U. eximius* is designated. *Lithoaeschnidium viohli* is considered as a synonym of *U. eximius*. A new species *Urogomphus nusplingensis* n. sp. is described from the Upper Jurassic Lithographic Limestone of Nusplingen, while the 20 other known specimens of this genus have been found in the Solnhofen Lithographic Limestone. *Urogomphus abscissus* is considered as conspecific with *Bergeriaeschnidia inexpectata*, and the holotype of the latter species is designated as neotype of *U. abscissus*, so

that its valid name is now *Bergeriaeschnidia abscissa* comb. nov. The phylogenetic position of *Urogomphus* and Aeschniidae is discussed, a new taxon *Neoanisoptera* is introduced, and an explanation for the extinction of Aeschniidae is proposed." (Author)] Address: Bechly, G., Institut und Museum für Geologie und Paläontologie, Geowissenschaftliche Fakultät der Eberhard-Karls-Universität, Sigwartstr. 10, D-72076 Tübingen, Germany. 807. **Bechly, G. (1998):** New fossil dragonflies from the Lower Cretaceous Crato Formation of north-east Brazil (Insecta: Odonata). *Stuttgarter Beiträge zur Naturkunde Ser. B*, 264: 1-66. (in English, with German summary). ["An overview of the fossil odonate fauna of the Crato Formation from the Lower Cretaceous of Brazil is given. Currently 351 specimens (241 adults and 110 larvae) in 12 families and 32 species are known to science. More than half of the adult and larval fossil odonates belong to the gomphid clade (= Gomphides), especially to the Cordulagomphinae which supports the hypothesis of an allochthonous origin of the aquatic insects. Six new species are described: *Araripegomphus andreli* n. sp. (Araripegomphidae), *Cordulagomphus (Procordulagomphus) stat. nov.* *senckenbergi* n. sp. (Proterogomphidae - Cordulagomphinae), *Araripephlebia mirabilis* n. gen. et n. sp. (Araripephlebiidae n. fam.), *Cratocordulia borschukewitzi* n. gen. et n. sp. (Araripephlebiidae), *Cretarchistigma (?) essweini* n. sp. (Zygoptera incertae sedis), and *Parahemiphlebia mickoleiti* n. sp. (Hemiphlebidae). With a wing length of only 9 mm the latter new species represents one of the smallest odonates of all times. *Araripephlebia mirabilis* n. gen. et n. sp. is classified in a new family Araripephlebiidae n. fam. which probably represents the sister-group of extant Chlorogomphoidea. A still unnamed new genus and species represents the first fossil record and the first New World record for Chlorogomphoidea s. str. Four further new species are illustrated, but not yet described. The phylogenetic relationship of several known species is discussed, and some diagnoses are amended or corrected. Giant dragonfly larvae of up to 70 mm length are described, regarded as older stages of *Nothomacromia sensibilis* (CARLE & WIGHTON, 1990), and considered as larval Aeschniidae. Consequently, the family-group taxa Sonidae PRITYKINA, 1986 and Nothomacromiidae CARLE, 1995 (= "Pseudomacromiidae" sensu CARLE & WIGHTON, 1990) are here regarded as junior subjective synonyms of Aeschniidae NEEDHAM, 1903. The position of Araripegomphidae in the stem-group of Gomphides rather than *Eurypalpida* (= Libelluloidea auct.) is advocated (contra LOHMANN 1996). The former genus *Procordu-*

lagomphus NEL & ESCUILLIÉ, 1994 is down-ranked to a subgenus of *Cordulagomphus*. "*Cordulagomphus*" *santanensis* CARLE & WIGHTON, 1990 is recognized as earwig and thus transferred from Odonata - *Cordulagomphinae* to *Dermaptera incertae sedis*. A comparison with the odonate fauna of the Upper Jurassic Solnhofen limestones reveals several remarkable differences. Because of the absence of typical Mesozoic odonate groups, such as "anisozygopteres", Archizygoptera and Steleopteridae, as well as the presence of extant families of Zygoptera, the odonate fauna of the Crato Formation appears to be significantly more advanced." (Author)] Address: Bechly, G., Institut und Museum für Geologie und Paläontologie, Geowissenschaftliche Fakultät der Eberhard-Karls-Universität, Sigwartstr. 10, D-72076 Tübingen, Germany. 812. **Brunelle, P.-M. (1998):** The status of *Somatochlora brevicincta* Robert 1954 (Odonata, Anisoptera, Cordulidae) in Nova Scotia. Report on study under a 1998 Nova Scotia Museum Research Grant. Unpubl. Report November 1998: 27 pp. (in English). ["*Somatochlora brevicincta*, the Quebec Emerald, is a rare Dragonfly of international conservation concern, IUCN 1996 Red List included, which had previously been known from a very limited range in mid-northern Quebec. Pilon and Lagace (1998) show 7 sites in Quebec for the species [...]. It

for the species [...]. It had recently been discovered to have been collected in the Cape Breton Island Highlands in the early 1980's, and in 1997 was taken in New Brunswick. The CBI range extension is approximately 1050 km, indicating both that the species has a substantially greater range than previously thought, and that it is very elusive throughout much of that range. In June of 1998 an abundant population of the species was found by Stuart Tingley at a small quaking bog on Highway 108 in mid-northern New Brunswick. This unexpected discovery indicated that our assumptions of habitat type and flight period, based upon knowledge of the species in Quebec, do not necessarily hold true for the Maritime Provinces. As a result, the sampling program undertaken by Brunelle in the summer of 1998 did not serve to address the habitat-specific characteristics of the species during what is now thought to be the appropriate season (June-July), although appropriate habitat was located which will assist in the search for breeding populations during 1999. Notwithstanding this, a female of the species was taken in Cumberland County in August. This collection is the furthest to the south that the species has yet been taken and the first record for the Nova Scotian mainland. In addition to its principal objective, the sampling program was intended to increase our knowledge of peatlands Dragonflies and Damselflies, and of general Odonate distribution in rarely-sampled areas of the province. A number of significant range extensions of species rare in the Province were discovered during the course of the work [...]. Due to the relatively low specific return of the survey, I have decided to present in this report detailed information on the overall distribution of the order in the Province. Such a review has not been done since Walker (1942), although general distribution was presented in Brunelle (1997). [...]. The report [...] is comprised of Section 1: Highlights of 1998 Survey Discoveries (*Somatochlora brevicincta*, *Aeshna subarctica*, *Enallagma aspersum*, *Aeshna sitchensis*, *Ophiogomphus aspersus*, *Somatochlora albicincta*, *S. incurvata*, *S. septentrionalis*, *S. tenebrosa*, *Nannothemis bella*, and *Pantala hymenaea* are treated in detail with colour picture of the species and habitats, and distribution maps), Section 2: Synthesis of Existing Knowledge: Figure 1: 186 Distribution Maps of Regional Odonata; Table 1: Distribution by County of Nova Scotian Odonata, and Table 2: Flight Periods of Nova Scotian Odonata." (Author). The study of P.-M. Brunelle was also funded by the INTERNATIONAL DRAGONFLY FUND.] Address: Brunelle, P.-M., 2460 John Street, Halifax, Nova Scotia, B3K 4K7, Canada

814. **Carbone, J.; Keller, W.; Griffiths, R.W. (1998):** Effects of changes in acidity on aquatic insects in rocky littoral habitats of lakes near Sudbury, Ontario. Resto-

ration ecology 6(4): 376-389. (in English). ["Benthic aquatic insects were collected from rocky nearshore areas (<1 m deep) of 17 lakes near Sudbury, Ontario, with a pH range of 4.7-7.3 and a size range of less than 10 ha to over 10,000 ha. These insect communities were composed of taxa common to lake soft-sediments and streams. Direct and indirect effects of lake acidity appeared to be major controls on the structure of these communities, implying that several factors may be involved in restructuring during acidification or recovery. Declines in abundances of several taxa of Ephemeroptera at pH below 5.5 were attributable to acid toxicity, while increases in the abundances of Odonata and Diptera at pH below 5.5 were associated with the absence of fish predators and other indirect effects of acidity. The communities of two experimentally neutralized lakes restructured rapidly within 5 years, approaching but not achieving community structures typical of our near-neutral survey lakes. Neutralization led to recolonization or increased abundance of the acid-sensitive mayfly, *Stenacron interpunctatum*, and the dragonfly, *Boyeria grafiana*; however, recolonization by other taxa expected to be present in near-neutral lakes (*Stenonema femoratum*, *Eurylophella*, and *Basiaesha janata*) was not observed. Consistent with results for the survey lakes, declines in the abundances of the dragonflies *Aeshna interrupta*, *Aeshna eremita*, and *Leucorrhinia glacialis* in the neutralized lakes were associated with reintroductions of *Salvelinus fontinalis* (aurora trout) and increased fish predation pressure, while reduced abundances of the dipterans *Ceratopogonidae*, *Psectrocladius*, and *Stackelbergina* may be related to indirect effects of acidity other than fish predation. Although community composition varied greatly across the acidity gradient, total species richness and abundance were not correlated with lake chemistry or number of fish species." 817. **Griffioen, R.H.W.; Uilhoorn, H.M.G. (1998)**: *Sympecma paedisca* (Brauer) in the Weerribben and the Kuinderplas. *Brachytron* 2(2): 35-43. (in Dutch, with English summary). ["Two populations of *Sympecma paedisca* [...] were discovered in 1997 and 1998 in the Weerribben (province of Overijssel) and the Kuinderplas (Flevoland). It was the first time in more than 20 years that populations of this species were found in the Netherlands. The populations are present in a lake created by sanding (Kuinderplas) and a lowland mire (the Weerribben). Similarities between the two Dutch locations are a forested environment and non-acidic, clear water with reed-beds. The reed-beds are characterised by an open vegetation structure and locally dead floating plant material. The fact that the species only survived here is somewhat surprising as both habitat-types were not mentioned in the Dutch literature as favoured habitats. In both areas neither groundwater nor water-level fluctuations play a major role. This is also in contrast with habitat information in foreign literature. The last two years *S. paedisca* was found from half August onwards into autumn. In the spring of 1998 the species was observed from the beginning of May until the beginning of June. Most reproductive activity took place during a warm spell in the beginning of May. The flight period in spring was later than expected on account of historical observations. The choice of substrate for oviposition was restricted, in both areas nearly only dead floating plant material was used (especially stalks of reed and reed-mace). The question why *S. paedisca* only survived here and its habitat requirements are discussed. The answer on the first question is rather speculative. Perhaps the acidification of the balks ('legakkers') and the intensity of haymaking during the summer are important factors. The habitat requirements are largely unclear. The Dutch populations survived under conditions which lacked elements that were thought to be essential. Minimal requirements for reproduction are non-acidic water which is available during the summer and is partly overgrown with water vegetation. For adult survival certain structural conditions must be met." (Authors)] Address: Griffioen, R., Uilhoorn, Karin, Trekker 82, NL-8447 BZ Heerenveen, The Netherlands. E-mail: uilhoorn@tip.nl

818. **Hardersen, S.; Wratten, S.D. (1998)**: The effects of carbaryl exposure of the penultimate larval instar of *Xanthocnemis zealandica* (Odonata: Zygoptera) on emergence and fluctuating asymmetry. *Ecotoxicology* 7: 1-8. (in English). ["The occurrence of pesticide residues in freshwater systems has become a concern in recent decades. In order to establish biomonitoring programs it is vital to investigate the response of organisms to varying concentrations of pesticides. Levels of pollutants fluctuate in freshwater systems and thus only some instars of aquatic insects may be exposed to pollution stress. Therefore it is important to investigate the effects of exposing selected instars of potential bioindicator species. In a laboratory experiment damselfly larvae of the penultimate instar were exposed to three concentrations of carbaryl (100 ppb, 10 ppb, 1 ppb) plus controls until the adult damselflies emerged. Carbaryl at 100 ppb reduced emergence by more than 90%. The lower carbaryl concentrations did not affect emergence success but increased the developmental speed slightly. The adult damselflies from the highest

concentration which did not affect emergence success (10 ppb) were analyzed for their level of fluctuating asymmetry (FA), deviation from bilateral symmetry, and compared with those from controls. The level of FA in cell patterns in wings was increased whereas the level of FA for wing length did not show any differences." (Authors)] Address: Hardersen, S., Lincoln Univ., Div. Plant Soil & Ecol. Sci., POB 84; Canterbury; New Zealand. E-mail: Framptoc@lincoln.ac.nz

824. **Ketelaar, R.; & Wal, B.G. van der (1998):** Return and habitat preference of *Gomphus vulgatissimus* in the eastern part of The Netherlands. *Brachytron* 2(2): 44-51. (in Dutch, with English summary). ["At the beginning of the 20th century, *G. vulgatissimus* was a moderately common species in The Netherlands. A sudden decrease occurred and the last specimen in the eastern part of The Netherlands was seen in 1925. In 1994, *G. vulgatissimus* was rediscovered along the Buurserbeek. More new localities were found in subsequent years (Overijsselse Vecht, Dinkel, Berkel and Slinge). The population of the Buurserbeek is probably the largest in The Netherlands. *G. vulgatissimus* inhabits larger streams and rivers, with a relatively high temperature and low water velocity. Most populated streams are canalised. Previous conclusions of *G. vulgatissimus* being a species of natural streams must be rejected. It is concluded that the recent improvement of the water quality positively influenced the expansion, of the species. Furthermore, the possible but largely unknown influence of the recent warm summers is discussed." 827. **Kleukers, R. M. J. C.; Reemer, M. (1998):** The return of the Yellow-legged Dragonfly [*Gomphus flavipes* (Charpentier)] to the Netherlands. *Brachytron* 2(2): 52-59. (in Dutch, with English summary). ["Until a few years ago *G. flavipes* was thought to be extinct in the Netherlands. The last records dated from 1902. The discovery of a larva of this species in the cooling-water filters of a powerstation in 1996 indicated that *G. flavipes* might have returned to the Netherlands. In 1998 more larvae were found at the powerstation and several fieldtrips were undertaken to confirm the return of the species. At eight localities along the river Waal (lower course of the Rhine) near Nijmegen in the eastern part of the Netherlands, teneral adults and/or exuviae were found. This proves that *G. flavipes* has returned as a breeding species in the Dutch riversystem. The recent return of *G. flavipes* corresponds with the expansion in Germany. The causes of the expansion are not clear. In

search for *G. flavipes* along the river Waal, several e-xuviae of *G. vulgatissimus* were found as well. This species had also not been recorded in large Dutch rivers for a long time." 834. **Moravec, F.; Skorikova, B. (1998):** Amphibians and larvae of aquatic insects as new paratenic hosts of *Anguillicola crassus* (Nematoda: Dracunculoidea), a swimbladder parasite of eels. *Diseases of aquatic organisms* 34(3): 217-222. (in English). ["Amphibians (tadpoles of the frog *Bombina orientalis* [L.] and the new *Triturus vulgaris* [L.]) and aquatic insects (larvae of the alderfly *Sialis lutaria* [L.] [Megaloptera], dragonflies *Sympetrum sanguineum* [Muller] and *Coenagrion puella* [L.] [Odonata], and the caddisfly *Oligotrichia striati* [L.] [Trichoptera]) were found to serve as paratenic hosts for the third-stage larvae (L-3) Of the nematode *Anguillicola crassus* Kuwahara, Niimi et Itagaki, 1974, a pathogenic swimbladder parasite of the eel *Anguilla anguilla* (L.) in Europe and elsewhere. This is the first evidence that, in addition to prey fishes and some aquatic snails, amphibians and aquatic insects can serve as paratenic hosts for this nematode parasite. A. crassus third-stage larvae were found, largely unencapsulated (encapsulated only in *S. lutaria*), mostly in the body cavity, on the gut surface and, less often, in the liver and in the subcutaneous tissue of legs in amphibians, and in the body cavity and on the gut surface in insect larvae; they could survive for at least 49 d in *T. vulgaris* and 69 d in *S. lutaria*. The capability of these larvae from *S. lutaria* (69 d post-infection) to infect the definitive host (eel) was confirmed by experimental infection of an eel." (Authors)] Address: Moravec, F., Acad. Sci. Czech Republic, Inst. Parasitol., Branisovska 31, CR-37005 Ceske Budejovice; Czech Republic. E-mail: moravec@paru.cas.cz

835. **Mostert, K. (1998):** Dragonflies (Odonata) in the agricultural landscape of South Holland. *Levende Natuur* 99(4): 142-149. (in Dutch, with English summary). ["Between 1994-1997 information on numbers and distribution of dragonflies was systematically collected in the province South Holland. Dragonflies were counted throughout summer in linear transects with a length of 50 m along various water bodies, after which numbers were extrapolated to the number of individuals per kilometer (table 2); all flying and resting dragonflies a-

long the neighbouring half of the water were included. Habitats were divided in meadows, arable land, nature reserves, recreational areas and urban areas (table 3). Water transparency was noted in six classes (varying from very turbid to very clear), width of the water was noted in four classes (table 1). Transects were randomly selected and are representative of the area. Only eight species made up 98% of the total number of individuals sighted. In 40% of the transects with Dragonflies the Blue-tailed Damselfly (*Ischnura elegans*) was the only species recorded. Numbers and densities of dragonflies in nature reserves were five times higher than those in areas with arable land and meadows; species variety was also much higher in nature areas than anywhere else. Furthermore, numbers near watercourses in urban areas were higher on average than those in agricultural areas. Numbers as well as densities are higher above water with high transparency. Moreover wide edge of vegetation and numbers of dragonflies are strongly correlated. Lowest densities were found near water with duck-weed (*Lemnaceae* and *Azolla filiculoides*) and, although less obvious, with sheetpiling. Numbers at eutrophic water are comparably low. It is concluded that small nature reserves created in agricultural areas will be beneficial for numbers and densities of dragonflies as well as for species diversity, as preliminary results have already shown." (Author)] Address: Mostert, K., Palamedesstraat 74, 2612 XS Delft, The Netherlands

836. **Nachtigall, W.; Kesel, A.; Kreuz, P. (1998):** The dragonfly wing as a static construction: bending by aerodynamic forces (Odonata: Anisoptera). *Entomologia Generalis* 23(1-2): 139-148. ["Using a high speed shutter camcorder changes of shape (twisting, camber and especially bending) of the wings of *Aeshna cyanea* [Müller 1764] and *Sympetrum vulgatum* [Linné 1758] were recorded in a natural environment during hovering, acceleration from hovering and fast vertical starting from a watching position. ... The nodus is an element that allows for a certain local bending between the distal and basal wing part. It is working even at lower aerodynamical loading. Its morphology is functionally interpreted. Wing bending is simulated with Finite Element calculations and compared to the field observations."] Address: Nachtigall, W., Univ. Saarland, Inst. Zool., D-66041 Saarbrücken, Germany

Diplomarbeit am Fachbereich 2 "Landschaftsnutzung und Naturschutz" der Fachhochschule Eberswalde: 148 pp, 2 Anhänge. (in German). [This is a very sound M.Sc.-thesis on the Odonata of the Island of Krk, Croatia. In 1997 and 1998, 45 water bodies were surveyed for Odonata. Each of these water bodies is described and mapped in detail (Annex 1). Prior to 1997, 27 taxa were known from published or personally communicated data (documented in tab. 3). 14 species could be traced for the first time after March 1997. Three species (*Coenagrion ornatum*, *Orthetrum albistylum*, *Selysiotthemis nigra*) remain without present-day record. Expressed as presence on a water body, the rarity of the species is shown in fig. 12. In Chapter 7 dragonfly zoenoses are worked out. Chapter 8 (species monographs) contains very interesting details on the odonate fauna of Krk: Distribution in Croatia and on the Island of Krk, phenology, ecology/biology, and in the cases of *Calopteryx splendens*, *Chalcolestes viridis* / *C. parvidens*, *Onychogomphus forcipatus*, *Somatochlora meridionalis*, and *Orthetrum coerulescens* / *O. anceps* remarks on taxonomic and morphological problems. Of special interest is the documentation of hybrids between *C. viridis* and *C. parvidens*. In a final chapter the water bodies are assessed for nature conservation purposes. Annex 2 provides distribution maps of all species on the Island of Krk.] Address: Olias, M., Schönberger Str. 51, D-08393 Meerane, Germany

851. **Salmah, M.R.C.; Hassan, S.T.S.; Abu-Hassan, A.; Ali, A.B. (1998):** Influence of physical and chemical factors on the larval abundance of *Neurothemis tullia* (Drury) (Odonata : Libellulidae) in a rain fed rice field. *Hydrobiologia* 389: 193-202. (in English). ["The influence of physical and chemical factors such as pH, temperature, conductivity, dissolved oxygen, nitrate, phosphate and chlorophyll a on larval populations of *Neurothemis tullia* (Drury) (Odonata:Libellulidae) were studied in a rain-fed rice field by collecting larvae and water samples weekly over two seasons of rice planting. Water availability was the main factor determining the presence or absence of larvae in the rice field. The larvae were most abundant during extended periods of continuously plentiful water supply except during flooding. Rapid larval population build-ups were observed soon after chemical applications or spells of dry periods reflecting continual oviposition and hatching of eggs. Pesticides and fertilizer applications resulted in low population densities due to direct or indirect mortality. A stepwise multiple regression showed that within its range, none of the physical and chemical factors measured in this study affected the abundance of *N. tullia*." (Authors)] Address: Salmah, M.R.C., Univ. Sains Malaysia; School Biol. Sci., Minden 11800; Penang; Malaysia

852. **Schorr, M. (1998):** Flußauenlibellen der Mosel und ihre Indikatorfunktion. Aut- und Ethoökologie ausgewählter Arten. Gutachten der Faunistisch-Ökologischen Arbeitsgemeinschaft, Trier im Auftrag der Bundesanstalt für Gewässerkunde / Ref. U3 (Tierökologie), Koblenz. 132 pp. (in German). [detailed compilation of literature data on *Ophiogomphus cecilia*, *Gomphus vulgatissimus*, *Stylurus flavipes*, *Calopteryx splendens*, *Cercion lindenii*, *Erythromma najas*, *Coenagrion mercuriale*, *Orthetrum brunneum*, and *Leucorrhinia caudalis* (larvae and imago); all species are treated according to the following items: Regional Distribution, (potential) occurrence in the River Mosel (Rheinland-Pfalz, Germany), general characterisation of the habitat, aut- and ethoecology of the species, threats, quite extensive bibliography; this compilation is based in most cases on unpublished theses, and provides detailed and unpublished observations; the bibliography comprises 1759 titles; available for DM 30,- plus shipping from the author] Address: IDF, c/o Martin Schorr, Waldfrieden 25, D-54314 Zerf, Germany

(1998):** Die Gebänderte Heidelibelle *Sympetrum pedemontanum* (ALLIONI, 1766) in Nordwest-Deutschland - Stand der Ausbreitung und Beschreibung neuer Fortpflanzungsgewässer (Odonata, Libellulidae). *Mitt. ArbGem. ostwestf.-lipp. Ent.* 14(3): 63-80. (in German, with English summary). ["The present distribution of *Sympetrum pedemontanum* (ALLIONI) in western Lower Saxony and the adjacent parts of Westphalia is described and mapped. The spatial and temporal process of the species' spreading is analysed. It is pointed out that the new records in the western part of the discussed area can obviously be traced back to populations in eastern Lower Saxony and the northern part of Westphalia, which were established in the seventies and eighties." The northwesternmost records are from Zeeland (The Netherlands).] Address: Dense, C., Süsterstr. 20, D-49074 Osnabrück, Germany

854. **Spedding, G.R.; Lissaman, P.B.S. (1998):** Technical aspects of microscale flight systems. *Journal*

of avian biology 29(4): 458-468. (in English). ["Micro Air Vehicles (MAVs) have excellent potential utility as flight platforms for optical, acoustic, electronic and chemical sensors for operation in hazardous sites with aerial access. The dimensions and performance specifications call for a 100 g take-off mass with 100-200 mm wingspan that must fly at 5-20 m/s for approximately 30 minutes. Owing to the low operating Reynolds number (Re), the aerodynamic performance of all lifting surfaces is degraded. The small scales and speeds also mean that atmospheric turbulence has a severe effect, and small thermal cycle engines that could profit from the high energy densities of fossil fuels are unavailable. It is thus difficult to obtain good performance. Studies have been made of vying plus propeller systems, rotor systems and napping wing systems. In all cases, L/D is in the range of 5-10. Flapping is about as efficient as propeller motion at this Re , but more complicated mechanically. The ThrustWing is a configuration derivative of the dragonfly, with characteristics lying between a helicopter and an ornithopter. It has both zero and forward flight capabilities, and appears to have good potential as a MAV configuration. Finally, the effects of atmospheric turbulence are described and shown to fall into four qualitatively different categories as turbulence intensity increases. Due to favourable scaling, the stresses in MAVs will be very low, and although turbulence will cause large G loads on the MAV, no structural damage will result." (Authors)] Address: Spedding, G.R., Univ. So. Calif., Dept Aerosp. Engrg, Los Angeles CA 90089 USA. E-mail: Geoff@ostrich.usc.edu

855. **Tani, J.; Qiu, J.; Yamaguchi, E (1998):** Emergence of the rhythmic movement of a dragonfly wing model. *ISME international journal series (C), Mechanical systems, machine elements and manufacturing* 41(4): 689-694. (in English). ["Living things have the ability to adapt themselves to various environmental conditions and keep the whole system functioning even if a part of it is out of order. Recently, biological systems of living things which can be modeled as autonomous distributed systems have become the focus of attention. In this paper the modeling of the rhythmic movement generating mechanism of dragonfly wings using nonlinear oscillators is described. A wing is approximately modeled as a 1-DOF or 2-DOF beam and the equations of motion are derived. The central pattern generators (CPG) which generate the rhythmic movement of wings are modeled as a set of Van der Pol nonlinear oscillators. By solving the equations of motion of the wing and the equations of oscillators simultaneously, the rhythmic movement of a dragonfly wing model is obtained. The synchronization of multiple wings is obtained by the interconnection of oscillators. It is found that various autonomous vibrations of dragonfly wings can be reproduced using this model." 856. **Van Buskirk, J.; Relyea, R.A (1998):** Selection for phenotypic plasticity in *Rana sylvatica* tadpoles. *Biological Journal of the Linnean Society* 65(3): 301-328. (in English). ["First we reared tadpoles in artificial ponds for 18 days, in either the presence or absence of *Anax* dragonfly larvae (confined within cages to prevent them from killing the tadpoles). These conditioning treatments produced dramatic differences in size and shape: tadpoles from ponds with predators were smaller and had relatively short bodies and deep tail fins. We

estimated selection by *Anax* on the two kinds of tadpoles by testing for non-random mortality in overnight predation trials. Dragonflies imposed strong selection by preferentially killing individuals with relatively shallow and short tail fins, and narrow tail muscles. ... These results indicate that selection is currently promoting morphological plasticity in *R. sylvatica*, and support the hypothesis that plasticity represents an adaptation to variable predator environments."] Address: Van Buskirk, J., Univ. Zürich, Inst. Zool., Winterthurerstr 190., CH-8057 Zürich, Switzerland. E-mail: Van Buskirk, J.: jvb@zool.unizh.ch

858. **Yoshida, M.; Yagi, T; Odonatological Society of Osaka (1998):** Dragonflies and Damselflies (Insecta: Odonata) of Shiga Prefecture, Honshu, Japan. Research Report of the Lake Biwa Museum 10: 284 pp. [Verbatim: Summary Outline of the study: Dragonflies and damselflies (Insecta: Odonata) were collected from Shiga Prefecture, western Honshu, Japan, at ca. 3,000 stations on ca. 700 days from 1985 through 1997 (total: ca. 30,000 occurrence records), mostly by the members of the Odonatological Society of Osaka. Number of species: From Shiga Prefecture 98 species of Odonata are recorded. This figure is one of the highest among Japanese prefectures. The mean number of species found in each of the 50 "Shi-Cho-Son" (city, town or village) districts in Shiga Prefecture is 70. This figure is higher than in any other Japanese prefecture. The number of Odonata species recorded from Otsu-shi is 96, the highest figure in all the Japanese Shi-Cho-Son districts. The reasons for the high species diversity: The great range of freshwater environments including Lake Biwa, rivers flowing into the lake, lakeside ponds etc. is certainly the most important reason for the high species diversity of Odonata in Shiga Prefecture. Another factor may be the low density of human population in Shiga in comparison with the Kyoto-Osaka-Kobe District. Distribution pattern: Distribution patterns of Odonata species in Shiga Prefecture may be classified into five types: a1) inhabiting all or most areas of Shiga, a2) inhabiting Lake Biwa and the lakeside, b1) temporary occurrence by overseas dispersal from the south, b2) temporary occurrence by overseas dispersal from the north and b3) other patterns of temporary occurrence. Distribution of rare species: Rare species of Odonata in lentic habitats of Shiga Prefecture are *Ceriagrion nipponicum*, *Aeschnophlebia anisoptera*, *Somatochlora clavata*, *Libellula angelina*, *Sympetrum maculatum* and *S. uniforme*. They also exhibit restricted distributions in neighboring prefectures, whereas *Sympetrum baccha matutinum* is common in the latter prefectures, but rare in Shiga. In lotic habitats of Shiga Prefecture, rare species of Odonata, *Calopteryx japonica*, *Platycnemis foliacea sasakii*, *Sinogomphus flavolimbatus*, *Davidius moiwanus taruii* and *Macromia daimoji*, tend to occur in the

western part of the prefecture and never occur in the eastern part. This may be attributed to the frequent lack of surface flow in the lower reaches of most rivers in the east. Odonata Fauna of Lake Biwa: The origin of the Odonata fauna of Lake Biwa may be compared with that of the freshwater fishes. A large part of the freshwater fish fauna of Japan is said to have originated in the fishes that inhabited the Second Setouchi Lakes (from Pliocene to middle Pleistocene) including Paleolake Biwa. The same history may also apply to the origin of the Odonata species with weak dispersal ability, such as *Trigomphus citimus tabei*, *T. interruptus*, *T. ogumai*, *Sympetrum gracile* etc. A group of freshwater fishes adapted to large rivers and large shallow lakes (Cyprinidae: Xenocyprinae and Cultrinae) were once (Pliocene) common in Japan, but are now almost extinct there. The history of the dragonfly genus *Stylurus* may be similar to that of these fishes. *Onychogomphus viridicostus* usually occurs in rivers with a gravel bottom, but it is also found on the rocky shore of Lake Biwa, where a characteristic fish fauna is known. Description of each species (pp. 21-118): The distribution, range of adult dispersal, habitat, life cycle, ecology-behavior and other characteristics of all 98 species are described. Two graphs showing the seasons of occurrence of the nymph (top of the respective page) and the adult (middle), and a map of the distribution in Shiga Prefecture (bottom), are presented for each species. Environment destruction: Means of destroying the habitats of Odonata through human modification of the environment are reviewed. Several examples of such destruction observed in the course of this field study are described. Original occurrence records (pp. 136-248): All of the occurrence records obtained in this study are listed. For each, the date is written in the order of "year-month-day", the locality includes the name of the Shi-Cho-Son and the name of the smaller "Ô-aza" district involved, and the seven-digit number refers to the distribution map's grid. Occurrence records from literature (pp. 249-281): Records of Odonata from Shiga Prefecture were compiled from ca. 100 papers, excluding those with doubtful identifications. Because of this exclusion, *Cordulia aenea amurensis* and *Stylogomphus ryukyuanus ryukyuanus* are no longer listed among the Odonata fauna of Shiga Prefecture. (Authors: pp.7-20, Masazumi YOSHIDA; pp.21-120, Takahiko YAGI; the other pages, the Odonatological Society of Osaka) (Translated by Shigekazu UCHIDA with linguistic help of Mark J. ["Soon after amputation of a leg from a final instar larva, granular haemocytes, supported by strands of clotted haemolymph plasma, form a thin cap over the wound, providing the initial wound closure. Cut nerves also appear to attract granular haemocytes and promote organization of a cell sheet covering the wound. Gradually, congregating cells transform the original sheet of cells into a sealing haemocytic plug. Within and across the plug, granular cells form a densely-packed, primary layer like a diaphragm that soon becomes melanized.

This is followed later by one or more deeper, secondary layers which also melanize, but to a lesser extent. The primary, melanized layer serves as a pseudocuticle. Its position appears to be determined by the reorganizing epidermis at the wound edge. Presumably the melanized cell layers reduce leakage of haemolymph plasma from the wound and establish barriers against intruding microbes and other foreign bodies. It is suggested that the sequence of cellular events is similar in all kinds of lesions caused to the zygopteran integument, whether by ectoparasitic invasion or physical damage. It is likely that a resultant alteration in the properties of the subepidermal basement membrane will elicit the haemocytic response." 862. **Aguero-Pelegrin, M.; Ferreras-Romero, M.; Corbet, P.S. (1999):** The life cycle of *Lestes viridis* (Odonata : Lestidae) in two seasonal streams of the Sierra Morena Mountains (southern Spain). *Aquatic insects* 21(3): 187-196. (in English). ["The life cycle of the zygopteran odonate *Lestes viridis* in two seasonal streams in the Sierra Morena Mountains is inferred from size-frequency analyses of handnet samples of larvae and records of presence and reproductive activity of adults during three consecutive years. The egg stage (duration 5-6 months) overwinters, larval development is brief (6-8 weeks) and adults undergo a protracted, prereproductive, summer diapause (up to 3 months) before mating and ovipositing in late September, about one week after the first appreciable fall of rain, but before surface water reappears in the streams after having been absent for about four months during the hot, dry summer. Comparison between this life cycle and those of more northerly populations reveals a latitude-correlated difference in phenology resembling that found in some other northern hemisphere odonates that, like *L. viridis*, maintain an obligatorily univoltine life cycle at different latitudes." 864. **Alzmann, N.; Kohler, B.; Maier, G. (1999):** Spatial distribution, food and activity of *Gomphus pulchellus* SELYS 1840 (Insecta; Odonata; Gomphidae) from a still water habitat. *Int. Revue für Hydrobiologie* 84(3): 299-313. (in English). ["Distribution patterns of *Gomphus pulchellus* larvae in different sediments with different density of prey organisms were studied in the field in a small gravel pit lake in the south of Germany. Larval burrowing behaviour at different temperatures as well as food preference, consumption rates and activity were studied in laboratory experiments. In the study lake *G. pulchellus* larvae lived exclusively in places where macrophytes were present and in fine sediments (mean grain size <3 mm) with detritus cover. There was a significant positive correlation between larval density and density of food organisms suggesting that abundance of food is one of the determinants of larval distribution. In late autumn larvae migrated to deeper places probably to survive the winter. Low temperatures simulated in laboratory experiments did not induce larvae to burrow deeper. Larvae were always found in a sediment depth of 0.59-0.74 cm. Experiments with mixed prey showed that *G. pulchellus* larvae preferred tubificid worms and chironomid larvae over gammarids and ephemeropterid larvae. However, chironomid larvae which stayed in their tubes had a higher survival rate than those outside of tubes. Single-prey experiments showed that *G. pulchellus* larvae can prey not only on benthic species but also on *Daphnia* from the open water. Functional-response experiments showed that one *G. pulchellus* larva consumes a maximum of 2 to 3 tubificid worms or chironomid larvae per day, which corresponds to a maximum biomass (freshweight) of 5 to 30 mg per day. Video recordings of activity showed that *G. pulchellus* larvae cover long distances of up to 52 m per night on the substrate surface and that activity on the substrate surface started after midnight and ceased before sunrise. Consumption of zooplankton prey and high activity above the substrate is interpreted as an adaptation of *G. pulchellus* larvae to the life in still water habitats." 866. **Andres, J.A.; Cordero, A. (1999):** The inheritance of female colour morphs in the damselfly *Ceragrion tenellum* (Odonata, Coenagrionidae). *Heredity* 82(3): 328-335. (in English). ["Female-limited polychromatism is found in many species of Odonata. In *Ceragrion tenellum* (Coenagrionidae) one of the morphs is red-coloured, like the conspecific male (androchrome, erythrogastrum morph), whereas most females are red and black (typica morph) or black (melanogastrum morph). Virgin females of this species were mated in the laboratory and their progeny reared (13 crosses). Results of these crosses indicate that colour morphs are controlled by one autosomal locus with female-limited expression. A second laboratory generation (two

crosses) confirmed this inheritance system. This locus has three alleles (one per phenotype) and a hierarchy of dominance: *typica* > *melanogastrum* > *erythrogastrum*. The dominance relationships of andro/gynochrome alleles in polymorphic damselflies so far studied are discussed. The frequencies of female morphs in natural populations are highly variable, but in all cases *typica* females are the commonest." 868. **Aoki, T. (1999):** Larval development, emergence and seasonal regulation in *Asiagomphus pryeri* (Selys) (Odonata: Gomphidae). *Hydrobiologia* 394: 179-192. (in English). ["Larval development and seasonal regulation in a spring-emerging gomphid dragonfly, *Asiagomphus pryeri* (Selys), was investigated mainly by repeated sampling in the field and also by laboratory experiments. Eggs exhibited direct development. Larval duration was usually 3 or 4 years. Larvae in the penultimate instar (i.e. F-1) that entered the final instar (F-0) synchronously in their third autumn emerged in the following spring but F-1 of the same age-cohort that failed to enter F-0 in the autumn did not emerge in the following spring (i.e. cohort splitting); they had a smaller head width, underwent a supernumerary ecdysis and entered F-0 in the following autumn together with a cohort one year younger. Reduction of temporal variation in emergence, which lasted about 3 weeks, from late May to mid June, was achieved by synchronized entry to F-0 in the previous autumn. No additional synchronisation was detected in the overwintering F-0 population. Long-day photoperiod (LD 15:9; corresponding to the summer solstice) induced in F-1 intense diapause which was terminated by intermediate photoperiod (LD 13:11; the equinox). In nature, such photoperiodic responses apparently mediate the synchronous entry to F-0 in autumn. Discussion on the mechanisms of seasonal regulation is made." 869. **Aoki, T.; Kondoh, S. (1999):** A note on reproductive behaviour of *Sympetrum striolatum imitoides* BARTENEF in Kobe. *Aeschna* 35: 37-40. (Japanese, with English summary). ["Reproductive behaviour of *Sympetrum striolatum imitoides* Bart. was observed at an artificial pond for birdwatching in Kobe [...] 4 times from 12 October to 16 November, 1997. It was similar to those which were reported by Matsura et. al. (1995) in *S. s. imitoides* and by Ottolenghi (1987) in *S. s. striolatum* in Italy. A characteristic precopulatory behaviour of the male, which is hardly seen in other Japanese *Sympetrum* species except *S. uniforme*, was a continuous hovering flight above the water. It began just before females coming to the water for oviposition (about

10:30 J.S.T.), and lasted for about an hour. There is, however, another group of males which waited for females by perching around the pond. Depending on their situation or other conditions, two tactics might be used for mating." (Authors)]. 873. **Azevedo-Ramos, C.; Magnusson, W.E. (1999):** Tropical tadpole vulnerability to predation: Association between laboratory results and prey distribution in an Amazonian savanna. *Copeia* 1999(1): 58-67. (in English). ["We tested concordance between patterns of tadpole assemblage structure seen in the field and in laboratory experiments to infer causal relationships. Based on a previous study that showed predators as the main proximal factor associated with tadpole distributions in an Amazonian savanna, we investigated interspecific patterns of vulnerability of six common tadpole species in relation to the distribution of predators in the field. The predators used were hydrophilid larvae (Coleoptera), libellulid naiads (Odonata), and adult *Gophagus* gr. *altifrons* (Cichlidae). Forty riverside aquatic sites were searched for predators and tadpoles during 28 months in a savanna area at the border of the Tapajos River, Central Amazonia. Tadpole species were tested for their vulnerability to predators in individual and choice tests. Prey unpalatable to fishes (*Bufo marinus*, *B. granulatus*, and *Hyla wavnini*) were palatable to invertebrates, *Leptodactylus macrosternum* and *Scinax rubra* were vulnerable to fish and invertebrate predators. *Lysapsus limellus* was not tested with fish, but it was vulnerable to naiads. Eggs had low vulnerability to predation, but there was generally little ontogenetic change in tadpole vulnerability. The vulnerability of tad-

poles in choice tests was significantly related to vulnerability in individual tests. A tadpole vulnerability index based on tadpole survivorship with different predators was significantly related to the distribution of predators in the field, indicating that it is possible to predict the coexistence of prey and predators in the field by screening species with simple laboratory predation experiments. In this study area, both vertebrate and invertebrate predators may potentially limit the distribution and the relative abundance of tadpole species through differential predation." 874. **Baker, L.; Elkin, C.M.; Brennan, H.A. (1999):** Aggressive interactions and risk of fish predation for larval damselflies. *Jour. Insect behav.* 12(2): 213-223. (in English). ["Larval damselflies frequently engage in aggressive interactions that may increase their risk of fish predation. To test this we analyzed the behavior of larval *Ischnura verticalis* exposed to both conspecifics and fish predators. Larvae in the presence of conspecifics oriented, struck, and swam more but crawled less compared to solitary larvae; the presence of fish reduced, or tended to reduce, all behaviors. Fish struck more at interacting larvae compared to noninteracting larvae. Increased attack rate by fish likely reflects the increase in the very active swimming behavior by larvae and suggests a conflict between antipredator behaviors. Swimming is an appropriate response to avoid predation by odonate larvae which normally ambush prey but is clearly dangerous when fast-swimming fish that cue in on movement are nearby." 877. **Beamish, F.W.H.; Noakes, D.L.G.; Rossiter, A. (1999):** Feeding ecology of juvenile Lake Sturgeon, *Acipenser fulvescens*, in Northern Ontario. *Canadian field naturalist* 112(3): 459-468. (in English). ["Dietary analyses of juvenile Lake Sturgeon in a resource-poor habitat showed them to be a general predator. Cladocera dominated numerically the prey taxa, but were recor-

ded in only four of the individual sturgeon examined and therefore excluded from stomach content analyses. Mayfly larvae (Ephemeroptera), primarily *Hexagenia*, were numerically the next most abundant (34% of all prey items) and the most widely taken (75% of all sturgeon) of the 10 prey categories. Others were Odonata, Annelida, Mollusca, Diptera and Trichoptera, each at 5-8% of all prey items. The remaining dietary categories represented < 3% of all prey items. No dietary partitioning was found over the length range of juvenile sturgeon, suggesting that fish throughout this size range are almost certainly competing for food. Lake Sturgeon diet did not differ from that for suckers, Lake Whitefish and, to some extent, Burbot, but was different from that for Northern Pike and Walleye. Extremely low invertebrate densities (95 individuals x m⁻²) and occurrence of all benthic species in the diet of juvenile Lake Sturgeon and several of the other dominant fishes suggests niche breadth to be wide and thus competition for food to be severe. The low food abundance is reflected in the comparatively slow growth rate of sturgeon in our study area. Apparently sturgeon are at survival threshold in this area. Further depletion of their food base likely would have serious repercussions for their growth and survival." (Authors)] Address: Noakes, D.L.G., Univ Guelph; Dept Zool., Guelph; ON N1G 2W1; Canada

(in German). [A Calluna-bog (Schwarzes Moor) near Schneverdingen, Niedersachsen, Germany was surveyed for the species. The habitat (*Sphagnum-Eriophorum*-quagmire) is described in some detail (climatic conditions, vegetation, water chemistry, [dragonfly] fauna). Differences in the morphological structures between *A. subarctica elisabethae* and *A. juncea* are presented in detail. Many of original observations on larval habitat and emergence of the species are documented. Predation behaviour of larvae was observed under laboratory conditions. The population ecology of *A. subarctica* is studied, with some emphasis on its competition with *A. juncea*. This very interesting M.Sc. thesis can be obtained from the author for DM 40,-.] Address: Borchers, R., Rotdornallee 18, D-29640 Schneverdingen, Germany

The identity of other taxa listed is doubtful as well.] Address: Bouguessa, S., Centre Universitaire de Tebessa, Département de Biologie, Route de Constantine, 12000 Tebessa, Algeria
894. **Brewer, S.K.; Atchison, G.J. (1999):** The effects of chlorpyrifos on cholinesterase activity and foraging behavior in the dragonfly, *Anax junius* (Odonata). *Hydrobiologia* 394: 201-208. (in English). ["We examined head capsule cholinesterase (ChE) and foraging behavior in nymphs of the dragonfly, *Anax junius*, exposed for 24 h to 0.2, 0.6 and 1.0 $\mu\text{g l}^{-1}$ of the organophosphorus (OP) insecticide, chlorpyrifos [O,O-diethyl O-(3,5,6-trichloro-2-pyridyl) phosphorothioate]. The invertebrate community is an important component of the structure and function of wetland ecosystems, yet the potential effects of insecticides on wetland ecosystems are largely unknown. Our objectives were to determine if exposure to environmentally realistic concentrations of chlorpyrifos affected foraging behavior and ChE activity in head capsules of dragonfly nymphs. Nymphs were exposed to different concentrations of chlorpyrifos and different prey densities in a factorial design. ChE activities and foraging behaviors of treated nymphs were not statistically different (p greater than or equal to 0.05) from control groups. Prey density effects exerted a greater effect on dragonfly foraging than toxicant exposures. Nymphs offered higher prey densities exhibited more foraging behaviors but also missed their prey more often. High variability in ChE activities within the control group and across treated groups precluded determination of relationships between ChE and foraging behaviors. It appears that *A. junius* is relatively tolerant of chlorpyrifos, although the concentrations we tested have been shown in other work to adversely affect the prey base; therefore the introduction of this insecticide may have indirect adverse effects on top invertebrate predators such as Odonata." 912. **Chelmick, D.G. (1999):** Larvae of the genus *Anax* in Africa (Anisoptera: Aeshnidae). *Odonatologica* 28(3): 209-218. (in English). [11 spp. of the genus *Anax* have been recorded from Africa and its offshore islands. The larvae of 7 of these are compared in this paper, and *A. chloramelas* Ris and *A. congoliath* Fraser are believed to be described for the first time. A simplified key is provided to assist in the identification of the known African species.] Address: Chelmick, D.G., 31 High Beech Lane, Haywards Heath, West Sussex, RH16 1SQ, UK
913. **Chippindale, P.T.; Dave, V.K.; Whitmore, D.H.; Robinson, J.V. (1999):** Phylogenetic relationships of North American damselflies of the genus *Ischnura* (Odonata: Zygoptera: Coenagrionidae) based on sequences of three mitochondrial genes. *Molecular phylogenetics and evolution* 11(1): 110-121. (in English). ["Relationships of North American damselflies of the genus *Ischnura* (Odonata: Zygoptera: Coenagrionidae) were investigated using a total of 1205 bp from portions of three mitochondrial genes: cytochrome b, cytochrome oxidase II, and 12S ribosomal DNA, Parsimony and neighbor joining analyses reveal a monophyletic group consisting of *I. damula*, *I. demorsa*, *I. parva*, *I. posita posita*, *I. posita atezca*, *I. verticalis*, and probably *I. denticollis*, likely reflecting a recent radiation in North America. *Ischnura kellicotti*, *I. barberi*, *I. prognata*, *I. hastata*, *I. ramburi*, and *I. capreola* appear to represent much earlier divergences in the group. Many previous hypotheses of relationships among North American species of *Ischnura* are not supported by the molecular-based analyses. However, there is agreement in many respects between the results of the molecular phylogenetic analyses and the morphologically based conclusions of Kennedy (1919, "The Phylogeny of the Zygoptera," Ph.D. Dissertation, Cornell University, Ithaca). Although results of single-gene phylogenetic analyses often differ, there are very few cases in which there is strong support for conflicting relationships using different partitions of the data. Combined analysis of all three genes yields trees with stronger support overall than the single-gene analyses, and the combined data trees that result from diverse data treatments are congruent with one another in most respects." 914. **Clarke, D. (1999):** The outpost populations of the Banded Demoiselle *Calopteryx splendens* (Harris) in the Solway Firth area, Cumbria: historical perspective and recent developments. *J. Br. Dragonfly Soc.* 15(2): 33-38. (in English). ["The Solway plain of Cumbria holds the most north-westerly populations of this species in Britain [...]. These occupy an extremely isolated position and, strangely, the species seems never to have been recorded in more southerly parts of the county. [...] The nearest colonies on the west of the Pennines are some 120km to the south of the Solway [...]. 1996, individuals were noted up to 20 km east of the known breeding areas on the river Waver. The following years yielded new records, and populations settled by the 1996 dispersal got strong populations of *C. splendens*.] Address: David Clarke, Tullie House Museum & Art Gallery, Carlisle CA3 8TP
915. **Clausnitzer, H.-J. (1999):** Bedeutung von Primärhabitaten für die mitteleuropäische Fauna. Schutz von Primär- oder Sekundärhabitaten?. *Naturschutz und Landschaftsplanung* 31(9): 261-266. (in German, with English summary). ["Importance of Primary Habitats for the Central-European Fauna - Conservation of Primary or Secondary Habitats? In the cultural landscape many animal species occur in secondary habitats and therefore depend on regular management measures. Some species develop a very high abundance rate, with these anthropogenic habitats being their optimum habitat. On the other hand, if land-use and hence the type of impact change, many of these species disappear. With specific management measures nature conservation imitates the former land-use in order to conserve the biodiversity of these secondary habitats. Some animal species still occur in primary habitats without human intervention, although these primary habitats may not necessarily be optimum habitats. Only if known primary habitats exist in sufficient size and number can management measures be reduced. It is therefore necessary that nature conservation should manage both optimum secondary habitats and protect primary habitats where they are of sufficient size." (Author) The requirements of *Orthetrum coerulescens* and *Ceragrion tenellum* on primary habitats are outlined in short.] Address: Clausnitzer, H.-J., Eichenstr. 11, D-29348 Eschede, Germany

919. **Corbet, P.S. (1999):** Dragonflies. Behaviour and Ecology of Odonata. Harley Books. Colchester. ISBN 0 946589 64 X: 829 pp. (in English). [This outstanding book complements and updates "A Biology of Dragonflies", Philip Corbet's highly acclaimed work of over thirty years ago. In the present work, the author provides a critical review of information, both published and unpublished, worldwide, on the behaviour and ecology of Odonata in all stages of the life cycle for both physical and biotic environments. The author integrates information about tropical and temperate species in functional and evolutionary contexts, and reviews facts and ideas in the perspective of current biological thinking. The treatment emphasizes diversity as well as broad patterns of behaviour and should help focus attention on potentially fruitful lines of future enquiry, within and beyond the Odonata. The book can be expected to be uniquely authoritative for decades and an invaluable resource for anyone working in this field.]
920. **Cordero, A. (1999):** Forced copulations and female contact guarding at a high male density in a calopterygid damselfly. *Jour. Insect Behav.* 12(1): 27-37. (in English). ["Territorial males of *Calopteryx damselfly* court females on territories that contain oviposition substrates. Nonterritorial males try to mate without courtship but very rarely obtain matings because females fail to bring up their abdomen to engage genitalia. Here I report the results of observations made on a very high-density population of *Calopteryx haemorrhoidalis* in central Italy. Mating activity was intense, and during 40 h of observation in an 8 m section of the stream, 209 matings were recorded (a maximum of 17 matings h⁻¹). Males were continuously disturbing ovipositing females and tried to achieve tandem forcibly. Of 84 cases, males achieved forced tandem in 53, and 49 ended with copulation. Forced tandems were the most common method to obtain a mating in this population (55% of 65 matings). Males guarded females after forced or courtship copulations and, in some cases, maintained physical contact with their mate, by perching on her wings. Confusion was common and males guarded nonmates frequently, which suggests that they were unable to recognize their mate individually." (Author)] Address: Cordero, A., Univ. Vigo, Dept Ecol. & Biol. Anim., Campus Univ., Pontevedra 36005; Spain. E-mail: acordero@u-vigo.es
921. **Cordero Rivera, A.; Andrés Abad, J.A. (1999):** Lifetime mating success, survivorship and synchronized reproduction in the damselfly *Ischnura pumilio* (Odonata: Coenagrionidae). *International Journal of Odonatology* 2(1): 105-114. (in English). ["A small population of *I. pumilio* in NW Spain was studied by marking and resighting in August-September 1996. A total of 142 males and 100 females were captured. Adults of *I. pumilio* appeared in two clear groups, starting on 31 August and 10 September. Population size was estimated about 1-2 individuals from 14 to 30 August but suddenly increased to 30-50 males and 40-120 females from 31

August to 13 September. A large fraction of males (43.6%) were never seen to mate, but only 13 females were never seen in copula. Androchrome females were rare (14 females) and did not differ from gynochrome females in fitness correlates. Copulation duration ranged from 1 to 5 h, and was dependent on time of day. The analysis of survival and recapture rates indicates that males and females have similar survivorship, but sex had a significant effect on recapture probability." (Authors)] Address: Adolfo Cordero Rivera; Jose Angel Andrés Abad, Departamento de Ecología e Biología Animal, Universidade de Vigo, E.U.E.T. Forestal, Campus Universitario, ES-36005 Pontevedra, Spain. E-mail: acordero@uvigo.es; jaandres@uvigo.es

922. **Cordero-Rivera, A.; Utzeri, C.; Santolamazza Carbone, S. (1999):** Emergence and adult behaviour of *Macromia splendens* (Pictet) in Galicia, northwestern Spain (Anisoptera: Corduliidae). *Odonatologica* 28(4): 333-342. (in English). ["Exuviae were found in sheltered places, most commonly in small cavities under the river banks. The species is able to breed in hydroelectric reservoirs that show marked changes in water level and where riverine vegetation is completely absent. At these places exuviae were found on dead trunks and big rocks, usually in a horizontal up-side-down position. In the laboratory, emergence followed the typical aeshnid sequence. Adult, full coloured males showed no yellow spots on abdominal segments 5 and 6, while the spots on segments 4 and 7 were widely variable. 37 adult males of a natural population at the river Lérez were marked. Of these, 12 were resighted 1 to 14 days after marking. Males patrolled over 50-150 m of the river, usually flying straight about 30 cm above the water. Females were observed at the river on 21 occasions, and in 19 cases oviposited as soon as they arrived at water. However, mating was recorded only once during 52 h of observation over 18 days. Two more matings were obtained with a tethered female. Since matings at the Oviposition sites seem to be rare, it is suggested that copulation is performed mainly at the feeding places. Eggs were scattered by the unaccompanied female by dipping the abdomen 3-10 times for no more than 2 min, in spots of the river as far as 1 m from each other. The importance of forested areas for conservation of this species is discussed." (Authors)]. Address: Utzeri, C., Dipartimento di Biologia Animale e dell'Uomo, Università "La Sapienza", Viale dell'Università 32, I-00185 Roma. Italy.

923. **Cordoba-Aguilar, A. (1999):** Male copulatory sensory stimulation induces female ejection of rival sperm in a damselfly. *Proc. Roy. Soc. London, Ser. B, Biol. Sci.* 266(1421): 779-784. (in English). ["Male damselflies possess very specialized genitalia. Females mate multiply and store sperm in two sperm storage organs, the bursa copulatrix and the spermatheca. During copulation, males physically remove the sperm stored in these organs using their genitalia. I document a novel mechanism by which males gain access to the spermatheca in *Calopteryx haemorrhoidalis asturica*. The mechanism is based on male stimulation of the female sensory system that controls egg fertilization and laying. During copulation, the aedeagus (a male genitalic structure indirectly involved in sperm transfer) distorts the cuticular plates in the female genital tract that bear mechanoreceptive sensilla. This stimulation results in sperm ejection from the spermatheca. Aedeagus width is positively correlated with the amount of sperm ejection.

I propose that males have exploited a pre-existing female sensory bias to gain access to otherwise physically unreachable sperm. These results shed light on the issue of the origin of female preferences in current models of sexual selection and on the evolution of genitalia via sexual selection. It is postulated that females might use this process as a form of post-copulatory sexual selection on the basis of males' genitalia." (Author)] Address: Cordoba-Aguilar, A., Univ. Sheffield; Dept Anim. & Plant Sci., Sheffield S10 2TN; S Yorkshire, UK. E-mail: sclab@sheffield.ac.uk

927. **Dahl, J.; Greenberg, L. (1999):** Effects of prey dispersal on predator-prey interactions in streams. *Freshwater biology* 41(4): 771-780. (in English). ["1. We studied the effect of mesh size (6 and 3 mm) on interactions between brown trout (*Salmo trutta*) and benthic invertebrates in enclosures placed in a stream in southern Sweden. We also compared how different prey

exchange rates affected interactions between trout and invertebrates. 2. Trout had strong impacts on some benthic taxa, and different mesh sizes produced different patterns. Trout affected the abundance of 10 of the 21 taxa examined, six in enclosures with 3 mm mesh and six in enclosures with 6 mm mesh. The abundance of nine of the prey taxa was lower in the presence of trout, only leptocerids were more numerous in the presence of trout. 3. Our measurements of prey immigration/emigration, together with trout diet data, suggest that direct consumption by trout, rather than avoidance behaviour by prey, explains most decreases in prey abundance. There was avoidance behaviour by only two of the twenty-one prey taxa, with trout inducing emigration of the mayflies *Baetis rhodani* and *Paraleptophlebia* sp. 4. Trout indirectly increased periphyton biomass in both 3 and 6 mm enclosures. The effect of trout on periphyton was probably due to strong effects of trout on the grazer, *Baetis rhodani*, *Heptagenia* sp. and *Paraleptophlebia* sp. 5. Our results suggest that mesh size, through its effects on exchange rates of prey, may affect interactions between predators and prey in running waters, but that the effects of dispersal and predation on invertebrates are taxon specific." (Authors) A few remarks are made on *Calopteryx* sp. consumed by the trout, and the effects of mesh size on the immigration of invertebrates including *Calopteryx* sp. into enclosures.] Address: Dahl, J., Department of Entomology, Cornell University, Ithaca, NY, 14853, USA. 929. **Damme, K. van; Dumont, H. (1999):** A drought-resistant larva of *Pantala flavescens* (Fabricius, 1798) (Odonata: Libellulidae) in the Lençóis Maranhenses NE-Brazil. *International Journal of Odonatology* 2(1): 69-76. (in English). ["A single male of *Pantala flavescens* was collected by chance with dry mud in the bed of a pond in the Lençóis Maranhenses (N-E Brazil) which had been dry for several months. It was noticed as a larva in an aquarium about seven days after the mud first had been wetted and it was then reared to the imaginal stage. Fifteen measurements were taken on three larval skins that could be recovered. These were fitted to literature data on larval development that had first been converted to exponential growth curves, in an effort to determine whether the drought-resistant stage had been an egg or a larva. It was found that that a drought-resistant egg was improbable, and that the larva had probably survived drought as an early instar (2-4). It is argued that early larval tolerance to drought may be common in *Pantala*, and may contribute as much to its success in semiarid environments as its rapid larval development." 933. **David, S. (1999):** Structure of the communities of dragonflies (Insecta: Odonata) and their biotops in the inundation of the Hron river potamal (SW Slovakia). *Krajinnöekologické plánovanie na Prahu. 3. tisícročia. 10.-11. maj 1999, Smolenice.* (Hrnciarová, T. & Z. Izakovicová (Eds.): 161-170. (in Slovakian, with English summary). ["Odonatological investigations were carried out in the Hron river basin in the lower part, a 75 km long section. We selected 26 stationary sites in the inundation of the study area (river, dead channels, gravel pits). The investigations were based on a total of 1564 individuals belonging to 33 species, which represents 48.83% of the dragonfly fauna of the Slovak Republic. The structure of the communities was analysed on the basis of the coenological characteristics established in view of the method used. These characteristics were in particular: species composition, species dominance and frequency, diversity and equitability. The degree of similarity of the aquatic biotopes similarity was estimated by Wishart's induce. The data were evaluated by cluster analysis (using the NCLAS programme with the complete linkage method). The structure of dragonfly communities was discriminated on the basis of their species composition. 4 groups of biotopes were separated on the first level of division. The same method was used to classify the odonate communities. Three cenoses could be separated: *Gomphus* - *Calopteryx splendens*, *Orthetrum* - *Libellula depressa*, and *Lestes* - *Sympetrum* - *Aeshna* (affinis, mixta) - cenosis." (Author)] Address: David, S., ÚKE SAV, Akademická 2, SK-94901 Nitra, Slovakia. E-mail: david@pribina.savba.sk

934. **De Marco, P.; Latini, A.O.; Reis A.P. (1999):** Environmental determination of dragonfly assemblage in aquaculture ponds. *Aquaculture Research* 30(5): 357-364. (in English). ["Odonate larvae are important components of aquatic environments in tropical areas. They also develop in aquaculture ponds, where they can cause economic losses. In this study, we have tried to describe the general community patterns in aquaculture ponds in Vicosá, south-eastern Brazil. Our aim is to evaluate how environmental and bionomic factors can determine their composition and species richness. We identified two groups of species (plants and bottom-dwellers) based on larval microhabitat preferences. Vegetation determines the occurrence of some species whose adults select certain plants for oviposition. The ponds with more extreme conditions (extensive cover of plants or vegetation absent) showed lower species richness than those with intermediate conditions, *Coryph-*

aeshna adnexa and Brachymesia furcata were of larger size but had low abundance or were only collected accidentally. Species of intermediate size (Tramea cophysa, Micrathyria spp., Orthemis discolor and Erythrodiplax fusca) were more abundant and are considered as potential predators of fish fry." (Authors)] Address: De Marco, P., Univ Fed. Vicosa, Dept Biol. Geral., BR-36571000 Vicosa; MG; Brazil

935. **De Marmels, J. (1999):** Rare Venezuelan dragonflies (Odonata) evaluated for their possible inclusion in the national Red Data Book. International Journal of Odonatology 2(1): 55-67. (in English). ["Of the 480 species and subspecies listed from Venezuela up to December 1996, 113 are "rare", i.e. with three or less individual records, or are known from three or less localities. Thirty-eight of them are distributed north and northwest of the Orinoco where 90% of the human population lives and, hence, negative impact on the ecosystems is more evident. The status of conservation of these species was assessed by applying the criteria published by the World Conservation Union (IUCN), in 1994. Sixteen species and subspecies are proposed for inclusion in the Venezuelan Red Data Book, viz. four Polythoridae, four Megapodagrionidae, one Lestidae, one Pseudostigmatidae, four Gomphidae, one Aeshnidae and one Libellulidae. Of the evaluated taxa, one genus and seven species are Venezuelan endemics. Forest fires, deforestation, pollution, water catchment constructions and human invasion of protected areas are some of the main factors which threaten these taxa." (Author) The following species are commented: Heteragrion macilentum Hagen in Selys, 1862; Palaemnema nathalia Selys 1886; Leptagrion siqueirai Santos 1968; Progomphus polygonus Selys, 1879; Brechmorhoga innupta Racenis 1954; Cora inca Selys 1873; Cora xanthostoma Ris 1918; Euthore fastigiata (Selys 1859); Polythore terminata Fraser 1946; Phyllogomphoides brunneus Belle 1981; Andaeschna timotocuica De Marmels, 1994; Sympetrum evanescens De Marmels, 1992; Mecistogaster modesta Selys 1860; Agriogomphus jessei (Williamson 1918); Erpetogomphus sabaeticus Williamson 1918; Phyllogomphoides semicircularis (Selys, 1854); Archilestes tuberalatus (Williamson, 1921); Philogenia ferox Racenis 1959; Philogenia polyxena Calvert 1924; Sciotropis cyclanthorum Racenis 1959; Sciotropis lattkei De Marmels 1994] Address: De Marmels, J., Instituto de Zoologia Agricola, Facultad de Agronomia, Universidad Central de Venezuela, Apartado 4579, Maracay 2101-A, Venezuela.

936. **Decocq, O.; Pieron, J. (1999):** Des larves de Cordulegaster boltoni (Insecta: Odonata) sous épicéa (Picea abies) dans le Parc naturel Viroin-Hermeton. Gomphus 15(2): 63-68. (in French, with English and Flemish summary). ["In three different small streams of the Belgian Ardennes (Viroinval, Namur province), larvae of C. boltoni were found between small plantations of spruce (Picea abies) surrounded by deciduous woodland. So, the question of larval development of that species under conifers is renewed; they might have a greater influence on imagines (egg laying, hunting, "patrolling" flights), or for emergence [...] Some favourable management measures in forest areas are proposed." 940. **Dijkstra, K.-D.B.; Mostert, K.; Velzen, J.-W. van; Witte, R.H. (1999):** Recent developments in the dragonfly fauna of the dunes of Holland and Zeeland. Brachytron 3(1): 15-29. (in Dutch, with English summary). ["The coastal dunes are isolated from the species-rich habitats on sandy soils inland by a belt of relatively inhospitable polders with peaty and clay soils. They also form an almost unbroken natural corridor through which dragonfly migration is possible, whilst the sea is a barrier that forces migrants from the east to settle. Remarkable invasions, colonizations and vagrancies by Odonata during the last five years along the Dutch coast, excluding the Wadden Sea islands, are listed. There were large invasions of Lestes barbarus, Aeshna affinis, Sympetrum danae, S. flaveolum and S. fonscolombii, all of which reproduced in the area subsequently. Sympecma fusca, Lestes dryas, Ischnura pumilio, Pyrrhosoma nymphula, Brachytron pratense, Aeshna isocetes, Libellula depressa, Crocothemis erythraea and Leucorrhinia rubicunda bred successfully. All of these species were either new in this sense, or had been absent for many years. Calopteryx splendens, Lestes virens, Hemianax ephippiger, Gomphus vulgatissimus, Somatochlora metallica and Leucorrhinia pectoralis reached the region as vagrants, thus proving they are capable of reaching new habitats when these are created. Habitat restoration, increasing observation intensity, prevailing weather and expanding ranges are discussed as factors to explain the new records. Most of the treated species appear to have reached the area with the help of easterly winds and fine weather. Habitat restoration has principally created opportunities for pioneer species and those adapted to fluctuating water levels. It is suggested that permanent, mesotrophic lakes should be restored in order to bring back species that

are extinct in the dunes, like *Cordulia aenea* and *L. pectoralis*." (Authors)] Address: Dijkstra, K.D., Oude Rijnburgerweg 38, NL-2342 BC Oegstgeest, The Netherlands

958. **Ewers, M. (1999):** Die Libellen zwischen Weser und Ems. Schriftenreihe des Staatlichen Museums für Naturkunde und Vorgeschichte Oldenburg 12: 112 pp. (in German). [detailed account on the odonate fauna of the northwestern part of Germany; all species (61) were treated monographically with information on diagnostic morphological structures, phenology, habitat, threat, map of distribution, and colour picture. On pages 8 to 38 some introductory information on general biology

of Odonata, and on typical dragonflies of different habitat types are given.] Address: Isensee Verlag, Haarenstr. 20, D-26122 Oldenburg, Germany

959. **Ezenwaji, H.M.G. (1999):** The abundance and trophic biology of *Clarias albopunctatus* Nichols and LaMonte, 1953 (Osteichthyes: Clariidae) in a tropical floodriver basin. *Hydrobiologia* 392(2): 159-168. (in English). ["The abundance, food and feeding biology of *Clarias albopunctatus* was studied over a period of 17 months in the lower River Anambra, Nigeria. The catfish was more abundant in late dry season (January-March) and early rainy season (April-June) than in other periods of the year in the small-sized Akwu pond than in other habitats. Feeding intensity was higher at night and at dawn (20.00-05.00 h) than during the day (08.00-17.00 h) in the 151-200 mm TL size class and during the rainy season (April-September). There was no sex-dependent variation in feeding intensity. Insects were the predominant food, followed by crustaceans. Of primary importance were Chironomidae (mainly *Chironomus* spp. and *Tanytus* sp.), Odonata nymphs, *Dytiscus* sp., mosquito larvae and pupae, *Gyrinus* sp., *Daphnia* sp., Ostracoda and *Tilapia* fry. Qualitative food composition and food richness were size, but not sex- or season-dependent. Diet breadth increased with catfish size and during the rainy season. The feeding behaviour of the catfish include foraging, shovelling and surface feeding. Abundant food and ability to switch to more available items enable *C. albopunctatus* to maintain its abundance in the River Anambra." (Author)] Address: Ezenwaji, H.M.G., Univ. 962. **Forbes, M.R.; Muma, K.E.; Smith, B.P. (1999):** Parasitism of *Sympetrum* dragonflies by *Arrenurus planus* mites: maintenance of resistance particular to one species. *Int. jour. parasitology* 29(7): 991-999. (in English). ["Using field surveys and histological methods, we show that a dragonfly species (*Sympetrum internum*) has an effective resistance, not seen previously in other odonates, to a mite parasite (*Arrenurus planus*). This mite is a generalist parasite known to effectively engorge on several other odonate species. We argue that selection is likely weak, favouring counter adaptations of *Arrenurus planus* to *Sympetrum internum*, in part because other host species are available. We further argue that this pattern is possibly linked to the fact that the mode of resistance is relatively novel, and because *Sympetrum internum* is rare compared to another host species, *Sympetrum obtusum* at our study site. Although resistance of *Sympetrum internum* is quite effective against *Arrenurus planus*, *Arrenurus planus* larvae still attach to this species, but less often than they attach to *Sympetrum obtusum*. Attachment to unsuitable hosts may reflect constraints operating on *Arrenurus planus* larvae during host discovery. Such factors influencing the evolution of resistance, when several potential host species exist, have not received much attention." (1999):** Biodiversity in the floodplain of Saone: a global approach. *Biodiversity and Conservation* 8(6): 839-864. (in English). ["Biodiversity of European floodplains is seriously threatened mainly due to

(1) modifications of river courses such as channelisation or embankments, and (2) changes in traditional agricultural practices (i.e. usually pastures), into intensive production using drainage and fertilisation. An upstream-downstream survey of the Saone floodplain (France) has been done to identify the contribution of habitats to the floodplain biodiversity. Selected taxa were aquatic and terrestrial vegetation, Odonata, Coleoptera, Amphibians, and birds. The taxa were sampled in different habitat types that were: forests, grasslands and aquatic habitats. Tributary confluences with the river and cut-off channels contributed greatly to the floodplain diversity according to their invertebrates and aquatic vegetation communities. The abundance of rare species (benefitting of a national or regional protection status) was the highest in hygrophilous grasslands. Moreover, we demonstrated that diversity of breeding bird communities was correlated with the size of these habitats. We demonstrated also that alluvial forests contributed to maintain some particular species as Middle-spotted Woodpecker (*Dendrocopus medius*), while new plantations were colonized by openland bird communities sensible to the edge effect. Grassland fragmentation for agriculture appeared to be a major cause in biodiversity loss. Any alteration of the floodplain dynamics must be avoided to preserve the present diversity of riverine wetlands." (Authors)] Address: Godreau, V., Univ Bourgogne; Lab. Ecol. 970. **Goodwin, F. (1999):** An on-going study of the relationships between ants, birds, and dragonflies during the phenomenon of swarms at Massachusetts Audubon Society's Ipswich River Wildlife Sanctuary. *Argia* 11(2): 14-15. (in English). ["In the summer of 1997 I was given the challenge to identify and to photograph species of birds and dragonflies involved in swarm feeding on small flying insects emerging from the soil. [...] The area of activity was on grass fields and lawns near the top of the drumlin at the Ipswich River Wildlife Sanctuary (IRWS) from mid-afternoon to dusk. The swarms mainly consisted of 30 to over 200 dragonflies with the swallows and swifts mixing in. [...] The first swarm of 1998 was observed on August 6 at 16:00 hrs. with over 100 dragonflies mixing in with swallows and swifts, feeding about 150 feet over a field forming the edge of the drumlin. [...] The swarm phenomenon at IRWS occurs only when certain weather conditions exist; heat, fairly high humidity, and moist soil. These are the conditions needed for the ants to leave the nest for their mating flights. The moist soil seems to be the main key. The queens need the soil to be softened for re-entry. The males (if they make it back to the ground) die. Two species of ants involved as prey in the feeding swarms have been identified as *Lasius neoniger*, the Labor Day Ant and, *Solenopsis molesta*, a species of fire ant. Two different species of subterranean ants were also caught. [...] The last swarm was observed on September 27, 1998. 30 to 50 dragonflies were flying just above our front lawn feeding on a flight of ants. I was able to net ten: 5 were *Aeshna umbrosa*, (all males); 4 were *A. clepsydra*, (3 males 1 female), and 1 was *A. verticalis*, (male). All were in rough shape with torn wings and missing body parts. During the 1998 season I recorded 16 swarms and netted 223 dragonflies: *Aeshna canadensis*, *A. clepsydra*, *A. constricta*, *A. tu-*

berculifera, *A. umbrosa*, *A. verticalis*, *A. junius*, *Somatochlora williamsoni*. Also I observed 2 *Pantallas* within the swarms, no species identification was made. Although the *Pantallas* feed with the other species they are not readily accepted. Several times one of the other species made a pass as if to attack. The *Pantallas* would turn on their afterburner and loop away, but did not leave the area of the swarm. The intensity of the dragonflies while feeding is hard to believe. Neither weather or several people swinging a net can deter them. One evening while working a large swarm, a cold front arrived with rain, thunder, and lightning. The dragonflies flew well into the storm until all the ants were either caught or had ceased flying. The time period from mid-August to Labor Day seems to be the peak of the ant mating season. If conditions are right several flights can erupt during the same evening. During this period the dragonfly numbers also peak. After Labor Day the numbers start to decrease and soon the swifts and swallows migrate south. [...]"] (Author)] Address: Goodwin, F., Massachusetts Audubon Society, Ipswich River Wildlife Sanctuary, 87 Perldns Row, Topsfield, MA 01983, USA. E-mail fgoodwin@massed.net

972. **Gorb, S.N. (1999):** Visual cues in mate recognition in the damselfly *Ischnura elegans* Vander Linden (Zygoptera: Coenagrionidae). *International Journal of Odonatology* 2(1): 83-93. (in English). ["Of the three recognised female morphs of *I. elegans*, only two occurred in Jagotin, Kiev Province, Ukraine. Andromorphs and infuscans together constituted 99.8% of females in the population, and only 0.2 % were infuscans-*obsoleta*. The present paper is an experimental study testing male responses to female and male models. Three questions were asked: (1) Is the colour of the model an important cue in mate recognition by males? (2) What is the area of male field of view, responsible for mate recognition? (3) Which is the preferred direction, from which each model elicits the maximal rate of copulatory responses? All colour forms of females regularly occurred in copula with males throughout the day. The violacea and andromorph female models were preferred by males. However, the manner of model presentation strongly influenced male response: copulatory responses were rare when models were presented above the male. Copulatory behaviour with a male model resulted in nearly 70% of cases when the approach was from behind, which was significantly more frequent than with female models. Among female models, the andromorph and grey-green females of the form *infuscans* were recognised as a female more frequently from behind than the violacea and brown females of *infuscans*. The role of different visual cues in mate recognition is discussed." ["Ditch Clearance Programme in the River Marsh in Bremen - Results of Floristic and Faunistic Investigations. Regular ditch clearance in areas of extensively cultivated meadows is a prerequisite for the preservation of species diversity and for the existence of rare species in the 'ditch' biotope type. The ditch system in the River Marshlands in Bremen ('Niedervieland') extends to approximately 200 km and is of high value for nature conservation. The ecologically orientated ditch clearance programme was implemented for five years and was accompanied by floristic and faunistic investigations. Generally, vegetation recovered very quickly after clearance. However, the Water Soldier (*Stratiodes aloides*), which is of particular significance for highly endangered species of dragonflies and damselflies in the area, did not readily regenerate. The transplantation of individuals, on the other hand, was successful. Fauna of low mobility, such as snails, were able to reach the original density quickly compared with species which have a development cycle of several years, such as dragonflies. From the survey results conclusions were drawn for future ditch maintenance." (Author) Special emphasize is given to *Aeshna viridis* and *Anaciaeschna isoceles*. A graph shows the effects of the ditch clearance technique on emergence rate of *A. viridis*, *A. isoceles*, and *Brachytron pratense*.] Address: Handke, K., Dehnestr. 28, D-27777 Ganderkesse, Germany

980. **Hardersen, S.; Wratten, S.D.; Frampton, C.M. (1999):** Does carbaryl increase fluctuating asymmetry in damselflies under field conditions? A mesocosm experiment with *Xanthocnemis zealandica* (Odonata: Zygoptera). *Journal of applied ecology* 36: 534-543. (in English). ["1. Previous laboratory experiments have shown that the insecticide carbaryl reduces emergence success and increases fluctuating asymmetry in cell patterns of damselfly wings. These effects were validated using mesocosms. Twenty artificial ponds, each containing *Xanthocnemis zealandica*, were exposed to three replicated (n = 5) concentrations of carbaryl contamination plus controls. Emergence success, level of fluctuating asymmetry in meristic and metric traits of the

wings, and average size of the damselflies were measured. 2. The degradation of carbaryl was relatively constant for the first 5 weeks but later increased considerably, probably because of enhanced biodegradation. 3. Carbaryl at 100 p.p.b. (nominal concentration) reduced emergence success 10 days after application, whereas carbaryl at 10 p.p.b. and 1 p.p.b. had no effect. 4. To investigate how the level of fluctuating asymmetry and size were affected by carbaryl, damselflies from ponds with the highest concentration where emergence success was not affected (10 p.p.b.) were analysed over four time periods. Fluctuating asymmetry of the wings increased during the season but was not affected by carbaryl at 10 p.p.b. 5. Size, measured as average length of the front wings, was affected by date of emergence but not by exposure to carbaryl at 10 p.p.b. 6. Three main reasons for the absence of increased levels of fluctuating asymmetry as a result of carbaryl exposure are suggested." (Authors)] Address: Hardersen, S. Ecology and Entomology Group, Division of Plant, Soil and Ecological Sciences. PO Box 84, Lincoln University, Canterbury, New Zealand

981. **Hardersen, S.; Frampton, C.M. (1999):** Effects of short term pollution on the level of fluctuating asymmetry - a case study using damselflies. *Entomologia experimentalis et applicata* 92(1): 1-7. (in English). ["Fluctuating asymmetry (FA), a measure of developmental stability, has been suggested as a monitoring tool for environmental pollution. However, there have been few investigations into the effects of short term pollution on the level of FA. This paper explores effects of exposing late instar larvae to short term pollution on the level of FA in the wings of adult damselflies. In these insects FA in wing length and in cell patterns have different 'windows of opportunity' in relation to environmental stress. If increased environmental stress is applied after the 'window of opportunity' of one trait had closed, while the window of the other trait was still open then the level of FA of the first trait should not be altered whereas that of the latter should increase. If short term pollution killed part of a population, symmetrical individuals (low FA) should survive better than highly asymmetrical ones, because FA reflects the overall ability of an individual to cope with stress. If the pollution event occurred at a time when the level of FA was already fixed, the level of FA of the remaining population should be lower than that in controls. An experiment was carried out, using 10 artificial ponds, each holding a population of larvae of the damselfly *Xanthocnemis zealandica* (McLachlan). Damselfly larvae were exposed to carbaryl at a nominal concentration of 100 $\mu\text{g l}^{-1}$, which reduced emergence success after 10-20 days by ca. 50%. Based on laboratory experiments, it was assumed that despite the high mortality, the short exposure to carbaryl late in the last instar would ensure that the wing cell patterns of the damselflies were not altered by the increased stress. The level of FA in wing length increased in the damselflies surviving the exposure to carbaryl but the level of FA in cell patterns did not differ significantly between the treatment and the control. The effects of differential mortality, as well as the effects of pollution, on the level of FA in traits with different 'windows of opportunity' need further investigation." 982. **Hawking, J.; Theischinger, G. (1999):** Dragonfly larvae (Odonata). A guide to the identification of larvae of Australian families and to the identification and ecology of larvae from New South Wales. AWT Identification Guide No. 4, CRCFE Guide No. 24 (Australian Water Technologies Pty Ltd, West Ryde, Cooperative Research Centre for Freshwater Ecology, Thurgoona: I-IV-218 pp. (in English). [general information: Terminology, Distribution and Glossary; keys to the families (larvae); checklist; monography presentation of the species of 20 odonate families: each species is treated the following way: Previous description information, Dimensions, Diagnostic description, Remarks, Notes on ecology, Distribution in Australia, and dot map of distribution in New South Wales. You will find a lot of black and white illustrations and some colour plates with larvae or adults]

983. **Hawking, J.H. (1999):** An evaluation of the current conservation status of Australian dragonflies (Odonata). In: Ponder, W. & D. Lunney (Eds.): *The Other 99%: The conservation and biodiversity of invertebrates*. Transactions of the Royal zoological society of New South Wales. Mosman 2088: 354-360. (in English). ["The conservation status of the Australian dragonfly fauna was evaluated against the 1996 IUCN Red List categories. Each species was assigned to one of six categories as follows: one species as Critically Endangered, 12 species as Endangered, 24 species as Vulnerable, 39 species as Near Threatened, 84 species as Data Deficient and the remaining 154 species as Least Concern. This highlights three major conservation concerns: (1) the high proportion of species which satisfy the IUCN guidelines as being of conservation concern, (2) the large number of priority species and (3) the lack of available information on which to adequately evaluate the status of many species. The unique Australian dragonfly fauna, with its high proportion of endemics, Gondwanan species and species with unusual biological characteristics is rightly deserving of formal protection." 984. **Hawking, J.H.; New, T.R. (1999):** The distribution patterns of dragonflies (Insecta: Odonata) along the Kiewa River, Australia, and their relevance in conservation assessment. *Hydrobiologia* 392: 249-260. ["Sampling of larval and adult Odonata from 16 sites along the Kiewa River, Victoria, yielded 34 species: 10 Zygoptera, 24 Anisoptera. Patterns of larval and adult incidence were appraised, and showed that most species were restricted in incidence to several consecutive sites along the river, and that there is clear distinction also between the faunas of the potamon, rhithron and eucrenon regions. Different species of some genera of Anisoptera displayed different zonal distributions, and patterns of incidence and relative abundance of larvae and adults confirmed zonal occupancy. For larvae, these distribution patterns transcended the mode of collection, although many species were found most abundantly in one microhabitat or by one of several sampling methods employed at each site. Sampling of the two stages separately showed considerable concurrence of distributional patterns, so that either stage alone may provide data of value in faunal and conservation assessment." 985. **Heath, P. (1999):** The past and present status of Norfolk Hawker *Aeshna isosceles* Müll. in Britain. *Atropos* 8: 13-21. (in English). [very detailed compilation of the status of *A. isosceles* including a lot of unpublished studies; discussion on the records of the Dale collection; detailed discussion on the trade off between *Stratiodes aloides* (Water Soldier) (ultimate egg-laying substratum of *A. isosceles*), the clearance of ditches and its effects on population of *S. aloides*, and the effects of modern drainage systems to keep dry grazing marshes on the possibilities of Water Soldier recolonising recently cleared dykes; a modern population increase, and dispersal of the species are described: "it probably has a wider distribution now than at any time over the last couple of hundred years". But the amount of suitable breeding habitats has been significantly reduced. Some fundamentals for reintroduction and population management of *A. isosceles* are discussed.] Address: Heath, P., The Broads Authority, 18 Colegate, Norwich NR3 1BQ, UK

986. **Heidemann, H. (1999):** Professor Dr Gerhard Jurzitza: A short biographic sketch and bibliography. *Odonatologica* 28(4): 321-332. (in English). ["A brief biography and appreciation of the work of Dr G. Jurzitza (born 30 Nov. 1929), Professor Emeritus of the University of Karlsruhe, Charter Member of *Societas Internationalis Odonatologica* and one of the leading European odonatologists, is followed by his Odonatological bibliography (1959-1998; 139 titles). Most of his works are related to the European and South American fauna, mostly in the fields of faunistics, taxonomy, ecology and behaviour. The list of taxa he has introduced in Odonata, and a bibliography of his odonatological photographic work are also included." (Author)]. Address: Heidemann, H., Au in den Buchen 66, D-76645 Bruchsal, Germany

987. **Heise, S.; Schrack, M. (1999):** Nachweis der Östlichen Moosjungfer (*Leucorrhinia albifrons* [Burmeister, 1839]) in der Radeburger Heide nördlich von Dresden (Insecta: Odonata: Libellulidae). *Faun. Abh. Staatl. Mus. Tierkunde Dresden* 21(13): 215-220. (in German, with English summary). [1995 and 1996 *L. albifrons* was first recorded in the district of Dresden, Saxonia, Germany; review of the distribution in Germany with special reference to Saxonia, and documentation of some further unpublished Saxonian records; characterisation in detail of the habitat (water chemistry, vegetation); detailed documentation of the phenology of emergence (records of exuviae).] Address: Schrack, M., Hauptstr. 48a, D-01471 Radeburg-Großdittmannsdorf, Germany

988. **Henson, S. (1999):** The newsletter of the British Dragonfly Society No. 35. 20 pp. (in English). [newsletter of BDS with a wealth of information on society business, activities of members, book reviews, "First and last dates for 1998"] Address: Henson, S., 10 Shotesham Road, Poringland, Norwich NR14 7LE, UK

989. **Hill, B.T.; Beinlich, B.; Plachter, H. (1999):** Habitat preference of *Lestes barbarus* (FABRICIUS, 1798) (Odonata, Lestidae) on a low-intensity cattle pasture in the Sava floodplain (Croatia). *Verhandlungen der Gesellschaft für Ökologie* 29: 539-545. (in English).

["In the European Community large-scale grazing schemes are being discussed as an alternative to conventional agriculture in those areas that are at risk of being abandoned. However, in Central Europe the data base regarding the effects of large-scale grazing systems is scarce, since this land use practice has almost vanished. Especially in traditionally used floodplains grazing systems are the predominant land use. Due to inundation or high groundwater level they also provide patches of limnic habitats. There are indications that low-intensity grazing may prove beneficial for species communities of these limnic and semi-terrestrial habitats. We investigated a communal pasture of 78 ha (»Allmende«) in the Sava floodplain (Croatia) to test this hypothesis using the example of the damselfly *L. barbarus*. Based on mark-recapture data, we studied the habitat preference and movement of the life-history stages of *L. barbarus*. After emergence, most damselflies quickly move to hedges surrounding the pasture. They stay close to these hedges for the entire maturation period. Damselflies have to cover distances of up to 880 m to reach the hedges. Some mature *L. barbarus* directly returned to the pond where they had emerged. However, many females turned to ungrazed areas and fallows, before engaging in reproductive activity. Suitability of hedges as maturation habitat significantly depends on their width and the width of adjacent margins. Densely vegetated pond habitats with vegetation heights between 20 and 50 cm are preferred reproduction sites for *L. barbarus*." (Authors)] Address: Hill, B., Fakultät für Biologie, Naturschutz, Phillips Universität Marburg, D-35032 Marburg, Germany

990. **Hill, P.M. (1999):** Early emergence of White-faced Darter *Leucorrhinia dubia* in Cheshire in 1999. *Atropos* 8: 53. (in English). Address: Hill, P.M.; 1 Clive Cottage, London Road, Allstock, Knutsford, Cheshire WA16 9LT, UK

991. **Hill, P.M. (1999):** Migrant insects reported during the first half of 1999. *Atropos* 8: 35-36. (in English). [*Anax parthenope* in Cornwall and Kent, *Anaciaeschna isosceles* "in the Broads", *Gomphus vulgatissimus* on the Thames] Address: Hill, P.M.; 1 Clive Cottage, London Road, Allstock, Knutsford, Cheshire WA16 9LT, UK

992. **Hirvonen, H. (1999):** Shifts in foraging tactics of larval damselflies: effects of prey density. *Oikos* 86(3): 443-452. (in English). ["I studied search activity and attack tactics of larval damselflies, *Lestes sponsa*, feeding on cladocerans, *Daphnia magna*, at nine densities ranging from 2 to 640 per 1.5 l. Search activity increased from low to intermediate densities (40 *Daphnia*) and declined again at higher prey densities, as has been predicted by theories on optimal tactics for energy maximising foragers. Similarly, frequency of pursuit attacks first increased and then decreased as prey density increased. Frequency of ambush attacks increased with a decelerating rate with prey availability. Thus the proportion of pursuit attacks decreased linearly as prey density increased. Profitability of pursuing increased faster than ambush profitability at low prey densities and remained higher up to 40 prey. At higher prey densities the profitabilities reversed. Relative profitability of pursuits proportioned to prey density peaked with 5 *Daphnia*. At other prey densities than 5, frequency of pursuit attacks decreased towards the end of the trials. This change in foraging mode accounted for accelerating proportional prey mortality to an intermediate D.

magna density and thus the potential for a dampening effect on the prey population. Adjusting foraging tactics in response to prey availability may be adaptive for the predator, and may also contribute to density dependence in the predator-prey relationship through effects on functional response." (Authors)] Address: Hirvonen, H.; Univ. Helsinki; Integrat. Ecol. Unit; Div. Populat Biol., Dept Systemativ & Ecology, POB 17; FIN-00014 Helsinki; Finland. E-mail: heikki.hirvonen@helsinki.fi

993. **Hoess, R. (1999):** Erstnachweis einer zweiten Jahresgeneration von *Ischnura elegans* (Vander Linden) in der Schweiz (Zygoptera: Coenagrionidae). *Libellula* 18(1/2): 63-68. (in German, with English summary). ["On 17 July, 1997 four immature adults and seven exuviae were found at a newly set up pool near Bern. The pool was created on 17 March, 1997. From several possibilities of import or colonization only oviposition into the vegetation of the pool by allochthonous female(s) in spring 1997 proved to be probable." (Author)] Address: Hoess, R., University of Bern, Institute of Zoology, Division of Population Biology, Baltzerstr. 3, 3012 Bern, Switzerland

["19 spp. were recorded from 15 localities in May 1990, May 1992, June and July 1993. Oldest records are evidenced for seven taxa, viz. *Ischnura elegans elegans*, *Anax imperator*, *A. parthenope*, *Orthetrum cancellatum*, *O. chrysostigma*, *Sympetrum fonscolombii*, and *Selysiothemis nigra*." (Authors)] Address: Hoess, R., University of Bern, Institute of Zoology, Division of Population Biology, Baltzerstr. 3, 3012 Bern, Switzerland

995. **Homes, V.; Hering, D.; Reich, M. (1999):** The distribution and macrofauna of ponds in stretches of an alpine floodplain differently impacted by hydrological engineering. *Regulated rivers research and management* 15(5): 405-417. (in English). ["The purpose of this study was to describe the impact of hydrological engineering on distribution, morphology and macrofaunal community composition of ponds in an alpine floodplain. The study was conducted in 1995 with the study sites being located on the Isar floodplain (Bavaria, Germany). The density of ponds was highest in a bypassed section of the floodplain with a residual flow regime and unrestricted peak floods (up to 40 ponds per river kilometre). In a channelized section and downstream of a reservoir, density was much lower. In 1995, about one third of the ponds were removed by floods or dried out in summer. About the same fraction was generated as a result of flood events. The composition of the macroinvertebrate and vertebrate faunas of 59 ponds was investigated. Cluster analysis classified the ponds into four groups. One of the faunal types was limited to ponds generated by the 1995 floods, where only a few predominantly rheophilic species occurred. The other types represented older successional stages and were inhabited by more species-rich faunas composed mainly of Odonata, Heteroptera and Coleoptera. In the channelized stretch of the Isar floodplain, and downstream of the reservoir only a single pond was generated by the 1995 floods; this caused a lower abundance and diversity of pond types." 1016. **Johansson, F.; Rowe, L. (1999):** Life history and behavioral responses to time constraints in a damselfly. *Ecology* 80(4): 1242-1252. (in English). [Time constraints, imposed by seasonality, are common to life histories. Recent theory in evolutionary ecology predicts independent behavioral and life history responses to such constraints, but this theory remains largely untested. In our two experiments on the damselfly *Lestes congener* we experimentally alter individual's perception of their proximity to a time constraint and ask whether their behavior and life history respond in the directions predicted by theory. We altered larval perception of their position in the season with light regime. In one group, we hatched larvae from winter diapausing eggs in a light regime that mimics a relatively early time in the season. In the other group we hatched larvae in a light regime that mimics a late time in the season. In the late (time constrained) group, larvae would have very little time to complete development and reach a large size so that they could attain their full reproductive potential prior to winter. In the first experiment, the behaviors we assess are activity rate, which is an indicator of foraging effort and willingness to take risks, and cannibalism, which is a component of the mortality risk of foraging. As predicted, time-constrained larvae increased their activity rates, perhaps in an attempt to increase weight gain, and as a result they suffered higher rates of cannibalism. In the second experiment, we measured development rate as the rate of molting and age at maturity. As predicted, time-constrained larvae accelerated development rate and thereby matured at a significantly earlier age and smaller size. Our analysis demonstrates that the behavioral and life history responses of these larvae were independent, in the sense that the life history responses did not result from the behavioral responses." (Authors)] Address: Rowe, L., Univ. Toronto; Dept Zool., 25 Harbord St; Toronto; ON M5S 1A1; Canada

1017. **Johansson, F.; Ivarsson, T. (1999):** The Distribution of Darter dragonflies (*Sympetrum*: Odonata) in central Norrland, Sweden. *Nord. Odonat. Soc. Newsl.* 5 (1): 4-5. [The occurrence and distribution of the *Sympetrum* dragonflies in central Norrland, Sweden is presented in 25x25 km square maps (*S. danae*, *S. vulgatum*, *S. flaveolum*), or discussed (*S. striolatum*, *S. sanguineum*).] Address: Johansson, Frank & Tobias Ivarsson, Ekologisk Zoologi, Umea Universitet, S-90187 Umea, Sweden

1019. **Johnston, T.A.; Cunjak, R.A. (1999):** Dry mass-length relationships for benthic insects: a review with new data from Catamaran Brook, New Brunswick, Canada. *Freshwater biology* 41(4): 653-674. (in English). ["1. We summarized previously published mass-length relationships for aquatic insects, and determined the relationship between dry body mass and body length for eight genera and seven families of benthic insects from Catamaran Brook, New Brunswick, Canada." In appendix 1 the relations between mass and linear measurements for 8 odonate species published

hed by Pavlov & Zubina (1990), *Hydrobiological Journal* 26: 99-103, and for *Pyrrhosoma nymphula* (Lawton, 1971, *Jour. anim. ecol.* 40: 385-423) are listed. "2. A power function was the most commonly used model in the earlier studies and best described the observed mass-length relationship for taxa from Catamaran Brook. 3. Predicted mass at length was highly variable (coefficient of variation > 25%) among models developed in different studies for the same family group. This variability presumably resulted from both variation in the methods used to construct the models, and in the natural spatio-temporal and taxonomic variation in mass at length, although the relative contributions of these two sources cannot be determined from existing data. 4. Several recommendations are made for the development and application of mass-length equations in future studies." (Authors)] Address: Johnston, T.A., Department of Fisheries and Oceans, Central and Arctic Region, Freshwater Institute, 501 University Cr., Winnipeg, Manitoba R3T 2N6, Canada; Cunjak, R.A., Department of Biology, University of New Brunswick, Bag Service 45111, Fredericton, New Brunswick E3B 6E1, Canada

1024. **Kambhampati, S.; Charlton, R.E. (1999):** Phylogenetic relationship among *Libellula*, *Ladona* and *Plathemis* (Odonata: Libellulidae) based on DNA sequence of mitochondrial 16S rRNA gene. *Systematic entomology* 24(1): 37-49. (in English). ["The type genus for the dragonfly family Libellulidae is *Libellula*. At present, *Libellula* s.l. includes twenty-nine species, whose distribution is largely Nearctic. Whether two other libellulid taxa, *Ladona* and *Plathemis*, should be considered synonyms of *Libellula*, subgenera of *Libellula*, or separate genera, has been a subject of intermittent debate for over a century. Earlier proposals concerning *Ladona* and *Plathemis* were based on a limited number of morphological characters and lacked rigorous phylogenetic analyses. Therefore, we used the DNA sequence of a portion of the mitochondrial 16S rRNA gene and parsimony, maximum likelihood and neighbour-joining analyses to explore whether *Ladona* and *Plathemis* are monophyletic lineages distinct from *Libellula*. We obtained approximately 415 bp of DNA sequence from twenty-three taxa including thirteen species of *Libellula* s.s., all three recognized species of *Ladona*, the two species of *Plathemis* and representatives of four other libellulid genera. *Tetragoneuria williamsoni* (Odonata: Corduliidae) was included as the outgroup. Parsimony analysis suggested that *Ladona* and *Plathemis* are monophyletic lineages distinct from *Libellula* s.s. with a sister group relationship between *Libellula* and *Ladona*. The monophyly of *Ladona*, *Plathemis* and *Libellula* was supported in > 90% of bootstrap replications and in trees five to ten steps longer than the most parsimonious trees. Relationships inferred from maximum likelihood and neighbour-joining analyses also supported the monophyly of *Ladona* and *Plathemis*. The four other libellulid genera included in the study formed a monophyletic clade distinct from *Libellula*, *Ladona* and *Plathemis*. Based on our analysis, we propose that *Ladona* and *Plathemis* be considered either genera or subgenera within Libellulidae." (Authors)] Address: Kambhampati, S., Kansas State Univ; Dept Entomol. Manhattan KS 66506; USA. E-mail: srini@ksu.edu

1025. **Karube, H. (1999):** A new species of the genus *Petaliaeschna* (Odonata, Aeshnidae) from Northern Vietnam. *Gekkan-Mushi* 338: 6-7. (in Japanese and English). [*Petaliaeschna flavipes* n. sp. is described from a male from Mt. Piaoac, Cao Bang Province, Northern Vietnam (May 1998). The new species is closely related to *P. corneliae* Asahina, 1982.] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan

1026. **Karube, H. (1999):** *Planaeschna cucphuongensis* spec. nov., a new dragonfly from northern Vietnam (Anisoptera: Aeshnidae). *Odonatologica* 28(3): 279-282. (in English). ["The new sp. is described and illustrated from a single male (holotype: Hoa Binh prov., Cue Phuong National Park, 2-VI-1998; deposited at Kanagawa Prefectural Mus. Nat. Hist., Odawara, Japan). It is similar to *P. chiengmaiensis* Asahina, from Thailand, from which it is distinguished by more slender and strongly bent superior appendages and by a different shape of the inferior appendages." (Author)] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan

1027. **Kirfel, G.; Komnick, H. (1999):** Differential absorption and esterification of dietary long-chain fatty acids by larvae of the dragonfly, *Aeshna cyanea*. *Archives of insect biochemistry and physiology* 40(4): 183-193. (in English). ["In order to evaluate whether dietary long-chain fatty acids were differentially absorbed, *Aeshna cyanea* larvae received 5 μ l oral doses containing combinations of two radiolabeled fatty acids at nearly equal radioactive and nmolar concentrations: (1) H-3-oleic and C-14-palmitic acids; (2) H-3-oleic and C-14-stearic acids; and (3) H-3-palmitic and C-14-stearic acids. After 3 h or 1 day, hemolymph samples, midgut tissue, midgut contents and fat body tissue were collected and assayed for labeled fatty acids. The H-3/C-14 ratios indicated that there was a preference for absorption of the monounsaturated oleic acid over both saturated palmitic and stearic acids and that the shorter palmitic acid was absorbed at a higher rate than the longer stearic acid. There were also differences in the H-3/C-14 ratios of the various lipid classes of the midgut wall, hemolymph, and fat body that reflected differential esterifications and transport of these fatty acids. *Arch. Insect Biochem, Physiol*, 40:183-193, 1999." (Authors)] Address: Komnick, H.; Univ. Bonn; Inst. Cell Biol., Ulrich Haberland Str 61A; D-53121 Bonn; Germany. E-mail: komnick@uni-bonn.de

1028. **Klapkarek, N.; Beutler, H. (1999):** Die Libellenfauna (Odonata) des NSG "Lieberoser Endmoräne" (Brandenburg). *Märkische entomologische Nachrichten* 1: 21-38. (in German, with English summary). [55 odonate species could be recorded in one of the most important German dragonfly habitats; some of the habitats are undisturbed by any anthropogenic influence. The extraordinary odonate conservationary value e.g. of Lake Drusche can be exemplified by the sympatric occurrence of all European species of the genus *Leucorrhinia*. Of special interest are *Nehalennia speciosa*, *Epithea bimaculata*, *Leucorrhinia albifrons*, *L. caudalis*, *Onychogomphus forcipatus*, *Gomphus vulgatissimus* (lake-population of these species of running waters), and *Cercion lindenii*. Some more species are discussed in some detail.] Address: Beutler, H., Kirschallee 3b, 15848 Stemmen, Germany; Klapkarek, N., Inst. Ökol. und Naturschutz, Coppistr. 1-3, 16227 Eberswalde, Germany. E-mail: q4961625@bonsai.fernuni-hagen.de

1029. **Klein, J.-P.; Vanderpoorten, A. (1999):** Étude écosystématique d'une gravière de l'ancien lit majeur du Rhin (Krafft-Erstein, Bas-Rhin, France). *Martinia* 15 (1): 3-13. (in French, with English summary). ["An integrated survey of a gravel pit located in the former alluvial floodplain of the Rhine was carried out between 1994 and 1997. The gravel pit is fed by groundwater and its water level is controlled by the floodpulse of the Rhine. The quality of the water was monitored monthly between 1995 and 1997 and was found to be alkaline, oligomesotrophic, moderately mineralised, calcareous and chloridic. Data dealing with adults and exuviae were compared with the quality of the water and the aquatic and riverine phytocenosis. In this man-made biotope, 24 species of Odonata were recorded. *Enallagma cyathigerum*, *Libellula fulva*, *Crocothemis erythraea*, *Ischnura elegans*, *Orthetrum cancellatum*, *Anax imperator*, and *A. parthenope* are the most common ones. Two species are protected at the national level, 3 are included within the French red list and 11 within the Baden-Württemberg red list, 3 within the red list of the European Council and 2 within the European list for Habitat directive. The dragonfly diversity in this recent gravel pit is similar to that of the oldest ones in this region and is not depressed as a cause of large populations of fish

and the low diversity of the phytocenosis. Nevertheless, the latter caused a low density in species such as *Platynemis pennipes* and *Cercion lindenii*. The diversity of the dragonfly assemblage in this gravel pit is linked to water quality, and also to its status of pioneer area acting as a refuge resembling the former side channels of the Rhine river before canalisation. This study can be used for future surveys to compare and evaluate the impact and consequences of the artificial flooding of the riverine landscape of the Erstein area owing to the later retention of the Rhine highflow." (Author)] Address: Klein, J.-P., Laboratoire d'Analyses et de Biologie Médicales Aubert, 22, rue des Carmes, F-54063 Nancy, France

1030. **Klein, J.-P. (1999)**: Les odonates des forêts rhénanes de Strasbourg, Bas-Rhin, France. *Opusc. zool. flumin* 168: 1-28. (in French, with English summary). ["During 1995-1996, 34 spp. were evidenced, including the locally rare *Calopteryx virgo*, *Coenagrion mercuriale*, *C. pulchellum*, *Aeshna grandis*, *Gomphus pulchellus*, *G. vulgatissimus* and *Onychogomphus forcipatus*. The habitats are briefly described in terms of their respective vegetation, and the odonate applicability in the wetland biological assessment is demonstrated. A comparison of the current status with the records of the early 1960s indicates the vulnerability of various spp. The present work renders a contribution towards the setting up of guidelines for the conservation and ecological management of aquatic habitats of the Strasbourg alluvial forests." (Author)] Address: Klein, J.-P., Laboratoire Aubert, Analyses médicales et biologiques, Département environnement et santé, 22, rue des Carmes, B.P. 664, F-54063 Nancy, France

1031. **Kohl, S. (1999)**: Libellenbeobachtungen auf der griechischen Insel Samos. *Libellula Suppl.* 2: 41-42. (in German, with English summary). ["In September 1996, 14 species were recorded. *Anax ephippiger* is new for the fauna of Samos." (Author)] Address: Kohl, S., Seestr. 107, CH-8610 Uster, Switzerland

1032. **Kopij, G. (1999)**: Food of the Cattle Egret (*Bubulcus ibis*) in South African grassland. *Vogelwarte* 40: 98-109. (in English). ["The study is based on stomach content and boli analyses originated from chicks and adult birds living in South African grassland. Most of the Cattle Egrets' diet consisted of insects (69% of total dry mass), other arthropods constitute 2% and vertebrates 28%. Insect prey consisted mainly of Orthoptera (47%, mainly Acrididae) and Isoptera (12%, exclusively *Hodotermes mossambicus*). Coleoptera, Lepidoptera and Diptera constituted only a supplementary insect ingredient. In the diet of the chicks, a two-fold higher proportion of vertebrates and a lower proportion of insects was shown in comparison with the adult diet. In the same colony, during the 1976/1977 breeding season (with higher rainfall) the proportion of invertebrates and vertebrates was similar, while during the 1993/1994 breeding season (lower rainfall), the proportion of invertebrates was much higher than that of vertebrates. In summer (September - March) most of the adult diet consisted of insects, whereas in winter (June - August) it consisted mainly of vertebrates. The proportion of invertebrates increased and that of vertebrates decreased in the diet of chicks, as they grow." (Author). The food composition is expressed as "percentage of food samples in which the category was recorded". For Odonata in total the frequency (sample size: n = 330) is 7,3 in the chicks: Aeshnidae: 3.0; Coenagrionidae: 4.2;

Libellulidae: 6.7. Odonata could be recorded 31 times in the boli of chicks of Cattle Egret (dry mass: 1.4%) in 1976/1977, and only once in 1993/1994.] Address: Kopij, G., Department of Biology, National University of Lesotho. P. O. Roma 180, Lesotho

1033. **Kornijów, R.; Scibior, R. (1999)**: Seasonal changes in macrofaunal feeding groups associated with *Nuphar lutea* (L.) Sm. leaves in a small eutrophic lake. *Polish journal of ecology* 47(2): 135-143. (in English). ["The epiphytic invertebrates associated with leaves of *Nuphar lutea* in a shallow small eutrophic Lake Glebokie (Lecznawodawa Lake District, eastern Poland) were pooled into one of three feeding groups: 1. algae-detritus feeders (25 taxa, average density 111 ind x 100 cm⁻²), 2. vascular plant feeders (3 taxa, average density 64 ind. x 100 cm⁻²), 3. predators (10 taxa, 4 ind.x 100 cm⁻²). The fauna feeding assemblages underwent clearly marked seasonal changes in their relative abundance, dominance structure and densities. The discussed mechanisms responsible for these changes included trophic conditions (development of periphytic and planktonic algae, nutritive value of the macrophytic tissue, amount of detritus originating from decomposing leaves), so called "dilution effect" (caused by fast increase in the colonizable leaf surface during summer), and the interactions between algae-detritus feeders and predatory invertebrates." (Authors) Odonate predators are: *Enallagma cyathigerum*, *Ischnura elegans*, *Coenagrion puella*, and *Coenagrionidae* n. det.] Address: Kornijów, R., Department of Hydrobiology and Ichthyobiology, E-mail: rkorn@ursus.ar.lublin.pl; Scibior, R., Department of Zoology, E-mail: radeks@ursus.ar.lublin.pl. ["Based on field trips in 1996, 1997, and 1998, and on literature data a review of the dragonfly fauna of Évia is given. At 41 localities 28 species were observed, 12 of them are new for the island. Altogether 31 species are recorded for Évia." (Author)] Address: Lopau, W., Kuhstedtermoor 26, D-27442 Gnarrenburg, Germany

1051. **Lutz, H. (1999):** Die unteroligozäne Insekten-Taphozönose von Sieblos/Rhön - ein Schlüssel für die Rekonstruktion des aquatischen Paläoenvironments. *Geol. Abhandl. Hessen* 104: 101-114. (in German, with English summary). ["This is an up to date summary of the insect taphocoenosis from Sieblos/Rhön. The specimens belong to two different facies types, 1) dysodils and 2) laminated carbonates. The present paper focuses on aspects of taphonomy. An analysis based on the terrestrial insect component of the taphocoenoses from 36 other aquatic paleoenvironments is of fundamental importance for an interpretation of the taphonomical phenomena from Sieblos. The effects of post-mortem surface drifting and sinking, i.e. the length of transport and the water-density affect the composition of local taphocoenoses within a single lagerstätte. This allows for horizons of the same age at the same lagerstätte to differentiate between near-shore and off-shore sites. In addition, the average contents of electrolytes can be determined by correlating the specific density with the sodium-chloridic salinity of marine paleoenvironments. It should be kept in mind however, that both low water-temperatures and contents of suspended matter may also raise the water-density. Nevertheless, the analysis allows for the recognition of normal (non-saline) lakes on the one hand, and brackish-marine to hyperhaline paleoenvironments on the other. Locally restricted lagerstätten of volcanic and/or tectonic origin like Sieblos and Maar-lakes, where many components of the aquatic flora and fauna indicate the predominance of freshwater, while others seem to point to an input of saline water, have been meromictic (salinity stratified) lakes with a high content of electrolytes in the monimolimnion. In these lakes storms or other events episodically caused partial turnovers that led to a more or less intensive increase of the contents of electrolytes within the lacustrine to oligohaline mixolimnion. Especially after periods of more intensive evaporation these partial turnovers may have caused mass mortalities among the stenohaline freshwater organisms. The comparison of the taphocoenoses of different facies or of single horizons within a lagerstätte makes changes of the specific density during the sedimentation of these facies or horizons obvious. Finally, on the basis of these tapho-

nomical informations, a dynamic model is given for the Sieblos-lake, that takes into account hydrological mid paleoclimatological changes during the sedimentation of the fossil bearing facies." (Author). Odonata dominate the insect-taphocoenosis of Sieblos (57,14% of all taxa in the facies of laminated carbonates; 0% in the facies of dysolids; 41,24% of both the facies). The Odonata of Sieblos are treated e.g. by Hagen, H.A. (1858): Zwei Libellen aus der Braunkohle von Sieblos. Palaeontographica 5, or Martini, E. (1971): Neue Insektenfunde aus dem Unter-Oligozän von Sieblos/Rhön. Senckenbergiana lethaea 52(4).] Address: Lutz, H., Naturhistorisches Museum / Landessammlung für Naturkunde Rheinland-Pfalz, Reichklaraste. 10., D-55116 Mainz, Germany.

["The new sp. is described and illustrated from the Ecuadorian Andes (holotype male, allotype female: Napo prov., Baeza, 26-V11-1996; deposited at FSCA, Gainesville). It is similar to *O. terminale* Sel. and *O. bruchi* Navas, from which it is differentiated by the shape of the cerci and the coloration on abdominal segments 8-10." (Author)] Address: Mauffray, W.F. International Odonata Research Institute, D.P.I., P.O. Box 147100, Gainesville FL 32614-7100, USA

1057. **McCarty, J.P.; Winkler, D.W. (1999):** Foraging ecology and diet selectivity of tree swallows feeding nestlings. *Condor* 101(2): 246-254. (in English). ["We studied the foraging ecology of a population of Tree Swallows (*Tachycineta bicolor*) breeding in New York State over a period of 5 years. While feeding nestlings, adult Tree Swallows tended to spend most of their time within sight of their nest box and less than 12 m above the ground. Major insect taxa captured include Diptera, Hemiptera and Odonata, ranging in length from mainly 0-10 mm, with some individuals up to 60 mm. The sex of the parent delivering the food had no significant effect on diet composition. Selection for or against food

categories was determined by comparing the proportion of insects of different types in the diet of Tree Swallows to the proportions available in the air column. Tree Swallows showed consistent selection for insects larger than 3 mm and against smaller insects, especially Diptera in the suborder Nematocera. Only minor differences in diet were observed among years, and the effects of the abundance of food available were generally small. The patterns of selectivity found in this population were consistent with those found in previous studies on this species carried out in other locations, and these patterns are likely the result of differences in the profitability or visibility of prey types." (Authors)] Address: McCarty, J.P., Univ. Maryland; Dept Biol., College Pk, MD 20742; USA. E-mail: jm395@umail.umd.edu

1058. **Ménard, B.; Hutchinson, R. (1999):** *Williamsonia fletcheri* Williamson (Odonata: Corduliidae) au Québec: nouvelles récoltes, habitats et notes biologiques. *Faberies* 24(2/3): 25-32. (in French, with English summary). ["The authors report two new records of *W. fletcheri* Williamson for the province of Québec. This species remains rarely found everywhere in its range. They present their observations on the habitats and the unique microhabitat of this odonate. They also summarize available natural history data and illustrate the larva." (Authors)]. 1065. **Nel, A.; Jarzembowski, E.A. (1999):** Fossil damselflies and dragonflies (Insecta: Odonata) from the late Upper Eocene of southern England. *Proc. geologist's ass.* 111(3): 193-201. (in English). ["Fossil dragonflies (sensu late) from the Bembridge Marls are discussed and five additional species are described: *Lestes* aff. *regina* Theobald, 1937 (Zygoptera: Lestidae); two new coenagrionoids; a corduliid and an enigmatic form of uncertain affinity. The palaeoenvironmental implications are considered." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@mnhn.fr
1066. **Nielsen, D.L.; Hillman, T.J.; Smith, F.J. (1999):** Effects of hydrological variation and planktivorous competition on macroinvertebrate community structure in experimental billabongs. *Freshwater biology* 42: 427-444. (in English). ["1. To study two factors which are predicted as causing changes to community structure in cut-off meanders (colloquially known in Australia as billabongs, a term of aboriginal origin), 16 experimental billabongs were constructed. These were designed to test two hypotheses: (a) that the structure of macrophyte and invertebrate communities within billabongs is altered by changing the pattern of flooding; and (b) that the presence of small planktivorous fish alters invertebrate community structure and diversity within billabongs. 2. An increase in the duration of flooding seems to favour animals better adapted to a greater availability of macrophyte habitat. Changing the seasonality of flooding resulted in prolonging of the time water was available over the summer months. 3. The presence of a planktivorous fish appears to affect macroinvertebrate communities through competition with other planktivores. Variable top-down pressure may create differing successional patterns and ultimately different communities at lower trophic levels." (Authors) Odonate taxa mentioned as follows: "immature damselflies", "*Ischnura* sp.", and "*Diplacodes* sp.". *Ischnura* sp. "may reflect duration of flooding and macrophyte availability.", and "Increasing numbers in the absence of fish. Effect increasing over duration of experiment.". *Diplacodes* sp.: "Seasonal effect. Numbers increase in the absence of fish during summer month, decreases in the winter month."] Address: Nielsen, D.L., Cooperative Research Centre for Freshwater Ecology, (Murray-Darling Freshwater Research Centre), PO Box 921, Albury 2640, New South Wales, Australia. E-mail: odenews@capecod.net
1071. **Norma-Rashid, Y. (1999):** Behavioural ecology of *Tyriobapta torrida* Kirby at the breeding and resting sites (Anisoptera: Libellulidae). *Odonatologica* 28(2): 139-150. (in English). ["*T. torrida* showed territoriality at the water bodies where breeding occurs and also site fidelity at the resting sites on tree trunks away from the water. At the latter, residentiality is very localised not only to a specific tree but to a narrow range of height on the tree. Activity patterns at the breeding sites commenced with the male arrival. The density and activity reached an initial peak during mid-morning which coincided with the high day temperature. Aggression peaked at this time although pursued only for brief periods. The duration for perching behaviour was low during reproductive periods which otherwise had longer bouts." (Author)] Address: Norma-Rashid, Y., Department of Zoology, Faculty of Science, University of Malaya, 59100 Kuala Lumpur, Malaysia
1072. **Novelo-Gutiérrez, R.; Garrison, R.W. (1999):** *Erpetogomphus erici* spec. nov. from Mexico, and a description of the male of *E. agkistrodon* Garrison (Anisoptera: Gomphidae). *Odonatologica* 28(2): 171-179. (in English). ["*E. erici* is described and figured from: El Muro, km 16 Rte 131, Altotonga-Tiapacoyan, Veracruz State, Mexico, and from Pemuxtitia, Rio Zacuala, and Molango, Laguna de Atezca (stream), both in Hidalgo State, Mexico. The allotype male of *E. agkistrodon* is described and illustrated from: Coatepec, Rio La Marina, Veracruz State, Mexico. Both are most closely rela-

ted to *E. schausi* Calvert, but differ in details of the appendages and occiput." (Author)] Address: Novelo-Gutiérrez, R., Departamento de Entomología, Institute de Ecología, A.C., Apartado Postal 63. 1095. **Paulson, D. (1999):** Dragonflies down under. *Argia* 11(1): 5-8. (in English). [report from an odonatological trip to Australia from Dec. 1998 to Jan. 1999; you will find notes on the following species: *Austropetalia patricia* (Tillyard 1910), *Eusynthemis tillyardi* Theischinger 1995, *Choristhemis flavoterminalata* Martin, 1901, *Hemigomphus comitatus* (Tillyard 1909), *Pseudagrion aureofrons* Tillyard 1906, *Pseudagrion ignifer* Tillyard 1906, *Pseudagrion microcephalum* (Rambur 1842), *Nososticta solida* Hagen in Selys 1860, *Diphebia nymphoides* Tillyard 1912, *Diphebia euphaeoides* Tillyard 1907, *Austrolestes minjerriba* Watson 1979, *Orthetrum boumiera* Watson & Arhington, 1978, *Traema eurybia* Selys 1878, *Ischnura aurora* Brauer 1865, *Petalura gigantea* Leach 1815, *Petalura ingentissima* Tillyard 1908, *Nannophya australis* Brauer 1865, *Agriocnemis argentea* Tillyard 1906, *Choristhemis olivei* (Tillyard 1909), *Eusynthemis netta* n.sp. (see OAS 1158) *Tonyosynthemis ofarrelli* (Theischinger & Watson, 1986), *Camacinia othello* Tillyard, 1908] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA

1096. **Paulson, D. (1999):** Dragonfly questions out of Africa. *W.D.A.'s Agrion* 3(1): 14-15. (in English). [a lot of very interesting subjects for people who don't know what about to write their M.Sc.- or Ph.D.-thesis] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA

1097. **Paulson, D.; Hukari, M.; Krotzer, S.; Krotzer, M.J. (1999):** New county records of South Dakota Odonata, with five new species for the state. *Argia* 11(1): 28-29. (in English). [new to South Dakota are *Argomphus cornutus* (Tough 1900), *Stylurus amnicola* (Walsh 1862), *Stylurus notatus* (Rambur 1842), *Leucorrhinia hudsonica* (Selys 1850), and *Sympetrum rubicundulum* (Say 1839).] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA

1098. **Paulson, D. (1999):** Odonata gleanings - dragons eating dragons. *Argia* 11(2): 15-16. (in English).

[discussion, and list of Anisoptera recorded preying on Odonata] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA

1099. **Paulson, D. (1999):** Odonata gleanings - phylogeny and perching behaviour. *Argia* 11(3): 14-15. (in English). [discussion on perching behaviour and its potential importance in constructing a phylogeny of the Libellula group] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA

1100. **Paulson, D. (1999):** Photo files for odonate records. *Argia* 11(3): 19-20. (in English). [state of art report on building up a photo record documentation of US Odonata] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA

1101. **Pedersen, H. (1999):** Records of rare and new dragonfly species in Denmark 1997 - 1998. Contribution No. 1 from "Gomphus - the Danish mapping project". *Nord.Odonat.Soc.Newsl.* 5 (1): 14-15. (in Danish). ["The Danish mapping project - Gomphus, has now put together all Odonata-records from Denmark since 1887, altogether more than 100.000 records. Both museum collections and hundreds of private contributions are recorded in a database linked to electronic distribution maps. *Sympecma fusca* was found new to Denmark in south Jylland in 1998. A second locality for *Nehalennia speciosa* is also noteworthy. *Epitheca bimaculata* and *Leucorrhinia albifrons* were rediscovered in 1998 after 30-40 years without records." Records of other rare species (*Platynemesis pennipes*, *Ischnura pumilio*, *Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Aeshna viridis*, *Anaciaeschna isocetes*, *Cordulegaster boltonii*, *Somatochlora arctica*, *Orthetrum coerulescens*, and *Leucorrhinia pectoralis*) are referred to. "A critical review of the new Danish Odonata book "De danske guldsmede" (O. F. Nielsen 1998) is also included." (Author)] Address: Pedersen, H., Møllevej 15, DK - 8800 Viborg, Danmark, E-mail: henning.pedersen@post12.tele.dk

1102. **Pelt, G.J. van (1999):** On dragonflies from Greece in the RMNH collection, Leiden, The Netherlands. *Libellula Suppl.* 2: 77-90. (in English, with German summary). ["Material of 41 species from 99 localities on the mainland of Greece (1984, 1995), and the islands of Samos and Icaria (1996, 1997) is reported upon. *Somatochlora metallica meridionalis* is reported from the Pelopónissos for the first time. From the island of Icaria 16 species are reported, among which *Calopteryx splendens*, *Enallagma cyathigerum*, *Anax immaculifrons* and *Cordulegaster insignis* are of particular interest." (Author)] Address: Pelt, G.J. van, Naturalis, P.O. 9517, NL-2300 RA Leiden, The Netherlands

1103. **Perrin, V.L. (1999):** Mixed pairing of *Libellula* species. *J. Br. Dragonfly Soc.* 15(2): 61. (in English). [mixed pair of a male *L. fulva* and a female *L. quadrimaculata*] Address: Perrin, V.L., 13 Pettits Lane, Dry Drayton, Cambridgeshire CB3 8BT, UK

1104. **Perrin, V.L. (1999):** Observations on the distribution, ecology and behaviour of the Hairy Dragonfly *Brachytron pratense* (Müller). *J. Br. Dragonfly Soc.* 15 (2): 39-45. (in English). ["This paper draws together information from many sources on the Hairy Dragonfly *Brachytron pratense*, collected as part of the recent Collective Knowledge Project of the British Dragonfly Society (BDS). Many of the observations have not been

published previously. It is intended to act as an overview of the species and to serve as a baseline of current knowledge. Additionally it is hoped that the paper may stimulate comment and further research work on this species which has as yet not been systematically studied over an extended period." (Author) Territorial and feeding behaviour, mating, oviposition aquatic habitat of larva and larval development, emergence, phenology.] Address: V. L. Perrin, 13 Pettits Lane, Dry Drayton, Cambridgeshire CB3 8BT, UK

1105. **Petrulevicius, J.F.; Nel, A.; Muzon, J. (1999):** A new libelluloid family from the upper Paleocene of Argentina. *Palaeontology* 42(4): 677-682. (in English). ["A new family of dragonflies, Palaeomacromiidae, based on *Palaeomacromia multicellulata* gen. et sp. nov., is described from the Late Paleocene Maiz Gordo Formation of north-western Argentina. The present discovery demonstrates that the present knowledge of the Early Cenozoic insect fauna of the Neotropical region remains very poor." (Authors)] Address: Petrulevicius, J.F.; Museo La Plata; Dept Cient Paleozool Invertebrados; Paseo Bosque S-N; RA-1900 La Plata; Argentina. E-mail: levicius@netverk.com.ar

1106. **Piper, W.; Krüner, U. (Eds.) (1999):** Libellen-nachrichten 2. 20 pp. (in German). [Newsletter of the Society of the German speaking Odonatologists with reports of its 18. meeting in Münster, (book) reviews, requests for cooperation, a report of the International Congress of Odonatology in Hamilton/USA in 1999, presentation of WDA, and some additions to "Dragonflies and literature"] Address: Piper, W., Kollenhof 31, D-22527 Hamburg, Germany

1107. **Plaistow, S.; Siva-Jothy, M.T. (1999):** The ontogenetic switch between odonate life history stages: effects on fitness when time and food are limited. *Animal behaviour* 58(3): 659-667. (in English). ["During the course of ontogeny, odonates switch from being aquatic larvae to being terrestrial adults. Ontogenetic niche shift theory proposes that such shifts are adaptive and have evolved to maximize a growth rate (size) to mortality rate ratio. Individuals should therefore switch from one niche to the other at an optimal size or state. Since the majority of odonates are seasonal breeders, the extent to which the switch is optimal will depend upon the time and the resources available during postembryonic development. We collected a cohort of larvae that varied in how close they were to eclosion and reared them on either a high-nutrition or a low-nutrition diet. We then determined the relative influence of both time and nutritional constraints on survival and development rate, as well as the body size, size-corrected flight muscle mass and fat reserves of individuals at eclosion. Damselflies in both high- and low-nutrition treatments responded to a short development period by developing faster and reducing their body size, but did not change their proportional investment in fat reserves and flight muscle. Reduced larval nutrition resulted in decreased body size, flight muscle mass and fat reserves at eclosion. However, it had no effect on survival to eclosion, or development rate. We discuss these results in terms of the influence that time and nutritional constraints have on odonate development patterns and fitness." (Authors)] Address: Plaistow, S., Univ Sheffield, Dept Anim. & Plant Sci., Sheffield S10 2TN, S Yorkshire, England

1108. **Powell, D. (1999):** A guide to the dragonflies of Great Britain. Arlequin Press. Chelmsford. ISBN 1 900159 01 5: 127 pp. (in English). [To me, this is a really outstanding book. Throughout with (water) colour pictures, you will find a lot of information in a somewhat free style, but nonetheless with exact scientific information. There is hardly any picture which don't express a very special mood: often the dragonfly within its habitat is portrayed - a very intrusive example for this is the chapter on *Aeshna caerulea*. In a monographic style, on finds information on morphological details useful for identification, on species which could be confused, on special behaviour, on conditions favourable to observe to see the species you want to see, what habitat is promising... One may say, this book is one for the beginner, but it equally is one for the advanced or professional odonatologist, because the pictures are directed to your soul. Hardly any book with photographs of dragonflies can express this wonderful harmony between landscape, dragonfly, and observer as is done by the colour pictures of Dan Powell. (M. Sch.)] Address: Arlequin Press, 26 Broomfield Road, Chelmsford, Essex CM1 1SW, UK

1109. **Pratt, P.D. (1999):** 1998 summary for southwestern Ontario. *Argia* 11(1): 26. (in English). [Information on *Stylurus notatus* (Rambur 1842), *Sympetrum vicinum* (Hagen 1861), *Enallagma anna* Williamson 1900, *Enallagma traviatum* Selys 1876, *Lestes eurinus* Say 1839, and *Enallagma basidens* Calvert 1902 are presented.] Address: Pratt, P.D., 7100 Matchette Rd, La Salle, ON, Canada, N9C 2S3. E-mail: prairie@netcore.ca

1110. **Prendergast, E. (1999):** Tanzania calling. *W.D.A.'s Agrion* 3(1): 16. (in English). [short report on some dragonflies of the Rufiji River, some 80 km by air from Dar es Salaam] Address: Prendergast E.D.V., Manor House, Bagber, Sturminster Newton, Dorset DT10 2EY, United Kingdom

1111. **Pryce, D.J. (1999):** The 1998 Cameroon dragonfly project expedition. *W.D.A.'s Agrion* 3(2): 24-25. (in English). [report of a 1998 trip to Cameroun, Africa with notes on the dragonfly fauna of some localities in the WWF-Mount Kupe Forest Project; *Aeshna scotias* Pinhey 1952, *Olpogastra lugubris* Karsch 1895, and *Phyllomacromia caneri* (Gauthier 1987) are some species among others mentioned] Address: Pryce, D.J., Moneybrook Lodge, Herford Rd, Meole Brace, Shrewsbury, SY3 9LB, UK

1112. **Radford, A.P. (1999):** Prolonged partial immersion of abdomen by male *Anax imperator* Leach. *J. Br. Dragonfly Soc.* 15(2): 60. (in English). [discussion on an *A. imperator* inserting the posterior third of the abdomen into the water] Address: Radford, A.P., Crossways Cottage, West Bagborough, Taunton, Somerset TA4 3EG, UK

1113. **Ramirez, A.; Paaby, P.; Pringle, C.M.; Aguero, G. (1999):** Effect of habitat type on benthic macroinvertebrates in two lowland tropical streams, Costa Rica. *Revista de biologia tropical* 46(Suppl. 6): 201-213. (in English). ["Benthic macroinvertebrate community structure was studied with respect to stream habitat type in two lowland tropical streams. Three reaches along the Carbon river and two within the Gandoca stream were chosen as study sites in Talamanca, Costa Rica. Ma-

croinvertebrates were collected from four habitat types: leaf packs in riffles, cobble in rimes, areas of sand in pools, and areas of gravel in pools. Communities were dominated by insects in the orders Ephemeroptera (*Thraulodes*, *Baetis*?), Diptera (*Chironomidae*, *Tipulidae*), Trichoptera (*Hydropsychidae*, *Glossosomatidae*, *Hydroptilidae*, *Calamoceratidae*), and Odonata (*Progomphus*, *Hetaerina*). Noninsect macroinvertebrates were dominated by shrimps (*Macrobrachium*) and snails (*Gastropoda*). Functional feeding group composition was dominated by collector-gatherers. In most reaches, both habitat types in rimes supported higher macroinvertebrate abundance and biomass than did habitats in pools. Leaf packs in rimes represent an important habitat that is present year-round in these aseasonal tropical systems. Community composition and diversity were similar to that reported for other areas of Central America." (Authors)] Address: Ramirez, A., Univ Georgia; Inst. Ecol., Athens; GA 30602; USA. E-mail: aramirez@arches.uga.edu

1114. **Ramirez, A.; Novelo-Gutierrez, R. (1999):** The Neotropical dragonfly genus *Macrothemis*: new larval descriptions and an evaluation of its generic status based on larval stages (Odonata: Libellulidae). *Jour. North-American benthol. soc.* 18(1): 67-73. (in English). ["The larvae of *Macrothemis aurimaculata* and *M. inequinguis* are described and illustrated. A redescription of *M. celeno* is also provided. *Macrothemis aurimaculata* can be separated from other species in the genus because it has reduced or vestigial dorsal protuberances on abdominal segments VII-IX. *Macrothemis inequinguis* can be differentiated by the presence of 7 setae on the labial palp, in contrast to less than or equal to 6 in other species. Both species inhabit streams in areas with slow-moving water. *Macrothemis celeno* closely resembles *M. inacuta* and *M. pseudimitans*. Some features to separate larvae of *Macrothemis* from its close relative *Brechmorhoga* are given. A key for identification of all the described larvae of *Macrothemis* is provided." (Authors)] Address: Ramirez, A., Univ Georgia; Inst. Ecol., Athens; GA 30602; USA. E-mail: aramirez@arches.uga.edu

1115. **Ramos Hernandez, J.M. (1999):** List of the Odonata (Insects; Odonata) from Cayo Caguanes and Cayo Palma, Sancti-Spiritus Province, central Cuba. *Argia* 11(3): 15-17. (in English). [checklist of 23 taxa] Address: Ramos Hernandez, J.M., Ap. Post. 2204, Sancti-Spiritus, CUBA Cp. 60100

1116. **Reder, G. (1999):** Wolfsspinnen (Araneae: Lycosidae) als Beutegreifer einer schlüpfenden Großlibelle (Anisoptera: Gomphidae). *Libellula* 18(1/2): 59-62. (in German, with English summary). ["Three individuals of *Pardosa amentata* (Clerck) attacked an emerging female of *Gomphus pulchellus* Selys successfully. The observation is briefly discussed." 1117. **Rehfeldt, G. (1999):** Massenentwicklung von *Sympetrum fonscolombii* (Selys) in Südfrankreich 1996 (Anisoptera: Libellulidae). *Libellula* 18(1/2): 103-106. (in German, with English summary). ["At the beginning of July 1996 *S. fonscolombii* showed mass development at rice fields of the Camargue. Relations with the immigration of the species in Central Europe are discussed." (Author)] Address: Rehfeldt, G., Zool. Inst. TU

Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: G.Rehfeldt@tu-bs.de

1118. **Reinhardt, K.; Seidenbusch, R. (1999):** Zur Libellenfauna des Ili-Gebietes, Kasachstan (Insecta: Odonata). Faunistische Abhandlungen, Staatliches Museum für Tierkunde Dresden 21(14): 221-228. (in German, with English summary). ["A field trip into the basin of the river Ili, SE Kazakhstan, yielded a total of 19 dragonfly species including new records for *Ischnura aralensis*, *Erythromma najas* and *Selysiothemis nigra*. The dragonfly fauna of the region between Lake Balkhash and the Tien Shan mountains as derived from a literature review now comprises 44 species, at least five of which appear doubtful. *Sympetrum tibiale* has not been recorded for nearly 100 years. Factors contributing to the probable underestimation of dragonfly species richness in that area are discussed." (Authors) Short remarks on the daily activities of *Sympecma paedisca*, predation by *Falco subbuteo*, *Merops superciliosus*, and missing of predation by *Motacilla flava feldegg* (Aves) on Odonata, the description of aggregations of *Libellula quadrimaculata* on dormitories, and notes on the morphology of *L. quadrimaculata* are of some interest.] Address: Reinhardt, K., Hauptstr. 38, D-09244 Oberlichtenau, Germany. E-mail: b5klre@pluto.rz.uni-jena.de

1119. **Reinhardt, R. (1999):** Kurzfassung und Auszüge aus dem Abschlußbericht des F/E-Projektes: Landesweit repräsentative, ortsgenaue Erfassung ausgewählter, Naturschutzrelevanter Insektengruppen sowie Benennung von Gebieten mit besonderer Bedeutung für die Entomofauna in Sachsen (Entomofauna Saxonica II). Mitt. Sächs. Entomol. 45: 2-29. (in German). [Status quo - report on the distribution of the Odonata of the federal state Sachsen, Germany (dot map of records on the basis of TK 25); check list with record resp. locality frequency of each of the 60 species presently known from Sachsen; further 7 species are assumed to be extinct; after 1990 four species (*Sympecma paedisca*, *Stylurus flavipes*, *Anax ephippiger*, and *Crocothemis erythraea*) were reported new for Sachsen; *Aeshna affinis*, and *Sympetrum fonscolombii* have been rediscovered in the 90th; 15 species can only be observed at less than 15 localities in the federal state] Address: Reinhardt, R., Burgstädter Str. 80a, D-09648 Mittweida, Germany

1120. **Relyea, R.A.; Werner, E.E. (1999):** Quantifying the relation between predator-induced behavior and growth performance in larval anurans. *Ecology* 80(6): 2117-2124. (in English). ["Because the nature and magnitude of species interactions are functions of the traits that species possess, understanding how individual traits affect performance is important to our understanding of community structure. To examine the relation between species traits and performance, we first assessed behavioral responses of two larval anurans to three predator species in the laboratory. We then correlated these responses with growth performance of the two anurans when they competed in the field. In the laboratory experiment, larval bullfrogs (*Rana catesbeiana*) and green frogs (*R. clamitans*) exhibited no reduction in activity or spatial avoidance to bluegill sunfish (*Lepomis macrochirus*), moderate reductions in activity and spatial avoidance of mudminnows (*Umbra limi*), and large reductions in activity and spatial avoidance of larval dragonflies (*Anax* spp.). In the field experiment,

these behavioral responses were directly related to corresponding reductions in growth of the anuran larvae. Thus, for both species, changes in growth in the field could be correlated to the behavioral responses observed in the laboratory. Further, proportional changes in behavior in the presence of the different predators appeared to be related to changes in competitive relations in the field." (Authors)] Address: Werner, E.E., Department of Biology, University of Michigan, Ann Arbor, Michigan 48109, USA

1121. **Rith, J. (1999):** Minnesota dragonfly survey project. *Argia* 11(1): 31-32. (in English). Box 453, Bemidji, MN 56619, United States

1122. **Roberts, S.P.; Harrison, J.F. (1999):** Mechanisms of thermal stability during flight in the honeybee *Apis mellifera*. *Jour. exp. biol.* 202(11): 1523-1533. (in English). ["Thermoregulation of the thorax allows honeybees (*Apis mellifera*) to maintain the flight muscle temperatures necessary to meet the power requirements for flight and to remain active outside the hive across a wide range of air temperatures (T-a). To determine the heat-exchange pathways through which flying honeybees achieve thermal stability, we measured body temperatures and rates of carbon dioxide production and water vapor loss between T-a values of 21 and 45 degrees C for honeybees flying in a respirometry chamber. Body temperatures were not significantly affected by continuous flight duration in the respirometer, indicating that flying bees were at thermal equilibrium. Thorax temperatures (T-th) during flight were relatively stable, with a slope of T-th on T-a of 0.39. Metabolic heat production, calculated from rates of carbon dioxide production, decreased linearly by 43 % as T-a rose from 21 to 45 degrees C. Evaporative heat loss increased nonlinearly by over 50%, with evaporation rising rapidly at T-a values above 33 degrees C. At T-a values above 43 degrees C, head temperature dropped below T-a by approximately 1-2 degrees C, indicating that substantial evaporation from the head was occurring at very high T-a values. The water flux of flying honeybees was positive at T-a values below 31 degrees C, but increasingly negative at higher T-a values. At all T-a values, flying honeybees experienced a net radiative heat loss. Since the honeybees were in thermal equilibrium, convective heat loss was calculated as the amount of heat necessary to balance metabolic heat gain against evaporative and radiative heat loss. Convective heat loss decreased strongly as T-a rose because of the decrease in the elevation of body temperature above T-a rather than the variation in the convection coefficient. In conclusion, variation in metabolic heat production is the dominant mechanism of maintaining thermal stability during flight between T-a values of 21 and 33 degrees C, but variations in metabolic heat production and evaporative heat loss are equally important to the prevention of overheating during flight at T-a values between 33 and 45 degrees C." 1123. **Rödel, M.O. (1999):** Predation on tadpoles by hatchlings of the freshwater turtle *Pelomedusa subrufa*. *Amphibia-Reptilia* 20(2): 173-183. (in English). ["Experiments with *Pelomedusa subrufa*, a widespread African freshwater turtle, showed that this species consumed large quantities of tadpoles. Tadpoles preyed upon, comprised between 0.05 and 21.55% of the turtle's biomass. This demonstrated that *Pelomedusa subrufa* was neither gape limited nor did it ignore very small prey. Tadpoles with an ovoid body shape (*Hemismus marmoratus*, *Hyperolius nitidulus*, *Ptychadena macrathyensis*), which shared, under natural conditions, the pond bottom microhabitat with the turtles, were more threatened than the robust tall-finned *Kassina* tadpoles that lived in the middle of the water column. The translucent, slow swimming *Phrynomantis microps* tadpole occurred in larger ponds and preferred the upper water column in deeper parts of the pond. This species was especially at risk in ponds with reduced water levels. Turtles, in contrast to fish or dragonfly larvae, are capable of migrating to other ponds. They therefore might have a profound regional influence on tadpole communities in ephemeral savanna ponds." 1129. **Schaffner, A.K.; Anholt, B.R. (1999):** Influence of predator presence and prey density on behavior and growth of damselfly larvae (*Ischnura elegans*) (Odonata: Zygoptera). *Jour. insect behav.* 11(6): 793-809. (in English). ["Foraging behavior is often determined by the conflicting benefits of energy gain and the risk of mortality from predation or other causes. Theory predicts that animals should have lower activity levels when either the risk of predation or the availability of resources in the environment is high. We investigated the adjustment of the behavior of *I. elegans* larvae to predator presence (*Anax imperator*) and prey density (*Daphnia* sp.) and their interaction in a completely crossed factorial experiment in the lab and the effect of behavior oil growth. The foraging activity of the *I. elegans* larvae was significantly reduced in the presence of a free-swimming predator but not a caged predator. Abdominal movements were significantly reduced at a low prey density, Growth was significantly reduced by the presence of a free swimming predator and low prey densities. These results provide evidence that these damselfly larvae adjust their behavior to the presence of predators to increase their survival at the expense of reduced growth and development." Braunschweiger naturkl. Schr. 5(4): 857-867. (in German, with English summary). [Niedersachsen, Germany; "The larval development of *Calopteryx splendens* was monitored from 1995 to 1998 in the river Oker and compared to that of *Calopteryx virgo* in the stream Lutter. Numbers and sizes of larval instars are given for both species. Larval development of *C. splendens* took one year, whereas *C. virgo* needed two years. Differences were discussed in terms of temperature, food and specific activity levels." (Authors)] Address: Schütte, C., Zool. Inst. TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany

1135. **Shieh, S.-H. B.; Kondratieff, C.; Ward, J. V.; Rice, D. A. (1999):** The relationship of macroinvertebrate assemblages to water chemistry in a polluted Colorado plains stream. Arch. Hydrobiol. 145(4): 405-432. (in English). ["Macroinvertebrate assemblages and 27 water chemistry variables were investigated at 8 sampling sites over a 4-year period (1992-1995) in the plains section of the Cache la Poudre River, north central Colorado, USA, influenced by urbanization and agricultural activities. Relationships between macroinvertebrate assemblages and water chemistry variables were examined along a longitudinal chemical gradient using ordination techniques [...]. Principal component analysis ordination diagrams provide a reasonable two-dimensional representation of both the macroinvertebrate and environmental data. Concentrations of cations (e.g. Ca, Mg, Na, and K ions) exhibited the strongest relationship with macroinvertebrate assemblages along the river section. The inorganic nutrients (e.g. ammonia, total Kjeldahl nitrogen, and total phosphorus), suspended solids, and turbidity were also associated with macroinvertebrate assemblage structure. Temporal trends of macroinvertebrate assemblages, investigated using Detrended Canonical Correspondance Analysis, showed that interannual and seasonal variations of macro-invertebrate assemblages were related to increases in concentrations of heavy metals and to decreases in concentrations of inorganic nutrients, suspended solids, and turbidity. Interannual variations were less important than seasonal changes in explaining temporal patterns of macroinvertebrate assemblages [...]."] (Authors). Appendix 1 lists the taxa collected at

the sampling sites. Coenagrionidae and Ophiogomphus severus are the only Odonata mentioned.] Address: Shieh, S.-H., Department of Biology, Colorado State University, Fort Collins, CO 80523, USA

1136. **Sibley, F. (1999):** A beginners random observations on winter dragonflies. Argia 11(1): 13-15. (in English). 1143. **Smith, G.R.; Rettig, J.W.; Mittelbach, G.G.; Valiulis, J.L.; Schaack, S.R. (1999):** The effects of fish on assemblages of amphibians in ponds: a field experiment. *Freshwater biology* 41(4): 829-837. (in English). ["1. Bluegill sunfish (*Lepomis macrochirus*) dominate fish assemblages of small lakes and ponds throughout the eastern United States and may play a major role in structuring aquatic communities. We examined the impact of adult bluegill on amphibian density by stocking bluegill at a range of densities into partitions of an experimental pond in which amphibians were free to colonize. 2. Adult bluegill had a major impact on the amphibian assemblage. By the end of the experiment, gray treefrog (*Hyla versicolor*) tadpoles were nine times less abundant, and red-spotted newt (*Notophthalmus viridescens*) adults were three times less abundant in the presence of adult bluegill than in their absence. In contrast, bullfrog (*Rana catesbeiana*) tadpoles tended to increase in the presence of adult bluegill. Adult bluegill also had a negative effect on the abundance of predaceous aquatic insects. [... Larval odonates (Aeshnidae and Libellulidae) were the most common insect predators in the pond, accounting for > 90% of all predaceous insects collected. The abundance of both of these odonate groups declined significantly with adult bluegill density ...] 3. There was no indication that interactions among amphibians were significant in determining the above patterns. We suggest that the strong impact of adult bluegill resulted from a combination of direct and indirect effects on amphibian larvae and predaceous aquatic insects." 1149. **Sternberg, K. & R. Buchwald (Eds) (1999):** Die Libellen Baden-Württembergs. Band 1. Verlag Eugen Ulmer, Stuttgart. ISBN 8001-3508-6. (approx. 50,- Euro): 468 pp. (in German). [This is the first part of a two-volume work on the Odonata of the region in the southwestern part of Germany. It presents a general but detailed account of the Odonata (Checklist, Fossile Odonata in Baden-Württemberg, Regional faunistics, Field methods, Threats and legal protection, Regionalised Red List, "Umbrella Species Concept", Habitats and management of waters, Systematics and evolution of Odonata, Functional morphology, Some aspects of biology of Odonata, Population ecology and dispersal, Reproduction behaviour, Man and dragonfly, Odonata as bioindicators, and Glossarium). The general introduction on Odonata is followed by a monographic treatment of the 26 species of Zygoptera recorded from Baden-Württemberg. The bibliography will appear in volume two, which also will cover 49 species of Anisoptera. For each zygopteran, there is a very detailed account encompassing global range of the species, distribution within Baden-Württemberg (including a distribution map), annual and diurnal phenology, larval habitat (including vegetation and physical and chemical properties of the water), the biotypes occupied by the adult at various stages of its life (feeding, breeding, roosting), a comprehensive section on the biology of the larva and adult and, finally, records of parasitism. The editors obviously intended to produce more than a standard regional study of dragonflies. It is a beautifully produced book, illustrated by marvellous photography. A more detailed critical review will be prepared after publication of volume two. This high quality book should not be missing in any odonatological library. (Martin Schorr, partly on the basis of R. Askew's review in the *J. Br. Dragonfly Soc.* 15: 64)]

De Bruyn, (1999): Lethal and sublethal costs of autotomy and predator presence in damselfly larvae. *Oecologia* 120(1): 87-91. (in English). ["We studied the costs of lamellae autotomy with respect to growth and survival of *Lestes sponsa* damselfly larvae in field experiments. We manipulated predation risk by *Aeshna cyanea* dragonfly larvae and lamellae status of *L. sponsa* larvae in field enclosures and compared differences in numbers, size and mass of survivors among treatments. In the absence of a free-ranging *A. cyanea* larva, about 29% of the *L. sponsa* larvae died. This was probably due to cannibalism. The presence of a free-ranging *A. cyanea* reduced larval survival by 68% compared to treatments in which it was absent or not permitted to forage on *L. sponsa* damselflies. Across all predator treatments, lamellae autotomy reduced survival by about 20%. The mean head width and mass of survivors was lower in the enclosures with a free-ranging *A. cyanea* compared to the other two predator treatments. This suggested that larvae grew less in the presence of a free-ranging predator, indicating that increased antipredator behaviours were more important in shaping growth responses than reduced population density. Mass, but not head width, of survivors was also reduced after autotomy. The fitness consequences of these effects for the adults may be pronounced. In general, these field data strongly suggest that lamellae autotomy affects population regulation of damselflies." 1151. **Strub-Siegenthaler, I. (1999):** Kind und Libelle: Rückschau auf meine Arbeit in der Schule. *Odonatologica* 28(4): 429-432. (in German, with English summary). ["In canton Berne, Switzerland, the primary school children, aged 6-8, are conscious of dragonflies even before the subject is treated in school. At this age, the child's imaginative faculty attributes to the dragonfly certain physical features, behavioural propensities, and an imaginary role in nature, which all are to be utilized by the teacher in the process of creating a realistic, simple and to the child comprehensible biological image of the insect. In the Berne school program, dragonflies are dealt with in the framework of the broader instructional topic, "Water". The steps in the instruction program, as developed by the Author during her 40 yr of teaching experience, are briefly outlined, and the scope and depth of the child's final knowledge on the dragonfly world are stated." (Author)] Address: Strub-Siegenthaler, I., Seestrasse 26J, CH-3600 Thun, Switzerland.

1152. **Summers, K. (1999):** The effects of cannibalism on Amazonian poison frog egg and tadpole deposition and survivorship in *Heliconia* axil pools. *Oecologia* 119: 557-564. (in English). ["This study investigated the influence of cannibalism on egg and larval mortality, and on the deposition strategies of adults, in a tropical anuran breeding in very small leaf axil pools. Patterns of egg and tadpole deposition and mortality in the Amazonian poison frog, *Dendrobates ventrimaculatus*, were monitored in rainforest near Pompeya in Sucumbios Province, Ecuador. Oviposition and tadpole deposition typically occurred in leaf axils of *Heliconia* plants. Pools typically received more than one oviposition. Egg survivorship was low, and significantly lower when eggs were deposited in pools with large tadpoles, indicating that cannibalism is an important source of mortality. Tadpole

survivorship was also associated with the presence of other tadpoles: most pools ended with only one surviving tadpole, regardless of the number of tadpoles deposited in the pool. Egg deposition was significantly less likely for pools that had a tadpole in them, suggesting that adults can detect the presence of tadpoles and avoid ovipositing in pools that contain them. This hypothesis was tested with a series of pool choice experiments, which revealed that *D. ventrimaculatus* avoid placing either eggs or tadpoles into a pool which contains a large tadpole. Several hypotheses which could explain multiple deposition in this species are discussed. [...] A diverse community of adult and larval vertebrates and invertebrates inhabits the *Heliconia* pools, and yet predators on *D. ventrimaculatus* eggs or tadpoles seem to be rare. since there was no association between egg or tadpole mortality and the presence of any of the other pool denizens. Perhaps most surprising was the absence of any odonate larvae, which are known predators of poison frog tadpoles (Fincke 1994). One dead odonate larva was found in an axil pool during the course of the study, whereas well over 500 pools were searched on and off the study site. The reason for this low prevalence is unknown, although it may be associated with the small size and generally low nutrient quality of the *Heliconia* pools." 1153. **Switzer, P.V.; Walters, W. (1999):** Choice of lookout posts by territorial amberwing dragonflies, *Perithemis tenera* (Anisoptera: Libellulidae). *Jour. insect behav.* 12(3): 385-398. (in English). ["Many territorial insects use specific perches, or lookout posts, from which they perceive and react to conspecific males and females. We investigated the lookout post choice of territorial male amberwing dragonflies (*Perithemis tenera*). An observational study indicated that males rarely perched directly at their oviposition site; rather they perched farther out from shore than, and within 2 m from, their oviposition site. In an experimental study, we provided an array of perches at different distances from the shore and oviposition site to eliminate perch limitation as a factor in perch choice. The results of the experimental study confirmed the patterns evident in the observational study; males perched farther from shore than their oviposition site was located. interestingly, in both the observational and the experimental study, when neighbors were close, a male perched away from his closest neighbor; which usually resulted in his oviposition site being closer to his neighbor than he was. Thus, male amberwings apparently alter their perch choice within their territories in response to the location of other males. These lookout post locations may provide the best opportunity for the territorial male to perceive passing females and intruding males, while minimizing conflict with their neighbors." 1160. **Thompson, D.J.; Purse, B.V. (1999):** A search for long-distance dispersal in the Southern damselfly *Coenagrion mercuriale* (Charpentier). *J. Br. Dragonfly Soc.* 15(2): 46-50. (in English). [A total of 1245 individuals of *C. mercuriale* were marked in 11 days in 1998 on Crockford stream, New Forest, Hampshire, UK. To spott dispersing individuals 27 volunteers were stationed on all known sites for *C. mercuriale* in distances between 200 m and 3.3 km. "One marked animal had clearly moved from a site at which it was searching for mates to another over 1km away at which it found one. The extent of its movement was similar to the one long-distance disperser reported by Hopkins & Day (1997). Indeed, it ended up in the same place. In order to get there it must either have crossed a considerable expanse of dry heath and a road, or followed the stream downstream through unsuitable habitat, including woodland or some combination of the two. Jenkins (1998) reported that *C. mercuriale* was extraordinarily reluctant to move from its home location even across a short open area. The absence of marked individuals at the sites closest to the marking site supports this view. However, *C. mercuriale* clearly has some potential to make relatively long movements after reaching maturity." ISBN 83-01-08125-2. [Conservation of insects on the threshold of the integration of Poland into the European Community]: 23. (in Polish). [The threat and the necessity for protection of the habitats of the odonate species of running waters in Poland is outlined. Two antagonistic amendments of the situation of the Odonata are described: the populations of the formerly rare species of streams and rivers as *Stylurus flavipes* are getting stronger in the last years, whereas the situation of the species of brooks and ditches is getting worse more and more. Reasons for that are the improvement of water quality in the streams and rivers on the one side, and the regulation of brooks, heavy environmental impacts on the running waters, and lowering of groundwater table on the other.] Address: Buczynski, P., Dept of Zool., Marie Curie-Sklodowska University, Akademicka 19, PO-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

1164. **Trueman, J. (1999):** An update on the above situation. *W.D.A.'s Agrion* 3(2): 23-24. (in English). [With reference to Ian Endersby's contribution "Disturbing news from "Downunder", the author outlines, that the habitat of *Petalura gigantea* was not affected by the 1998 collapse of Wingecarribee Swamp, Australia. A few individuals including an ovipositing female could be observed in January 1999. Now, a management plan is developed, e.g. to prevent the lasting rests of the swamp from drying out and getting invaded by "nasty foreign weeds".] Address: Trueman, J., Research School of Biol. Sciences, Australian National University, Canberra, ACT 0200, Australia. E-mail: trueman@rsbs.anu.edu.au
1165. **Truscott, L. (1999):** The Hornet Robberfly *Asilus crabroniformis* L. (Diptera, Asilidae): Odonata as prey. *J. Br. Dragonfly Soc.* 15(2): 50. (in English). [new observations from UK on *Enallagma cyathigerum* as prey of *A. crabroniformis*] Address: Truscott, L., 59 Cremyll Road, Torpoint, Cornwall PL11 2DZ, UK

1167. **Van Buskirk, J.; McCollum, S.A. (1999):** Plasticity and selection explain variation in tadpole phenotype between ponds with different predator composition. *Oikos* 85(1): 31-39. (in English). ["Experiments demonstrate the existence of phenotypic plasticity in many organisms, and suggest that it can affect interactions among species. Put rarely do we know whether naturally occurring phenotypic variation results primarily from plasticity, as assumed by the experiments, or also from processes such as local adaptation and viability selection. The data on predator-induced plasticity in amphibians are virtually all from artificial pond or laboratory experiments, so we sampled tadpoles of *Hyla versicolor* in two ponds with different numbers of predators, in southern Michigan, USA. Cornfield Pond had few predators, while Tinkle's Marsh (300 m away) had many predatory insects (11.4/m²) and *Ambystoma* salamanders (1.0/m²). Tadpoles from Tinkle's Marsh had shorter and shallower bodies than those from Cornfield Pond. and relatively long, deep, and brightly colored tails. We then asked whether the phenotypic difference could be predicted from experimental studies of plastic responses to the presence or absence of caged *Anax* dragonflies in cattle tanks, and of selection imposed by feeding *Anax* and in predator-free ponds. Plasticity accurately predicted observed population differences in traits such as tail color, tail depth, and body length. However, for some other traits, such as tail length and body depth, naturally occurring phenotypic variation was more likely produced by selection for divergent traits in the two ponds. We also collected tadpoles from both ponds and subjected them to free-ranging *Anax* in a short-term predation trial. Tadpoles from Tinkle's Marsh, where predators were common, survived 16% better, suggesting that naturally occurring phenotypic variation is associated with changing vulnerability to predation: as has been found for experimentally reared tadpoles. Our results show how experimental studies of plasticity and selection can be combined to predict phenotypic variation in nature, and phenotypic variation in nature, and suggest that such variation can modify species interactions." (Authors)] Address: Van Buskirk, J., Univ Michigan, Dept Biol, Ann Arbor, MI 48109 USA
1168. **Van Gossum, H.; Stoks, R.; Matthysen, E.; Valck, F.; De Bruyn, L. (1999):** Male choice for female colour morphs in *Ischnura elegans* (Odonata, Coenagrionidae): testing the hypotheses. *Animal behaviour* 57(6): 1229-1232. (in English). ["The occurrence of different conspecific female colour morphs, with one of the morphs resembling the male, is supposed to have consequences for mate choice. There are two hypotheses linking mate choice and female colour polymorphism. First, males may mate predominantly with female morphs that differ from the male because they do not recognize androchrome females as females (male mimic hypothesis). Second, males may be more attracted to the most common morph in the population (habituation hypothesis). We tested these hypotheses in five populations of the same species, *Ischnura elegans*, with a range of androchrome frequencies. In each population we performed binary choice experiments in small cages. Males did not consistently prefer gynochrome females but mated predominantly with the most common morph in the population. Moreover, a reanalysis of the available damselfly data in the literature also supported the habituation hypothesis" (Authors)] Address: Van Gossum, H., Evolut Biol Grp, Univ. 1169. **van Konijnenburg-van Cittert, J.H.A.; Schmeissner, S (1999):** Fossil insect eggs on Lower Jurassic plant remains from Bavaria (Germany) . *Palaeography - Palaeoclimatology - Palaeoecology* 152 (3-4): 215-223. (in English). ["Imprints of fossil insect eggs (oviposition slits of endophytic eggs) on Lower Jurassic plants from Franconia (Bavaria, Germany) are described. Two forms can be distinguished. Form A (2.5-3 mm long, 0.5-0.7 mm wide) is comparable to *Hysterites friesii* Nathorst 1876, who described it on *Podozamites* leaves (Coniferales) and considered it to be fungal remains. The present oviposition slits are, however, all on *Schmeissneria microstachys* leaves (Ginkgoales), and are therefore not considered to be conspecific with Nathorst's species. Form B (ca. 2 mm long, 0.7 mm wide) is more rare, and has only been found on *Podozamites distans* leaves but cannot be identical with Nathorst's material because they demonstrate a different shape. Form A has been deposited by dragonflies (Odonata); the insects that deposited form B may also have belonged to this group but this cannot be said with certainty. Comparison with other fossil insect egg/plant relationships are made, e.g. with comparable eggs on Triassic material of *Equisetites arenaceus*. The parent plants must have lived in an aquatic, or more probably semi-aquatic environment." (Authors)] Address: van Konijnenburg-van Cittert, J.H.A.; Palaeobot. & Palynol. Lab., Budapestlaan 4; NL-3584 CD Utrecht; Netherlands . E-mail: j.ha.vanKonijnenburg@bio.uu.nl
1170. **Vanderhaeghe, F. (1999):** Een beknopt overzicht van de huidige verspreiding en status van *Coenagrion scitulum* (Rambur, 1842) in België en Noord-Frankrijk. *Gomphus* 15(2): 69-85. (in Flemish, with English and French summaries). ["Present distribution and status of *C. scitulum* in Belgium and Northern France.

France. In 1998 *C. scitulum* was observed for the first time in Belgium since 1973. This article gives an overview of these recent Belgian findings together with an account of recent data from the North of France. Data are interpreted for Belgium together with a discussion about habitat. Conclusion is that the species will probably penetrate Belgium in other regions, although likely the species will not be common. It proves to be clear that at least some individuals do show vagrant behaviour. These might be seen in any habitat. Therefore it seems convenient to watch out for this species everywhere. The most likely regions are cited." (Author)] Address: Vanderhaeghe, Floris, Lijsterstraat 20, B-8800 Roeselare, Belgium; E-mail: Floris.Vanderhaeghe@rug.ac.be

1171. **Verbeek, P.J.M. (1999):** The habitat of *Symptetrum depressiusculum* in North-western Europe and its future in The Netherlands. *Brachytron* 3(1): 3-11. (in Dutch, with English summary). ["The habitat preferences of *S. depressiusculum* in the north-west of its range are discussed on the basis of the literature and personal observations. The most important characteristics are listed. An extensive zone of shallow water must be present. This zone should be vegetated, but not too densely. The water level must be stable or lowered between the time of oviposition and emergence of the larvae. The zone may even be completely dry during winter. The waters generally are not very eutrophic or acidic. The presence of a well-structured imaginal habitat is also important. The principal factor appears to be the stable or lowered water level in winter. [...] Most waters in the region have a raised water level in winter and are therefore unsuitable for the species. Most localities where the species occurs therefore have an artificially controlled water level. The reason why this winter drought is so important remains unclear. Freezing of the eggs, as suggested by earlier authors, appears to be of no importance as the species occurs in Mediterranean rice-fields and cooling-water ponds of factories in Belgium. The absence of dragonflies with multi-annual life cycles (that could be caused by drought or freezing) as competitors for food seems unimportant too, as they have been found with *S. depressiusculum*. The described hydrological factors result in high water temperatures in spring. This, and the resulting high availability of prey, might speed up larval and egg development to the level required for survival. It is suggested that the species evolved in conditions with relatively high water temperatures in spring. The high habitat specificity makes *S. depressiusculum* a rare and vulnerable species in the north-west of its range. Changed management and eutrophication forms a direct threat to populations, which are dependent of the maintenance of artificial conditions for their survival. Besides this vulnerability the species disperses rather weakly, as compared to its relatives. Individuals are generally not found more than 20 km away from source populations. Almost all recent Dutch records are probably the result of dispersal from populations in Belgium, not far from the border. Although reproduction was proven for the first time in The Netherlands (RUTTEN & KALKMAN, 1999) in 1998 (in atypical habitat) it is expected that the only chance for the species would be if suitable habitat is created or restored by man." 1179. **Wazalwar, S.M.; Tembhare, D.B. (1999):** Mouthpart sensilla in the dragonfly, *Brachythemis contaminata* (Fabricius) (Anisoptera: Libellulidae). Odonatologica 28(3): 257-271. (in English). ["The mouthpart sensilla in *B. contaminata* comprise trichoid sensilla, acanthae, basiconic sensilla, campaniform sensilla, microtrichia, papillae, sensory pegs and spines. There are various types of trichoid sensilla: 8 labral, 7 mandibular, 14 hypopharyngeal, 8 maxillary and 17 labial. They differ in size and distribution from one another. The acanthae are of 2 types, the labral in the adult and the mandibular in the larva. The basiconic sensilla are found on the labrum of the adult only. The campaniform sensilla are present on the maxillae and labium of the adult and are lacking in the larva. There are 7 types of microtrichia evident on the labrum, hypopharynx and maxillae of the larva and on the hypopharynx and maxillae of the adult. The papillae are present on the inner surface of the labrum in both the larva and the adult. The sensory pegs are confined to the labium of the adult. The spines are located on the labium of the larva and are lacking in the adult. This study is based on SHM and neuro-anatomical staining techniques." 1189. **Ali, D.W. (1997):** The aminergic and peptidergic innervation of insect salivary glands. *Journal of Experimental Biology* 20(14): 1941-1949. (in English). ["Insect salivary glands are glands associated with nutrient intake whose secretions are generally involved in the digestion and lubrication of food. They are under the control of neuroactive substances and may be innervated from several sources including the suboesophageal ganglion, the stomatogastric nervous system and the unpaired median nerves. Both amines and peptides have been suggested to play roles in the control of insect salivation, as indicated by their association with terminals on salivary glands, their effects in salivary gland bioassays and their ability to alter second messenger levels and ion channel conformations. Serotonin and dopamine appear to be the most prominent amines associated with insect salivary glands. Either one or both of these amines are found associated with the salivary glands of the locust, stick insect, cockroach, cricket, dragonfly, mosquito, adult moth and kissing bug. Their roles, although not fully elucidated, appear to be in the control of salivary secretion. Several peptides, including members of the FMRFamide-related family of peptides, are also found associated with insect salivary glands. Sources of peptidergic innervation are as varied as those for aminergic innervation, but information regarding the physiological role of these peptides is lacking. The relevance of the different levels of complexity of salivary gland innervation, which range from the absence of innervation in some species (blowfly) to the presence of several distinct sources in others (locust, cockroach), is not well understood. This review serves to consolidate what is known of the phenotype of salivary neurones in relation to the control of salivation." (Author)] Address: Ali, D.W., Institution Montreal Gen. Hosp. Res. 1190. **Andrew, R.J.; Tembhare, D.B. (1997):** The development and structure of the ovaries in the dragonfly *Tramea virginia* (Rambur) (Libellulidae: Odonata). *Journal of Advanced Zoology* 18(2): 86-95. (in English). ["In *Tramea virginia*, the ovary is composed of numerous strings of panoistic ovarioles. Each ovariole is differentiated into four regions the apical terminal filament, germarium, vitellarium and the distal pedicel. In the ultimate nymph, the terminal filament comprises a thick strand of germinal tissue. The germarium is filled with the primary and secondary oogonia and primary oocytes. The vitellarium is filled with pre-vitellogenic oocytes

while the pedicel is in the form of compact mass of mesodermal cells. Vitellogenesis is evident in mature adults and it passes through the successive early vitellogenic, midvitellogenic, late-vitellogenic and maturation stages. The lateral oviducts are mesodermal in origin and initially run along the outer margin of the ovaries. The median oviduct is short and its anterior region is mesodermal while posterior region is ectodermal in origin." (Authors)] Address: Tembhare, D.B., Post-Grad. Dep. Zool., Nagpur Univ. Campus, Nagpur 440 010, India

1191. **Anselin, A.; Knijf, G. de (1997):** The Belgian Dragonfly Working Group. *Levende Natuur* 98(5): 184-188. (in Dutch). ["The Belgian Dragonfly Working Group Gomphus, a volunteer organization, was founded in 1983. The main goal was to promote studies in dragonfly faunistics and increase protection measures. One major activity from the start was the organization of an atlas project of Odonata distribution in Belgium. This project is now in its last phase. A special effort has been made to achieve a good coverage of the territory during the last five years. These data will form a base for future comparison. As a result of the atlas project, an increasing number of people have carried out detailed faunistical surveys in smaller regions. The Gomphus database has been used for the composition of the Red list of Dragonflies in Flanders, a project of the Institute of Nature Conservation. Gomphus is also active in the field of nature protection and gives advice for dragonfly-friendly management of wetlands. It takes part in a monitoring project in Wallonia and is currently examining the possibilities of setting up a similar scheme in the Flemish part of the country." 1192. **Bazzanti, M.; Chiavarini, S.; Cremisini, C.; Soldati, P. (1997):** Distribution of PCB congeners in aquatic ecosystems: A case study. *Environment International* 23(6): 799-813. (in English). ["Polychlorinated biphenyls (PCB) congeners were determined in water samples, sediments and animal species in the frame of a survey of the River Arrone (Central Italy, near Rome) after a major contamination episode. Animal species were selected on the basis of their living and feeding habits and evaluated as candidate bioindicators of PCB pollution in this lotic ecosystem. Total PCB concentrations in water were found to be low (ng/L level), and in sediments, ranged from about 10 to 200 mug/kg dry weight, depending on the distance from the contamina-

tion source. PCB patterns in sediments showed a prevalence of higher chlorinated congeners over time. Concentrations in macroinvertebrates (*Calopteryx splendens* and *Anax imperator*) ranged from 60 to 400 µg/kg dry weight, showing significantly different species to species patterns. PCB concentrations were almost parallel in sediments for different sampling stations, while differences in patterns among species can be explained in terms of bioaccumulation/excretion mechanisms. Freshwater shrimps (*Palaemonetes antennarius*) were not found close to the contamination source, as a consequence of their extreme sensitivity to chemicals, and showed a peculiar pattern (almost exclusively determined by congeners 153, 138, and 180) probably originating from biodegradation mechanisms. Fish samples (*Rutilus erythrophthalmus*) showed the highest concentrations, as a combination of feeding habit, lipid content and, probably, less effective biodegradation/excretion pathways. Congener patterns closely match those of Aroclor 1260, which originates from the contamination source. This study confirms that congener physical and chemical parameters, different degradation rates, feeding habits, and mobility of the analysed aquatic organisms, metabolism, and excretion mechanisms, are to be considered to explain the distinctive PCB patterns of different samples." 1193. **Beccaloni, G.W. (1997):** Ecology, natural history and behaviour of ithomiine butterflies and their mimics in Ecuador (Lepidoptera: Nymphalidae: Ithomiinae). *Tropical Lepidoptera* 8(2): 103-124. (in English). ["The ithomiine butterfly species (Nymphalidae: Ithomiinae) which occur at Jatun Sacha Biological Station, Napo Province, Ecuador were found to participate in eight discrete mimicry complexes. These complexes involve a total of 124 insect species: 55 ithomiine species, 34 species which belong to other butterfly families or subfamilies, 34 moth species, and 1 species of damselfly. All species are illustrated and identified, and aspects of their behaviour are discussed. Literature on the chemical defences of the species is reviewed and a study of their ultraviolet reflectance patterns is presented. Data from a mark-release-recapture study show that the majority of individuals in the mimicry complexes studied were ithomiines. Hypotheses to explain polymorphism in Batesian and Mullerian mimics are discussed, in view of the finding that seven species of ithomiines, five other butterfly species, and the single damselfly species were polymorphic at Jatun Sacha." (Author)] Address: Beccaloni, G.W., Dep. Entomol., Natural History Museum, Cromwell Road, London SW7 5BD UK

1194. **Chung, M.G.; Kang, S.S.; Yeeh, Y. (1997):** Genetic diversity and structure in Korean populations of *Sympetrum darwinianum* and *S. eroticum eroticum* (Odonata: Libellulidae). *Jap. J. Ent.* 65(2): 427-435. (in English). ["The levels of genetic diversity and structure in Korean populations of *Sympetrum darwinianum* (Selys, 1883) and *S. eroticum eroticum* (Selys, 1883) were examined. Starch gel electrophoresis was conducted on 343 individuals in eight populations of the two species. Electrophoretic data revealed that the two species exhibit considerably higher levels of genetic variation than those of most other insects. Expected mean population heterozygosity (He, 0.361 vs. 0.333) and percent polymorphic loci (P, 81.5% vs. 87.2%) found in *S. dar-*

winianum were very comparable to those for *S. eroticum eroticum*. Analyses of WRIGHT's fixation indices, calculated for all polymorphic loci across populations in each species, indicated that, overall, a near conformance of genotype frequencies to Hardy-Weinberg expectations, suggesting that mating was nearly panmictic. The results indicated that the two species might have very similar phylogenetic histories, and/or ecological and life history traits." (Authors)] Address: Chung Myong Gi Institution Dep. Biol., Gyeongsang Natl. Univ., Chinju 660-701, South Korea

1195. **Clarke, D.; Hewitt, S. (1997):** Vagrant Emperor Dragonfly, *Hemianax ephippiger* (Burmeister) at Caerlaverock, Dumfriesshire. *Glasgow Naturalist* 23(2): 58. (in English). 1196. **Currie, R.S.; Fairchild, W.L.; Muir, D.C. (1997):** Remobilization and export of cadmium from lake sediments by emerging insects. *Environmental Toxicology & Chemistry* 16(11): 2333-2338. (in English). ["Emerging insects including, Diptera, Odonata, Ephemeroptera, and Trichoptera were collected from Lake 382 (L382) in 1991 and 1992 to estimate quantitatively the export of Cd by aquatic insects from a natural system having elevated Cd concentrations in the water and sediment. L382 is a Canadian Shield lake, located within the Experimental Lakes Area in northwestern Ontario, that received experimental additions of Cd from 1987 to 1992. Emerging Diptera (mostly Chironomidae), Odonata, and Ephemeroptera had mean Cd concentrations of 1.41, 0.11, and 0.30 µg/g wet weight, respectively. An estimated 1.32 to 3.90 g of Cd per year were exported from the sediments of L382 depending on the estimate of production rates used for these groups of insects. Approximately 0.05 to 0.17% of the whole-lake Cd load in L382 sediments was exported annually or 0.12 to 0.39% of the epilimnion Cd sediment load. Insect emergence may have resulted in greater Cd export from L382 relative to losses via the outflow. Cadmium exported from the sediments by insects may be remobilized and become more available to aquatic organisms or enter the terrestrial ecosystem and become available to insectivores." lichen Vorlandes: Fundortliste, Korrekturen und Ergänzungen. Mitt. naturwiss. Verein Goslar 5: 151-154. (in German). [Harz Mountains region, Niedersachsen and Sachsen-Anhalt, Germany; records of 13 species previously unpublished are listed and shortly commented] Address: Hartmann, G., Werenbergstr. 26, D-38640 Goslar, Germany

1199. **Dolmen, D. (1997):** "Freshwater prawns" and other invertebrates: A faunistic report from the lakes Reddalsvannet and Landvikvannet, Grimstad. Fauna (Oslo) 50(1): 36-42. (in Norwegian). ["In June and July 1992 and June and August 1996, numerous "freshwater prawns" *Palaemonetes varians* were recorded in three brackish-water lakes at Grimstad, Aust-Agder county: Reddalsvannet, Landvikvannet, and lakelet north of Inntjore. This is the first reliable record of the species in Norway, at least for many decades. The remaining fauna consisted of both limnic and marine animals, and included rare species like *Brachytron pratense* (Odonata) and *Gyrinus caspius* (Coleoptera)."] (Author)] Address: Dolmen, D., Institution NTNU Vitenskapsmuseet, N-7004 Trondheim, Norway

1200. **Ferreras-Romero, M. (1997):** The life history of *Boyeria irene* (Fonscolombe, 1838) (Odonata: Aeshnidae) in the Sierra Morena mountains (southern Spain). Hydrobiologia 345: 109-116. (in English). ["The life history of *Boyeria irene* is inferred from size-frequency analyses of sweep-net samples taken during five years in a permanent stream in the Sierra Morena Mountains. There the species is apparently mainly semivoltine, although a few larvae require three years to complete development. The instar distribution during winter is that of a 'summer species' (sensu Corbet, 1954). Metamorphosis is confined to spring and there is a long flying season. Similarities between *B. irene* and congeneric species in North America are discussed."] (Author)] Address: Ferreras-Romero, M., Departamento de Biología Animal (Zoología), Facultad de Ciencias, Universidad de Córdoba, Avda. San Alberto Magno s/n, E-14004 Córdoba, Spain

1201. **Fincke, O. (1997):** Conflict resolution in the Odonata: implications for understanding female mating patterns and female choice. Biological Journal of the Linnean Society 60(2): 201-220. (in English). ["Predictions of mating patterns in animals have focused on males and how they compete for fertilizations by controlling females. With reference to the Odonata, a taxon in which mating requires cooperation of the female, the active role that females play in mating decisions is often ignored, leading to the premature conclusion that male coercion of females is common. A critical review of the outcome of sexual conflict among odonates leads me to alternative explanations of female mating patterns that need, to be refuted before concluding that males coerce matings. Because Anisoptera males have greater control over tandem formation, they have a greater potential for coercion than Zygoptera males. However, Anisoptera females may simply be willing to remate more often if they receive insufficient sperm to fertilize an entire egg clutch. Contrary to prior assumptions, in both suborders, male defence of oviposition sites does not preclude females from choosing among sites or among males. I find that the evolution of non-aggressive sexual signals by males is a reliable indication that sexual conflict has been resolved in favour of female interests. Although I predict that the benefits to females of choice of male phenotype should rarely exceed the cost of such

such discrimination in Odonata, female choice is most likely to evolve in territorial species whose males must endure high physiological stress in order to mate, and when site quality is not a reliable predictor of the genetic quality of a potential mate."] (Author)] Address: Finke, O.M., Dept Zool., Univ. Oklahoma, 730 Van Vleet Oval, Room 314, Norman, OK 73019, USA

1202. **Fincke, O.M.; Waage, J.K.; Koenig, W.D. (1997):** Natural and sexual selection components of odonate mating patterns. In: Choe, J.C. & B.J. Crespi (Eds.): The evolution of mating systems in insects and arachnids. Cambridge Univ. Press. Cambridge: 58-74. (in English). ["Traditionally, students of odonate reproductive behavior have focussed on how males compete for access to mates and fertilizations. This tendency has yielded considerable information on male reproductive strategies and on the proximate and ultimate mechanisms involved in male-male competition, but has left numerous gaps in our knowledge of other aspects of odonate mating systems. We review relevant aspects of odonate biology and examine the extent to which current data on mating patterns support predictions arising from sexual selection theory. Although long-term studies offer some such support, they also indicate that natural selection for longevity and stochastic factors such as weather play critical roles in influencing reproductive success. Relatively little of the variance in male reproductive success in odonates has been traced to variance in male phenotype. We emphasize the role of females as determinants of odonate mating patterns and discuss sexual conflicts of interest over mating, fertilization, and oviposition decisions. Finally, we explore ways in which natural selection underlies female mating decisions and how larval and adult ecology interact to influence adult reproductive behavior."] (Authors)] Address: Finke, O.M., Dept Zool., Univ. Oklahoma, 730 Van Vleet Oval, Room 314, Norman, OK 73019, USA

1203. **Gee, J.; Smith, B.D.; Lee, K.M.; Griffiths, S. W. (1997):** The ecological basis of freshwater pond management for biodiversity. Aquatic Conservation 7(2): 91-104. (in English). ["1. Macrophyte and macroinvertebrate species richness, and the extent of aquatic vegetation, were surveyed in 51 newly created or renovated ponds in mid and west Wales, together with a range of environmental variables. These data are analysed in relation to management issues including pond size, rate of development, planting for oxygenation, stocking with fish and shading by riparian trees. 2. Richness of both plants and invertebrates increases with vegetated area, but the relationships are weak. Similarities among assemblages in ponds are low and not related to the proximity of the ponds. It is likely that two small ponds would together support more species than a single large pond. 3. New ponds are colonized rapidly by plants and invertebrates. There is no relationship between age and the number of species in ponds that were at least one year old, except for invertebrates in ponds that were isolated from other wetland. As expected, the extent of aquatic vegetation increases with age. 4. Minimum dissolved oxygen levels decrease with the cover of floating plants and with extent of vegetation in relation to pond size. 5. There is no evidence that stocking with fish (mainly salmonids at low densities) influences the total number of species of either macrophytes or macroinvertebrates. However, the number of anisopteran (Insecta: Odonata) species is lower in stocked ponds and the number of trichopteran (Insecta) species is high-

her. 6. Macrophyte species richness increases with the percentage of the margin shaded by trees to a peak between 22% (emergent species) and 30% (submerged and floating species), and then declines. The number of species of invertebrates with short-lived flying adults (Odonata, Ephemeroptera, Trichoptera) decreases with the extent of riparian trees. Other invertebrates are unaffected. 7. The relationship between the survey results and existing management recommendations is discussed, emphasizing the need for field experiments to provide empirical support." 1204. **Gorb, S.N. (1997):** Ultrastructural architecture of the microtrichia of the insect cuticle. *Journal of Morphology* 234(1): 1-10. (in English). ["The ultrastructure of the microtrichia (MT) of the insect cuticle was studied using scanning electron microscopy (SEM). After dissolving the protein matrix of chitin-protein microfibrils with NaOH, the orientation of the axial chitin fibers was three-dimensionally demonstrated. Microfibrils of the outermost exocuticular lamella lie parallel to the slope of the cone surface of the MT and rotate slightly on the top of the MT. Microfibrils of the external lamella of the transitional area between planar cuticle and conical cuticle of the MT corresponded to the shape of the surface within one lamella and preferred directions of MT's microfibrils in the successive lamella rotated. In the deeper layers of the cuticle, the rotation of both the microfibrils and successive lamella results in the twisted straw architecture of the microfibrils' composition within the MT. The deepest microfibrils that are located close to the axis of the MT form compact clusters of fibrils (1.0-1.5 μ -m length). The twisted-straw architecture of microfibrils in the MT is derived from principles of development of extracellular fibrous composites. It is suggested, however, that this architecture has an additional functional significance as a strategic design with particular mechanical properties." 1206. **Habdija, I.; Radanovic, I.; Primc-Habdija, B. (1997):** Longitudinal distribution of predatory benthic macroinvertebrates in a karstic river. *Archiv für Hydrobiologie* 139(4): 527-546. (in English). ["The longitudinal distribution of predatory macroinvertebrates and their diversity were investigated on boulder, cobble and gravel substrates along the River Kupa, a karstic river in the NW Dinarid area (Croatia). Depending on substrate type and river section, the predator biomass constituted 6.9% to 20.2% of the total macroinvertebrate biomass. In the headwater streams more than 80% of predator biomass was represented by rhyacophilid, perlid and perlodid larvae. In the upper river section Hirudinea

species, rhyacophilids and the dipteran larva, *Atherix ibis*, constituted approximately equal percentages of total predators. In the lower river section Hirudinea species, Odonata larvae, tanipod and ceratopogonid larvae were the most dominant predators. Along the river gradient the increase of predator biomass corresponded with the increase of scraper, collector-gatherer and filterer biomass. The Shannon index of diversity showed that the diversity of predators increased from the area to the downstream reaches. A significant and positive association was found between diversity of predators and diversity of collector-gatherers. This positive relationship between predators and collector-gatherers may be interpreted as the diversity response of predators to the diversity of prey." (Authors) In tab. 2 the mean annual biomass (mg wet biomass m^2) of *Platycnemis* sp., *Cordulidae* not det., *Gomphus vulgatissimus*, and *Onychogomphus* sp. is listed.] Address: Habdija, I., Department of Zoology, Faculty of Science, University of Zagreb, Rooseveltov trg 6, CRO-10000 Zagreb, Croatia

1207. **Hassan, S.T. (1997):** Action thresholds of wet rice arthropods for pest management decision-making in Malaysia. *Pertanika Journal of Tropical Agricultural Science* 20(1): 65-74. (in English). ["Action thresholds to aid pest population management decision-making of 11 categories of wet rice arthropods are suggested in terms of mean population density per hill (x) and proportion of infestation ($P(I)$) of the field sampling units. The thresholds are the (x) and $P(I)$ values at the point of saturation of a polynomial regression curve obtained by plotting (x) against $P(I)$ for each arthropod category. The respective values for pests are: 3.38, 0.92 (*Nephotettix* spp.), 6.28, 1.00 (*Nilaparvata lugens*), 1.37, 0.72 (*Cnaphalocrocis medinalis*-*Pyralidae*), 2.42, 0.90 (*Recilia dorsalis*), 3.81, 0.97 (*Sogatella furcifera*), and for predators are: 3.89, 0.98 (*Cyrtorhinus lividipennis*), 2.39, 0.85 (*Anatrichus pygmaeus*-*Diptera*), 2.02, 0.82 (Odonata), 1.65, 0.81 (*Casnoidea* spp), 1.61, 0.64 (*Paederus fuscipes*), and 1.60, 0.69 (spiders). $P(I)$ is significantly ($P < 0.001$) affected by arthropod category and growth stage of the crop. The observed $P(I)$ indicated high fits (most $r^2 > 0.90$) to clumped- and Poisson-based distribution models." (Authors)] Address: Hassan, S.T.S., Dep. Biol., Fac. Sci. Environ. Studies, Univ. Putra Malaysia, 43400 UPM, Serdang, Selangor, Malaysia

1208. **Hassan, S.T.; Rashid, M.M. (1997):** Presence/absence sequential plans for pest management decision-making for arthropods of wet rice ecosystem in Malaysia. *Pertanika Journal of Tropical Agricultural Science* 20(1): 51-63. (in English). ["Presence-absence sequential sampling plans are presented for 11 arthropod categories to assist in management of their populations in the multipest-infested rice crop in Malaysia. Data from visual inspection of 204 samples with 40 and 100 hills per sample, were used to develop the plans. Action threshold for each of the 11 (5 pests 6 predators) arthropod categories was obtained through a fourth-order polynomial regression of proportion of infestation against mean population densities, at the point of saturation of infestation. The pest species are: *Nephotettix* spp., *Nilaparvata lugens*, *Recilia dorsalis*, *Sogatella furcifera* and *Cnaphalocrocis medinalis* (*Pyralidae*), and the predators: *Cyrtorhinus lividipennis*, *Anatrichus pygmaeus* (*Diptera*), spiders, Odonata, *Paederus fuscipes* and *Casnoidea* spp. Risk levels of Type I (α) and Type II error (β) were prefixed at 0.3, since lower levels

entail taking a larger number of samples. The sequential plans were then generated using the SEQUAN computer program of Talerico and Chapman (1970). During field operation on not more than 50 ha at a time, it is suggested that at least ten hills should be examined visually before recommending any pest management action. Simultaneous sampling of pests and predators enables status of predators' populations to be considered before recommending any decision." (Authors)] Address: Hassan, S.T.S., Dep. Biol., Fac. Sci. Environ. Studies, Univ. Putra Malaysia, 43400 UPM, Serdang, Selangor, Malaysia

1209. **Hawking, J.H. (1997):** The conservation status of dragonflies (Odonata) from south-eastern Australia. Mem. mus. Victoria 56(2): 537-542. (in English). ["The conservation status of the dragonflies from south-eastern Australia is documented and the species with limited distributions and/or larval habitats which are vulnerable are discussed. One hundred and seven species are recorded from South Australia, Victoria, Tasmania and southern New South Wales. No species is considered endangered, but nine species have high conservation priority. These species are endemic to Australia and all have restricted distributions. The vulnerability of the larval habitats is discussed and suggestions for their conservation and management are made." (Author)] Address: Hawking, J.H., Murray-Darling Freshwater Research Centre, Cooperative Research Centre for Freshwater Ecology, P.O. Box 921, Albury, NSW 2640, Australia

1210. **Hooper, R.E.; Siva-Jothy, M.T. (1997):** "Flybys": A prereproductive remote assessment behavior of female *Calopteryx splendens xanthostoma* (Odonata: Calopterygidae). Journal of Insect Behavior 10(2): 165-175. (in English). ["Before reproductive events, female *Calopteryx splendens xanthostoma* show a distinctive flight behavior over patches of oviposition substrate guarded by territorial males. We term such flights 'flybys.' Since females fly most frequently (and nonrandomly) over the site which they eventually utilize, the flight type appears to be related to the female's selection of a reproduction site. When males were experimentally excluded females made flybys over more sites than when males were present. We manipulated the levels of agonistic interactions between males to determine the effect of fighting on flybys. The frequency of flybys by females over each patch did not change with different levels of male agonistic activity, but females landed and copulated on patches where fighting between males was lowest. Moreover, when females secured access to an oviposition site without copulating with the reholding male, they made flybys over more sites than when they secured access to a site by copulating with the territorial male. The results suggest that one function of flybys is to allow females to assess remotely potential male interference at oviposition sites." (Authors)] Address: Hooper, R.E., Lab. Wildlife Conservation, National Inst. Environmental Studies, Tsukuba 305, Japan

1211. **Horwitz, P. (1997):** Comparative endemism and richness of the aquatic invertebrate fauna in peatlands and shrublands of far south-western Australia. Mem. Mus. Victoria 56(2): 313-321. (in English). ["A study of the peatlands and shrublands in far south-western Australia was undertaken to examine patterns of endemism and richness in aquatic invertebrate faunas. Samples of surface water, interstitial water and

crayfish burrow water were analysed from about 45 sites and in each season over a twelve month period in 1993. Six groups of aquatic invertebrates were chosen for more detailed analyses (mites, oligochaetes, isopods, decapods, dipterans, and odonats) and resolved to species level. For each species an assessment was made of its distributional status as either widespread and common, regionally endemic (to the southwest), or locally restricted to within the study region. Sites with high levels of local endemism were plotted geographically and their characteristics compared to other sites. The data are related to existing hypotheses concerning the depauperate nature of the freshwater fauna of the south-western part of the continent. It was found that such hypotheses need to be tempered by the role of salt in flowing systems, and the occurrence of hot spots of local endemism for freshwater fauna in the extreme south-west in non-flowing waters (and often subterranean habitats) where groups of non-insect invertebrate fauna show apparently elevated species richness." 1213. **Iwasaki, K.; Otsuka, T.; Nakayama, K. (1997):** Middle- and large-sized aquatic animal assemblages associated with submerged riparian plants in the Kamo River, Kyoto. *Japanese Journal of Limnology*. 58(3): 277-291. (in Japanese with English summary). ["Middle- and large-sized aquatic animal assemblages associated with the submersed leaves, stems and roots of the reed *Phragmites japonica* and other riparian plants were studied in the Kamo River, Kyoto with a focus on the faunal differences in both longitudinal and seasonal distribution. At the upper and middle sites, mayfly larvae inhabiting slow riffles and shallow pools were dominant in winter and spring. Several lentic hemipteran insect species such as water scorpions and back swimmers associated chiefly with hydrophytes in ponds and marshes were also found in summer or autumn within the stands of monocotyledonous plants on the wide gravel bar of the middle site. At the lower site within the Kyoto city limits, water slaters, leeches and snails were abundant from spring through autumn. In addition, many larvae of calopterygid and coenagrionid dragonflies were collected in spring and summer, respectively. Juvenile fishes of dark chub and lizard go-

by were abundant in summer and autumn at all three sites. Riparian plants were thus suggested to increase species diversity of lotic fauna, providing habitats not only for lotic invertebrates but also for lentic insects and juvenile fishes." (Authors)] Address: Iwasaki, K., Inst. Natural Sci., Nara Univ., 1500 Misasagi-chou, Nara 631, Japan

1217. **Land, M.F. (1997):** The resolution of insect compound eyes. *Israel Journal of Plant Sciences* 45(2): 79-91. (in English). ["The spatial resolution of compound eyes is determined by their interommatidial angles, by the optical quality and rhabdom dimensions of the ommatidia, and by illumination level. Among insects, interommatidial angles vary from tens of degrees in Apterygota, to as little as 0.24 degree in dragonflies. Resolution better than this is not attainable in compound eyes of realistic size, because of the limit imposed by diffraction. The smaller the interommatidial angle, the greater the distance at which objects-prey, predators, foliage, or flowers-can be resolved. Insects with different lifestyles have contrasting patterns of interommatidial angle distribution, related to forward flight, capture on the wing, and predation on horizontal surfa-

ces." (Author)] Address: Land, M.F., School Biol. Sci., Univ. Sussex, Brighton BN1 9QG, UK

1218. **Larson, D. (1997):** Habitat and community patterns of tropical Australian hydradephagan water beetles (Coleoptera: Dytiscidae, Gyrinidae, Noteridae). *Australian Journal of Entomology* 36(3): 269-285. (in English). [A study was undertaken to describe patterns of water beetle co-occurrence in a tropical environment and to compare these with water beetle community structure in temperate regions. Dytiscidae, Noteridae, and Gyrinidae were sampled quantitatively and qualitatively from a variety of habitats in the Atherton Tableland region of tropical Queensland from September 1990 to February 1991. [...] Quantitative samples from rice fields and a temporary pond demonstrated that a suite of species were quick to colonize and breed in newly formed habitat. Many of these species breed before other predators such as fish or Odonata become established."] Address: Larson, D., Institution Dep. Biol., Memorial Univ., St. John's, Newfoundland A1B 3X9, Canada

1219. **Lasswell, J.L.; Mitchell, F.L. (1997):** Survey of dragonflies (Odonata: Anisoptera) in ponds of central Texas. *Journal of the Kansas Entomological Society* 70 (1): 52-63. (in English). [Anisoptera "were collected for five quarters, from October 1994 through December 1995, from 12 ponds located in Erath County, Texas. Nymphs were collected from each of the ponds quarterly, while adults were taken whenever possible. Other collection records from Erath County are also noted. A total of 38 dragonfly species were identified. Nymphs of 28 species were collected from the ponds, while the remaining 10 species were determined from adult collections. Thirty-six species of adults were collected. Two species were found as nymphs, but not collected as adults. Peak dragonfly abundance in ponds occurred during the third quarter - July through September." (Authors)] Address: Lasswell, J.L., Institution Texas Agric. Exp. Stn., Route 2 Box 00, Stephenville, TX 76401, USA.

1220. **Laurila, A.; Kujasalo, J.; Ranta, E. (1997):** Different antipredator behaviour in two anuran tadpoles: effects of predator diet. *Behav. Ecol. Sociobiol.* 40(5): 329-336. (in English). ["Recent investigations have indicated that animals are able to use chemical cues of predators to assess the magnitude of predation risk. One possible of such cues is predator diet. Chemical cues may also be important in the development of antipredator behaviour, especially in animals that possess chemical alarm substances. Tadpoles of the common toad (*Bufo bufo*) are unpalatable to most vertebrate predators and have an alarm substance. Tadpoles of the common frog (*Rana temporaria*) lack both these characters. We experimentally studied how predator diet, previous experience of predators and body size affect antipredator behaviour in these two tadpole species. Late-instar larvae of the dragonfly *Aeshna juncea* were used as predators. The dragonfly larvae were fed a diet exclusively of insects, *R. temporaria* tadpoles or *B. bufo* tadpoles. *R. temporaria* tadpoles modified their behaviour according to the perceived predation risk. Depending on predator diet, the tadpoles responded with weak antipredatory behaviour (triggered by insect-fed predators) or strong behaviour (triggered by tadpole-fed predators) with distinct spatial avoidance and lowered activity level. The behaviour of *B. bufo* in predator diet treatments was indistinguishable from that in the control

treatment. This lack of antipredator behaviour is probably related to the effective post-encounter defenses and more intense competitive regime experienced by *B. bufo*. The behaviour of both tadpole species was dependent on body size, but this was not related to predator treatments. Our results also indicate that antipredator behaviour is largely innate in tadpoles of both species and is not modified by a brief exposure to predators." 1221. **Liebherr, J.K.; Polhemus, D.A. (1997):** Comparison to the century before: the legacy of R.C.L. Perkins and Fauna hawaiiensis as the basis for a long-term ecological monitoring program. *Pacif. Sci.* 51(4): 490-504. (in English). ["As one means of assessing the impact of the past 100 yr of development and biological alteration in Hawai'i, the damselfly (Odonata: Coenagrionidae) and carabid beetle (Coleoptera: Carabidae) collections of R. C. L. Perkins made in the 1890s are compared with similar collections made one century later during the 1990s. Two islands that have experienced very different histories of development are compared: O'ahu and Moloka'i. Of eight native damselfly species originally inhabiting O'ahu, one has been extirpated from the island, another is now reduced to a single population, and three more are at risk. Of the eight species originally found on Moloka'i, by contrast, there is only one species that has not been rediscovered, although there is reasonable probability that it has simply eluded capture because of inherent rarity, whereas the remaining species retain large and stable populations. Capture frequencies (based on specimens collected per decade) are lower now than in the preceding century for most species on O'ahu, even allowing for modern collectors retaining fewer specimens. The only species on O'ahu for which captures have increased between the 1890s and the 1990s are those that breed away from lotic and lentic habitats, indicating a severe negative impact from introduced aquatic biota for species that breed in such freshwater situations. On Moloka'i, all damselfly species except one have higher capture rates now than in the 1890s, explainable in large part to improved access to previously remote terrain. [...]. (in English). ["Cape Sable Seaside Sparrows (*Ammodramus maritimus mirabilis*) breeding within eastern Everglades National Park were philopatric and moved only short distances between clutches. Incubation required 12 days, nestlings fledged at 9.2 days, and fledgling care ranged from eight to 20 days. The total nest cycle encompassed 34-44 days. Nestlings were fed spiders and insects, primarily Orthoptera, Lepidoptera, and Odonata. Diet varied between years and study sites. With the onset of summer rains, predation rate increased, and nest success decreased. Breeding activity diminished through-

hout June, coinciding with rising water in nest areas. Our results indicated that the lack of breeding habitat and the onset of summer flooding limit the breeding potential of Cape Sable Seaside Sparrows."(Authors)] Address: Lockwood, Julie, Dep. 1236. **Orr, A.G.; Cranston, P.S. (1997):** Hitchhiker or parasite? A ceratopogonid midge and its odonate host. J. nat. hist. 31: 1849-1858. (in English). ["The ceratopogonid genus Forcipomyia Meijyen (Diptera: Ceratopogonidae) contains species with a wide range of adult biologies. Species of the subgenus Pterobosca Macfie are phoretic and apparently parasitic on the wing veins of other insects, notably odonates and sometimes lacewings. We describe F. (Pterobosca) debenhamae from Brunei as new to science, taking the authorship of Cranston, tabulate the morphological diversity of the subgenus, and speculate on the phylogeny. The behaviour of adult female midges, which have been found only upon the thorax of hosts predominantly of Libella-

go hyalina (Odonata: Chlorocyphidae), appears to deleteriously impact on the quality and duration of territory holding of the host. The lack of any confirmation of host feeding leads us to speculate on the nature of the association." (Authors)] Address: Cranston, P.S., Biol. Dep., Univ. Brunei Darussalam, Bandar Seri Begawan, Negara, Brunei

1237. **Ottvall, R. (1997):** The dragonflies Hemianax ephippiger and Sympetrum fonscolombei (Odonata: Aeshnidae and Libellulidae) found on the Baltic island of Oland. Entomologisk Tidskrift, Stockholm 118(4): 193-196. (in Swedish with English summary). [The first Swedish records of the dragonflies Anax ephippiger and Sympetrum fonscolombii are reported. Three males and 3 females of A. ephippiger "were accidentally caught in a trap designed for migrating birds at Ottenby Bird Observatory at the southern point of the Baltic island of Oland, June 25 and 26 1995. This record of several individuals, and reports of unusual occurrences in central Europe, suggests an "invasion" reaching at least as far north as the Baltic Sea region. Warm, easterly winds in late May probably carried the dragonflies to Sweden. It is probable that during the unusually hot summer, the species was breeding in Sweden and larval development may have succeeded to emergence. In the same trap 3 males and 1 female of S. fonscolombii were trapped between July 7 and 21 1997. Extremely warm and moist air with high temperatures in southern Sweden in early July could explain the occurrence which is the first record of this species in Scandinavia."] Address: Ottvall, R., Ottoson, Dag Hammarskjolds vag 5G, S-224 64, Lund, Sweden

1239. **Peacor, S.D.; Werner, E.E. (1997):** Trait-mediated indirect interactions in a simple aquatic food web. Ecology 78(4): 1146-1156. (in English). ["This investigation examines the role of trait-mediated indirect interactions in a simple aquatic food web. We conducted the experiments in cattle watering tanks in order to establish whether competitive and predator-prey interactions between two species are affected by other species in the system; i.e., are pairwise interaction strengths affected by the background species assemblage? We examined the survival and growth response of small bullfrog (Rana catesbeiana) and small green frog (Rana clamitans) tadpoles in the presence and absence of a competitor (large bullfrogs), the lethal presence of the larval odonate predator Tramea lacerata, and the nonlethal (caged) presence of the larval odonate predators Anax junius and Anax longipes. We demonstrate that large bullfrog competitors and caged Anax affect traits (foraging activity level) of small bullfrog and small green frog tadpoles and that these changes in traits, in turn, affect interactions of the small tadpole species with each other and with the other species. In particular, the following four trait-mediated indirect interactions were evident: (1) Presence of large bullfrog competitors increased the predation rate of

Traumea on small green frogs and small bullfrogs. (2) Presence of nonlethal Anax reduced the predation rate of Traumea on small green frogs. (3) Presence of nonlethal Anax increased the competitive advantage of bullfrogs over green frogs. (4) Presence of nonlethal Anax facilitated midge invasion of the experimental units. The proposed mechanisms (changes in small tadpole activity) involved in these trait-mediated indirect interactions were supported by observational data on tadpole activity and relevels in the experimental units, and in laboratory experiments examining tadpole activity responses to predators. The occurrence of strong trait-mediated indirect interactions in this simple food web underscores the potential importance of such interactions in animal communities." 1240. **Richter, B.D.; Braun, D.P.; Mendelson, M.A.; Master, L.L. (1997):** Threats to imperiled freshwater fauna. *Conservation Biology* 11(5): 1081-1093. (in English). ["Threats to imperiled freshwater fauna in the U.S. were assessed through an experts survey addressing anthropogenic stressors and their sources. Specifically, causes of historic declines and current limits to recovery were identified for 135 imperiled freshwater species of fishes, crayfishes, dragonflies and damselflies, mussels, and amphibians. The survey was designed to identify threats with sufficient specificity to inform remanagers and regulators faced with translating information about predominant biological threats into specific, responsive actions. The findings point to altered sediment loads and nutrient inputs from agricultural nonpoint pollution; interference from exotic species; and altered hydrologic regimes associated with impoundment operations as the three leading threats nationwide, accompanied by many lesser but still significant threats. Variations in threats among regions and among taxa were also evident. Eastern species are most commonly affected by altered sediment loads from agricultural activities, exotic species, habitat removal/damage, and altered hydrologic regimes predominate in the West. Altered sediment loading from agricultural activities and exotic species are dominant problems for both eastern mussels and fishes. However, eastern fishes also appear to be suffering from municipal nonpoint pollution (nutrients and sediments), whereas eastern mussels appear to be more severely affected by altered nutrient impacts from hydroelectric impoundments and agricultural runoff. Our findings suggest that control of nonpoint pollution associated with agriculture activities should be a very high priority for agricultural producers and governmental support programs. Additionally, the large number of hydropower dams in the US. subject to federal re-licensing in coming years suggests a significant opportunity to restore natural hydrologic regimes in the affected rivers." 1241. **Rödel, M.-O.; Lensenmair, K.E. (1997):** Predator-induced swarms in the tadpoles of an African savanna frog, *Phrynomantis microps*. *Ethology* 103(11): 902-914. ["Aggregations in tadpoles of the West African savanna frog *Phrynomantis microps* were often observed in their breeding ponds in our study area, situated in Comoe National Park, Ivory Coast. Experiments under seminatural conditions demonstrated that this be-

haviour was only shown while predators were present. The tadpoles reacted differently to different predators. Factors inducing swarm behaviour were optical (the predator) and/or chemical (liquid from injured tadpoles). Alarm substances are not species-specific. Kinship seems not to play a role in swarm formation." (Author). Odonate predators tested are *Traumea basilaris*, *Pantala flavescens*, and *Anax imperator*. Swarm formation was induced solely via visual stimuli, for odonate larvae with their labium amputated induced swarm formation as well. "... Our results showed that swarms considerably outlived the removal of predators (*Traumea*). In 160 controls during 50 h following the removal of the predator we found 41 swarms in those containers where the dragonfly larvae had successfully hunted and 19 swarms in those with dragonfly larvae with amputated labium. Median duration of swarm persistence was 6 h when predation had really happened and 1 h in those trials with manipulated dragonfly larvae. In both cases however, the range of swarm persistence duration was 1-48h after the removal of the predators. Thus differences between the two experiments were not significant. After 50 h all swarms had dissolved."] Address: Rödel, M.-O., Lehrstuhl Tierökologie, Theodor-Boveri-Inst. Biowissenschaften, Am Hubland, D-97074 Würzburg, Germany. E-mail: roedel@biozentrum.uni-wuerzburg.de

1242. **Rogelio, D.-L.; Rodriguez, M.H.; Arrendondo-Jimenez, J.I.; Hernandez-Avila, M.; Mallorca, C. (1997):** Aquatic insects associated with *Anopheles albimanus* (Diptera: Culicidae) breeding sites in southern Mexico. *Environmental Entomology* 26(4): 828-838. (in English). ["Aquatic Coleoptera, Hemiptera, and Odonata associated with *Anopheles albimanus* Wiedemann larval habitats (defined by dominant plant vegetation) were investigated in various hydrological types along the coastal plain of southern Chiapas, Mexico. Aquatic insects were sampled by manual dragging nets, and mosquito larvae were sampled with standard dippers. Aquatic Coleoptera were the most abundant and diverse group, represented by 20 genera, followed by Hemiptera and Odonata, each with 16 genera. Aquatic insects were more abundant in permanent and temporary lagoons in *Hymenachne amplexicaulis* (Rudge) Nees and *Lippia nodosa* (L.) Michx. habitats, whereas mosquito larvae were most abundant in *Ceratophyllum demersum* L. and *Crinum erubescens* Soland. habitats, where aquatic insects were moderately abundant. Significant association in regression models with the addition of quadratic terms were found in aquatic Coleoptera and Odonata with respect to mosquito larvae. However, adjusted models that included environmental parameters proved these associations to be nonsignificant." (Authors)] Address: Danis-Lozano, R., Centro Investigacion Paludismo, Inst. Nac. Salud Publica, P.O. Box 537, Tapachula, Chiapas 30700, Mexico

1243. **Rolff, J.; Martens, A. (1997):** Completing the life cycle detachment of an aquatic parasite (*Arrenurus cuspidator*, Hydrachnellae) from an aerial host (*Coenagrion puella*, Odonata). *Canadian Journal of Zoology* 75(4): 655-659. (in English). ["Water mites are very important parasites of aerial stages of aquatic insects. Their larvae parasitize semiaquatic hosts and must detach while the host is in a suitable habitat for reproduction of parasite and host. Therefore, water mites should respond to stimuli indicating this situation. Different stimuli were tested experimentally in the host-parasite

system *Coenagrion puella* - *Arrenurus cuspidator* in outdoor cages; this method provides exact data on the initial intensity of mite larvae per host. It was found that mites detach during tandem oviposition by the host. The detachment rate does not correlate with the host's sex or with the intensity of mite larvae per host. Ectoparasitic water mites are apparently influenced by the host's condition because mites did not detach from dead hosts even in water. Proximity to water also seems to have an impact: mites exposed at a height of 10 mm above water detached, whereas mites exposed at 25 mm or higher did not. We suggest that detachment of mite larvae is triggered by a group of stimuli associated with the egg-deposition behaviour of the host." (Authors)] Address: Rolff, J., Zool. Inst. TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany

1244. **Sandberg, E. (1997):** Benthic predator-prey relationships and abiotic stress. The effects of physical disturbance and oxygen deficiency. *Acta Academiae Aboensis Ser. B Mathematica et Physica - Matematik Naturvetenskaper Teknik* 56(2): 1-42. (in English). ["Potential competition for food between predators of different ecological origin in the Baltic Sea was evident as the marine isopod, *Saduria entomon* (L.), and the limnic dragonfly larva, *Libellula quadrimaculata* (L.), exhibited similar prey choice and similar predation efficiency in a series of aquarium experiments. Despite the potential for the predators to affect a specific prey population no effect on the total community was seen in a field enclosure experiment. To examine these contradictory results from aquarium and field experiments the relative importance of direct predation, sediment stability (sediment resuspension) and sediment quality (sand and mud) was studied separately and combined using *S. entomon* as predator and juvenile bivalves, *Macoma balthica* (L.) as prey. Direct predation, sediment stability and quality had little effect on the survival of juvenile clams. The combined effect of these factors significantly increased the mortality of the clams as the combination of predation and sediment resuspension demonstrated synergistic negative effects on *M. balthica* survival. [...] As a secondary effect of eutrophication, the risk for exposure to oxygen deficiency (hypoxia) of benthic communities is increasing and important biotic couplings might be altered. [...] These results show that important structuring functions, such as predator-prey interactions, are altered already at sublethal oxygen levels, which consequently affect the benthic community structure before the system shows numerical signs of changes beyond background variation." 1248. **Scheuhammer, A.M.; McNicol, D.K.; Mallory, M.L.; Kerekes, J J. (1997):** Relationships between lake chemistry and calcium and trace metal concentrations of aquatic invertebrates eaten by breeding insectivorous waterfowl. *Environmental Pollution* 96(2): 235-247. (in English). ["Ca, P, Al, and trace metal (Cu, Ni, Zn, Cd, and Pb) concentrations were measured in several aquatic invertebrate taxa used as food by breeding insectivorous waterfowl, sampled from three sites in eastern Canada with widely varying water chemistry. Ca concentrations were highest in molluscs (snails and clams), averaging 200-300mg g⁻¹ (shells included). Aquatic insects of varying sizes, life stages and habits (caddisfly larvae, dragonfly larvae, adult backswimmers, waterstriders, and whirligig beetles) had much lower mean Ca concentrations, ranging from about 0.6 mg g⁻¹ (beetles) to 1.8 mg g⁻¹ (caddisflies). Invertebrate-Ca concentrations decreased with increasing body mass for several taxa with smaller and larger individuals providing similar absolute amounts of Ca. Ca concentrations in most aquatic insects (but not molluscs) were reduced under acidic, low Ca, high Al, low dissolved organic carbon (DOC) and/or low total phosphorus (TP) conditions. In stepwise multiple regressions, pH was consistently the main factor explaining variability in invertebrate-Ca, after controlling for the negative relationship between invertebrate-Ca and body mass for some taxa. Molluscs were absent from lakes below pH 5.3. In general, concentrations of P and metals in invertebrate taxa were not significantly correlated with lake pH. Levels of Al, Cd, or Pb were not sufficiently high to be considered toxic to potential consumers of these organisms. For waterfowl and other birds breeding in acid-stressed habitats and relying on aquatic invertebrates as a of food, a reduced availability of dietary Ca is more likely than an increased exposure to toxic metals to negatively affect reproductive success, especially when other adverse effects of acidification (lower diversity of prey) are considered." 1249. **Skevington, J.; Carmichael, I. (1997):** Dragonflies and damselflies (Odonata) of Bosanquet (North Lambton County, Ontario). *Proceedings of the Entomological Society of Ontario* 128: 3-12. (in English). ["The odonate fauna of Bosanquet (North Lambton County, Ontario) is surveyed. Sixty-two species of Odonata are recorded for Bosanquet, bringing the Lambton County odonate total to 66 species. Thirty-five species are added as new to Lambton County. *Enallagma travium* is new to Canada and the record of *Enallagma basidens* signifies that this species is continuing to expand its range northward. *Pachydiplax longipennis* is discovered on the Lake Huron shoreline for the first time, away from its regular haunts along Lakes Erie and Ontario. *Libellula quadrimaculata* and *Nannothemis bella* were recorded in Lambton County by Walker and Corbet (1973) but were not discovered in our study. They are presumed to be extirpated." (Authors)] Address: Skevington, J.; Dep. Entomol., Univ. Queensland, Brisbane, QLD 4072, Australia

1250. **Switzer, P.V. (1997):** Past reproductive success affects future habitat selection. *Behavioral Ecology & Sociobiology* 40(5): 307-312. (in English). ["Correlational studies have shown that an individual's past reproductive success often increases its breeding site fidelity (i.e., the tendency to return to a previously occupied location), suggesting that individuals use their reproductive experience to assess habitat quality. However, the causality of the relationship between reproductive success and site fidelity is still uncertain. In a field experiment, the effect of mating success on site fidelity was isolated from potential confounding variables in a territorial dragonfly, the eastern amberwing (*Perithemis tenera*). The experiment controlled for site quality, intrinsic characteristics of males, previous territorial experience at the site, arrival order, and territorial evictions. Males that were prevented from mating were much more likely to change sites the following day than control males that were allowed to mate. This result was not affected by age, the amount of time a male spent on the site, or mortality. These results imply that individuals use their own reproductive success to assess the quality of the habitat. The benefit to an individual of using its reproductive success to determine habitat quality is discussed relative to other sources of information." 1251. **Thorp, A.G.; Jones, R.C.; Kelso, D.P. (1997):** A comparison of water-column macroinvertebrate communities in beds of differing submersed aquatic vegetation in the tidal freshwater Potomac River. *Estuaries* 20(1): 86-95. (in English). ["Macroinvertebrates are a major food for fish species and macrophyte beds are hypothesized to harbor a rich community of these organisms. Macroinvertebrates inhabiting the water column in two macrophyte beds and an adjacent open area were sampled in a small embayment of the tidal freshwater Potomac River. One macrophyte bed consisted of an almost complete monoculture of *Hydrilla verticillata*, while the second community was a more diverse mixture of plant species. In samples with substantial amounts of submersed aquatic vegetation (SAV), macroinvertebrate density was two orders of magnitude higher than and substantially more taxa were found than at the

open water site. Total macroinvertebrate abundance was significantly greater at the *H. verticillata* site than at the mixed site in July, but no significant difference was observed in August. Taxa richness did not vary between the two vegetated sites in July but was higher in the mixed bed in August. While the two vegetated sites shared similar taxa, they differed in their abundance. The *H. verticillata* site harbored more hydrobiid snails, and the mixed site was characterized by more chironomids and hydroptilid caddisflies. Differences between July and August collections were even greater than between sites. Numbers of hydroptilid caddisflies, baetid mayflies, and coenagrionid damselflies were substantially higher in August, while oligochaetes, hydrobiids, and chironomids were reduced. Results support the hypothesis that water-column macroinvertebrates are greatly enhanced in the presence of macrophytes. The ecological significance of the less substantial differences in macroinvertebrates between macrophyte beds requires further study." (Authors)] Address: Jones, R.C., Dep. Biol., George Mason Univ., 4400 University Dr., Fairfax, VA 22030, USA

1252. **Tsubaki, Y.; Hooper, R.E.; Siva-Jothy, M.T. (1997):** Differences in adult and reproductive lifespan in two male forms of *Mnais pruinosa costalis* Selys (Odonata: Calopterygidae). *Researches on Population Ecology* 39(2): 149-155. (in English). [Males of *Mnais pruinosa costalis* are dimorphic, existing as clear-winged - non-territorial 'sneakers'- and orange-winged territorial 'fighters'. "Here we report the results of population census data and behavioural observations in the field and laboratory, and present estimates of emergence period, reproductive period, total lifespan, and reproductive success of each morph. Clear-winged males are smaller and have lower daily reproductive success than orange-winged males, but live for longer in the field and laboratory. We accounted for the difference in the 'operational reproductive life' of the two morphs and estimated lifetime reproductive success: there was no difference between clear-winged and orange-winged males. We discuss possible mechanisms for the maintenance of the two forms." (Authors)] Address: Siva-Jothy, M.T., Department of Animal and Plant Sciences, University of Sheffield, Sheffield, S10 2TN, UK

1253. **Van Buskirk, J.; McCollum, S.A.; Werner, E.E. (1997):** Natural selection for environmentally induced phenotypes in tadpoles. *Evolution* 51(6): 1983-1992. (in English). ["Models suggest that phenotypic plasticity is maintained in situations where the optimal phenotype differs through time or space, so that selection acts in different directions in different environments. Some empirical work supports the general premise of this prediction because phenotypes induced by a particular environment sometimes perform better than other phenotypes when tested in that environment. We have extended these results by estimating the targets of selection in *Pseudacris triseriata* tadpoles in environments without predators and with larval *Anax* dragonflies. Tadpoles displayed significant behavioral and morphological plasticity when reared in the presence and absence of nonlethal dragonflies for 32 days in cattle tanks. We measured selection in the absence of free predators by regressing growth and survival in the tanks against activity and several measures of tail and body shape. We measured selection in the presence of predators by exposing groups of 10 tadpoles to *Anax* in overnight predation trials and regressing the average

phenotype of survivors against the number of tadpoles killed. Selection in the two environments acted in opposite directions on both tail and body shape, although the affected fitness components were different. In the presence of *Anax*, tadpoles with shallow and narrow body, deep tail fin, and wide tail muscle survived best. In the absence of free predators, tadpoles with narrow tail muscle grew significantly faster, and those with shallow tail fin and deep body grew somewhat faster. Activity was unrelated to survival or growth in either environment. Developmental plasticity in tail shape closely paralleled selection, because tail fin depth increased after long-term exposure to *Anax* and tail muscle width tended to increase. In contrast, there was no plasticity in body shape in spite of strong selection for decreasing body depth. Thus, when confronted with a dragonfly predator, *P. triseriata* tadpoles adjusted their tail shape (but not body shape) almost exactly in the direction of selection imposed by *Anax*. These results suggest that phenotypic plasticity in some morphological traits, such as tail depth and tail muscle width, has evolved under intermittent selection by dragonflies. Other traits that undergo selection by dragonflies, such as body morphology, appear developmentally rigid, perhaps because of historically strong opposing selection in nature or other constraints." (Authors)] Address: Van Buskirk, J., Inst. Zool., Univ. Zürich, CH-8057 Zürich Switzerland

1254. **Weiherr, B.; Komnick, H. (1997):** Digestion of phosphatidylcholines, absorption and esterification of lipolytic products by *Aeshna cyanea* larvae as studied in vivo and in vitro. *Arch. Insect Biochem. Physiol.* 36(4): 273-293. (in English). ["Digestion and absorption of phosphatidylcholine by *Aeshna cyanea* larvae were studied in vivo and in vitro with the isolated digestive juice and isolated midgut. The experiments were performed with stable ether analogues (1-alkyl-2-acyl-1,2-dialkyl phosphatidylcholine, and 1-monoalkyl-lysophosphatidylcholine) with radioactive 1,2-diacylphosphatidylcholine alternatively labelled in the acyl- and choline moieties, and with several phosphatidylcholine derivatives (1-(1-¹⁴C)acyl- and 1-(3H)alkyl-lysophosphatidylcholine, (1-¹⁴C)oleic acid, (2-¹⁴C)glycerol, phosphoryl (methyl-¹⁴C)choline, and (methyl-¹⁴C)choline). Chromatographic analyses of the digestion products revealed that phosphatidylcholine was degraded via two interconnected hydrolytic pathways involving phospholipase C, phospholipase A2, lipase, and alkaline phosphatase. Complete hydrolysis by these pathways yielded the same four end products: free fatty acid, glycerol, choline, and Pi, which were absorbed by the midgut enterocytes. Of the intermediate hydrolysates, lysophosphatidylcholine, monoacylglycerol, and possibly phosphorylcholine were also absorbed. Radiolabelled oleic acid, glycerol, lysophosphatidylcholine and monoacylglycerol (as judged from monoalkylglycerol absorption) were incorporated into phospholipids and acylglycerols of the midgut enterocytes and were released into the haemolymph primarily in the form of diacylglycerols. In the case of glycerol ingestion, a small fraction of haemolymph radioactivity was associated with free glycerol and glycerolphosphate. After absorption by the enterocytes, radiolabelled choline was partly oxidized to betaine, partly phosphorylated, and partly incorporated into lyso- and phosphatidylcholine. It was recovered from the haemolymph predominantly as free choline, phosphorylcholine, and betaine." (Authors)] Address: Komnick, H., Univ. Bonn, Inst. Cell Biol., Ulrich-Haberland-Str. 61a, 53121 Bonn, Germany

[Phylogenetic relationships among the holometabolous insect orders were inferred from cladistic analysis of nucleotide sequences of 18S ribosomal DNA (rDNA) (85 exemplars) and 28S rDNA (52 exemplars) and morphological characters. Odonata were used as out-group taxa.] Address: Whiting, M.F., Dep. Zool., M.L. Bean Life Sci. Museum, Brigham Young Univ., Provo, UT 84602 USA.

1256. **Wolf, L.L.; Waltz, E.C.; Klockowski, D.; Wakeley, K. (1997):** Influence on variation in territorial tenures of male white-faced dragonflies (*Leucorrhinia intacta*) (Odonata: Libellulidae). *Journal of Insect Behavior* 10(1): 31-47. (in English). ["Some individuals in species with extended periods of territorial occupancy may change territory locations within a single bout of territorial activity. Length of occupancy of mating territories among males in a local population of white-faced dragonflies (*Leucorrhinia intacta*) varied from more than 6 h to 15 min or less. Males with short tenures often established territories in several locations on the pond during a day. Several hypotheses have been proposed to explain shifting territorial sites rather than remaining in a single site during one bout of territoriality. We attempted to test the hypothesis that males shift to leave low-quality sites. Site quality may be affected by costs of defense in relation to intruder rate and the mating benefits of holding the territory. To test whether variation in these possible effects of benefits and costs of territoriality influenced tenure, we manipulated local quality of oviposition substrate and perch density. The quality of oviposition substrate, but not perch density, influenced both potential benefits and costs of territoriality. Female density was higher in areas with good substrate, but so were rates of males intruding into the territories, rates of chasing by territorial males, and local density of territorial males. More matings occurred in areas with good substrate, but among males with tenures of 15 min or more, mating success per male and tenure lengths did not differ statistically among treatments. Defense costs were low for all treatments and perhaps were not an important influence on tenure duration. Territorial males in this population probably adjusted local density to expected mating success by initial choice of site rather than by varying tenure length. Variation in tenure length at a site resulted, in part, from stochastic external factors, such as predation attempts." (Authors)] Address: Wolf, L., Institution Dep. Biol., Syracuse Univ., Syracuse, New York 13244-1270, USA

1257. **Abro, A. (1998):** Structure and development of sperm bundles in the dragonfly *Aeshna juncea* L. (Odonata). *J. Morphol.* 235: 239-247. (in English). ["A re-examination of the origin and development of sperm bundles in aeshnid dragonflies (Odonata, Anisoptera) was carried out using light and electron microscopy. During their elongation, intracyst spermatids of the testis of the dragonfly *A. juncea* form a slender cytoplasmic protrusion, the acrosomal conicoid, beyond the nucleus and acrosome rodlet. Gathering and paral-

lel alignment of the transforming spermatids into a tight bundle take place inside the cyst. The original, rigid spermatid foreparts eventually associate, initially by becoming adhesive and swelling progressively to intertwine, and thus come to constitute a cap that binds together all sperm heads within a cyst in a spermatodesma. The development of the spermatodesma seems to occur disjunct from somatic cyst cells. Bundled in this form, the sperms are transferred to the intratestis canal and moved down the spermiduct to the seminal vesicle. They are then forwarded to the male copulatory apparatus, from which they are transmitted to the female. Individual, fully formed sperms are seen to be liberated from the bundle when in the female receptaculum seminis. The remnant of the cytoplasmic acrosomal conicoid, which is considered an envelope of the acrosome rodlet, is then dissolved. The spermatodesmata are large sperm aggregates that constitute efficient vehicles for transmission of amounts of filamentous sperm to the female." (Author)] Address: Åbro, A., Inst. Anat., Univ. 1270. **Caldwell, J.P.; De Araujo, M.C. (1998):** Cannibalistic interactions resulting from indiscriminate predatory behavior in tadpoles in poison frogs (Anura: Dendrobatidae). *Biotropica* 30(1): 92-103. (in English). ["Poison frogs in the genus *Dendrobates* have very small clutch sizes (2-6 eggs among species for which there are data) and typically transport their tadpoles singly to small phytotelmata [...]. Tadpoles of many species are predaceous, consuming larvae of insects that use the same microhabitat for breeding, such as giant damselflies and mosquitoes. Previous studies and observations on the behavior of poison frog tadpoles led us to question whether tadpoles might be cannibalistic. We studied a population of *Dendrobates castane-*

oticus in lowland rainforest in Para, Brazil; additional data were collected on *Dendrobates auratus* in Nicaragua. At the study site in Brazil, we established a grid of 40 Brazil nut capsules, the microhabitat used by *D. castaneoticus* for tadpole deposition. Of 42 tadpoles deposited during the 55 days of the study, 20 were killed or died; 16 of these were presumably killed by conspecific tadpoles. Growth rate and time to metamorphosis was higher among tadpoles that consumed three or more tadpoles or relatively large larvae of the mosquito *Trichoprosopon digitatum*, a colonist of newly opened Brazil nut capsules. We propose that selection has favored the development of predatory behavior in poison frog tadpoles primarily as a mechanism to eliminate predators from the small phytotelmata in which they develop and that cannibalism is a secondary outcome of this behavior. Predatory behavior also provides tadpoles with food, which is frequently limited in these microhabitats. Additional studies of the biology of tadpoles of other species of *Dendrobates* are needed to determine the evolution of predatory and cannibalistic behavior in the clade." 1275. **France, R.L. (1998):** Density-weighted delta¹³C analysis of detritivory and algivory in littoral macroinvertebrate communities of boreal headwater lakes.

Annales Zoologici Fennici 35(3): 187-193. (in English). ["Investigations of the incorporation of terrestrial detritus into aquatic macroinvertebrates through delta13C analysis are becoming frequent for streams and wetlands, but comparatively little information exists for forest-fringed oligotrophic lakes. Although the most accurate assessment of community patterns in carbon dependency will be made through an organism density-weighted analysis of delta13C, this has never previously been undertaken for any freshwater system. Littoral macroinvertebrates (predominantly amphipods, ephemeropterans and dipterans, as well as odonates and trichopteran) from boreal lakes in northwestern Ontario, Canada displayed ranges of 6 per mill to 9 per mill in delta13C, all centred about -26 per mill. The closer agreement between the density-weighted delta13C distribution for these macroinvertebrates to tree rather than epilithon values, suggests that these organisms may be relying more substantially upon allochthonous detritivory than upon autochthonous algalivory for energy sustenance. This finding therefore challenges the precept in some timber management guidelines that dismisses riparian trees as an important energy for lake foodwebs." (Author)] Address: France, R.L., Harvard Univ., Graduate Sch. Design, 48 Quincy St., Cambridge, MA 02138, USA

1276. **Fuhrmann, M. (1998):** Untersuchungen zur Libellenfauna (Odonata) der Neyetalsperre im Oberbergischen Kreis (NRW). *Bucklige Welt*, Wiehl 2: 48-60. (in German). [Transect study of the Odonata of the damed brook Neye, Nordrhein-Westfalen, Germany; 19 species were recorded; dominance of species is presented for each of the four transects] Address: Fuhrmann, M., Zum Großen Wald 19, D-57223 Kreuztal, Germany

1277. **Fuller, R.M.; Groom, G.B.; Mugisha, S.; Ipulet, P.; Pomeroy, D.; Katende, A.; Bailey, R.; Ogotu-Ohwayo, R. (1998):** The integration of field survey and remote sensing for biodiversity assessment: A case study in the tropical forests and wetlands of Sango Bay, Uganda. *Biological Conservation* 86(3): 379-391. (in English). ["Field surveys of plants and animals were combined with satellite remote sensing of broad vegetation types to map biodiversity and thereby help plan conservation in the Sango Bay area, some 30 by 100 km bordering Lake Victoria in Uganda. A statistical classifier applied to satellite images identified 14 land-cover classes including water, swamp, dry grasslands, degraded woody vegetation, semi-natural forest classes and intensive land uses. Validation, using 240 sample sites, recorded 86% correspondence between field and map data. Intensive land use makes up 23% of the area, water and swamps 27%, dry grasslands 29%, woody vegetation 21% with semi-natural forests covering 15% of the area. The species data from sample-based field surveys included flowering plant species, dragonflies, butterflies, fish, amphibians, reptiles, birds and mammals. The species data were used to generate biodiversity ratings, based on species 'richness' and 'rarity', which could be related to the vegetation cover. This inter-relation helped to generate a biodiversity map of the Sango Bay area which has since been used to aid conservation planning." (Authors)] Address: Fuller, R.M., Inst. Terrestrial Ecol., Monks Wood, Huntingdon, Cambridgeshire PE17 2LS, UK

1278. **Futahashi, R.; Araki, Y. (1998):** New records of *Anax guttatus* from Toyama Pref. *Tombo* 41: 6-8. (in Japanese with English summary). [At 76 areas in Toy-

ama Pref., Japan between August and November 1998 many adult of the species were collected.] Address: not stated

1279. **Geister, I. (1998):** A list of Slovene dragonfly names. *Exuviae* 5(1): 1-5. (in Slovenian with English summary). ["The Slovene standard nomenclature is presented for the families, genera and species known or expected to occur in Slovenia and adjacent regions. The names are artificial rather than based on the available folk appellations. They were constructed with reference to the peculiarities in general appearance, colour, behaviour, habitat and phenology of the taxa concerned. Family and generic names are uninominal, species-group names are binominal, the infraspecific taxa are not considered. This nomenclature was in experimental use since 1992, and becomes compulsory with the present publication." (Author)] Address: Geister, I., Kocjancici 18, SI-6276 Pobegi, Slovenia

1280. **Glaser, B. (1998):** Besiedlung von neugeschaffenen Gewässern in der Chemnitzau bei Heinersdorf durch Libellen, Fische und Lurche. *Veröffentlichungen des Museums für Naturkunde Chemnitz* 21: 131-138. (in German). [Documentation of colonisation by Odonata, Amphibia, and Pisces of six newly created water bodies near Chemnitz, Saxonia, Germany; 27 odonate species could be recorded three years after finishing work on the water bodies; of some regional faunistic interest are *Erythromma viridulum*, *Ischnura pumilio*, *Lestes barbarus*, *L. dryas*, *Sympecma fusca*, and *Sympetrum pedemontanum*.] Address: Glaser, E., Alfred-Neubert-Str. 8, D-09123 Chemnitz, Germany

1281. **González Soriano, E.; Novelo-Gutiérrez, R. (1998):** *Oplonaeschna magna* sp. nov. (Odonata: Aeshnidae), from Mexico with a description of its larva. *Rev. biol. trop.* 46(3): 705-715. (in English). ["*Oplonaeschna magna* sp. nov. (Odonata: Aeshnidae) (holotype male and allotype female deposited at CNIN UNAM-MEX., Mexico, D. F.) is described and illustrated from specimens collected in the states of Estado de Mexico, Guerrero, Hidalgo, and Morelos, Mexico. This is the second species of the genus *Oplonaeschna*. Adults of *O. magna* can be separated from those of *O. armata* (Hagen, 1861) by their larger size and broader thoracic stripes. The larva of the new species is also easily distinguished from that of *O. armata* by its larger size and longer prementum, and by structural differences of palpal lobes and epiproct. The larva of *O. armata* is briefly redescribed, illustrated and compared to that of *O. magna*. Notes on the biology of the new species are provided." (Authors)] Address: Novelo-Gutiérrez, R., Departamento de Entomología, Instituto de Ecología A.C., Km 2.5. antigua carretera a Coatepec, Apartado Postal 63, 91000 Xalapa, Veracruz, Mexico. 1306. **Polyanovskii, A.D. (1998):** Phototransduction in insects: Two strategies of calcium homeostasis? Sensornye Sistemy 12(3): 245-254. (in Russian). ["In rhabdomeral photoreceptors of arthropods, light causes steep elevation of cytosolic free calcium concentration. The consensus model of the phosphoinositide signaling cascade attributes this phenomenon to the inositol 1,4,5-trisphosphate (InsP3)-mediated calcium release from the intracellular stores, submicrovillar endoplasmic cisternae (SMC). It is generally accepted that the depletion of SMC is an indispensable step in photoexcitation. This paradigm appears to fit most of insects with a fused-type rhabdom (Hymenoptera, Orthoptera, Odonata, Blattodea), whose photoreceptors contain large SMC able to actively accumulate calcium and release it upon illumination through the InsP3- and ryanodine-sensitive mechanisms. However those with an open-type rhabdoms (Diptera, some Hemiptera and Coleoptera) conflict with the paradigm. Studies on *Drosophila* suggest that in open-rhabdom eyes the calcium homeostasis is mediated via a co-operation of at least three distinct mechanisms: (1) extracellular ommatidial cavity represents a principal calcium store responsible for a light-induced calcium influx; (2) specialized cytosolic domain containing a novel calcium-binding protein, calphotin, might function as a calcium-buffering "sponge"; (3) heavily reduced SMC do not express an InsP3-sensitive calcium release mechanism and do not participate in phototransduction directly. Hence the same task of the transformation of light into a receptor signal seems to be resolved in insects." (Authors)] Address: Polyakovskii, A.D., I. M. Sechenov Inst. Evol. Physiol. Biochem., Russ. Acad. Sci., pr. M. Toreza 44, St. Petersburg 194223, Russia

1307. **Ramirez, J.; Vogt, R.C.; Villarreal-Benitez, J.-L. (1998):** Population biology of a neotropical frog (*Rana vaillanti*). Journal of Herpetology 32(3): 338-344. (in English). ["We studied the population dynamics, food habits, and growth of a population of *Rana vaillanti* in a

permanent lake in Southern Veracruz, Mexico from April 1984 through March 1985. [...] *Rana vaillanti* is a sit and wait predator with a diverse diet including birds, fish, and conpecifics. They consume a higher proportion of invertebrates than vertebrates, principally insects (Coleoptera and Odonata) and spiders." (Authors)] Address: Vogt, R.C., Estacion Biol. 1308. **Roehrdanz, R.L.; Degrugillier, M.E. (1998):** Long sections of mitochondrial DNA amplified from fourteen orders of insects using conserved polymerase chain reaction primers. *Annals of the Entomological Society of America* 91(6): 771-778. (in English). ["The combination of highly conserved or universal polymerase chain reaction (PCR) primers with techniques that allow for the amplification of PCR products greater than a few thousand base pairs (long PCR) makes it possible to amplify the complete mitochondrial genome of virtually any insect as a small number of overlapping segments. Twelve conserved primers from 7 mitochondrial genes were used in 17 pair combinations. The size of the amplified segments ranged from 3.3 to 14.1 kb. Total genomic DNA from 33 insect species representing 14 orders served as the template. In most instances, 2 fragments sufficed to include the whole mitochondrial DNA (mtDNA). Less frequently 3 or more fragments were required to cover the complete mtDNA. Fragments that combined contain all of the mtDNA were amplified from 26 of 33 species. For the remaining species, >67% of the mtDNA was amplified. Any of the large amplicons are convenient for restriction fragment comparisons and they are also suitable as a template for nucleotide sequencing of either small mtDNA regions or the complete mtDNA of diverse taxa in conjunction with population or phylogenetic investigations. The procedures described here can be used to amplify the A+T or control region as part of a larger fragment and provides an opportunity for a more detailed analysis of this region." (Authors)] Address: Roehrdanz, R.L., Institution Biosci. Res. Lab., USDA-ARS, P.O. Box 5674, Fargo, ND 58105, USA

1309. **Schaffner, A.K.; Anholt, B.R. (1998):** Influence of predator presence and prey density on behavior and growth of damselfly larvae (*Ischnura elegans*) (Odonata: Zygoptera). *Journal of Insect Behavior* 11(6): 793-809. (in English). ["Foraging behaviour is often determined by the conflicting benefits of energy gain and the risk of mortality from predation or other causes. Theory predicts that animals should have lower activity levels when either the risk of predation or the availability of resources in the environment is high. We investigated the adjustment of the behaviour of *I. elegans* larvae to predator presence (*Anax imperator*) and prey density (*Daphnia* sp.) and their interaction in a completely crossed factorial experiment in the lab and the effect of behaviour on growth. The foraging activity of the *I. elegans* larvae was significantly reduced in the presence of a free-swimming predator but not a caged predator. Abdominal movements were significantly reduced at a low prey density. Growth was significantly reduced by the presence of a free swimming predator and low prey densities. These results provide evidence that these damselfly larvae adjust their behaviour to the presence of predators to increase their survival at the expense of reduced growth and development." (Authors)] Address: Anholt, B.R., Dept Biology, Univer-

sity of Victoria, PO Box 3020, Victoria, BC, V8W 3N5, Canada; E-mail: banholt@uvic.ca

1310. **Schmidt, E. (1998):** Aphorismen zur Odonatenfauna der Ruhraue bei Mühlheim. *Verh. West. Entomol. Tag 1997*: 205-212. (in German). [Checklist of the odonate fauna of the alluvion of Ruhr, Nordrhein-Westfalen, Germany; detailed discussion of factors determining the odonate habitat suitability in the region incl. interesting observations on the (negative) influence of *Branta canadensis* (Aves) on habitat of *Cercion lindenii* and *Erythromma viridulum*; of special faunistic interest are records of *Libellula fulva*, *Sympetrum pedemontanum*, and *Coenagrion pulchellum*] Address: Schmidt, E., Biologie und ihre Didaktik, FB9/S05, Universität GH Essen, D-45117 Essen, Germany

1311. **Schmidt, E. (1998):** Die ökologische Nische von *Sympetrum flaveolum* (L., 1758) und die Problematik von Artenschutz und Einstufung in Rote Listen bei Odonaten mit temporärer Habitat-Besiedlung (Odonata: Libellulidae). *Entomologia Generalis* 23(1-2): 129-138. (in German). ["[...] The ecological niche of *Sympetrum flaveolum* has the following key stone factors: • Water regime, which fits only in certain years, thus breeding only temporarily can be successful and dispersal is necessary for a new colonisation. • Good weather conditions during spring for the larval development and during the flying season as well for reproductive behaviour as for dispersal. • Microclimate: The microhabitats have a more continental microclimate compared with the surroundings. This fits to the rather northern distribution across the Euro-Siberian continent and preference of mountain regions in the southern parts of the distribution area. In NW-Germany temporarily floated areas at running waters, lakes and swamps decreased strongly. So the species lost most breeding habitats except some few places (mainly under nature conservancy or in sand dune valleys on the wadden sea islands). The vegetation structure preferred under natural conditions is favoured by poor soil, and so it suffered very much from fertilization everywhere. Special water and vegetation management in swamps may help for saving breeding habitats. [...] Red Data Books do not have an adequate category for species like *S. flaveolum* confined to only temporarily fitting breeding microhabitats." (Author)] Address: Schmidt, E.G., Univ. Essen (GHS), FB 9 S05, D-45117 Essen, Germany

1312. **Schmude, K.L.; Jennings, M.J.; Otis, K.J.; Piette, R.R. (1998):** Effects of habitat complexity on macroinvertebrate colonization of artificial substrates in north temperate lakes. *Journal of the North American Benthological Society* 17(1): 73-80. (in English). ["The purpose of this study was to determine the effects of substrate complexity on community structure of macroinvertebrates in littoral zones of lakes. Artificial substrates were used to simulate characteristics of structures commonly placed on the lake bed along shorelines. Cement balls in a wire basket simulated rock riprap, whereas concrete patio blocks simulated retaining walls; the samplers had nearly equal surface areas. Samplers were placed in the littoral zones of 3 dissimilar lakes in Wisconsin, and in front of 3 types of shorelines: rock riprap, vertical retaining wall, and natural shorelines. Colonization periods were 40-45 d starting immediately after ice-out. Significantly greater numbers of organisms colonized basket samplers ($1947 \pm 155/m^2$, mean ± 1 SE) than block samplers ($951 \pm 73/m^2$). Taxa richness was significantly higher on baskets (31 ± 1)

versus blocks (22 ± 1). Hydra, Turbellaria, Oligochaeta, Crustacea, Ephemeroptera, and Odonata were significantly more abundant on baskets than on blocks. [...] Neither abundance nor richness differed significantly among shoreline types, but a trend of higher values for both variables was observed along rock riprap. The results were consistent with the hypothesis that the more complex, 3-dimensional artificial substrate with its greater substrate heterogeneity, surface complexity, and interstitial space, will support a more diverse and abundant macroinvertebrate community in lakes compared to the less complex, 2-dimensional artificial substrate. Shoreline management practices that reduce habitat complexity may reduce local invertebrate diversity." (Authors)] Address: Schmude, K.L., Lake Superior Res. Inst., Univ. Wis.-Superior, Superior, WI 54880, USA

1313. **Seki, T.; Vogt, K. (1998):** Evolutionary aspects of the diversity of visual pigment chromophores in the class insecta. *Comparative Biochemistry & Physiology - B: Comparative Biochemistry* 119(1): 53-64. (in English). ["In the class Insecta, three retinal congeners are used as the chromophore of visual pigments: retinal, (3R)-3-hydroxyretinal and (3S)-3-hydroxyretinal. The distribution of retinal and 3-hydroxyretinal superimposed on the phyletic tree of insects indicates that the original chromophore of visual pigments was retinal, and that some insects arose around the end of the Carboniferous period acquired the ability to use 3-hydroxyretinal. Xanthophylls possessing 3-hydroxy-beta-ring have been considered to be precursors of 3-hydroxyretinal, and the "oxygen pulse" in the late Paleozoic era is discussed as a possible contributory factor in obtaining the ability to use 3-hydroxyretinal as the visual pigment chromophore. Xanthophylls possessing 3-hydroxy-beta-ring produced by plants and bacteria have only the (3R)-beta-ring, so the 3-hydroxyretinal produced directly from such xanthophylls is expected to be (3R)-3-hydroxyretinal. On investigating the absolute structure of 3-hydroxyretinal in insect compound eyes, using a chiral column, the orders Odonata, Hemiptera, Neuroptera, Coleoptera, and Lepidoptera, and suborders Nematocera and Brachycera of the Diptera were found to have only (3R)-3-hydroxyretinal. The members of the dipteran suborder Cyclorrhapha, however, were found to contain a mixture of both the (3R)- and (3S)-enantiomers of all-trans 3-hydroxyretinal and (3S)-11-cis 3-hydroxyretinal. The Cyclorrhapha, which arose in the Jurassic period, have obtained the ability to produce (3S)-3-hydroxyretinal, but the metabolic pathway by which these "higher flies" form (3S)-3-hydroxyretinal has yet to be clarified." 1314. **Swisher, B.J.; Soluk, D.A.; Wahl, D.H. (1998):** Non-additive predation in littoral habitats: influence of habitat complexity. *Oikos* 81(1): 30-37. (in English). ["The combined effects of predators on prey in structurally complex habitats may not always be described by additive models. Changes in habitat complexity can affect the rates of consumption by individual predators as well as alter the interactive, combined effects of predators with contrasting foraging styles. We examined the combined consumption of a common prey by two predators across a gradient of three habitat complexities. In microcosm experiments, consumption of larval mayfly prey (*Cloeon cognatum*) by juvenile bluegill sunfish (*Lepomis macrochirus*) and libellulid dragonfly larvae

(*Erythemis simplicicollis*) exceeded additivity at low habitat complexity, but were additive at higher levels of complexity. Prey capture by odonates was unaffected by fish presence during both day and night. At low stem density, fish capture more mayfly larvae than expected in the presence of dragonflies than in their absence, while consumption by dragonflies is unchanged in the presence of fish. Both the behavioral attributes of predators and prey as well as structural complexity of their habitat affect encounter rates, and thus their net interaction." 1316. **Velasco, J.; Millan, A. (1998):** Feeding habits of two large insects from a desert stream: *Abedus herberti* (Hemiptera: Belostomatidae) and *Thermonectus marmoratus* (Coleoptera: Dytiscidae). *Aquatic Insects* 20(2): 85-96. (in English). ["Feeding preference experiments were conducted to determine the feeding habits of *Abedus herberti* (Heteroptera, Belostomatidae) and *Thermonectus marmoratus* (Coleoptera, Dytiscidae), two large insects in Sycamore Creek, an intermittent Sonoran desert stream, Arizona, U.S.A. Numbers of live versus dead prey consumed were tested between and across three prey sizes. Five prey species were offered simultaneously (5 live and 5 dead specimens) in each size class. We found that *A. herberti* preferred live prey of small and medium size, but it chose mainly dead prey in the large size class. These results fitted the model of size-selective predation (Zaret, 1980). Size dependent predators selected prey of increased size, according to their visibility, but only up to where difficulty in handling and probability of escape affect successful consumption. Snails were the most preferred prey of *A. herberti*. By contrast, *T. marmoratus* consumed only dead prey of all sizes, but it preferred soft organisms with thin cuticle, such as immature larvae of some mayflies, beetles, dragonflies or fishes." 1319. **Williams, P.H.; Gaston, K.J. (1998):** Biodiversity indicators: Graphical techniques, smoothing and searching for what makes relationships work. *Ecography* 21(5): 551-560. (in English). ["Knowledge of the distribution of biodiversity remains poor. This situation might more readily be resolved if the species richness of certain groups of organisms indicated the richness of other, less well known groups. A spatially explicit exploration of the pattern in the predictive power that one taxon (a potential 'indicator group') might have for the diversity of another has been performed previously. In this paper we respond to three important points that have been raised. First, we describe an additional graphical technique for visualizing spatial aspects of indicator relationships. Second, we examine some of the consequences of smoothing species richness data on observed indicator relationships. Third, we consider some of the factors that may contribute to strong indicator relationships." (Authors)] Address: Williams, P.H., Biogeography Conservation Lab., Natural Hist. Museum, London SW7 5BD, UK

1337. **Benke, A.C.; Huryn, A.D.; Smock, L.A.; Wallace, J. B.. (1999):** Length-mass relationships for freshwater macroinvertebrates in North America with particular reference to the southeastern United States. *Journal of the North American Benthological Society*.

18(3): 308-343. (in English). ["Estimation of invertebrate biomass is a critical step in addressing many ecological questions in aquatic environments. Length-dry mass regressions are the most widely used approach for estimating benthic invertebrate biomass because they are faster and more precise than other methods. A compilation and analysis of length-mass regressions using the power model, M (mass) = $a L$ (length) b , are presented from 30 y of data collected by the authors, primarily from the southeastern USA, along with published regressions from the rest of North America. A total of 442 new and published regressions are presented, mostly for genus or species, based on total body length or other linear measurements. The regressions include 64 families of aquatic insects and 12 families of other invertebrate groups (mostly molluscs and crustaceans). Regressions were obtained for 134 insect genera (155 species) and 153 total invertebrate genera (184 species). Regressions are provided for both body length and head width for some taxa. In some cases, regressions are provided from multiple localities for single taxa. When using body length in the equations, there were no significant differences in the mean value of the exponent b among 8 insect orders or Amphipoda. The mean value of b for insects was 2.79, ranging from only 2.69 to 2.91 among orders. The mean value of b for Decapoda (3.63), however, was significantly higher than all insects orders and amphipods. Mean values of a were not significantly different among the 8 insect orders and Amphipoda, reflecting considerable variability within orders. Reasons for potential differences in b among taxa are explained with hypothetical examples showing how b responds to changes in linear dimensions and specific gravity. When using head width as the linear dimension in the power model, the mean value of b was higher (3.11) than for body length and more variable among orders (2.8-3.3). Values of b for Ephemeroptera (3.3) were significantly higher than those for Odonata, Megaloptera, and Diptera. For those equations in which ash-free dry mass was used, % ash varied considerably among functional feeding groups (3.3-12.4%). Percent ash varied from 4.0% to 8.5% among major insect orders, but was 18.9% for snails (without shells). Family-level regressions also are presented so that they can be used when generic equations are unavailable or when organisms are only identified to the family level. It is our intention that these regressions be used by others in estimating mass from linear dimensions, but potential errors must be recognized." (Authors)] Address: Benke, A., Aquatic Biology Program, Department of Biological Sciences, University of Alabama, Tuscaloosa, AL, USA

1338. **Bönsel, A. (1999):** Der Einfluss von Rothirsch (*Cervus elaphus*) und Wildschwein (*Sus scrofa*) auf die Entwicklung der Habitate von *Aeshna subarctica* Walker in wiedervernässten Regenmooren (Anisoptera: Aeshnidae). *Libellula* 18(3/4): 163-168. (in German with English summary). ["In two rewetted bogs in Mecklenburg-Vorpommern, Germany, vegetation has developed so fast that after already 4 years areas of *Sphagnum cuspidatum* have been replaced by the next stadium of succession swing grass areas. Because of this the potential breeding places of *A. subarctica* disappeared. But those are constantly being recreated by red deer and wild pig. Therefore these mammals play an important role for the survival of *A. subarctica* in these areas." (Author)] Address: Bönsel, A., Vasenbusch 15, D-18337 Gresenhorst, Germany

1339. **Bohonak, A.J. (1999):** Effect of insect-mediated dispersal on the genetic structure of postglacial water mite populations. *Heredity* 82(4): 451-461. (in English). ["Assaying population structure in species that differ in dispersal ability can help to determine whether population differentiation is dependent on the movement of individuals between populations. Here, allozyme variation is analysed in over 1100 individuals from nine species and two species complexes of *Arrenurus* water mites collected throughout north-eastern North America. As larvae, eight taxa are obligate parasites of winged adult insects that provide the primary opportunity for dispersal. Three additional species have lost the ability to parasitize insects and do not disperse in this manner. Consistent with the glaciated history of the region, very low allozyme heterozygosity was found in these taxa ($H_o = 0.00-0.12$), near panmixia in five out of seven species for which population differentiation was calculated and no patterns of isolation by distance over spatial scales up to several hundred kilometres. Nonetheless, in two out of three comparisons between sister species with and without parasitic larvae, parasitism was significantly associated with higher heterozygosity. Population differentiation could also be contrasted for two of these sister pairs; in each case, lower estimates of F_{ST} were found in the mites able to disperse on insects. The statistical significance of these contrasts was dependent on the method used to estimate variance. At the scale of the genus, behavioural differences among insect vectors allows for broader hypothesis that relate water mite genetic diversity to dispersal ability. For the genus, rank correlations of dispersal ability with direct count heterozygosity ($n = 11$) and population differentiation ($n = 7$) were not significantly different from zero. These results are consistent with the hypothesis that allozyme population structure is primarily the result of historical patterns in these regions. However, comparisons between sister species suggest a limited role for dispersal in homogenizing populations genetically, even when drift-gene flow equilibrium has not been achieved." (Author)] Address: Bohonak, A., Center for Conservation Research and Training, University of Hawaii, Honolulu, HI, 96822, USA

1345. **Buczynski, P. (1999):** The checklist and the "Red list" of the dragonflies (Insecta: Odonata) of the Lublin Province. In: *Instytut Ochrony Przyrody Polskiej Akademii Nauk* (Ed.): *Chronmy Przyrody Ojczyzna*. *Dwumiesięcznik*. R. LV (55) - 1999 - Zeszyt 6 (Listopad-Grudzien). Kraków: 23-39. (in Polish with extensive English summary). [Checklist of the Odonata of the southeastern part of Poland including vernacular and Latin names and an assessment of the threat of the species according to the IUCN categories] Address: Buczynski, P., Dept of Zool., Marie Curie-Skłodowska University, Akademicka 19, PO-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

1346. **Buczynski, P. (1999):** Dragonflies (Odonata) of spring areas in Poland - state of research and proposes of further study. *Zródła Polski*. Stan badan, monitoring i ochrona. *Wyzsza Szkola Pedagogiczna*. Olsztyn: 31-36. (in Polish with English summary). [List of odonate species known to develop in Polish mountain regions

(n=5) and lowland regions (n=3) spring habitats; additional information is given on the species of flush systems (natural drainage systems) of the peat bogs (*Somatochlora arctica*, *Leucorrhinia albifrons*); the author stresses the lack of data on the odonate fauna of springs in Poland] Address: Buczynski, P., Dept of Zool., Marie Curie-Skłodowska University, Akademicka 19, PO-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

1347. **Buttstedt, L.; Zimmermann, W. (1999):** Die Vogel-Azurjungfer (*Coenagrion ornatum*) im Grenzraum von Sachsen-Anhalt und Thüringen. *Pedemontanum* 3: 6-9. (in German). [In 1995 *C. ornatum* was recorded at some ditches near Wallhausen, Sachsen-Anhalt, Germany. In 1998 in subsequent ditches of the Helme floodplain (Thüringen) some more local, in most cases small, populations of the species could be detected. 10 populations are known now. In all cases *C. mercuriale* co-occurs.] Address: Zimmermann, W., von-Hoff-Str. 31, D-99867 Gotha, Germany

1348. **Calil, E.R.; Carvalho, A.L. do (1999):** Descriptions of the last instar larvae and the adult of *Triacanthagyna septima* (Selys, 1857) (Odonata, Aeshnidae) with notes about the biology of the species. *Revista Brasileira de Entomologia* 43(1-2): 73-83. (in Portuguese). [The last instar larva and the adult of *T. septima* are described and illustrated. The rarely being collected larvae develop occasionally in temporary and unstable ponds, and marshes. A key to the larvae of the four hitherto described larvae of the genus is provided. The last instar larva of *T. septima* can be distinguished by the length of the cerci, distinctly shorter than the e-piproct. The adults of *T. septima* occur during all the year in the southeastern Brazil, being more common in the winter. They are crepuscular in activity and sometimes assemble in collective flights adopting migratory behaviour.] Address: Calil, E.R., Departamento de Zoologia, Instituto de Biologia, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ Brazil

1349. **Chalmel, R.; Dommanget, J.-L. (1999):** Rubrique bibliographique. *Martinia* 15(4): 131-135. (in French). [Additions to the French odontological bibliography] Address: Dommanget, J.-L., 7, rue Lamartine, F-78390 Bois-d'Arcy, France

1350. **Clausen, W. (1999):** *Gomphus flavipes* (Charpentier) in der Aller, Niedersachsen (Anisoptera: Gomphidae). *Libellula* 18(3/4): 187-188. (in German with English summary). ["On 14-VII-1999, one exuvia was recorded at the Aller near Eilte 12 km SSW Walsrode, Germany" (Author).] Address: Clausen, W., Zur Bockwindmühle 60, D-32351 Stemwede-Oppenwehe, Germany

1351. **Clausnitzer, V. (1999):** A checklist of the dragonflies (Odonata) of Kenya. *African Journal of Ecology* 37: 400-418. (in English). ["A checklist of Odonata has been compiled for Kenya. It is based on an inventory of museum material, publications and personal observations made between 1978 and 1997. Changes of scientific names and synonyms are documented. The list contains 194 valid dragonfly species recorded for Kenya." (Author)] Address: Clausnitzer, Viola, Zum Lahnverg 14, D-35032 Marburg, Germany

1352. **Conrad, K.F.; Willson, K.H.; Harvey, I.F.; Thomas, C.J.; Sherratt, T.N. (1999):** Dispersal characteristics of seven odonate species in an agricultural

landscape. *Ecography* 22(5): 524-531. (in English). ["Dispersal is an ecological phenomenon which is of fundamental importance to population biology. While dispersal behaviour of many orders of winged insects has received a great deal of attention, the dispersal characteristics of odonates have been poorly documented. We used capture-mark-recapture techniques to study dispersal behaviour of seven species of odonates breeding on a network of 11 small ponds in Cheshire, U.K. The ponds ranged in size from 615 to 1300 m² and varied from 30 to 860 m apart. We found surprisingly high rates of dispersal between ponds with 10-47% per species of recaptured individuals moving from their natal pond. The mean probability of dispersal differed significantly among species but the relationship between the probability of dispersal and distance moved consistently followed a simple negative exponential curve for all species. Most individuals stayed at their natal pond, but a few moved long distances. Neither the age at which an individual was marked (teneral vs sexually mature) nor its sex significantly affected its tendency to disperse. The negative exponential relationship suggests that dispersal should be relatively easy to incorporate in more complex models of odonate spatio-temporal dynamics. To our knowledge, this is the first large-scale, multi-species study to assess dispersal behaviour of odonates by direct observation." (Authors) The following species were surveyed: *Ischnura elegans*, *Coenagrion puella*, *C. pulchellum*, *Lestes sponsa*, *E-nallagma cyathigerum*, *Pyrrhosoma nymphula*, and *Sympetrum sanguineum*] Address: Thomas, C.J., Dept of Biological Sciences, Durham University, Durham, DH1 3LE, UK

1353. **Czachorowski, S.; Buczynski, P. (1999):** Biocenosis naturalness index - a prospective instrument in the evaluation of the ecological state of Polish peat-bogs, as exemplified by Odonata and Trichoptera. In: Radwana, S. & R. Kornijowa (Rds.): *Problemy aktywnej ochrony ekosystemów wodnych i torfowiskowych w Polskich Parkach Narodowych*. Wydawnictwo Uniwersytetu Marii Curie-Skłodowskiej. Lublin: 153-158. (in Polish with English summary. A German translation of the paper is available from the author or IDF). [Fischer's (1996) "biocenosis naturalness indexes" (Fischer, J.: *Beurteilungsverfahren zur Quellfauna*. *Crunoecia* 5: 227-240), in the modification of Czachorowski (1998), are proposed for assessing and biomonitoring peat-bogs. Index values for 26 Polish peat-bogs and fens in mountain and lowland ranges are calculated, analysed and discussed. In Tab. 1 the indices are developed on a cline of typical to a-typical species for each peat bog and fens. Some sphagnum peat-bog indexes calculated for dragonfly species are higher for fen species than for sphagnum peat-bog species. In the case of caddisflies some fens are characterised by a sphagnophilous fauna. These results are interpreted as follows: (1) The biotops are impacted by factors not yet visible. (2) Fen-fauna is very dispersive and able to settle in peat-bogs too, which may be suboptimal habitats (3) The classification of species based on their known habitat requirements is not precise yet. The "biocenosis naturalness indexes" are considered to be a good tool for assessment conservation priorities for the specific fauna of bogs.] Address: Buczynski, P., Dept of Zool., Marie Curie-Skłodowska University, Akademicka 19, PO-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

1354. **Czczuga, B.; Godlewska, A.; Mrozek, E. (1999):** Zoosporic fungi growing on dead dragonflies (Odonata). *International Journal of Odonatology* 2(2): 187-197. (in English). ["The mycoflora developing on dead specimens of 11 species of dragonfly, collected while floating on the water surface, was investigated under laboratory conditions. Sixty-six zoosporic fungus species were found to grow on the fragments of dragonfly investigated, including 15 Chytridiomycetes and 51 Oomycetes. Of these 66 species, 18 are known as parasites or necrotrophs of fish. Three fungus species were recorded for the first time from Poland." (Authors)] Address: Bazyli Czczuga, Anna Godlewska & Edyta Mrozek, Department of General Biology, Medical University, Kilinskiego 1, 15-230 Białystok 8, Poland. E-mail: Dzia/Nau@AMB.AC.Bialystok.PL

The authors suppose that the element "rom" of the name came from ronken (snoring). The element "bout" is explained as an expression of a metall pole or stick.] Address: Eigenhuis, K.J., Rietgorsstraat 1, NL 1431 VT Aalsmeer, The Netherlands

1361. **Englund, R.A. (1999):** The impacts of introduced poeciliid fish and Odonata on the endemic Megalagrion (Odonata) damselflies of Oahu Island, Hawaii. *Journal of Insect Conservation* 3(3): 225-243. (in English). ["Since the beginning of this century there have been substantial declines in the distribution and abundance of native Megalagrion damselies on the Hawaiian Island of Oahu. Native damselies have also vanished from most low elevation areas on other Hawaiian Islands, although historically, lotic and wetland dwelling damselfly species were once common throughout the archipelago. It is hypothesized that poeciliid fish introduced for biological control have caused the decline of four stream-breeding damselfly species on Oahu, and the extinction or near-extinction of two other species in Hawaii. This study documents the presence of remnant Megalagrion populations in Oahu streams, wetlands and estuaries, and records the elevational distributions of introduced sh in each waterbody surveyed. The distributions of introduced Odonata are also recorded, because the seven species of damselflies and dragonflies introduced to Oahu since 1936 present another potential threat to native Hawaiian damselies. Native damselfly and introduced poeciliid fish distributions were mutually exclusive on Oahu, and it is concluded that this is probably due to predation by the introduced fish. By contrast, even the rarest native Megalagrion damselflies were found in areas containing introduced damselflies and dragonflies." (Author)] Address: Englund, R.A., Natural Sciences Department, Bishop Museum, 1525 Bernice Street, Honolulu, HI, 96817 USA.

1362. **Ezenwaji, H. (1999):** The abundance and trophic biology of *Clarias albopunctatus* Nichols & La-Monte, 1953 (Osteichthyes: Clariidae) in a tropical floodriver basin. *Hydrobiologia* 392: 159-168. (in English). [The abundance, food and feeding biology of *Clarias albopunctatus* was studied over a period of 17 months in the lower River Anambra, Nigeria. Insects were the predominant food, followed by crustaceans. Of primary importance were Chironomidae (mainly *Chironomus* spp. and *Tanytus* sp.), Odonata nymphs, *Dytiscus* sp., mosquito larvae and pupae, *Gyrinus* sp., *Daphnia* sp., Ostracoda and *Tilapia fry*.] Address: Ezenwaji, H., Fisheries and Hydrobiology Research Unit, Department of Zoology, University of Nigeria, Nsukka Nigeria

(in German with short English summary). [First record of *S. arctica* in the Hunsrück mountains in Rheinland-Pfalz, Germany; the larva was collected (1997 and 1998) in a hollow of a

Sphagnum layer developend on a swampy trail.] Address: Fromhage, L., St. Sebastiansstr. 6, D-55128 Mainz, Germany

1364. **Gaino, E.; Rebor, M. (1999):** Larval antennal sensilla in water-living insects. *Microscopy research and technique* 47: 440-457. (in English). ["An overview of larval antennal sensilla in hemimetabolous and holometabolous water-living insects is given by updating current knowledge on the fine structure of these, sensory systems. In the absence of successful electrophysiological studies, the possible function of sensilla is deduced from their architecture. Various kinds of sensilla are described in hemimetabolous insects such as "Odonata (*Libellula depressa*) and "holometabolous insects [...]. Their possible function in responding to stimuli from the freshwater environment is illustrated and discussed. The importance of sensilla as taxonomic and phylogenetic traits is reported in Baetidae (Ephemeroptera) and in Diptera Nematocera. [...]. Particular features, such as cuticle without pores in chemosensory sensilla and naked perikarya, are so far found exclusively in some water-living arthropods, thus reflecting a possible adaptation to the aquatic habitat. The structure of sensilla and chloride cells, which have a similar external morphology, is presented and discussed in various insect groups, considering the possible derivation of the chloride cells from sensilla." (Authors)] Address: Gaino, El-da & Manuela Rebor, University of Perugia, Dipartimento di Biologia Animata ed Ecologia, Via Elce di Sotto, I-06123 Perugia, Italy. E-mail: gaino@unipg.it

1365. **Göcking, C. (1999):** Lebenszyklus von *Platycnemis pennipes* (Pallas) und *Calopteryx splendens* (Harris) in zwei Fließgewässern Brandenburgs (Zygoptera: Platycnemididae, Calopterygidae). *Libellula* 18 (3/4): 147-162. (in German with English summary). ["The larval development of both spp. was monitored in two different running waters in Brandenburg, Germany from Mai to September 1995. For *C. splendens* a two-year life cycle is suggested, *P. pennipes* seems to be univoltine." 1366. **Grandstaff, E.D.; Bulow, F.J (1999):** The claw sampler - A macroinvertebrate sampler for scuba divers. *North American Journal of Fisheries Management* 19(1): 219-220. (in English). ["A device is described that can be used by scuba divers to obtain quantitative macroinvertebrate samples from flat surfaces. Called the "claw sampler," it was designed to collect macroinvertebrates colonizing spawning benches in Tennessee reservoirs. The spawning benches, 3.0-m X 25-cm wood slabs attached to 30-cm concrete blocks, were used to simulate logs under which smallmouth bass *Micropterus dolomieu* spawn. The claw sampler effectively collected quantitative samples of coleopterans, dipterans, ephemeropterans, odonates, trichopterans, cladocerans, and gastropods that colonized the spawning benches and provided a readily available food supply for age-0 smallmouth bass other fishes." (Authors)] Address: not available

1367. **Groot, T. de; Wasscher, M. (1999):** Has *Leucorrhinia pectoralis* shifted its habitat in The Netherlands? *Brachytron* 3(2): 18-25. (in Dutch with English summary). ["At the moment *L. pectoralis* is a rare and declining species in the Netherlands. The species is listed as "threatened" in the Dutch Red List. During the

first half of the century large numbers were found in several kinds of habitats, such as marshland near rivers, and also coastal dune lakes. Usually these habitats were mesotrophic with a well-developed riparian vegetation. Nowadays there are two main habitats: small mesotrophic waters on sandy soils and peat marshes. Numbers on sandy soils have decreased dramatically and the species is now only recorded sporadically there. On the other hand, large numbers (up to 40 individuals on a 150 m stretch of ditch) have been found in De Wieden and Weerribben, two peat marsh areas in the northwestern part of the province of Overijssel, in the last few years. It is not clear whether these populations had been overlooked in the past, or whether this species has only recently developed higher numbers here. Currently, the region supports one of the largest populations in northwestern Europe." (Authors)] Address: Wasscher, M., Minstraat 15bis, NL-3582 CA Utrecht, The Netherlands, E-mail: m.wasscher@broekhuis.nl

1368. **Groot, T. de (1999):** The dragonflies of five peat mires. *Levende Natuur* 100(4): 112-117. (in Dutch). ["In The Netherlands the presence of dragonflies in five large peat mires of Natuurmonumenten has been studied. The study is focussed on characteristic peat mire species and one peat mire specialist and includes five species of the Red List. This paper deals with differences and similarities between the dragonfly populations in these five areas. All known peat mire dragonflies can be found in two of the areas (De Wieden and De Vechtplassen). Moreover large numbers of *Aeshna viridis* and *Leucorrhinia pectoralis* have been found in De Wieden. In great parts of Western-Europe six out of seven peat mire dragonflies are being threatened. This paper stresses the importance of the Dutch populations of these dragonflies and also their habitats in peat mires. Protection of habitats is needed, specifically for the threatened dragonflies which are dependant on certain stages of succession in peat mires. In order to start new succession of the vegetation new peat holes are being dugged the last few years. This can be of great importance for the dragonflies." (Author)] Address: Groot, T. de, Simon Bolivarstraat 89, NL 3573 ZK Utrecht, The Netherlands

1374. **Hilfert-Rüppel, D. (1999):** To stay or not to stay: decision-making during territorial behaviour of *Calopteryx haemorrhoidalis* and *Calopteryx splendens splendens* (Zygoptera: Calopterygidae). *International Journal of Odonatology* 2(2): 167-175. (in English). ["The effect of copulation and presence of predators on territorial behaviour of male *Calopteryx haemorrhoidalis* (in southern France) and of male *C. splendens splendens* (in northern Germany) was studied in nature. A male obtaining a copulation early in the day often secured more copulations later that day than did males not obtaining an early copulation. Predators such as Green frogs, *Rana esculenta*, and water spiders, *Dolomedes* sp., affected subsequent behaviour of male *Calopteryx* that they attacked but failed to catch. A male *C. haemorrhoidalis* that had only recently occupied a territory when attacked by a spider, vacated the territory immediately, whereas a male first attacked after having occupied a territory for more than three hours and that had already courted females there remained, while avoiding the predator's immediate location. Results are discussed in the context of the value of the territory as a resource."(Author)] Address: Hilfert-Rüppel D., Zool. Inst. TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: d.hilfert@tu-bs.de

1375. **Holusa, O. (1999):** The first record of *Orthemtrum coerulescens anceps* (Schneider, 1845) in Slovenia (Anisoptera: Libellulidae). *Exuviae* 5(1): 13-16. (in English with Slovene summary). [On 16-VII-1997 a tandem of the taxa was caught near the village of Boreci, NE Slovenia] Address: Holusa, O., Muzeum Beskyd, prirodovedné oddeleni, Zámecké náměstí 1264, CZ-738 01 Frydek-Místek. 1376. **Hong Sung-Jong; Woo Ho-Chun; Lee Soo-Ung; Huh Sun (1999):** Infection status of dragonflies with *Plagiorchis muris* metacercariae in Korea. *Korean Journal of Parasitology* 37(2): 65-70. (in English). ["*Plagiorchis muris* has been found in both house and field rats as well as in humans. The infection status of the second intermediate hosts of *P. muris* is prerequisite in understanding their biological features in an ecosystem. Six species of dragonflies were caught in a wide range of areas in Korea; and they were *Sympetrum darwinianum*, *S. eroticum*, *S. pedomontanum*, *S. infuscatum*,

Pantala flavescens, *Calopteryx atrata*, and *Orthetrum albistylum speciosum*. The occurrence of *P. muris* metacercariae in dragonflies was nationwide with various infection rates. The metacercarial burden of *P. muris* in the surveyed areas was the highest in *S. eroticum* followed by *S. darwinianum*, *S. pedomontanum*, and *C. atrata*. The highest infection rate by *P. muris* metacercariae was found in *S. darwinianum* followed by *S. eroticum*. The metacercarial burden was particularly heavy in the dragonflies found in Hamyang-gun and Kosong-gun, Kyongsangnam-do. It is, therefore, likely that dragonflies play a significant role as the second intermediate host in the life cycle of *P. muris* in Korea." (Authors)] Address: not available

1377. **Hooper, R.E.; Tsubaki, Y.; Siva-Jothy, M.T. (1999):** Expression of a costly, plastic secondary sexual trait is correlated with age and condition in a damselfly with two male morphs. *Physiological Entomology* 24(4): 364-369. (in English). ["Males of the damselfly *Mnais costalis* Selys [...] are morphologically and behaviourally polymorphic, typically existing as clear-winged non-territorial 'sneaks' and orange-winged territorial 'fighters'. The amount of orange pigment in the wing, as measured with a chromameter, varied between individuals, and decreased as the reproductive season progressed. Young individuals maintained in the laboratory on high or low nutrient diets differed in the amount of pigment that developed in the wing. Males in the high nutrient group developed darker wings faster than those in the low nutrient group. Young adults of both sexes and morphs were fed ¹⁴C-radiolabelled tryptophan or tyrosine (precursors of the pigments ommochrome and melanin, respectively). Ommochrome was restricted to the pseudoptero stigma of the males of both morphs and was not present in females. The presence of tyrosine in the wing cells of orange males, but not of clear males, indicated that the orange pigment is at least partly constituted from melanin. These data show that at least some pigment levels must be maintained continuously in the wings of orange males, and that maintenance is costly as it is compromised at low nutrient levels." (1999):** Massenentwicklung von *Sympetrum fonscolombii* (Selys) und Entwicklungsnachweis von *Anax ephippiger* (Burmeister) in Überschwemmungsflächen am südlichen Oberrhein (Anisoptera: Libellulidae, Aeshnidae). *Libellula* 18(3/4): 189-195. (in German with English summary). ["In 1999, *Sympetrum fonscolombii* emerged in four and *Anax ephippiger* in two gravel pits. In one area that was inundated for 10 to 12 weeks between middle of May and end of July 1999, a mass reproduction with several 100,000 individuals of *S. fonscolombii* occurred. In years without exceptionally high and prolonged ground water level, this area is completely dry. It was observed that larvae of *S. fonscolombii* are able to survive for at least two weeks after their larval habitat has dried up. In the

dried up. In the same area, a summer generation of *Ischnura pumilio* developed successfully." (Authors)] Address: Hunger, H., Institut für Naturschutz und Landschaftsanalyse (INULA), Am Pfahlgraben 8, D-79276 Reute, Germany

1380. **Jacquemin, G.; Boudot, J.-P. (1999):** Les libellules (Odonates) du Maroc. Société Française d'Odonatologie. ISBN 2-9507291-3-4: 150 pp. (in French with English summary). ["This work synthesise all the available faunistic data already published, dealing with Moroccan Damselflies and Dragonflies, and adds a lot of new unpublished data. It can be used within the limits of Morocco, Algeria and Tunisia, and is the first modern book dealing with the Odonata of the Maghreb. A general part gives the most useful informations about the past faunistic research in Morocco and on the biology and ecology of the Dragonflies in the Maghreb. A detailed and illustrated key allows the identification of all species of Odonata known from Morocco, Algeria and Tunisia. A commented list provides for each Moroccan Dragonfly: its local status, the previously and newly known localities where it has been observed, the most useful information on its distribution (including a map), as well as biological and ecological notes (particularly the flight period), and, when necessary, a taxonomic discussion. Chorological considerations and a discussion on nature preservation are also approached. A detailed bibliographic section with more than 150 references ends the text part of this book. A number of high quality colour photographic plates illustrate the most representative habitats and all species of dragonflies living in Morocco (males and many of the females). The plates are complemented by pterographies showing the precise wing venation of each species." (taken from the announcing leaflet)] Address: Jacquemin, G., Biologie des Insectes, Université H. Poincaré, Nancy 1, BP 239, F-54506 Vandoeuvre-lès-Nancy, France

1383. **Jong, T.H. de (1999):** *Aeshna viridis* in the province of Utrecht (NL). *Brachytron* 3(2): 11-17. (in Dutch with English summary). ["In 1998 localities with *Stratiotes aloides* (mostly ditches in agricultural land) in the province of Utrecht were surveyed for *A. viridis*. The species was found at 29 of the 56 visited sites. Oviposi-

tion was recorded at nineteen locations. The total number of individuals seen was 75. The maximum number of specimens found at a single locality was eleven. Vegetations with *A. viridis* were on average more extensive, the water was deeper and the cover of *Azolla filiculoides*, *Elodea nutallii* and green algae was less. Homogeneous *Stratiotes* vegetations with a surface of 400 m² or more and only a slight cover of *Lemna spec.*, *Azolla filiculoides* and *Etoda nutallii*, were preferred for oviposition. At such sites, the density of *Stratiotes* is about 20 plants per m² with leaves protruding at least 15 cm above the water surface. It was observed that females oviposit in all accessible leaves of a single plant before moving on to another plant. They seemed to prefer plants with withered, brown leaf tips. It is suggested that such plants have narrower leaves, which makes them easier to grasp for the female. Besides *A. viridis* twelve other species of Odonata were seen at the *Stratiotes* vegetations. *Lestes sponsa* and *Coenagrion pulchellum* appear to show a similar habitat preference to *A. viridis*. In contrast however *Erythromma viridulum* and *Orthetrum cancellatum* seem to avoid such localities. Although the leaves of *Stratiotes* are thought to protect the larvae against predators, fish larger than 10 cm were often found in open spots in the vegetations and fish smaller than 10 cm were even seen between the plants." 1386. **Kern, D. (1999):** Langzeituntersuchungen zur Populationsentwicklung und zum Lebenszyklus von *Gomphus vulgatissimus* (Linnaeus) an einem nordwestdeutschen Fließgewässer (Anisoptera: Gomphidae). *Libellula* 18(3/4): 107-132. (in German with English summary). ["From 1989 to 1999 larvae were collected in a draining ditch in the Kreis Diepholz (Germany) and quantitative investigations of emergence were made. Based on biometric data of more than 8000 larvae, a three to four years development is suggested. The annual collections of exuviae featured an average emergence periode of 21 days and an EM50 of 6-7 days. A mean of 467 exuviae per year was collected in a 800 m section. Generally, the females were predominant with a mean of 52.7 %. The time of emergence seemed to be dependent on the actual lowest and highest daily water temperature. Some aspects of the larval development and the emergence are discussed in comparison to the results on *G. vulgatissimus* from the large ri-

ver Oder." (Author)] Address: Kern, D., Taxusweg 2, D-27232 Sulingen, Germany

1387. **Kido, M.H.; Heacock, D.E.; Asquith, A. (1999):** Alien rainbow trout (*Oncorhynchus mykiss*) (Salmoniformes: Salmonidae) diet in Hawaiian streams. *Pacific Science* 53(3): 242-251. (in English). ["Diet of rainbow trout, *Oncorhynchus mykiss* (Walbaum), introduced by the State of Hawai'i into tropical headwater streams of the Waimea River in the Koke'e area of the Hawaiian island of Kaua'i, was examined in this study through gut content analysis. In Wai'alae Stream, rainbow trout were found to be opportunistic general predators efficient at feeding on invertebrate drift. Foods eaten ranged from juvenile trout, to terrestrial and aquatic arthropods, to algae and aquatic mosses. Native aquatic species, particularly dragonfly (*Anax strennus*) and damselfly (*Megalagrion heterogamias*) naiads, lymnaeid snails (*Erinna aulacospira*), and atyid shrimp (*Atyoida bisulcata*), were determined to be major foods for alien trout. Terrestrial invertebrates (primarily arthropods), however, provided a substantial (albeit unpredictable) additional food supply. Based on results of the study, it is cautioned that large numbers of rainbow trout indiscriminantly released into lower- to middle-elevation reaches of Hawaiian streams could do substantial damage to populations of native aquatic species through predation, competition, and/or habitat alteration." 1392. **Laurila, A.; Kujasalo, J. (1999):** Habitat duration, predation risk and phenotypic plasticity in common frog (*Rana temporaria*) tadpoles. *Journal of Animal Ecology* 68(6): 1123-1132. (in English). [1. Common frogs (*Rana temporaria*) breed readily in small pools and thus expose their offspring to catastrophic mortality by desiccation. Amphibian larvae exhibit considerable phenotypic plasticity in metamorphic traits, and some species respond to environmental uncertainty by metamorphosing earlier and at smaller size. In a factorial laboratory experiment, we studied whether common frog tadpoles possess this ability. 2. We also studied the interaction between pool drying and predation risk, because in a previous study the presence of a predatory dragonfly larva delayed metamorphosis of the tadpoles. 3. We gradually removed water from half the experimental containers, while in the other half the water volume was kept constant. In the laboratory it was possible to remove the effect of increased water temperature in the decreasing volume treatment by using fluorescent lights. Tadpoles responded to decreasing volume by metamorphosing earlier and at smaller size. A greater proportion of the tadpoles metamorphosed in the decreasing volume treatment. 4. Tadpoles were less active at decreasing water level and there were significant positive correlations between activity late in the experiment and metamorphic size. This suggests that the metamorphic response to habitat drying is behaviourally mediated. 6. Early in the experiment, tadpoles developed slower in the presence of predators. At metamorphosis presence of a dragonfly larva had no effect in the whole data set, but when the constant volume treatment was analysed separately, larval period was longer in the presence of a predator. 7. Our results indicate that common frog larvae are able to respond to pond-drying adaptively by speeding up their development, and that temperature advantage is not needed to induce this adaptive plasticity. Furthermore, pond-drying seems to be a more important determinant of development rate than the presence of odonate predators." 1393. **Logan, J.A. (1999):** Extraction, polymerase chain reaction, and sequencing of a 440 base pair region of the mitochondrial cytochrome oxidase I gene from two species of acetone-preserved damselflies (Odonata: Coenagrionidae, Agrionidae). *Environmental Entomology* 28(2): 143-147. (in English). ["Preserved insects are an important data for many molecular systematics projects. This study investigates the use of acetone-preserved specimens in molecular DNA research. Two species of damselflies, *Enallagma civile* (Hagen) and *Hetaerina americana* (F.), were soaked in acetone before drying. Total genomic DNA was successfully extracted, amplified, and sequenced from the acetone-preserved damselflies with no noticeable effect from either the acetone or preservation time. Nucleotide sequences of a 440 bp region of the mitochondrial cytochrome oxidase I gene are presented for *E. civile* and *H. americana*. These 2 species have reached a saturated divergence level and it seems that the COI gene will not be useful for developing phylogenies at this taxonomic level." (Author)] Address: not available

1399. **Mochizuki, H.; Morita, M.; Masuda, K; Kusamichi, I. (1999):** Flow mechanism around a dragonfly. *Memoirs of the Faculty of Agriculture Kagoshima University*. 35(43): 17-24. ["The flapping of the wing of the dragonfly and the flow generated by the flapping at full speed were observed by the high-speed video camera and the film camera. As the result, the relation between the movement of the wing and the flow was analyzed and clarified. The wings of the dragonfly move one cycle drawing a letter of "8" from the beginning of the downstroke to the end of the upstroke. Moreover, the gradient of the downstroke becomes larger than that of the upstroke, fetching larger velocity of the wing tip for the downstroke in comparison with the upstroke. The wakes generated by such flappings let their flow states the horizontal-, downward- and upward downstream directions depending on the horizontal-, upward- and downward flights. Almost all the amount of the air which enters into the region around the body and the wing is sucked from the upper side of the wing to compensate the air which has been exhausted by flapping. The edge of the wake generated by the flapping proceeds more downstream at faster velocity than that of the uniform flow. In this way, it can be confirmed that the thrust and the lift are generated by the flappings of the wings." (Authors)] Address: Masuda, K., Lab. Agric. Phys., Fac. Agric., Kagoshima Univ., Kagoshima, Japan

1400. **Mogi, M.; Sunahara, T.; Selomo, M. (1999):** Mosquito and aquatic predator communities in ground pools on lands deforested for rice field development in Central Sulawesi, Indonesia. *Journal of the American Mosquito Control Association*. 15(2): 92-97. (in English). [study area: Toili, Kabupaten Luwu-Banggai, eastern peninsula of Central Sulawesi; "Aquatic habitats, mosquitoes, and larvivorous predators were studied on deforested lands in Central Sulawesi, Indonesia. Open ground pools, mainly in depressions made by the treads of bulldozers and other heavy equipment, were numerous but because of their small size, comprised ca. 1% or less of the total area of the deforested

lands studied. The dominant mosquitoes in these pools were *Anopheles vagus*, *Culex vishnui*, *Culex tritaeniorhynchus*, and *Culex gelidus*. The 1st 2 species were dominant in clear pools, whereas the latter 2 species were dominant in turbid pools. The dominant metazoans other than mosquitoes were Crustacea, Ephemeroptera, and Chironomidae. Both aquatic and surface predators were abundant. Dominant among aquatic predators were Anisoptera and Zygoptera nymphs, Dytiscidae, and Notonectidae. These results are discussed in relation to mosquito control on deforested lands that transitionally but inevitably appear during the course of rice field development projects in Indonesia." 1408. **Nelson, B. (1999):** The status and habitat of the Irish damselfly *Coenagrion lunulatum* (Charpentier) (Odonata) in Northern Ireland. *Entomologist's Monthly Magazine* 135: 59-68. (in English). ["The N. Ireland population of *Coenagrion lunulatum* was surveyed in 1996. The main findings were: 1, the species was thought to be present at 23 sites in N. Ireland. Of these only 17 can now be regarded as definite. Albeit that 6 colonies were presumed on insubstantial evidence, 6 have disappeared. In other words a quarter of the known UK colonies have disappeared. 2, the size of individual colonies is smaller than previously suggested; only two colonies support large numbers. 3, the colonies are found on mesotrophic lakes and large bog pools. Habitat change caused by eutrophication is seen as the major threat to the species." (Author)] Address: Nelson, B.; Zoology Department, Ulster Museum, Botanic Gardens, Belfast, BT9 5AB, UK

1409. **Nessimian, J.L.; Sanseverino, A.M.; Oliveira, A.L.H. de (1999):** Trophic relationships of Chironomidae larvae (Diptera) and its importance on the food-webs in a sand dune marsh on the littoral of Rio de Janeiro State. *Revista Brasileira de Entomologia* 43(1-2): 47-53. (in Portuguese). ["A Food web study was carried out, based on direct observations and gut content analysis of macroinvertebrates sampled from Jan. 1987 to Feb. 1988, in Brejo-canal de Itaipuacu marsh, Marica, whose structure and composition have changed seasonally. Chironomid larvae and microcrustaceans were

the main taxa among the macroinvertebrates, being keystone prey groups in the trophic system. [...] The whole group showed an approximated mean of 14 trophic links per species against the medium value of 9 links per species for all macroinvertebrates sampled. The main alimentary items observed for chironomid larvae were chlorophytes, desmids diatoms, cladocerans, copepods, oligochaetes and chironomid larvae, besides poriferans, mites and vegetal fibers. On the other hand, chironomid larvae were constant items in Odonata, Hemiptera and Coleoptera diets. The variation in the number of interactions was due to the water column, the macrophyte and algae life cycles. Spring and summer observations showed the biggest number of links. The consequent changes in the availability of alimentary items was reflected, at least relatively, on the diversity of chironomid diet." (Authors)] Address: Nessimian, J. L. , Departamento de Zoologia, Instituto de Biologia, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brazil

1410. **Palmer, M.A. (1999):** The application of biogeographical zonation and biodiversity assessment to the conservation of freshwater habitats in Great Britain. *Aquatic Conservation: Marine and freshwater ecosystems* 9(2): 179-208. (in English). ["1. Twelve biogeographical zones for freshwater habitats in Great Britain were derived, using detrended canonical correspondence analysis of data on climate, relief, geology, soils and land use, in conjunction with occurrence data for more than 300 native freshwater species. 2. The taxonomic groups used were aquatic macrophytes, dragonflies (Tab. 6), freshwater molluscs, amphibians and selected leeches, water beetles and crustaceans. The computer database of the Institute of Terrestrial Ecology's Biological Records Centre was used as the principal of species data. 3. Within each of the 12 biogeographical zones, 10 X 10 km square 'hotspots' for species richness and rarity were identified. 4. The significance of this work for the conservation of freshwater habitats and species in Great Britain is discussed." (Author)] Address: Palmer, Margaret, Apple Barn Cottage, Fotheringhay, Peterborough, PE8 5JB, UK.

1411. **Paoletti, M.G.; Dunxiao, H.; Patrik, M.; Ningxing, H.; Wenliang, W.; Chunru, H.; Jiahai, H.; Liwan, C. (1999):** Arthropods as bioindicators in agroecosystems of Jiang Han Plain, Qianjiang City, Hubei China. *Critical Reviews in Plant Sciences*. 18(3): 457-465. (in English). [Arthropods on the soil surface and on vegetation were periodically surveyed in two villages on the Jiang Han Plain from April to September 1994. Odonata are mentioned in Tab. 4 without further discussion.] Address: Hu Dunxiao, China Agricultural University, Beijing, P.R. China

1412. **Parker, A.R. (1999):** Reflected glory: the key to insect colours. *Biologist* 46(5): 206-210. (in English). ["There are basically three categories of structures that cause colour in insects: (i) elements which cause scattering, (ii) diffraction gratings and (iii) single- and multi-layer reflectors. The last two mechanisms cause specular (directional) reflections, and therefore often appear relatively bright and 'metallic', whereas the first provides on omnidirectional reflectance. Generally within all of the categories, only transparent materials are involved in producing colour. [...] Scattering - blue: [...] A gradation from blue to white scattering ('small' to 'large' particles) occurs on the wings of the dragonfly *Libellula pulchella* (Mason, 1926). Blues resulting from this 'Ray-

leigh' scattering can also be found in other dragonflies and damselflies [...] In some, the epidermal cells contain minute colourless granules, which scatter the short wavelengths, and a dark base. These granules are absent in the females of the species. The males of some other species produce a waxy secretion that scatters light over their dark cuticle. The green of the female *Aeshna cyanea* is the combined result of Rayleigh scattering and a yellow pigment, both within the epidermal cells (degradation of the yellow pigment turns a dead dragonfly blue) [...] (Fox and Vevers, 1960)." (Author)] Address: Parker, A., Dept Zoology, University of Oxford, South Parks Road, Oxford OX1 3PS, UK

1413. **Petrulevicius, J.F. (1999):** Cenozoic insects from Argentina. *Revista de la Sociedad Entomologica Argentina* 58(1-2): 95-103. (in Spanish with English summary). ["A review of the information about cenozoic insects is presented. Paleogene insects are mentioned from different regions and formations. The *Siricinae Urocerus patagonicus* Fidalgo & Smith, 1987 is the unique nominated species from Laguna del Hunco Formation (Paleocene-Eocene; Chubut Province). This subfamily has at present a North Hemisphere distribution. The *Formicidae Polanskiella smekali* Rossi de Garcia, 1983 and the *Myrmecinae Ameghinoia piatnitzkyi* Viana & Haedo Rossi, 1957 are the two nominated species from Ventana Formation (Eocene-early Oligocene; Chubut Province), together with other (aquatic and terrestrial) insects. The *Myrmecinae* have at present an Australian distribution. Insects (*Curculionoidea*, *Elate-roidea* and *Formicidae*) are cited for the first time from Canadon Hondo Formation (Eocene; Chubut Province), as well as isolated elitra of *Coleoptera* from Olmedo Formation (lower Paleocene; Jujuy Province). Maiz Gordo Formation (upper Paleocene; northwestern Argentina) provided 37 species of *Orthoptera*, *Dermaptera*, *Hemiptera* (*Homoptera* and *Heteroptera*), *Trichoptera* and *Coleoptera*. Since 1993, new findings were carried out by the author in these insect layers. Thus far, representatives of six orders and several families have been found, including *Blattaria*, *Odonata*, *Mecoptera*, *Neuroptera*, *Diptera*, *Hymenoptera*, *Tettigoniidae* and *Lygaeidae*. Isolated tegmina of *Grylloidea* and elitra of *Coleoptera* (*Curculionoidea*) are known from *Lumbrera* Formation (lower Eocene; northwestern Argentina). Pleistocene insects are cited from two outcrops in Buenos Aires Province: puparia moulds of *Calliphoridae* in association with an articulated skeleton of *Carnivora* from the "Ensenadense", and an insect assemblage from Santa Clara Formation. The migratory subspecies *Schistocerca cancellata paranensis* (Burmeister, 1861) was found in an archaeological Holocene site in Tucuman Province." (Author)] Address: Petrulevicius, JF; Museo La Plata; Dept Cient Paleozool Invertebrados; Paseo Bosque S-N; RA-1900 La Plata; Argentina. E-mail: levicius@netverk.com.ar

1414. **Pirnat, A. (1999):** Study of emergence in *Pyrrosoma nymphula* (Sulzer) (*Zygoptera*: *Coenagrionidae*). *Exuviae* 5(1): 6-12. (in English with Slovene summary). ["From 21-IV to 12-V-1994 the emergence of *Pyrrosoma nymphula* was studied at a small forest pond in Ljubljana, central Slovenia. A total of 798 exuviae were collected and the daily emergence rate, synchronization of emergence and sex ratio were studied. A short note on mortality and predation [by Spiders, ants, lizards, and birds] during emergence is also appended." (Author)] Address: Pirnat, Alja, Biological Insti-

tute ZRC SAZU, Novi trg 5, SI-1000 Ljubljana, Slovenia. E-mail: alja.pirnat@guest.arnes.si

1415. **Polyanovskii, A.D. (1999):** Phototransduction in insects: Two strategies for calcium homeostasis? *Sensory Systems* 12(3): 181-187. (in English). [This is the English version of the paper abstracted as OAS 1306] Address: Polyanovskii, A.D., I. M. Sechenov Institute of Evolutionary Physiology and Biochemistry, Russian Academy of Sciences, 44 M Torez Prospekt, 194223 St. Petersburg

1416. **Reinhardt, K. (1999):** The reproductive activity of two *Pseudagrion* species in the same habitat (*Odonata*: *Coenagrionidae*). *African Entomology* 7(2): 225-232. (in English). ["The reproductive activity of two closely related species, *Pseudagrion massaicum* Sjöstedt and *P. salisburyense* Ris was examined relative to environmental factors. The abundance of both species was positively correlated, suggesting a weak influence of interspecific competition. The most important abiotic factor influencing the activity of the two species was cloud cover. Males of the two species showed a strong spatial separation in perching position relative to vegetation type, perch height and distance to the banks. The proportion of males actively engaged in reproduction rose significantly with time of day but was independent of total male density and the relative importance of either patrolling or perching behaviour. Males of both species were found to be non-territorial, which is exceptional for the genus *Pseudagrion*. This is discussed relative to high territory retention costs at high dragonfly densities." (Author)] Address: Reinhardt, K., Hauptstr. 38, D-09244 Oberlichtenau, Germany. E-mail: b5klre@pluto.rz.uni-jena.de

1417. **Reinhardt, K.; Kempke, D. (1999):** Thoracic temperatures in four libellulid dragonflies (*Anisoptera*: *Libellulidae*). *Notul. odonatol.* 5(4): 41-43. (in English). ["The thoracic temperatures in *Orthetrum cf. caffrum*, *Trithemis arteriosa*, *T. dorsalis* and *Palpopleura lucia* were measured in the field. All spp. belong to the percher type. Their thoracic temperatures were between 0.7 and 10.5°C above ambient temperature. The pale blue *O. cf. caffrum* had a higher body temperature than the dark blue *T. dorsalis*. The thorax temperature was positively correlated to abdomen length but not forewing length between species with a similar trend within *T. dorsalis*." 1419. **Rolff, J. (1999):** Parasitism increases offspring size in a damselfly: Experimental evidence for parasite-mediated maternal effects. *Animal Behaviour* 58(5): 1105-1108. (in English). ["The effects of parasites on host fitness and the fitness effects of maternal effects are widely discussed. In this study, I conducted an experiment linking both aspects. I manipulated the ectoparasite load (*Acari*: *Arrenurus cuspidator*) of damselflies, *Coenagrion puella*, and found that larvae from mothers with high parasite loads were larger (assessed by head width) than larvae from mothers with low parasite loads. Furthermore, there was a negative correlati-

on between the number of eggs laid and parasite load. Parasitized mothers thus seemed to have fewer, but probably better, offspring. The ecological significance of these parasite-mediated maternal effects remains to be tested. However, size-dependent cannibalism almost certainly has important consequences for population dynamics." 1423. **Sahlén, G. (1999):** The impact of forestry on dragonfly diversity in central Sweden. *International Journal of Odonatology* 2(2): 177-186. (in English). ["A survey of 32 lakes for dragonfly larvae, aquatic plants and forestry regime in the surrounding boreal forests was performed. The highest diversity was found in undisturbed forests. Lakes rich in aquatic plants were shown also to be rich in dragonflies. A rich plant community is proposed to provide a wider range of microhabitats thereby increasing dragonfly biodiversity. If the forest surrounding a lake has been logged, a decrease in the species-richness of dragonflies with partivoltine life-cycles can be observed after a 5 year "lag phase." Increased fluctuations in water temperature and leakage of nutrients into the water are two possible causes. Univoltine species are not affected and appear to be less dependent on constant water conditions. The water plant community is only moderately affected, but a slight decrease in the number of species can be observed. A return to more species-rich conditions can be observed after more than 15 years, but whether the original community is restored or replaced with more "trivial" species is an open question." (Author)] Address: Sahlén, G., Systematic Zoology, Evolutionary Biology Centre, Uppsala University, Norbyvägen 18D, S-752 36 Uppsala, Sweden. E-mail: goran.sahlen@zoologi.uu.se

Premier bilan des observations" (*Martinia*, 15 (1): 22). *Martinia* 15(4): 121-123. (in French with English summary). ["The authors rectify the check-list reported by Bouguessa et al., in a short note (*Martinia*, 15(1): 22). Out of the nine listed species, only two, *Cercion lindenii* and *Coenagrion mercuriale*, may have been correctly identified. The present communication provides a list of the Zygoptera recorded so far, in Oued Meskiana and the surroundings."] Address: Samraoui, B., Laboratoire de Recherche des Zones Humides, 4, rue Hassi-BeTda, Annaba, Algeria; Jödicke, R., Grossenging 14, D-49699 Lindern, Germany

1426. **Sanders, M.D. (1999):** Common aquatic invertebrate taxa vary in susceptibility to capture by Black Stilt chicks. *Notornis* 46(2): 311-318. (in English). ["I tested the ability of captive Black Stilt chicks (*Himantopus novaezelandiae*) to capture and consume common aquatic invertebrates. Waterboatmen (*Sigara* sp.), segmented worms (*Oligochaeta*), and larvae of a damselfly (*Xanthocnemis zealandica*), midge (*Chironomus zealandicus*), mayfly (*Deleatidium* spp.), and caddisfly (*Aoteapsyche colonica*) were captured and consumed quickly and easily by chicks of all ages (2 - 30 days). They were also consumed in the greatest contrast, two aquatic snails (*Physa acuta* and *Lymnaea tomentosa*), and larvae of two cased caddisflies (*Triplectides* sp. and *Hudsonema amabilis*) were captured and consumed with difficulty and in low numbers by young chicks (< 7 days). Young chicks appeared to take longer than older chicks to capture prey, to spend more time manipulating prey in their bills before swallowing, and to drop prey frequently. In contrast, 21 - 30 day old chicks appeared to capture, manipulate and swallow most types of prey efficiently and quickly. These results augmented biomass as a measure of the value of aquatic invertebrate food supplies in wetlands." (Author). Most *Xanthocnemis zealandica* were consumed in most trials, and it was pecked at more rapidly than oligochaetes, molluscs and cased caddisflies. "Larvae of *X. zealandica* struggled vigorously when captured, and were sometimes able to escape from 2-3 day old chicks, by 'flicking' their abdomens while the chicks were manipulating them in their bills. [...] *X. zealandica* is likely to be easily captured and consumed in the wild, as it was in the experiment." (Author)] Address: Sanders, M., Department of Conservation, Private Bag, Twizel, New Zealand

1427. **Sandhu, R.; Walia, G.K. (1999):** Karyology of male and female *Pseudoagrion rubriceps* (Zygoptera : Coenagrionidae). *Bionature* 19(1): 1-5. (in English). ["Chromosomal analysis has been carried out on male and female individuals of *Pseudoagrion rubriceps* collected from the states of Jammu and Kashmir, Punjab, Assam and Meghalaya in India. Majority of mitotic and meiotic stages possess the diploid numbers 27 in males and 28 in females with XO - XX sex determining me-

chanism. The autosomes include a tiny pair of m chromosome in both sexes. Numerous plates showing autosomal fragmentations in different meiotic stages of the same individual have been observed. In these, diploid numbers vary from 27 to more than 45. Female karyotype and autosomal fragmentations have been reported for the first time in this damselfly." (Authors)] Address: Sandhu, R., Dep. Zool., Punjabi Univ., Patiala-147 002, Punjab, India

1428. **Sawada, K. (1999):** Female sexual receptivity and male copula guarding during prolonged copulations in the damselfly *Ischnura senegalensis* (Odonata: Coenagrionidae). *Journal of Ethology* 17(1): 25-31. (in English). ["Laboratory experiments were conducted to clarify the relationship between female sexual receptivity and male copula guarding in *I. senegalensis*, a species that copulates for several hours. In insectaries, most copulations were initiated early in the morning, and terminated relatively synchronously between 11 00 and 13 00. Females refused males with wing-flutter display and oviposited alone in the afternoon regardless of copulation events of that morning. Females could sexually receive males only in the morning. Males copulated for several hours until 12 00 after which females could oviposit. To determine whether copulations that last for hours function as male copula guarding or only of sperm displacement, emerged males were kept at various densities and permitted to copulate with virgin and mated females in insectaries. Both with virgin and mated females, "social" (not solitary; 2-4 males / insectary) males initiated copulations early in the morning and always terminated at around 12 00. However, both with virgin and mated females, solitary (one male / insectary) males terminated copulations in the morning. In both cases, duration of copulations did not significantly differ for virgin females and mated females. Therefore, long (several hour) copulation is more likely to function as male copula guarding than as sperm displacement, and duration of copulations is predicted to be shortened when male density is very low." (Author)] Address: Sawada, K., Kashii High School, 2-9-1, Kashii, Higashi-ku, Fukuoka, 813-0011, Japan

1429. **Schiel, F.-J.; Rademacher, M. (1999):** Wiederfunde von *Gomphus flavipes* (Charpentier) am Oberrhein in Baden-Württemberg (Anisoptera: Gomphidae). *Libellula* 18(3/4): 181-185. (in German with English summary). ["As a result of a systematic survey between 20 and 29-VII-1999, two exuviae of *G. flavipes* were found at two sites at the Upper Rhine south of Karlsruhe and south of Kehl, respectively. The habitat is briefly described and the circumstances of the records are shortly discussed. Remarkable is the record of one exuviae of *Ophiogomphus cecilia* at the main course of the Upper Rhine north of Karlsruhe." 1433. **Shieh, Sen-Her; Yang, Ping-Shih (1999):** Colonization patterns of aquatic insects on artificial substrates in a Taiwan stream. *Zhonghua Kunchong* 19(1): 27-50. (in English). ["Experiments on colonization patterns of artificial substrates by aquatic insects were conducted in the upper Chingmei Stream, Taiwan. Artificial substrates were colonized by aquatic insects for periods of 3, 6, 12, 21, 30, and 42 days from 15 Dec. 1990 to 26 Jan. 1991 at 2 sites: a polluted site caused by coal mining activities (Site 1) and a recovery site further downstream of the polluted site (Site 2). Total numbers of individuals and taxa were significantly affected by exposure period of experimental substrates and sites, indicating the occurrence of succession and the detrimental effect of coal mining activities on aquatic insect communities. At Site 1, only *Caenis* sp., *Euphaea* sp., and Chironomidae occurred on all sampling dates and were abundant. The other taxa may have just continued to drift away from the site. The chironomid larvae were most abundant. They accounted for over 90% of the colonizing individuals from day 12 to day 42. At Site 2, *Baetis* spp. and Chironomidae were most abundant. They accounted for over 80% of individuals during the experiment, except on day 21. The relative abundance shifted from *Baetis* spp. to Chironomidae with an increase in colonization time. A large number of positive correlation was found within the functional groups of filter-feeders and predators at Site 2. Taxa within the two groups tended to overlap in their distribution among baskets. The lognormal distribution was a better fit at Site 1 than at Site 2, suggesting that it is easier for a community to attain a state of equilibrium in a stressed environment than in a less-polluted environment. Mechanisms determining the colonization patterns of aquatic insects were reflected by the susceptibility of organisms to mining activities at Site 1, and the influence of biological interactions and disturbance caused by high discharges at Site 2 during the experimental period." (Authors)] Address: Shieh, Sen-Her, department of Entomology, National Taiwan University, Taipei, 106, Taiwan

1434. **Southcott, R.V. (1999):** Larvae of *Leptus* (Acarina: Erythraeidae), free-living or ectoparasitic on arachnids and lower insects of Australia and Papua New Guinea with descriptions of reared post-larval instars. *Zoological Journal of the Linnean Society* 127(2): 113-276. (in English). [*Leptus* larvae (Acarina: Erythraeidae) of Australia and New Guinea, collected either free-living or ectoparasitic on Arachnida or lower Insecta, are comprehensively reviewed. For Australia new species are described from Scorpionida: 8, from Araneae:1, from Insecta (Archaeognatha: 1, Blattodea: 1, Phasmatodea: 1, Orthoptera, Acridoidea: 7, Hemiptera: 5), and free-living only: 2. From Papua New Guinea new species are described parasiting on Acridoidea: 1, Orthoptera: 1, and free-living: 3. Additional host and other records are given for previously described species, originally described as ectoparasites of Insecta (from Australia) and from Papua New Guinea including *L. draco* Southcott (Odonata, Acridoidea, Tettigoniodea, Phasmatodea, Hemiptera).] Address: Southcott, R.V., 2 Taylors Road, Mitcham, SA, 5062 Australia.

1435. **Sovinc, A. (1999):** Restoration ecology. *Proteus, Ljubljana* 62(4): 152-160. (in Slovene with English summary). ["Restoration Ecology is an emerging profession within the Ecology; it is an attempt to reverse the human induced ecological changes and to stimulate the natural or semi-natural processes in habitats, ecosystems, and landscapes. The article discusses different terms in the restoration processes, such as habitat rehabilitation, reconstruction, enhancement, re-creation, transplantation and creation, mitigation, and others, and provides a set of basic considerations when planning and implementing restoration measures. These include: a) the line up to which nature should be 'helped' has to be carefully considered; restoration should, in principle, only encourage, accelerate, allow or imitate natural processes; b) nature restoration projects should never be undertaken in indigenous areas with a high conservation or biodiversity value; c) nature restoration projects should never be used to justify environmentally damaging developments. Examples of already implemented wetland restoration projects include the creation of substitute habitats along the Ljubljanica river during the construction of a new motorway, including habitat creation for amphibians, the construction of small ponds, revitalisation of oxbows and floodplains. Other examples include the creation of wetland habitats during the dredging of the Zbilje reservoir, the construction of a pond at Trzin and a restoration of a section of the Bicje river near Grosuplje." (Author). *Orthetrum brunneum* is the single odonate species mentioned in the article.] Address: Sovinc, A., Pod Kostanji 44, SI-1000 Ljubljana, Slovenia

1436. **Stav, G.; Blaustein, L.; Margalith, J. (1999):** Experimental evidence for predation risk sensitive oviposition by a mosquito, *Culiseta longiareolata*. *Ecological Entomology* 24(2): 202-207. (in English). ["1. Females should choose to oviposit in habitats where risk of predation and competition are low. The ovipositional responses of a mosquito, *Culiseta longiareolata*, to a predator and to species sharing the same trophic level as this mosquito (controphic species) were assessed experimentally in outdoor artificial pools. 2. The predator, larval *Anax imperator*, which strongly reduced larval *C. longiareolata* survival, resulted in a 52% reduction of *C. longiareolata* egg rafts. The controphic species (primarily *Daphnia magna*), which had a small but statisti-

cally significant negative effect on the survival of *C. longiareolata* larvae, did not have a statistically significant influence on the number of egg rafts. 3. Laboratory trials indicated that only a small fraction of the reduced number of egg rafts seen in predator pools may be due to consumption of the egg rafts by *A. imperator*. 4. The experimental evidence indicates that the reduced number of *C. longiareolata* egg rafts found in the presence of *A. imperator* is due largely to oviposition habitat selection, i.e. *C. longiareolata* females choose pools with low risk of predation for their offspring." 1439. **Stoks, R. (1999):** Autotomy shapes the trade-off between seeking cover and foraging in larval damselflies. *Behavioral Ecology and Sociobiology* 47(1/2): 70-75. (in English). ["Animals commonly choose between microhabitats that differ in foraging return and mortality hazard. I studied the influence of autotomy, the amputation of a body part, on the way larvae of the damselfly *Lestes sponsa* deal with the trade-off between foraging or seeking cover. Survival of *Lestes* larvae when confronted with the odonate predator *Aeshna cyanea* was higher in a complex than in a simple microhabitat, indicating that this more complex microhabitat was safer. Within the simple microhabitat, larvae without lamellae had a higher risk for mortality by predation than larvae with lamellae, showing a long-term cost of autotomy. When varying the foraging value (food present or absent) and predation risk (encaged predator or no predator) in the simple microhabitat, larvae with and without lamellae responded differentially to the imposed trade-off. All larvae spent more time in the simple microhabitat when food was present than when food was absent. Larvae without lamellae, however, only sporadically left the safe microhabitat, irrespective of the presence of the predator. In contrast, larvae with lamellae shifted more frequently towards the risky microhabitat than those without lamellae, and more often in the absence than in the presence of the predator. These decisions affected the foraging rates of the animals. I show for the first time that refuge use is higher after autotomy and that this is associated with the cost of reduced foraging success. The different microhabitat preferences for larvae with and without lamellae are consistent with their different vulnerabilities to predation and demonstrate the importance of intrinsic fac-

tors in establishing trade-offs." (Author)] Address: Stoks, R., Evolutionary Biology Group, Department of Biology, University of Antwerpen (RUCA), Groenenborgerlaan 171, B-2020 Antwerpen, Belgium. E-mail: stoks@ruca.ua.ac.be

1459. **Witte, R.H.; Groenendijk, D. (1999):** The occurrence of dragonfly larvae in the Dutch Delta in relation to salinity. *Brachytron* 3(2): 3-10. (in Dutch with English summary). [(Promille-Zeichen fehlt im Lidos) "[...] At about 225 localities in the mostly brackish Dutch Delta area dragonfly larvae were caught (or exuviae were collected) and salinity values were measured simultaneously. [...] Results showed that only *Ischnura elegans* was found to be able to breed successfully in polyhaline waters. However, numbers decreased strongly when ion concentrations exceeded 4.5 . *Aeshna mixta* (larvae) was found regularly in mesohaline waters with an average ion content of 4.3 , temporarily increasing during summer to a maximum value of 6.8 . A maximum of only 2 was formerly known for this species in The Netherlands. *Aeshna cyanea* larvae were found in oligohaline waters, in which the salt concentration increased up to 18 during a short period in summer. This observation is highly congruent with results from Denmark, where larvae of *Orthetrum cancellatum* occurred in brackish waters with an ion content of 13 . It seems that larvae of several dragonfly species can survive during short periods of high salinity. However, it is highly likely that larval development will be inhibited during these temporary situations. Oviposition in mesohaline waters was recorded for *Erythromma viridulum* and *Enallagma cyathigerum*. However, no successful reproduction could be proven. In Canada *E. cyathigerum* larvae have been found in brackish waters, as well as *Sympetrum danae* larvae. Several *Sympetrum* species are known to be tolerant for brackish water conditions and in the Delta area egg-laying behaviour was even recorded in polyhaline waters during some occasions. In addition, exuviae of *Lestes sponsa* and *L. barbarus* were found in oligohaline waters. Larvae of several *Sympetrum* species and *E. viridulum* were recorded here also. No other dragonfly species in the Delta area could be traced in brackish waters, although some other species were found in brackish waters elsewhere in Europe." 1462. **Zeiss, C.; Martens, A.; Rolff, J. (1999):** Male mate guarding increases females' predation risk? A case study on tandem oviposition in the damselfly *Coenagrion puella* (Insecta: Odonata). *Canadian Journal of Zoology* 77(6): 1013-1016. (in English). ["To estimate whether male mate guarding alters the predation risk for females, we conducted experiments in field cages with the damselfly *Coenagrion puella*. We experimentally compared the risk for females ovipositing solitarily versus in tandem with the male. The backswimmer *Notonecta glauca* was used as a predator. Owing to the oviposition behaviour of the damselflies, *N. glauca* only preys on females, therefore it was possible to determine whether the presence of males decreases or increases females' predation risk. Females in tandem were more frequently touched and grasped by *N. glauca* than solitary females. In most tandem pairs, the female showed the first reaction to the attack and the male responded subsequently. After an attack, most solitary females left the oviposition site but most tandem females stayed. Once grasped by the predator, more solitary females were killed." (Authors)] Address: Zeiss, C., Zool. Institut der Technischen Universität Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany

1463. **Zhu, H.-q.; Zhang, X.x. (1999):** *Somatochlora shanxiensis* spec. nov., a new dragonfly from Shanxi, China (Anisoptera: Cordulidae). *Odonatologica* 28(3): 289-292. ["The new species (holotype male and allotype female: Mang-he river bank, Yangcheng Co., Shanxi, China. 27/28-VIII-1991; deposited at Shanxi University, Taiyuan, Shanxi, China) is described and illustrated. 1464. **Zipfel, C. (1999):** Zoogeographie und Verbreitungsmuster der Pokal-Azurjungfer *Cercion lindenii* (Odonata, Coenagrionidae). - Vergleichende Untersuchungen mit morphologischen und Isoenzym-PAGE-Methoden. Diplomarbeit. Fakultät für Biowissenschaften, Pharmazie und Psychologie, Inst. für Zoologie, Universität Leipzig: 93 pp. (in German). [*C. lindenii* occurs in Germany with at least two isolated populations that are considered to represent different subspecies.

C. lindenii has been increasing its geographical distribution significantly since the early eighties and the isolation may be overcome within the next years. In this investigation, therefore, 117 adult specimens from five localities have been investigated regarding their wing morphometry and protein differences in electrophoresis: two each from southwestern (Giessen, Hessen; St. Leon, Baden-Württemberg) and central (Rheine, Nordrhein-Westfalen; Hameln, Niedersachsen), and one from eastern Germany (Großer Schwansee, Brandenburg). Wing morphometry showed significant differences (euclidian distance and UPGMA) between the eastern and all other populations. The males of the eastern population had larger wings whereas there was no significant difference between the females. This corresponds to earlier results (Beutler, H., 1985, Faun. Abh. Staatl. Mus. Tierk. Dresden 49, 82) but may, however, not definitively indicate the occurrence of an eastern subspecies, whereas odonate populations from colder regions tend to have larger wings (Carius, W., 1993, Dissertation, Univ. Bremen). 5 of 21 enzymes tested were polymorphic (IDH, esterases, PGM, GPD, diaphorase); in all cases but one the less frequent allele(s) occurred only in heterozygotes. Specimens from central Germany showed the highest heterozygosity (up to half of the population in IDH) whereas all other locations tested showed very high frequencies of one allele and low frequencies of all others or were homozygote. Also similarities between distant populations are often higher than to those from nearer locations. Regarding the isoenzyme patterns found, the German *C. lindenii* populations appear to be biochemically rather uniform and the variability is too low for postulating two subspecies. The evaluation of the total protein spectrum, however, showed that two groups can be differentiated: one group comprising all western populations investigated (Hameln, Rheine, Giessen, St. Leon) showed a homogeneous pattern of protein bands (within and between populations). The protein samples from the Schwansee population, however, differed significantly. The similarity between the Schwansee and the other populations decreased continuously from north to south. (Slightly modified from the Abstract submitted to *Zoology* 103, Suppl. II; Proc. of the 93 th Annual Meeting of the Deutsche Zoologische Gesellschaft, Abstract 92.1, 2000; Zipfel, A. & W.E.R. Xylander)] Address: Xylander, W., Staatliches Museum für Naturkunde Görlitz, PF 300154, D-02806 Görlitz, Germany

1465. **Zwick, P. (1999):** Historische Dokumente zur Fauna der Elbe bei Dresden vor hundert Jahren. *Lauterbornia* 37: 97-112. (in German with English summary). [35 plates with drawings and water colour paintings by Karl G. Schiller (author of the plates in Rostock & Kolbe, 1888: *Neuroptera germanica*. Die Netzflügler Deutschlands. Zwickau.) left by the late Joachim Illies show various invertebrates, including Odonata. The following species are documented on colour plates: *Lestes dryas*, *Erythromma najas*, and *Sympetrum sanguineum*. Not documented are the plates with *Ischnura elegans*, *Enallagma cyathigerum*, *Coenagrion hastulatum*, *C. puella*, *Ophiogomphus cecilia*, and *Aeshna* (cf. mixta). The plates provide evidence for the past occurrence of several species of water insects in the river Elbe at Dresden between 1883 and 1906, some that are today no longer found in Saxony. This refers not to Odonata. P. Zwick outlines the circumstances on the discovery of the colour plates, the evaluation of the identifications of the species, and the entomological "life

history" of Karl Schiller.] Address: Zwick, P., Limnologische Fluß-Station des Max-Planck-Instituts für Limnologie, PF 260, D-36105 Schlitz. E-mail: pzwick@mpil-schlitz.mpg.de

1471. **Bedjanic, M. (2000):** Description of the last larval instar of *Epophthalmia vittata cyanocephala* Hagen,

1867 (Anisoptera: Corduliidae). *Odonatologica* 29(1): 57-61. (in English). [The specimen was collected near Anuradhapura, Sri Lanka. The present knowledge of the larval forms of the genus is briefly discussed.] Address: Bedjanic, M., Fram 117/A, SI-2313 Fram, Slovenia. E-mail: matjaz.bedjanic@guest.arnes.si

1472. **Bernard, R.; Samol, J. (2000):** An interesting record of *Crocothemis erythraea* (Brullé) in mid-western Poland (Anisoptera: Libellulidae). *Notul. odonatol.* 5(5): 64-65. (in English). [On 26/8/1999 the species was recorded in a gravel pit near Bielice (52.21N 14.58E). The habitat is characterized, and all hitherto Polish records are discussed in brief.] Address: Bernard, R., Zakład Zoologii Ogólnej, Uniwersytet im. A. Mickiewicza, ul. Fredry 10, PL-61-702 Poznan, Poland. E-mail: rbernard@main.amu.edu.pl

1473. **Bernard, R. (2000):** On the occurrence of *Cercion lindenii* (Sélys, 1840) in Poland (Odonata: Coenagrionidae). *Opusc. zool. flumin.* 177: 1-11. (in English). [The known Polish localities (30) - restricted to the midwestern part of the country - are listed, and the strength of the respective local populations is estimated. It is suggested that the variation in the latter is due to the weather conditions prevailing in particular years. The Polish (i.e. the northeastern-most) part of the species range is described and defined in terms of the local climatology (early spring, long summer, short and mild winter, relatively small annual air temperature amplitudes, wind sheltered - lake - biotops) and topography (larger and medium-sized rivers) and against the species situation in central Europe.] Address: Bernard, R., Zakład Zoologii Ogólnej, Uniwersytet im. A. Mickiewicza, ul. Fredry 10, PL-61-702 Poznan, Poland; E-mail: rbernard@main.amu.edu.pl

1474. **Bos, F. (2000):** Mogelijke Nederlandse namen voor Zuid- en Oosteuropese libellen. Inclusief Rhodos en de Canarische Eilanden. *Mededelingen van de Nederlandse Vereniging voor Libellenstudie* 4(1): 13. (in Dutch). [Proposal for a Dutch name of the Odonata of South- and East-Europe including the Greek Island Rhodos and the Canarian Islands.] Address: Bos, F., Havenstraat 17, NL-6701 CK Wageningen, The Netherlands. E-mail: frank@bos.nl

1475. **Brockhaus, T. (2000):** Aktualisierte und korrigierte Fassung des kommentierten Verzeichnisses der Libellen (Odonata) des Freistaates Sachsen. *Mitteilungen Sächsischer Entomologen* 49: 8-14. (in German). [Up dated and commented checklist of the Odonata of Saxonia, Germany incl. an extensive regional bibliography; very useful are comments on species which are in need for conservation action plans] Address: Brockhaus, T., An der Morgensonne 5, D-09387 Jahnsdorf, Germany. E-mail: T.Brockhaus@t-online.de

1476. **Brockhaus, T. (2000):** Zur Geschichte der sächsischen Libellenkunde. *Mitteilungen Sächsischer Entomologen* 49: 15-21. (in German). [Detailed contribution to the origins and the development of the odonatalogical activities in Saxonia, Germany; nice maps with information on the historical hot spots of odonatalogical work; interesting search for traces of *Thecagaster bidentata* in old Saxonian publications on the opportunity of the so called first record in 1994: we have to suppose that it was known to Saxonian entomologists already 140 years ago!] Address: Brockhaus, T., An der Morgensonne 5, D-09387 Jahnsdorf, Germany. E-mail: T.Brockhaus@t-online.de

1477. **Brunelle, P.M. (2000):** A new species of *Neurocordulia* (Odonata: Anisoptera: Corduliidae) from eastern North America. *Canadian Entomologist* 132(1): 39-48. (in English with French summary). [*Neurocordulia michaeli* sp. nov. from New Brunswick (Canada) and Maine (USA) differs from other northeastern species in the genus (*Neurocordulia molesta* (Walsh 1863), *Neurocordulia obsoleta* (Say 1839), and *Neurocordulia yamaskanensis* (Provancher, 1875)) in its short mesotibial keel and from all congeners in the great width of its abdomen. "The species is obligate crepuscular and can be locally abundant at its riverine habitat. Larvae of the species have the lowest dorsal spines in the genus and cling to the underside of rocks in rapids."] Address: Brunelle, P.-M., 2460 John Street, Halifax, Nova Scotia, B3K 4K7, Canada
1478. **Buczynski, P. (2000):** On the occurrence of *Coenagrion armatum* (Charpentier, 1840) in Poland (Odonata: Coenagrionidae). *Opusc. zool. flumin.* 179: 1-10. (in English). ["All Polish localities (38, incl. 6 new) are listed, their grid references are stated whenever possible, and the respective habitats are briefly characterized. The distribution of the sp. in Poland is mapped, and its occurrence and habitat choice are briefly discussed and compared with those in other regions of central and eastern Europe." (Author)] Address: Buczynski, P., Dept of Zool., Marie Curie-Sklodowska University, Akademicka 19, PO-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl
1479. **Cham, S. (2000):** Discovery of a 'new' population of the Scarce Chaser *Libellula fulva* Müller on the River Stour in the Dedham Vale. *J. Br. Dragonfly Society* 16(1): 17-19. (in English). [In July 1997 (near Nayland) and July 1998 (near Burnes) males of *L. fulva* were observed along the River Stour. During July 1999, further reconnaissance along much of the river revealed a sizeable population between Bures and Nayland. In addition, adult *L. fulva* were observed at Earls Colne on the nearby River Colne in North Essex during 1999. Such observations suggest that the River Stour population may have already started to colonize the River Colne. These records are discussed with emphasize to improvement of water quality in the past years. Additional notes are made to the strong increase of the populations of *Platycnemis pennipes* and *Erythromma najas* in the same area.] Address: Cham, S., 45 Weltmore Road, Luton, Bedfordshire LU3 2TN
1480. **Chovanec, A.; Schiemer, F.; Cabela, A.; Gressler, S.; Grotzer, C.; Pascher, K.; Raab, R.; Teufel, H.; Wimmer, R. (2000):** Constructed inshore zones as river corridors through urban areas - The Danube in Vienna: Preliminary results. *Regulated rivers research and management* 16(2): 175-187. (in English). ["Over the last 125 years, river regulation has considerably changed the ecological conditions of the Austrian Danube and its floodplains such that the system is now very fragmented. Within the municipal area of Vienna, these changes have been particularly severe: river embankments and a bypass channel (the 'New Danube'), separated from the main river by an artificial island ('Danube Island'), are the key elements of flood control, and river levels are controlled by the Vienna hydroelectric power plant ('Freudenau'). During construction of the hydroelectric power plant, the previously straight shoreline of the 21 km long Danube island with its steep embankments, was restructured by creating shallow water areas, gravel banks, small permanent backwaters and temporary waters. This paper describes the scheme and the results from the first year of a 4-year monitoring programme ('Danube Island Monitoring Programme', DIMP) investigating the colonization and successional processes of these areas by monitoring relevant indicator groups (vegetation, dragonflies, amphibians, reptiles, waterfowl)." (Authors)] Address: Chovanec, A; Univ. Wien, Inst. Zool., Dept Limnologie, Althanstr 14; A-1090 Wien Austria
1481. **Clancy, S. (2000):** Reports from Coastal Stations - 1999: Dungeness area, Kent. *Atropos* 9: 65-67. (in English). [*Sympetrum fonscolombii*; *Anax parthenope*, "poor year"] Address: not stated
1482. **Corbet, P.S. (2000):** Book review: A Guide to the Dragonflies of Great Britain, Arlequin Press, Chelmsford, Essex CM1 1SW, England (1999) 21 x 15cm, 128pp.; £15.95 incl. post and packing (softback). ISBN 1 900159 01 5. Illustrated by Dan Powell; with text by Dan Powell and Colin Twist; edited by Colin Twist. *J. Br. Dragonfly Society* 16(1): 31-32. (in English). [Assessment of the dragonfly season 1999 including records of 15 species; it was an average year for *Sympetrum striolatum* and a good season for *S. sanguineum*, but "with an interesting clustering of [19] night-time records indicating periods of migration."] Address: Dewick, S.; Curry Farm, Bradwell-on-Sea, Southminster, Essex, CM0 7NL, UK

1489. **Dewick, S.; Gerussi, R. (2000):** Small Red-eyed Damselfly *Erythromma viridulum* (Charpentier) found breeding in Essex - The first British records. *Atropos* 9: 3-4. (in English). [On 17 July 1999 the first specimen of *E. viridulum* and a colony of the species were detected in "an area of unspoilt countryside in Essex", UK. Nearby situated a second - strong - population was discovered on 15 August.] Address: Dewick, S.; Curry Farm, Bradwell-on-Sea, Southminster, Essex, CM0 7NL, UK

1490. **Dey, D. (2000):** County focus: The Odonata of Sussex. *Atropos* 10: 15-18. (in English). [Odonatological facts referring landscape and habitats of Sussex, UK are shortly outlined; recent records of 32 species are commented with special emphasize on the migrant species] Address: Dey, D., 26 Manor Avenue, Hassocks, West Sussex, BN9 8NG, UK

1491. **Diesel, R.; Schubart, C.D. (2000):** Die außergewöhnliche Evolutionsgeschichte jamaikanischer Felskrabben. *Biologie in unserer Zeit* 30(3): 136-147. (in German with English summary). [The exiting evolution of the life history of Jamaican crabs: The Decapoda are

among the animal groups that most recently colonised land. This important evolutionary step occurred several times independently in the tropics and subtropics and produced convergent adaptations in the life history [...] With a further advancement into terrestrial habitats, the crabs colonised habitats with small aggregations of water that became nurseries for larvae and juveniles, for example the shells of large land snails and leaf axils of bromeliad plants filled with rainwater. The larvae thereby develop in the vicinity of the mother. High predation risk, scarce food resources, and unfavourable abiotic conditions for the larvae and the young triggered in species like [...] the bromeliad crab, *Metopaulias depressus*, the evolution of an outstanding parental care. The bromeliad crab mother, for example, does control and manipulate the acidity and calcium content of the water in the leaf axil with the brood. Bromeliad crabs live most of their life on a single bromeliad plant, and the characteristics of such a life supported a remarkable social organisation, comparable with cooperative breeding vertebrates." (Author) On page 143 a short notice on the maternal care from odonate predation is made. This refers to the results of a study published in *Animal Behaviour* 43: 803-812: Diesel, R. (1992): Maternal care in the bromeliad crab, *Metopaulias depressus*: protection of larvae from predation by damselfly nymphs: "*Metopaulias depressus* (Decapoda, Grapsidae) is a crab that breeds in water-storing leaf axils of large Jamaican bromeliads. This study examined whether and how maternal care protects crab larvae from predation by damselfly nymphs. The nymph of the bromeliad-breeding damselfly, *Diceratobasis macrogaster*, is the major predator on bromeliad crab larvae. Laboratory tests revealed that a nymph kills on average five larvae per day. Both the damselfly and the bromeliad crabs prefer the bromeliad *Aechmea paniculigera* as a breeding site. Nymphs were abundant: 87% of the *A. paniculigera* held 1-16 nymphs. Bromeliad crabs release on average 50 larvae into a prepared nursery axil where they develop for 9-10 days into young crabs. In field experiments maternal care reduced larval mortality from predation by 60%. A calculation based on predator abundance and killing potential suggests that female brood desertion would lead to 54-100% loss of their reproductive investment, depending on the female's body size and age (egg number is positively correlated with body size). Protected broods showed on average only 22% mortality during the larval period. In the bromeliad crab, predation on larvae exerts strong selection on the maintenance of maternal care for larvae." Address: Diesel, R., Max-Planck-Institut für Verhaltensphysiologie, Abt. Winckler, D-82305 Seewiesen, Germany

1492. **Dieterich, M.; Anderson, N.H. (2000):** The invertebrate fauna of summer-dry streams in western Oregon. *Archiv für Hydrobiologie* 147(3): 273-295. (in English). [Report on invertebrate communities and habitat associations of species in summer-dry streams of western Oregon, USA: 202 aquatic and semi-aquatic species, including at least 13 previously undescribed taxa. "Species richness in temporary forest streams (>125 species) exceeded that in a permanent headwater (100 species). Richness in ephemeral streams was 35 species or less. Duration of flow. exposure (shaded or open), riffle-pool structure and summer-drought conditions were key factors shaping community composition between and within stream types. We conclude that the potential of summer-dry streams with respect to habitat function is still widely underestimated." (Authors).

In Appendix 1 *Cordulegaster dorsalis* is characterised as a species obligate - facultative for permanent streams and obligate for forest streams.] Address: Dieterich, M., Philipps-Universität-Marburg, Fachbereich Biologie, AG Tieröko-logie, D-35032 Marburg, Germany

1493. **Dijkstra, K.-D. (2000):** Libellen in Wit-Rusland. Mededelingen van de Nederlandse Vereniging voor Libellenstudie 4(1): 11-12. (in Dutch). [In 1999 Netherlands and Belo-russian hydrobiologists surveyd the Odonata of the Svinavod region and the Hvojensk region in the southern part of the floodplains / marshes of the river Pripjat, Belo-Russia. 43 species including species of the EU Habitat Directive as *Sympecma paedisca*, *Leucorrhinia pectoralis*, *L. albifrons*, and *Aeshna viridis* could be recorded. *Coenagrion armatum*, *C. pulchellum*, *Erythromma najas*, *Nehalennia speciosa*, *Anaciaeschna isosceles*, *Aeshna subarctica elisabethae*, *Epitheca bimaculata*, *Somatochlora flavomaculata*, and *S. arctica* should be mentioned too.] Address: Dijkstra, K.D., Oude Rijnburgerweg 38, NL-2342 BC Oegstgeest, The Netherlands

1494. **Dunkle, S. (2000):** The many joys of dragonfly-ing. *American Butterflies* 8(2): 26-32. (in English). [Sid Dunkle particularly contrasts dragonflies with butterflies. The paper contains 10 colour photos of North American odonates.] Address: American Butterfly Association, 4 Delaware Rd., Morristown, NJ, USA 07960

1495. **Āervek, U.; Sameja, M. (2000):** *Orthetrum coerulescens anceps* (Schneider) as a prey of larval Mantis religiosa (L.) Anisoptera: Libellulidae; Dictyoptera: Mantodea. *Notul. odonatol.* 5(5): 65. (in English). [Near Zadar, Croatia on 23 July, 1998 *M. religiosa* was observed devouring an adult *O. coerulescens anceps*.] Address: Āervek, U., Ul. Veljka Vlahovića 35, SI-2000 Maribor, Slovenia

1496. **Ellenrieder, N. van (2000):** Additions to the description of *Gomphomacromia nodisticta* Ris, 1928 (Anisoptera: Corduliidae). *Bulletin of American Odonatology* 6(1): 7-11. (in English). [*Gomphomacromia nodisticta* Ris 1928, not found since its original description, was recorded in an Andean locality of NW Argentina. The structure of the penis is described, and some additional measurements and illustrations of diagnostic value are provided, as well as a comparison with the other species of the genus *G. paradoxa*, *G. etcheveryi*, *G. chilensis*, *G. fallax*, and *G. mexicana*.] Address: Ellenrieder, Natalie von, Instituto de Limnología "Dr. Raúl A. Ringuelet", C.C. 712, AR-1900, La Plata, Argentina. E-mail: ellenr@ilpla.edu.ar

1497. **Ellenrieder, N. von (2000):** Species composition and temporal variation of odonate assemblages in the subtropical-pampasic ecotone, Buenos Aires, Argentina. *Odonatologica* 29(1): 17-30. (in English). ["Odonata assemblages present in the ecotone between subtropical forest and pampasic grassland in Punta Lara were characterized and compared. Four pools, one in the forest, two in grassland (one within a protected area) and one at the limit of both environments, were sampled during July 1996-June 1998. For each sampling station species richness and diversity were calculated, and were compared through two similarity coefficients (Jaccard and Winer). The highest species richness and diversity were registered in the forest, and the lowest in the protected grassland. Cluster analysis showed different schemes according to the similarity coefficient considered; a greater similarity between the

forest and intermediate pools (Jaccard coefficient), or a greater similarity between grassland areas (Winer coefficient). Some biogeographical implications are discussed." (Author)] Address: Ellenrieder, N. von, Instituto de Limnología "Dr. Raúl A. Ringuelet", C.C. 712, AR-1900 La Plata, Argentina. E-mail: ellenr@ilpla.edu.ar

1499. **Goudsmits, K.; Wasscher, M. (2000):** Is er voorkeur bij de eiafzetplek van de Houtpantserjuffer *Lestes viridis*? Mededelingen van de Nederlandse Vereniging voor Libellenstudie 4(1): 8. (in Dutch). [Is there any preference in oviposition substrat in *Lestes viridis*? *Fraxinus excelsior* and *Alnus glutinosa* are preferred oviposition substrates for *C. viridis* near the estate Rijwijk, The Netherlands. In general, trees with smooth bark seems to be preferred for oviposition.] Address: Wasscher, M., Minstraat 15bis, NL-3582 CA Utrecht, The Netherlands, E-mail: m.wasscher@broekhuis.nl

1500. **Hämäläinen, M. (2000):** Ten species added to the list of Peninsular Malaysian Odonata. *Notul. odonatol.* 5(5): 53-55. (in English). [First records are the following species: *Amphicnemis ecornuta*, *A. sp.*, *A. gracilis*, *Lestes praecellens*, *Podolestes buwaldai*, *Oligoaeschna foliacea*, *Burmagomphus arthuri*, *Orchithemis pruinans*, *Tyriobapta kuekenhali*, and *Zyxomma obtusum*.] Address: Hämäläinen M., Dept Applied Zool., P.O.Box 27, FIN-00014 University of Helsinki, Finland; E-mail: matti.hamalainen@helsinki.fi

1501. **Hill, P.M. (2000):** Migrant Hawker *Aeshna mixta* using Buddleia Bush as a Feeding Station. *Atropos* 10: 57. (in English). [In early September 1999 *Aeshna mixta* was patrolling around a Buddleia and "periodically attempting to prey upon the various butterflies present, mainly Peacock *Inachis io* and Red Admiral *Vanessa atalanta*. Although the dragonfly was present for two or three days, I never actually saw it take a butterfly. Presumably it was successful otherwise it would have given up its vigil. Interestingly, a Robin (*Erithacus rubecula*, Aves) was also in attendance on several evenings, feeding on moths attracted to the Buddleia bush, flycatcher-fashion."] Address: Hill, P.M., 1 Clive Cottage, London Road, Allostock, Kniitsford, Cheshire WA16 9LT, UK

1502. **Jödicke, R. (2000):** Reiseberichte: Tunesien. *Libellennachrichten* 3: 18-19. (in German). [Report on the more recent activities in surveying the Odonata of Tunisia with some remarks on new additions to the checklist of the Tunesian Odonata, and voltinism of some species.] Address: Jödicke, R., Großenging 14, D-49699 Lindern, Germany. E-mail: r.joedicke@t-online.de

1503. **Johansson, F. (2000):** The slow-fast life style characteristics in a suite of six species of odonate larvae. *Freshwater Biology* 43: 149-159. (in English). ["1. The validity of the slow-fast lifestyle dichotomy proposed by Sih (1987) was tested in a suite of six odonate species from a restricted geographical area. Data on activity and microhabitat use were obtained in a laboratory study. Further necessary information on life history, macrohabitat (ephemeral-permanent) use and vulnera-

bility to fish predation was provided by a literature survey. 2. Activity was estimated as number of moves and distance moved for the six odonate larvae. *Aeshna juncea*, *Lestes sponsa* and *Sympetrum danae* were categorised as high-active species, whereas *Coenagrion hastulatum*, *Cordulia aenea* and *Leucorhinia dubia* were categorised as low-active species. 3. *C. hastulatum* and *L. sponsa* exploited microhabitats close to the water surface, *C. aenea* and *L. dubia* close to the bottom, and *A. juncea* and *S. danae* were intermediate in their water depth utilisation. 4. A principal component analysis of the data from the laboratory experiment and the literature survey supported the slow-fast life style dichotomy since the variables activity, macrohabitat use, life cycle length and sensitivity to fish predators were highly correlated." (Author)] Address: Johansson, F., Department of Ecology and Environmental Science, Animal Ecology Group, Umea University, 90187 Limed, Sweden. E-mail: frank.johansson@eg.umu.se

1504. **Jones, S.P. (2000):** First proof of successful breeding by the Lesser Emperor *Anax parthenope* (Sélys) in Britain. *J. Br. Dragonfly Society* 16(1): 20-23. (in English). ["*A. parthenope* has been proven to breed successfully in Britain for the first time by the discovery of a male exuvia on the Lizard peninsula on 31 July 1999. Additional exuviae discovered approximately 75 km to the northeast at Bake Farm Pools shortly afterwards allow the possibility that the species may have established itself over a wide area of Cornwall, especially as adults were noted at two other sites in the county during 1999. Current knowledge of the larval development time for *A. parthenope* indicates that, in Europe, larval development is likely to take two years (Robert, 1958), suggesting that the original oviposition would have occurred during the summer of 1997. However it is not inconceivable that in the right conditions, such as the shallow pools of the Lizard site where there is a high degree of exposure to sunshine, *A. parthenope* could complete its larval development in one year (P.S. Corbet, pers. comm.). If so, it is possible that oviposition could have occurred during the summer of 1998, when there were numerous sightings of adult *A. parthenope* in Cornwall." (Author) Morphological characters of male exuviae of *A. parthenope* and *A. imperator* for separating the species are discussed in detail.] Address: Jones, S., Hyfield, Chapel Hill, Brea, Cornwall TR14 9BP, UK

1505. **Jonsen, I. D.; Taylor, P. D. (2000):** Fine-scale movement behaviors of calopterygid damselflies are influenced by landscape structure: an experimental manipulation. *Oikos* 88: 553-562. (in English). ["We explore the effect of differences in landscape structure, arising from habitat loss, on the fine-scale movement behaviors of two congeneric damselflies - *Calopteryx aequabilis* and *C. maculata*. Both species require streams for breeding and naiad development and both often use forest for foraging. We compare movement behaviors across three types of landscape: forested landscapes, where stream and forest habitat are adjacent; partially forested landscapes, where streams and forest habitat are disjunct, and non-forested landscapes, where little to no forest habitat is available. We employ a reciprocal transplant experiment to determine the extent to which movement along and away from streams is influenced by landscape structure and historical behavior or morphological adaptations. For both species, we show that both the propensity to move away from streams and

and rates of net displacement differ among landscape types. Both species move away from streams on landscapes with high or moderate levels of forest cover but neither moves away from streams on landscapes with little or no forest. Furthermore, *C. maculata* native to predominantly forested landscapes are more likely to move away from streams, regardless of the landscape structure they encounter, than are individuals native to moderately forested or non-forested landscapes. There was no effect of natal landscape on *C. aequabilis*. Comparisons with microlandscape studies suggest that there may be some general similarities among the different systems but these are clouded by uncertainty regarding the similarity of the underlying processes responsible for observed behavioral responses to landscape structure. Despite this uncertainty, animal movement behaviors are contingent upon the structure of the broader landscape, regardless of the absolute scale of the landscape." (Authors)] Address: Jonsen, D.I., Lethbridge Research Centre, Agriculture & Agri-Food Canada, P.O. Box 3000, Lethbridge, AB, Canada T1J 4B1. E-mail: jonseni@em.agr.ca

1518. **McPeck, M.A.; Brown, J.M. (2000):** Building a regional species pool: diversification of the *Enallagma* damselflies in eastern North America. Ecology 81(84): 904-920. (in English). ["We use a phylogeny of the North American *Enallagma* damselflies, derived from molecular and morphological data, to examine how the patterns of local and regional assemblage structure developed in this taxon across eastern North America. The two primary clades in the genus have nearly identical numbers of extant species, but the centers of diversity and the diversification rates for the two clades are quite different. One clade has its center of diversity in

New England and radiated very recently from three species to give the current 18. Although most of this radiation involved the creation of new species in the ancestral fish-lake habitat, at least two independent lineages invaded and adapted to a new habitat: ponds and lakes lacking fish but supporting large numbers of large predatory dragonflies. The other clade with greatest diversity in the southeastern United States, contains species that inhabit only water bodies that support fish populations. This "south-eastern" clade diversified at a much slower and more steady pace within the fish-lake habitat than the "New England" clade, but four speciation events in this clade appear to have occurred at the same time as the northern radiation. Combined with our current understanding of local community structure in fish and fishless lakes, these results indicate that most of the species in this regional assemblage were created by speciation mechanisms other than filling empty niches, which have resulted in many locally coexisting species that are very similar in their ecological characteristics. Damselflies in eastern North American ponds and lakes appear to exemplify features of both a regulated component of the littoral food web (i.e., a functional group) and an assemblage whose local community composition is influenced by nonadaptive macroevolutionary processes that have operated on a much larger regional scale." (Authors)] Address: McPeck, M., Dept Biol. Sci., Dartmouth College, Hanover, New Hampshire 03755, USA. E-mail: mark.mcpeek@dartmouth.edu

1519. **Misof, B.; Anderson, C.L.; Hadrys, H. (2000):** A phylogeny of the damselfly genus *Calopteryx* (Odonata) using mitochondrial 16S rDNA markers. Molecular phylogenetics and evolution 15(1): 5-14. (in English). ["[...] In this study, we concentrate on establishing phylogenetic information from parts of the 16S rDNA gene, which we sequenced for nine *Calopteryx* species and five outgroup species. The mt 16S rDNA data set did not show signs of saturated variation for ingroup taxa, and phylogenetic reconstructions were insensitive to variation of outgroup taxa. Parsimony, neighbor-joining, and maximum-likelihood reconstructions agreed on parts of the tree. A consensus tree summarizes the significant results and indicates problematic nodes. The 16S rDNA sequences support monophyly of the genera *Mnais*, *Matrona*, and *Calopteryx*. However, the genus *Calopteryx* may not be monophyletic, since *Matrona basilaris* and *Calopteryx atrata* are sister taxa under every parameter setting. The North American and European taxa each appear as monophyletic clades, while the Asian *Calopteryx atrata* and *Calopteryx cornelia* are not monophyletic. Our data implies a different paleobiogeographic history of the Eurasian and North American species with extant Eurasian species complexes shaped by glacial periods, in contrast to extant North American species groups." 1528. **Olberg, R.M.; Worthington, A.H.; Venator, K.R. (2000):** Prey pursuit and interception in dragonflies. *Jour. comp. physiol. (A), Sensory, neural and behavioral physiology* 186(2): 155-162. (in English). ["Perching dragonflies (Libellulidae; Odonata) are sit-and-wait predators, which take off and pursue small flying insects. To investigate their prey pursuit strategy, we videotaped 36 prey-capture flights of male dragonflies, *Erythemis simplicicollis* and *Leucorrhinia intacta*, for frame-by-frame analysis. We found that dragonflies fly directly toward the point of prey interception by steering to minimize the movement of the prey's image on the retina. This behavior could be guided by target-selective descending interneurons which show directionally selective visual responses to small object movement. We investigated how dragonflies discriminate distance of potential prey. We found a peak in angular velocity of the prey shortly before take-off which might cue the dragonfly to nearby flying targets. Parallax information from head movements was not required for successful prey pursuit." (Authors)] Address: Olberg, R.M., Union Coll, Dept Biol. Sci., Schenectady, NY 12308 USA; Siena Coll, Dept Biol, Loudonville, NY 12222 USA. E-mail: olbergr@union.edu

1551. **Stevani, C.V.; Porto, J.S.; Trindade, D.J.; Bechara, E.J.H. (2000):** Automotive clearcoat damage due to oviposition of dragonflies. *Journal of applied polymer science* 75: 1632-1639. (in English). ["Automotive industries are increasingly interested in learning how to pro-long the clearcoat resin lifetime and avoid its thermal, photochemical, and chemical degradation. While chemical degradation by acid rain has been well known since the beginning of the decade and the subject of many studies, chemical degradation of the automotive clearcoat by living organisms (except by bird droppings) is a newly recognized problem. In this work, we report the chemical degradation of the automotive clearcoat caused by oviposition of dragonflies. These insects, very common in Brazil, are attracted by the reflecting surface of cars exposed in the sun and lay eggs on them. We observed that the eggs, at the high temperatures (50-92°C) of the car surface, can cause damage similar to that of acid rain. In experiments on resin-coated plates, we excluded the involvement of H₂O₂- or hydroquinone-derived radicals, of enzyme-catalyzed hydrolysis, and of photosensitizer-induced damage. The damage was very similar, however, to that produced by the sulfur-containing amino acids, cysteine and cystine, at high temperature. Due to this similarity, and because

the eggs are rich in sulfur amino acids, we propose a mechanism involving cysteine and cystine residues in the clearcoat damage." 1552. **Stevani, C.V.; Faria, D.L.A. de; Porto, J.S.; Trindade, D.J.; Bechara, E.J.H. (2000):** Mechanism of automotive clearcoat damage by dragonfly eggs investigated by surface enhanced Raman scattering. *Polymer Degradation and Stability* 68: 61-66. (in English). ["Dragonflies are attracted by the reflection of sunlight on car surfaces and lay their eggs on the clearcoat resin. Considering that the surface can reach up to 93°C and that during the egg hardening process (sclerotization) H₂O₂ is released, cysteine and cystine residues present in the egg protein can be oxidized to sulfinic and sulfonic acids. These are strong acids which, like acid rain, can hydrolyze the acrylic/melamine resin causing damage where the eggs were laid. Confocal Raman spectroscopy revealed that the spectra obtained from damaged and intact portions of the clearcoat were similar, in agreement with infrared absorption spectroscopy data. These data demonstrate that the attack by eggs, H₂SO₄ and cysteine/H₂O₂ only promotes solubilization of resin through acid hydrolysis of the resin ester and amide moieties. Furthermore, surface enhanced Raman scattering (SERS) spectra obtained from dragonfly eggs and cysteine/H₂O₂ reaction products treated with a silver colloid were very similar, thus confirming the presence of sulfinic and sulfonic acids. [...] Conclusion: Altogether the data support the proposition that the damage caused by dragonfly eggs to acrylic/melamine resins is due to acid hydrolysis. [...] As the sulfinic/sulfonic acids putatively formed are attached to the protein structure of the eggs, only damage in the contacted area between eggs and resin takes place. Contrarily, in the case of either acid rain or "acid solutions" tested in the laboratory, the acids are free in solution and can extend the damage to a greater surface area as well as to inner layers of the clearcoat. Once inner layers are destroyed, significant changes in the structure of the polymeric material can thereafter occur." (Authors)] Address: Bechara, E.J.H., Instituto de Química, Universidade de São Paulo, C.P. 26077, 05599-970, São Paulo, SP, Brazil. E-mail: ebechara@quim.iq.usp.br

1553. **Stoks, R.; De Block, M. (2000):** The influence of predator species and prey age on the immediate survival value of antipredator behaviours in a damselfly. *Archiv für Hydrobiologie* 147(4): 417-430. (in English). ["The efficacy of antipredator behaviours may depend on both intrinsic and extrinsic factors. We experimentally studied the effects of predator species and prey age on the immediate survival value of swimming and lamellae loss in larval damselflies. Four predators: two invertebrates (the notonectid, *Notonecta viridis* and the dragonfly larva *Aeshna cyanea*), and two vertebrates (the three-spined stickleback *Gasterosteus aculeatus* and the sunfish *Lepomis gibbosus*) were tested with all combinations of two instars of the damselfly *Lestes sponsa* (F-0 and F-2). The number of escapes by swimming away were much lower when larvae were attacked by the two fishes than by the two invertebrates. Moreover *Lepomis* never removed lamellae and killed all larvae. The instars did not differ in the number of escapes by swimming, but F-0 instars were caught more

at the lamellae than F-2 instars. All larvae that survived a capture were caught at the lamellae and the majority (90 %) did so by autotomy. The ontogenetic increase in the immediate survival value of this antipredator behaviour was dependent upon the predator species. It was highest in captures by the *Notonecta* (40 %), and lower when larvae were caught by the *Aeshna* or *Gastrophysus* (ca. 17 %). This was probably because the biological relevance of the magnitude of the speed difference between damselfly instars depends upon the predator's attack performance. We discuss the consequences of these findings for the macrohabitat distribution of the larvae and for the multicomponent antipredator behaviours prey may use." 1560. **Ward-Smith, A.J.; Sussex, D.J.; Cham, S.A. (2000):** Flight characteristics of the Brilliant Emerald *Somatochlora metallica* (Vander Linden) in south-east England. *J. Br. Dragonfly Society* 16(1): 24-28. (in English). [The three different forms of flight styles of male *S. metallica* observed at woodland ponds near Bracknell in South-east Berkshire, UK are described and discussed: Flight style I: This flight style is typically at a height of about 1 m above the water and close to the edge. It takes the dragonfly beneath overhanging vegetation, where it is prone to loiter with spells of hovering, and into regions of shade. The male appears to be searching for ovipositing females that use water margins for egg-laying. Flight style II: In this style the male patrols back and forth along a regular beat in the sunshine with a slow, controlled flight, occasionally punctuated by hovering. [...] Typically the flight is about 2-3 m above the water, but where the pond has steeply sloping banks the dragonfly will occupy airspace as high as 6 m above the water level. Over small ponds (up to about 20 m diameter) the dragonfly occupies an area above the centre of the pond. but in larger ponds the flight is typically within an airspace about 4-6 m from the edge. When several males are present, as happens on rare occasions, they space out, each patrolling over different parts of the pool. This flight style may represent general territorial behaviour. Flight style III: In this style the dragonfly upon visiting a site flies around it on an irregular flight path. These visits typically last 1-2 minutes, but may be as short as 20 seconds, sometimes longer than 2 minutes. During this brief period *S. metallica* maintains a sense of urgency, flying faster than in the first two flight styles. Its height above the water varies. *S. metallica* appears to be carrying out a general reconnaissance of a site. The observations are discussed with reference to the energy consumption during flight. "It is conjectured that the slow, controlled flight adopted by *S. metallica* during FS I and FS II is the equivalent of the minimum-power speed of aircraft flight" (Ward-Smith, 1984). "At this flight speed, the dragonfly is able to remain airborne whilst adopting an energy-conservation strategy."] Address: Ward-Smith, A., The Ridge-way, Bracknell, Berkshire RG12 9QU, UK

[Book review submitted in November 1999 to *Vierteljahrsschrift der Naturforschenden Gesellschaft in Zürich*. [In German]. The English translation that follows has been approved by the author of the review.

Dragonflies date from the Lower Permian. During their more than 250 million years' existence their body plan has remained remarkably conservative, although they show striking diversity of ecology and behaviour. Among the insects in the order one sees displayed a range of specializations: the aquatic larva possesses a feeding mechanism equipped with pincers that can be protracted explosively, and a multifunctional hindgut (rectum) that serves for nutrient intake, respiration, ionic regulation, energy storage and jet propulsion. Adult dragonflies are impressive as astonishingly agile and enduring flyers. Their gigantic compound eyes form a morphological and physiological mosaic, the highly developed perception encompassing a high flicker threshold and resolving power, and colour and polarization receptors with a corresponding capability for image processing in the nervous system. Unique for all dragonflies is the typical copulation wheel, and associated with this a variety of strategies for mating and egg-laying. A model organisms, dragonflies have been studied to investigate biological principles and processes. For several decades they have been among the front-runners in zoological research in the fields of behavioural ecology, ecophysiology, reproductive biology and neurobiology. The principles of territoriality and sperm displacement during copulation, widespread in many animal groups, were first described for insects in dragonflies. To an increasing extent dragonflies also feature in applied ecology, especially in land management and nature conservation: Because they exhibit many habitat specializations, dragonflies provide local species-spectra by which the quality of aquatic habitats can be assessed. In Philip S. Corbet's "Dragonflies" a monumental work on the biology of dragonflies has appeared, for which the international readership has waited impatiently for almost twenty years. From the standpoint of knowledge at the end of the 20th Century, the book treats all current fields of ecology and behaviour with reference to the global fauna, comprising some 5000 species. Information is presented throughout in an evolutionary context; yet the book is more than a compendium on behavioural ecology as this discipline is currently perceived. Besides addressing causal (proximate) and functional (ultimate) aspects of behaviour, the book gives ample attention to descriptive biology in its variety at the species level, providing an important foundation for posing questions in future. "Dragonflies" is arranged according to the dragonfly life cycle and begins with habitat selection, egg-laying and developmental biology. More chapters follow on larval biology with especial reference to respiration, feeding, biotic and abiotic factors, growth, metamorphosis and emergence, in which predation and parasitism are duly treated. About half the text is devoted to the adult stage. Such general themes as maturation, activity patterns, thermoregulation, foraging and dispersal are treated in detail. Most space is devoted to the field of odonatology that has made special progress in the last two decades: reproductive biology. The last chapter, entitled "Dragonflies and people" focuses mainly on aspects of nature conservation. Despite the book's unassuming subtitle, Corbet does not confine himself to behaviour and ecology. Wherever an opportunity offers to improve overall understanding of ecological and behavioural principles, corresponding knowledge from the neighbouring

disciplines of physiology and functional morphology is presented. For example the foraging behaviour of adult dragonflies is discussed in the context of flight performance, compound eyes and the nervous system. This approach offers a more comprehensive view than if prey capture were to be treated in isolation. Likewise, correlations are shown between reproductive behaviour and both sperm competition and microscopic anatomy, as well as between behavioural ecology of larvae and their respiration and osmoregulation. Corbet's strength lies in synthesis. He has succeeded in ordering an immense body of information, put in a clear general context and in a challenging way that leads one to a total view, provided not least by the information-rich tables in the text and the appendix. How much labour this entailed is evident from the cited references: the bibliography includes some 4,000 entries. In addition to works cited in English are those in German, Japanese and various other languages. Thus "Dragonflies" represents an extraordinarily comprehensive biology of dragonflies, the significance of which extends far beyond this animal group. The new "Corbet" will indubitably belong among the classic organism-based texts of the 20th Century, like its predecessor from 1962, "A Biology of Dragonflies" - certainly the most often cited publication in odonatology. A final remark about the illustrations: all 96 colour photographs are biologically documented, and complement the text in an excellent way. Obviously the fundamental criteria for selection and compilation were their morphological, ecological and behavioural merits rather than their technical or aesthetic quality. Thus one has to accept a certain lack of uniformity in some plates. Most diagrams and drawings derive from original publications, inevitably causing a mish-mash of styles and also resulting in places in poor resolution of detail. However, new illustrations would have resulted in a higher price and further delay in the book's appearance. The small shortcomings are therefore pardonable. It is superfluous to say that these minor blemishes hardly detract from an otherwise very carefully edited work. Thus it is that "Dragonflies" belongs in the library of every researcher and committed teacher. (Hansruedi Wildermuth)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rütli, Switzerland. 1575. Arai, Y. (1997): Some ecological observations on *Sympetrum pedemontanum elatum* Selys. *Tombo* 40: 15-20. (in Japanese with English summary). ["During a period from 1996 to 1997, some ecological observations on *Sympetrum pedemontanum elatum* Selys were carried out at Yatsuda and its vicinity in Yorii-machi, Saitama Prefecture. The results are summarized as follows: 1. Although the emergences were seen in one rice field, no emergences were observed in the other adjacent rice field. The cause of this difference is thought to be water condition meaning whether the field dried up or not even temporarily during the period of larvae. 2. In the rice field the emergences began in the beginning of July and ended in the beginning of Sep-

tember, but in the flume to the field the emergences started in the latter part of August and finished in the end of September. The difference will come from the fact that the water temperature of the flume is lower than that of the rice field. 3. The teneral or immature dragonflies used to remain near the site of emergence, and after getting mature they dispersed. 4. The male insect did not make his territory, but when he found the female under both in flying and sitting conditions he caught her and copulated. 5. They usually laid eggs to the slow-running water of the flume and small stream by striking the surface with the tip of female's abdomen in tandem, but occasionally to the still water and rarely to the wet mud." 1592. Ishizawa, N. (1997): A drop of haemolymph in the forewing of a female *Anax parthenope julius*. Gekkan-Mushi 320: 39-40. (in Japanese). [On December 8, 1996, I caught a larva of *Anax parthenope julius* at Omori flood controlling pond at Miyadera, Iruma City, Saitama Prefecture, which is a spring pond, and bred it indoors. From the larva, a female emerged on January 9, 1997. I kept the dragonfly covered with a basket overturned on a table. When I saw it on January 22, it was still alive and a light green drop of haemolymph was seen near the tip of the right forewing [...]. As the dragonfly perched hanging from the top of the basket with its wings hanging down perpendicularly, haemolymph seemed to be accumulated in the wing. When I moved the dragonfly into the warm room out of the basket, it unfolded the wings and warmed up, and in around ten minutes the drop disappeared, absorbed into the body. I returned the dragonfly to the basket, and the phenomenon was seen on the next day too. Circulatory flow of haemolymph into wings was experimentally proved by Münchberg (1966), and the wings are said to be easily broken by the lack of the haemolymph flow into the wings (Wigglesworth, 1950). (taken from DJOSC 6)] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozava City, Saitama Pref., Japan

1593. Ishizawa, N. (1997): Record of a male of *Sympetrum depressiusculum* from Saitama Prefecture. Tombo 40: 33. (in Japanese with English summary). ["A male of *Sympetrum depressiusculum* Selys was captured at a spring in Iruma City, Saitama Prefecture on October 29, 1997. This is the first record from the Kanto district. The abdominal length is 23.3 mm, thoracic height: 5.6 mm. hind wing: 27.2 mm. This specimen lacks the right hind wing from outer side of the node. Its face was rather whitish, and pterostigmas were dark brown. The ratio of the thoracic height to the length of hind wing was 0.206, which coincides with that (0.20) calculated from Naraoka's data, and is significantly different from that of *Sympetrum frequens* (0.23)."] (Author)] Address: see above.
1594. Kita, H. (1997): Four cases of unusual copulation and/or connection in dragonflies. Tombo 40: 27-28. (in Japanese with English summary). [In 1997 four cases of abnormal copulation and/or connections in dragonflies were observed as follows: "1. Heterospecific copulation: *Leucorrhinia dubia orientalis* Selys male x *Sympetrum frequens* Selys female. 2. Heterospecific connection: *Cercion sexlineatum* Selys male - *Cercion plagiolum* Needham female. 3. Oviposition in triple-connection of *Sympetrum frequens* Selys male - male - female (Type A) 4. Male-male tandem: *Mnais p. pruinos*a Selys male - male. In this position the first male transferred sperm to his sperm bursa, and the second male bended his abdomen like a female." [Of special interest are *Mortonagrion seleni*, *Nehalennia speciosa*, *Lyriothemis pachygastra*, and *Sympetrum kunkeli* which are rare in Aomori Prefecture, Japan. A total of 34 species was observed in 1994 and 1995. (taken from DJOSC 8)] Address: Naraoka, H., 36-71, Aza-Motoizumi, Fukunoda, Itayanagi-cho, Kita-gun, Aomori Prefecture, 038-3661, Japan
1599. Naraoka, H. (1997): Reproductive Behavior of *Sympetma paedisca paedisca* (Odonata, Libellulidae). New Entomol. 46 (1/2): 20-25. (in Japanese with English summary). ["The reproductive behaviour of *S. p. paedisca* was studied at a small pond in Shiura village, Kita-gun, Aomori-Pref., northern Japan, from May to August, 1996. Hibernated adults appeared at the pond side from mid May, and a few adults remained until early August. Reproductive behavior was observed on fine and warm days from late May to mid July. The peak was the first half of June [...]. A male seized a female without courtship and display immediately after he found her. Sperm transfer ($x=60.8$ seconds) was carried out just after the tandem was formed at a perching place. Copulations were observed between 7:30 and 14:30 with the peak from 9:00 to 10:00, and it was divided into three stages, in each of which the characteristic pumping was seen [...]. Duration of copulation was 15 minutes 47 seconds in average (Stage 1 : 14 m 42 s., n : 93.4 s., E: 10.3 s.). Sperm displacement was recognized by comparing the volumes of female's sperm storage organ collected at precopula, copula and postcopula [...]. Tandem ovipositions were done soon after copulation to the leaves of the reed *Phragmites communis* above the water during 8:00 to 16:00 with the peak from 10:00 to 12:00 [...]. Interspecific tandem concerned to this species was observed in 3 cases." 1606. Subranabian, M.A.; Reni Prabha, A.; Varadaraj, G. (1997): Effect of tannery effluent on biochemistry of larvae of the dragonfly *Pantala flavescens* (Fabricius) (Libellula: Anisoptera). *Fraseria* (N.S.) 4: 5-8. (in English). ["By static bioassays, the 96 hr LC 50 value of the tannery effluent of the antepenultimate larvae of *P. flavescens* was found to be 15%. The larvae required 36 days to become adult. The moulting is arrested in the larvae treated to sublethal concentrations of the effluent and all of them died between 30-36 days. Various biochemical constituents in the tissues decreased significantly. However, lactic acid accumulated in all the tissues implying the shifting of metabolism towards anaerobic side to meet excess energy under the stress of tannery effluent. The diminution of organic compounds and accumulation of lactic acid could be the casuative factor for the mortality of effluent - treated larvae." (Authors)] Address: Subramanian, M.A.; P.O. and Research Department of Zoology Chikkaiah Naicker College, Erode - 638 004, Tamil Nadu, India.

1607. Suzuki, K.-J., Saitoh, K.; Sawano, J. (1997): Male germ-line chromosomes of *Davidius moiwanus taruii* Asahina et Inoue (Anisoptera: Gomphidae). Tombo 40: 12-14. (in Japanese with English summary). ["Using three immature males of *Davidius moiwanus taruii* Asahina et Inoue, 1973, obtained in Kamisaibara-son of Okayama Prefecture, germ-line chromosomes were examined by conventionally air-dried and Giemsa-

stained testis-preparations. The spermatogonial diploid complements comprise 23 chromosomes, including a single X and a pair of m chromosomes. The X is the largest in size in the complement. The m is much smaller in size than the rest. In the first and second divisions in spermatocytes, the haploid complements consist of twelve chromosomes. The parallel arrangement of sister chromatids is apparent in the X at diakinesis. At early anaphase II, the undivided, rod-shaped X is easily distinguishable from the rest of dumbbell-like shape. The male is therefore the heterogametic sex. Each of the n, 13 complements observed in the first division in the male (No. 3) includes a minute univalent which is smaller in size than the m. This element might be a B chromosome." (Authors)] Address: Suzuki, K., Toyama University, Dept of Biology, Faculty of Sciences, 3190 Gofuku, Toyama, 930, Japan

1613. Anderson, T.M.; Anderson, N. H. (1998): The life history of *Arrenurus hamrumi*, a water mite from rangeland springs in central Oregon, USA. In: Botosaneanu, L. (Ed.): *Studies in crenobiology: The biology of springs and springbrooks*. ISBN 90-73348-04-8.: 63-74. (in English). ["Water mites, which have both predatory and parasitic life stages, make an important contribution to the biodiversity and trophic dynamics of spring ecosystems. We studied the life history of the water mite, *Arrenurus hamrumi* Anderson & Smith (Hydrachnida: Arrenuridae) and its damselfly host, *Argia vivida* Hagen (Odonata: Coenagrionidae), which occur in small springs in rangeland habitats in central Oregon, USA. A common feature of these springs is the dominance of emergent vegetation, while hydrologic and thermal regimes are quite variable. Through field collections and laboratory observations we associated all life stages of *A. hamrumi* and documented its interaction with *A. vivida*. Adult mites occur in the springs throughout the year where they feed on ostracods. In the field sex ratios favour females, but equal numbers of males and females emerged in the laboratory. Mite larvae locate hosts in the benthic habitat and become phoretic under their wingpads until the damselfly emerges and the mites then become parasitic. Phoretic mite larvae occur year-round in the springs, while the parasitic stage is limited to the flight season of the damselfly. The extended period of phoresy by the larvae prior to becoming parasitic seems to facilitate synchronization of the life cycles of the water mite and its host, which has a two-year life cycle. The occurrence of deutonymphs begins after the first parasitic larvae of the season detach and transform (usually in early May), and lasts well into the fall. Features of the life history of *A. hamrumi* seem to be directed toward successfully parasitizing its host, *A. vivida*, rather than being adaptations specific to existence in spring environments. The trophic structure of these habitats is detritus-driven and favors abundance of ostracods and Chironomidae, which are the primary food resources for the predatory stages of the two species that we studied." (Authors)] Address: Anderson, Tracey, Institution Dep. Entomol., Oregon State Univ., Corvallis, OR 97331, USA
1614. Aoki, T.; Azuma, T. (1998): A report from Hyogo Prefecture on the reduction of population size of *Sympetrum maculatum* Oguma. *Nature and Insects* 33(10): 18-20. (in Japanese). ["Description of habitat; life history, ecology; possible impact of insecticide spraying on the species; the importance of pine forests in the habitat of the species is discussed (see DJOSC 10).] Address: Aoki, T., Rokko Island High School, Naka 4-chome, Koyo-cho, Higashinada-ku, Kobe, 658-0032, Japan. E-mail: taoki@ma3.justnet.ne.jp
1615. Arai, Y. (1998): Records of the activities of Conservation committees: "Other dragonfly" group. *Tombo* 41: 60-61. (in Japanese with English translation of the title.) Address: Arai, Y., 1233-2, Oaza Sueno, Yorii-machi, Osato-gun, Saitama Pref., 369-12, Japan.
1616. Arunachalam, A.; Subramanian, M.A. (1998): Tannery induced alterations on total haemocyte counts in the larvae of dragonfly, *Pantala flavescens* (Fabricius) (Anisoptera: Libellulidae). *Fraseria* (N.S.) 5: 19-21. (in English). ["When the last three larval instars of *P. flavescens* were reared in sublethal concentrations of tannery effluent, there was no moulting at all in the larvae throughout the experimental period. They died between day 30 and 36. In various concentrations of the effluent, the number of haemocytes in the blood of the larvae were found to decrease leading to leucopenia. This pathological condition, in turn, could have increased the toxicity of the effluent on the larvae resulting in mortality. The reduction in number of haemocytes could possibly cause a restricted transport of moulting hormone from the site of secretion to the tissues. This might also be the probable cause for the death of the effluent-treated larvae without undergoing moulting and metamorphosis." (Authors)] Address: Arunachalam, A. & M. A. Subramanian, P. G. & Research Department of Zoology, Chikkaiah Naicker College, Erode - 638 004, India
1617. Asahina, S. (1998): Reminiscences of an odonatologist. *Tombo* 41: 52-54. (in Japanese with English translation of the title.) Address: Asahina, S., 4-4-24 Takadanobaba, Shinjuku-ku, Tokyo 160, Japan
1618. Bhawane, G.P.; Gaikwad, A.R.; Nikam, D.S. (1998): Thoracic muscle trehalase the larvae and adults of *Pantala flavescens* (Anisoptera: Libellulidae). *Fraseria* (N.S.) 5: 23-28. (in English). ["The optimal pH, the optimal temperature and Km of the enzyme trehalase of thoracic muscle in the last instar larvae and adults of *Pantala flavescens* were determined. The pH of 5.6 and the temperature of 40°C was optimum for thoracic muscle trehalase of larvae and male dragonfly. The Km for the muscle trehalase of larvae was 1.7621×10^3 M of trehalose. The half life period for thoracic muscle trehalase at 50°C was 29 minutes. A period of 60 minutes was fit for the linear activity of thoracic muscle trehalase. Both, NaCl and KCl accelerate the enzyme activity even at the concentration of 0.01 M in reaction mixture. The specific enzyme activity is more in the larvae as compared to the adults." (Authors)] Address: Bhawane, G.P., Department of Zoology, Shivaji University, Kolhapur 416 004, India
1619. Bönsel, A. (1998): Verbreitung und Bestandsabschätzung der Hochmoor-Mosaikjungfer - *Aeshna subarctica* (Walker 1908) in Mecklenburg-Vorpommern. *Naturschutzarbeit in Mecklenburg-Vorpommern* 41: 32-38. (in German). [Documentation of the present status of *Aeshna subarctica elisabethae* Djakonov, 1922 in six

- bogs in Mecklenburg-Vorpommern, Germany. In Tab. 1 the associated odonate species are listed.] Address: Bönsel, A., Vasenbusch 15, D-18337 Gresenhorst, Germany
1620. Chandler, C.R.; Lindemann, S.A.; Kinsey, A.A.; Shuford, R. (1998): Late-summer congregation of swallow-tailed kites in southeast Georgia. *Oriole* 62(3-4): 29-34. (in English). [Altamaha River (Tattnall County, Georgia, USA); late-summer congregation; "By late July, dragonflies (tentatively identified as *Pantala flavescens* and *Tramea carolina*) were more apparent around the field and among the insects on which kites were feeding."] Address: Chandler, C.R., Institution Dep. Biol., Ga. South. Univ., Statesboro, GA 30460, USA
1621. Dévai, G.; Miskolczi, M.; Olajos, P. (1998): Faunistical data on dragonflies (Odonata) from the floodplain area of River Tisza between Tiszabercel and Balsa (HNBM Programme, Pilot Project). *Studia odonologica hungarica* 4: 73-82. (in Hungarian with English summary). [Observations and collections were carried out 1996 in a part of the active floodplain of River Tisza along the left side, over the administrative area of the settlement Gávavencsello (3 localities), Hungary. 33 species were found to occur in the area.] Address: Dévai, G., Department of Ecology, Kossuth L. University, H-4010 Debrecen, P.O. Box 71, Hungary
1622. Dévai, G.; Miskolczi, M. (1998): Faunistical data on dragonflies (Odonata) from the geographical region Tisza-Bodrog-Köze (NE-Hungary). *Studia odonologica hungarica* 4: 5-10. (in Hungarian with English summary). [23 species including *Leucorrhinia caudalis* and *L. pectoralis* could be recorded between 1970 and 1987 in this region.] Address: Dévai, G., Department of Ecology, Kossuth L. University, H-4010 Debrecen, P.O. Box 71, Hungary
1623. Dévai, G.; Miskolczi, M. (1998): Previous faunistical data on dragonflies (Odonata) from the floodplain area of River Tisza between Tiszabercel and Balsa (HNBM Programme, Pilot Project). *Studia odonologica hungarica* 4: 53-63. (in Hungarian with English summary). [24 species are listed from the River Tisza between Tiszabercel and Balsa.] Address: Dévai, G., Department of Ecology, Kossuth L. 1624. Dévai, G.; Szilagyi, G.; Kiss, B.; Olajos, P. (1998): Proposal for the unification of locality names in the floodplain area (HNBM Programme, Pilot Project) of River Tisza between Tiszabercel and Balsa (NE-Hungary). *Studia odonologica hungarica* 4: 99-110. (in Hungarian with English summary). ["A proposal in order to unify the usage of locality names during the preparatory works of the biotic data collection in the Pilot Project area of the Hungarian National Biodiversity Monitoring (HNBM) Programme is introduced. Experiences of the development of the Natural Wildlife Information System as well as that of the Hungarian Odonatological Database and the National Biodiversity-monitoring System have proven, that besides the identification of sampling sites by geo-coordinates it is necessary to indicate the topographical names of them as well. [...]."] (Authors)] Address: Dévai, G., Department of Ecology, Kossuth L. University, H-4010 Debrecen, P.O. Box 71, Hungary
1625. Eda, S. (1998): Annual meeting of the Japanese Society for Odonatology in 1998. *Tombo* 41: 63. (in Japanese with English translation of the title.) Address: Eda, S., Matsumoto Dental University, Gobara, Hirooka, Shiojiri, Nagano 399-0781, Japan
1626. Eda, S. (1998): Dragonflies on stamps in the world, 14th report. *Tombo* 41: 55-58. (in Japanese with English translation of the title.) Address: Eda, S., Matsumoto Dental University, Gobara, Hirooka, Shiojiri, Nagano 399-0781, Japan
1627. Englund, R. (1998): Response of the orangeblack Hawaiian damselfly (*Megalagrion xanthomelas*), a candidate threatened species, to increases in stream flow. *Bishop Museum Occasional Papers* 56: 19-24. (in English). [Although formerly one of the most common damselflies in the Hawaiian Islands, USA the O'ahu populations of *M. xanthomelas* have been reduced to little more than 95 m of stream habitat located within the Tripler Army Medical Center (TAMC). Because of continued stable stream flow, the damselfly numbers increased from May 1997 (17 males and two females) to a total in February 1998 of 162 damselflies (123 males and 39 females). Besides drying up of the channel, introduced fishes are the major threat for *M. xanthomelas*.] Address: Englund, R., Hawaii Biol. Survey, Bishop Mus., 1525 Bernice St., Honolulu, HI 96817, USA
1628. Fischer, J.; Fischer, F.; Schnabel, S.; Wagner, R.; Bohle, H.W. (1998): Die Quellfauna der Hessischen Mittelgebirgsregion. Besiedlungsstruktur, Anpassungsmechanismen und Habitatbindung der Makroinvertebraten am Beispiel von Quellen aus dem Rheinischen Schiefergebirge und der osthessischen Buntsandsteinlandschaft. In: Botsaneau, L. (Ed.): *Studies in Crenobiology*. Backhuys Publishers. Leiden: 181-199. (in German with English summary). [*Thecagaster bidentata* is recorded from the spring of the brook Ohe, a secondary tribute of the middle range of River Lahn (Hessen, Germany).] Address: Bohle, H.-W., Fachbereich Biologie - Zoologie, Karl-von-Frisch-Str., D-35032 Marburg, Germany.
1629. Futahashi, R.; Araki, Y. (1998): Successive invasion and colonization of Odonate species into reclaimed land Koshino-kata. Shinminato City. Toyama Pref. (Addition). *Tombo* 41: 32. (in Japanese with English summary). [*Indolestes peregrinus* (Ris, 1916), *Anax nigrofasciatus nigrofasciatus* Oguma, 1995, *Anax guttatus* (Burmeister, 1839), *Epithea marginata* (Selys, 1883), *Sympetrum pedemontanum elatum* (Selys, 1872), *Sympetrum risi risi* Barteneff, 1914, and *Sympetrum croceolum croceolum* (Selys, 1883) were newly added to the fauna of the reclaimed land Koshino-kata, Shinminato City, Toyama Pref. A total of 38 species have been recorded from this land since 1988.] Address: not stated
1630. Gupta, A.; Gupta, S. (1998): Sensilla on the antenna and leg of the larvae of *Crocothemis servilia* (Drury) (Anisoptera: Libellulidae). *Fraseria* (N.S.) 5: 29-32. (in English). ["Major sensillar types on the antenna and leg of the larva of *Crocothemis servilia* [...] are described with the help of scanning electron microscopy. The 7-segmented antenna has sensilla campaniformia, sensilla trichoidea and hemispheroidal cuticular protuberances. The coxa and trochanter of each leg have hairplate proprioceptive sensilla some of which

may be bimodal in function. The 'tibial comb' comprises polydentate sensilla chaetica, which are also present along the outer tarsal margin. Besides, the tarsus also has sensilla trichoidea of two distinct types." (Authors)] Address: Gupta, A., Department of Ecology, Assam University, Silchar, 788 011, India

1631. Hayford, B.; Herrmann, S.J. (1998): Migration patterns of four macroinvertebrates along a thermal spring rheocrene. In: Botosaneanu, L. (Ed.): Studies in crenobiology: The biology of springs and springbrooks. Backhuy Publishers. Leiden. ISBN 90-73348-04-8.: 75-83. (in English). ["We studied migration patterns of *Argia vivida* [...], *Hyalella azteca* Saussure (Crustacea, Amphipoda), *Paracymus* sp. (Coleoptera, Hydrophilidae), and *Chimarra utahensis* Ross (Trichoptera, Philopotamidae) along the thermal gradient of Poncha Hot Spring (T48N, R8E, S15), Colorado, U. S. A. Samples were taken once each month from September 1991 through February 1992. Chemical analyses revealed moderate ion concentrations for a thermal spring, with little variation along the rheocrene. Conductivity remained relatively constant, while pH ranged from 7.9 to 8.5. Temperatures ranged from 22 °C to 42 °C over the six month period. Two-way ANOVAs were used to determine migration. *Argia vivida*, *H. azteca*, and *Paracymus* sp. migrated" [towards the spring source, but no clear pattern of movement and no apparent temperature preference along the rheocrene; "However, decreasing water temperatures below the study area represented an environmental pressure pushing *A. vivida* upstream"] "for a portion of the study period. There was only marginal evidence that *C. utahensis* migrated. Migration patterns were interpreted as a form of behavioural thermoregulation." (Authors)] Address: Hayford, Barbara, Kansas Biol. Survey, 2041 Constant Ave., Lawrence, KS 66045, USA

1632. Hiratsuka, K. (1998): An ethological study on the genus *Sympetrum* at Harutori lake, Kushiro City. Bulletin of the Hokkaido Odonatological Society 10: 1-9. (in Japanese). [*Sympetrum striolatum* imitoides, *S. frequens*, *S. flaveolum*, *S. danae*; maturation period; interspecific relations during the immature period; searching for females and mating; oviposition; post-reproduction period. (taken from DJOSC 9)] Address: Hiratsuka, K., 2-20-113, Honcho 2 jo-9, Higashi-ku, Sapporo City, 065-0042, Japan

1633. Hunger, H. (1998): Biozöologische Untersuchungen zum Habitatschema der Pokal-Azurjungfer (*Cercion lindenii* Selys 1840) in der südlichen Oberrheinebene. Naturschutz am südlichen Oberrhein 2: 159-166. (in German, with English summary). ["[...] In the study area, *C. lindenii* is a common damselfly species occurring predominantly in quite large waters characterized by ground water influence or slow current. These waters usually display buffered seasonal and diurnal changes of water temperature. The water temperature, however, always reaches high values in shallow regions during the summer. In the southern Upper Rhine plains, *C. lindenii* is a typical species of gravel pits on the one hand and river arms and oxbows on the other hand. It has the ability to utilize parts of helophytes or floating debris for oviposition when hydrophyte vegetation misses or is very scarce. Submerged parts of hydrophytes can become available for oviposition because of the female's ability to lay their eggs under water. Therefore, it can thrive in young gravel pits as well

as in angling ponds kept almost free of water vegetation. In such waters, single water plants may play an important role for oviposition. *C. lindenii* tolerates stronger wave action than *Erythromma viridulum*. This might be explained by a relatively lower risk during emergence owing to *C. lindenii*'s preference for vertical structures for emergence. However, the species is also capable of emerging horizontally." (Author)] Address: Hunger, H., Institut für Naturschutz und Landschaftsanalyse (INULA), Am Pfahlgraben 8, D-79276 Reute, Germany

1634. Hunger, H. (1998): Biozöologische Untersuchungen zum Habitatschema des Kleinen Granatauges (*Erythromma viridulum* Charpentier 1840) in der südlichen Oberrheinebene. Naturschutz am südlichen Oberrhein 2: 149-158. (in German, with English summary). ["[...] In the study area, *E. viridulum* inhabits different types of stagnant waters such as ponds and gravel pits as well as areas of oxbows with slowed water movement. Waters suitable for reproduction have to be furnished with fine-leaved submerged vegetation which is probably required as larval habitat. These hydrophytes have to reach the surface at least partly and during a certain period of time in order to be available as substrates for oviposition and as emergence sites. Hydrophytes with swimming leaves can occur in addition, whereas pure waterlily vegetation is not sufficient. Other limiting factors for colonization of waters by this holomediterranean damselfly species are insufficient warming of the water during the summer, strong inflow of ground water or surface water, and wave action. Waters which are ice-free during the winter are usually too cool during the summer to be used as reproduction habitats by *E. viridulum*. Protection of the water vegetation - threatened by strong fishing or leisure activities (swimming, boating) is the most important measure for protection of *E. viridulum*." (Author). Baden-Württemberg, Germany] Address: Hunger, H., Institut für Naturschutz und Landschaftsanalyse (INULA), Am Pfahlgraben 8, D-79276 Reute, Germany

1635. Inoue, K.; Aiura, M. (1998): Distribution of the dragonflies of Tsushima Island, Nagasaki Prefecture, Part 6. Tombo 41: 46-48. (in Japanese with English summary). ["Many immature males and females of *Sympetrum depressiusculum* and *S. cordulegaster* have been found in Tsushima Island during June 6 to September 27, 1998 rather successively. This fact strongly suggests that these northern species emerged there, though neither larvae nor exuviae have been found. Three males and four females of the latter species collected by Aiura on September 20 were sent in cool condition to Inoue, and they started to fly when placed at the room temperature. They were photographed and measured, and revealed to be of the normal size: not so large as those bred from eggs by the late Dr Obana in Osaka Pref. (Obana and Inoue, 1982). The problem why such postponed emergence occurred is left to be discussed. On the other hand, southern species *Anax guttatus* and *Tramea transmarina euryale* were found. It is to be noted that many fresh insects of the former species were found even on September 1 and 3, 1998." (Authors)] Address: Inoue, K., 5-9 Fuminosato 4-chome, Abeno-ku, Osaka 545, Japan

1636. Inoue, K. (1998): Information on the S.I.O.. Tombo 41: 62. (in Japanese with English translation of the title.) Address: Inoue, K., 5-9 Fuminosato 4-chome, Abeno-ku, Osaka 545, Japan

1637. Ishizawa, N. (1998): Adaptability of male *Anax guttatus* to the environment of Honshu in autumn. *Tombo* 41: 13-16. (in Japanese with English summary). [Twenty males of *A. guttatus* were collected at Omori pond in Iruma City, Saitama Prefecture, Japan in the middle of October. 1998. The mean weight of the dragonfly was 1.18 ± 0.07 g. The thoracic length, and lengths of abdomen, forewing and hindwing were longer than that of *A. parthenope julius*. The relative wing loading of *A. guttatus* was larger than that of *A. parthenope julius*. Therefore, *A. guttatus* flew faster without gliding, while sympatric *A. parthenope julius* often glided during flying. The warm-up rate was $2.1^\circ\text{C}/\text{min}$, less than half of that of *Anax concolor*. The body temperature of the initiation of flight was 35.5°C , which was lower than that of *A. junius*. Mean body temperature of patrolling *A. guttatus* was $40.4 \pm 1.1^\circ\text{C}$, higher than air temperature by about 14°C . The high body temperature in flight seems to be due to the large relative wing load and the lower air temperature in the temperate zone. Males of *A. guttatus* showed a reversible colour change, controlled by temperature. The blue of the dorsal parts of the second and third abdominal segments changed to dark blue with decreasing temperature, and the reverse colour change occurred when temperature increased. Based upon these facts it is considered that *A. guttatus* seems to be able to adapt to the environment of Honshu in autumn.] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozavva City, Saitama Pref., Japan
1638. Johnson, P. (1998): Scissor-tailed flycatcher in Peach County, Georgia. *Oriole* 62(3-4) (1997): 46-47. (in English). [The bird perched on a power line above a small horse pasture and "caught a variety of insects, including some dragonflies."] Address: Johnson, P., 901 Santa Fe Trail, Macon, GA 31220, USA
1639. Kagimoto, B. (1998): Some observations on the two cases of heterospecific tandem between *Orthetrum albistylum speciosum* male and *O. poecilops miyajimaense* female. *Tombo* 41: 50-51. (in Japanese with English translation of the title.) Address: not stated
1640. Kalaskar, K.; Kalaskar, A.S. (1998): Odonate wealth of Pench National Park, Maharashtra State, India. *Fraseria* (N.S.) 5: 33-35. (in English). [The Pench National Park is rich in odonate fauna. Large number of spp belong to only two families, Coenagrionidae with 7 spp and Libellulidae with 13 spp. *Ceriagrion coromandelianum*, *Ischnura aurora*, *Orthetrum sabina*, *Crocothemis servilia*, and *Diplocodus trivialis* occur regularly throughout the year. Identification of odonates of other families is in progress.] Address: Kalaskar, A.S., Divisional Forest Officer, Maharashtra Forest Department, Chandrapur Maharashtra State, India
1641. Kanou, K.; Miyahata, T.; Okazaki, K.; Kobayashi, F. (1998): Sperm transference by *Chlorogomphus brunneus costalis* Asahina before tandem formation. *Gekkan-Mushi* 333: 39-40. 10-VI-1997, Materiya, Amami-oshima Island, Japan] Address: Kanou, K., 5-19-17-01, Koishikawa, Bunkyo-ku, Tokyo, 112-0002, Japan
1642. Kato, S. (1998): A fresh female of *Lyriothemis pachygastra* wateched at Tochigi Pref. in late autumn. *Tombo* 41: 58. (in Japanese with English translation of the title.) Address: not stated
1643. Kato, T. (1998): New record of *Sympetrum fonscolombei* from Aichi Prefecture. *Tombo* 41: 18. (in Japanese with English translation of the title). Address: not stated
1644. Knott, B.; Jasinska, E.J. (1998): Mound springs of Australia. In: Botosaneanu, L. (Ed.): *Studies in Crenobiology. The biology of springs and springbrooks*. Backhuys Publishers. Leiden. ISBN 90-73348-04-8: 23-38. (in English). ["The present state of knowledge of mound springs in Australia is reviewed. Points of groundwater discharge, characterised by mounds of peat or calcarenite about the spring boil, they function as mesic refuges for plants and animals in an arid landscape. [...] In terms of the mound spring fauna, results of distributional surveys and physiological tolerance tests of a number of fish and hydrobiid molluscs show that even species endemic to springs with nearly constant physicochemistry tolerate a wide range of temperatures and salinities. The origins and mechanisms of dispersal of the fish and hydrobiid snails from the springs are also addressed. [...] The Ellenbrook mound springs are raised peat structures and occur only in a restricted area but comprise discrete plant and animal communities which include endemic species and northern outlier populations of mesic species which now occur only in the wetter southwest of Western Australia. The conservation of all Australian mound springs is under threat from three principal causes: groundwater abstraction from their source aquifers; physical destruction either by land-clearing or cattle-grazing; and invasion of exotic plant and animal species." (Authors) Odonata are listed in Tab. 1 on the family level as a spring fauna (Lake Eyre Supergroup) of high vagility which also occurs in temporary waters.] Address: Knott, B., Jasinska, Edyta, Department of Zoology, The University of Western Australia, Nedlands, Western Australia 6907
1645. Kohl, S. (1998): Odonata. Anisoptera-Exuvien (Großlibellen-Larvenhäute) Europas. Bestimmungsschlüssel. Privately published. 27 pp. (in German). [This is a well organised determination key for the exuviae of most of the anisopteran Odonata of Europe; species not included in this key are listed on page 7. It compiles the relevant European literature up to 1998 on the morphology of the anisopteran exuviae, and provides a binomical key with figures of the morphological structures. Identifications are made easy by the arrangement of discriminative characters on one page opposite to each other. This synthesis of the work of many experienced odonatologists is definitely the most useful and cheapest determination key on the European anisopteran exuviae at present on the market.] Address: Kohl, S., Seestr. 107, CH-8610 Uster, Switzerland
1646. Kumar, A.; Mitra, A. (1998): Odonate diversity at Sahstradhara (Sulphur springs) Dehra Dun, India with a note on their habitat ecology. *Fraseria* (N.S.) 5: 37-45. (in English). ["A detailed study on the Odonate diversity at Sahastradhara (Sulphur Springs, alt 700 m), a perennial hill stream situated 13 km away from the city, has been made during the years 1996-98. An annotated list of 50 species from the area has been provided along with their habitat ecology. *Lestes praemorsus*, *Anormogomphus heteropterus*, *Nepogomphus modestus*, *Orthetrum b. brunneum*, *O. glaucum*, *O. japonicum internum* Mac Lachlan, and *Neurothemis intermedia* more recently listed by Singh & Prasad and Prasad

- & Singh, and *Gynacanthaeschna sikkima* (Karsch) recorded by Hämäläinen from this locality, could not be recorded during the present study. This may probably be due to their habitat degradation/loss by the increasing anthropogenic pressures the excessive influx of tourists and creation of hotels and tea shops in vicinity of the stream. However, *Ceriagrion fallax cerinomelas* Lieftinck, *Onychogomphus biforceps* (Selys) and *Anax nigrofasdatus nigrolineatus* Fraser are the 3 species recorded for the first time not only from this locality but also from the Dehra Dun Valley itself, whereas *Copera vittata serapica* (Selys), although previously reported from Dehra Dun Valley, is recorded for the first time from this locality." (Authors)] Address: Kumar, A. & A. Mitra, Northern Regional Station, Zoological Survey of India, Dehra Dun - 248 195, India
1647. Lahiri, A.R. (1998): New records of Odonata (Insecta) from little Andaman Island. *Fraseria* (N.S.) 5: 57-59. (in English). [Commented checklist of 28 odonate species recorded from an artificial lake in 740 m a.s.l. near Combrailles, France.] Address: Leroy, T., Le Bourg, F-63210 Heume-L'Église, France
1650. Matsuki, K. (1998): Description of the larva of *Neurothemis tullia tullia* obtained from Taiwan (Libellulidae). *Tombo* 41: 29-31. (in Japanese with English summary). [Detailed description of *N. tullia*; comparison with *N. stigmatizans braminea*] Address: Matsuki, K., 1575-14, Funabashi, Japan
1651. Matsuki, K. (1998): Records of the activities of Conservation committees: "*Libellula angelina*" group. *Tombo* 41: 59-60. (in Japanese with English translation of the title.) Address: Matsuki, K., 1575-14, Funabashi, Japan
1652. Matsuki, K. (1998): Threatened dragonfly species in Japan. *Nature and Insects* 33(10): 2-3. (in Japanese). [General introduction into the current activities in Japan to protect dragonflies. *Mortonagrion Hirosei*, *Libellula angelina*, and *Mnais pruinosa costalis-forma edai* (the latter threatened by over-collecting!) are commented shortly. In a tab. Japanese species listed in the Red Data Book of Odonata are compiled. *Sympetrum maculatum* will be added to the Red Data Book. (see DJOSC 10).] Address: Matsuki, K., 3-1575-14, Hazama, Funabashi City, Chiba Pref., 274-0822, Japan
1653. Mitra, T.R. (1998): Development of Indian Odonatology. *Fraseria* (N.S.) 5: 9-14. (in English). ["The first Odonata species based on Indian materials was *Rhyothemis variegata* (Linné). It was recorded from East India in 1768 by Johannson. Since 1768 till date 494 species and subspecies have been recorded from India (political area). In 1933, 1934 and 1936 F.C. Fraser published three volumes of Fauna of British India, including Ceylon and Burma. In post-Independent India, taxonomy, morphology, anatomy, ecology, neuroendocrinology, reproductive biology, physiology, cytology and various aspects of behaviour and applied significance are being studied. In advancement of Indian Odonatology, Zoological Survey of India played a pioneer role all the while. The SIOROSA (Societas Internationalis Odonatologica, Regional Office South Asia) is indeed, a source of communication, transaction and inspiration." (Author)] Address: Mitra, Tridib Ranjan, Zoological survey of India, 18/L Dakshin Para Road, Calcutta 700 028, India
1654. Nakahara, M. (1998): The difference of the larval period of *Oligoaeschna pryeri*, hatched from eggs of the same female. *Tombo* 41: 48-49. (in Japanese with English summary). ["In May, 1992, I got about 400 eggs laid by a female of *Oligoaeschna pryeri* (Martin) into wet paper in a vessel." During a period between 40 and 65 days after oviposition, 184 larvae hatched. After rearing in the laboratory, only 2 adults emerged in May, 1993, and 7 adults emerged in April, 1994. ["It seems to be very interesting that there is a difference in the larval period, one year and two years, among the larvae hatched from eggs laid by the same female even in a laboratory condition." (Author)] Address: not stated
1655. Naruse, K.; Eda, S. (1998): The first record of *Aeshna nigroflava* from Chiba Pref.. *Tombo* 41: 43. (in Japanese with English summary). [Record of this - in Japan - alpine distributed species at Ichikawa city adjacent to the Tokyo metropolis on 21 August, 1998] Address: Eda, S., Matsumoto Dental University, Gohara, Hirooka, Shiojiri, Nagano 399-0781, Japan.
1656. Ogata, Y. (1998): An investigation on *Calopteryx atrata* in the Yonezawa basin, Yamagata Pref., by a citizens' activity. *Tombo* 41: 41-43. (in Japanese with English translation of the title.) Address: not stated
1657. Olsvik, H.; Hungnes, T. (1998): *Kongeoyensikker* (Odonata) funnet på Vestlandet. *Insekt-Nytt* 15(3): 3-4. (in Norwegian). [Norway, *Cordulegaster boltonii*] Address: Olsvik, H., N-6694 Foldfjorden, Norway. E-mail: haolsvik@frisurf.no
1658. Paulson, D.R.; Minakawa, N.; Gara, R.I. (1998): Recent collections of Odonata from the Kuril Islands. *Species diversity* 3: 75-80. (in English). ["17 species of Odonata were collected in 1994-1996 from 21 localities in the Kuril Islands. *Mnais pruinosa*, *Aeshna nigroflava*, *Cordulia aenea*, and *Pseudothemis zonata* are first records from the archipelago, and the last species represents a significant range extension from Honshu. *Enallagma belyshevi* is synonymized with *E. circumlatum*, which is considered a valid species rather than a subspecies of *E. boreale*." (Authors) *Libellula quadrimaculata asahinai* Schmidt, 1957 is considered a poorly differentiated subspecies.] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dpaulson@ups.edu

1659. Pirnat, A. (1998): Fauna and ecology of dragonflies (Odonata) at Ljubljana Moor. M.Sc. Thesis, University of Ljubljana, Biotehniška Fakulteta, Oddelek za Biologijo: 92 pp. (in Slovene with English summary). [The odonate fauna of the Ljubljana Moor, situated in central Slovenia, was surveyed in detail. At 126 localities 32 species were recorded of which 27 species are reproducing successfully. The odonate fauna of each of the localities is documented in detail. The species are detailed in a monographic way, the odonate communities of the drainage ditch system are analysed, the conservation value of the Odonata of the region is assessed, and management measures of the ditch system are suggested.] Address: Pirnat, Alja, Vosnjakova 4a, SI-1000 Ljubljana, Slovenia. E-mail: alja.pirnat@guest.arnes.si
1660. Plantinga, J.-E. (Red.) (1998): De Südheide in vogelvlucht. Waarnemingen van de Lüneburg kampen 1998. *Amoeba*, Amsterdam 72(3): 140-146. (in Dutch). [19 localities of the heathlands in the Lüneburg-region (Niedersachsen, Germany) were surveyed for different groups of flora and fauna including Odonata. Antoine van der Heyden and Laurens Sparrius traced 38 species including *Ceriagrion tenellum*, *Ophiogomphus cecilia*, *Somatochlora arctica*, *S. flavomaculata*, *Orthetrum brunneum*, *O. coerulescens*, and *Sympetrum depressiusculum*.] Address: Sparrius, L., Kongsbergstraat 1, NL-2804 XV Gouda, The Netherlands
1661. Rai, T. (1998): 1998 observations on the emergence-season of *Sympetrum frequens* at Narashino, Chiba Pref.. *Tombo* 41: 51. (in Japanese with English translation of the title.) Address: not stated
1662. Roy, S.P. (1998): Energetics and trophic biology of larval odonates with special reference to their role in the management of aquatic ecosystem. *Fraseria* (N.S.) 5: 47-56. (in English). ["The present paper deals with the seasonal variations in the energy contents, productivity in terms of grams/m²/day/month/year, food and feeding biology and foraging ratio (FR) of *Mesogomphus lineatus*, *Cordulegaster* sp., and *Ischnura* sp. of a fish pond of Bhagalpur (Bihar, India). The maximum calorific values of *M. lineatus* Selys and *Cordulegaster* sp. (5.487 ± 0.003 Kcal/gram dry weight and 5.430 ± 0.00 Kcal/gram ash-free dry weight) was recorded in September. However, the minimum calorific value (4.133 ± 0.09 Kcal/gram dry weight) was recorded in January. The calorific values of *Ischnura* sp. (3.706 ± 0.032 Kcal/gram dry weight and 3.470 ± 0.034 Kcal/gram ash-free dry weight) was measured. It was investigated that the calorific values of these larvae varied from instar to instar, month to month and upon the physiological state of the animals. The annual productivity was measured as 2.414 g. dry wt./cub. met/year with monthly productivity being 0.210 g. dry wt./cub. met/ month. The gut content analysis of the larval odonates revealed that the Rotifera, Cladocera, Rhizopoda and aquatic insects form the maximum percentage of food items in *Ischnura* sp. but in *M. lineatus* Selys and *Cordulegaster* sp. Rhizopoda were recorded in very small quantity and other food items such as Rotifera, Cladocera, Copepoda, aquatic insects and other animal tissues were found in maximum percentage in the foregut. Due to the utilization of food present at various trophic levels of the food chains, they have regulatory impact in the management of the aquatic ecosystems as well as their mere presence indicates healthy and non-contaminated environments." (Author)] Address: Roy, S.P., University Department of Zoology, T. M. Bhagalpur University, Bhagalpur - 812 007, India
1663. Sawano, J.; Itani, Y.; Zhi-Hui Su; Osawa, S. (1998): Evolutionary distance between *Orthetrum poecilops poecilops* and its subspecies *O. p. miyajimaense*. *Tombo* 41: 28. (in Japanese with English summary). ["The difference of mitochondrial COI gene sequence between *Orthetrum poecilops poecilops* Ris from Hongkong, China and *O. p. miyajimaense* Yuki et Doi from Miyajima, Japan was very small, suggesting that the Miyajima population is a relic of what invaded Japan from south-east China fairly recently." (Authors)] Address: not stated
1664. Schiel, F.-J. (1998): Zur Habitatbindung der Becher-Azurjungfer (*Enallagma cyathigerum* Charpentier 1840) (Odonata: Zygoptera) am südlichen Oberrhein. *Naturschutz am südlichen Oberrhein* 2: 139-147. (in German, with English summary). ["In 1994 and 1995 the habitat requirements of *E. cyathigerum* were investigated at 28 water bodies located in the Upper Rhine valley and additionally in the northern Black Forest (South-west Germany). In the investigated area, *E. cyathigerum* breeds exclusively in still waters at an early stage of succession. 42 % of the examined waters are distinguished by hydrophyte vegetation typical for oligo- to mesotrophic conditions (e.g. *Utricularietum australis*, *Charetum hispidae*, *Eleocharitetum acicularis*). In a quarter of the investigated localities submerged vegetation is missing completely and in the last third eutrophic hydrophytes only cover small ranges. In only a few water bodies floating vegetation (e.g. *Nuphar lutea*) is developed to a very small extent. Though *E. cyathigerum* does not depend on a special type of reed vegetation, a minimum coverage of vertical vegetation structures on the shoreline is regarded as an essential habitat element for this species. *E. cyathigerum* needs a certain minimum size of open water; the smallest water body bearing a large population has a size of 80 m². All other measured morphological, physical and hydrochemical parameters do not influence the occurrence of the species. In most waters fish are abundant." (Author)] Address: Schiel, F.-J., Institut für Naturschutz und Landschaftsanalyse (INULA), Friesenheimer Hauptstr. 20, D-77948 Friesenheim, Germany
1665. Schiel, F.-J. (1998): Zur Habitatbindung des Großen Granatauges (*Erythromma najas* Hansemann 1823) (Zygoptera: Coenagrionidae) am südlichen Oberrhein. *Naturschutz am südlichen Oberrhein* 2: 129-138. (in German, with English summary). ["In 1994 and 1995 the ecological requirements of *E. najas* were studied at 24 waters located in the Upper Rhine valley. Floating water vegetation (*Nuphar lutea* and/or *Nymphaea alba*) provides the most important structural resources for *E. najas*, because the single leaves of the water lilies are preferred as perches by the males and the blossom stalks by the females for oviposition. If there exists a submerged vegetation layer, which can be utilized for oviposition, water lily-leaves can be replaced structurally by freely floating pleustophytes such as *Hydrocharis morsus-ranae*. Other plants play a minor role for *E. najas*, despite a minimum of reed vegetation in the border line is needed. The minimum size of the investigated standing waters covers 100 m². All waters are shallow with maximum depths between 2 and 4 meters and a mostly mighty muddy ground. Most breeding sites are

- oxbows located within or very close to forest. In 1994 and 1995 the observed changes in water levels were up to 2.3 meters high. Hydrochemically the waters are characterized by pH-values between 7.2 and 8.3, a total hardness between 8.8 and 17.6°dH and a conductivity between 280 and 705 $\mu\text{S} / \text{cm}$. Remarkably high is the nymph's tolerance to low oxygen levels (down to a 2 % concentration measured at the water surface). Habitat requirements, threats and protection are discussed. (Author)] Address: Schiel, F.-J., Inst. Naturschutz und Landschaftsanalyse, Friesenheimer Hauptstr. 20, D-77948 Friesenheim, Germany. E-mail: Jupp@INULA.de

1675. Takasaki, Y. (1998): Dragonflies of the projected site of the exposition at Seto City, Aichi. *Kakocho* 50(195): 33-42. (in Japanese). [Assessment of the dragonfly fauna of the area the EXPO 2005 is scheduled to be realised. 66 species correspond to app. 70% of the species so far observed in Aichi Prefecture. (for more details see DJOSC 10).] Address: Takasaki, Y., 1-14, Fujimori, Myoto-ku, Nagoya City, 465-0026, Japan
1676. Tembhare, D.B. (1998): Odonate ovary and vitellogenesis. *Fraseria* (N.S.) 5: 15-18. (in English). ["The female reproductive system in Odonata consists of a pair of ovaries and a post ovarian genital complex. The system is well-developed in the newly emerged adult female. Each ovary consists of large number of panoistic type of ovarioles. Oogenesis is initiated in the larval stage while vitellogenesis starts after the emergence of adult female. The process of vitellogenesis

passes through five consecutive stages, pre-vitellogenic, early-vitellogenic, mid-vitellogenic, late-vitellogenic and maturation. Yolk deposition starts from the early to late vitellogenic stages while the egg-membranes are formed during the late-vitellogenic and maturation stages. During vitellogenesis, the developing oocytes grow gradually and the follicular epithelium shows cytological modifications. The yolk material is composed of protein, carbohydrate and lipid. It is transported from haemolymph into the vitellogenic oocytes. The egg membranes are secreted by the follicular epithelium. The medial A neurosecretory cells of the brain and the corpora allata play important role during vitellogenesis. The histochemical evidence of steroidogenesis in odonate ovary producing ovarian hormone is quite obvious. Hormonal control of vitellogenesis has been discussed." (in Japanese with English summary). *Anotogaster sieboldii*, *Polycanthagyna melanictera*, *Orthetrum albistylum speciosum*, *Pseudothemis zonata*, and *Pantala flavescens* are recorded in 1998 from the Nij-jima Islands.] Address: not stated

1999

1688. Akaishi, S.; Yokoyama, T. (1999): A record of the forty first odonate species at Nishioka reservoir, Sapporo city. Bulletin of the Hokkaido Odonatological Society 11: 9. (in Japanese). [*Somatochlora viridiaenea*] Address: not translated

1689. Artiss, T. (1999): Molecular phylogenetic analyses of the odonate genera *Libellula*, *Ladona* and *Plathemis*. *Argia* 11(4): 8-12. (in English). ["There are three important conclusions from this study. (1) The genus *Orthemis* is traditionally distinguished from *Libellula* on wing venation characters. However, my results indicate that the monophyly of *Libellula* was not supported, and *Orthemis ferruginea* was found to be part of *Libellula* s.l.. I employed statistical tests to determine whether this tree was significantly different from trees where *Orthemis* was constrained to be an outgroup to *Libellula* s.l.. There were no significant differences in these trees. Given the indecisiveness of the molecular data on this point, I suggest that, because it is conventionally favored by morphological data, we should continue to accept the current hypothesis of *Libellula* monophyly and a corresponding outgroup position for *O. ferruginea*. However, I caution that traditional classification of these taxa may be based on potentially homoplastic (similarities not due to common ancestry) characters, and suggest that further research is needed to assess the natural delineations of taxa in these groups. (2) The results of my study indicate that *Plathemis* and *Ladona* are distinct monophyletic lineages within *Libellula* s.l.. My results indicate that *Plathemis* forms the basal sister group to the remainder of *Libellula* s.l., and that *Ladona* is the next most basal clade within the *Libellula* lineage. All three analytical approaches supported the monophyly of *Plathemis* and *Ladona*, and there was strong quantitative support (bootstrap values >90%) for these groups. Bootstrap values indicate the percent support for clades based on the randomization tests (a bootstrap value of 100 indicates that clade was supported in 100% of randomization tests). These results therefore support the original classification proposed by Needham (1897) in regard to the delineation of natural groups, with the exception that *Libellula depressa* and *Libellula fulva* would both need to be included within *Ladona* s.l. were it accorded generic or subgeneric status. Based on my results, I propose that the separate generic or subgeneric ranks be adopted for *Plathemis* and *Ladona* within *Libellulidae*; a conclusion that was supported by a previous molecular phylogenetic study on these groups (Kambhampati and Charlton 1999). (3) Phylogenetic relationships within *Libellula* s.s. generally supported the subgeneric classifications of Kennedy (1922 a,b). While Kennedy proposed that *L. angelina*,

semifasciata and *quadrifasciata* were separate subgenera, I found strong support for these species forming a monophyletic clade. I also found support for the subgenera *Neotetrum* (*forensis*, *pulchella*, *nodistica*), *Belonia* (*foliata*, *saturata*, *croceipennis*), and *Holotania* (*axilena*, *composita*, *jesseana*, *flavida*, *auripennis*, *luciosa*, *cyanea*, *comanche*, *incesta*, *vibrans*). The only exception to Kennedy's classification was *L. composita* which he assigned to *Holotania*, but I found to be part of, or sister taxon to *Belonia*." 1690. Batzer, D.P.; Rader, R.B.; Wissinger, S.A. (Eds) (1999): *Invertebrates in Freshwater Wetlands of North America*. John Wiley & Sons, New York. ISBN 0-471-29258-3: 1100 pp. (in English). ["This volume provides an excellent overview of the different wetland types of North America and their characteristic invertebrate communities. It is the most comprehensive book in existence on this topic, consisting of 41 chapters, written by 87 authors, who collectively address a range of different wetland types. The book covers marshes, peatlands, wetland forests and restored/man-made wetlands, with the main focus on marshes and temporary pools and ponds. Although the book is entitled 'Invertebrates in freshwater Wetlands of North America', it primarily deals with wetlands in the conterminous U.S.A. Alaska's wetlands are not considered, although they make up 62% of the present wetlands of the U.S.A. Canada has about three times the area of wetlands found in the lower 48 states, with most of the area covered by peatlands. One chapter on Canadian springs, two chapters on peatlands, and three chapters on the well-studied Delta-Marsh in Manitoba cover Canadian wetlands. [...] As many of the wetlands discussed are temporary, specific attention is devoted to life history and colonization strategies of invertebrates (e.g. chapters 14 and 15). It was shown that species richness normally increases with the duration of the hydroperiod, but an extended inundation period can also be a disturbance to some wetland invertebrates, as demonstrated for limesink wetlands in southeast U.S.A. (chapter 9). In addition, the invertebrate communities in floodplain pools differ from those in seasonal wetland pools, as fish have access to them during flooding (chapter 29). The large variety of invertebrate and vertebrate predators makes many wetlands unique among freshwater ecosystems (e.g. the Everglades, chapter 2). Most chapters discuss conservation issues and management schemes for individual wetland types and the potential role of invertebrates therein. The book's 41 chapters are organized into six parts that mainly correspond to different geographic regions across North America. It starts with an introductory chapter that provides an overview of North American wetlands, their physicochemical properties, and their characteristic plant and invertebrate communities. Part 1 (chapters 2-11) discusses marshes and swamps of the southeast, ranging from the Florida Everglades [...] to the fascinating life in pitcher plant wetlands. Part 2 introduces woodland ponds, peatlands and marshes of the north and northeast (chapters 12-20). Part 3 presents selected wetlands of the central prairies and the Mississippi River basin (chapters 21-29). Part 4 introduces wetlands of the western mountains, deserts and valleys, including springs and California ricelands (chapters 30-35). Part 5 gives an overview of coastal freshwater wet-

lands, in particular, the bayous of the Gulf of Mexico and coastal wetlands of the Great Lakes. In part 6, Wissinger summarizes the different aspects discussed in the previous chapters, and provides general conceptual models that can help to understand wetland ecosystems better. [...] (Klement Tockner, *Freshwater Biology* 45(1): 103-104). Odonates are mentioned in many chapters of the book. Odonatologist should pay special attention to the chapters 6 (Okefenokee Swamp, Georgia and Florida), 8 (Carolina Bays, North and South Carolina), 10 (Beaver-impounded wetlands of the southeastern coastal plain, Alabama), 15 (Beaver pond wetlands in northwestern Pennsylvania), 17 (Canadian peatlands), 21 (Wetlands of the prairie Pothole region (southern Canada and northern USA), 26 (Playas of the Southern High Plains, Texas), 30 (Wetlands of Grand Teton and Yellowstone National Parks, Wyoming), and 31 (Subalpine Wetlands in Colorado: Habitat Permanence, salamander predation, and invertebrate communities).]

1693. Buczynski, P. (1999): Dragonflies (Odonata) of sandpits in south-eastern Poland. *Acta Hydrobiol.*, *Cracow* 41: 219-230. (in English). ["Dragonflies of sandpits and their succession were studied in 10 sand mines in south-eastern Poland in the years 1996-1998, based mainly on larval communities. 41 species were collected, of which 28 were autochthonous, and 6 probably autochthonous. A rapid succession of larval communities was observed. Many Mediterranean species occurred in the sandpits, of which the most interesting were: *Lestes barbarus*, *Aeshna affinis*, *Hemianax ephippiger*, *Anax imperator*, *Sympetrum fonscolombii*, and *S. meridionale*. Dragonflies inhabiting sand- and gravelpits in Central Europe, and the importance of these secondary biotopes for protection of the endangered dragonflies are briefly discussed." (Author)] Address: Buczynski, P., Dept of Zool., Marie Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

1694. Butler, M.A. (1999): Is evolution in the color vision system of Hawaiian damselflies adaptive or neutral? *American Zoologist* 39(5): 33A. (in English). 1695. Butler, S.G. (1999): Further additions to the knowledge of the fauna of the island of Corfu, Greece. *Notul. odonatol.* 5(3): 25-27. (in English). [In June 1998, 19 species were recorded including *Chalcolestes viridis*, *Anaciaeschna isosceles*, *Anax parthenope*, *Brachytron pratense*, and *Sympetrum meridionale* as new additions to the fauna of the island. The records of *Pyrrosoma elisabethae* Schmidt 1948, *Coenagrion pulchellum*, and *Gomphus schneiderii* should be mentioned too.] Address: Butler, S.G., Red Willow, All Stretton, Shropshire SY6 6HN, UK

1696. Costa, J.M.; De Souza-Franco, G.M.; Takeda, A.M. (1999): Description of the larva of *Diastatops intensa* Montgomery, 1940 and morphology of different instars (Odonata: Libellulidae). *Boletim Museu Nacional Rio de Janeiro, Zoologia* 410: 1-14. (in Portuguese with English summary). [80 males and 40 females "of different instars of *D. intensa* were collected monthly from associations with *Eichornia azurea* and *E. crassipes* at three habitats (Rio Ivinheima Lagoa dos Patos e Lagoa do Guarana), from March 1992 to February 1993. The larvae from Rio Ivinheima, associated with *E. azurea* were used in this study. Sex identification was observed after the 7th instar. Two specimens of the ultimate instar larvae were identified as *D. intensa* through structure of wing pads and by presence of the adults at the same place. Five adults (3 males and 2 females) were collected on only one day during every period and identified as *D. intensa*. The immature form collected in Rio Ivinheima is presented in various stages of growth of the instars including the ultimate instar, from June 1992 to December 1993. The presence of 11 instars was confirmed. Differences observed among the several instars and descriptions of the ultimate instar are presented and compared with the larvae of *D. obscura*." 1705. Eklov, P.; Werner, E.E. (1999): Multiple predator effects on size-dependent behavior and mortality of two species of anuran larvae. *Oikos* 88(2): 250-258. (in English). ["This study examined the effects of multiple predators on size-specific behavior and mortality of two species of anuran larvae. Particularly, we focused on how trait changes in predators and prey may be transmitted to other species in the food web. In laboratory experiments, we examined the effects of bluegill sunfish, *Lepomis macrochirus*, and the odonate larva *Anax junius* on behavior and mortality of tadpoles of the bullfrog, *Rana catesbeiana*, and the green frog *R. clamitans*. Experiments were conducted with predators alone and together to assess effects on behavior and mortality of the tadpoles. The experiments were replicated on five size classes of the tadpoles to evaluate how responses varied with body size. Predation rates by *Anax* were higher on bullfrogs than on green frogs, and both bullfrogs and green frogs suffered greater mortality from *Anax* than from bluegill. Bluegill only consumed green frogs. Predation rates by both predators decreased with increasing tadpole size and decreased in the non-lethal (caged) presence of the other predator. Both anuran larvae decreased activity when exposed to predators. Bullfrogs, however, decreased activity more in the presence of *Anax* than in the presence of bluegill, whereas green frogs decreased activity similarly in the presence of both predators. The largest size class of green frogs, but not of bullfrogs, exhibited spatial avoidance of bluegill. These responses were directly related to the risk posed by the different predators to each anuran species. *Anax* activity (speed and move frequency) also was higher when alone than in the non-lethal presence of bluegill. We observed decreased predation rate of each predator in the non-lethal presence of the other, apparently caused by two different mechanisms. Bluegill decreased *Anax* mortality on tadpoles by restricting the *Anax* activity. In contrast, *Anax* decreased bluegill mortality on tadpoles by reducing tadpole activity. We discuss how the activity and spatial responses of the tadpoles interact with palatability and body size to create different mortality patterns in the prey species and the implications of these results to direct and indirect interactions in this system." (Authors)] Address: Eklov, P., Dept of Ecology and Environmental Science, Animal Ecology, Umea Univ., SE-901 87, Umea, Sweden
1706. Ellenrieder, N. von (1999): Description of the last larval instar of *Aeshna* (*Hesperaeschna*) *cornigera planaltica* (Odonata: Aeshnidae). *Revista de la Sociedad Entomologica Argentina* 58(3-4): 151-156. (in English with Spanish summary). ["The last larval instar of *Aeshna* (*Hesperaeschna*) *cornigera planaltica* Calvert, 1952 (Odonata: Aeshnidae) is here described and compared to its closest allies and other known larvae of this genus from Argentina. It differs from them mainly in the prementum ratio width/length, the shape of prothoracic processes and the relative length of the abdominal lateral spines." 1707. Englund, R. (1999): New records and range extensions of native Odonata (Coenagrionidae) and intro-

duced aquatic species in the Hawaiian islands. Bishop Museum Occasional Papers 59: 15-19. (in English). [Record of *Megalagrion pacificum* believed extirpated from Hawai'i Island in a tributary of Ma'ili Stream without introduced fishes in 1998; probably due to two introduced fish species the damselfly didn't dwell the main stream. *Orthemis ferruginea* was first recorded in 1977 at Hale'iwa, O'ahu; it now appears to be established throughout the Hawaiian Archipelago. The records of the species on Hawai'i are documented.] Address: Englund, R., Hawaii Biol. Survey, Bishop Mus., 1525 Bernice St., Honolulu, HI 96817, USA

1708. Englund, R.A.; Filbert, R.B. (1999): Flow restoration and persistence of introduced species in Waikele Stream, O'ahu. *Micronesica* 32(1): 143-154. (in English). ["Unintentional stream flow restoration in Waikele Stream, O'ahu, Hawai'i resulted from the demise of sugar cane cultivation on O'ahu and subsequent cessation of direct surface water diversions in 1989. Previous artificial stream studies in Hawai'i have suggested that increases in the base flow of a diverted stream would displace or reduce introduced fish populations. Surveys of Waikele Stream, conducted in 1993 and 1997-1998 from the Waikele Springs area downstream to the beginning of the tidal reach found that despite an increase in stream flow, introduced fish remained abundant and native species appeared to have declined. In fact, two new introduced aquatic taxa, a dragonfly and a shrimp, had appeared. These results indicate that although restoring hydrological conditions is an important first step in overall restoration of degraded aquatic ecosystems, flow restoration alone is not a panacea, especially in O'ahu streams with naturally low discharge rates. For stream and wetland restoration to fully succeed, introduced fish and other alien aquatic species must be eradicated by methods other than simply increasing stream base flows. [...] Introduced dragonflies and damselflies dominated the aquatic insect fauna of Waikele Stream. All damselfly species were introduced (Table 2). Native *Megalagrion* damselflies were not observed in lower Waikele Stream in 1993 or 1998. The indigenous dragonfly *Anax junius* was common around Waikele Springs, and the introduced dragonfly *Crocothemis servilia* was absent in 1993, but common in 1998." (Authors) Dates of introduction: 1936: *Ischnura posita*, *Enallagma civile*; 1973: *Ischnura ramburii*; 1977: *Orthemis ferruginea*; 1994: *Crocothemis servilia*.] Address: Englund, R.A.; Filbert, R.B., Hawai'i Biological Survey, Bishop Museum, 1525 Bernice Street, Honolulu, HI, 96817, USA

1709. Ferreras-Romero, M.; Corbet, P.S. (1999): The life cycle of *Cordulegaster boltonii* (Donovan, 1807) (Odonata: Cordulegastridae) in the Sierra Morena Mountains (southern Spain). *Hydrobiologia* 405: 39-48. (in English). ["The life cycle of the dragonfly *Cordulegaster boltonii* was studied for five consecutive years, mainly by systematic sampling of larvae, in a permanent upland stream in southern Spain, towards the southern part of this species' range. The instar distribution during winter is that of a 'spring species' (Corbet, 1964) in which larvae destined to emerge in the next spring are predominantly in the final instar. During larval development a hatching cohort divides into "slow" and "fast" components which respectively complete development in three and two years, the former component predominating. Signs of advanced metamorphosis (in the last larval instar) are confined to late winter and spring. E-

mergence is protracted, there being a long "tail" after most of" the population has emerged, resulting in a long flying season." (Authors)] Address: Ferreras-Romero, M., Departamento de Biología Animal (Zoología), Facultad de Ciencias, Universidad de Córdoba, Avda. San Alberto Magno s/n, E-14004 Córdoba, Spain

1710. Fleck, G.; Nel, A.; Martinez-Delclos, X. (1999): The oldest record of libellulid dragonflies from the Upper Cretaceous of Kazakhstan (Insecta: Odonata, Anisoptera). *Cretaceous Research* 20(5): 655-658. (in English). ["*Palaeolibellula zherikhini* gen. nov., sp. nov. ... is the oldest record of the dragonfly family Libellulidae. This discovery extends the stratigraphic range of the family about 60 my into the past, hence emphasizing the incompleteness of present knowledge of the Mesozoic insect fauna." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrs1.mnhn.fr

1711. Fuchs, H.-J.; Kistner, A. (1999): Die Wüstung Pferdsfeld im Soonwald nach 20 Jahren: eine landschaftsökologische Bestandsaufnahme, Bewertung und Konzeption einer sozial-ökologischen Inwertsetzung. *Mitt. Pollichia* 86: 35-68. (in German with English and French summaries). [The abandoned settlement of Pferdsfeld in the Soonwald after 20 years: an ecological analysis, evaluation and conception for a socio-ecological implementation. - Due to the serious noise impact of the Bundeswehr-airfield Pferdsfeld, Rheinland-Pfalz, Germany, 400 inhabitants decided to resettle voluntarily in 1979, and the village Pferdsfeld closely located to the runway was immediately flattened completely. After the transfer of the phantom-fighter group and the closing of the military airfield of Pferdsfeld in 1997, the abandoned settlement gained in significance. During the last 20 years, a number of outstanding, biologically valuable areas with a very interesting flora and fauna have developed at the place of the former village. These areas have been mapped, characterised and evaluated in the course of an ecological analysis. A detailed concept for a future use of the Pferdsfeld area was worked out. Some common central European Odonata are mentioned.] Address: Fuchs, H.-J., Geographisches Institut, Johannes Gutenberg-Universität Mainz, 55099 Mainz, Germany

1712. Fudalewicz-Niemczyk, W.; Petryszak, A.; Rosciszewska, M. (1999): Cuticular sensory organs of the mouthparts of larvae of the dragonfly *Libellula* (Odonata: Libellulidae). *Acta Biologica Cracoviensia Series Zoologia* 41: 25-33. ["The following types of sense organs were found ...: sensilla trichodea, s. chaetica, s. coeloconica, s. papillacea, s. campaniformia, s. canaliculata, and hair plates. The occurrence and arrangement of sensilla were compared between the larva and imago of the dragonfly. It is suggested that sensilla can be helpful in determining the homology of modified appendages." 1716. Gorb, S.N. (1999): Serial elastic elements in the damselfly wing: Mobile vein joints contain resilin. *Naturwissenschaften* 86(11): 552-555. (in English). ["Two main types of joints occur in the damselfly wing: mobile and immobile. Some longitudinal veins (RP2⁻, RP3&4⁻, and MP⁻) are elastically joined with cross veins, whereas other longitudinal veins (1R1⁺, 1R2⁺, MA⁺, CuA⁺) are firmly joined with cross veins. In this study we mapped the distribution of serial elastic elements in the wing. The occurrence of resilin, a rubberlike protein, in

mobile joints suggests that the automatic twisting mechanism of the leading edge by aerodynamic force works not by flexibility but by the elasticity of these joints. First, it should result in elastic energy storage in the distal areas of the wing. Second, serial elastic elements of wing presumably act as dampers of an aerodynamic force, which are responsible for gradual twisting of the leading edge." (Author) *Enallagma cyathigerum*] Address: Gorb, S., Max-Planck-Institut für Entwicklungsbiologie, Spemannstr. 35, D-72076 Tübingen, Germany. E-mail: stas.gorb@tuebingen.mpg.de

1717. Guiliazova, E.V. (1999): Effects of environmental pollution on the nestling diet of Pied Flycatcher *Ficedula hypoleuca* on the Kola Peninsula, Russia. *Vogelwelt* 120, Suppl.: 371-374. (in English). [Nesting diet differed between the two surveyed sites (heavy and less polluted). Odonata were not preyed but were present in random samples of invertebrates available as potential prey to Pied Flycatchers in frequencies between 1.12 to 3.23 %.] Address: Guiliazova, Elena, Lapland Biosphere Reserve, Zeleny, 8, 184280 Monchegorsk, Murmansk reg., Russia. E-mail: root@zap.mgus.murmansk.su

1718. Hämäläinen, M.; Prashanth-Mohanraj, Veenukumari, K. (1999): Additions to the odonate fauna of the Andaman and Nicobar Islands, Indian Ocean. *Notul. odonatol.* 5(3): 27-29. (in English). [Nine species are recorded for the first time from the Andaman and Nicobar islands, of which *Neurothemis r. ramburii* and *Zyxomma obtusum* are new for the fauna of the territories of the Indian Union. New species for the fauna of each of the 2 island groups are also presented.] Address: Hämäläinen M., Dept Applied Zool., P.O.Box 27, FIN-00014 University of Helsinki, Finland; E-mail: matti.hamalainen@helsinki.fi

1719. Harthun, M. (1999): Der Einfluss des europäischen Bibers (*Castor fiber albus*) auf die Biodiversität (Odonata, Mollusca, Trichoptera, Ephemeroptera, Diptera) hessischer Bäche. *Limnologica* 29(4): 449-464. (in German with English summary). ["Due to the return of the beaver an increasing number of brooks become restored to a natural condition. It is characterized by an alternation of flowing and standing sectors. In the summer of 1995, different groups of organisms (Odonata, Mollusca, Trichoptera, Ephemeroptera, Diptera) of two brooks in the Spessart mountains (Hesse, Germany) were studied to compare the composition of invertebrates in beaver homeranges and in the non-influenced sectors above. The new living conditions resulted in the disappearance of some species (*Drusus anulatus*, *Trich.*, *Sericostoma personatum*, *Trich.*, *Radix peregra*, *Gastr.*). Nevertheless the beaver homeranges accommodate a significant higher number of species of dragonflies and damselflies, molluscs and caddisflies than the brooks above the homeranges. The heterogeneity of natural river systems make a coexistence of running water and silent water organisms possible. The examinations result in a significant higher group dominance of ephemeras (i.p. *Cloeon dipterum*) in a beaver pond than in lenitic sectors conditioned by the gradient without beaver influence. Here the dominance of chironomids was much higher. High current sectors with their characteristic organisms are also present in the beaver homeranges. The higher number of insects is the basis of nourishment for predatory insects and fishes. The potential effects of beaver ponds on fishes are discus-

sed." (Author)] Address: Harthun, M., Landesverband Hessen e.V., Naturschutzbund Deutschland (NABU), D-35531 Wetzlar, Germany

1720. Hiratsuka, K. (1999): Odonata of Horonobe-cho, north of Rumoi District. Bulletin of the Hokkaido Odonatological Society 11: 2-4. (in Japanese). [Ten odonate taxa are reported from four localities in Horonobe-cho, Japan. *Nehalennia speciosa*, *Aeshna nigroflava*, *Coenagrion lanceolatum*, *C. ecornutum*, *Cordulia aenea amurensis*, *Lestes dryas*, *L. sponsa*, *Sympetrum risi*, *Cercion calamorum*, *Enallagma boreale circulatum*] Address: not translated

1731. Kreuzweiser, D.P.; Capell, S.S.; Scarr, T.A. (1999): Acute lethal and sublethal effects of a neem-based insecticide on nontarget aquatic insects in stream channels. *Bulletin of Environmental Contamination & Toxicology* 63(3): 365-371. (in English). [Extracts from seeds and leaves of the neem tree, *Azadirachta indica*, express insecticidal activity against a broad range of insect pests. The primary active ingredient in neem extracts is the triterpenoid, azadirachtin. Because several common forest pests are among the most susceptible insects to azadirachtin, the use of neem-based insecticides in Canadian forest pest management programs is being investigated. Insecticide applications to forests may result in some of the product entering nearby water bodies and it is therefore important to ensure that these insecticides do not pose a risk of adverse effects on aquatic organisms. Small streams are particularly susceptible to contamination by runoff from adjacent sprayed areas because of low dilution potential, and from inadvertent overspray because they are difficult to avoid during aerial applications. The authors investigated the potential for adverse effects on stream insects by applying a neem-based insecticide to outdoor stream channels and measuring acute lethal and sublethal responses. Experiments were conducted at the Icewater Creek Research Area, 50 km north of Sault Ste. Marie, Ontario, Canada. In a laboratory study, at a concentration of 0.84 mg/L azadirachtin, only the stonefly *Isogenoides* sp. exhibited a drift rate (64%) that was significantly different from controls. At concentrations of 0.28 mg/L azadirachtin the drift was not significantly different from controls. Survival of *Isogenoides* sp., the mayfly *Isonychia bicolor/rufa*, and the caddisfly *Hydropsyche bifida/recurvata* were negatively affected by exposure to the maximum test concentration of 0.84 mg/L azadirachtin. Nor drift rate nor mortality of *Ophiogomphus* sp. was affected by azadirachtin.] Address: Kreuzweiser, D.P., Canadian Forest Service,

1732. Krotzer, S. (1999): *Erythemis vesiculosa* (Fabricius), Great Pondhawk, new for Alabama. *Argia* 11(4): 7-8. (in English). [Alabama, USA, Grand Bay Savanna Nature Preserve, August 14, 1999] Address: Krotzer, S., 6010 Woodvale Drive, Helena, AL 35080, USA. E-mail: smjkrotzer@aol.com

1733. Lang, C. (1999): Zur Biologie und Mikrohabitatwahl der Larven von *Cordulegaster heros* Theischinger, 1979 und *Cordulegaster bidentata* Selys, 1843 (Insecta: Odonata) im Weidlingbach (Niederösterreich). Diplomarbeit, Formal- und Naturwissenschaftliche Fakultät der Universität Wien. 97 pp. (in German with English summary). ["Between May 1997 and April 1998, the biology and ecology of larvae of *Cordulegaster heros* and *C. bidentata* were examined in the catchment area of the Weidlingbach (Lower Austria). A total of 688 *C. heros* and 314 *C. bidentata* larvae at 12 sampling sites were collected, measured biometrically (caput width, whole length, length of tibia, mentum and wing pad, and mentum width), and their occurrence related to physical and chemical parameters. With increasing developmental stage, *C. heros* larvae are larger than *C. bidentata*, and females larvae are bigger than males. The last five of a total of 14 stages (DOMBROWSKI, 1989) are particularly well delimited from each other in both species. Applying the rule of DYAR reveals an exponential increase in caput width per developmental stage. A life cycle diagram shows that larval development from stage F-4 to F-1 takes place within a year. The last molt to F occurs in autumn. The larvae hibernate in stage F until they leave the larval developmental cycle by imaginal ecdysis in late May to early June. Certain differences were recorded between *C. heros* and *C. bidentata* in connection with hydrological parameters. *C. heros* larvae tolerate higher velocities and water depth than *C. bidentata*, which counteract drift by burrowing into the sediment. Especially earlier, smaller developmental stages of *C. bidentata* often colonize microhabitats at the margin of the brook with low velocity and shallow water depth. A high negative correlation was found between water depth and water temperature, enabling the larvae to avoid freezing in winter. In general the larvae are exposed at right angles to the current; the stronger the current (> 5 cm/s), the less sectional area the animals expose to the current. The preference for coarse sediment increases with developmental stage, except the last instar, where the trend reverses. *Cordulegaster* larvae are mostly found totally burrowed and lying in wait, exposing only the antennae and the anal pyramid. Smaller individuals, which settle zones with weaker current, are uncovered or less covered with sediment than larger animals colonizing sites with higher velocity. In winter, at low water temperature, most of the animals are totally covered with sediment; about the half the *C. heros* larvae (n = 36) were burrowed as deep as 4 cm. Prior to imaginal emergence, most *Cordulegaster* larvae apparently stay in moist mud outside the water (1-69 cm) for physiological transformation to the adult. Generally, *C. heros* and *C. bidentata* are able to syntopically colonize a brook because of overlapping ecological valences. *C. bidentata* prefers smaller waters with slower flow, higher conductivity and water hardness than *C. heros*. This preference is also reflected in the different abundance of both species at sampling sites PI to PI 2. PI 1 and P 12 are outside both ecological va-

lences because of the high flow ($> 0,03 \text{ m}^3\text{s}^{-1}$) and great depth ($> 19 \text{ cm}$); consequently, they do not serve as a breeding water for *Cordulegaster*." 1735. Léonard, N.J.; Forbes, M.R.; Baker, R.L. (1999): Effects of a mite, *Limnochares americana* (Hydrachnida: Limnocharidae), on the life-history traits and grooming behaviour of its damselfly host, *Enallagma ebrium* (Odonata: Coenagrionidae). *Can. J. Zool.* 77: 1615-1622. (in English). ["We examined whether experimental parasitism by a mite *L. americana* (Lundblad) affected survivorship and maturation of adult damselflies *E. ebrium* (Hagen). We then tested whether differences in grooming activity between control and exposed individuals (within different age or sex categories of host) mirrored reductions in fitness that resulted from experimental parasitism. We based our choice of experimental numbers of mites on our finding that adult damselflies had between 0 and 12 mites (71% had 0 mites), and mature adults had a higher prevalence and intensity of parasitism than did prereproductive damselflies in two of three field surveys. Low numbers of mites did not affect survivorship of teneral or mature males and females: however, high numbers of mites significantly depressed survivorship of teneral males and females and mature males, and were associated with a delay in maturation of females of teneral individuals, only females groomed more than controls when challenged with low numbers of mites: mature individuals of both sexes groomed more than controls in response to high numbers of mites but not in response to low numbers. Our results suggest that variation in grooming behaviour partially reflects variation in fitness costs, due to mite parasitism, across age and sex categories of hosts." 1737. Marden, J.; Fitzhugh, G.H.; Wolf, M.R.; Arnold, K.D.; Rowan, B. (1999): Alternative splicing, muscle calcium sensitivity, and the modulation of dragonfly flight performance. *Proceedings of the National Academy of Sciences of the United States of America* 96(26): 15304-15309. ["Calcium sensitivity of myosin cross-bridge activation in striated muscles commonly varies during ontogeny and in response to alterations in muscle usage, but the consequences for whole-organism physiology are not well known. Here we show

that the relative abundances of alternatively spliced transcripts of the calcium regulatory protein troponin T (TnT) vary widely in flight muscle of *Libellula pulchella* dragonflies, and that the mixture of TnT splice variants explains significant portions of the variation in muscle calcium sensitivity, wing-beat frequency, and an index of aerodynamic power output during free flight. Two size-distinguishable morphs differ in their maturational pattern of TnT splicing, yet they show the same relationship between TnT transcript mixture and calcium sensitivity and between calcium sensitivity and aerodynamic power output. This consistency of effect in different developmental and physiological contexts strengthens the hypothesis that TnT isoform variation modulates muscle calcium sensitivity and whole-organism locomotor performance. Modulating muscle power output appears to provide the ecologically important ability to operate at different points along a tradeoff between performance and energetic cost." 1740. McPeck, M. (1999): Biochemical evolution associated with antipredator adaptation in damselflies. *Evolution* 53(6): 1835-1845. (in English). ["Previous studies have shown that at least two lineages of *Enallagma* damselflies (Odonata: Coenagrionidae) shifted from inhabiting lakes with fish as top predators to inhabiting ponds and lakes with large dragonflies as the top predators. In adapting to living with the new predator type, these lineages evolved much greater swimming speeds to avoid attacking dragonflies. In this paper, I test whether biochemical adaptations to fuel swimming arose in concert with previously identified morphological changes that increase swimming speed. I assayed the mass-specific enzyme activities of three enzymes involved in fueling strenuous activity: pyruvate kinase and lactate dehydrogenase (enzymes involved in glycolysis) and arginine kinase (the enzyme that recharges the ATP pool). Enzyme activities were determined for 14 *Enallagma* species from across the genus. Species that coexist with dragonfly predators had significantly higher mass-specific arginine kinase activities than species that coexist with fish. and the results of evolutionary contrasts analyses indicate that this difference between the two groups is the result of evolutionary change associated with the habitat shifts of lineages from fish lakes to dragonfly lakes. Although significant evolution was documented for lactate dehydrogenase and pyru-

vate kinase across the genus, evolutionary change in the activities of these enzymes was not consistent with adaptation to coexisting with dragonfly predators. Swimming bouts to avoid dragonfly predators last for only a few seconds, and the action of arginine kinase to phosphorylate ADP to make ATP will extend the duration of maximal exertion for swimming for a few seconds. However, much longer time periods (over 45 sec) are required to generate ATP via glycolysis. Therefore, selection may have favored adaptation only at the arginine kinase locus." (Author)] Address: McPeck, M., Dept Biol. Sci., Dartmouth College, Hanover, New Hampshire 03755, USA. E-mail: mark.mcpeek@dartmouth.edu

1741. Miller, M.N.; Fincke, O.M. (1999): Cues for mate recognition and the effect of prior experience on mate recognition in *Enallagma damselflies*. *Journal of Insect Behavior* 12(6): 801-814. (in English). ["In many coenagrionid damselflies, sexually mature females exhibit color polymorphisms, with some females resembling conspecific males. Although it has been suggested that the latter function as male mimics, this does not appear to be the case for those in the genus *Enallagma*. We found that sexually dimorphic coloration of the female abdomen and thorax are important cues for sexual recognition by males. We demonstrate for the first time in the Odonata, that males learn to recognize andromorphs as potential mates. After 2 days in an enclosure, sexually mature males exposed to only andromorphic females initiated more sexual interactions with tethered andromorphs than with heteromorphs, the majority morph in the natural population. Exposure to only heteromorphic females tended to decrease males' sexual responses to andromorphs, but not significantly so. Because the frequency of female morphs often varies within a population, learned mate recognition would be advantageous for males that search for mates. Our results lead to a novel, frequency-dependent hypothesis for the occurrence and maintenance of female-limited color polymorphisms." (Authors)] Address: Fincke, O.M., Dept Zool., Univ. Oklahoma, 730 Van Vleet Oval, Room 314, Norman, OK 73019, USA

1745. Müller, H. (1999): Zur Phänologie und Ökologie der Imagines von *Cordulegaster heros* Theischinger, 1979 und *Cordulegaster bidentata* Selys, 1843 (Insecta: Odonata) im Weidlingbach (Niederösterreich). *Diplomarbeit, Formal- und Naturwissenschaftliche Fakultät der Universität Wien*. 90 pp. (in German with English summary). ["Between June and August in 1997 and 1998 the biology and ecology of the Odonata species *Cordulegaster heros* and *C. bidentata* were examined in the catchment of the Weidlingbach (Lower Austria). Four main sampling sites with a length of respectively 100 m were visited regularly and eight secondary sampling sites, which were patrolled for mapping, were selected. A total of 89 individuals of *C. heros* and 23 of *C. bidentata* of both sexes were measured biometrically (wingspan, forewing, hindwing, total length). *C. heros* is clearly larger and this species can therefore be delimited taxonomically from the *C. boltoni* and *C. picta*. *C. bidentata* coincides both biometrically and regarding its species-specific black-yellow pattern with existing bibliographical data (e. g. ASKEW, 1988). Both odonates belong to the late spring species because of their short emergence period between late May and early June; on average, *C. bidentata* appears seven days earlier than *C. heros*. For imaginal emergence, larvae select vegetational structures directly next to the brook at a horizontal distance of 2.3 - 3.0 m and at an average height of 1.2 - 1.5 m. Sites with certain substructures (twigs, leaves, branch stigmata) at the hatch site are preferentially sought out. After a maturation period of about two weeks, during which the dragonflies also colonize sites far from the brook, the sexually mature imagines return to their breeding waters. *C. bidentata* males largely patrol smaller brooks with a maximal width of 200 cm. The main flying direction over the water is upstream; the males return to the starting point in rapidly flight over land. *C. heros* males overfly brooks with a maximum width of 350 cm and patrol the water both upwards and downwards in the same frequency. Changes in flight direction are caused by barriers such as debris dams or bushes projecting over the brook. A positive correlation was found between flight height and water width as well as with the number of barriers in the water. Such patrol flights can be distinguished from hunting flights based on higher flying speed and larger distance from the surface. Moreover, there is a correlation between unfavorable meteorological conditions and inactivity of the imagines of *C. heros* and *C. bidentata*. Females located by males during patrol flights are grasped and taken into the bank vegetation for subsequent copulation (> 40 min). After copula, the females search for shallow,

search for shallow, less flooded sites (max. depth 4 cm) to deposit the eggs into the sediment with their robust ovipositor. Flying speed and flight height coincide with those of patrolling males. The frequency of oviposition is ca. 1-2 per second and more than 100 holes may be made at suitable sites. The "Cordulegaster-Ophiogomphus-coenosis" defined by JACOB (1959) could not be verified at the Weidlingbach." 1754. Prat, N.; Toja, J.; Sola, C.; Burgos, M.D.; Plans, M.; Rieradevall, M. (1999): Effect of dumping and cleaning activities on the aquatic ecosystems of the Guadiamar River following a toxic flood. *The sciences of the total environment* 242: 231-248. (in English). ["The main aim of the study was to document the recovery of the aquatic ecosystem after the release of toxic mining waste in the Guadiamar River Basin (Sevilla, SW Spain) in April 1998. Samples of water, plankton, periphyton and macroinvertebrates were taken once a month at nine sampling stations (six affected by the toxic release and three for control).[...] After 6 months of cleaning operations, in November 1998 the macroinvertebrate community of the river was composed mainly of species of short life cycles typical of ponds (Heteroptera,

ra, Coleoptera and Odonata ["Coenagrionidae"]), while typical riverine species found at the upstream control station had not recolonised the river due to the transformation of the river into a series of artificial ponds constructed as sediment traps. An analysis of variance showed significantly higher values ($P < 0.05$) for all heavy metals analysed (Zn, Cu, Pb, As, Cd, Sb, Tl) in plankton and macroinvertebrate communities from impacted sites. Values found in invertebrates were highly variable, with a mean concentration of the most abundant metals, Zn and Cu, between two and three times those found in unpolluted areas. Values for As were up to five times higher while Pb, Sb and Tl showed up to 10-fold increases. At the affected stations, the metal concentrations found in biofilms, plankton and particulate material were more than five times greater than those in invertebrates. The slow recovery of the aquatic ecosystem clearly reflected the impact of metal discharge and the subsequent cleaning activities following the mine spill, as well as the sewage inputs at two of the stations studied." 1756. Riffell, S.K. (1999): Road mortality of dragonflies (Odonata) in a Great Lakes coastal wetland. *Great Lake Entomologist* 32(1/2): 63-73. (in English). ["Although road mortality of vertebrates has been well studied, road mortality of invertebrates has rarely been studied or considered in management scenarios. Mackinac Bay is an extensive coastal wetland in northern Michigan. It is bordered by a two-lane paved highway that separates the marsh, where dragonflies defend territories and breed, from the adjacent forest where dragonflies forage and rest. During mid-summer of 1997, daily collections of dragonfly corpses from the road and road edge were used to estimate daily mortality rates and sex ratios among casualties. Daily mortality was highly variable, ranging from 10 to 256 casualties per kilometer. Sex ratios among casualties were generally male-skewed (60% or higher). Life-history differences between the sexes present a parsimonious explanation for male-specific mortality. Mortality was even or female-skewed for some species, and impacts of road mortality may be more severe in populations where mortality is female-skewed. More research about the effects of roads on dragonflies is warranted because dragonfly populations are small relative to many invertebrates and are restricted to wetland habitats which are being degraded or destroyed in many regions." (Authors) 29 odonate taxa are considered in this study.] Address: Riffell, S.K., Department of Zoology, Michigan State University, East Lansing, MI 48824, USA

1757. Rolff, J.; Schröder, B. (1999): Regaining the water: a simulation model approach for *Arrenurus* larvae (Hydrachnellae) parasitizing damselflies (*Coenagrion puella*: Odonata). In: Bruin, J., L.P.S. van der Geest & M. Sabelis (Ed.) *Evolution and Ecology of Acari*, Kluwer Academic Publishers: 359-366. (in English). ["A matrix population model is presented which describes the po-

pulation dynamics and the return rate of parasitic *Arrenurus* larvae to the pond. This is a function of hosts' post-emergence life history and mating success. Three different aspects were simulated: a change in daily miteload, the impact of weather on hosts oviposition probability and a combination of both. It was found that a high abundance of larval water mites drastically reduces their return rate mites due to the high parasite-induced mortality of the hosts. Reduced oviposition probabilities of *Coenagrion puella* also decrease dramatically the number of mites detaching. The model may be applicable to other water-mite/host systems if the life-table data of the host are known."] Address: Rolff, J., Zool. Inst. 1760. Schmid, U. (1999): Das Makrozoobenthos des Unteren Odertals - Faunenzusammensetzung und Besiedlungsdynamik in einer Flußäue. *Limnologie aktuell* 9: 317-336. (in German with English summary). ["The macrozoobenthos from nine sampling sites in the Lower Oder Valley (Brandenburg, Germany) was investigated from December 1993 to May 1997. Samples were collected from permanent water bodies of the former and the active floodplain and from the River Oder. Additional samples were taken from the alluvial plains. The area is flooded extensively every year. It is characterized by a high number of rare and endangered species. In summer, species composition in the active floodplain is similar to that of the former floodplain. In the active floodplain, the floodpulse causes a gradient of species composition during spate. With the flood, species of the running water enter the Alte Oder, an old arm of the river. Due to man-made regulation of the water regime, these species are confronted with unfavourable conditions in these water bodies. Numerous taxa of the macrozoobenthos have developed strategies to survive the alternation of flooding and desiccation, i.e. drought resistance, or recolonization during each flooding period by means of egg-laying, drift, or active migration." (Author). 20 odonate taxa are listed including a first record of *Gomphus pulchellus* in the Federal State of Brandenburg which urgently is in need to be confirmed. Although *Stylurus flavipes* is well represented along the Oder, it is not listed.] Address: Schmid, Ulrike, Freie U-

natural history texts of the twentieth century". For an extensive review see OAS 1565.] Address: Siva-Jothy, M.T., Department of Animal and Plant Sciences, University of Sheffield, Sheffield, S10 2TN, UK. E-mail: m.siva-jothy@sheffield.ac.uk

1767. Siva-Jothy, M.T. (1999): Male wing pigmentation may affect reproductive success via female choice in a calopterygid damselfly (Zygoptera). *Behaviour* 136: 1365-1377. (in English). ["Male calopterygid damselflies show striking morphological and behavioural secondary sexual traits which are known to function in intrasexual contests. The distribution of pigment in the sexually dimorphic wing 'spot' is prominently displayed to the female during courtship, yet there is little empirical evidence that this trait functions in an epigamic context. Observations of marked field populations revealed (a) there was variation in wing pigment distribution in males, (b) the pigmentation was fixed in reproductively active males, (c) resource holding males had less heterogeneity in the distribution of the wing pigment than males that were never observed to hold a resource and (d) that females frequently (60,3%) rejected males after courtship. An experiment was conducted in which the frequency of key reproductive behaviours (female inspection flights, courtships, copulations, and oviposition) was measured for the same male utilising the same territory before and after treatment or control manipulation of wing pigment parameters. Increasing the heterogeneity (and decreasing the area) of the wing pigmentation by removing small areas of pigmented cuticle from their wings resulted in a decrease in the measured reproductive behaviours (control males that had non-pigmented areas removed from their wings showed no decreases). Since females cannot be coerced into these behaviours, the experimentally induced decrease suggests females avoided males with higher levels of wing pigment heterogeneity. The results are discussed in the context of the benefits females might receive as a consequence of their reproductive decisions." (Author)] Address: Siva-Jothy, M.T., Department of Animal and Plant Sciences, University of Sheffield, Sheffield, S10 2TN, UK. E-mail: m.siva-jothy@sheffield.ac.uk

1768. Stoks, R.; De Block, M.; Van Gossum, H.; De Bruyn, L. (1999): Phenotypic shifts caused by predation: Selection or life-history shifts? *Evolutionary Ecology* 13(2): 115-129. (in English). ["Predators can impose both selection and life-history shifts in prey populations. Because both processes may affect phenotypic distributions, the estimates of selection differentials may be biased. We carried out two field experiments to disentangle these separate effects. We studied whether dragonfly predation by *Aeshna cyanea* changes the distributions in body size and lamellae morphology in the damselfly *Lestes sponsa*. Damselflies have caudal lamellae which are used in escapes by swimming. In a first experiment, we manipulated predator presence (No *Aeshna*, Encaged *Aeshna* or Free-ranging *Aeshna*) and stopped the experiment when all larvae had moulted once. In a second experiment, larvae were confronted with a Free-ranging *Aeshna* but collected before moulting, and survivors were compared with a control sample taken at the start of the experiment. The presence of *Aeshna* largely reduced the survival probabilities of the *Lestes* larvae at a very similar rate in both experiments. Daily survival probabilities did not differ between the No *Aeshna* and Encaged *Aeshna* treatments. In the Free-ranging *Aeshna* treatment of the first experiment,

size was reduced compared to the other two treatments, creating a significant apparent selection differential. This was probably mainly due to predator-induced reduced growth because in the second experiment, where growth effects were excluded, size of the survivors did not differ from the control sample. In both experiments there was a significant selection pressure for larger lamellae. Standardized directional selection differentials were similar in both experiments (0.57 and 0.28 phenotypic standard deviation units). No survival selection on lamellae shape was detected. These results are in agreement with previous findings that lamellae size, but not lamellae shape, enhances swimming performance and thereby predator escape in this species." 1773. Wataji, M.; Maruyama, F.; Kanou, M.; Yoshinuma, T.; Taguchi, M. (1999): Present situation, behaviour and life history of *Nehalennia speciosa* (Coenagrionidae, Odonata) at a disappearing habitat, Shinoro Fukui bog, situated in the wetland zone of Ishikari River, Hokkaido. (1) Adult stage. Bulletin of the Hokkaido Odonatological Society 11: 10-18. (in Japanese). [Brief description of the habitat, seasonal occurrence, population density, food habit, mating, oviposition, number of eggs in the ovaries, territorial behavior, movement] Address: not translated

1774. Watanabe, Y.; Yokota, H.; Kato, K.; Hatakeyama, M. (1999): Artificial parthenogenesis in the dragonfly, *Stylurus ocellatus* (Odonata). Proc. Arthropod. Embryol. Soc. Japan 34: 31-32. (in Japanese). [Parthenogenesis in insects have been so far reported in all the orders except Odonata [...]. We used the females of *S. ocellatus* captured at the Biwa lakeside. Females of the species conduct in general flying-oviposition into the water, and prior to oviposition they usually perch on the sand making an egg mass on the abdominal tip. We captured a female just making an egg mass on the sand, and collected eggs (normally oviposited eggs) by soaking the abdominal tip into a film case filled with water. As a female that appears to an oviposition site, usually has mature eggs in ovaries, which lie in 1st -9th segment, we separated the thorax and the abdomen, from which we cut off 4 posterior segments with seminal receptacle, and pulled out the anterior part of the ovaries and collected eggs. These eggs (experimented group) were divided into three groups and kept in plastic petri dishes filled with the city water; 1st group dissected from ovaries. 2nd: dissected from ovaries and macerated with sperm, 3rd: dissected from ovaries and macerated without sperm. [...] The eggs of Odonata generally exhibit chorionic pigmentation when they start normal embryonic development (Corbet, 1962). All of normally oviposited eggs exhibited chorionic pigmentation, and also in the dissected groups 83-93% of the eggs were chorionically pigmented. In further development of embryos, eye pigmentation can be observed. In almost all the normally oviposited eggs pigmentation occurred, and from them normal larvae were seen hatched. In the

ched. In the experimented groups lastly less than 20 % of the eggs hatched, however, a lot of the hatched larvae were morphologically abnormal, some without some segments or legs. Among the groups there were no significant difference of hatchability, therefore, these larvae seemingly hatched from the eggs of parthenogenesis, not from fertilized eggs. So we tried the same treatments on other females, and made chromosome specimens from the embryos soon before the eye pigmentation, and examined the chromosome [...]. In the genus *Stylurus*, the number of chromosomes is reported 23 XO in the male and 24 XX in the female (Katatani, 1995). In the normally oviposited eggs, the number was 23 or 24, and this is assumed to be similar to that of other *Stylurus*. In the larvae hatched from the eggs of 2nd and 3rd group none of them had 23 chromosomes, but some had 24 chromosomes, and others had cells mixed with 12 and 24 chromosomes. Thus, these facts suggests that unfertilized mature eggs of *S. oculatus*, activated in the water, developed as haploid cells, and the chromosomes were doubled by some factors and continued development. The occurrence of many morphologically abnormal larvae in the experimented groups may be related to the high frequency of larvae, the number of which chromosomes was abnormal. (Verbatim, translation from DJOSC 10.) Address: Watanabe, Yoko, 4-14, Nishida-cho, Nishinomiya City, Hyogo Pref., 662-0034, Japan

1775. Weihmann, T. (1999): Untersuchung von Makroinvertebratengemeinschaften in ausgewählten Kleingewässern im Gebiet des Tagebaues Berzdorf bei Görlitz. Diplomarbeit. Fakultät für Biowissenschaften, Pharmazie und Psychologie. Inst. für Zoologie. Universität Leipzig: 150 pp. (in German). [Investigation of the macroinvertebrates of small waters in brown coal mining regions in southeastern Germany; 24 odonate species were recorded in eleven waters including *Coenagrion lunulatum* and *Sympetrum depressiusculum*. The dominance of the species is discussed, and some species are shortly commented. For more details see: Xylander, W.E.R.; Stephan, R., 1998, OAS 1683] Address: Staatliches Museum für Naturkunde Görlitz, PF 300154, D-02806 Görlitz, Germany

1776. Williamson, M.; Gaston, K.J. (1999): A simple transformation for sets of range sizes. *Ecography* 22(6): 674-680. (in English). ["Transformation of data to normality may be illuminating and useful statistically. There are two standard families of transformations, power transformations for positive numbers, bounded at the left, and folded transformations for proportions, bounded both at the left and the right. It has been shown that there is no one satisfactory power transformation for range size data. However, such measures are limited to the right as well as the left, and we consider applying folded transformations to them. Seven data sets of range sizes recorded by 10 km squares are studied. Six are British (native and introduced plants, mammals, dragonflies and two breeding bird surveys) the seventh is of Swiss breeding birds. Using these we show that the right hand limit of the distribution can be estimated and the best folded transformation found. In all cases the right hand limit is larger than the range size of the most widespread species and smaller than the national scope of the survey. In all cases the logit or flog, the logarithmic folded transformation, is satisfactory; in five cases it is the best. It is well known that abundance is approximately (though not exactly) log-normally distributed.

The relationship of that to our discovery that range size data are approximately logit-normal is discussed. There is no fully satisfactory explanation for either observation at present." (Authors)] Address: Williamson M., Dept of Biology, Univ of York, York, YO10 5DD, UK

1777. Xylander, W.E.R. (1999): Aquatic insects in mining and post-mining sites: Investigations on a species rich dragonfly coenosis. Abstracts of the International Symposium "Ecology of Post-Mining Landscapes. EcoPoL '99". Brandenburg University of Technology at Cottbus, Germany, March 15-19, 1999: 1 p. (in English). ["Investigations of about 50 ponds (of the 250 present) and two creeks in the former brown coal mining site of Berzdorf (Upper Lusatia, Saxonia, Germany) from summer 1996 to autumn 1998 showed that a species rich dragonfly coenosis occurs in this habitat. 48 species (of 80 species found in Germany and 67 in Saxonia) could be observed in this area. 31 of the species found are on the red list of dragonflies in Saxonia; a few of the threatened species can be found at some ponds in high numbers (e. g. *Coenagrion lunulatum*, *Orthetrum brunneum*). The post-mining site at Berzdorf holds the highest number of dragonfly species in such a small scale area all over Germany. For this species richness the mosaic of aquatic habitats in the mining site is responsible. The highest number of species (36 species) could be found in a number of larger formerly separated ponds made in the late seventies and recently fused due to recultivation activities. These ponds therefore form a temporary mosaic of several younger and older subbiotopes at different stages of succession (with large groups of *Typha*, large areas covered with *P. natans* vs. no vegetation at all). Other species rich ponds arose since the eighties by slipping of the edge of the mining site that still holds on resulting in permanent changes of the area (32 species). High numbers (between 20 and 30 species) could, however, also be observed in artificial older ponds at the periphery and younger ones in the center of the recultivation area. The age of the artificial ponds had some influence on species richness but other factors like depth, vegetation of the ponds and the surroundings, exposure to sun and shelter from wind seem to be of higher importance; water chemistry is of low significance. The recultivation activities of the next years - actually transferring the mining into post-mining sites - should consider not only the terrestrial and larger aquatic habitats but also the ponds and creeks and their biocoenoses which comprise a large number of endangered species that have found their transitory home in this secondary biotope." 1785. Andres, J.A.; Cordero, A. (2000): Copulation duration and fertilization success in a damselfly: An example of cryptic female choice? *Animal Behaviour* 59 (4): 695-703. (in English). ["Copulation duration is highly variable (0.5-3 h) in the damselfly, *Ceriatrigon tenellum* (Coenagrionidae). Using laboratory experiments, we tested four adaptive hypotheses to explain this variation: the effect of time constraints, in-copula mate guarding, sperm displacement and cryptic female choice. Copulation duration was negatively correlated with time of day, as predicted by the first two hypotheses, and positively correlated with male density, as predicted by the mate-guarding hypothesis. Males prolonged copulation in response to the volume of sperm stored by females, suggesting they were able to detect and quantify the amount of sperm stored. This behaviour is not explained by mate guarding or time constraint effects. Males removed all the sperm from the bursa copulatrix in just 10 min. Our results also suggest that, because the duct is too narrow to allow male genitalia to enter, males do not remove spermathecal sperm. Therefore, direct sperm removal could not explain long copulations. Prolonged copulations could also have evolved as a result of cryptic female choice if they increase male fertilization success by female-mediated processes. Our results support this idea: male fertilization success was greater after long copulations. Apparently, male copulatory behaviour elicits female responses that increase male fertilization success." (in English). ["On 2 evenings in late Oct. 1999 several females were observed laying eggs in almost dry mud and sand and under mosses, within a temporary pond system, surrounded by rain forest, near Tiradentes, Minas Gerais, Brazil. The ponds are filled with water during the rainy season (Oct. - March) but dry up entirely by the end of the dry season (Aug. - Sept.). Data compiled from field records, Odonatological collections and literature showed that in Brazil *G. bifida* stays on the wing throughout the year. Apparently, the sp. possesses a univoltine life cycle with 2 generations of larvae, one during the warmer rainy season and another in the early dry season (Oct./Nov. - Jan./Feb. and Feb./March - May/June, respectively). Mud attached to the terminal abdominal segments of 9 specimens in Odonatological collections was used as an evidence of an oviposition mode comparable to that observed in the field." 1801. Buskirk, J. van; McCollum, S.A. (2000): Functional mechanisms of an inducible defence in tadpoles: morphology and behaviour influence mortality risk from predation. *Jour. evol. biol.* 13: 336-347. (in English). ["In many amphibian larvae a suite of morphological and behavioural characters varies together in an induced defence against predators, but it remains unclear which features are functionally related to defence. We independently manipulated behaviour and morphology in tadpoles of *Hyla versicolor* and assessed their consequences for swimming performance and predator escape. Data on burst swimming showed that tadpoles which accelerated rapidly were elongate, with shallow bodies and tails. Predator escape was measured by exposing tadpoles to predators (larval *Anax longipes* dragonflies or larval *Ambystoma salamanders*) and recording time until death. Tadpoles were first reared for 30 days in ponds containing either caged *Anax* or no predators; individuals responded to predators by developing large brightly coloured tails and short bodies. We placed tadpoles of both morphological phenotypes into plastic tubs, and manipulated their behaviour using food and chemical cues from predators. Mortality risk experienced by the predator-induced phenotype was about half that of the no-predator phenotype, and risk increased with time spent swimming. An interaction between morphology and behaviour arose because increasing activity caused higher risk for tadpoles with deep tail fins but not shallow tail fins." (Authors)] Address: Buskirk, J. van & S.A. McCollum, Department of Biology, University of Michigan, Ann Arbor, MI 48109 USA

1802. Buskirk, J. van (2000): The costs of an inducible defence in anuran larvae. *Ecology* 81(10): 2813-2821. (in English). ["Costs of inducible phenotypes are a central component of theoretical treatments for the evolution of plasticity but have proved difficult to measure empirically. I estimated the costs of responding to predators for 15 species of anuran tadpoles, in artificial pond experiments performed over a period of several years. The experiments included a treatment without predators

and another treatment with aeshnid dragonfly larvae (*Aeshna cyanea*, *Anax junius*, *A. longipes*, *A. imperator*) confined within cages; experimental protocols and ponds were generally similar. Tadpoles in the caged-predator treatment were not at risk of predation, but they responded as if predators were present. The cost of the predator-induced response was estimated by the difference in growth rate or survival between the two treatments. There was considerable variation among species (experiments) in growth and survival. Across all species there was a highly significant reduction in growth rate in the presence of predators, but no tendency for a survival cost of responding to predators. I tested whether particular components of the anti-predator response are especially costly by comparing, within a phylogenetic context, the magnitude of costs with the magnitude of predator-induced plasticity in behavior and morphology. The absence of significant correlations in this analysis indicated that evolutionary changes in specific phenotypic responses to predators have not been accompanied by changes in the cost. The prevalence of growth costs of responding to predators, but not survival costs, supports models of induced defenses that assume that fitness costs arise from shifts in allocation of time and energy." 1803. Carchini, G.; Chiarotti, F.; Di Domenico, M.; Paganotti, G. (2000): Fluctuating asymmetry, size and mating success in males of *Ischnura elegans* (Vander Linden) (Odonata: Coenagrionidae). *Animal behaviour* 59 (1): 177-182. (in English). ["Fluctuating asymmetry (FA) is thought to be an indicator of developmental stability and negatively related to male mating success in many animal taxa. We investigated the relationships between mating success of males, body size and FA for both wing length and number of setae on the legs in the damselfly *Ischnura elegans*. Males were classified as mated or unmated at the time of sampling. Fluctuating asymmetry, expressed as right - left differences, showed normal distributions without evidence of directional asymmetry or antisymmetry. Univariate analyses showed a significant negative correlation between size and mating success, and significant negative correlations between FA and mating success for both characters. On the other hand, with a multivariate analysis, new to studies on FA, the effect of body size was still significant but FA did not reach significance for either character. We conclude that the multivariate analysis should be used to assess the role of the different factors affecting mating success." 1806. Corbet, P.S. (2000): The first recorded arrival of *Anax junius* Drury (Anisoptera: Aeshnidae) in Europe: A scientist's perspective. *International Journal of Odonatology* 3(2): 153-162. (in English). ["In September and October 1998 adults of *Anax junius* (Common Green Darner) were encountered in small numbers at coastal sites in southwestern U.K. Circumstantial evidence supports the inference that they reached there on winds originating from New Brunswick and Quebec, Canada in early September, a time when this species regularly migrates southwards along the Atlantic Canada and New England coasts of northeastern North America. Although identification of the specimens to species as currently denned seems secure, attempts to retain a voucher specimen were frustrated, making it impossible to re-evaluate the identification in the light of future taxonomic knowledge. Two physiological subspecific entities of *Anax junius* are currently recognized in North America and it is not known to which entity the arriving individuals belonged. Capture of a voucher specimen for The Natural History Museum, London was prevented by vigilante action on a Cornwall Wildlife Trust nature reserve at Penlee, despite prior permission to collect having been granted by the Trust. The incident was followed by wide dissemination of e-mails from an individual endorsing the vigilante action mounted against the would-be collector. Recommendations are offered for safeguarding the interests of scientists who deem it necessary to obtain voucher specimens." 1807. Cordero Rivera, A. (2000): Distribution, habitat requirements and conservation of *Macromia splendens* Pictet (Odonata: Corduliidae) in Galicia (NW Spain). *Int. Jour. Odonatology* 3(1): 73-83. (in English). ["The range of *Macromia splendens*, a rare anisopteran, includes SE France and some scattered localities on the Iberian Peninsula. During 1996-1998, I made an exhaustive search for the characteristics of the species' larval and adult habitat, flight period and adult activity in NW

Spain. Nine populations were found, greatly increasing its known range. Adults were observed on slowly flowing rivers, with deep, warm water. Seven populations were found on natural rivers, but two inhabited man-made hydroelectric reservoirs, where aquatic and riverine vegetation are absent. One population was found inside a Natural Park. Populations concentrated in zones with a mean annual temperature higher than 13°C. Larvae live among tree roots or flattened on the muddy substrate and emerge in May-June from eggs laid in June-July two years earlier. Pollution and habitat destruction are the main problems for the conservation of this species." 1808. Córdoba-Aguilar, A. (2000): Reproductive behaviour of the territorial damselfly *Calopteryx haemorrhoidalis asturica* Ocharan (Zygoptera: Calopterygidae). *Odonatologica* 29(4): 295-305. (in English). ["The reproductive behaviour of *C. h. asturica* is described. Males fought with each other for the possession of territories which contained the oviposition resource required by females. Females arrived at territories and either copulated and left the territory, copulated and oviposited in that territory or oviposited without a preceding copulation with the territorial male. Territorial males seemed to have a higher mating success than nonterritorial males. Males carried out courtship displays before and after copulation until females finished oviposition. Copulation was divided in two stages which were characterised by the nature of the male's abdominal flexions. The number of abdominal flexions during stage I and II was 50.2 ± 7.2 and 54.5 ± 16.7 (mean \pm s.d.) respectively. The sexual behaviour of both sexes is discussed under current knowledge of sexual selection studies in Calopterygidae." (Author)] Address: Córdoba-Aguilar, A. Departamento de Entomología, Instituto de Ecología, A.C., Apdo Postal 63. MX-91000 Xalapa, Ver. Mexico

1809. Costa, J.M.; Santos, T.C. (2000): *Neocordulia mambucabensis* spec. nov., a new dragonfly from Rio de Janeiro, Brazil (Anisoptera: Corduliidae). *Odonatologica* 29(3): 247-253. (in English). ["The new sp. is described and illustrated and its affinities are discussed. Holotype male, allotype female: Brazil, Rio de Janeiro, Serra da Bocaina, Rio Mambucaba, 22-XI-1979; deposited at MNRJ, Rio de Janeiro. The known spp. of the subgenus *Neocordulia* are keyed." 1810. Czachorowski, S.; Buczynski, P. (2000): Threats to and protection of water insects in Poland. *Wiad. entomol.* 18, Suppl. 2: 95-120. (in Polish with English summary). [Based on literature data, enquiries filled in by specialists and collections of the authors the present status of more than 3340 species of aquatic insects occurring in Poland is reviewed. No information on threat of app. 80 % of the species is available. 30 % of the better recognised species are vulnerable. Current activities aimed at the protection of the water insects of Poland are reviewed, and proposals for intensified activities to protection and study of the water insects are made. The authors propose legal protection of some species living in freshwater habitats. Odonata are trea-

ted in chapter 3.2.3, and the habitats of Odonata in tab. III. Most endangered species are those of high and transitional bogs, running waters, and the species of stagnant, small waters without adaption to temporal water levels. The following odonate umbrella species are introduced: *Calopteryx virgo*, *Stylurus flavipes*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia*, *Cordulegaster boltonii*, *Thecagaster bidentata*, *Orthetrum brunnum*, *O. coerulescens*, *Sympetrum pedemontanum* (running waters), *Cercion lindenii* (lakes), *Coenagrion armatum* (small stagnant waters), *Nehalennia speciosa*, *Aeshna caerulea*, *A. juncea*. *A. subarctica* (elisabethae), *Soatochlora arcitia*, *S. alpestris*, *Libellula fulva*, *Leucorrhinia albifrons*, *L. caudalis*, and *L. dubia* (bogs)] Address: Buczynski, P., Dept of Zool., Marie Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. 1818. Dijkstra, K.-D.; Dingemans, N.J. (2000): New records of *Crocothemis sanguinolenta* (Burmeister, 1839) from Israel, with a critical note on the subspecies *arabica* Schneider, 1982. *International Journal of Odonatology* 3(2): 169-171. (in English). [*C. sanguinolenta* is a widespread Afrotropical species whose area of distribution extends into the south of the Arabian Peninsula. Additionally, isolated populations have been found in the Dead Sea Basin. The first report from this region is by Morton (1924). The species is known from Jordan (Schneider 1982, 1985). In Israel it is thus far known only from En Gedi on the Dead Sea coast (31°27'N, 35°22'E). Morton (1924) already noticed that his specimens differed from African ones. These were later described as a separate subspecies, *Crocothemis sanguinolenta arabica* Schneider, 1982. According to Schneider (1982) the male of the subspecies *arabica* differs from the nominate in being smaller, having a more open venation, less yellow on the wing bases and no dark markings on the abdomen. The single male from Israel is compared with material from Jordan, Yemen, Oman and Uganda in Table 1. It is obvious that the distinction between *arabica* and *sanguinolenta* is not clear-cut and that intermediate forms occur. The authors take a Levantine subspecies not justified to recognise a subspecies *arabica*.] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

1819. Dolédec, S.; Olivier, J.M.; Statzner, B. (2000): Accurate description of the abundance of taxa and their biological traits in stream invertebrate communities: effects of taxonomic and spatial resolution. *Arch. Hydrobiol.* 148(1): 25-43. (in English). ["Studies of biodiversity and ecosystem function require to consider the identification level that accurately describes the functional diversity of communities, in terms of their biological traits, at different spatial scales. Therefore, we combined three published data sets of stream macroinvertebrate" (including Odonata) "abundances collected at three spatial scales with a database of functional species traits (e.g. life history, morphology, physiology, and behaviour). We investigated the abundance of taxa and their traits at five levels of taxonomic (from species to class) and three levels of spatial resolution (from local habitat to catchment). We used multivariate analyses and correlations to evaluate the accuracy of community descriptions through the stability of such descriptions, the degree of similarity of site ordinations, and the overall community structure expressed at each taxonomic level. The accuracy of community descriptions based on the abundance of taxa depended on the spatial scale considered. The accurate description of the abundance of taxa required identifications to genera and/or families on the local habitat scale, while species identifications were needed on the catchment scale. In contrast, the accurate description of the abundance of biological traits was achieved by identifications to species, genera, or families on all three spatial scales. Thus, species identifications may not be necessary for future studies on the functional diversity of the stream benthos at different spatial scales." (Authors)] Address: Statzner, B., CNR, Ecologie des Eaux Douces et des Grands Fleuves, Université Lyon I, F-69622 Villeurbanne Cedex, France. E-mail: sylvain@biomserv.univ-lyon1.fr

1826. Dudgeon, D. (2000): Indiscriminate feeding by a predatory stonefly (Plecoptera: Perlidae) in a tropical Asian stream. *Aquatic Insects* 22(1): 39-47. (in English). ["The diet of an undescribed species of *Kamimuria* was investigated in Tai Po Kau Forest Stream, Hong Kong, by comparing larval gut contents with the array of available prey living on and among cobble substrates. Diets were dominated by chironomids and philopotamid caddisflies, with Baetidae, Heptageniidae, Hydropsychidae and Simuliidae comprising secondary dietary items. These six taxa made up 94% of the prey individuals eaten by *Kamimuria*. Data analysis using a selectivity index revealed that these stoneflies fed indiscriminately, eating individual prey taxa in proportion to their availability in the environment. Large and small *Kamimuria* exploited essentially the same prey. A comparison of the diet of *Kamimuria* with the diets of four sympatric Odonata indicated that the degree of interspecific similarity was determined by the extent of overlap in microhabitat use. Diets of *Euphaea decorata* [...] larvae, which live under cobbles, were most similar to *Kamimuria*. This is the first - albeit limited - study of the gut contents of a tropical Asian stonefly. The results suggest that these predators have the potential to limit benthic invertebrate abundance but, because *Kamimuria* larvae feed unselectively, community structure may not be affected by their activities." (Author)] Address: Dudgeon, D., Department of Ecology and Biodiversity, University of Hong Kong, Pokfulam Road, Hong Kong, China
1827. Dyrce, A.; Flunks, H. (2000): Potential food resources and nestling food in the Great Reed Warbler (*Acrocephalus arundinaceus arundinaceus*) and Eastern Great Reed Warbler (*Acrocephalus arundinaceus orientalis*). *J. Ornithol.* 141: 351-360. (in English with German summary). ["The main ecological difference between the Great Reed Warbler and Eastern Great Reed Warbler lies in the density of breeding population,

which in the Eastern subspecies studied in Japan is on average 10 times higher than that of European populations of the Western subspecies. In this study it is shown that potential food resources of the Great Reed Warbler in Japan are more than ten times more abundant than those in Poland, with respect both to the number of potential prey items (invertebrates) and to their total biomass. This strongly suggests that such high densities of Great Reed Warbler in Japan are at least partly due to more plentiful food supply. Other factors which could explain the difference between breeding densities in Japan and Poland are the predation by Marsh Harrier (*Circus aeruginosus*) in Poland and lack of competition with Reed Warbler (*Acrocephalus scirpaceus*) in Japan. The abundance of food on the sample plot in Japan resulted primarily from outbreaks of dipterans of the suborder Nematocera, the most common of which were Chironomidae. Although Chironomidae were not the preferred prey, they made up a substantial proportion of the diet of nestlings. In both studied areas, apart from dipterans, the greatest proportion of nestlings' diet constituted arachnids. Differences in nestlings' diet between study sites resulted mainly from a greater proportion of Nematocera and lower proportion of Coleoptera and Odonata in Japan." (Authors) The potential availability of Odonata as food (collected by the sweep-net method in reed and herbaceous vegetation) is greater in Poland than in Japan (Fig. 4 and 5). The proportion of Odonata in the food composition (number of individuals) of nestlings is in Poland app. 10%, and in Japan app. 5%.] Address: Dyrz, A., Department of Avian Ecology, University of Wrocław, Sienkiewicza 21, 50-335 Wrocław, Poland; Flinks, H., Am Kuhm 19, D-46325 Borchen, Germany

1828. Eklov, P. (2000): Chemical cues from multiple predator-prey interactions induce changes in behavior and growth of anuran larvae. *Oecologia* 123(2): 192-199. (in English). ["Chemical signals are used as information by prey to assess predation risk in their environment. To evaluate the effects of multiple predators on prey growth, mediated by a change in prey activity, I exposed small and large bullfrog (*Rana catesbeiana*) larvae (tadpoles) to chemical cues from different combinations of bluegill sunfish (*Lepomis macrochirus*) and larval dragonfly (*Anax junius*) predators. Water was regularly transferred from predation trials (outdoor experiment) to aquaria (indoor experiment) in which activity and growth of tadpoles was measured. The highest predation mortality of small bullfrog larvae in the outdoor experiment was due to *Anax*, and it was slightly lower in the presence of both predators, probably resulting from interactions between predators. There was almost no mortality of prey with bluegill. The activity and growth of small bullfrog larvae was highest in the absence of predators and lowest in the presence of *Anax*. In the presence of bluegill only, or with both predators, the activity and growth of small bullfrog tadpoles was intermediate. Predators did not affect large tadpole activity and growth. Regressing mortality of small bullfrog tadpoles against activity and growth of bullfrog tadpoles revealed a significant effect for small bullfrog larvae but a non-significant effect for large bullfrog larvae. This shows that the response of bullfrog tadpoles to predators is related to their own body size. The experiment demonstrates that chemical cues are released both as predator odor and as alarm substances and both have the potential to strongly alter the activity and growth of prey. Different mechanisms by which chemical cues

may be transmitted to species interactions in the food web are discussed." (Author)] Address: Eklov, P., Department of Ecology and Environmental Science, Animal Ecology, Umea University, S-901 87 Umea, Sweden

1829. Ellenrieder, N. von (2000): *Aeshna tinti* sp. nov. from Chile and redescription of *A. elsia* Calvert (Anisoptera: Aeshnidae). *Odonatologica* 29(4): 347-358. (in English). ["*A. tinti* sp. n. is described and illustrated from the Chilean Tarapaca and Antofagasta regions (holotype male and allotype female: Chile, Antofagasta, El Loa prov., Tilopozo, 23°49'S 68°15'W, 1-1996; deposited at MLP, Argentina). A redescription and drawings of *A. elsia* Calvert are provided, as well as a comparison of the new sp. with all the sympatric *Aeshna* spp." (Author). *A. variegata*, *A. brevifrons*.] Address: Ellenrieder, Natalie von, Instituto de Limnología "Dr. Raúl A. This autumnal emergence is probably due to a period of extraordinary warm weather in September." (Authors)] Address: Traute und Heinrich Fliedner, Louisa-Seegelken-Str. 106, D-28717 Bremen, Germany

1837. Fonseca, T. de (2000): The dragonflies of Sri Lanka. WHT Publications, Colombo. ISBN 955-9114-19-0: 303 pp. (in English). [The dragonflies of Sri Lanka provides a comprehensive review of the Odonata of the Indian-Ocean island of Sri Lanka. It draws together such information on taxonomy, distribution and ecology as is presently available in the published literature. The dragonflies of Sri Lanka includes complete descriptions of the imagines, keys to the imagines (adults) of all species hitherto recorded from the island. In addition, it also includes keys to and descriptions of the larval stages of many of the species. The black and white drawings are taken - in most cases - from different publications of Fraser or Lieftinck. For each species, there are also information on references, its synonymy, and distribution. ["The book is intended to serve as an introduction to a more comprehensive exploration of this remarkable fauna, which includes some 52 species endemic

to Sri Lanka. The fauna is far from well known, however, and future studies will undoubtedly bring several more species to light; this guide is intended to lay a foundation for future research. [" 20 colour plates, information on rearing of dragonfly larvae, information on "Making and keeping a collection", a checklist of the Sri Lankan Odonata in the National Museum, Colombo, a glossary, a bibliography, and a species index will provide a lot of useful information on the Sri Lankan Odonate fauna. I enjoyed this book. It should not be missing in any odonatological library. (M. Schorr)] Address: WHT Publications, 95 Cotta Road, Colombo 8, Sri Lanka

1838. Frat, J. (2000): Première observation de *Leucorrhinia pectoralis* (Charpentier, 1825) dans le département de l'Allier (Odonata, Anisoptera, Libellulidae). *Martinia* 16(1): 15-17. (in French, with English summary). [*L. pectoralis* was detected on May 29, 1999 near Chevagnes, Département Allier, France.] Address: Frat, J., Les Hauts Goths, F-03230 Lusigny, France

1839. Fürst von Lieven, A. (2000): The transformation from monocondylous to dicondylous mandibles in the Insecta. *Zoologischer Anzeiger* 239(2): 139-146. (in English with German summary). ["The evolution of the dicondylous mandible of insects can be reconstructed because the Lepismatidae show an intermediate condition between monocondylous and dicondylous mandibles. Monocondylous mandibles as in the Entognatha and Archaeognatha have only the dorsal (primary) condyle found in all Mandibulata and are moved around a vertical axis. Dicondylous "biting-type" mandibles as in the Pterygota have an additional (secondary) articulation anterior to the primary articulation, so that movement is limited to a transverse adduction around a horizontal axis of swing. Mandibles of the Lepismatidae have been considered intermediate with respect to their elongated shape and their musculature (BORNER 1909). Video recordings of the feeding movements of *Lepisma saccharina* L., 1758 show an unexpected motion pattern of the mandibles. The anterior articulation of *L. saccharina* comprises a clypeal and a tentorial condyle forming a guide for two sclerotized ridges on the dorsal surface of the mandible. Contrary to orthopteroid mandibles, which possess ball and socket type articulations, the movement of lepismatid mandibles is mainly a pro- and retraction. The secondary articulation acts as a guide. The same components of the secondary articulation as in the Lepismatidae can be found in larval Ephemeroptera, where the tentorial condyle is attached to the inner ridge of the mandible. In Odonata and Neoptera the secondary articulation is a ball joint, formed between the clypeal condyle and the ridges. These results show that the mandibles in the Lepismatidae have an intermediate condition in regard to shape, musculature and function of the secondary articulation. The further transformation of the insect mandible took different paths in Ephemeroptera and Metapterygota." 1840. Garcia Berthou, E.; Moreno Amich, R. (2000): Food of introduced pumpkinseed sunfish: ontogenetic diet shift and seasonal variation. *Journal of Fish Biology* 57(1): 29-40. (in English). ["The pumpkinseed sunfish *Lepomis gibbosus* introduced into Lake Banyoles (Spain) were predominantly littoral but there was a tendency of large fish to use deeper zones. Their diet was

dominated by littoral macrobenthos, particularly amphipods (*Echinogammarus* sp.). There was ontogenetic variation in the diet, with small young-of-the-year (L-F < 4 cm) feeding on several littoral microcrustaceans, especially the cladoceran *Ceriodaphnia reticulata*, whereas larger fish shifted to a freshwater shrimp (*Atyaephyra desmaresti*), snails and damselfly larvae. Seasonal variation in diet was linked to resource availability, with consumption of fish eggs and plant debris in spring and summer. In autumn, pumpkinseeds were partially zooplanktivores, preying on the cladoceran *Daphnia longispina*. The diet of pumpkinseeds in Lake Banyoles and other Iberian populations shows less molluscivory than North American populations. The potential ecological impact of this successful exotic species involves mainly predation on fish eggs and molluscs." (Authors)] Address: Garcia Berthou, E., Univ. 1841. Geenen, S.; Jordaens, K.; de Block, M.; Stoks, R.; De Bruyn, L. (2000): Genetic differentiation and dispersal among populations of the damselfly *Lestes viridis* (Odonata). *J. N. Am. Benthol. Soc.* 19(2): 321-328. (in English). ["We investigated genetic differentiation among 8 populations of the protected damselfly *L. viridis* (Vander Linden, 1825) in permanent ponds in northern Belgium by means of allozyme electrophoresis and isoelectric focusing, and estimated levels of gene flow using F-statistics. In addition, we did a capture-mark-recapture experiment to estimate direct levels of gene flow. Our aim was to test whether populations of *L. viridis* represented a single, large panmictic population or formed a series of demographically isolated populations, which may be defined as appropriate management units (MU). None of the marked individuals moved among the ponds, indicating a strong fidelity for adults to their breeding pond. Only 1 population was genetically strongly differentiated, whereas little or no differentiation was observed among the 7 other ponds. Absence of adult dispersal but genetic homogeneity between ponds thus suggested substantial general dispersal. We observed large heterozygote deficiencies at 2 loci (*Fdh* and *Est*). Significant differences in allele frequencies among ponds suggests that populations of *L. viridis* in northern Belgium may consist of >1 MU. Management plans for conservation should therefore take into consideration the presence of several MUs in this species." 1844. Gillooly, J.F.; Dodson, S.I. (2000): The relationship of egg size and incubation temperature to embryonic development time in univoltine and multivoltine aquatic insects. *Freshwater biology* 44: 595-604. (in English). ["1. We used published data to investigate the combined influence of egg size and incubation temperature on embryonic development time for a broad assortment of aquatic insects at four different incubation temperatures (10, 15, 20 and 25 °C). 2. Embryonic development time (EDT) was positively correlated with egg size at each of the four temperatures, but with diffe-

rent relationships for univoltine and multivoltine aquatic insects. The relationships of embryonic development time to egg size expressed in degree-days did not significantly differ in slope ($P > 0.50$) or intercept ($P > 0.05$) for either univoltine or multivoltine aquatic insects at each of the four temperatures. 3. The relationship of EDT (degree-days) to egg mass in multivoltine aquatic insects ($EDT = 885 \times 0,19$, $P < 0.0001$, $r^2 = 0.48$) is similar in slope and intercept to that for other oviparous animals (i.e., zooplankton, fish, amphibians and reptiles), and to the relationship of embryonic development time to neonate mass in mammals. Univoltine species on average require 3-5 times longer to develop ($EDT = 14190 \times 0,29$, $P < 0.001$, $r^2 = 0.29$) than most other animals of equivalent egg mass, but the relationship of embryonic development time to egg mass is similar in slope to that of most other animals. Together, these relationships provide a basis for evaluating differences in embryonic development time among aquatic insects." (Authors). Data of *Diplacodes bipunctata*, *Diplacodes haematodes*, *Orthetrum caledonicum*, *Enallagma vernale*, *Enallagma ebrium*, and *Coenagrion puella* are involved in this study.] Address: Gillooly, J.F., 104 13th Avenue, St Pete Beach, FL 33706, USA. 1848. Gorb, S.N. (2000): Ultrastructure of the neck membrane in dragonflies (Insecta, Odonata). *Journal of Zoology* 250(4): 479-494. (in English). ["This study describes and quantifies the microsculpture and ultrastructural design of the neck membrane of adult Odonata using scanning and transmission electron microscopy. The membranous cuticle has a complex pattern of microfolds, which appear to have a specialized mechanical function. The membrane has two layers of cuticle: the epicuticle and exocuticle. The outermost layer is the electron-opaque epicuticle, which repeats the shapes of the microfolds. The epicuticle has no fibrillar elements. The exocuticle is electron-lucent and rather thin (0.5-1.5 μm) compared with the sclerite cuticle. The cuticle microfibrils in successive lamellae are at angles to each other. The epidermal cells underlying the membrane have an electron-lucent matrix filled with electron-opaque spherical vesicles of 0.1-0.4 μm in diameter. The behaviour of the membrane folds under loading was studied by shock-freezing experiments; these showed that the shape of the folds changed in response to head movements, and stretched under loading. A comparison of the surface patterns of the membrane in 10 odonate species from seven families [...] had not revealed any correlation of the measured parameters with the size, sex or systematic position of species studied." (in English). ["A new dragonfly species, *Risioenemis seidenschwarzi* spec. nov. (holotype male: Philippines, Cebu, Tabunan, 9.II.1999) is described, illustrated and compared with the closely related *R. rolandmuelleri* Hämäläinen. The new species appears to be endemic to Cebu, where it, as a forest stream dweller, has a very limited area left for survival. Its endangered status is emphasized and its remaining habitat in the Tabunan forest area is characterized in detail."] (Author)] Address: Hämäläinen M., Dept Applied Zool., P.O.Box 27, FIN-00014 University of Helsinki, Finland; e-mail: matti.hamalainen@helsinki.fi

1853. Hardersen, S. (2000): Effects of carbaryl exposure on the last larval instar of *Xanthocnemis zealandica* - fluctuating asymmetry and adult emergence. *Entomologia experimentalis et applicata* 96(3): 221-230. (in English). ["Fluctuating asymmetry (FA), a measure of developmental stability, has been suggested as a monitoring tool for environmental pollution. Aquatic pollution events are often transitional and the level of FA in populations exposed to such incidents has not yet been investigated. Research into the morphological effects of transitional pollution also provides a tool to elucidate the timing and duration of any 'window of opportunity' for the determination of FA in the developing organism. The present study was undertaken to investigate if exposure of the last instar of the damselfly *X. zealandica* [...] to different levels of insecticidal stress resulted in different levels of FA in the wings of the adult insects and if adult emergence was altered by different concentrations of pesticide. Three concentrations of carbaryl (40 ppb, 2 ppb and 0.1 ppb) and a control were used. The emergence success of the damselflies was not affected by any treatment, but the insecticide had a stimulatory effect on the developing larvae. Exposure of the last instar of *X. zealandica* to carbaryl at 40 ppb had no consistent effect on FA in metric traits and increased FA in meristic traits compared with the control. Segregation of the emerged adults into two groups revealed more details about the 'window of opportunity' in the meristic traits. Larvae which had already completed more than half of their development when the experiment started did not show significant differences in the level of FA. In contrast, damselflies which were exposed for more than half of the final instar showed a clear difference in their levels of FA. The greater difference in the latter group was mainly caused by a decrease of FA in the controls rather than by an increase in the treatment. These data suggest that the 'window of opportunity' for the determination of the level of FA of the meristic traits

in damselfly wings closes approximately halfway through the final larval instar." (Author)] Address: Hardersen, S., Tiergartenstr. 111, D-47533 Kleve, Germany. E-mail: sonke7hard@aol.com

1854. Hardersen, S.; Wratten, S.D. (2000): Sensitivity of aquatic life stages of *Xanthocnemis zealandica* (Odonata: Zygoptera) to azinphos-methyl and carbaryl. *New Zealand Journal of Marine & Freshwater Research* 34(1): 117-123. (in English). ["The susceptibility (48-h LC50 values) of aquatic life stages of *Xanthocnemis zealandica* McLachlan to azinphos-methyl and carbaryl was investigated. The LC50 values of azinphos-methyl did not correlate with instar. The most susceptible stage was instar 7 (LC50 value: 26.6 ppb), and the least susceptible were instars 2 (LC50 value: 50.2 ppb) and 13 (LC50 value: 45.1 ppb). In contrast, LC50 values for carbaryl were positively related to larval instar (instar 2: LC50 value: 156.6 ppb; instar 13: LC50 value: 760 ppb). Damselfly eggs were exposed to insecticide solutions (azinphos-methyl: control, 0.04, 0.4, 4, and 40 ppb; carbaryl: 0.6 and 6, 60, and 600 ppb) and hatching success evaluated. Only carbaryl at 600 ppb reduced hatching success significantly. Although the investigation on eggs was carried out at a higher temperature than the LC50 experiments it can be concluded that the egg stage is more resilient to both insecticides than the larval stages." (Authors)] Address: Hardersen, S., Tiergartenstr. 111, D-47533 Kleve, Germany. E-mail: sonke7hard@aol.com

1855. Hardersen, S. (2000): The role of behavioural ecology of damselflies in the use of fluctuating asymmetry as a bioindicator of water pollution. *Ecological Entomology* 25: 45-53. (in English). *Xanthocnemis zealandica* (McLachlan, 1873), "1. Fluctuating asymmetry has been used widely to investigate questions concerned with evolution and behaviour, and to study the effects of environmental pollution. Damselflies have been used to answer questions in both fields, but no attempt has been made to combine the knowledge from these areas to investigate whether and how evolutionary ecology and behaviour interfere with the use of fluctuating asymmetry as a bioindicator of water pollution. 2. Four hypotheses were formulated to investigate possible interferences: (1) Paired males should be less asymmetrical than unpaired males. (2) Males caught at breeding sites should be less asymmetrical than females caught at breeding sites. (3) Damselflies caught earlier in the season should be less asymmetrical than those caught later in the year. (4) Damselflies caught at control sites should be less asymmetrical than those caught at sites within areas of high pesticide usage. 3. No significant difference in asymmetry levels was found between paired and unpaired males. 4. Males were significantly less asymmetrical than females. 5. Damselflies caught earlier in the year were less asymmetrical than those caught later. 6. The data used to test the hypothesis that fluctuating asymmetry in the wings of mature damselflies reflects the level of pesticides used in the surrounding environment were equivocal. 7. The findings suggest that evolutionary ecology and behaviour interfere with the suitability of fluctuating asymmetry in mature damselflies as a biomonitoring tool and it is concluded that fluctuating asymmetry in emerging adults should be much more appropriate as a bioindicator." (Author)] Address: Hardersen, S., Tiergartenstr. 111, D-47533 Kleve, Germany. E-mail: sonke7hard@aol.com

1856. Haritonov, A.Yu. (2000): Charter meeting of the Russian section of Societas Internationalis Odonatologica (R.S.S.I.O.). Notul. odonotol. 5(3): 29-31. (in English). 1858. Harrison, J.F.; Roberts, S.P. (2000): Flight respiration and energetics. Annual review of physiology 62: 179-205. (in English). ["We use a comparative approach to examine some of the physiological traits that make flight possible. Comparisons of related fliers and runners suggest that fliers generally have higher aerobic metabolic capacities than runners but that the difference is highly dependent on the taxa studied. The high metabolic rates of fliers relative to runners, especially in insects, are correlated with high locomotory muscle cycle frequencies and low efficiencies of conversion of metabolic power to mechanical power. We examine some factors that produce variation in flight respiration and energetics. Air temperature strongly affects the flight metabolic rate of some insects and birds. Flight speed interacts with flier mass, so that small fliers tend to exhibit a J-shaped power curve and larger fliers a U-shaped power curve. As body size increases, mass-specific aerobic flight metabolism decreases in most studies, but mass-specific power output is constant or increases, leading to an increase in efficiency with size. Intraspecific studies have revealed specific genetically based effects on flight metabolism and power output and multiple ecological correlates of flight capabilities." (Authors); *Anax junius* is mentioned] Address: Harrison, J.F., Arizona State Univ., Dept Biol., Tempe, AZ 85287, USA. E-mail: j.harrison@asu.edu

1859. Herren, B.; Herren, K. (2000): Entwicklung von *Onychogomphus forcipatus unguiculatus* in einem See (Odonata: Gomphidae). *Libellula* 19(1/2): 105-106. (in German with English summary). ["In 1998, 2 exuviae were collected at the Italian part of the Lago di Lugano. This is the first breeding record of the ssp. in a lentic habitat." 1860. Hill, B.; Beinlich, B. (2000): The dragonfly community of a communal cattle pasture in the Sava floodplain (Croatia) with special reference to the biology of *Lestes barbarus* (Fabricius, 1798) (Zygoptera: Lestidae). *Exuviae* 7: 1-18. (in English with Slovene summary). ["A total of 25 dragonfly species were recorded between May and September 1997 on the communal cattle pasture of Lonja village and its surrounding area

in the Lonjsko Polje Nature Park. At least 10 dragonfly species were reproducing successfully in the astatic ponds. *Sympetrum* spp. were dominating the community as they accounted for 95 % of all exuviae collected. Their high productivity in astatic environment is shown by average densities of over 70 exuviae/m²/year. By employing mark-recapture techniques it was stated that after emergence, *L. barbarus* covers distances of 80 to 880m to reach the hedges surrounding the pasture, where the animals spend the entire maturation period. Suitability of hedges as maturation habitat depends on their width and the width of adjacent margins. When mature, nearly all animals observed returned to the pond where they had emerged. Densely vegetated pond habitats with vegetation heights between 20 and 50cm are preferred reproduction sites for *L. barbarus*. The highest recorded age for individuals was 69 and 68 days for males and females respectively. The importance of low-intensity pasturing systems for nature conservation is briefly discussed." 1861. Hoekstra, J.D.; Smith, R.L. (2000): Reproductive behavior of two *Argia* spp. (Odonata: Coenagrionidae) at an Arizona stream. *Int. Jour. Odonatology* 3(1): 85-94. (in English). ["Here we provide a first report on the reproductive behavior of *Argia sabino* Garrison and *Argia pima* Garrison from observations at Sabino Creek, Arizona. Both species reproduce in autumn (September-October) following late summer rainstorms. Tandem pairs of *A. sabino* submerge to oviposit on rock substrates. The oviposition substrate is abundant and widespread. Male *A. sabino* defend mate-encounter territories in the morning at boulder fields or rock outcrops away from the stream. Copulation may last 30 minutes or more. Ovipositing females submerge in tandem with males, typically to depths of 10-30 cm, and pairs may remain submerged for over 30 minutes. Male submergence with females can be interpreted as contact mate guarding promoted by sperm competition and/or as a male investment in the female's survival and oviposition success. We discuss evidence for both possibilities based on field observations. Whereas ovipositional resources for *A. sabino* are ubiquitous at Sabino Creek, *A. pima* uses patchily distributed, discrete ovipositional habitats (wetter rootlets of riparian trees at waterfalls and riffles). Males of *A. pima* employ a mixture of contact and noncontact mate-attendance strategies. Females occasionally submerge to oviposit. Often they oviposit along the margins of torrential cascades. Male *A. pima* have been observed to release submerging mates just before their own wings become wetted, and to monitor submerged ovipositing females from a nearby perch thereafter." 1863. Holmen, M. (2000): Comments on Henning Pedersen's paper about rare and new dragonfly species in Denmark 1997-1998. *Nordic Odonatological Society Newsletter* 6(1): 16-17. (in Danish with English summary). ["In recent, almost identical papers in this and two other magazines, Henning Pedersen presented new records of several dragonfly species rare or new to the Danish fauna. The papers also includes a severe criticism on the presented distribution of species in the book on Danish dragonflies by Nielsen (1998). The present paper comments on the often very unprecise and reduced data, that are so far available from Henning Pedersen and his Danish mapping-project GOMPHUS. It also emphasizes the need to bring forward knowledge relevant for the protection of species and their habitats. A few corrections about older records mentioned in Henning Pedersen's paper are suggested. It is also suggested, that the specimen published by Ole Fogh Nielsen as *Sympetrum fonscolombei* new to Denmark, is actually a female *S. flaveolum*." (Author)] Address: Holmen, M., Gadeledsvej 48, Gadevang, DK.-3400 Hillerød, Denmark. E-mail: ma@fa.dk

1864. Hunter, M. (2000): Broad-bodied Chaser *Libellula depressa* in County Durham. *Atropos* 11: 58. (in English). [September record of *L. depressa* in north-east England.] Address: Hunter, M., 45 Brinkburn Avenue, Darlington, Co. Durham, DL3 0JN, UK.

1865. Illmonen, J.; Korkeamäki (2000): The fourth nordic meeting for odonatologists. *Nordic Odonatological Society Newsletter* 6(1): 8-10. (in English). [Report from the 4th meeting of the Scandinavian odonatologists on 26-28 June 1998 in Konnevesi Research Station, Finland. In the framework of the meeting, 28 species on five localities surveyed could be recorded, including species as *Platycnemis pennipes*, *Erythromma najas*, *Coenagrion armatum*, *C. johanssoni*, *Aeshna subarctica elisabethae*, *Ophiogomphus cecilia*, *Somatochlora flavomaculata*, *Leucorrhinia albifrons*, *L. caudalis*, *L. pectoralis*, and *Sympetrum flaveolum*.] Address: Korkeamäki, E., Karkunkatu 18 a 4 b, FIN-48600 Karhula, Finland.

1866. Jiang, Y.-H. (2000): Verification and distribution of genus *Aeschnophlebia* Selys (Odonata: Aeschnidae) in China. *Zhonghua Kunchong* 20(1): 63-67. (in Chinese with English summary). ["This article discusses the identity of two species of *Aeschnophlebia* Selys 1883, *A. anisoptera* Selys and *A. logistigma* Selys, in China. The author fully recognizes the presence of the latter by the specimen obtained from Nanjing and Yuntai Mountain in the northern part of Jiangsu Province. *A. anisoptera* Selys is not present in China. Descriptions and illustrations of these two species are provided. This article also states that *A. kolthoffi* Sjöstedt 1925 is a new synonym of *A. longistigma* Selys 1883." 1867. Jödicke, R.; Borisov, S.N.; Haritonov, A.Y.; Popova, O. (2000): Additions to the knowledge of *Sympetrum sinaiticum* Dumont (Odonata: Libellulidae). *International Journal of Odonatology* 3(2): 131-140. ["New information shows that *S. sinaiticum* is not divided into subspecies, as hitherto supposed. The subspecific name *tarraconense* Jödicke, 1994 must be regarded as a

junior synonym of *sinaiticum*. In contrast, the name *arenicolor* Jödicke, 1994 denotes a taxon at full species rank, characterized by its larval and ligula morphology. This species is taxonomically identical to *S. s. deserti* Jödicke, 1994. Since the latter name has been established in the same work, we determine the precedence of *arenicolor* as the valid name for the Asiatic species. Range, seasonality, and habitat selection of *S. sinaiticum* are outlined." (Authors)] Address: Jödicke, R., Großenging 14, D-49699 Lindern, Germany. E-mail: r.joedicke@t-online.de

1868. Jödicke, R. (2000): Späte Herbstnachweise von *Lestes sponsa* und *Sympetrum striolatum* (Odonata: Lestidae, Libellulidae). *Libellula* 19(1/2): 113-115. (in German with English summary). ["*L. sponsa* was on the wing until 07-XI-1999 in Baden-Württemberg, southwestern Germany, and *S. striolatum* until 17-XII-1994 in Switzerland. Both observations are the latest autumnal records of these species in Central Europe." (Author)] Address: Jödicke, R., Großenging 14, D-49699 Lindern, Germany. E-mail: r.joedicke@t-online.de

1869. Jödicke, R.; Arlt, J.; Kunz, B.; Lopau, W.; Seidenbusch, R. (2000): The Odonata of Tunisia. *Int. Jour. Odonatology* 3(1): 41-71. (in English). ["Between 1987 and 1999 several visits to 69 localities in Tunisia were made. Altogether 46 species of Odonata, including 10 new to Tunisia, were recorded, raising the Tunisian checklist to 52 species. Our observations cover early May to mid June and late September to early November. Using as a basis for inference data from nearby Numidia that cover the period missing from our own observations, we assume that many species have a long flight period. Among such species, some are known to be univoltine, exhibiting protracted aestivation as a prereproductive adult, whereas some others, we suggest, may be bivoltine." (Authors)] Address: Jödicke, R., Großenging 14, D-49699 Lindern, Germany. E-mail: r.joedicke@t-online.de

1870. Johnson, M.D. (2000): Evaluation of an arthropod sampling technique for measuring food availability for forest insectivorous birds. *J. field ornithol.* 71: 88-109. (in English). 1871. Jourde, P. (2000): Nouvelles données de captures d'odonates par un végétal non carnivore. *Martinia* 16(1): 3-7. (in French with English summary). [More than 200 individuals of *Calotperyx splendens*, *Platycnemis latipes*, *Ischnura elegans*, *Cercion lindenii*, *Ceragrion tenelleum*, and *Sympetrum striolatum* were seen caught by the bristles of Rough Bristle-grass *Setaria verticillata* growing along the river Charente in the French départements of Charente and Charente-Maritime.] Address: Jourde, P., 4, rue du Fressin, Les Creuseaux, 17250 Romegoux, France

1872. Jurzitza, G. (2000): *Der Kosmos Libellenführer. Die Arten Mittel- und Südeuropas.* Kosmos Naturführer. Franckh. Stuttgart. 2. überarbeitete und aktualisierte Ausgabe. ISBN 3.440-08402-7: 191 pp. (in German). [When in 1978 Gerhard Jurzitza's book on the Central European Odonata was published, a corner stone of Central and Western European odonatology was set. I can hardly imagine what would have happen with my li-

fe if I had not purchased this book as a schoolboy. I think, it was the most important book in my life. This book was translated into several languages and I suppose it has influenced many of us. Ten years later a new edition - with the species from southwestern Europe added - was published. The reader got a sound introduction into odontology, and many very good colour pictures which enabled people to enjoy and to identify dragonflies. The book was modern and the information given up-to-date. The second edition is improved by some amendments. The checklist of European dragonflies is quite complete, including species from Italy and southeastern Europe. The book is now hard bound. It is regrettable that the opportunity was not taken to produce a completely new book on the Odonata of Central and Southern Europe (as the title suggests!), Colour photographs of all species (except of *Cordulegaster charpentieri*?) are available and thus all species could have been covered. Additional species for France (*Somatochlora meridionalis*) are also not documented. Although this is a fine book, it contains no real new information compared to the 1988 edition. I never will forget the merits Dr. G. Jurzitza earns for his 1978 book and his odontological vita. Therefore it is very sad that he was not given the opportunity to write a completely new book on the (southern) European Odonata. (M. Schorr)]

1873. Kalkman, V.J. (2000): Records on the dragonfly fauna of northwestern Albania (Odonata). *Libellula* 19 (1/2): 107-111. (in English with German summary). ["A total of 24 Odonata species were recorded in June and July 1996. The characters of the ssp. of *Lestes virens* conform with neither with ssp. *virens* nor with ssp. *vestalis*. As expected the specimens of *Lestes viridis* belong to the ssp. *parvidens*." (Author)] Address: Vincent J. Kalkman, National Museum of Natural History, P.O. Box 9517, NL-2300 RA Leiden, The Netherlands. E-mail: Kalkman@naturalis.nnm.nl

1874. Kamimura, Y. (2000): Possible removal of rival sperm by the elongated genitalia of the earwig, *Euborellia plebeja*. *Zoological science* 17(5): 667-672. (in English). ["Sperm displacement is a sperm competition avoidance mechanism that reduces the paternity of males that have already mated with the female. Direct anatomical sperm removal or sperm flushing is known to occur in four insect orders: Odonata, Orthoptera, Coleoptera and Hymenoptera. In a fifth order, Dermaptera (earwigs), I found that the virga (the elongated rod of the male genitalia) of *Euborellia plebeja* seems to be used to remove rival sperm from the spermatheca (a fine-tubed female sperm storage organ). In this species, copulation lasted on average 4.6 minutes, during which time the male inserted the virga deep into the spermatheca, and then extracted it ejaculating semen from the opening of the virgal tip. The extraction of virgae (with its brim-like tip) appeared to cause removal of stored sperm in the spermatheca. The virga was as long as the body length of males, and the spermatheca was twice the female body length. The long length of the spermatheca and the possible removal function of the virga may select for virgal elongation." (Author)] Address: Kamimura, Y., Tokyo Metropolitan Univ., Dept Biol., Minamiosawa 1-1, Hachioji, Tokyo 0397, Japan. E-mail: kamimu@comp.metro-u.ac.jp

1875. Kempe, R. (2000): Das NSG "Heidemoor bei Ottermoor" und die "Otterheide". *Naturschutz in der*

Samtgemeinde Tostedt 11: 10-12. (in German). [In a more popular account on the flora and fauna of two bog-dune habitats near Tostedt (Niedersachsen, Germany) 15 odonate species not further detailed are mentioned. A freshly emerged *Aeshna subarctica elisabethae* is pictured.] Address: Kempe, R., Wörner Weg 3, D-21256 Höckel, Germany. E-mail: JureiKempe@aol.com

1876. Kenner, R.D.; Cannings, R.A.; Cannings, S.G. (2000): The larva of *Leucorrhinia patrica* Walker (Odonata: Libellulidae). *Int. Jour. Odonatology* 3(1): 1-10. (in English). [The final-stadium larva of *L. patricia* is described from six exuviae with associated teneral adults collected in northern British Columbia, Canada. "*L. patricia* belongs to the group of nearctic *Leucorrhinia* that has larvae with three ventral stripes. The larvae are very similar to those *L. hudsonica* (Sélys) larvae that are small and lack dorsal spines. Several characters help to separate these species, at least in the western part of their range: length of the epiproct and patterns of the profemora and abdomen. The preparation of a more definitive key awaits the analysis of more material of *L. patricia* and *L. hudsonica*." (Authors)] Address: Cannings, R.A., Royal British Columbia Museum, 675 Belleville Street Victoria, British Columbia V8W 9W2. Canada. E-mail: rcannings@royalbcmuseum.bc.ca

1877. Kinvig, R.G.; Samways, M.J. (2000): Conserving dragonflies (Odonata) along streams running through commercial forestry. *Odonatologica* 29(3): 195-208. (in English). ["Commercial afforestation of natural ecosystems is increasing worldwide. There is little information however, on the extent to which biodiversity is being affected by this practice. This is especially so for stream fauna, including the conspicuous Odonata. Some dragonflies and damselflies may decline when their natural environment is anthropogenically changed and, as a group, they are sensitive to the impact of afforestation. The sites were four pine plantations in KwaZulu-Natal, South Africa. 14 environmental factors were recorded along stretches of streams running through each of the four sites. The diversity of odonate spp. and their abundances along these streams were measured. There was a strong positive correlation between certain abiotic factors, for example, boulder cover and shade, with the local distributions of these insects. Water pH was also a strong correlate. Most spp. required both unpolluted water and a sunlit stream. Particular vegetation type and exact distance of pine trees from the water's edge (so long as they did not shade the stream) were not strong correlates. This meant that species diversity dropped dramatically where the water was completely shaded by a closed canopy, whether it was from natural forest or from exotic trees. It is recommended that no plantation trees should shade a stream edge, and should be planted at least 30m from the water. All highly invasive, dense-canopy weeds, especially *Acacia mearnsii*, should be removed, and extensive and intensive cattle trampling of the banks avoided." (Authors)] Address: Samways M.J., Invertebrate Conservation Research Centre, Dept Zool. & Entomol., University of Natal, P/Bag X01, Scottsville 3209, Pietermaritzburg, South Africa. e-mail: samways@zoology.unp.ac.za

1878. Kobayashi, H.; Sekizawa, Y.; Aizu, M.; Umeda, M. (2000): Lethal and non-lethal responses of spermatozoa from a wide variety of vertebrates and invertebra-

tes to lysenin, a protein from the coelomic fluid of the earthworm *Eisenia foetida*. *Journal of Experimental Zoology* 286(5): 538-549. (in English). ["Lysenin, a novel protein that we isolated from the coelomic fluid of the earthworm *Eisenia foetida*, binds specifically to sphingomyelin (SM) among various phospholipids found in cell membranes, and causes cytolysis. The plasma membrane of mammalian spermatozoa is known to contain SM at relatively high levels and we therefore examined the effects of lysenin on the spermatozoa of various animals. Lysenin had lethal effects on spermatozoa of 5 of 33 species of invertebrates tested and on spermatozoa of 30 of 39 species of vertebrates. We postulated that plasma membranes of the spermatozoa of most invertebrates might not contain SM whereas those of most vertebrate species might contain SM. These possibilities were supported by our failure to detect SM chemically in the testes of three species of invertebrates, in none of which spermatozoa responded to lysenin. In contrast, we detected SM in the testes of all 25 vertebrate species examined, irrespective of a negative or positive response of spermatozoa to lysenin. None of the six species of Protista examined was affected by lysenin. Our survey suggests that, in general, the spermatozoa of animals can be grouped into two categories, invertebrate and vertebrate, depending on the absence or presence of SM in their plasma membrane. The incorporation of SM into spermatozoa seems first to have occurred in protochordates during the course of evolution. Discussions about the exceptional responses to lysenin observed in the spermatozoa of five species of invertebrates and of nine species of vertebrates are made from phylogenetic and reproductive viewpoints." (Authors) *Crocothemis servilia*, *Orthetrum albistylum japonicum*, *Sympetrum darwinianum*, *Sympetrum frequens*] Address: Kobayashi, H., 3-16-17 Kamisaginomiya, Nakano-ku, Tokyo, 165-0031, Japan

1879. Kuhn, J. (2000): Pflegeproblematik in präalpinen Mooren am Beispiel von Libellen und Amphibien. In: Schutzgemeinschaft Libellen in Baden-Württemberg (SGL). 1882. Laurila, A. (2000): Behavioural responses to predator chemical cues and local variation in antipredator performance in *Rana temporaria* tadpoles. *Oikos* 88(1): 159-168. (in English). ["Antipredator behaviour is an important factor influencing survival probability of prey animals, and it may evolve rapidly as a response to changes in predator regime. I studied antipredator behaviour of common frog (*Rana temporaria*) tadpoles from three populations that differ in predator regimes. In the first experiment, tadpoles obtained from four natural matings in each population were subjected to chemical cues from either European perch (*Perca fluviatilis*) or from larvae of the dragonfly *Aeshna juncea*. Tadpoles decreased their activity in response to both predators, but the spatial behaviour of tadpoles differed between the two predator treatments. In general, there were no differences in behaviours among the populations, but in three out of four studied behaviours there were differences between parentages within the populations suggesting that these behaviours may be genetically determined. The lack of a significant Predator X Population interaction suggests no differences in plastic antipredator behaviour among the populations, while the lack of significant Predator X Parentage interaction suggests no genetic variance within the populations for plastic antipredator behaviour. In the second experiment, tadpoles from the three populations were exposed to predation by a free-ranging *A. juncea*. In line with the first experiment, there were no differences in survival rate between the populations. *R. temporaria* tadpoles seem to rely heavily on plastic antipredator behaviour as their main response to predator chemical cues. There was very little indication of local behavioural differentiation and the possible reasons for the lack of divergence among populations are discussed." (Author)] Address: Laurila, A., Dept of Population Biology, Evolutionary Biology Centre, Uppsala Univ., Norbyvagen 18d, SE-75236, Uppsala, Sweden

1884. Lingenfelder, U. (2000): Die Libellenfauna (Odonata) des Wieslautertales und ausgewählter Seitentäler im Pfälzerwald. Diplomarbeit, FB Sozial- und Umweltwissenschaften, Fachrichtung Biogeographie, Universität des Saarlandes: 186 pp. (in German). [The Pfälzerwald-region is situated in the southwestern part of Rheinland-Pfalz, Germany. The natural heritage of this region is outstanding, and so is its odonate fauna. Most important are the so called "Wooge", standing waters with a flora and fauna of transition bogs. Of European importance are the running waters with their strong populations of *Ophiogomphus cecilia*, and other river dwelling odonate species. One of these running waters, the Wieslauter, and the waters situated close to this brook, were investigated in 1999. 32 species could be observed. Each of the species is treated in a monographic way, and the records are mapped localitywi-

se. This is a very sound regional fauna with a lot of interesting details.] Address: Lingenfelder, U., Seebergstr. 1, 67716 Heltersberg, Germany

1885. Lohr, M. (2000): Reproduction de *Trithemis annulata* (Palisot de Beauvois, 1805) dans le département des Pyrénées-Orientales (Odonata, Libellulidae). *Martina* 16(2): 51-52. (in French with English summary). [July 5, 1999 two exuviae of *T. annulata* were found on the banks of River Tech near its mouth at the Mediterranean Sea, 15 km south-east of Perpignan, France.] Address: Lohr, M., An der Kirche 22, D-37671 Hörter, Germany

1886. Lucker, T. (2000): Revitalisierung von Fließgewässern der Agrarlandschaft - Ergebnisse limnologischer Effizienzuntersuchungen und Schlußfolgerungen für die Praxis. *Artenschutzreport* 9 (1999): 48-55. (in German with English summary). ["Since 1990 the nature conservation project „Revitalisierung in der Ise-Niederung" has taken a variety of measures to revitalise the cultivated land in the catchment area of the river Ise (east Lower Saxony). Scientific efficiency controls were carried out to determine the results for nature conservation aims. An increase of macrozoobenthos species diversity over a period of 7 years has been observed. However the number of rheotypical species showed more growth compared to limnotypical or indifferent species. These positive changes were analysed and discussed. References for establishing nature conservation achievements in landscapes of intensive farming were given from the limnological point of view." (Author). 7 odonate species including *Calopteryx splendens*, *Gomphus vulgatissimus*, and *Ophiogomphus cecilia* are recorded from 3 sample localities.] Address: Lucker, T., Otter-Zentrum, D-29386 Hankensbüttel, Germany

1887. Mahato, M. (2000): Resource partitioning among larvae of six coexisting odonate species of the Kali Gandakiriver, central Nepal (Anisoptera). *Odonatologica* 29(3): 209-223. (in English). ["Odonate larvae were collected from 50-1190 m elevation in central Nepal's Gandaki River from 1984 to 1986. Resource partitioning among coexisting odonate spp. at high (>500m) and low (<500m) elevations was investigated by examining their gut contents. At both elevations, diet differences between *Anisogomphus occipitalis* and *Davidius* sp. were statistically significant. *A. occipitalis* ate mostly midges whereas *Davidius* sp. ate mayflies and caddisflies as well as midges. At low elevation there was no diet difference between *A. occipitalis* and *Paragomphus lineatus* nor between the libellulids *Crocothemis servilia* and *Trithemis festiva*. Analyses of niche breadths indicate overlap between *Davidius* sp., *Macromia moorei*, *C. servilia*, and *T. festiva*, and between *A. occipitalis* and *P. lineatus*. Significant diet differences in both *A. occipitalis* and *Davidius* sp. between low and high elevations may indicate negative interactions in the presence of other coexisting species at low elevation. Similarly, at low elevation both spp. have a narrow niche breadth, a low average number of prey items per gut, and also more empty guts than at high elevation. Mean body weights of studied Odonata were relatively higher at lower elevation than at higher elevation. Predatory interactions seemed to be of little or no importance in structuring this lotic odonate assemblage, in contrast with lentic Odonata in other studies." (Author)] Address: Mahato, M., URS Greiner Woodward

1888. Mardulyn, H. (2000): Évolution des populations d'Odonates dans la réserve naturelle du Bec du Feyi, en Ardenne. *Gomphus* 16(1): 37-48. (in French with English and Dutch summaries). ["Since the creation of the nature reserve of Bec du Feyi in 1992, its dragonfly populations have been systematically monitored [...]. After seven seasons, 25 species have been found. The noticeable increase of observed annual species number, from 1993 to 1999, could be a result of the conservation and management measures taken in the reserve. Possible causes of important populations fluctuations noticed in some species are discussed." (Author) Emphasize is given to the development of the populations of *Coenagrion puella*, *Lestes sponsa*, and *Gomphus pulchellus*.] Address: Mardulyn, H., Avenue de la Liberté, 101, B-1080 Bruxelles, Belgium

1889. Marinov, M. (2000): Pocket field guide to the dragonflies of Bulgaria. Eventus Publishing House, Sofia. ISBN 954-90613-1-0: 104pp. (in Bulgarian). [In fact this is the first color field guide for any invertebrate group for Bulgaria. Only imagines are dealt with. Twelve color photos (page 14-17) represent different types of habitats in Bulgaria. The identification key (page 18-32) is organized using color computer graphics with arrows pointed to the exact morphological features. All 66 species so far known for Bulgaria are illustrated (page 34-95) and the color graphics from the identification key are added. In addition very short information for each species is provided. It refers to the species dimorphism (if any) - sexual and age dependend; closely related species; subspecies in Bulgaria (only for established ones); ecological notes (larval preferences); flying period (according to the earliest and latest observation dates for Bulgaria) and measurements (total length and wing span). The guide suffers from some mistakes the most significant of which is the coloration of the abdominal tip in female *Ischnura pumilio* (page 19 and 57), which is illustrated like in the male. (Autorreferat Milen Marinov). On page 79 frons and wing venation of *Somatochlora meridionalis* and *S. metallica* seem to be exactly the same computer graphs which correspond to *S. metallica*. The distribution maps of the species are useful. "The British Government, through the British Embassy in Bulgaria, decided to fund the publication because such a well-designed guide, used properly, can help in encouraging an interest of nature among young people in Bulgaria. We hope that the guide will bring a great deal of enjoyment to many people, and help them to appreciate and become more involved in Bulgaria's nature heritage."] Address: Marinov, M., P.O. Box 134, BG-1000 Sofia, Bulgaria. E-mail: mgmarinov@yahoo.com

1890. Martens, A. (2000): Group oviposition in *Coenagrion mercuriale* (Charpentier) (Zygoptera: Coenagrionidae). *Odonatologica* 29(4): 329-332. (in English). ["Pairs aggregate during oviposition. Discrimination experiments with pairs of floating leaves of *Berula erecta* show that tandems land preferentially on leaves where a single motionless male in the typical vertical position of a tandem male is present." 1893. McIntyre, P.B.; McCollum, A.S. (2000): Responses of bullfrog tadpoles to hypoxia and predators. *Oecologia* 125: 301-308. (in English). [Low dissolved oxygen concentrations present numerous challenges for non-air-breathing aquatic organisms. Amphibian larvae and their predators can respond to oxygen levels by altering their behavior and physiology, but the ecological consequences of these responses are generally unknown. We conducted two laboratory experiments to study the effects of dissolved oxygen on respiratory behavior and susceptibility to predation of larval bullfrogs (*Rana catesbeiana*). In the first, we exposed small, lungless tadpoles to a predatory salamander larva (*Ambystoma tigrinum*) under high and low oxygen conditions. More tadpoles were consumed in high oxygen tanks than in low ones, presumably because salamanders remained near the surface in the low oxygen tanks while most tadpoles rested on the bottom. Tadpole activity depended on both oxygen and predator presence: swimming decreased after addition of salamanders under high oxygen, but increased under low oxygen. In the second experiment, we examined the effect of predator chemical cues on the air-breathing rate of large tadpoles with well-developed lungs under low oxygen conditions. In the presence of chemical cues produced by dragonfly larvae (*Anax longipes*) consuming bullfrog tadpoles, air-breathing and swimming were significantly reduced relative to controls. These experiments demonstrate the potential impact of dissolved oxygen on predator-prey interactions, and suggest that outcomes depend on the respiratory ecology of both predator and prey." (Authors)] Address: McIntyre, P.B., Department of Ecology and Evolutionary Biology, Corson Hall, Cornell University, Ithaca, NY 14853-2701, USA
1894. McMillan, V.E. (2000): Postcopulatory behavior in *Libellula pulchella* Drury (Odonata: Libellulidae) and female tactics for avoiding male interference with oviposition. *Journal of insect behavior* 13(4): 573-583. (in English). [Postcopulatory behavior was studied in *Libellula pulchella*, a North American dragonfly in which ovipositing females face frequent harassment by unpaired males seeking matings. Although males performed noncontact guarding of their mates after copulation, females received minimal protection since their guards tended to leave on extended chases of other males when harassment was intense. Ovipositions by unguarded females were even more likely to be terminated by harassment and were disrupted sooner. Female tactics to minimize interference included rapid escape flights, repeated return visits to the water within short time periods, perching when severely harassed, and proceeding with mating when clasped. Female use of multiple oviposition sites is discussed in the context of guarding effectiveness and mate recognition by males." (Author)] Address: McMillan, Vicky, Colgate Univ., Dept. Biol., 13 Oak Dr. Hamilton, NY 13346, USA . E-mail: vmcmillan@mail.colgate.edu
1895. Meurgey, F.; Herbrecht, F.; Gurliat, P.; Dortel, F.; Boureau, A.; Duscoulier, F.; Williamson, T. (2000): Atlas préliminaire des Odonates de Loire-Atlantique. *Martinia* 16 (Suppl. 1): 1-28. (in French with English summary). [Commented maps of the 54 Odonata species recorded so far in Loire-Atlantique département, France.] Address: Meurgey, F., 2, rue Bossuet, F-44000 Nantes, France
1896. Meyer, E.; Meyer, A.; Billen, M. (2000): Fallbeispiel Sauer, ein Karstbach der Paderborner Hochfläche. *Natur- und Umweltschutz Akademie Nordrhein-Westfalen - Seminarberichte* 5: 121-128. (in German). [In a case study the macrozoobenthos of a carstic brook in the east of the federal state Nordrhein-Westfalen, Germany was surveyed from January to October 1996. *Calopteryx splendens* (larva) was found at a single sampling point.] Address: Meyer, Elisabeth, Inst. 1899. Moore, N.W. (2000): Interspecific encounters between male aeshnids: do they have a function? *International Journal of Odonatology* 3(2): 141-151. (in English). ["Male aeshnid dragonflies at a small pond (circumference ca 90 m) in Cambridgeshire, U.K. generally pursued males of other aeshnid species as well as their own. As a result of these encounters the pursued insect frequently left the pond, particularly when it belonged to a smaller species. Libellulids, which differed greatly from the aeshnids in size and appearance, were also pursued. Male aeshnids attacking males of other species frequently pressed home their attacks even when they were close enough apparently to identify the pursued insect. Consequently interspecific pursuits appear to have a function over and above ensuring that no opportunity is lost to mate or to drive out a conspecific rival. It is suggested that a positive function of interspecific pursuit is practice in developing fighting skills against conspecifics." (Author)] Address: Moore, N.W., The Farm House, 117 Boxworth End, Swavesey, Cambridge, CB4 5RA, UK.

1900. Moritz, K. (2000): Beitrag zur Insektenfauna des Bezirks Mattersburg, Burgenland. *Zeitschrift der Arbeitsgemeinschaft Österreichischer Entomologen* 52(1-2): 35-54. 1903. Nelson, B. (2000): Irish Odonata Recording Project. *Atropos* 11: 60. (in English). (Verbatim) ["A new project to record the distribution of Odonata in Ireland, DragonflyIreland, has been launched. This ambitious four-year project is supported by Dúchas, The Heritage Service, Environment and Heritage Service, and the Ulster Museum, Belfast. The active participation of all dragonfly recorders and naturalists is sought, and we would especially welcome records from anyone visiting Ireland. Old records would also be very welcome. Full details of the scheme can be found on the Dragonfly-Ireland webpages at <http://www.ulstermuseum.org.uk/> cedar or by contacting the scheme organiser Robert Thompson, 8 Weaver's Court, Banbridge, Co Down BT32 4RP. Enquiries about species or habitats can be

addressed to me at the address below."] Address: Nelson, B., Dept. of Zoology, Ulster Museum, Botanic Gardens, Belfast BT9 5AB, UK

1904. Nessimian, J.L.; Ribeiro, J.R.I. (2000): On the biology of *Buenoa platycnemis* (Fieber) (Insecta, Heteroptera, Notonectidae) at Restinga de Marica, Rio de Janeiro State, Brazil. *Revista Brasileira de Zoologia* 17 (1): 229-239. (in Portuguese with English summary). ["A monthly quantitative study on *B. platycnemis* (Fieber, 1851) was carried out in a sand dune marsh, on the littoral of Rio Janeiro State. The aims of this study were to correlate the life cycle of the species with the seasonal regime of the water body, defining steps of the annual cycle, age structure, and to indicate oviposition sites and trophic relations. The species shows a marked seasonal tendency. The major steps of the life cycle obtained were an invernal (weak) with a predominance of imagines, followed by another of population expansion, characterized by the absence of adults, massive eclosures and predominance of low instar nymphs. Probably, *B. platycnemis* has a sensibility to water level variation and might be influenced by the concentration of *Spirogyra* sp. (Chlorophyceae) in the water column. In relation to oviposition, *B. platycnemis* has not shown preference for any macrophyte [...]. The observed predators of *B. platycnemis* were *Anax amazilli* (Burmeister, 1839) (Aeshinidae), *Erythemis credula* (Hagen, 1861) (Libellulidae) and other Odonata [...]" (Authors)] Address: Nessimian, J.L.; Ribeiro, J.R.I., Departamento de Zoologia, Instituto de Biologia, Universidade Federal do Rio de Janeiro, 21944-970 Rio de Janeiro, RJ Brazil

1905. O'Brien, M. (2000): A brief history of odonatologists at the University of Michigan Museum of Zoology. *Argia* 12(2): 13-16. (in English). [Edward Bruce Williamson, Clarence H. Kennedy, Dolly Gloyd, Mike Wright; for German odonatologists the paragraph on Friedrich Förster ist of special interest; this contribution will be of enormous importance for all odonatologists interested in the history of odonatology because it opens a window to new and unexpected sources of information.] Address: O'Brien, M., Insect Division, Museum of Zoology, University of Michigan, Ann Arbor, MI 48109-1079, USA. 1919. Peters, G. (2000): Unbekannte Bekannte: die Anax-Species in Europa (Odonata: Aeshnidae). *Libellula* 19(1/2): 53-64. (in German with English summary). ["The records of a fifth Anax species in Europe, namely *A. junius* (DRURY), invited comment on the systematics and nomenclature of the taxon Anax in general and the westpaleartic species in particular, supplemented by remarks on their species-specific characters, including a determination key for their exuviae. It seems likely that *A. junius* will appear again in western Europe. Thus

strong emphasis should be put on accurate observations of the activities of living specimens as well as on safeguarding of voucher specimens and their examination by specialists." (Author)] Address: Peters, G., Museum für Naturkunde, Institut für Systematische Zoologie, Invalidenstr. 43, D-10115 Berlin, Germany. E-mail: dirzool@rz.hu-berlin.de

1920. Pinkney, A.E.; McGowan, P.C.; Murphy, D.R.; Lowe, T.P.; Sparling, D.W.; Ferrington, L.C. (2000): Effects of the mosquito larvicides temephos and methoprene on insect populations in experimental ponds. *Environmental Toxicology and Chemistry* 19(3): 678-684. (in English). ["The nontarget effects of Abate(r) 4E (44.6% temephos) at 0.054 kg of active ingredient (a.i.) per 1 ha and of Altosid(r) Liquid Larvicide (5% methoprene) at 0.011 kg a.i./ha were investigated in 18 experimental ponds (average area, 202 m² maximum depth. 0.7 m) at Patuxent Wildlife Research Center, Laurel, Maryland, USA. Ponds were sprayed three times at 3-week intervals. Six ponds were sprayed with Abate, six with Altosid, and six with distilled water. Two insect-emergence traps per pond collected for 7 d and were then harvested 1 d before each spray and 13 to 14 days afterward. A repeated measures analysis of variance (ANOVA) revealed significant reductions in Shannon diversity, equitability, and numbers of individuals, species, and families in the Abate ponds relative to controls. Significant reductions also occurred in Ephemeroptera, Odonata, Diptera, Chironomidae, and Chaohorus sp. Hester-Dendy samplers were installed before spray one and harvested 16 d after spray three. Based on one-way ANOVA, Shannon diversity, equitability, and number of Ephemeroptera and Chironomidae were significantly reduced in the Abate ponds. Emergence data indicate only isolated cases with significant reductions in the Altosid ponds relative to controls, and the Hester-Dendy data indicate no significant differences between the Altosid and control ponds." (Authors)] Address: Pinkney, A., U.S. Fish and Wildlife Service, Chesapeake Bay Field Office, 177 Admiral Cochrane Drive, Annapolis, Maryland 21401 tU.S. Geological

1921. Piper, W.; Krüner, U. (2000): Libellennachrichten. *Libellennachrichten* 4: 1-20. (in German). [Volume 4 of the newsletter of the Society of German Speaking Odonatologists contains information on recent activities of the society as well as the minutes of the 19th meeting, announcement of meetings, reviews of odonatological publications and CD-ROM's, new theses on Odonata, calls for cooperation ...] Address: Krüner, Ulrike, Gelderner Str. 39, D-41189 Mönchengladbach, Germany

1922. Plaistow, S.J.; Tsubaki Y. (2000): A selective trade-off for territoriality and non-territoriality in the polymorphic damselfly *Mnais costalis*. *Proceedings of the Royal Society Biological Sciences Series B*. 267(1447): 969-975. (in English). ["Males of the damselfly *Mnais costalis* occur as territorial orange-winged 'fighter' males or non-territorial clear-winged 'sneaker' males. Their morph life histories differ considerably but the estimated lifetime reproductive success is the same for the two morphs. In this study we compared the developmental and reproductive costs associated with the two morphs. Orange-winged male and female reproductive costs resulted in a decline in adult fat reserves with increasing age. In contrast, the fat reserves of clear-winged males remained constant with adult age. Body size was posi-

tively correlated with mating success in orange-winged males, but had no influence on the mating success of clear-winged males. The orange-winged male flight muscle ratios (FMRs) were significantly higher than the clear-winged male and female FMRs. However, there was no difference in the size-corrected fat reserves of the two morphs; both had higher fat reserves than females. The gain in mass between eclosion and reproduction in orange-winged males and females was almost double the mass gained by clear-winged males, suggesting that clear-winged male development is less costly. An experiment in which pre-reproductive levels of nutrition were manipulated confirmed this." (Authors)] Address: Plaistow, S.J.; Tsubaki Y., Laboratoire Ecologie-Evolution (UMR CNRS 2155 Biogeosciences), Université de Bourgogne, 6 Boulevard Gabriel, F-21000 Dijon, France

1923. Pritchard, G.; Harder, L.D.; Kortello, A.; Krishnaraj, R. (2000): The response of larval growth rate to temperature in three species of coenagrionid dragonflies with some comments on *Lestes disjunctus* (Odonata: Coenagrionidae, Lestidae). *International Journal of Odonatology* 3(2): 105-110. (in English). ["Larval growth rate has the same temperature coefficient in three species of coenagrionids, but *Argia vivida* and *Amphiagrion abbreviatum*, which frequently live in geothermally heated water, grow fastest at 29.0-30.0°C compared with 23.4°C for *Coenagrion resolutum*, which lives in cooler water. Survival below 15°C in the laboratory was much better in *C. resolutum*. These characteristics are reflected in the distributions of the three species, *C. resolutum* ranging much further north in North America than the other two species, but not penetrating as far south. By contrast, the temperature coefficient for *Lestes disjunctus* is higher than that of the coenagrionids, and this is related to a different life history. In the coenagrionids, one or more winters are spent in the larval stage. In *L. disjunctus*, winter is spent in the egg stage, and larval growth must be completed quickly." (Authors)] Address: Pritchard, P., Department of Biological Sciences, University of Calgary, 2500 University Drive NW, Calgary, Alberta, Canada T2N 1N4. E-mail: gpritcha@ucalgary.ca

1924. Ramirez, A.; Paulson, D.R.; Esquivel, C. (2000): Odonata of Costa Rica: Diversity and checklist of species. *Revista de biología tropical* 48(1): 247-254. (in English). ["An updated list of the Odonata of Costa Rica is presented containing 268 species. Since the last published list for the country, 41 additional species have been reported. The country is the best studied in Central America. The most species-rich families are Libellulidae, Coenagrionidae, Gomphidae, and Aeshniidae, together comprising similar to 75% of the total fauna. Most species in the country are also found in South America, indicating a tendency for wide ranges rather than endemism. However, about a fifth of the species appear to be endemic to the Costa Rica-Panama region. Estimates of the range of the proportion of total world species occurring in Costa Rica lead to predictions of a range of 5 600-9 000 species of Odonata worldwide." 1929. Relyea, R.A.; Werner, E.E. (2000): Morphological Plasticity in Four Larval Anurans Distributed along an Environmental Gradient. *Copeia* 2000(1): 178-190. (in English). ["We investigated morphological plasticity to the presence of predators in the tadpoles of four ranid frog species distributed along a pond hydroperiod gradient in southeast Michigan. We first reared all four species (Wood Frog, *Rana sylvatica*, Leopard Frog *R. pipiens*, Green Frog, *R. clamitaw*, and Bullfrog, *R. catesbeiana*) under identical laboratory conditions in the presence and absence of caged larval dragonflies (*Anax* spp. [*A. junius*, *A. longipes*]). We then reared wood frog and leopard frog in outdoor mesocosms to examine the predator-induced responses during ontogeny. Finally, we reared leopard frog with predators fed either leopard frog or wood frog larvae to determine whether prey responses depended upon predators consuming conspecific prey. All four ranids exhibited some degree of morphological change in the presence of *Anax*; these differences were species specific and fairly robust to

different experimental conditions. The responses over ontogeny indicated that the changes were direct responses to the predator's presence and not an indirect result of the predator slowing anuran growth or development. Finally, larval leopard frog responded similarly to predators feeding on conspecifics and congeners. Taken together, these results suggest that morphological responses to predators may be relatively common in larval anurans. Further, because many of the responses are known to be adaptive antipredator strategies, predator-induced morphological plasticity has important evolutionary and ecological implications." 1935. Rolff, J.; Antvogel, H.; Schrimpf, I. (2000): No correlation between ectoparasitism and male mating success in a damselfly: Why parasite behavior matters. *Journal of insect behavior* 13(4): 563-571. (in English). ["The mating success of individually marked male damselflies parasitized by water mites was closely followed. The number of ectoparasites could be determined exactly from knowledge of the parasite's life cycle. In contrast to previous studies no correlation between water mite infestation and male mating success was revealed. The reasons for this discrepancy may be explained by the inclusion of the parasite's behavior. The body fat content of the males was negatively correlated with the mite load, indicating that parasitism reduces host's condition. It is hypothesised that the water mites damselfly system is not valuable for testing the Hamilton and Zuk hypothesis. Furthermore, selection exerted or mediated by parasites should act during the teneral phase." (Authors) *Enallagma ebrium*, *Coenagrion puella*] Address: Rolff, J., Tech. Univ. Braunschweig, Inst. 1936. Rolff, J. (2000): Water mite parasitism in damselflies during emergence: two hosts, one pattern. *Ecography* 23: 273-282. (in English). ["The infections of emerging damselfly cohorts by ectoparasitic water mites *Arrenurus cuspidator* were followed closely over two years in two populations. In one pond *Coenagrion puella* was the single host species, whereas in the second pond *C. hastulatum* co-occurred. The prevalences found were close to 100%. The mean daily abundance of mites ranged from 1 to 45 mites per host with a peak after roughly one third of the emergence period. The water mites displayed a clumped distribution on their hosts measured by the variance/mean ratio. No differences in parasite abundance due to host sex, head width, or host species could be detected. The abundance of mites was synchronised with host's emergence patterns. This was stronger in the system with two host species. Shaw and Dobson recently showed a generalised relationship of variance/mean of parasite abun-

dance combining data from 269 host parasite systems. The data presented here and some other water mite associations show a significant deviation from this general rule." 1943. Schorr, M. (2000): Störungsökologische Wirkungen von Bootsportaktivitäten auf Fließgewässer-Libellen - dargestellt am Beispiel der Wieslauter (Pfälzerwald, Rheinland-Pfalz). *Fauna und Flora in Rheinland-Pfalz* 10: 663-679. [Possible conflicts between boating activities on running waters and the needs of conservation - exemplified by dragonflies (Odonata) along the brook Wieslauter (Pfälzerwald, Rheinland-Pfalz, Germany). The Wieslauter, a brook situated in the District Südwestpfalz (Rhineland-Palatinate), is of European importance as far as nature conservation is concerned. Over the past few years the brook has been increasingly used by canoeists and this has caused a lot of problems with local people owning property on its banks and it has also caused conflict with the conservationists. As the problems escalated, it became necessary to resolve them by using official administrative procedures ("Regelung des Gemeingebrauchs durch Kanuten an der Wieslauter"). This paper focuses on the odonatological arguments used to solve the conflicts. (1) Canoeing seriously affects the habitats of the early stages of Odonata: scraping along the bed of a brook causes a catastrophic drift of larvae and ova; people getting in or out of canoes can hurt or even cause death in larvae living in the substrate near the shore line; drifts of fine sand particles block the rectum of larvae and this can cause suffocation, especially among the later instars (see Tobias 1996). (2) The wash of moving canoes can seriously harm individuals emerging near the waterline, often causing deformities in abdomen and wings. Those affected by the wash will try to remove the water drops by moving the abdomen up and down and by beating the wings, actions which make them more detectable for predators such as birds. Heavy wash can also remove an individual from its chosen emergence site, which will lead to its death by drowning. (3) Passing canoes in smaller parts of a brook have an impact on the territories of the males by causing them to move away; they will also disturb ovipositing females and even prevent them from egg laying. When such disturbances occur frequently, the residents and dispersing individuals along the brook will leave it; in some species, females only use a short period of the day for egg laying and, if distracted in this period, no reproduction is possible. Both factors have serious effects on the reproduction success of a population. To solve the problems between canoeists and the needs of conservation, it may, in a few cases, become necessary to curb such disruptive activities in order to preserve the biotopes. It is vital for the preservation of

such key stone species as *Ophiogomphus cecilia* (species of the European Habitats Directive) to have brooks without any canoeing at all. In other cases it may be possible to find solutions for a common enjoyment of running waters by sportsmen and dragonflies. 1946. Simpkin, J.L.; Britten, H.B.; Brussard, P.F. (2000): Effects of habitat fragmentation and differing mobility on the population structures of a Great Basin dragonfly (*Sympetrum corruptum*) and damselfly (*Enallagma carunculatum*). *Western North American Naturalist* 60(3): 320-332. (in English). ["The population structure of 2 Great Basin odonate species was assessed using protein electrophoresis. Analyses included 7 populations of *Sympetrum corruptum* [...], a migratory and highly mobile dragonfly and 8 populations of *Enallagma carunculatum* [...], a weak flier that is not known to migrate far from natal water sources. Though we expected the damselfly (*E. carunculatum*) to show greater genetic isolation than the dragonfly (*S. corruptum*). Both species apparently had high levels of gene flow ($\theta = 0.0604$ for *S. corruptum*, $\theta = 0.0485$ for *E. carunculatum*) and showed no evidence for isolation by distance. These results suggest that both species are highly vagile and that the most important factors affecting population structure of these odonates may be ecological conditions such as habitat patchiness and the ephemerality of water sources." (Authors)] Address: Simpkin, Janice, Life Sciences. College of Southern Idaho, Twin Falls, ID 83303, USA

1947. Sokolovska, N.; Rowe, L.; Johansson, F. (2000): Fitness and body size in mature odonates. *Ecological Entomology* 25(2): 239-248. (in English). ["The relationship between body size and fitness components in odonates was examined using a meta-analysis of 33 published studies. There was a positive and significant overall effect of body size on mating rate and lifetime mating success among males. There was also a weaker but still significant positive effect of body size on survivorship of males. The relationship between body size, mating rate, longevity, and lifetime mating success differed significantly between males of territorial species. The effect of body size was significant for all fitness components in territorial species but significant only for longevity and lifetime mating success in nonterritorial species. Effect sizes appeared to be strongest on longevity in both sexes, and on male mating rate in

territorial species. Other effect sizes, even when significant, were small. Despite a much smaller data set, female fitness also increased significantly with body size. Both clutch size and longevity showed a significant positive relationship with body size. These results suggest that there is a general fitness benefit to large size in odonates. Nevertheless, significant heterogeneity is apparent in this effect, which can be attributed to sex, mating system, and fitness component. Finally, these analyses point to inadequacies in the current data that need further study before the potentially rich patterns in size effects on fitness can be explored more thoroughly." 1952. Stoks, R. (2000): Components of lifetime mating success and body size in males of a scrambling damselfly. *Animal Behaviour* 59(2): 339-348. (in English). ["Sexual selection is hypothesized to favour small body size in males of scrambling species, that is, those in which males obtain matings by actively searching for females. I tested this hypothesis in a natural population of the scrambling emerald damselfly, *Lestes sponsa*. Mating efficiency (matings/visit to the pond) was the most important factor explaining variation in male lifetime mating success (LMS; 71%). This suggests a large potential for sexual selection. Path analysis of male LMS suggested a quality factor that positively affected both mating efficiency and life span. In contrast with the small-male mating advantage hypothesis, part of this potential for sexual selection was realized as stabilizing selection on male body size, indicating that there may also be a lower limit to body size for mating efficiency. This also illustrates that the constancy of body size may be explained by sexual selection alone. Survival explained about 20% of the variation in LMS and random processes were potentially important for determining LMS. My results show the problems of using mating efficiency as a measure for the intensity of sexual selection and the need to distinguish between potential and realized selection pressures, especially when comparing the importance of natural and sexual selection. I discuss mechanisms that may have caused the intermediate-male mating advantage in this scrambling species." 1953. Stoks, R. (2000): De Bruine Korenbout (*Libellula fulva*) in Vlaanderen in de jaren '90: vooruitgang of status quo? *Gomphus* 16(1): 49-60. (in Dutch with English and French summaries). ["*Libellula fulva* in Flanders in the '90: advance or status quo? - The dragonfly *Libellula fulva* is a critically endangered species in Flanders. In the period 1996-1999 there was a sharp increase in both the number of observations and observation sites. Analysis of the new records showed that the new sites were almost always very close to the known sites in the regions Klein-Brabant and northeast Limburg. Furthermore, at a lot of the observation sites there is no proof of local reproduction and even if there is proof, populations are always small. Therefore, the increase in records probably does not reflect a real increase in numbers and may just reflect an increase in

observation intensity and the status of the species in Flanders probably has not changed. Some evidence is given for the existence of a population north of Antwerpen. At least in Belgium, the species seems to have a broad habitat spectrum with a preference for lentic or lotic water depending on the region. The apparent difference in habitat choice of the species between countries and its potential reasons and implications for species conservation are discussed." Notes on the larval habitat, life history pattern and emergence are added." (Author)] Address: Suri Babu, B., Scene of Crime Mobile Unit, Police Control Room, Jagdalpur-494001 (M.P.), India

1956. Switzer, P.V.; Grether, G.F. (2000): Characteristics and possible functions of traditional night roosting aggregations in rubyspot damselflies. *Behaviour* 137(4): 401-416. (in English). ["Many species of animals congregate into groups when roosting. While studies exploring roosting behavior are common, relatively few detailed, quantitative studies have been done on the roosting behavior of insects, and the adaptive value of roosting aggregations are still unclear for most edible (non-distasteful) species of any taxon. We investigated night roosting aggregations of the rubyspot damselfly, *Hetaerina americana*, along a creek in the Coastal Range Mountains of California. Both male and female rubyspots were found in roosting aggregations, although the aggregations tended to be male-biased relative to the population sex ratio. Rubyspots roosted on the west side of slow moving sections of the creek; within this habitat they were highly aggregated but were not associated with any particular habitat features. The spatial pattern of site use tended to change gradually over time and sites with a relatively large number of individuals were more likely to be used on subsequent nights. These results suggest that within suitable habitat, the specific locations of roosting aggregations were traditional (socially learned). Rubyspot roosting patterns, when taken in combination with other aspects of this species' biology, do not support habitat limitation, thermal or desiccation benefit, foraging, and aposematic hypotheses for the function of rubyspot roosting aggregations. Rather, the roosting aggregations most likely serve an anti-predator function or are the result of using conspecifics to choose safe sites." 1963. Thompson, D.J. (2000): On the biology of the damselfly *Vestalis amabilis* Liefinck (Odonata: Calopterygidae) in Borneo. *International journal of Odonatology* 3(2): 179-190. (in English). ["The habitat, territorial and reproductive behaviour of the Bornean calopterygid damselfly *V. amabilis* are described. Males are territorial and will remain at the same site defending a territory for up to three weeks. Territories take the form of sun flecks whose physical location changes slowly throughout the day as the sun moves across the sky. There is a considerable amount of fighting between males, ranging from simple, short chases to more extensive escalated contests. Longer contests are thought to be brought about due to confusion over residency as the physical location of the territory changes. Courtship is brief and simple, copulation duration is around 2 minutes and females oviposit alone while being non-contact guarded by the male. Oviposition takes place in dead leaves, usually over about 30 minutes during which time the pair is harassed by other males. Matings are infrequent and females prospect either the territories or the territory owners before accepting courting males, resulting in more copulations later in the day." (Author)] Address: Thompson, D.J., Population Biology Research Group, School of Biological Sciences (Nicholson Building), University of Liverpool, P.O. Box 147, Liverpool, L69 3BX, UK
1964. Tóth, S. (2000): Comparative analysis of dragonfly (Odonata) fauna living in the streams flowing into shallow lake Balaton. *Folia Musei historico-naturalis Bakonyiensis* 15 (1996): 53-73. (in Hungarian with English and German summaries). [The odonate fauna of the running waters feeding Lake Balaton was surveyed in 1994 and 1995. 29 species are recorded and documented locality wise. Of some interest is the strong population of the rare European *Coenagrion ornatum* along the small running waters.] Address: Toth, S., Széchenyi u. 2, H-8420 Zirc, Hungaria. E-mail: flycatcher@freemail.hu
1965. Trockur, B.; Mauersberger, R. (2000): Vergleichende ökologische Untersuchungen an *Epitheca bimaculata* Charpentier 1825 im Saarland und in der Uckermark (Odonata: Corduliidae). *Beiträge zur Entomologie* 50(2): 487-518. (in German with English summary). [Between 1988 and 1998, more than one hundred habitats of the rare *E. bimaculata* were studied in the western parts of the Saarland (SW-Germany) including the adjacent parts of Luxembourg and France (especially the valleys of the rivers Saar and Mosel), and in the Uckermark („Biosphärenreservat Schorfheide-Chorin“, NE-Germany). In the Saarland-region, "the species inhabits eutrophic to polytrophic artificial backwaters, gravelpits and fish-ponds, whereas in the Uckermark it occurs in small natural, predominantly eutrophic lakes. Relevant characteristics of the *Epitheca*-habitats in both regions are: ● calm waters of small area: 85% of the habitats are less than 10 ha, 63% less than 4 ha; ● relatively shallow water body without distinct stratification: maximum water depth between 1.1 and 12 m (91% less than 8 m, 67% between 2 and 6 m, only 12% with complete temperature stratification) ● low oxygen content in deeper strata: usually less than 2 mg O₂/l below 4 m; ● water clouded by phytoplankton, eutrophic to polytrophic: breeding sites between 0.5 and 3.1 m median Secchi-depth (68% with visibility of less than 2 m); ● water surface with abundant floating or submerged vegetation, more rarely also tree trunks or reed: substrates for oviposition and habitats of the younger larvae; ● water surrounded by shrubs and/or deciduous woodland; ● water inhabited by fish populations; ● the dragonfly communities are dominated by *Orthetrum cancellatum*, *Cordulia aenea* and *Erythromma* species; aeshnids usually occur at low densities. The typical habitats of *Epitheca* in central and western Europe are not large, oligotrophic lakes or slightly acetous bog ponds, but still waters in the flood plain (river lagoons or gravel pits) and small lakes inhabited by fish populations." (Authors).] Address: Trockur, B., Schulstr. 4, D-66636 Tholey-Scheuern, Germany.
1966. Valley, S. (2000): Some interesting observations of *Tanypteryx hageni*. *Argia* 12(2): 9. (in English). 1967. Vick, G.S. (2000): *Mesumbethemis takamandensis* gen. nov., spec. nov., a new genus and species of the Tetrathemistinae from Cameroon, with a key to the African genera of the subfamily (Anisoptera: Libellulidae). *Odonatologica* 29(3): 225-237. (in English). ["The new sp. is described from a single male from Cameroon (South West Prov., Manyu, Takamanda Forest Reserve, Assam, 06°01'N, 09°18'E, alt.140 m, 20-II-1998). The holotype will be deposited in the collection of the Natural History Museum (London). The justification for the placement of the new genus in the Tetrathemistinae is presented. Because of the combination of characters of wing venation which it possesses, the new sp. does not fit into any existing genus and the new genus *Mesumbethemis* is erected to accommodate it. The unique shape of the anal appendages and the accessory genitalia can at this stage also be regarded as characteristic of this presently-monotypic genus. A key to the African Tetrathemistinae genera is provided." (Author)] Address: Vick, G.S., Crossfields, Little London, Tadley, Hants RG26 5ET, United Kingdom
1968. Viessmann, R. (2000): Libellen - Odonata. Pflanzen und Tiere in Rheinland-Pfalz - Berichtsjahr 1999 - Heft 10: 195-209. (in German). [Compilation of dragonfly records from different habitats situated in the eastern and southern parts of Rheinland-Pfalz, Germany. Of faunistical interest are the records of *Coenagrion mercuriale*, *C. pulchellum*, *Erythromma najas*, *Ischnura pumilio*, *Lestes barbarus*, *Sympetma fusca*, *Brachytron pratense*, *Aeshna affinis*, *Anax parthenope*, *Ophiogomphus cecilia*, *Crocothemis erythraea*, *Libellula fulva*, *Orthetrum brunneum*, and *Sympetrum flaveolum*.] Address: Viessmann, R., Gängelstockweg 8, D-67295 Bolanden, Germany

1972. Watanabe, M.; Taguchi, M. (2000): Behavioural protandry in the damselfly *Mnais pruinosa costalis* Selys in relation to territorial behaviour (Zygoptera: Calopterygidae). *Odonatologica* 29(4): 307-316. (in English). ["The reproductive strategy of the male *M. p. costalis* can be defined as an attempt to maximize the number of females mated. Males exhibit wing colour dimorphism: one form has orange wings, and the other has hyaline wings which resemble female wings. The former is usually territorial and the latter uses sneaky mate securing tactics around the territories of orange-winged males. Although the length of the emergence period varied from year to year, no evidence of protandry was observed. Studies over 10 years have shown that if the length of the sexually active period in females is stable, the orange-winged males should become sexually mature before females do to achieve maximal reproductive success. On the other hand, the hyaline-winged males do not mature before females due to the fact that they utilize the territories of orange-winged males. This study shows that behavioural protandry should be considered a reproductive strategy of the orange-winged males for establishing territories." (Authors)] Addresses: Watanabe, M., Department of Biology, Faculty of Education, Mie University, Tsu, Mie 514-8507, Japan. E-mail: watanabe@edu.mie-u.ac.jp. 1973. Wazalwar, S.M.; Tembhare, D.B. (2000): Innervation of mouthpart sensilla in the dragonfly *Brachythemis contaminata* (Fabricius) (Anisoptera: Libellulidae). *Odonatologica* 29(4): 359-364. (in English). ["Neuroanatomical studies demonstrate single dendritic innervation of trichoid sensilla, basiconic sensilla and microtrichia, and multidendritic innervation of the papillae and sensory pegs. These sensilla can therefore be considered as mechano- and chemo-receptors respectively. The campaniform sensilla are innervated by several dendrites and may function as proprioceptors. No innervations of the spines, teeth, hooks and acanthae was observed suggesting non-sensory nature." (Authors)] Address: Tembhare, D.B., Dept Zool., Nagpur Univ. Campus, Amravati Road, Nagpur-440010, Maharashtra, India

1974. Weidel, B.C.; Josephson, D.C.; Krueger, C.C. (2000): Diet and prey selection of naturalized smallmouth bass in an oligotrophic Adirondack lake. *Journal of freshwater ecology* 15(3): 411-420. (in English). ["Smallmouth bass (*Micropterus dolomieu*) introduced nearly 50 years ago have established a permanent population in Little Moose Lake, NY. Over 500 smallmouth bass were collected by angling in the littoral zone from June to August. Gut contents were compared for differences based on length of bass, date of capture, and substrate type where each fish was caught. Crayfish were the most frequent diet item and made up the largest percent composition by number. The average number of crayfish per stomach increased with bass length as did the number of fish per stomach. Crayfish, Ephemeroptera, Odonata, and fish made up 77% of the total number of diet items, excluding zooplankton. A noticeable diet shift from smaller diet items (Ephemeroptera) to larger ones (crayfish and fish) occurred when smallmouth bass approached 150 mm. A high amount of diet overlap occurred between bass caught over different substrate types and among most size classes. Smallmouth bass in Little Moose Lake were opportunistic feeders, using benthic, terrestrial, and pelagic littoral zone food resources. The most likely processes by which smallmouth bass affect salmonid and native fishes in Little Moose Lake are competition for food resources and predation." (Authors)] Address: Josephson, D.C., Cornell Univ., Dept Nat. Resources, Fernow Hall, Ithaca, NY 14853, USA. E-mail: dcj3@cornell.edu

1975. Weihrauch, F. (2000): A note on *Brachytron pratense* (Müller, 1764) from coastal Istria, NW Croatia (Anisoptera: Aeshnidae). *Exuviae* 7: 19-26. (in English with Slovene summary). ["A good population of *Brachytron pratense* was recorded on 25-IV and 28-IV-2000 from Lake Palud near Rovinj, representing its first record for the Istria peninsula. All relevant references as well as known unpublished data were gathered in order to outline and discuss the distribution of the species in the Adriatic region. In addition, April records for five other dragonfly species, observed at eight localities in Croatian Istria, are appended." 1977. Wildermuth, H. (2000): *Lestes barbarus* bei der Eiablage in einem subalpinen Hochmoor der Schweizer Alpen (Odonata: Lestidae). *Libellula* 19(1/2): 93-96. (in German with English summary). ["On 22 August 1999 a single female was seen ovipositing in stems of *Scheuchzeria palustris* and *Trichophorum caespitosum* in a small alpine bog at 1690 m a.s.l. near the natural tree line. The record is unusual regarding the climatic situation as well as the habitat type." (Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rütli, Switzerland. E-mail: wildermuth@swissonline.ch

1978. Wildermuth, H. (2000): Totstellreflex bei Großlibellenlarven (Odonata). *Libellula* 19(1/2): 17-39. (in German with English summary). ["Larvae of 18 European Anisoptera species, mainly final instar, were studied with respect to reflex immobilization (RI). In *Brachytron pratense*, *Somatochlora flavomaculata*, *S. meridionalis*, and *S. metallica* RI revealed an obligatory reaction to disturbance in the water. An additional 4 species exhibited facultative RI. All the other species reacted by rapid escape or became immobile for some time but only when they were brought on land. RI was released exclusively by tactile stimulation, especially by a firm grip on the thorax or abdomen, but not on the legs or antennae. In 3 *Somatochlora* spp. RI lasted 83, 87 and 154 s (median values) and varied between 5 and 679 s. The posture during RI, depicted in 10 line drawings, differed according to the species. In *Somatochlora* up to 3 postures were recorded: larvae either extended their legs laterally or folded them closely against the body or held them obliquely upwards. In individuals that were successively stimulated, the duration of RI tended to decrease, but not in all cases. Larvae of 2 *Somatochlora* alpestris, *S. arctica* and *S. flavomaculata* exhibited RI already in the first free-living larval instar. The adaptive value of RI which is assumed to be an antipredation strategy, is discussed with respect to the species, microhabitats and potential predators." (Author)] Occurrence of reflex immobilization of the following species is compiled in a tab.: *Aeshna cyanea*, *A. juncea*, *Anax imperator*, *Cordulegaster boltonii*, *Cordulia aenea*, *Epithea bimaculata*, *Libellula quadrimaculata*, *Libellula fulva*, *Orthetrum cancellatum*, *Orthetrum coerulescens*, *Sympetrum striolatum*, *Leucorrhinia dubia*, and *L. pectoralis*.] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rütli, Switzerland. Annotation to this issue of OAS:

(1) Persons interested in Japanese odonatology profit from the journal TOMBO. Reading the Odonatological Abstracts in *Odonatologia* it becomes clear that there are some other journals in which odonatologists publish the result of their studies or observations. Regrettably in most cases these publications are written in Japanese, a language not understood by most odonatologists, and the papers are published in journals not available in any of the western libraries.

I was more than surprised to get information from Dr. Klaus Sternberg, Germany on an English written journal on Japanese odonatology that covers these small, scattered publications on dragonflies. In March 2000 number 10 of the "Digest of Japanese Odonatological Short Communications" (DJOSC) was released, with translations of many small, but noteworthy papers on Odonata.

In October 2000 I contacted the editor of the Digest, Naoya Ishizawa, and arranged an exchange between the Digest and OAS. So users of OAS can profit from the Digest. In OAS abstracts taken from the Digest are identified as follows: "taken from DJOSC No. nn". The journal is worth to be subscribed. Only with the Digest one has full access to the information of papers published in different Japanese journals.

Persons interested in this journal should contact:

Naoya Ishizawa
1644-15, Yamaguchi
Tokorozawa City
Saitama Pref., 359-1145
Japan

(2) OAS profits from the cooperation with many odonatologists who send their reprints or give copies of papers not known to us. We cordially thank them all. Of special value is the help of Pawel Buzcynski, Poland, and Hidenoi Ubukata, Japan, who translated papers in their languages into English. We have an extraordinarily good cooperation with Jill Silsby and Wolfgang Schneider.

(1998): Zur Fauna der Stadt Oldenburg: Erste Übersicht ausgewählter Gruppen: Säugetiere, Vögel, Reptilien, Amphibien, Libellen, Heuschrecken, Laufkäfer, Schmetterlinge. Oldenburger Jahrbuch 98: 247-319. (in German). [On the basis of so called functional ecological areas in the town of Oldenburg, Germany, 23 odonate species are recorded. They are listed in a tab. and shortly commented.] Address: Brux, H., c/o IBL Umweltplanung, Unterm Berg 39, D-26123 Oldenburg, Germany

1986. Endersby, I.D. (1998): Dragonflies of Mount Buffalo National Park. Victorian Entomologist 28(5): 83-85. (in English). [At 6 localities situated within the Mount Buffalo National Park, Victoria, Australia, 12 odonate species were recorded. The habitats of *Synthemis eustalacta* and *Austroaeschna flavomaculata* are shortly discussed.] Address: Endersby, I., 56 Looker Rd, Montgomery, Victoria 3094, Australia. E-mail: endersby@werple.net.au

1987. Holusa, O. (1998): On the occurrence of dragonfly *Leucorrhinia pectoralis* (Charpentier, 1825) (Odonata: Libellulidae) in the Czech and Slovak Republics. Sbornik Přírodovědného klubu v Uh. Hradisti 3: 45-53. (in Czech with extensive English summary). [Between 1995-1998 12 new localities of *L. pectoralis* in the Czech Republic could be traced. All published data on the occurrence of this species in the Czech and Slovak Republics are summarized and plotted in a distribution map. Figures demonstrate the abundance at the Dobra - Kamenec locality in the season of 1997 and 1998 as well as the number of localities according to the sea level and phenology in the Czech and Slovak Republics. The habitats of some localities are described in some detail.] Address: Holusa, O., Muzeum Beskyd, přírodovědné oddelení, Zámecké náměstí 1264, CZ-738 01 Frydek-Místek. E-mail: holusao@post.cz

1988. Hughes, S.J.; Furse, M.T.; Blackburn, J.H.; Langton, P.H. (1998): A checklist of Madeiran freshwater macroinvertebrates. Bolm Mus. munic. Funchal 50 (284): 5-41. (in English with Portugese summary). [The checklist of the Madeira's 240 freshwater macroinvertebrates includes 6 Odonata compiled from literature data; the taxa are briefly annotated. *Ischnura senegalensis*, *I. pumilio*, *Anax imperator*, *Sympetrum nigrifemur*, *S. fonscolombii*, *Gomphus* sp.] Address: Hughes, Samantha, Laboratório Regional de Engenharia Civil, Departamento de Recursos Naturais e de Hidráulica, Rua Agostinho Pereira de Oliveira, PT-9000-264 Funchal, Madeira. E-mail: samjhughes@hotmail.com

1989. Lopez, R.; Espinoza, P.; Lopez-Q., M.M.; Valle, S.; Rivera, P.; Garcia, I. (1998): Las libelulas (Insecta: Odonata) come bioreguladores de larvas de mosquitos en Nicaragua. Revta nicarag. Ent. 45: 1-6. (in Spanish with English summary). [During 1996, the mosquito-regulation capacities of larval *Ischnura ramburii*, *Anax amazillii*, and *Pantala flavescens* were examined in the laboratory. These species can be successfully used in mosquito control, but *A. amazillii* is the most effective.

The numbers of the consumed mosquito larvae per day are stated for habitats with vegetation and for those without it.] Address: Lopez, R., Centre Nac. de Diagnostico y Referencia, Ministerio da Salud, A.P. 2900, Managua, Nicaragua

1990. Richards, S.; Kawanamo, M.; Torr, G. (1998): Insects part 2: Odonata (Dragonflies and damselflies). Conservation International: A biological assessment of the Lakekamu basin, Papua New Guinea. Washington. Rapid Assessment Programm 9. ISBN 1-881173-20-8: 10-11, 47-49, 144-148. (in English). [The Odonata of the Lakekamu Basin, Papua New Guinea were surveyed in Nov. to Dec. 1996, yielding a total of 34 species. Among these there is at least one, possibly three, undescribed species and possibly a new genus. Taxonomic knowledge of south PNG's Odonata is poor enough that certain identification of just these 34 species is extremely difficult. One species collected appears to be identical to a species previously known only from Misool Island (*Diplacina erigone*). A checklist (Appendix 7) and a compilation of the habitat preferences and some taxonomic remarks of each species (Appendix 8) are also presented.] Address: Richards, S., James Cook University, Department of Zoology, Townsville, QLD 4811, Australia. E-mail: stephan.richard@jcu.edu.au

1999

1991. Bönsel, A. (1999): Das Kleine Granatauge (*Erythromma viridulum* Charp., 1840) in Mecklenburg-Vorpommern. Naturschutzarbeit in Mecklenburg-Vorpommern 42(1): 48-56. (in German). [Documentation of the dispersion of *E. viridulum* in Mecklenburg-Vorpommern, Germany, and discussion of factors influencing colonisation success of water bodies. Presence of *Ceratophyllum*- or *Myriophyllum*-vegetation, and weather conditions with high temperatures, high global radiation and low precipitation are discussed as the most important factors for the range extension of the species into northern Central Europe.] Address: Bönsel, A., Vasenbusch 15, D-18337 Gresenhorst, Germany. E-mail: andre.boensel@gmx.de

1992. Braun, M.; Braun, U. (1999): Fliegende Edelsteine. Libellen im Naturpark Nassau. Zweckverband Naturpark Nassau (Hrsg.): 32 pp. (in German). [This is a nicely produced booklet (reprint from: Heimatjahrbuch Rhein-Lahn-Kreis 2000: 97-128) on the dragonflies of the Regional Park Nassau, Rheinland-Pfalz, Germany. Chapter 2 contains a general introduction into biology and ecology of the Odonata, chapter 4 some remarks on dragonfly conservation, and chapter 5 a short bibliography. In chapter 3 the 33 species known from the region are treated in a monographic way. Information on morphology is accompanied in most cases by excellent colour pictures; in addition notes on the regional phenology and the habitats are given. The booklet is directed to a more general readership, but as in many other cases it contains very interesting information for the advanced odonatologist: here it is a picture of a lizard (*Lacerta agilis*) devouring an imago of *Orthetrum concellatum*. This is one of the rare documents of predation of reptiles on Odonata.] Address: Braun, Ursula, Im Mühlbachtal 2, D-56377 Nassau, Germany

1993. Chao, H.-f.; Zhu, H. (1999): A new species of *Nihonogomphus* from Guangxi, China (Odonata: Gomphidae). *Wuyi Sci. J.* 15: 17-18. (in English with Chinese summary). [*N. huangshaensis* sp. n. is described, illustrated and compared with *N. lieftincki*. Holotype male: Huangsha, Guangxi prov., no date; deposited at the institution of the first author.] Address: Chao, H.-f., Biol. Control Res. Inst., Fujian Agric. Univ., Fuzhou-350002, Fujian, P.R. China

1994. Chao, H.-f. (1999): New or little-known gomphid dragonflies from China, 1 [recte: 2] (Odonata: Gomphidae). *Wuyi Sci. J.* 15: 12-16. (in English with Chinese summary). [*Paradavidius* sgen. n. is proposed in *Davidius* (type sp.: *D. fruhstorferi* Martin); the 9 subgeneric distinctions in *Nihonogomphus* are stated; and *Mergomphus vespertinus* sp. n. is described, illustrated and compared with the two Chinese congeners. Holotype male: Lushan Co., Sichuan prov., mid-V / mid-VIII-1997; deposited at Author's institution.] Address: Chao, H.-f., Biol. Control Res. Inst., Fujian Agric. Univ., Fuzhou-350002, Fujian, P.R. China

1995. Darblade, S.; Avignon, S. (1999): Effect of water treatment and site reallocation on Odonates (Arjuzanx, Landes). *Gibier Faune Sauvage* 16(4): 339-353. (in French with English and German summaries). ["Many aquatic organisms are closely dependent on the physico-chemical quality of the water and the morpho-dynamic characteristics of the biotopes in which they are evolving and often adapt to the environmental changes the latter are submitted to over more or less long periods. In a former mining site in Arjuzanx (Landes), which was reallocated and became a National Hunting and Wildlife Reserve, we studied the effect of wetland basification treatments (in particular by liming with 'Champagne chalk') on dragonflies, Odonata [...]. We monitored several environmental parameters (pH, conductivity, turbidity, quantity of dissolved oxygen and temperature) as well as biological ones (species presence/absence at adult/larval stages) that had been delineated across small shallow water basins and their edges from April to August 1998. We showed that when left untreated the water basin's basification (pH 3.5-4 to 8.2) took only fifteen years (1985-1998). 29 Odonate species (representing about one-third of the Odonate species present in France) could be listed. When evaluating Odonate presence with respect to the two adult and larval stages, the Odonate species frequented the untreated habitats more intensively than the treated ones ($P < 0.05$), probably because of a lesser degree of turbidity ($P < 0.05$), all other physico-chemical parameters being the same. At the adult and larval stages, however, the indicator species of sensitivity to habitat treatment were not the same. The Arjuzanx site is classified as a site of special patrimonial interest, because of the presence of two dragonfly species with a special protection status: *Leucorrhinia pectoralis* and *L. albifrons*. Management of this type of habitat for Odonates, thus should be directed towards favouring species diversity, and towards protecting the rare species which are often associated with endangered habitats." (Authors). A further species of interest is *Coenagrion scitulum*.] Address: Darblade, Stéphanie, Reserve Naturelle de l'E-tang Noir, Avenue du Hall des Sports, F-40510 Seignosse, France

1996. David, S. (1999): Dragonfly research in Slovakia. *Sbornik z mezinárodního semináře "Vážky 1999"*,

CSOP Vlasim: 83-92. (in Slovakian with English summary). [This paper is a short introduction into the odonatological history of Slovakia. Distribution maps of *Thecagaster bidentata* and *Crocothemis erythraea* and a checklist of the 73 species known to occur in Slovakia are presented. In a Red List the species are classified according to the criteria of IUCN.] Address: David, S., ÚKE SAV, Akademická 2, SK-94901 Nitra, Slovakia. E-mail: nrukdavi@savba.sk

1997. De Marmels, J. (1999): A new species of *Dimeragrion* Calvert 1913 from Pantepui, Venezuela (Odonata: Megapodagrionidae). *Boln Ent. venez.* 14(1): 27-36. (in English with Spanish summary). [*Dimeragrion clavijoi* sp. n. (holotype male: Venezuela: Amazonas, Cerro Yutaje, lat 05°43'35"N, long 66°08'03"W, 1750 m, 12/19.ii.1995; MIZA) is described and illustrated on the basis of eighteen males and eight females. A key to the species of *Dimeragrion* Calvert 1913 and distributional maps are provided. The supposed larva of *D. percubitale* Calvert 1913 is described and figured." (Author)] Address: De Marmels, J., Inst. Zool. Agricola, Fac. Agronomia, Univers. Central de Venezuela, Apdo. 4579, Maracay 2101, Edo. Aragua, Venezuela

1998. Düttmann, H. (1999): Die Marka-Mittelradde-Niederung. Plädoyer für ein bedeutendes Feuchtgebiet in Nordwestdeutschland. *Oldenburger Jahrbuch* 99: 333-357. (in German). [This is a natural history of a marsh region the northwestern part of Germany (Emsland, Niedersachsen) with special emphasize on its importance for nature conservation purposes. 15 odonate species are listed; the data are resulting from different sources including unpublished expertices.] Address: Düttmann, H., Institut für Naturschutz und Umweltbildung, Hochschule Vechta, Driverstr. 22, D-49377 Vechta, Germany.

1999. Endersby, I.D. (1999): Dragonflies of the Organ Pipes national Park. *Victorian Entomologist* 29(3): 51-52. (in English). [The Organ Pipes National park is situated 30 km NW of Melbourne, Australia. 4 trips in 1997 to 1999 yielded in 12 odonate taxa including *Rhadinosticta simplex*.] Address: Endersby, I., 56 Looker Rd, Montgomery, Victoria 3094, Australia. E-mail: endersby@werple.net.au

2000. Holusa, O. (1999): The dragonflies (Odonata) in the surroundings of Vsetín and Valasské Mezirici. *Sbornik Přírodovedneho klubu v Uh. Hradisti* 4: 82-102. (in Czech with extensive English summary). [Between 1992-1998 some localities in the surroundings of Vsetín and Valasské Mezirici (south-eastern region of the Czech Republic) were investigated. Different habitats were studied - from stagnant waters in lowlands (274 m a.s.l.) to streams in mountain regions (650 m a.s.l.). 36 species are known from the region, 33 species were recorded in the framework of this study. *Thecagaster bidentata* was very abundant, *Brachytron pratense*, and *Leucorrhinia pectoralis* belong to the very rare species.] Address: Holusa, O., Muzeum Beskyd, prirodovedné oddelení, Zámecké náměstí 1264, CZ-738 01 Frydek-Místek. E-mail: holusao@post.cz

2001. Holzinger, W.E.; Ehmann, H.; Schwarz-Waubke, M. (1999): Rote Liste der Libellen Kärntens (Insecta: Odonata). *Naturschutz in Kärnten* 15: 497-507. (in German). [917 data sets of odonatological data known from the Federal State Kärnten, Austria are analysed and compiled in a commented list of 60 species (name

of the species, habitat, records prior 1980, records of 1980 and the following years, classification according to the Red List criteria). The distribution of *Coenagrion hastulatum*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia*, *Orthetrum albistylum*, *O. cancellatum*, *Leucorrhinia pectoralis*, *L. albifrons*, *Somatochlora flavomaculata*, and all localities with records of Odonata in Kärnten are mapped. Some of the old records are discussed, and a bibliography of odonatological publications from Kärnten is annexed.] Address: Schwarz-Waubke, Maria, Eben 21, A-4202 Kirschsschlag, Austria

2002. Jost, W. (1999): Libellenfauna rund um Wiesbaden. *Jahrbuch des nassauischen Vereins für Naturkunde* 120: 75-81. (in German). [Hessen, Germany; this paper is a mixture of general remarks on Odonata, a checklist of 25 species from the Wiesbaden region based on 15 years of investigation, and some notes on localities of special odonatological or conservational interest. Examples of impacts of recreational fishing on habitats and species are outlined.] Address: Jost, W., Dr.-Jakob-Witte mann-Str. 20, D-65527 Niedernhausen, Germany

2003. Jourde, P.; Allenou; Caupenne, M.; Thirion, J.-M. (1999): Contribution à l'Inventaire des odonates de Charente-Maritime. *Annales de la société des sciences naturelles* 8(8): 967-972. (in French, with English summary). [For more details, see OAS 1022] Address: Jourde, P.; La Grande Métairie, 20 rue de Charnay, F-17250 Pont-L'Abbé-D'Arnoult, France

2004. Lange, L. (1999): Ganzliner Torfstiche - ein Lebensraum für gefährdete Libellen. *Naturschutzarbeit in Mecklenburg-Vorpommern* 42(2): 64-65. (in German). [29 odonate species are reported from the localities situated in the southwestern part of Mecklenburg-Vorpommern, Germany. Of special interest is the record of *Leucorrhinia albifrons*.] Address: Lange, L., Deichreihe 21, D-25599 Wewelsfleth, Germany.

2005. Papazin, M. (1999): Les odonates de Guyane française I. Les Calopterygidae (Odonata, Zygoptera). *L'entomologiste* 55(6): 235-239. (in French with English summary). [In French Guyana, Calopterygidae are represented by two genera, *Hetaerina* and *Mnesarete* including six species. *Hetaerina gallardi* Machet, 1989 has been rediscovered at the locus typicus. A key, based on the wing coloration, is proposed to identify the males of the six known species. Male appendices are figured.] Address: Papazian, M., Le Constellation Bât. A, 72 avenue des Caillols, F-13012 Marseille, France

2006. Romstöck-Völkl, M.; Rebhan, H.; Völkl, W. (1999): Folgen des Auswinterns von Stillgewässern. Veränderungen der Libellenfauna im NSG Craimoosweiher. *Naturschutz und Landschaftsplanung* 31(5): 143-146. (in German, with English summary). [Consequences of the Winter Draining of Ponds - Changes in the Fauna of Damselfly and Dragonflies in the Nature Reserve 'Craimoosweiher' (Bavaria) In the nature conservation area 'Craimoosweiher' (administrative district of Bayreuth), 25 species of Odonata were recorded between 1995 and 1997. The abundance of most damselfly species declined in 1997 compared to 1995. The most conspicuous decline was found in *Erythromma viridulum* (population extinct in 1997) and *Erythromma najas* (only few individuals in 1997) whilst the abundance of Anisoptera varied only slightly. The most important reasons for the dramatic reduction in damselfly a-

bundance may be the drainage of the pond and the severe frost during winter 1995/96. This thoughtless measure resulted in the disappearance of the submerse vegetation which had provided oviposition sites for adult damselflies and hiding-places for larvae." (Authors)] Address: Romstöck-Völk, Maria, Hohe Eiche 6, D-95517 Seybothenreuth, Germany

2007. Rumpf, M. (1999): Nachweis der Zierlichen Moosjungfer *Leucorrhinia caudalis* im Naturpark Feldberger Seenlandschaft. *Naturschutzarbeit in Mecklenburg-Vorpommern* 42(2): 81- (in German). [In 1999 a strong population of the rare *L. caudalis* which was thought extinct in Mecklenburg-Vorpommern, Germany was recorded in a *Cladium mariscus* marsh in the NSG Krüselin-Mechowseen.] Address: Rumpf, M., Blumenstr. 13, D-17268 Warthe, Germany

2008. Schulz, R.; Mühle, R.-U.; Wilke, T. (1999): Zur Odonatenfauna des einstweilig gesicherten Teichgebietes Lakoma. *Veröff. Potsdam-Museum* 33: 71-76. (in German with English summary). [Brandenburg, Germany; in July 1994 19 odonate species were recorded at 10 localities; *Orthetrum coerulescens*, *Sympetrum depressiusculum*, *S. pedemontanum*] Address: Mühle, R.U., Universität Potsdam, Inst. Ökologie und Naturschutz, Lennéstr. 7a, D-14471 Potsdam, Germany.

2009. Starke, W.; Wachlin, V. (1999): Konzept für ein Monitoring zum LIFE-Projekt "Erhaltung und Wiederherstellung des Trebeltalmooses". *Naturschutzarbeit in Mecklenburg-Vorpommern* 42(1): 41-47. (in German). [Mecklenburg-Vorpommern, Germany; the monitoring concept includes the Odonata] Address: Wachlin, V., Karrenderfer Str. 3, D-17498 Leist, Germany

2010. Usseglio-Polatera, P.; Thomas, S.; Beisel, J.-N.; Moreteau, J.-C. (1999): Illustration de la valeur indicatrice des caractéristiques biologiques des macroinvertébrés d'une communauté benthique à différentes échelles d'observation. *Annls Limnol.* 35 (1): 71-80. (in French with English summary). ["The faunal assemblage of a river ecosystem integrates the spatial and temporal variability of the habitat. Taxa with appropriate combinations of adaptations, concerning especially traits related to survival and reproduction use particular habitat types. Consequently, the synthesis of published autecological information on macroinvertebrate taxa can be used to demonstrate some of the environmental changes of an ecosystem. Mesohabitats were sampled in spring and autumn 1993 and 1994 in twelve study sites on 1st to 4th order streams in three river catchments located in the northeast of France. Sites were selected to exhibit high microscale heterogeneity. Affinities of taxa for modalities of biological traits and/or ecological strategies were described. The investigation of the relationship between traits and distributions of taxa can demonstrate some of the characteristics of both faunal community and environment and provide clear information on changes in biotopes across different spatial scales (mesohabitat, station, catchment basin). The benthic assemblage of each mesohabitat type displayed a specific combination of biological traits. Thus, taxa can provide insights about mesohabitat characteristics in terms of stability, diversity or trophic potentialities of their potential ecological niches." (Authors) Odonata are treated on the family level.] Address: Usseglio-Polatera, P.; ESA 5023 CNRS, Ecologie des Eaux Douces et des Grands Fleuves, 43 Bd du 11 No-

vembre 1918, F-69622 Villeurbanne Cedex, France. E-mail: usseglio@sciences.univ-metz.fr

2011. Uvíra, V.; Jeziorski, P.; Hanel, L.; Holusa, O. (1999): Aquatic Invertebrates of the Pálava Biosphere Reserve of UNESCO: Odonata. *Folia Fac. Sci. Nat. Univ. Masaryk. Brun., Biol.*, 101: 173-180. (in English). [So far 69 species of dragonflies have been recorded in the territory of the Czech Republic; in the Pálava Biosphere Reserve (in its extended concept) 45 species have been ascertained, i.e. 65 % of the total number known to occur in the Czech Republic. The paper outlines some general introduction into Odonata, collection methods, the history of odonatological investigation of the Pálava Biosphere Reserve, some species of special faunistic interest (*Epitheca bimaculata*, *Stylurus flavipes*, *Anax ephippiger*, *Sympetrum fonscolombii*), the potential for monitoring, and some information referring conservation of Odonata. All records are documented in detail.] Address: Holusa, O., Muzeum Beskyd, prírodovedné oddelení, Zámecké náměstí 1264, CZ-738 01 Frydek-Místek. E-mail: holusao@post.cz

2012. Wachlin, V.; Müller-Motzfel, G. (1999): Monitoring von Insekten in Mecklenburg-Vorpommern. *Naturschutzarbeit in Mecklenburg-Vorpommern* 42(1): 17-23. (in German). [According to the Fauna-Flora-Habitat-Directive of the European Union monitoring of species and habitats is mandatory for the Natura 2000 areas. This paper lists the present status of the species of Appendix II of the Directive in Mecklenburg-Vorpommern, Germany, and proposes insect orders and methods suitable for monitoring. The results of an inventory in 1997 and 1998 of the Odonata are presented. *Sympecma paedisca*, *Aeshna viridis*, *Leucorrhinia albifrons*, and *L. pectoralis* were recorded in 1998, while *Stylurus flavipes*, *Ophiogomphus cecilia*, and *L. caudalis* could not be traced.] Address: Wachlin, V., Karrenderfer Str. 3, D-17498 Leist, Germany

2013. Weissmann, M.J.; Kondratieff, B.C. (1999): An inventory of arthropod fauna at Great Sand Dunes National Monument, Colorado. *Spec. Publ. Univ. Kansas not. Hist. Mus.* 24: 69-80. [USA, Colorado; *Lestes congener*, *L. dryas*, *L. unguiculatus*, *Aeshna constricta*, *A. palmata*, *Sympetrum corruptum*, and *S. occidentale*] Address: Weissmann, M.J., Dept Bioagric. Sci. & Pest Manag., Colorado St. Univ., Fort Collins, CO 80523, USA

2014. Wernicke, P.; Rumpf, M.; Mösch, W. (1999): Die Vorkommen bedeutsamer Lebensräume und Arten im Naturpark Feldberger Seenlandschaft. *Naturschutzarbeit in Mecklenburg-Vorpommern* 42(2): 15-26. (in German). [Habitats, flora and fauna of special interest are described for this 34500 ha large area in Mecklenburg-Vorpommern, Germany. 52 odonate species are reported, but only *Leucorrhinia pectoralis* and *Aeshna viridis* are briefly discussed.] Address: Wernicke, P., Dorfstr. 33c, D-17237 Thurow, Germany

2015. Wieland, A. (1999): Surveys of flora and fauna in the Senné fishpond area, Slovakia, spring 1997. Report of the Working Group International Wader and Waterfowl Research 65: 85 pp. (in English). [The Senné fishponds, situated in eastern Slovakia, have been surveyed between April 15 and June 9, 1997. During the migration season up to 20000 waterbirds are present regularly. Thus this report stresses on birds. In addition, data on dragonflies, butterflies, amphibians, mammals,

and plants are also presented. The odonatological results - 12 species including *Coenagrion pulchellum*, *Erythromma najas*, and *Brachytron pratense* - are compiled in tab. 7. Additions to this list can be taken from a list of 24 species (including *Erythromma viridulum*, *Crocothemis erythraea*, *Sympetrum flaveolum*) with observations between 6th and 16th of August 1998 (Appendix 3). In total 27 species could be observed in the Senné fishponds.] Address: WIWO, P.P. Box 925, NL-3700 AX Zeist, The Netherlands

2016. Wolf, F. (1999): Die Tier- und Pflanzenwelt im Hütter Wohld: Kartierungen der Libellen (Odonata), Süßwassermollusken (Gastropoda et Bivalvia) und Laufkäfer (Carabidae) des "Hütter Wohldes". *Archiv d. Freunde Naturg. Mecklenburg* 38: 309-326. (in German). [Germany, Mecklenburg-Vorpommern; commented list of 13 odonate species] Address: Wolf, F., Martin-Andersen-Nexo-Ring 7, D-18106 Rostock, Germany

2017. Xylander, W.E.R.; Stephan, R. (1999): Habitatwahl und ökologische Ansprüche ausgewählter Libellenarten im Braunkohletagebauegebiet Berzdorf. *Ber. Naturforsch. Gesell. Oberlausitz* 7/8: 95-100. (in German with English summary). ["Habitat selection and ecological demands of selected dragonfly species from the brown coal mining site Berzdorf. During investigations of small ponds in the former brown coal mining site Berzdorf (Upper Lusatia. Saxonia. Eastern Germany) 48 dragonfly species were documented from May 1996 until October 1998. Some of these species developed in ponds and a smaller river which significantly differ - with regard to their biological and physico-chemical properties - from the habitat demands described in the literature. At several ponds coenoses occur, the species of which should not share the same habitats according to their postulated habitat preferences. Selected dragonfly species and their habitats in the former brown coal mining site are described and compared with data from the literature." (Authors) *Leucorrhinia dubia*, *L. rubicunda*, *Ophiogomphus cecilia*] Address: Xylander, Dr. W., Staatliches Museum für Naturkunde Görlitz, PF 300154, D-02806 Görlitz, Germany. E-mail: Naturmuseum. GR.Dr.Xylander@t-online.de

2018. Zhou, W.-b. (1999): A new species of the genus *Phaenandrogomphus* from Yunnan (Odonata: Gomphidae). *Wuyi Sci. J.* 15: 40-41. (in Chinese with English summary). [*P. yunnanensis* sp. n. is described, illustrated and compared with *P. aureus* Laidlaw holotype male: Simao, Yunnan prov., 20-IV-1996.] Address: Zhou, W.-e., Zhejiang Mus. Nat. Hist., Gu-shan, Hanzhou-310012, P.R. China

2019. Zhu, B. (1999): A new species of *Lamelligomphus* Fraser from Yunnan, China (Odonata: Gomphidae). *Wuyi Sci. J.* 15: 36-37. (in Chinese with English summary). [*L. chaoi* sp. n. is described and illustrated from a single female: Canshan, Dali, Yunnan prov., China, 5-VI-1998; deposited at Dali Teacher Training Coll., Dali, China.] Address: Zhu, H.-q., 42-38. Shanxi University, Taiyuan 030006 Shanxi. China

2020. Zhu, H.; Zhou, W.. (1999): A new species of the genus *Anisopleura* Selys from Yunnan (Odonata: Euphaeidae). *Wuyi Sci. J.* 15: 33-35. (in Chinese with English summary). ["*A. yunnanensis* sp. n. is described and illustrated. Holotype male: Canshan, Dali, Yunnan prov., China, 15-V-1987; deposited at Shanxi Univ.; several paratypes of both sexes. The new species is rela-

ted to *A. subplatystyla*, from which it differs in the colour of prothorax, legs and abdomen, and in the structure of anal appendages."] Address: Zhu, H.-q., 42-38. Shanxi University, Taiyuan 030006 Shanxi. China

2021. Zhu, H.; Mao, B. (1999): The first descriptions of the male *Indolestes assamica* Fraser, 1930 and the female *Gynacantha incisura* Fraser, 1935 (Odonata: Lestidae, Aeshnidae). *Wuyi Sci. J.* 15: 30-32. (in Chinese with English summary). [The allotypes of *I. assamica* are described from Canshan, Dali city, Yunnan prov., China, and are deposited in Dept Biol., Dali Teacher Training Coll., Dali-671000, Yunnan, P.R. China. *G. incisura* is a new record for China.] Address: Zhu, H.-q., 42-38. Shanxi University, Taiyuan 030006 Shanxi. China

2000

2022. Anonymus (2000): Mitarbeiter des Arbeitskreises Libellen NRW treffen sich in Herne. *LÖBF-Mitteilungen* 3/00: 14. (in German). [Announcement of the 6th meeting of the working group of dragonfly researchers in the Federal State Nordrhein-Westfalen, Germany.] Address: <http://www.ak-libellen-nrw.de>

2023. Anonymus (2000): Warum gelingt der Libellenflug? *Klett-Magazin* 24: p? (in German). [Description of the role of the protein Resilin giving the wings of dragonflies elasticity; for more details see the paper abstracted as OAS 1716.] Address: not stated

2024. Bailey, M.P. (2000): Predation of Four-spotted Chaser *Libellula quadrimaculata* L. by otter *Lutra lutra* L.. *J. Br. Dragonfly Society* 16(2): 64. (in English). [Wings and other fragments of *L. quadrimaculata* were found on a route used by an otter and close by an Otter spraint. The diet of Eurasian Otter has been investigated in some detail but this observation appears to be the first record instance of predation on adult Odonata.] Address: Bailey, M.P., Countryside Council for Wales, Plas Gogerddan, Aberystwyth, Ceredigion SY23 3EE, UK

2025. Bal, B. (2000): L'inventaire des odonates de Haute-Savoie. *Bulletin romand d'entomologie* 18: 59-64. (in French). rus plagiatus are new for Nevada, USA.] Address: Baumann, R.W., Brigham Young University, Provo, Utah 84602, USA

2028. Bechly, G. (2000): Two new fossil dragonfly species (Insecta: Odonata: Pananisoptera: Aeschnidiidae and Aktassiidae) from the Solnhofen lithographic limestones (Upper Jurassic, Germany). Stuttgarter Beiträge zur Naturkunde Serie B (Geologie und Paläontologie) 288: 1-9. (in English with German summary). ["Two new dragonfly taxa are described from the Upper Jurassic Solnhofen Limestone (Bavaria, Germany) Solnhofenia stobeneri n. g., n. sp. is the sixth species of Aeschnidiidae from this locality and also the smallest one. Aeschnogomphus kuempeli n. sp. (Petalurida: Aktassiidae) is one of the biggest dragonflies known from this locality and even from the whole post-Triassic Mesozoic and Cenozoic." (Author)] Address: Bechly, G., Staatliches Museum für Naturkunde, Abt. Paläontologie, Rosenstein 1, D-70191 Stuttgart, Germany. E-mail bechly@gmx.de

2029. Belz, A.; Fuhrmann, M. (2000): Die Libellen des Kreises Siegen-Wittgenstein. Der Sauerländische Naturbeobachter 27: 45-48. (in German with English summary). [For a more detailed presentation of this paper see OAS 2030] Address: Fuhrmann, M., Zum Großen Wald 19, D-57223 Kreuztal, Germany

2030. Belz, A.; Fuhrmann, M. (2000): Libellen. Beiträge zur Tier- und Pflanzenwelt des Kreises Siegen-Wittgenstein 6: 83 pp. (in German). [This regional fauna on the Odonata of the low mountain range in the southern region of the federal state Nordrhein-Westfalen, Germany, gives information on 35 species of which 28 are assessed as autochthonous. Each species is treated in a monographic style, providing information on regional distribution (the maps are plotted against altitude), habitat, and habits. The species are documented by colour photographs.

(Auf der Informationsbasis eines etwa 25 jährigen Untersuchungszeitraums legen die Autoren Albrecht Belz und Markus Fuhrmann eine 83 Seiten umfassende Regionalfauna vor. Im Bundesland Nordrhein-Westfalen gelegen grenzt der Landkreis Siegen-Wittgenstein an Rheinland-Pfalz und Hessen. 35 nachgewiesene Arten, von denen 28 als bodenständig angesehen werden, dokumentieren eine eher artenarme Mittelgebirgs-Libellenfauna, was jedoch angesichts der Höhenlage (meist über 400 m und bis über 750 m NN) nicht weiter verwundert. Das Werk gliedert sich in 7 Kapitel: Einleitung, Geschichte der odonatologischen Kartierungen im Landkreis, Einführung in die regionale Geographie, Methoden und allgemeine Angaben zu Libellen, Liste und monographische Abhandlung der nachgewiesenen Arten, Anmerkungen zu Gefährdungen und Schutzmaßnahmen, Literatur. Den Artunterkapiteln sind jeweils Angaben zu "Verbreitung und Bestand", "Lebensraum", "Lebensweise" und - selten - "Besonderheiten" oder "Kuriosa" (u.a. Hinweis auf eine zwergwüchsige Aeshna cyanea) zu entnehmen. Beigegeben sind Rasterverbreitungskarten sowie ein Flugzeitendiagramm und - im Regelfall - ein Farbfoto der jeweiligen Art, jedoch nur dann, wenn das Belegfoto im Landkreis angefertigt werden konnte. Willenkommen ist dieses Buch für alle, die sich für Regionalfaunen und Ergänzungen im Flickenteppich der Verbreitungskarte der deutschen Libellenfauna interessieren. Für mich am interessantesten

waren einige Hinweise - manchmal nur am Rande erwähnt - zur (Wieder-?)besiedlung des Landkreises durch einige Arten vor dem Hintergrund der Landschaftsveränderungen und der klimatischen Änderungen in den zurückliegenden zwei Dekaden. (Martin Schorr)] Address: NABU Siegen-Wittgenstein e.V., In der Hüttenwiese 30, D-57072 Siegen, Germany

2031. Bernard, R. (2000): State of knowledge of the occurrence and biology of Cordulegaster boltonii (Donovan, 1807) in Poland (Odonata: Cordulegastridae). Roczn. nauk. Pol. Tow. Ochr. Przyr. "Salamandra" 4: 55-87. (in Polish with extensive English summary). ["All literature data on the occurrence of C. boltonii in Poland are summarized and new localities are added. Distribution, habitat, period of flight, location of exuviae and selected aspects of behaviour of the species in Poland are presented and discussed. C. boltonii is a vulnerable species in Poland. Threats are given and ways to stop a regressive trend are proposed." (Author)] Address: Bernard, R., Department of General Zoology, Adam Mickiewicz University, Fredry 10, PL-61-702 Poznan, Poland; E-mail: rbernard@main.amu.edu.pl

2032. Bezdecka, P. (2000): Effect of extreme floods in July 1997 on the dragonfly diversity (Odonata) in the middle section of the river Morava (Moravia, Czech Republic). In: Hanel, L. (Ed.): Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chráněné krajinné oblasti Trebonsko 15.-18.6.2000. Vlasim. ISBN 80-86327-12-4: 37-51. (in Czech with English summary). [The author compares the dragonfly diversity in the middle section of the Czech river Morava (river km 98,9-172,15) on the basis of investigation in 1955-1956, 1995-1996, and 1997-1998. "In July 1997, the northeastern part of the Moravian territory and north-east part of the Bohemian were afflicted by intensive rains lasting several days, and as a result, the water streams in the drainage areas of the rivers Morava, Odra, Orlice and in the upper part of the drainage of the river Labe were marked of extreme flood flows, which attained or surpassed the level of so called Q 100 years' flows." A total of 42 odonate species are known from the study area. "[...] It is interesting that extreme floods in July 1997 had no negative influence on dragonfly diversity, even the increasing of dragonfly diversity was found during two years after floods in most examined localities (backwaters)."] Address: Bezdecka, P., V. Vaculky 994, 686 05 Uherské Hradiste, Czech Republic. E-mail: pbezdecka@iol.cz

2033. Binot-Hafke, M.; Buchwald, R.; Clausnitzer, H.-J.; Donath, H.; Hunger, H.; Kuhn, J.; Ott, J.; Piper, W.; Schiel, F.-J.; Winterholler, M. (2000): Ermittlung der Gefährdungsursachen von Tierarten der Roten Liste am Beispiel der gefährdeten Libellen Deutschlands - Projektkonzeption und Ergebnisse. Natur und Landschaft 75(9/10): 393-401. (in German with English summary). ["This presented project aims on national level a compilation of causes of threat for the animal species of the Red List. For this there was a catalogue developed, which contains general causes of threat and enables to evaluate results comprehensive for all animal groups. It was tested exemplary for the dragonflies, if this catalogues is suitable for using. By means of expert opinions the data admit conclusions about causes of threat for each species, responsible groups and trends. The results confirm the procedure. In future the catalogue and

the number of sampling must be optimized for the survey of the causes of threat of other animal groups." (Authors)] Address: Binot-Hafke, Margret, Bundesamt für Naturschutz, FG I1.1, Konstantinstr. 110, D-53179 Bonn, Germany. E-mail: binotm@bfn.de

2034. Bönsel, A.; Kühner, A. (2000): (Odonata) aus der Sammlung des Zoologischen Instituts der Universität Rostock. *Libellula* 19(3/4): 199-211. (in German with English summary). [Mecklenburg-Vorpommern, Germany. "The collection includes 92 specimens of 33 spp. Most specimens were collected by Mr A. GUNDLACH between 1906 and 1909 in the vicinity of Neustrelitz, northern Germany. That area is known for one of earliest faunistic works in northern Germany (FÜLDNER 1855). The data on collecting sites were compared with a map from 1882 and the recent situation. There was a drastic decrease in swamps and fens which could be related to changes in species composition." (Authors)] Address: Bönsel, A., Vasenbusch 15, D-18337 Gresenhorst, Germany. E-mail: andre.boensel@gmx.de

2035. Bönsel, A.; Matthes, H.; Matthes, J. (2000): Wo existiert noch ein bodenständiges Vorkommen der Torf-Mosaikjungfer, *Aeshna juncea* (L. 1758), in Mecklenburg-Vorpommern? *Naturschutzarbeit in Mecklenburg-Vorpommern* 43(2): 44-45. (in German). [This paper compiles the current knowledge on the distribution of *A. juncea* in the Federal State Mecklenburg-Vorpommern, Germany, and intends to make faunists sensible for the species. Surprisingly this species is very rare. The authors give some advice to the identification of the species.] Address: Bönsel, A., Vasenbusch 15, D-18337 Gresenhorst, Germany. E-mail: andre.boensel@gmx.de

2036. Boness, M. (2000): Massenflug der Schabrackenlibelle *Hemianax ephippiger* Burmeister an der Küste der Algarve (Portugal). *Atalanta* 31(3/4): 585. (in German). [Near Ferragudo, Portugal, September 16, 1999, several hundreds to thousands immature *Anax ephippiger* perched on shrub vegetation or near the ground directly in front of the cliff. The following days only few specimens could be traced. The possibility of an influx originating from Africa or Spain is shortly discussed.] Address: Boness, M., Birkenweg 18, D-51381 Leverkusen, Germany

2037. Bornholdt, G.; Braun, H.; Kress, J.C. (2000): Erfolgskontrollen im abgeschlossenen Naturschutzgroßprojekt "Hohe Rhön / Lange Rhön". *Angewandte Landschaftsökologie* 30: 261 pp.- (in German with English summary). ["It is the aim of this survey to gather experience in controlling the success of large scale national nature projects and to find practical guidelines for future projects. For that model success controls were made in the large scale conservation project „Hohe Rhön / Lange Rhön" during the vegetation periods of 1996 and 1997. They dealt with the flora, the vegetation, birds, amphibians, ground beetles, bugs, cicadas and dragonflies. Furthermore changes in the structure of the landscape and its use were analysed. [...]". Measures for Odonata nearly totally failed; the population of *Cordulegaster boltonii* and *Calopteryx virgo* diminished greatly. *Thecagaster bidentata* could not be observed. Due to priority for conservation measures directed to the Black Grouse (*Aves: Tetrao tetrix*), which is highly sensitive against human impacts including scientific studies, it was not possible to assess measures reali-

sed to increase populations of odonate bog species.] Address: not stated

2038. Breuer, M.; Douma-Petridou, E. (2000): A Greek mountain stream (N Peloponnesus) as habitat of *Callaieschna microstigma* (Odonata: Aeshnidae). *Libellula Suppl.* 3: 1-7. (in English with German summary). ["The odonate fauna of a small stream, bordered with plane trees in the mountain area of Panahaikon (SE Patras, Achaia, Greece), was studied in 1994 and 1997. Two species were found: *Callaieschna microstigma* and *Calopteryx virgo festiva*. The flight period of *C. microstigma* lasted from May to August, with a maximum emergence in the first half of June. The adult behaviour was inconspicuous and flight occurred until late dusk. *C. microstigma* seems to be restricted to a definite habitat. The following habitat characteristics may be important for its occurrence: (1) a wooded or at least tree-bordered shaded small watercourse, and (2) fast running water with calmer areas. The latter seem to serve as larval habitats." (Authors)] Address: Breuer, M., Zoological Institute, Laboratory for Developmental Physiology and Molecular Biology, Katholieke Universiteit Leuven, Naamsestraat 59, B-3000 Leuven, Belgium. E-mail: michael.breuer@bio.kuleuven.ac.be

2039. Breuer, M.; Douma-Petridou, E.; Koutsaftikis, A. (2000): Seasonal distribution of Odonata in brackish temporary wetlands of the NW Peloponnesus, Greece. *Libellula Suppl.* 3: 9-24. (in English with German summary). ["For at least one annual cycle, three different waters at the wooded coastal area of Strofilia (district Achaia) were studied. 17 species were recorded, some in rather high numbers. Limiting factors might be the salinity and the temporary character of the waters. A range of adaptations to these conditions are discussed: deposition of drought-resistant eggs, early and late appearance of the adults and protracted emergence. Several species appear to be multivoltine. High densities of *Aeshna mixta* and *A. affinis* as well as occurrence of hibernating adults of *Sympetrum striolatum* are noteworthy. Many species recorded at the Strofilia area are well known as dispersing insects." (Authors)] Address: Douma-Petridou, E., University of Patras, Faculty of Science, Department of Biology, Section of Animal Biology, GR-26110 Patras, Greece

2040. Brown, D. (2000): Lilac Beauty *Apeira syringaria* (L.) (Lep.: Geometridae): a second generation specimen at Charlecote Warwick. *Entomologist's record and Journal of variation* 112: 170. 2041. Bruyn, L. de; Grootaert, P.; Pollet, M.; Knijf, G. de (2000): Hebben ongewervelden een toekomst in onze tuinen? *Ankora, Antwerpse Koepel voor Natuurstudie, Jaarboek 1999*: 68-83. (in Dutch). [Is there any future for invertebrates in our gardens? - The role of garden habitats in protection of Syrphidae (Diptera) and Odonata was investigated in the surroundings of Antwerpen, Belgium. In comparison to nature reserves, garden habitats are inhabited by ubiquitous species only.] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. E-mail: geert.de.knijf@instnat.be

2042. Buczynski, P. (2000): Dragonflies (Odonata) of some existing and proposed peat bog reserves in the

region Polesie Lubelskie. Roczn. nauk. Pol. Tow. Ochr. Przyr. "Salamandra" 4: 89-101. (in Polish with extensive English summary). [Between 1992 and 1997, 39 species are recorded in four peat bogs in the Polish part of the region Polesie (border region to Belarussia and Ukraine). The most interesting species are "Sympecma fusca, Orthetrum albistylum, Libellula fulva, and Sympetrum pedemontanum. The northern range limits of the former two species run in eastern Poland, and the last compact complexes of localities of these species are known in the study area; northwards only single localities occur [...]. The development of *O. albistylum* in peat bog waters confirms also its wide habitat spectrum in mideastern Poland [...]. *L. fulva* and *S. pedemontanum* are widely distributed, but they occur rarely. *S. pedemontanum* was known from only one locality in the Polish Polesie [...]. *L. fulva* is given from this region for the first time and two other new records are also given. Both species are probably more frequent in the region, but they need intensive investigations focused on their typical habitats. [...]" (Author)] Address: Buczynski, P., Dept of Zool., Marie Curie-Sklodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

2043. Buczynski, P. (2000): Großlibellen auf Kiefernadeln aufgespießt (Odonata: Libellulidae). *Libellula* 19(3/4): 213-216. (in German with English summary). ["Dragonflies speared by pine needles (Odonata: Libellulidae) - Adult *Orthetrum cancellatum* and *Sympetrum danae* pinned to coniferous needles were found at peatbogs in southeastern Poland. The imago of *S. danae* had survived and flew dexterously with a pin impaling its abdomen. It is suggested that this phenomenon was caused by shrikes." (Author)] Address: Buczynski, P., Dept of Zool., Marie Curie-Sklodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pbuczyns@biotop.umcs.lublin.pl

2044. Buczynski, P.; Pakulnicka, J. (2000): Odonate larvae of gravel and clay pits in the Mazurian lake district (NE Poland), with notes on extremely northern localities of some Mediterranean species. *Notul. odonatol.* 5(6): 69-72. (in English). [Larvae of 30 spp. were collected during 1998 and 1999 at 6 localities. Of special interest are *Orthetrum albistylum*, *Sympetrum depressiusculum*, *S. fonscolombii*, *S. meridionalis*, *S. striolatum*, and *Leucorrhinia pectoralis*. The localities for *O. albistylum* lie far from its hitherto known area of distribution.] Address: Pakulnicka, J., Chair of Ecology and Environment Protection, Warminko-Mazurski University, Zolnierska 14, PL-10-561 Olsztyn, Poland

2045. Burbach, K.; Weihrach, F. (2000): Entwicklung von drei Gomphiden-Arten in einem Baggersee bei München (Odonata: Gomphidae). *Libellula* 19(3/4): 237-240. (in German with English summary). ["In June 2000, exuviae of *Gomphus pulchellus*, *G. vulgatissimus* and *Onychogomphus f. forcipatus* were collected at an old gravel pit lake near Munich, Bavaria, Germany. In September 2000, these species were recorded as larvae in the same lake. This is the first record for Central Europe of the concurrent development of three gomphid species in stagnant waters." (Authors)] Address: Burbach, K., Griesfeldstr. 5a, D-85354 Freising, Germany. E-mail: klaus.burbach@gmx.de

2046. Burbach, K. (2000): Nachweis einer zweiten Jahresgeneration von *Enallagma cyathigerum* und

Ischnura pumilio in Mitteleuropa (Odonata: Coenagrionidae). *Libellula* 19(3/4): 217-227. (in German with English summary). ["South of Neuburg/Donau, Bavaria, Germany (48°41'N, 11°11'E) two freshly emerged adults and five exuviae of *E. cyathigerum* as well as one emerging and two fresh emerged imagines of *I. pumilio* have been recorded on 26-VIII and 30-VIII 1998, respectively. The site was a newly built pond which was flooded on 20-V-1998. The only probable origin of the odonates is from oviposition into the vegetation in spring 1998. The development from egg to adult must have taken place in about 100 days and was favoured by warm weather, high water temperature and lack of competition. Long flight periods and late emergence records suggest that a second generation is not uncommon and may often be overlooked due to methodical problems. The variation of life cycles in both spp. is discussed." (Author)] Address: Burbach, K., Griesfeldstr. 5a, D-85354 Freising, Germany

2047. Burkart, W.; Lopau, W. (2000): Libellen im Landkreis Rotenburg (Wümme). *Naturkundliche Schriftenreihe der Stiftung Naturschutz im Landkreis Rotenburg (Wümme)* 2: 175 pp. (in German). [The Landkreis Rotenburg (Wümme) is situated in the north of the Federal State Niedersachsen, Germany, south-west of Hamburg. The odonate fauna of this region is treated in a very nice, sophisticated book. In a general part the authors present an introduction into the natural history (geology, climate etc.) and the typical dragonfly habitats; maps and colour photos illustrate the given information. Furthermore the data basis is outlined, including a short history of odonatological research in the region. The book is directed to the advanced amateur and a more general public, thus: a biology of dragonfly is not lacking. Part II treats in a monographic style 55 odonate species. Each species is introduced by a colour photo and characterised more generally. Special emphasize is given to the distribution and the habitats in the Landkreis Rotenburg (Wümme). A map, a figure with phenology, information on threat, and possible conservation measures provide a lot of sound information of more than regional interest. A quite extensive chapter is directed to the protection of dragonflies under a more regional view. Some habitats and species in the Landkreis Rotenburg (Wümme) are of national importance in view of conservation view. The appendix includes a glossary and a regional bibliography. No doubt, this is a book which should not be missing from your odonatological library. (M. Schorr)] Address: Stiftung Naturschutz im Landkreis Rotenburg (Wümme), Postfach 1440, D-27344 Rotenburg (Wümme), Germany

2048. Buskirk, J. van; Schmidt, B.R. (2000): Predator-induced phenotypic plasticity in larval newts: trade-offs, selection, and variation in nature. *Ecology* 81(11): 3009-3028. (in English). ["Phenotypic plasticity has important ecological consequences because the strengths of species interactions can change with the behavior and morphology of interacting individuals. Evolutionary studies of plasticity can predict conditions under which shifts in phenotypes will occur and, therefore, may modify species interactions. We studied evolutionary mechanisms maintaining an induced response to predators in *Triturus* newt larvae, which are among many taxa in freshwater habitats exhibiting predator-induced plasticity. When exposed to caged (nonlethal) *Aeshna* dragonfly larvae, newts of two species (*T. alpestris* and *T. helveticus*) spent more time hiding in the leaf litter,

had darker pigmentation in the tail fin, and developed larger heads and larger tails relative to their body size, in comparison with newts in predator-free ponds. The two phenotypes faced a performance trade-off across environments with and without odonates: the predator-induced phenotype survived twice as well as the no-predator phenotype when exposed to free dragonflies, but the predator-induced phenotype of both species grew more slowly until just before metamorphosis. For *Triturus alpestris*, a direct comparison of performance between phenotypes was complicated because predator-induced newts emerged later in the summer but at a larger body size. Nonrandom mortality imposed by hunting dragonflies caused selection favoring increasing tail size, but we found no selection on specific traits in predator-free ponds. Head shape was not subject to selection in either environment; we suspect that head shape is involved in consuming different prey in the presence and absence of predators and is unrelated to predator escape. *Triturus* in 25 natural populations from which we collected quantitative samples in 1997 and 1998 exhibited extreme spatial variation in predation regime (density of large predators ranged from 0 to 24 individuals/m²). Variation among populations in head shape was exactly as predicted by experimental results (*Triturus* of both species had relatively large heads when exposed to predators), but results for tail shape were consistent with the experiments in only one of the two years. The evolutionary mechanisms maintaining plasticity in *Triturus* and other amphibian larvae should apply to many organisms inhabiting freshwater ponds, so trait-mediated indirect effects seem especially likely to occur in these habitats." (Authors). *Aeshna cyanea*, *Anax imperator*] Address: Buskirk, J. van, Institute of Zoology, University of Zürich, CH-8057 Zürich, Switzerland. E-mail: jvb@zool.unizh.ch

2049. Bußmann, M. (2000): Libellenfunde im nord-westlichen Sauerland - eine vorläufige, kommentierte Artenliste. *Der Sauerländische Naturbeobachter* 27: 49-56. (in German with English summary). 2057. Couteyen, S.; Papazin, M. (2000): Contribution à la connaissance des Odonates de l'île de la Réunion 2. Description de la larve de *Gynacantha bispina* Rambur. (Odonata, Aeshnidae). *L'entomologiste* 56(5): 215-219. (in French with English summary). ["The ultimate instar larva of *Gynacantha bispina* Rambur, 1842 is described and figured. Some biological notes are added. It is compared to the larva of *Anax imperator mauricianus* Rambur, 1842, the other known Aeshnidae from La Réunion." (Authors)] Address: Couteyen, S., 188, Chemin Nid Joli, F 97430 Le Tampon, La Réunion

2058. Couteyen, S.; Papazin, M. (2000): Contribution à la connaissance des odonates de la Réunion 3. *Hemicordulia asiatica* Sélys, 1878, une espèce nouvelle pour l'île (Odonata, Corduliidae). *Martinia* 16(3): 107-110. (in French with English summary). [*H. asiatica* was observed December 17, 1998. A checklist of the Réunionian Odonata is added.] Address: Couteyen, S., 188 chemin Nid Joli, F-97430 Le Tampon, La Réunion, France

2059. Couteyen, S.; Papazin, M. (2000): Contribution à la connaissance des odonates de l'île de la Réunion 1. Présence de *Gynacantha bispina* Rambur, 1842 (Odonata, Aeshnidae). *Entomologiste* 56(3): 127-134. (in French with English summary). [*Gynacantha bispina*, *G. radama*, *G. malgassica*, and *G. hova* are known to occur on the isles of Madagascar, Réunion, Mauritius, and the Comores. The specimens of the genus known from Réunion are analyzed, and turned out to belong exclusively to *G. bispina*. Thus, *G. radama* has to be eliminated from the checklist of the Odonata from Réunion; a new checklist (16 species) is given in the appendix of the paper. The species (excl. *G. hova*) are figured, *G. bispina* is described, and compared in detail with *G. malgassica*.] Address: Couteyen, S., 188 chemin Nid Joli, F-97430 Le Tampon, La Réunion, France

2060. Couteyen, S. (2000): Déterminisme de la posture de guet chez *Trithemis annulata haematina* (Rambur, 1842) (Odonata, Libellulidae). *Martinia* 16(3): 101-106. (in French with English summary). [Réunion; the perch site selection of *T. haematina* is studied in dependence of day time, temperature of air, temperature of perch surface, wind, and on of four differed perch positions previously occupied.] Address: Couteyen, S., 188 chemin Nid Joli, F-97430 Le Tampon, La Réunion, France

2061. Cruden, R.W.; Gode, O.J. (2000): The Odonata of Iowa. *Bulletin of American Odonatology* 6(2): 13-48. (in English). ["We report 108 species from Iowa, which include 103 species collected since 1985, two accidentals, and three species that were probably extirpated many decades ago. We discuss reports of 20 additional species whose presence in the state is questionable. As many as 31 species may be imperiled or critically imperiled. This reflects, at least in part, that the distributional ranges of 19 species barely reach Iowa. Most of the imperiled species occur in lotic habitats or wetlands, habitats most affected by human activity. Dramatic post-settlement changes in the state's river systems

were followed by the movement of species into lotic systems, e.g., *Argia moesta*, *Enallagma anna*, *Gomphus externus*, *Progomphus obscurus*, and *Stylurus notatus*. [...] *Hagenius brevistylus*, *Gomphus fraternus*, *G. exilis*, have become less common or were extirpated due to stream degradation. Further, prior to settlement there were few deep lakes and ponds in the state and virtually no wetlands or ponds in southern Iowa. The construction of farm ponds, gravel pits, etc., and the elimination of wetlands dramatically changed the lentic fauna. Species that were absent from Iowa, rare, or restricted to eastern Iowa early in the 1900s are now common across the state, e.g., *Epitheca princeps*, *Celithemis eponina*, and *Perithemis tenera*. In contrast, at least one wetland species was possibly extirpated, i.e., *Lestes vigilax*, and the ranges of others probably contracted, e.g., *Aeshna verticalis*, *Nasiaeschna pentacantha*, and *Sympetrum ambiguum*." (Authors)] Address: Cruden, R.W., Department of Biological Sciences, University of Iowa, Iowa City, IA 52242, USA. E-mail: robert-cruden@uiowa.edu

2062. Czachorowski, S.; Buczynski, P.; Walczak, U.; Pakulnicka, J. (2000): Cover species (umbrella species) in the protection of insects. *Przegląd Przyrodniczy* 11(2-3): 139-148. (in Polish with English summary). ["Current laws on nature protection in Poland are grounded on experiences with protection of vertebrates and plants. However, they are often insufficient and ineffective in case of insects. Moreover, they also make difficult basic studies on faunistics and ecology which are vital to plan proper protection activities. Such activities, outside protected areas (National Parks and Nature Reserves) are proposed in this article, using the so-called 'cover species' ('umbrella species') method. The umbrella species for variable biotopes in Poland are suggested, including the caddisflies, dragonflies, water beetles, water bugs, and butterflies." (Authors) A German translation of the paper is available from Pawel Buczynski.] Address: Buczynski, P., Dept of Zool., Marie Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. 2066. David, S. (2000): Bibliography of dragonflies (Insecta: Odonata) of Slovakia. III (1993-2000). Sborník referátu III. celostátního semináře odonatologi v CHKO Trebonsko, 2000: 175-183. (in Slovakian with English summary). [The third part of the Slovakian odonatological bibliography compiles 86 publications.] Address: David, S., ÚKE SAV, Akademická 2, SK-94901 Nitra, Slovakia. E-mail: nrukdavi@savba.sk

2067. David, S. (2000): Dragonfly (Odonata) communities and water habitats in the inundation of the Hron river potamal (SW Slovakia). Ekológia (Bratislava) 19 (Suppl. 2): 137-150. (in English with Slovakian summary). ["The species composition in the dragonfly communities of lentic and lotic habitats in the inundation area of the Hron River is analysed. The investigation was carried out from April 1987 to October 1993, neglecting the winter period. A total of 61 samples were taken in 20 habitats. A total of 33 species were captured, 28 of which were found in the larval stage. One of these - *Sympetrum danae* (as a peat-moos species) is recorded for the first time in the Hron floodplain. Among endangered and rare species, *Onychogomphus forcipatus*, *Sympetrum meridionale*, *S. pedemontanum*, and *Somatochlora metallica* respectively, may be mentioned about. Surprising is the finding of the peat-moss and moorland species *S. danae*. According to origin 17 Mediterranean and 10 Palearctic species dominate. Five species originate from Ponto-Caspian refuge area. 17 species are wide-spread in Euro-Siberian and west-Siberian areas, Palearctic area harbours 9 species and 5 species are wide-spread in the area extending from Mediterranean region to southern Scandinavia and Russia. *Erythromma viridulum*, *Aeshna affinis*, *Anax imperator*, and *Crocothemis erythraea* are species of invasion character. The types of habitat could be separated into the four groups of different community structure. The ordination and classification of the dragonfly communities were set up using NCLAS and PRINCOMP programs. We have identified odonatocenoses: *Gomphus - Calopteryx splendens* in the Hron river (rheophile communities) and small defined species communities of *Orthetrum - Lihellula depressa* in study area. The habitats present here are the Hron branches (oxbow lakes) and the big gravel pits. The habitats of the richest communities of species *Lestes - Sympetrum - Aeshna* (*mixta*, *affinis*) are gravel pits filled with soil and oxbow lakes of Hron. Despite the difficulties with interpretation of the results obtained by ordination (indirect gradient analysis), the presented methods of numeric data elaboration are considered to be a contribution to the study on community composition problems of dragonflies." (Author)] Address: David, S., ÚKE SAV, Akademická 2, SK-94901 Nitra, Slovakia. E-mail: nrukdavi@savba.sk

2068. David, S. (2000): Dragonfly fauna (Insecta: Odonata) of the Stiavnické vrchy Mts. Entomofauna carpathica 12: 25-31. (in Slovakian with English summary). [The dragonfly fauna of 25 localities in the Stiavnické vrchy Mts. (middle Slovakia) was investigated from 1990 to 1998. 28 species are documented in detail and zoogeographically analyzed. A total of 33 odonate species is known from the region. The records of *Coenagrion ornatum*, *Thecagaster bidentata*, *Orthetrum brunneum*, and *Leucorrhinia pectoralis* are the most considerable faunistic results from the surveys of the Stiavnické vrchy Mts.] Address: David, S., ÚKE SAV,

2071. Dolný, A. (2000): Dragonflies (Odonata) as biological indicators. In: Hanel, L. (Ed.): Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chránené krajinné oblasti Trebonsko 15.-18.6.2000. Vlasim. ISBN 80-86327-12-4: 8-23. (in Czech with English summary). [Dragonflies are suitable to determine the saprobity of running waters based on a calculation of the saprobic index of the community. "In this contribution the author sums the knowledge about the possibilities of using dragonfly (Odonata) larvae for bioindication. [...] Dragonflies are also a suitable group of insects for bioindication of the naturalness level of zoocenoses and for monitoring the ecological state of biotops significant from the point of view of conservation of the nature and namely peat bogs."] Address: Dolný, A., Katedra biologie a ekologie, Přírodovědecká fakulta Ostravské univerzity, Bráfova 7, 701 03, Ostrava 1, Czech Republic

2072. Dommangeat, J.-L.; Mashaal, M. (2000): Les Départements et Territoires d'Outre-mer français. Généralités. Martinia 16(3): 85-94. (in French with English summary). [This is a general introduction into the political and geographical situation of the French overseas departments and territories in the framework of a special issue of Martinia on the Odonata of these countries. They represent an area of about 120000 km² and a population of more than 2,2 millions inhabitants. "Most of these territories are tropical and have therefore weather conditions favorable to Odonata. A general introduction is followed by some information about the geography, the climate and the economy of the different territories. The odonatological interest of each is also mentioned, mainly for the territories not covered in other articles of the present issue." (Authors)] Address: Mashaal, M., 2, rue Meilhac, F-75015 Paris, France

2073. Dommangeat, J.-L. (2000): Note préliminaire sur des collections d'odonates exotiques mises à disposition de la SFO. Martinia 16(3): 133- (in French). [Short

notice with reference to specimens from different countries waiting for determination, including some identifications from Guadeloupe.] Address: Dommanget, J.-L., 7, rue Lamartine, F-78390 Bois-d'Arcy, France

2074. Donath, H. (2000): Bergbaufolgelandschaft - Leit- und Zielarten zur Beurteilung von Naturschutzkonzepten. Teil 2: Odonata. Biologische Studien, Luckau 29: 25-41. (in German). [Odonata were surveyed between 1995 and 2000 in the abandoned brown-coal-mining area Schlabendorf Nord and Schlabendorf Süd, Brandenburg, Germany. 43 (27 autochthonous) species could be recorded. In addition data of the Stoßendorf See (colonisation by Odonata after flooding) and the Tornower Waldsee are presented. The author defines umbrella species (e.g. species of ponds, acid lakes, high bogs, ubiquitous) dwelling the brown coal waters and compares their habitat selection with different stages of succession of these waters. Factors discussed are pH, age, water level, wind exposition, or vegetation. The author concludes that measures for species of late succession stages with reed belts and hydrophyte and submerged vegetation should be given priority.] Address: Donath, H., Caule Nr. 1, D-15926 Zieckau, Germany

2075. Donnelly, N. (2000): A hybrid *Ophiogomphus* female - again. *Argia* 12(4): 9. (in English). ["A few years ago I reported on a strange *Ophiogomphus* female collected by the late Richard Forster. It was found on the Squannacook River at West Groton, Middlesex Co., Massachusetts, on 10 Aug. 1996. Its characters were almost precisely halfway between *O. rupinsulensis* and *carolus*, and I determined it to be a hybrid between those two species. This summer Jeremiah Trimble found a second example, on the Machias River, Washington Co., Maine, on 26 June 2000. It is also a female and is essentially identical to the Forster specimen. The morphological character that is most significant in both examples is the post-occipital horn, which is similar to that of *rupinsulensis*, but very thin. (*O. carolus* lacks a horn here). It is curious that these two specimens are females; generally males show their hybrid origins much more clearly." (Verbatim)] Address: Donnelly, T., 2091 Partridge Lane, Binghamton, NY 13903, USA. E-mail: tdonnel@binghamton.edu

2076. Donnelly, N. (2000): Hybrid between *Enallagma anna* and *civile* - from Ontario and Iowa!. *Argia* 12(4): 8-9. (in English). [The male appendages of *E. anna* and *E. civile*, and of *E. anna* x *civile* are figured. The case of *E. optimolocus* Miller & Ivie, 1996 is discussed; the species could possibly be a hybrid between *E. anna* and *E. carunculatum*. Nick Donnelly concludes: "Hybridization may be more frequent than we think."] Address: Donnelly, T., 2091 Partridge Lane, Binghamton, NY 13903, USA. E-mail: tdonnel@binghamton.edu

2079. Duhé, R. (2000): Ant lion eats *Erythemis*. *Argia* 12(4): 9. (in English). [Texas, USA; "[...] there was a female *Erythemis simplicicollis* apparently "stuck" to the ground and flapping its wings wildly. Closer observation showed the dragon had, most unfortunately, chosen a bare spot on the bank only a few square inches in area that happened to be the site of an antlion's den! An ill-fated rescue attempt (mostly to discover the predator's true identity) only yielded the dragonfly minus its abdomen. The mostly clay with sand bank was too difficult to dig fast enough to yield the culprit." (Author)] Address: Rand Duhé. E-mail: duhe@infohwy.com

2080. Duinen, G.-J. van ; de Bruijn, L.; Hanzen, D.; Kleef, H. van; Kuper, J.; Scarse, D.; Esselink, H. (2000): Do restoration measures help to restore dragonfly communities in raised bog remnants? Proceedings of the Section Experimental & Applied Entomology of the Netherlands Entomological Society (N.E.V.) 11: 151-158. (in English). ["Until now it is unknown whether restoration of raised bog remnants in The Netherlands result in the restoration of fauna communities characteristic of intact raised bog systems. Preliminary results of a comparative study in four different raised bog remnants under restoration show remarkable differences in dragonfly density and species composition. A main factor seems to be the presence or absence of variation in water quality, as found in intact raised bog complexes, including natural transitions to the surrounding landscape. Influence of atmospheric deposition, present spatial configuration of raised bog remnants, and hydrological interactions may hinder restoration efforts." (Authors) Abundance and total number of individuals were counted using the transect method. All species observed (n = 30) were divided into ecological categories. An analysis of the current species composition compared with these categories concluded that dragonfly communities of both ombrotrophic raised bog centres (*Aeshna subarctica elisabethae* and *Somatochlora arctica*, the latter not present in the study area) and of gradients to more minerotrophic parts of the systems are still not completely present in the studied raised bog remnants.] Address: Duinen, G.-J. van, Department of Environmental Studies, Bargerveen Foundation, University of Nijmegen, 6500 GL, Nijmegen, Netherlands

(in German with English summary). [19 odonate species were recorded in 1996. *Platycnemis pennipes* and *Ischnura elegans* are dominant. The following species are discussed in some detail: *Brachytron pratense*, *Erythronia najas*, *Coenagrion puella*, *C. pulchellum*, *Sympecma fusca*, *Gomphus vulgatissimus*, *Libellula fulva*, *Calopteryx splendens*, *P. pennipes*, *I. elegans*, *Somatochlora metallica*, *Orthetrum cancellatum*, *Sympetrum sanguineum*.] Address: Oelke, J., Fachhochschule Eberswalde, Fachbereich Landschaftsnutzung und Naturschutz, Schicklerstr. 3-5, D-16225 Eberswalde, Germany

2085. Eklov, P.; Werner, E.E. (2000): Multiple predator effects on size-dependent behavior and mortality of two species of anuran larvae. *Oikos* 88(2): 250-258. (in English). [This study examined the effects of multiple predators on size-specific behavior and mortality of two species of anuran larvae. Particularly, we focused on how trait changes in predators and prey may be transmitted to other species in the food web. In laboratory experiments, we examined the effects of bluegill sunfish, *Lepomis macrochirus*, and the odonate larva *Anax junius* on behavior and mortality of tadpoles of the bullfrog, *Rana catesbeiana*, and the green frog *R. clamitans*. Experiments were conducted with predators alone and together to assess effects on behavior and mortality of the tadpoles. The experiments were replicated on five size classes of the tadpoles to evaluate how responses varied with body size. Predation rates by *Anax* were higher on bullfrogs than on green frogs, and both bullfrogs and green frogs suffered greater mortality from *Anax* than from bluegill. Bluegill only consumed green frogs. Predation rates by both predators decreased with increasing tadpole size and decreased in the non-lethal (caged) presence of the other predator. Both anuran larvae decreased activity when exposed to predators. Bullfrogs, however, decreased activity more in the presence of *Anax* than in the presence of bluegill, whereas green frogs decreased activity similarly in the presence of both predators. The largest size class of green frogs, but not of bullfrogs, exhibited spatial avoidance of bluegill. These responses were directly related to the risk posed by the different predators to each anuran species. *Anax* activity (speed and move frequency) also was higher when alone than in the non-lethal presence of bluegill. We observed decreased predation rate of

each predator in the non-lethal presence of the other, apparently caused by two different mechanisms. Bluegill decreased *Anax* mortality on tadpoles by restricting the *Anax* activity. In contrast, *Anax* decreased bluegill mortality on tadpoles by reducing tadpole activity. We discuss how the activity and spatial responses of the tadpoles interact with palatability and body size to create different mortality patterns in the prey species and the implications of these results to direct and indirect interactions in this system." (Authors)] Address: Eklov, P., Dept of Ecology and Environmental Science, Animal Ecology, Umea Univ., SE-901 87, Umea Sweden

2086. Elkin, C.M.; Baker, R.L. (2000): Lack of preference for low-predation-risk habitats in larval damselflies explained by costs of intraspecific interactions. *Animal Behaviour* 60(4): 511-521. (in English). [Many studies indicate prey organisms select microhabitats with high structural complexity as a way of reducing risk of predation. We used laboratory experiments to show that damselfly larvae, *Ischnura verticalis*, suffer higher predation rates from pumpkinseed sunfish in low-density vegetation. However, larvae do not preferentially occupy microhabitats with high vegetation density in either the presence or absence of sunfish; when given a choice, the number of larvae per stem of vegetation was equal across all densities of vegetation. That larvae do not congregate in dense vegetation may reflect costs of aggressive interactions. Results from laboratory experiments indicated larval interactions increase conspicuous behaviours (most notably swimming) and consequently increase fish predation. A subsequent experiment indicated that frequency of larval interactions increases with increased vegetation density when number of larvae/stem is constant. Thus, larval microhabitat selection may reflect a trade-off between reduced risk of predation in areas of high vegetation density, caused by reduced fish foraging ability, and increased aggressive larval interactions, due to decreased proximity of larvae." 2087. Endersby, I.D. (2000): Common names for dragonflies. *Victorian Entomologist* 30(4): 53-54. (in English). [The author compiles on the family level common names for Australian Odonata; he compares the names used in UK, USA, and New Zealand. In the cases of species occurring in New Zealand and Australia common names on the species level are adopted. He concludes that except for Gomphidae ("Clubtails") and Corduliidae ("Emeralds") "Australia can feel free to produce a unique set of vernacular names as there is no international standard to which it should conform."] Address: Endersby, I., 56 Looker Rd, Montgomery, Victoria 3094, Australia. E-mail: endersby@werple.net.au

2088. Endersby, I.D. (2000): Dragonfly conservation in Victoria. *Victorian Entomologist* 30(4): 47-51. (in English). [This is a general introduction into problems of dragonfly conservation in Victoria, Australia. Special emphasis is given on defining so-called flagship species. For those species which are known to occur in Victoria, Hawking's (1999) (see OAS 983) assessment of their Australian status is delimited to the Victorian regional situation. 74 species are listed; *Hemiphysbia mirabilis* is listed as 'Vulnerable', 11 species as 'Near threatened', 55 as 'Least concern', and 7 as 'Data defi-

cient'.] Address: Endersby, I., 56 Looker Rd, Montgomery, Victoria 3094, Australia. E-mail: endersby@werple.net.au

2089. Endersby, I.D. (2000): Nomenclatural changes affecting Victorian dragonflies. *Victorian Entomologist* 30(3): 40-41. (in English). [A full catalogue of Victorian Odonata is given in Endersby (2000) (see OAS 1831). This paper summarises the family level taxonomy changes as they affect the Victorian Odonata.] Address: Endersby, I., 56 Looker Rd, Montgomery, Victoria 3094, Australia. E-mail: endersby@werple.net.au

2090. Etter, W.; Kuhn, O. (2000): An articulated dragonfly (Insecta, Odonata) from the Upper Liassic Posidonia shale of northern Switzerland. *Palaeontology* 43(5): 967-977. (in English). ["An articulated dragonfly from the Lower Jurassic Posidonia Shale of northern Switzerland is described. The specimen is assigned to *Liassogomphus brodiei* (Buckman). This is the first description of an articulated member of the family Liassogomphidae, hitherto known from isolated wings only. Almost identical wings were previously described as *Phthitogomphus angulatus* (Handlirsch) and *Palaeogomphus propinquus* (Bode). The latter is now treated as synonymous with *Liassogomphus brodiei*, and the genus *Palaeogomphus* Handlirsch is therefore a junior synonym of *Liassogomphus* Cowley. The structures of the head, eyes, thorax, legs, and first segments of the abdomen confirm the state of the Liassogomphidae within the Anisoptera (or Pananisoptera) and point perhaps to a close relationship of the Liassogomphidae to the extant family Aeshnidae. This has already been stated previously based on wing venation patterns alone. The taphonomy of dragonflies in marine settings is briefly addressed. Only a combination of several exceptional circumstances led to the fossilization of this remarkable fossil." 2092. Falck, J.; Johansson, F. (2000): Patterns in size, sex ratio and time at emergence in a south Swedish population of *Sympetrum sanguineum* (Odonata). *Aquatic Insects* 22(4): 311-317. (in English). ["Differences between sexes in life history patterns of *Sympetrum sanguineum* were studied in a small pond in southern Sweden by means of exuviae and adult sampling. Emergence occurred from 4 to 28 July, and mean emergence date was 10 July for both males and females. The sex ratio at emergence (53% females) did not differ from 1:1, but significantly more females emerged during the first 5 days of the emergence period. Size of emerging individuals (immatures) decreased as season progressed and males emerged at a larger size than fema-

les. While immature males were heavier than immature females, no such difference was found in mature individuals. We suggest that the sexual differences in size and emergence patterns observed are the result of different optimisation by males and females with respect to the growth-mortality risk trade-off in the larval and adult stages." (Author)] Address: Johansson, F., Department of Ecology and Environmental Science, Animal Ecology Group, Umeå University, 90187 Limed, Sweden. E-mail: frank.johansson@eg.umu.se

2093. Faton, J.-M. (2000): L'intérêt odonatologique du Marais de Printegarde, au confluent de la Drôme et du Rhône. *Sympetrum* 15: 39-49. (in French). [41 species of which 34 are considered autochthonous, are reported from a marsh situated in the confluent of the rivers Drôme and Rhône, France. In tab. 2 the species turn over of the periods 1985 to 1991 and 1994 to 1997 is compared. In fig. 1 the population density of *Coenagrion mercuriale*, *C. puella*, *C. pulchellum*, *C. scitulum*, and *Cercion lindenii* is presented. First results of a transect walk to document the abundance and dominance of the species is presented in tab. 3 and fig. 2.] Address: Faton, J.-M., Réserve Naturelle des Ramières, les Garis, F-26120 La Baume Cornillane, France

2094. Fischer, U.; Weigel, A. (2000): Beitrag zur Fauna des Geschützten Landschaftsbestandteiles "Wiese am Kirchsteig" und dessen Umfeld bei Niederböhmersdorf (Thüringen: Landkreis Greiz). *Thüringer Faunistische Abhandlungen* 7: 21-44. (in German with English summary). [Between 1995 and 2000, 27 odonate species including *Coenagrion hastulatum*, *Erythromma najas*, *Sympetrum flaveolum*, and *S. pedemontanum* are recorded. They are listed and interesting species are shortly discussed.] Address: Fischer, U., Anton-Günther-Str. 12, D-08340 Schwarzenberg, Germany

2095. Fitzstephens, D.M.; Getty, T. (2000): Colour, fat and social status in male damselflies, *Calopteryx maculata*. *Animal Behaviour* 60(6): 851-855. (in English). ["In the black-winged damselfly, *Calopteryx maculata*, younger males challenge and displace older males from mating territories. Fatter males tend to win fights. These fights were initially interpreted as wars of attrition based on fat reserves, but the distributions of fat at the end of fights suggests at least some assessment of the opponent's condition. Alternatively, new models have been developed that show how the observed pattern could result without assessment. We show that there is a subtle but reliable cue to fat reserves: colour. Females are a relatively drab brown-black. Males are a strikingly iridescent blue-green colour, resulting from a multilayer constructive interference reflector system in the epicuticle. In fatter males the lamellae are more compressed and the peak reflectance is at shorter wavelengths (blue). Leaner, greener males have greater spacing between lamellae and reflect longer wavelengths. The peak reflectance is as predicted from transmission electron micrograph measurements of the lamellar spacing. The rate of change in spacing over time can be manipulated experimentally by manipulating the diet. Individuals on a higher food diet remained blue longer and at the end of the experiment were fatter and bluer. In our studies, colour is a better predictor of territorial status than fat." 2097. Flint, O. (2000): *Nehalennia pallidus* in Texas! *Argia* 12(4): 3-4. (in English). [Odonate specimens from a 1918 collection made in Texas yielded to be *N. pallidus*. This species was formerly thought to be endemic for Florida, USA] Address: Flint, O.S., Natn Mus. Nat. Hist., Smithsonian Inst., Washington, DC 20560, USA
2098. Flint, O. (2000): *Sympetrum signiferum* at Leslie Canyon, Arizona. *Argia* 12(4): 6-7. (in English). [*S. signiferum* was recorded from August 30 until around November 20, 2000.] Address: Flint, O.S., Natn Mus. Nat. Hist., Smithsonian Inst., Washington, DC 20560, USA
2099. Garcia-Berthou, E.; Moreno-Amich, R. (2000): Food of introduced pumpkinseed sunfish: Ontogenetic diet shift and seasonal variation. *Journal of Fish Biology* 57(1): 29-40. (in English) ["The pumpkinseed sunfish *Lepomis gibbosus* introduced into Lake Banyoles (Spain) were predominantly littoral but there was a tendency of large fish to use deeper zones. Their diet was dominated by littoral macrobenthos, particularly amphipods (*Echinogammarus* sp.). There was ontogenetic variation in the diet, with small young-of-the-year (LF<4 cm) feeding on several littoral microcrustaceans, especially the cladoceran *Ceriodaphnia reticulata*, whereas larger fish shifted to a freshwater shrimp (*Atyaephyra desmaresti*), snails and damselfly larvae. Seasonal variation in diet was linked to the availability, with consumption of fish eggs and plant debris in spring and summer. In autumn, pumpkinseeds were partially zooplanktivores, preying on the cladoceran *Daphnia longispina*. The diet of pumpkinseeds in Lake Banyoles and other Iberian populations shows less molluscivory than North American populations. The potential ecological impact of this successful exotic species involves mainly predation on fish eggs and molluscs."] (Authors).] Address: Garcia-Berthou E., Departament de Ciències Ambientals and Institut d'Ecologia Aquàtica, Universitat de Girona, E-17071, Girona, Catalonia, Spain
2100. Gassmann, D. (2000): Revision of the Papuan *Idiocnemis bidentata*-group (Odonata: Platycnemididae). *Zool. Med. Leiden* 74 (23): 375-402. (in English). ["Eight species of the Papuan genus *Idiocnemis* Selys, 1878, sharing common traits in ligula structure and colour pattern, referred to here as the *Idiocnemis bidentata*-group, are redescribed or newly described. Taxonomy and distribution are updated and one new taxon, *Idiocnemis polhemi* spec. nov., is described from South-East New Guinea." (Author) *Idiocnemis bidentata*, *I. dagnyae*, *I. mertoni*, *I. nigrivertris*, *I. obliterateda*, *I. inaequidens*, *I. pruinescens*. An identification key to the species (males and females) and a distribution map of the *I. bidentata*-group in New Guinea are also provided.] Address: Dirk Gassmann, Institute of Evolutionary and Ecological Sciences, Leiden University, c/o National Museum of Natural History, P.O. Box 9517, 2300 RA Leiden, The Netherlands. E-mail: Gassmann@rulsfb.leidenuniv.nl

"Based on collections of exuviae, *Gomphus flavipes*, *G. pulchellus*, *G. vulgatissimus*, *Ophiogomphus cecilia*, and *Onychogomphus f. forcipatus* were recorded from the southern Midrhine in 2000. The most abundant species, *G. flavipes* and *G. vulgatissimus*, emerged on a variety of substrates which, in contrast to other studies, included boulder embankments but not trees. The origin of the populations is discussed." (Author)] Address: Geissen, H.-P., Brunnenstr. 34, D-56075 Koblenz-Stolzenfels, Germany
2103. Gemeinhardt, M. (2000): Zur Fauna der Unstrutniederung bei Heldrungen (Kyffhäuserkreis/Thüringen). *Thüringer Faunistische Abhandlungen* 7: 45-64. (in German with English summary). [The floodplain of the river Unstrut, Thüringen, Germany was investigated in 1996 and 1999. 19 odonate species are recorded. One oxbow of the River Unstrut is of special importance as habitat of a strong population of the rare *Coenagrion pulchellum*.] Address: Gemeinhardt, M., Rathenastr. 24, D-99085 Erfurt, Germany
2104. Geraeds, R.P.G.; Hermans, J.T. (2000): Dragonfly *Ophiogomphus cecilia* (Fourcroy, 1785) along the River Roer. *Natuurhistorisch Maandblad* 89: 254-259. (in Dutch with English summary). ["*O. cecilia* has always been a rare dragonfly in the Netherlands, where it had been extinct since 1936. In 1995 and 1996, a few animals were found at the Geleen-beek brook. In August and September of 2000, the species was spotted in low densities along the river Roer near Melick. The animals were mostly found perching in full sunlight on sandy soil, pieces of dead wood and vegetation on the banks of the river. Two females were observed while ovipositing. How *O. cecilia* managed to reach the river Roer after such a long time is not clear. An explanation could be that the animals drifted towards the Roer from the nearest populations in Germany and France. Another option could be that a small, undiscovered population of this species has lived along the river Roer for a longer period of time. The improving quality of the water could have made this possible. Further investigations

will have to show whether the Roer is a suitable habitat for *O. cecilia*." (Authors)] Address: Geraeds, R.P.G., Julianalaan 46, NL-6042 JH Roermond, The Netherlands

2105. Gilard, B.; Dommagnet, J.-L. (2000): 3e rencontres odonatologiques de France. Saint-Beuzire (Haute-Loire), 29 et 30 juin, 1er, 2 et 3 juillet 2000. Bilan et perspectives. *Martinia* 16(4): 175-184. (in French with English summary). [This is a detailed report of the third odontological meeting of France. In a chronological order lectures and field trips are documented. The data of the field trips are documented, including records of the rare *Coenagrion lunulatum*.] Address: Dommagnet, J.-L., 7, rue Lamartine, F-78390 Bois-d'Arcy, France

2106. Gilard, B. (2000): Une visite au "Lac du Lauzon" (Lus-la-Croix-Haute, massif du Dévoluy, Drôme). *Symptetrum* 15: 51-53. (in French). [France; at 1935 m asl, *Aeshna juncea* and *Coenagrion puella* are recorded.] Address: Gilard, B., 6, Route du Saut du Loup, F-63340 Le Beuil-sur-Couze, France

2107. Goffart, P. (2000): Compte-rendu de l'excursion aux étangs de Virelles et Roly du samedi 1er juillet 2000. *Gomphus* 16(2): 150-151. (in French with Dutch summary). [Belgium; *Coenagrion scitulum*, *Cercion lindenii*, *Anax parthenope*, *Somatochlora flavomaculata*, *Epithea bimaculata*, *Crocothemis erythraea*, and *Symptetrum fonscolombii* are among the species observed.] Address: Goffart, P., Unité d'Écologie et de Biogéographie, 5, Place Croix-du-Sud, B-1348 Louvain-la-Neuve, Belgium. E-mail: goffart@ecol.ucl.ac.be

2108. Goffart, P. (2000): Compte-rendu de l'excursion du samedi 26 août 2000 dans la région de Spa. *Gomphus* 16(2): 151-153. (in French with Dutch summary). [14 odonate species are reported from this trip to Spa, Belgium. *Aeshna subarctica elisabethae* could not be traced. Of some interest is the record of *Lestes barbarus*.] Address: Goffart, P., Unité d'Écologie et de Biogéographie, 5, Place Croix-du-Sud, B-1348 Louvain-la-Neuve, Belgium. E-mail: goffart@ecol.ucl.ac.be

2109. Goffart, P. (2000): Statut des espèces prioritaires d'Odonates du programme "Inventaire et Surveillance de la Biodiversité en Wallonie": bilan décennal (1990-1999). *Gomphus* 16(2): 139-149. (in French with English and Dutch summaries). ["The aim of this article is to offer a very concise survey of the 21 species considered priority in Wallonia. The survey is based on data collected in Wallonia during the last decade. A number of data of 2000 have also been used. All the information is presented in the form of synoptic tables. Among those priority species 4 have clearly declined, so have probably 6 others more (= 48%); one species (*Aeshna isosceles*) probably has disappeared. The others show a status-quo or some even a possible expansion. The tables show for each of these 21 species: natural regions, habitat, number of populations, threats and appropriate conservation measures." (Author)] Address: Goffart, P., Unité d'Écologie et de Biogéographie, 5, Place Croix-du-Sud, B-1348 Louvain-la-Neuve, Belgium. E-mail: goffart@ecol.ucl.ac.be

2110. Gomez-Anaya, J.A.; Novelo-Gutierrez, R.; Arce-Perez, R.A.C (2000): The Odonata in the zone affected by the Central Hydroelectric Plant of Zimapan named for Engineer Fernando Hiriart Balderrama, Hidalgo, Mexico. *Folia Entomologica Mexicana* 108: 1-34. (in Spanish with English summary). ["A faunistic study of

Odonata, based mainly in the larval stage, was carried out in Zimapan's influence area, which is located at the boundaries of Hidalgo and Queretaro States, Mexico. Samples were taken monthly, from August-95 to July-96 in five water bodies. The whole community structure of each water body was described and compared regarding to the others in terms of richness, Shannon diversity index, Hill's evenness index, rareness and density. Ecological distributional and seasonal data are provided for the majority of species, a list of species and an illustrated key to larvae species were also included. A total of 10,943 larvae and 193 imagoes belonging to 41 species of 23 genera included in seven families were caught. We found the highest richness, diversity, rareness and evenness in San Francisco River, whereas Tula River had the lowest density and diversity values. Fourteen species were recorded for the first time for Hidalgo State: *Argia pallens*, *A. pulla*, *A. sedula*, *A. tezpi*, *Ischnura ramburii*, *Aeshna dugesi*, *Anax walsinghami*, *Erpetogomphus crotalinus*, *Brechmorhoga praecox postlobata*, *Dythemis maya*, *Erythemis plebeja*, *Paltothemis lineatipes*, *Perithemis intensa*, and *Pseudoleon superbus*." (Authors)] Address: Novelo-Gutiérrez, R., Departamento de Entomología, Instituto de Ecología A.C., Km 2.5. antigua carretera a Coatepec, Aparatdo Postal 63, 91000 Xalapa, Veracruz, Mexico. E-mail: novelor@sun.ieco.conacyt.mx

2111. Goodyear, K.G. (2000): A comparison of the environmental requirements of larvae of the Banded Demoiselle *Calopteryx splendens* (Harris) and the Beautiful Demoiselle *C. virgo* (L.). *J. Br. Dragonfly Society* 16 (2): 33-51. (in English). [The only previous detailed work on the habitats and ecological requirements of the two *Calopteryx* species in UK covered the Wey river system of Hampshire and Surrey. In this paper the author observed that there has been considerable variation in the reported habitat requirements of these species compared with the study of Prendergast (1988). 20 locations were surveyed for their (co-occurring) dragonfly fauna, physical factors (water temperatures, water flow, depth, volume), chemical factors (hydrogen-ion concentration, oxygen, nitrate), and ecological factors (aquatic, emergent, and marginal vegetation).] Address: Goodyear, K.G., 26 Twynham Avenue, Christchurch, Dorset BH23 1QU, UK

2112. Gorb, S.N.; Kesel, A.; Berger J. (2000): Microsculpture of the wing surface in Odonata: Evidence for cuticular wax covering. *Arthropod Structure & Development* 29(2): 129-135. (in English). ["The insect wing membrane is usually covered by scales, hairs, and acanthae, which serve diverse functions, such as species-specific coloration pattern, decrease of wind resistance during flight or decrease of wing wettability. Representatives of Palaeoptera (Odonata and Ephemeroptera) have no hairy structures on the wing membrane, but both its sides are fine-sculptured. In this study, the nature of the wing covering was studied using acoustic microscopy, scanning- and transmission electron microscopy followed by a variety of chemical treatments. It was shown that wing microsculptures are not cuticular outgrowths, but a wax covering, which is similar to pruinosity, which has been previously described in several odonate taxa. Data from scanning acoustic microscopy revealed that scratches on the wax covering have material density different from the surrounding material. Various functions of the wax covering are discussed." (Authors)] Address: Gorb, S., Max-Planck-Institut für Entwicklungsbiologie,

Planck-Institut für Entwicklungsbiologie, Spemannstr. 35, D-72076 Tübingen, Germany. E-mail: stas.gorb@tuebingen.mpg.de

2113. Grand, D. (2000): Influence d'une éclipse de soleil sur une population d'odonates. Bulletin romand d'entomologie 18: 84-91. (in French). [15 km NE of Lyon, France along a line transect abundance and activities of Odonata were observed during the 91,2% solar eclipse of August 11, 1999.] Address: Grand, D., Impasse de la Voûte, F-69270 St. Romain-au-Mont d'or, France

2114. Grand, D. (2000): USA été 1979. Sympetrum 15: 55-58. (in French). [15 common taxa from six localities from eastern USA are listed.] Address: Grand, D., Impasse de la Voûte, F-69270 St. Romain-au-Mont d'or, France

2115. Grand, D. (2000): Voyage en Martinique. Martinia 16(3): 127-132. (in French with English summary). [In April and early May 2000, 14 odonate species were observed in Martinique, including *Tholymis citrina* which seems to be a new species for the Lesser Antilles.] Address: Grand, D., Impasse de la Voûte, F-69270 St. Romain-au-Mont d'or, France

2116. Grangier, C. (2000): Les araignées au menu de ces demoiselles. Sympetrum 15: 3-4. (in French). [Usually Odonata are preyed by spiders. This article reports two examples of spider preying Odonata from France. (1) *Ischnura elegans* devours a small *Araniella cucurbitina* (or *A. inconspicua*). (2) *Sympecma fusca* preyed on a very small, probably immature indetermined spider.] Address: Grangier, C., Le Trio, F-8460 Optevoz, France

2117. Greis-Harnischmacher, W. (2000): Bemerkungen zum Vorkommen von *Cordulegaster bidentata* in Hagen. Der Sauerländische Naturbeobachter 27: 115-120. (in German with English summary). [*Thecagaster bidentata* has been found on three localities of the Hagen region, Nordrhein-Westfalen, Germany. The reproduction habitats are gathering areas, where the larvae live buried in fine-sediments. The author used an interesting method to reveal the larvae by digging small hollows in which water and fine sediments can gather. After a few hours he succeeded in sifting out larvae from these hollows. Some advice in identification of early instar larvae of *T. bidentata* is given (dark spots on the ventral side of young larvae).] Address: Greis-Harnischmacher, W., Arndtstr. 20, D-58097 Hagen, Germany

2118. Grether, G.F.; Switzer, P.V. (2000): Mechanisms for the formation and maintenance of traditional night roost aggregations in a territorial damselfly. Animal Behaviour 60(5): 569-579. (in English). ["Communal roosting has been studied extensively in birds, but the mechanisms and functions of this taxonomically widespread behaviour pattern remain poorly understood. We studied the roosting behaviour of rubyspot damselflies, *Hetaerina americana*, in relation to sex and territorial status, and conducted field experiments to test for specific mechanisms of roost formation and maintenance. Both sexes tended to return close to their previous night's roost, but only males were significantly more roost site faithful than chance expectations based on individual day ranges. Males were more roost site faithful when they held mating territories. After acquiring a territory, males usually began roosting closer to the territory after a delay of a few days. Roosts were not lo-

cated at sites that reduced the daily commuting distance between hunting areas and territories; males generally hunted closer to their territories than to their roosts. In field experiments, sites 'seeded' with synthetic models of male rubyspots attracted more recruits than vacant control sites and control sites seeded with nonrubyspot (clear-winged) damselfly models. Sites seeded repeatedly with rubyspot models often remained popular for roosting after the models were removed, suggesting that the models established new traditional roosts. These results indicate that conspecific attraction and individual spatial memory together may be sufficient to explain, at a proximate level, the traditional night roost aggregations of this species. We discuss these results in relation to functional hypotheses for roost site choice and fidelity." (Authors)] Address: Grether, G.F., Department of Organismic Biology, Ecology and Evolution, University of California, 621 Charles E Young Drive South, Los Angeles, CA, 90095. USA. [In most cases unpublished reports of the Groupe de Recherche et de Protection des Libellules "Sympetrum" are compiled. There are many studies referring to one locality or some referring to species of special interest like *Leucorrhinia pectoralis* and *Coenagrion mercuriale*.] Address: Deliry, C., La Paluette, 2338 route de Belley, F-38490 Aoste, France

2120. Gurliat, P. (2000): Les Odonates de Loire-Atlantique. Bull. soc. sci. nat. Ouest de la France N.S. 21(2): 83-89. (in French with English summary). [Commented checklist of the 55 Odonata species recorded so far in the Loire-Atlantique département, France.] Address: Meurgey, F., 2, rue Bossuet, F-44000 Nantes, France

2121. Hämäläinen, M. (2000): The status of *Calopteryx okinawana* Matsumura, 1931 (Zygoptera: Calopterygidae). Notul. odonatol. 5(6): 83. (in English). ["In his '6000 illustrated insects of Japan-Empire', S. Matsumura (1931, p. 1454) described and illustrated *Calopteryx okinawana* Mats. as a new species from Okinawa, Japan. This is conspecific with *Matrona basilaris japonica* Förster, 1897. However, as far as I know, this synonymy has not been presented in any publication. Consequently, in their catalogues, C.A. Bridges (1994) and H. Steinmann (1997) list *okinawana* as a good species in *Calopteryx*, though the former hesitantly so, with a question mark after the genus name. Thus: *Matrona basilaris japonica* Förster, 1897, *Calopteryx okinawana* Matsumura, 1931, syn. nov.." (Author)] Address: Hämäläinen M., Dept Applied Zool., P.O.Box 27, FIN-00014 University of Helsinki, Finland; E-mail: matti.hamalainen@helsinki.fi

2122. Hájek, J.; Mocek, B. (2000): The occurrence of the dragonfly *Sympecma annulata* (Selys, 1887) (Odonata: Lestidae) in the Czech Republic. In: Hanel, L. (Ed.): Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chránené krajinné oblasti Trebonsko 15.-18.6.2000. Vlasim. ISBN 80-86327-12-4: 52-59. (in Czech with English summary). [Three notes on the occurrence of *Sympecma paeidisca* in the area of the Czech Republic are resulting from the 30s and 40s of the past century. Thus, the species has been catalogued in the Red List of dra-

gonflies of the Czech Republic as missing. It now was rediscovered during surveys of insects of reclaimed dumps of lignite from the Sokolov region in the years 1998-2000. A revision of the known data and of the stored specimens in the collections of the National museum shows that *S. paedisca* is restricted in the Czech Republic to the north-western Bohemian districts Sokolov and Karlovy Vary (Sokolov basin, one locality reaching as far as to the Doupovské hory mountains). "New findings originate from strongly anthropic localities, which are recultivated dumps of lignite, where the species prefers only several years old reservoirs and wet-grounds that are only sparsely covered by herbal vegetation." A successive concentration of high mineral salt content in water has been recorded. Ten adults were observed from May till September. [...] It seems that the species has been overseen in this area, or that an extensive survey of dragonflies has not been done there, for more than fifty years." The Czech population is considered as an isolated population on the western border of the area. Abstracters note: The publications of Bönisch, R. (1994): Die Odonaten der Naab-Wondreb-Senke / Nordost-Bayern unter besonderer Berücksichtigung von *Sympetrum depressiusculum*. Naturschutzzentrum Wasserschloß Mitwitz - Materialien 1/94: 85-88 and Pröse, H. (1954): *Sympetma paedisca* Brau., neu für Nordbayern. Nachbl. bay. Entomol. 3: 55-56 seem to be unknown to the authors. These publications document a Bavarian / Czech population of *S. paedisca* closely related resp. ranging to the Sokolov region.] Address: Mocek, B., Regional Museum of Eastern Bohemia, Dept Natural History, Eliscino Nábřeží 465, CZ-50001 Hradec Králové, Czech Republik. E-mail: mvc@mvc.anet.cz

2123. Hanel, L. (2000): The influence of the solar eclipse on dragonfly activities. In: Hanel, L. (Ed.): *Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chráněné krajinné oblasti Trebonsko 15.-18.6.2000*. Vlasim. ISBN 80-86327-12-4: 30-34. (in Czech with extensive English summary). [...] From the observation it is clear that dragonfly imagoes reacted in a similar way during the solar eclipse like during any other unpleasant change of weather. The majority of the individuals left the vegetation near the bank and hid in the near-by growth. The individuals that stayed near the bank were not active and remained sitting on the vegetation most of the time (at the maximum of the eclipse the least number of individuals was found in the area - four - out of whom only one was flying). A similar behaviour was observed during a bad change in the weather (overcast, breeze, light shower during the walk from 11.50 till 12.00). After the eclipse had terminated, dragonflies returned back gradually to the banks of the pond, the same number of individuals were counted approximately 30 minutes after the solar eclipse had ended." (Author)] Address: Hanel, L., Správa chráněné krajinné oblasti Blaník, 257 06 Lounovice pod Blaníkem 8, Czech Republik. E-mail: blanik@schkocr.cz

2124. Hauck, S. (2000): Die Ausbreitung der Gebärderten Prachtlibelle (*Calopteryx splendens*) im mittleren Lennetal. *Der Sauerländische Naturbeobachter* 27: 134. (in German with English summary). [Presentation of some counts of *C. splendens* along the River Lenne, Nordrhein-Westfalen, Germany in the period between 1993 and 1997.] Address: Hauck, S., Schulstr. 15, D-58513 Lüdenscheid, Germany

2125. Hedge, T.A.; Crouch, T. E. (2000): A catalogue of the dragonflies and damselflies (Odonata) of South Africa with nomenclatural clarification. *Durban Museum Novitates* 25: 40-55. (in English). ["The past 10 years have been marked by a renewed interest in the biogeography and conservation of southern African Odonata. While significant advances have been made within these fields, the taxonomy of this group last received attention during the 1980s. One of the consequences of this neglect is the perpetuation of orthographic errors and incorrect and inconsistent usage of species names in subsequent literature. In order to obviate further confusion, a catalogue of the Odonata of southern Africa is presented. It is a synopsis of current odonate literature, names in current usage, authors and dates at all cited taxonomic levels. Families, genera and species are listed alphabetically within each superfamily and no synonymies are given. The catalogue is thus taxonomic rather than systematic, with emphasis on clarification and correction of earlier nomenclatural irregularities appearing in literature. All species recorded for the country, irrespective of the current status of these records, have been included. Two suborders, six superfamilies, 11 families, 59 genera, 147 species and 13 subspecies, are recorded from past literature as South African. Of the 170 species-group taxa listed, 10 do not occur in South Africa as the nominotypical taxon, but as subspecies thereof, three are known from only one collection, one is known from only two collections and two are of doubtful provenance in South Africa." (Authors)] Address: Crouch, T. E., Durban Natural Science Museum, Durban, 4000 South Africa

2126. Heimann, H. (2000): Libellenvorkommen im Raum Schwerte und Holzwickede. *Der Sauerländische Naturbeobachter* 27: 121-128. (in German with English summary). [Nordrhein-Westfalen, Germany. 2135. Juliand, C.; Juliand, P.; Ladet, A. (2000): Bilan de neuf années de prospection odonotologique dans le département de L'Ardeche. *Sympetrum* 15: 5-18. (in French). [A total of 66 species (68 taxa) is reported from the department L'Ardeche, France. Each of the species is shortly commented. In tab. 2 some interesting altitude records of ten species are documented. Of special interest are the records of *Coenagrion mercuriale*, *C. caerulescens*, *C. hastulatum*, *Gomphus graslini*, *Oxygastra curtisii*, *Macromia splendens*, *Somatochlora arctica*, *Sympetrum depressiusculum*, and *Leucorrhinia dubia*.] Address: Juliand, Christine, Le Serre, F-07110 Joannas, France

2136. Kenner, R. D. (2000): *Somatochlora kennedyi* (Odonata: Corduliidae): A new species for British Columbia, with notes on geographic variation in size and wing venation. *Journal of the Entomological Society of British Columbia* 97: 47-49. (in English). ["The first confirmed record for *S. kennedyi* in British Columbia is reported. Specimens of this species from the northern Yukon are smaller than those from elsewhere in its range and have a reduced number of cells in certain parts of the wings." (Author)] Address: Kenner, R. D., 5560 Linscott Court, Richmond, BC, V7C 2W9 Canada

2137. Kesel, A.B. (2000): Aerodynamic characteristics of dragonfly wing sections compared with technical aerofoils. *Journal of Experimental Biology* 203(20): 3125-3135. (in English). ["During gliding, dragonfly wings can be interpreted as acting as ultra-light aerofoils which, for static reasons, have a well-defined cross-sectional corrugation. This corrugation forms profile valleys in which rotating vortices develop. The cross-sectional configuration varies greatly along the longitudinal axis of the wing. This produces different local aerodynamic characteristics. Analyses of the CL/CD characteristics, where CL and CD are the lift and drag coefficients, respectively (at Reynolds numbers Re of 7880 and 10 000), using a force balance system, have shown that all cross-sectional geometries have very low drag coefficients ($CD_{min} < 0.06$) closely resembling those of flat plates. However, the wing profiles, depending upon their position along the span length, attain much higher lift values than flat plates. The orientation of the leading edge does not play an important role. The detectable lift forces can be compared with those of technical wing profiles for low Re numbers. Pressure measurements (at $Re=9300$) show that, because of rotating vortices along the chord length, not only is the effective profile form changed, but the pressure relationship on the profile is also changed. Irrespective of the side of the profile, negative pressure is produced in the profile valleys, and net negative pressure on the upper side of the profile is reached only at angles of attack greater than 0 degree. These results demonstrate the importance of careful geometrical synchronisation as an answer to the static and aerodynamic demands placed upon the ultra-flight aerofoils of a dragonfly." (Author)] Address: Kesel, Antonia B., Department of Zoology, Technical Biology and Bionics, University of Saarland, D-66041, Saarbrücken, Germany. E-mail: a.kesel@rz.uni-sb.de

2138. King, R.S.; Nunnery, K. T.; Richardson, C. J. (2000): Macroinvertebrate assemblage response to highway crossings in forested wetlands: Implications for

biological assessment. *Wetlands Ecology & Management* 8(4): 243-256. (in English). [USA, North Carolina; "Despite the mandate of the Clean Water Act to protect the physical, chemical, and biological integrity of the USA's wetlands, the use of biota to assess wetland condition has not been well explored. During June, 1996, we evaluated the response of macroinvertebrate assemblages to fill-culvert highway crossings in two bottomland forested wetlands in North Carolina. Our objective was to apply biological assessment methods and metrics that have been effectively used in streams to explore their applicability in forested wetlands. We found significant changes in several metrics as a function of distance from the highway crossings. Areal and numerical taxon richness increased within at least 40 m of highway when compared to control locations. Percent dominant taxon values were lowest within 10 m of the highway. Percent herbivores also increased significantly within at least 40 m of the highway, reflecting the lower % crown closure and associated shift in primary production from trees to herbaceous macrophytes and algae. The North Carolina Biotic Index, a metric of tolerance, did not reflect assemblage changes near the highway. Ordination and permutation tests revealed that assemblage composition was significantly different from controls at 10 and 40 m distances from the highway crossings. In particular, algal grazers such as the mayflies *Caenis* sp. and *Callibaetis* sp. responded positively and the damselflies *Ischnura* spp. and the finger-nail clams *Sphaerium* spp. responded negatively to the crossings. Favorable algal and herbaceous detrital resources, greater patchiness and habitat complexity, and overall high tolerance to natural stressors probably contributed to the increase in taxon richness near the highway. However, significant deviation from control locations indicated the highway was a source of perturbation. Our findings illustrate the potential utility of macroinvertebrate assemblages for wetland assessment, but suggest the importance of defining the reference condition as well as the need for development of metrics for specific classes of wetlands." (Authors) *Nehalennia irene*, *Ischnura posita*, *I. prognata*, *Erythemis simplicollis*, *Pachydiplax longipennis*, *Libellula* sp., *Epitheca* sp.] Address: King, R.S., Duke Wetland Center, Nicholas School of the Environment, Durham, NC, 27708 USA

2139. Knab, N.; Göcking, C.; Knab, D.; Schelden, A.; Willigalla, C. (2000): Zur Verbreitung von *Gomphus vulgatissimus* (L.) im Einzugsgebiet der Ems im Kreis Warendorf (Odonata: Gomphidae). *Natur- und Umweltschutzakademie Nordrhein-Westfalen - Seminarbericht* 6: 76-81. (in German). [The distribution of *G. vulgatissimus* in the River Ems system, Nordrhein-Westfalen, Germany, was studied in 1999. *G. vulgatissimus* occurs in all stretches of the Ems and in many stretches of its tributaries. This increase of records is discussed under the aspects of reduced maintaining measures of river banks, improvement of water quality, favourable climate conditions in the past years, and optimised methods for collecting exuviae.] Address: Göcking, C., Zum Hiltruper See 9, D-48161 Münster, Germany. 2140. Knaus, P. (2000): Emergenzstudien an *Somatochlora alpestris* in den Zentralalpen (Odonata: Corduliidae). *Libellula* 19(3/4): 117-142. (in German with English summary). ["*S. alpestris* was analysed in regard to

to its emergence period and emergence ecology. The study was carried out in 1997 and 1998 at »Barenseewen«, a subalpine plateau with several ponds at 2000 m a.s.l. in the Prättigau valley (Orisons, Switzerland). The emergence lasted about 3.5 hours and the behavioural pattern of *S. alpestris* was similar to that of other corduliids. Emergence took place mainly within a strip of 1 m on either side of the water line and at a median height of 9.0 cm above ground. In total 674 exuviae at 16 ponds were collected during the emergence period in 1998. The density per pond ranged from 0.03 to 5.51 emerging adults per m². The mortality during emergence was 7.1 %. As a typical spring species *S. alpestris* has a synchronised emergence with an EM50 of 5.5 days. The emergence period in 1998 lasted 37 days, beginning on 19 June. With 44.0 % males the sex ratio was significantly different from 1:1, and males emerged earlier than females. The results are discussed in respect to habitat preference and adaptation strategies and are compared with those of other corduliids." (Author)] Address: Peter Knaus, Schweizerische Vogelwarte, CH-6204 Sempach, Switzerland. E-mail: peter.knaus@vogelwarte.ch

2141. Knijf, G. de; Demolder, H. (2000): Een populatie van *Coenagrion mercuriale* en *Libellula fulva* in de Gaume (Belgisch Lotharingen). *Gomphus* 16(2): 115-122. (in Dutch with English and French summaries). ["A population of *Coenagrion mercuriale* and *Libellula fulva* in the Gaume (Belgium). A population of both species was discovered in June 2000 in the Gaume, the most southern part of Belgium. Until then, only two, respectively three populations were known from the Walloon part of Belgium. We suspect that both species have colonized the region the last years from the adjacent northern part of France, but it is possible that they were already present for many years. We suppose that the very good weather in the spring of the year 2000, has contributed to a higher number of individuals in the population of both species so that the probability to catch them becomes greater. We presume that it is possible to find more populations from both species in some of the many similar valleys in the Gaume."(Authors) The habitat is described and co-occurring Odonata are briefly discussed.] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. E-mail: geert.de.knijf@instnat.be

2142. Kordges, T. (2000): Die Libellenfauna der Stadt Hattingen. *Der Sauerländische Naturbeobachter* 27: 57-66. (in German with English summary). [Since 1985 a total of 28 species of dragonflies was recorded in the district of Hattingen, Nordrhein-Westfalen, Germany. In the period since this to 1999 *Coenagrion pulchellum* and *Aeshna grandis* have become extinct, while *Erythromma vindulum*, *Gomphus vulgatissimus*, and *G. pulchellum* were recorded for the first time. *Libellula quadrimaculata*, *Lestes sponsa*, *Sympetrum flaveolum*, and *S. danae* seem to become rare. On the other hand the situation especially in some rheophilous species obviously has become better within this time due to the better water quality of the river Ruhr and some brooks. "Within the study area more than 78% of the species prefer the Ruhr valley, where species diversity and the population density reach the highest values. Few species are widely distributed in the region but prefer the hillsides in the south of Hattingen (*P. nymphula* and *A.*

cyanea), while *C. virgo* and *C. boltonii* are mainly restricted to this hillside area." Address: Kordges, T., Feldstr. 79, D-54549 Sprockhövel, Germany

2143. Kordges, T.; Keil, P. (2000): Erstnachweis der Frühen Heidelibelle *Sympetrum fonscolombii* (Selys) im Ruhrgebiet. Dortmund Beiträge zur Landeskunde, Naturwiss. Reihe 34: 117-121. (in German). [Near Essen, Nordrhein-Westfalen, Germany freshly emerged *S. fonscolombii* were recorded on September 7, 1999. On July 14, 2000 at the same water several specimens of *Lestes barbarus* but no *S. fonscolombii* could be observed. The flora of the water body prior and after clearing the shrub on the water's edge is described. A total of 21 odonate species is listed.] Address: Kordges, T., Ökoplan, Husmannshofstr. 10, D-45143 Essen, Germany

2144. Kruijs, I. (2000): [Butterfly watching: An alternative to collecting]. *Fauna och Flora* (Stockholm) 95(3): 105-112. (in Swedish with English summary). ["It is no longer necessary to collect and preserve the larger insects which are identifiable in the field in order to add to our knowledge of their distribution and behaviour. Killing insects can be a daunting factor in furthering entomology as a field of interest. The main advantage of collection, the ease of identification, can be matched by developing identification techniques without having to catch and kill specimens. Like bird watching, insect watching can be an interesting pastime and can do much to add to our knowledge, especially where butterflies and dragonflies are concerned. Though collectors gain much knowledge through their experience, the very aim to collect as many species as possible puts the occurrence of species that they already have in their collections in the background. The art of identifying butterflies in the field includes the use of binoculars that reduces the need to use a net. Since different butterfly families have characteristic types of flight, many species can be identified by observing their flight, much in the same way as watching birds. Records can be made as to locality, occurrence and estimation of numbers, behaviour with notes on temperature, weather, as well as date and time. Behaviour studies can include effects of temperature, territorial behaviour, courtship and mating, egg-laying and choice of foodplant. Taking photographs and video films might be a useful aid and can satisfy the need to collect, if collecting actual sightings is in itself not satisfying." (Author)] Address: not stated

2145. Kuhn, J. (2000): Libellen (Odonata) am Schmiechener See 1980-1999-Zwischenbilanz einer Langzeitstudie. *Verhandlungen des Westdeutschen Entomologen Tag 1999*: 185-190. (in German with English summary). ["The "Schmiechener See" (SW Germany, Bayern) is a shallow 50 ha lake strong and irregular in water-level. Composition and abundances of the fauna (42 species) are subject both to heavy short-term fluctuations and to pronounced long-term changes. Special attention is directed to the efficiency of conservation and management measures, particularly with regard to survival of the target species *Lestes dryas* and *Sympetrum flaveolum*." [Germany, Niedersachsen, River Weser, 29-VII-1999] Address: Leitfeld, D., Projektgruppe Weserniederung, Lehrgebiet Tierökologie, Universität Paderborn, Fachhochschulabteilung Höxter, An der Wilhelmshöhe 44, D-37671 Höxter, Germany. E-mail: dleitfeld@fh-hoexter.de

2150. Loos, G.H. (2000): Libellen im Siedlungsbereich. *Der Sauerländische Naturbeobachter* 27: 129-133. (in German with English summary). [The occurrence of Odonata in typical water bodies of urban zones is outlined and exemplified in the district of Unna, Nordrhein-Westfalen, Germany. 23 species are listed including rare species as *Ceriagrion tenellum* and *Sympetrum depressiusculum*. The draft of typical urban dragonfly ponds and species composition of different waterbodies is presented.] Address: Loos, G.H., Ruhr-Universität Bochum, AG Geobotanik und Geographisches Institut, ND 03/175, D-44780 Bochum, Germany

2151. Lopau, W. (2000): Bisher unveröffentlichte Libellenbeobachtungen aus Griechenland II (Odonata). *Libellula* Suppl. 3: 81-112. (in German with English summary). ["More than 1 000 Odonata records provided by 9 workers are listed. The data for 57 of the 73 species known from Greece, were recorded between 30-III-1970 and 27-IV-2000." (Author)] Address: Lopau, W., Kuhstedtermoor 26, D-27442 Gnarrenburg, Germany. E-mail: lopi@t-online.de

2152. Lotzing, K. (2000): Untersuchungen zur aktuellen Libellen-Fauna (Odonata) in ausgewählten natürlichen Binnenland-Salzstellen am Südrand der Magde-

burger Börde (Sachsen-Anhalt). *Entomologische Nachrichten und Berichte* 44(3): 175-182. (in German with English summary). [27 odonate species are recorded for three saline habitats situated in the Magdeburger Börde, Sachsen-Anhalt, Germany. The species are shortly commented; a special halophile odonate fauna is not represented. *Lestes barbarus* and *Sympetrum pedemontanum* are typical for sparsely-vegetated and thermally favoured waters which are protected from wind. The rare *Sympetrum flaveolum* is represented with high population densities.] Address: Lotzing, K., Am Hollschen Bruch 4c, D.39435 Unseburg, Germany

2153. Lytle, D.A. (2000): Biotic and abiotic effects of flash flooding in a montane desert stream. *Archiv für Hydrobiologie* 150(1): 85-100. (in English). ["Flash floods in desert streams can be more sudden, brief, and severe compared to floods in mesic streams. To determine their biotic and abiotic effects, substrate composition, organic detritus abundance, and aquatic animal taxonomic richness and abundance were measured 8-16 d before and 7 d after a flash flood in a 122 m reach of a montane desert stream (Chihuahuan Desert, USA). The flash flood severely altered channel morphology by scouring and depositing substrates, but it did not change the overall abundance of any substrate particle size class. The flood removed most coarse detritus from the stream reach, although the quantity of organic particles <2 mm was unchanged. High losses were observed in most animal taxa (95 % overall), and reach-wide taxonomic richness was reduced from 35 to 21 taxa. Ephemeroptera were entirely eliminated from the study reach. The taxon experiencing the lowest percent loss (the belostomatid hemipteran *Abedus herberti*, 14 % loss) is known to possess behavioral mechanisms for flash flood avoidance. Compared to studies of flooding in mesic streams, this study suggests that flash floods in montane desert streams cause greater mortality in animal populations and remove more detritus. Ecologically, these high local mortality rates stress the importance of recolonization mechanisms. Evolutionarily, flash floods provide a strong selection pressure that may influence the genetic structure of populations." (Author) "*Argia*" and *Cordulegaster diadema* were eliminated from the reach (100% loss), "early instars" were reduced by 87%.] Address: Lytle, D.A., Dept. of Ecology & Evolution, University of Chicago, 1101 E. 57th St., Chicago, IL 60637, USA. E-mail: dalytle@uchicago.edu

2154. Maillet, G. (2000): Note pratique sur l'observation des libellules et l'utilisation d'une pochette en plastique. *Martinia* 16(4): 171-173. (in French with English summary). ["The author presents a method for observing Odonata adults in the field. It consists in using transparent plastic bags in which the insect can be immobilized without damage, and released after identification." (Author)] Address: Maillet, G., Château de la Touvière, F-38690 Chabons, France

2155. Malmqvist, B.; Hoffsten, P.-O. (2000): Macroinvertebrate taxonomic richness, community structure and nestedness in Swedish streams. *Archiv für Hydrobiologie* 150(1): 29-54. (in English). ["Taxonomic richness and community composition were related to environmental variables in 88 streams in an area of 60,000 km² in central Sweden. In all, 247 macroinvertebrate taxa were recorded and taxonomic richness observed per site ranged from 21 to 77. Partial least squares regression analysis suggested that taxonomic richness

was positively and most strongly correlated with channel width and catchment size. Correlations were also positive, but weaker, with the percentage of lakes in the catchment, temperature and macrophyte abundance, whereas the degree of shading, moss coverage and distance to upstream lakes showed negative associations with species richness. The number of 'rare' (found at <25 % of the sites) and 'very rare' (found at <10 % of the sites) taxa, showed similar trends although the correlation with distance below upstream lakes was positive rather than negative in the 'very rare' taxa category. The most taxa-rich sites were found in streams of intermediate size leading to a significant quadratic relationship between catchment size and taxonomic richness. Canonical correspondence analysis indicated that catchment area, distance from upstream lakes, substratum, temperature, altitude, amount of macrophytes, pH, colour, and *Fontinalis* spp. were the variables explaining most variation in community composition. Ephemeroptera, Plecoptera, Trichoptera and Diptera: Simuliidae showed nested distribution patterns, i.e. species-rich sites tended to be inhabited by species present also at species-poor sites. Some taxa, however, deviated from expected distributions possibly because they are sensitive to biotic interactions, restricted to small streams, or specialised with respect to some habitat features. In comparisons with other studies of Swedish macroinvertebrates, we observed differences suggesting that the design of studies, including the selection of geographical regions and limited range of stream sizes, can importantly influence the results." (Authors) 10 odonate species are listed in the appendix. In most cases species are represented "very rare" at the sampling sites.] Address: Malmqvist, B., Department of Ecology and Environmental Science, Umea University SE-90187 Umea, Sweden. E-mail: bjorn.malmqvist@eg.umu.se

2156. Marigo, P. (2000): Étude de la faune des tourbières subalpines du Plateau des Lac du massif du Taillefer (Isère). *Sympetrum* 15: 19-37. (in French). [Selected species of Hemiptera, Mollusca, Araneae, and Odonata characteristic for the subalpine bogs in the Massif du Taillefer (Isère, France) are discussed - but in most cases on the basis of literature - in some detail. *Aeshna juncea*, *Somatochlora alpestris*, *S. arctica*, *S. metallica*, *Leucorrhinia dubia*.] Address: Marigo, P., 20 allée du Bouchon, F- 74940 Annecy Levieux, France

2157. Marinov, M. (2000): An atypical *Caliaeschna microstigma* (Schneider) habitat in Bulgaria (Anisoptera: Aeshnidae). *Notul. odonatol.* 5(6): 83. (in English). ["On 22-VI-1999, numerous males were sighted flying over a small forest stream, the Izgrevsko Dere, in the village of Izgrev, Mt Strandja, SE Bulgaria. Surprisingly, the rivulet is completely devoid of any kind of vegetation, whether aquatic or on the banks. The bottom is stony and stones are spread along the bank as well. The surrounding trees (mainly *Alnus*) are casting a deep shade, as peculiar for the *Caliaeschna* habitats. The sole exuviae found was sitting on the bark of a tree." (Author)] Address: Marinov, M., P.O. Box 134, BG-1000 Sofia, Bulgaria. E-mail: mgmarinov@yahoo.com

2158. Mashaal, M. (2000): Bref souvenirs odonatologiques de Guadeloupe, Martinique et Réunion. *Martinia* 16(3): 123-126. (in French with English summary). [Lists of species from Guadeloupe (9 localities/11 taxa), Martinique (4 loc./6 taxa), and Réunion (11 loc./11 ta-

xa)] Address: Mashaal, M., 2, rue Meilhac, F-75015 Paris, France

(2000): Factors controlling the bioaccumulation of mercury, methylmercury, arsenic, selenium and cadmium by freshwater invertebrates and fish. *Archiv environment. Contain. Toxicol.* 38(3): 283-297. (in English). ["Concentrations of Hg, MMHg, As, Se, and Cd were measured in atmospheric deposition, stream water, and biota in two streams in Maryland, USA. They are stated for *Aeshna* sp., compared with other insect orders, and discussed."] Address: Mason, R.P., Cent. Envir. Sci., Chesapeake Biol. Lab., Univ. Maryland, P.O. Box 38, Solomons, MD 30688, USA

2160. Mauersberger, R. (2000): Artenliste und Rote Liste der Libellen (Odonata) des Landes Brandenburg. *Naturschutz und Landschaftspflege in Brandenburg* 9(4, Beilage): 22 pp. (in German). [This is an introduction into the Odonata of the Federal State Brandenburg in Germany. Several aspects of the odonate fauna e.g. climatic or anthropogenic factors responsible for the occurrence on the geographic scale of the state, information on invasive species, reasons for threats, a commented checklist of the 66 species known to occur in Brandenburg, an assessment according to the criteria of the Red List, main tasks for conservation action plans, and a bibliography are briefly outlined or compiled. This is a short but sound contribution to the knowledge of the Odonata in the eastern part of Germany written by one of the leading German odonatologists.] Address: Mauersberger, R., Waldstr. 4, D-16278 Steinhöfel, Germany

2161. Maxted, J.R.; Harbour, M.T.; Gerritsen, J.; Porretti, V.; Primrose, N.; Silva, A.; Penrose, D.; Renfrow, R. (2000): Assessment framework for mid-Atlantic coastal plain streams using benthic macroinvertebrates. *Journal N. Am. benthol. Soc.* 19(1): 128-144. (in English). ["A collaborative study among 6 states along the mid-Atlantic seaboard of the USA developed a consistent approach for collecting and interpreting macroinvertebrate data for low-gradient streams of the coastal plain. The study had 3 objectives: (1) to evaluate the validity of aggregating reference site data into a single bioregion, (2) to select biological metrics that best discriminated reference sites from sites impaired by habitat disturbance and organic pollution, and (3) to combine these metrics into an index of biological quality. Macroinvertebrate, physical habitat, and water-quality data were collected in 106 streams during autumn 1995. Fifty-five sites were referenced, 34 sites had habitat stresses, and 17 sites had water-quality stresses. Classification of reference sites divided the coastal plain into 3 bioregions, separated N and S by Chesapeake Bay and separated E and W by ecoregion. - 20 odon. genera are listed, with annotations on tolerance values and clinger habit."] Address: Maxted, J.R., Delaware Dept Natural Resour. & Envir. Control, 89 Kings Highway, Dover, DE 19903, USA)

2162. McMillan, V. (2000): Aggregating Behavior During Oviposition in the Dragonfly *Sympetrum vicinum* (Hagen) (Odonata: Libellulidae). *Am. Midl. Nat.* 144: 11-18. (in English). ["This study examined the adaptive significance of ovipositing near conspecifics by pairs of the dragonfly *Sympetrum vicinum*. Studies were conducted at two artificial ponds in New York using a series of 1 m² plots along their shorelines. Although the major-

ity of pairs oviposited alone, pairs also tolerated the presence of others only 5-10 cm away, and sometimes 2-7 pairs oviposited together within a single plot. Habitat selection (preference for certain plots over others) partially accounted for such behavior. However, where adjoining plots were homogeneous (i.e., used equally for oviposition), newly arriving pairs were more likely to begin dipping in a plot in which one or more pairs were already present, thus also suggesting mutual attraction among pairs. Oviposition efficiency (measured as no. abdominal dips/s) was apparently not compromised by ovipositing near conspecifics. Harassment from unpaired males had little effect on oviposition since unpaired males were uncommon and rarely approached pairs. However, lone pairs were attacked relatively more frequently by frogs than were pairs present simultaneously in the same plot. Although none of the 112 predation attempts I recorded were successful, frog attacks forced pairs to change sites, thereby lengthening the time required for oviposition. The absence of frogs or frog attacks at a site provided favorable conditions for pairs to accumulate at a site; thus the presence of conspecifics may have signaled a safe area for oviposition." (Author)] Address: McMillan, Vicky, Colgate Univ., Dept. Biol., 13 Oak Dr. Hamilton, NY 13346-1398, USA . E-mail: vmcmillan@mail.colgate.edu

2163. Meitzner, V.; Martschei, T. (2000): Neue Funde europäisch geschützter Insektenarten. *Naturschutzarbeit in Mecklenburg-Vorpommern* 43(1): 70-71. (in German). [Mecklenburg-Vorpommern, Germany. Records of species of the Appendix II of the European Fauna-Flora-Habitat-Directive are shortly reported. *Leucorrhinia pectoralis* is given for two localities.] Address: Meitzner, V.; Bischofstr. 13, D-17033 Neubrandenburg, Germany

2164. Mey, D. (2000): Vorkommen der Gestreiften Quelljungfer *Cordulegaster bidentata* (Insecta, Odonata, Anisoptera) an Kalksinterbächen in Nordwestthüringen. *Rudolstädter naturhist. Schr.* 10: 33-46. (in German with English summary). [In April 1998 a habitat of *Thecagaster bidentata* was discovered in the border region of Thüringen and Hessen, Germany. This is the first breeding record of the species in Thüringen. The localities are characterised in detail by vegetation, morphology of the krenal, and chemical and physical factors. Observations on larval habitat, emergence, hunting of imagos, oviposition, and accompanying fauna are dealt with.] Address: Mey, D., Karl-Hermann-Str. 3, D-99848 Wutha-Farnroda, Germany

2165. Mielewczyk, S. (2000): Wazki (Odonata). *Flora i Faua Pienin - Monografie Pieninskie* 1: 143-145. (in Polish with English summary). [This short paper summarizes the current knowledge on the dragonfly fauna of the Pienin mountains, Poland based on historical and recent data. A total of 38 species is known from the region; *Sympetrum pumilum*, *Anax ephippiger*, *Thecagaster bidentata*, and *Sympetrum pedemontanum* are stressed.] Address: Mielewczyk, S., Zaklad Badan, Srodowiska Rolniczego i Lesnego, Polska Akademia Nauk, ul. Bukowska 19, 60-809, Poznan, Poland

2166. Ministerium Ländlicher Raum Baden-Württemberg; Landesanstalt für Umweltschutz Baden-Württemberg (Hrsg) (2000): *NATURA 2000 in Baden-Württemberg*. Ministerium Ländlicher Raum Baden-Württemberg. Stuttgart: 162 pp. (in German). [This is a recom-

modation for the realisation of the European Flora-Fauna-Habitat-Directive directed to the general public. Some elucidation of the aims and task of this directive are outlined, and the Directive is printed in a German translation. Each of the habitats and the species listed in the annexes of the Directive and represented in Baden-Württemberg, Germany are briefly characterised, their distribution in Baden-Württemberg is mentioned, the importance for nature conservation is outlined, each habitat type and species are documented by very good colour photographs. Three odonate species included in the Annex II of the Directive occur in Baden-Württemberg: *Coenagrion mercuriale*, *Leucorrhinia pectoralis*, and *Ophiogomphus cecilia*.] Address: Ministerium Ländlicher Raum Baden-Württemberg, Kernerplatz 10, D-70182 Stuttgart, Germany. 2167. Miserendino, M.L.; Pizzolón, L.A. (2000): Macroinvertebrates of a fluvial system in Patagonia: altitudinal zonation and functional structure. *Archiv für Hydrobiologie* 150(1): 55-83. (in English). [This "study of altitudinal zonation of macrobenthic communities in the Patagonian Andes was carried out at 14 sampling stations along 51 km of the Esquel-Percy River system over a 1000 m altitudinal gradient. Untreated sewage of Esquel City discharges in the middle section of the system. The main species assemblages of the monitored sites were identified and a functional categorization of the taxa was produced. Population distribution patterns were analyzed throughout a complete annual cycle [...] The macrobenthic community found along the Esquel-Percy system is rich and diverse, except at middle-stretch stations, which are altered by anthropogenic perturbations. Specific composition, diversity and density were influenced by the topographic gradient, geochemical (conductivity and total alkalinity) and anthropogenic factors (BOD and oxygen saturation), and the seasonality of the system. [...] The biomass of shredders and predators decreased, while collectors increased, downstream from the headwaters. Collector-gatherers were the most important group at all sites. Functional organization showed better correspondence with the RCC model if biomass was used instead of macroinvertebrate density. We found that local and regional characteristics produced deviations from the RCC model, but it is still useful as a comprehensive framework for stream ecology in the Patagonian Andes." (Authors) "*Aesha variegata*?" is listed for one sampling site.] Address: Miserendino, Laura, Laboratorio de Ecología Acuática, Sarmiento 849, Universidad Nacional de la Patagonia, Sede Esquel, 9200 Esquel, Chubut, Argentina. 2168. Monaghan, K.A.; Peck, M.R.; Brewin, P.A.; Masiero, M.; Zarate, E.; Turcotte, P.; Ormerod, S.J. (2000): Macroinvertebrate distribution in Ecuadorian hill streams: the effects of altitude and land use. *Archiv für Hydrobiologie* 149(3): 421-440. (in English). [To assess the effects of altitude and land use on stream fauna macroinvertebrates were sampled from riffle and marginal habitats of 45 streams in three regions of the Ecuadorian Andes. "Assemblage structure and richness were assessed in relation to habitat character, water chemistry and catchment land use. Land use varied from humid montane forest in the Western and Eastern Cordillera to transition forest and Parámo in the Central Valley. However, c. 30 % of sites in each region were

located in managed catchments of cleared forest, pasture or crop plantations. Water chemistry and stream habitat varied significantly between regions, altitudes and land use. Invertebrate assemblages were dominated by Baetidae, Leptophlebiidae, Tricorythidae, Elmidae, and Chironomidae, but ordination revealed major variations in assemblage structure with altitude. Hydropsychidae, Philopotamidae, Ptilodactylidae and Gomphidae" (and "Calopterygidae", "Libellulidae", and "Zygoptera A") were restricted to lower altitude whereas Scritidae and Gammaridae characterised higher altitude sites. Secondary variations in assemblage structure were correlated with habitat structure and metal concentrations (Al, Fe and Mn), and in turn were reflected in taxon richness. Classification revealed generally similar patterns, but showed also potential effects on assemblage structure in the Western Cordillera where humid montane forest had been cleared for agriculture. We conclude that, as in other mountain regions, major downslope patterns are clear among aquatic invertebrates in the Ecuadorian Andes. However, from these data altitude affects assemblage composition more than richness. Downslope patterns might have been modified by human activity at the catchment scale, and also by local site attributes such as habitat structure and stream chemistry." (Authors) "*Aeshnidae*" are restricted to the Eastern Cordillera.] Address: Monaghan, K.A., Catchment Research Group, School of Biosciences, Cardiff University, P.O. Box 915, Cardiff, CF10 3TL, UK. 2169. Moskowitz, D. (2000): A new county record of *Archilestes grandis* in New York with notes on habitat and water quality. *Argia* 12(4): 7-8. (in English). ["On 3 October 2000 a male *Archilestes grandis* was collected on Mine Brook in Mt. Pleasant, Westchester County, New York. This appears to be the first record for Westchester County and only the second confirmed record for the state. [...] When combined with other measured parameters and field data including dissolved oxygen and temperature, Mine Brook is best characterized as moderately impaired. This is consistent with other reports of *A. grandis* habitats [...]" (Author)] Address: Moskowitz, D. c/o EcolSciences, Inc. 75 Fleetwood Drive, Suite 250 Rockaway, New Jersey 07866 dmoskowi@ecolsciences.com

2170. Müller, H. (2000): Untersuchungen zu *Cordulegaster heros* Theischinger, 1979 und *C. bidentata* Selys, 1843. Teil 1: Imagines. *Anax*, Wien 3: 19-22. (in German with English summary). [In 1997 and 1998, data about the phenology and ecology of *Cordulegaster heros* and *C. bidentata*, co-occurring syntopic, were obtained in the catchment of the Weidlingbach (Lower Austria). Emergence, dimigration and habitat during the maturation period, dependence of the high of patrol flights of males from the width of the brook, dependence of velocity of the patrol flight in relation to riffles and pools (preferred egg deposition habitats), and reproduction behaviour of the females were examined. For more details see OAS 1745.] Address: Müller, Heidemarie, Muhrhoferweg 1-5/4/42, A-110 Wien, Austria. E-mail: lang.mueller@EUnet.at

2171. Müller, J. (2000): Untersuchungen zur Ökologie und Verbreitung der Sibirischen Azurjungfer (*Coenagrion hylas*) im Tiroler Lechtal (Odonata: Coenagrionidae). Zulassungsarbeit zur wissenschaftlichen Prüfung für das Lehramt an Gymnasien. Fach Biologie, Institut

für Experimentelle Ökologie der Tiere der Universität Ulm.: 118 pp. (in German). [The very rare *C. hylas* is known from the Ural mountains in Russia to Japan, and from a disjunct area in the European alpes. This study enlarges our knowledge on ecology and distribution in this disjunct area of the species in quite extent. Seven habitats with records of *C. hylas* are known now, all situated in the valley of the River Lech. In detail the habitats are described and figured, and characterised by chemical and physical parameters. Larval, emergence, maturation, hunting, reproduction, oviposition, and perching (dormitories) habitats and ethoecology are analyzed. Information on phenology with special reference to emergence period, abundance, morphology of larvae, and co-occurring Odonata are given. In considerable detail conservation measures are outlined. This publication is a corner stone on ecology of one of the most interesting and threatened western palearctic damselflies.] Address: Müller, J., Goethestr. 25, D-89601 Schelklingen, Germany

2172. Müller, J. (2000): Zur Schutzwürdigkeit und nachhaltigen Entwicklung der Elbe unter besonderer Berücksichtigung der Libellen-Fauna. 7. Landschaftstag 1999. Flusslandschaft Elbe: 24-31. (in German). [This is an introduction into the odonate fauna of the rivers and their floodplains in central Germany exemplified with the river Elbe. The main factors characterising the floodplain, its vegetation, and its fauna and flora with special emphasize to the species of the European Bird habitat- and Fauna-Flora-Habitat- directives are outlined. The bioindicatorial value of Odonata for different habitats in the river-floodplain landscape is assessed, and characteristic species are presented. A cross-section through the river and the floodplain gives an insight into the use of habitats by odonate larva and imago. The booklet can be ordered at a price of DM 3,- from: Landeshauptstadt Magdeburg, Umweltamt, D-39090 Magdeburg, Germany.] Address: Müller, J., Frankefelde 3, 39116 Magdeburg, Germany. jmueller@mu.lsa-net.de

2173. Müller, O.; Schütte, C.; Artmeyer, C.; Burbach, K.; Grand, D.; Kern, D.; Leipelt, K.G.; Martens, A.; Petzold, F.; Suhling, F.; Weihrauch, F.; Werzinger, S. (2000): Entwicklungsdauer von *Gomphus vulgatissimus*: Einfluss von Gewässertyp und Klima (Odonata: Gomphidae). *Libellula* 19(3/4): 175-198. (in German with English summary). ["*G. vulgatissimus* lives in different waters and completes its life cycle in two, three or four years. These different life cycles indicate that the duration of larval development depends on the type of water or climatic situation. Therefore, in the middle of October 1999 larvae were collected at 11 localities in Central Europe. Larval population structures were investigated by measuring the head widths of larvae. The data show that larval development could be finished within two years in warm, shallow rivers like the Oder and the Ems. In streams with low temperatures and lakes the sp. has a three or four year life-cycle. The population structures and duration of life cycles did not show any clear dependence on climate or latitude." (Authors)] Address: Müller, O., Birkenweg 6d, D-13206 Libbenichen, Germany. E-mail: olemuller@freenet.de

2174. Needham, J.G.; Westfall, M.-J.; May, M.L. (2000): *Dragonflies of North America*. Revised Edition. Scientific Publishers. Gainesville. Washington, Hamburg. Lima. Taipei. Tokyo. ISBN 0-945417-94-2: I-XY,

940 pp. (in English). [Everyone interested in the Odonata of the North American continent will welcome this book. It is a manual with special emphasize on larval and imaginal taxonomy and morphology. Many (colour) illustrations and keys will enable people to identify all North American species including *Erythrodiplax bromeliicola* Westfall n. sp. from Jamaica. I am not the position to criticize this impressive work. For a detailed review see Donnelly (2000, *Argia* 12(4): 11-13). But if I may criticize one aspect of the book: I miss information on habitats and habits of the species. (M. Schorr)] Address: Scientific Publishers, Inc., 4460 SW 35th Terrace, Suite 305, Gainesville, FL 32608, USA

2175. O'Brien, M. (2000): New additions to the University of Michigan Museum of Zoology Odonata Library. *Argia* 12(4): 10. (in English). ["We recently received a shipment of books belonging to the estate of Leonora (Dolly) K. Gloyd from her son, Roger Gloyd, of Plano, TX. Mrs. Gloyd had been an adjunct curator of Odonata at the UMMZ for nearly 50 years, and although we had her reprints and specimens here at the UMMZ, her personal library had been sent to her son when she left the museum to live in Texas. Dolly had acquired many books on Odonata, some of which are quite rare. All of the Odonata-related books will be housed in the Williamson-Kennedy-Gloyd Odonata Library. [...]"] (Author)] Address: O'Brien, M., Insect Division, Museum of Zoology, University of Michigan, Ann Arbor, MI 48109-1079, USA. E-mail: mfbrien@umich.edu

2176. Ott, J. (2000): Die Ausbreitung mediterraner Libellenarten in Deutschland und Europa - die Folge einer Klimaveränderung? *Berichte der Niedersächsischen Naturschutzakademie* 2/2000: 13-35. (in German). [This paper discusses extensively the current range extensions or changes in odonate faunas with focus on Europe. There is evidence that in the past years some species extended their distribution area to the north and to higher altitudes, with an increase in breeding habitats and population size; best studied species is *Crocothemis erythraea*. The author presents some additional examples of species for which global warming is advantageous. He also discusses amendments of regional species composition giving indication for processes of dominance of "Mediterranean" species over "Nordic" or "Eurosiberian" species.] Address: Ott, J., Friedhofstr. 28, D-67705 Trippstadt, Germany. 2179. Peacor, S.D.; Werner, E.E. (2000): Predator effects on an assemblage of consumers through induced changes in consumer foraging behavior. *Ecology* 81(7): 1998-2010. ["This investigation examines how a predator-induced reduction in activity of a prey species (a "nonlethal" predator effect) affects the growth rate of the prey and, indirectly, the growth rate of competitors of the prey. We further determine how the magnitudes of these effects depend on density of the prey species. We develop a foraging model that predicts a predator will reduce the growth of a focal prey species at low prey density but have little effect at high prey density. The model also predicts that presence of the predator will indirectly facilitate growth of a competitor of the focal species, and that this effect will be negligible at low, and maximal at high, focal species density. Thus it is precisely where the effect of the predator on the growth of the focal species is minimum that the indirect effect on the competitor is maximum. We tested these predictions using a system of three species/size classes of anuran larvae and a larval odonate predator (*Anax longipes*) in cattle watering tanks. By caging the predator we isolated its effect on foraging behavior of the anuran larvae from that of density reduction. We manipulated the density of small green frog larvae (*Rana clamitans*) while holding density of small bullfrog (*R. catesbeiana*) and large green frog competitors constant. Small green frogs and bullfrogs reduce their activity in the presence of caged *Anax* whereas the large green frogs do not. Results were in accord with the model predictions. Caged *Anax* reduced small green frog and bullfrog growth at low small green frog density but had no effect at high small green frog density. In contrast, caged *Anax* had a positive effect on large green frog growth, but this effect was negligible at low small green frog density and maximal at high small green frog density. The results also showed that the indirect effects of the predator that arose through reduction in prey foraging activity were comparable in magnitude to those expected through reduction in prey density. These results suggest that the nonlethal effects of a predator on prey and, indirectly, on competitors of their prey, can be large in magnitude and depend strongly on relative species densities." (in French). [A small population of *E. civile* was discovered in 1999; its habitat is described in detail.] Address: Ruel, Y., 760, chemin Saint-Louis, Quebec, Que., G1S 1C3, Canada

2183. Peters, G.; Günther, A. (2000): Frühjahrsbeobachtungen an *Anax ephippiger* auf Rhodos nebst Anmerkungen über den Invasionsraum der Art (Odonata: Aeshnidae). *Libellula Suppl.* 3: 49-61. (in German with English summary). ["The numerous specimens recorded during the last week of March 1999 and the few which lingered at the island until the last days of April, are interpreted as being members of a mass invasion in mid March. More than 50 % of the *Anax ephippiger* sightings in the area of the Aegean Sea occur in springtime, up to the first third of May. Observations made in late summer and autumn confirm the development of a summer generation of larvae and adults. The probability of the existence of resident populations in the Mediterranean, produced by successful hibernation of larvae and subsequent emergence of adults, remains to be proved. It seems likely, that *Anax imperator*, *A. parthenope* and *A. junius*, have been unable to produce diapause larvae, which would allow them to survive under conditions of low temperature." (Authors)] Address: Peters, G., Museum für Naturkunde, Institut für Systematische Zoologie, Invalidenstraße 43, D-10115 Berlin, Germany. 2184. Pfau, H.K. (2000): *Erasipteron larischi* PRUVOST, 1933, *Eugeuropterun lunatum* RIEK, 1984 und die Evolution der Verstellpropeller-Flügel der Libellen. *Mitt. Schweiz. Entomol. Gesell.* 73: 223-263. (in German with English summary). ["The functional morphology of the dragonfly wing base is shortly described using a mechanical model (details see PFAU, 1986). Special attention has been put on the mechanism of supinatory twisting of the wing in the range of upstroke pitch (Aufschlagsdrehbereich). In this range the fulcroalar muscle, a pronator which reduces the wing twist, is most essential for enhancement of forward thrust. The wings of *Erasipteron larischi* PRUVOST, 1933 and *Eugeuropterun lunatum* RIEK, 1984, which have been classified amongst the oldest representatives in the stem group of Odonata, are "reanimated" by postulation of various functional wing characters (mainly joints between veins) concerning wing twisting. These fossil wings are interpreted as early steps of an evolutionary sequence, which led from *Erasipteron* to *Eugeuropterun* (in contrast to the sequence proposed by RIEK & KUKALOVA-PECK, 1984, based on morphological considerations). In this sequence the efficiency of wing twisting in the range of upstroke pitch (Aufschlagsdrehbereich) is enhanced. This is due mainly to evolution of the mid and posterior arculus, since frontal veins of the wing were integrated into the twisting part of the wing (Cubital-sector), enlarging it considerably by adding their distal surface parts. As a next step, the formation of a further (frontal) part of the arculus, the anterior arculus, integrated a very large part of the wing (including the wings tip!) into the cubital sector. This was followed by the evolution of the nodus, a most essential joint of the "variable-pitch propeller wing" of dragonflies. The

further functional development of the nodus and the improvement of co-operation of arculus and nodus presumably then happened in a petiolate zygopteroid wing with a proximally situated nodus. It is postulated that this was the wing-type of the common ancestor of all extant Odonata (i.e. of the stem species of *Odonata). The Protanisoptera, possessing a primitive "distal" nodus and a very oblique ("soft") anterior and mid arculus are considered as a "transition stage" on the way to the Protozygoptera and the "Odonata. The complicated mechanical interaction between the wing base, arculus, and nodus has been tested in different constellations using working models. Within the *Odonata the wings again broadened and the nodus was shifted distally resulting in a functional bisection of the wing into a proximal bearing-surface part ("airfoil") and a distal twisting part. It is possible that this evolution, which led to Anisozygoptera+Anisoptera, included groups of Zygoptera ("Lestine Complex", "Calopterygoidea"), supporting the hypothesis of paraphyly of Zygoptera (FRASER, 1957). Convergence, however, could not be excluded. At the base of the Anisozygoptera+Anisoptera - and again at the base of Anisoptera - the wing also broadened in its proximal part (mainly the hind wings). This evolution proceeded with parallel changes in the flight apparatus as a whole: alteration of the basic (i.e. thorax-integrated) angle of wing stroke-plane, simplification and strengthening of the flight motor (the latter mainly in the metathorax)." 2185. Pither, J.; Taylor, P.D. (2000): Directional and fluctuating asymmetry in the black-winged damselfly *Calopteryx maculata* (Beauvois) (Odonata: Calopterygidae). *Canadian Journal of Zoology* 78(10): 1740-1748. (in English). ["Directional asymmetry (DA) has received considerably less attention than fluctuating asymmetry (FA) in the literature. Evidence for DA, however, is building among insect taxa. We examined asymmetries in two wing traits within both sexes of the damselfly *Calopteryx maculata* [...] sampled from three sites in southeastern Ontario. After accounting for measurement error, we show that proximal segments within right fore and hind wings are consistently longer than those in the left in all but one sample group. Full wing lengths, however, exhibited FA rather than DA. Mean asymmetry values for both traits (segment and length) occurred in the direction of right-wingedness significantly more often than expected by chance. Patterns of asymmetry were generally consistent among the sexes and sites, although males tended to exhibit more pronounced DA. We suggest that the wings of *C. maculata* may undergo compensatory development, so that full lengths are more bilaterally symmetrical than their component parts." 2189. Reder, G.; Vogel, W. (2000): Wellenschlag als limitierender Faktor bei der Emergenz von Libellen? Beobachtungen beim Schlupf von *Gomphus flavipes* (Charpentier) (Anisoptera: Gomphidae). *Fauna Flora Rheinland-Pfalz* 9(2): 681-685. (in German). [A male of *Stylurus flavipes* was traced emerging on the margin of a groyne in River Rhine near Worms, Rheinland-Pfalz, Germany. The specimen was caught by the wash off of a boat and washed into the open water of the river. The abdomen still stuck into the larval skin. After ten minutes the authors caught the specimen and put it near the bank onto a log. The specimen had put its abdomen out of the skin floating in the water. After 40 min the specimen take off to its maturation flight.] Address: Reder, Gerd, Am Pfortengarten 37, D-67592 Flörsheim-Dalsheim, Germany. E-mail: PG.Reder@t-online.de

2190. Rejl, J. (2000): Finding of dragonflies in bird's nets. In: Hanel, L. (Ed.): *Vazky 2000. Sborník referátu III. celostátního semináře odonatologu, který se konal v Chráněné krajinné oblasti Trebonsko 15.-18.6.2000*. Vlasim. ISBN 80-86327-12-4: 34-35. (in Czech with English summary). [In the framework of catching of birds living in reeds in the National Reserve Bohdanecký rybník pond and the pond Matka *Orthetrum cancellatum*, *Aeshna cyanea*, and *A. mixta* were regularly caught in mist nets. Rare species (first proof of the existence in the region of Eastern Bohemia) are: 19.7.1999 *Ophiogomphus cecilia*, and 2.8. 1999 *Anax parthenope*. In the meadows of the Svratka river (township territory Krizánky, region Zďár nad Sázavou, mapping field no. 6362a) *Cordulegaster boltonii* was caught in a mist net on 17.6.1998.] Address: Rejl, J., Agentura ochrany přírody a krajiny CR, Bozeny Nemcové 2625, 530 02 Pardubice, Czech Republic

2191. Relyea, R. (2000): Trait-mediated indirect effects in larval anurans: reversing competition with the threat of predators. *Ecology* 81(8): 2278-2289. (in English). ["Ecologists recently have been focusing on the role that trait-mediated indirect effects can have on community structure and composition. To date, this

work has primarily focused on the effects of predator-induced behavioral plasticity on communities. However, predator-induced morphological plasticity, which has been documented in many taxa, might also lead to trait-mediated indirect effects. Here, I examined how predators altered the behavior and morphology of larval wood frogs (*Rana sylvatica*) and leopard frogs (*R. pipiens*) and how these phenotypic changes altered the outcome of competition between the two species. Competition in the absence of caged predators was asymmetric; when reared separately, leopard frogs grew more than wood frogs, but when competing (without predators), wood frogs grew faster than leopard frogs. The presence of caged predators reversed the outcome of competition between the two anuran prey. In the presence of larval dragonflies (*Anax* spp.) or caged mudminnows (*Umbra limi*), leopard frogs grew faster than wood frogs while total tadpole biomass production remained unchanged. Thus, there was a predator-mediated indirect effect. Because predators alter both the behavior and morphology of larval anurans and both of these traits are known to affect resource consumption and growth, both are potential mechanisms to explain the change in competitive outcome. Changes in behavior were not related to changes in growth, but changes in morphology (specifically mouth width and tail length) were related to changes in growth. When competitors were added (without predators), wood frogs increased their mouth width by 10% and their tail length by 3%, while leopard frogs increased their mouth width by 5% and did not change their tail length. The greater increase in mouth width for wood frogs should increase their forage intake, since tadpoles feed by scraping periphyton; the importance of a 3% longer tail in competitive ability is unknown. The presence of the predator threat (via chemical cues from the caged predators) reduced both the mouth width and tail length in the two prey species to pre-competition levels. This response corresponded with the reduced competitive ability of the wood frogs. This work demonstrates that both competitors and predators can alter prey morphology and suggests that changes in morphology can cause trait-mediated indirect effects." (Authors)] Address: Relyea, R.A., Dept Biol. Sciences, University of Pittsburg, Pittsburgh, Pennsylvania 15260, USA. E-mail: rarelyea@pitt.edu

2192. Schlüpmann, M. (2000): Die Libellen des Hagerer Raumes - Verbreitung, Bestand und Lebensräume. Der Sauerländische Naturbeobachter 27: 71-115. (in German with English summary). [Starting in 1980 324 small stagnant water bodies and 65 running water segments were surveyed in the Hagen area. The distribution of the 32 dragonflies species is displayed as 1 square km grid maps. Up to now data has been collected for 184 grid areas. "Distribution and frequency is characterized by percentage of the populated grid areas and populated bodies of water, the indigeneness or rather, the probability of it, is included in derived values and a frequency index is formed." *Aeshna cyanea* is the most widespread and frequent species. *Pyrrhosoma nymphula* was recorded in 40%, *Ischnura elegans* in 35% of the water bodies. *Coenagrion puella* and *Libellula depressa* belong to these widespread species, too. All the other species achieve low frequency indices. Some examples of regional fluctuation in species representation are given: *Gomphus pulchellus* was observed for the first time in 1994. *Erythromma najas* could be observed on old branches of the Ruhr-

River-Valley until 1980, however, it was impossible to find it between 1980 and 1989. In 1997 *Erythromma viridulum* was discovered in the Lenne floodplain for the first time. *Platycnemis pennipes*, which was present in the seventies, but was missing in the eighties, could just recently be confirmed on three places in the Ruhr-Valley. In 1983 and 1984, *Ischnura pumilio* was only observed in the region of the Lenne-Valley and the adjoining region; it was never been seen since that time. Special emphasize ist given to the regional distribution, and their habitat preference (small body of water type, general characteristics of the body of water, vegetation).] Address: Schlüpmann, M., Hierseier Weg 18, D-58119 Hagen, Germany. E-mail: martin-schluempmann@t-online.de

2193. Schlüpmann, M. (2000): Die Libellen des Südwestfälischen Berglandes. Der Sauerländische Naturbeobachter 27: 5-55. (in German with English summary). [The distribution of Odonata in Southern Westphalia, Germany is grid mapped. Information from 172 topographic maps from a possible total of 219 has been made available. 45 dragonfly species are known from the region, 3 of them couldn't be traced in the framework of this study. 35 species are indigenous, *Sympetrum pedemontanum* appeared temporarily in the eighties. In 1998 *Sympetrum fonscolombii* and in 2000 *Ophiogomphus cecilia* were found for the first time. The status for another six species remains questionable. *Aeshna cyanea* and *Pyrrhosoma nymphula* are the dominate species in the region. An analysis of the distribution of the species on the basis of geographic landscapes ("Naturräume") shows that higher altitudes are represented by a clearly defined smaller amount of species. Many species have only been found in peripheral regions only. *Leucorrhinia dubia* and *L. pectoralis* are confined on a few boggy habitats of the higher region of the study area. Due to the water quality improvement of the rivers a population increase of *Calopteryx splendens* has been observed. *Anax imperator* and *Erythromma viridulum* could also increase their populations during the last 10 years - the reason might be an increase in temperatures. A population decrease is to be observed in species of oligotrophic to mesotrophic habitats (*Aeshna juncea*, *Sympetrum danae*, *S. flaveolum*). The regional distribution, population and habitat ecology, and range extensions of the species are described and discussed in some detail.] Address: Schlüpmann, M., Hierseier Weg 18, D-58119 Hagen, Germany. E-mail: martin.schluempmann@t-online.de

2194. Schmidt, E. (2000): Emergenzuntersuchungen an *Gomphus vulgatissimus* und *G. pulchellus* (Odonata: Gomphidae) am Dortmund-Ems-Kanal bei Lüdinghausen (Westmünsterland). Verhandlungen des Westdeutschen Entomologen Tag 1999: 191-197. (in German). [Nordrhein-Westfalen, Germany; emergence patterns in 1999 (long emergence period) and in 2000 (short emergence period) are compared and discussed.] Address: Schmidt, E., Biologie und ihre Didaktik, FB9/S05, Universität GH Essen, D-45117 Essen, Germany

2195. Schnapauff, I; Ullmann, K.; Suhling, F. (2000): Die Libellen-Lebensgemeinschaft griechischer Reisfelder (Odonata): Auswirkungen von Habitatdauer, Anbaumethode und Vegetationsdichte. *Libellula* Suppl. 3: 63-80. (in German with English summary). ["The Odonata of experimental rice-fields situated in the Nestos-delta (NE Greece) were studied from May to September

1994. The number of species breeding successfully in rice-fields was lower than that in ponds and ditches in the vicinity. Only species with a larval period of less than 120 days were able to emerge from the rice-fields. The phenology of adults and the emergence of *Sympetrum fonscolombii* from rice-fields are described. The larval densities of *Ischnura elegans* and *S. fonscolombii* are not significantly different between pesticide-free rice-fields and those treated with propanil and parathion. On the other hand, the number of emerging individuals of both species differed between the treatments. A significant negative correlation between the density of rice plants and the larval density of *I. elegans* in the experimental fields was found. The comparability of results from small experimental plots with original rice-fields is discussed." (Authors)] Address: Suhling F., Zool. Inst., TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

2196. Schöll, F.; Fuksa, J. (2000): Das Makrozoobenthos der Elbe vom Riesengebirge bis Cuxhaven. Bundesanstalt für Gewässerkunde Koblenz. T.G. Masaryk Water Research Institute Prag. Internationale Kommission zum Schutz der Elbe. Koblenz: 29 pp. (in German). [Compilation of faunistic data of the River Elbe covering the fauna from the spring in the Czech Republic up to the estuary in Germany. The data are arranged in an appendix according to four ecoregions: (1) Bohemian Elbe (Krkonoše [Riesengebirge], Vrchlabí - Decín), (2) Upper range (Decín - Pirna, Pirna - Hirschstein) [Czech Republic], (3) Middle range (Hirschstein - Magdeburg, Magdeburg - Geesthacht), and (4) Tide influenced region (Geesthacht - Wedel, Wedel - Cuxhaven) [Germany]. 9 odonate species are listed; this list of course is far away of being complete even for rheophiles species or species of the floodplain of the river Elbe. In spite of this the paper gives a good introduction into the ecological importance of this river in Europe and the fauna of the different ranges of the Elbe. Characteristic species are figured (colour pictures) and some chemical factors influencing the macrozoobenthos are presented in graphs.] Address: Bundesanstalt für Gewässerkunde, Kaiserin-Augusta-Anlagen 15-17, D-56068 Koblenz, Germany; T.G. Masaryk Water Research Institute, Podbabska 30, Praha 6, Czech Republic.

2197. Schulz, C.-J. (2000): Aquatische Insekten der Wipper, einem salzbelasteten Fluß Nordthüringens. Mitt. dtsh. Gesell. allgem. angew. Entomol. 12: 249-254. (in German with English summary). ["Decline of potassium mining in Northern Thuringia led to a decrease in salinity of the river Wipper during the last years. Up to now, drainage waters from the salt heaps cause a salinization, reaching an annual mean value of 1,528 mg Cl⁻ l⁻¹ at the sampling location at the village of Hachelbich in 1998. However, this is only little compared to a decade ago (1989: 7,080 mg Cl⁻ l⁻¹). This severe salinization affected also the aquatic insect community of the river Wipper. Whereas records from the beginning of this century report a diverse aquatic insect fauna, Chironomidae started dominating nearby the potassium mines in the 1930's. Since the beginning of the 1950's, mass developments of a few species, mostly Chironomidae, had characterized long sections of the river. This remained so until in 1994 chloride concentration dropped to 1,575 mg l⁻¹ (annual mean at Hachelbich). From then on, taxa such as *Sialis*, *Agabus* and *Polamonectes* occurred, most of them being euryhaline." (Author)] Also *Calopteryx virgo* and *C. splendens* could be

recorded in the sampling period 1992-1998.] Address: Schulz, C.-J., Staatliches Umweltamt Sondershausen, Postfach 36, D-99701 Sondershausen, Germany

2198. Schwarz-Waubke, M.; Schwarz, M. (2000): Die Libellenfauna im Stadtgebiet von Salzburg (Österreich) - Ergebnisse einer Biotopkartierung aus den Jahren 1994 und 1995. Linzer biologische Beiträge 32(2): 1093-1162. (in German with English summary). [In 1994 and 1995 the dragonfly fauna of 173 water bodies in the city of Salzburg, Austria was investigated. A total of 41 odonate species has been found (hitherto 46 species are known from the city of Salzburg and its environs). The distribution of the species in the Federal State Salzburg and habitat requirements are discussed, and their distribution is mapped. The odonate fauna of twenty waters was examined more intensively with special emphasis on indigeneity and abundance.] Address: Schwarz-Waubke, Maria, Eben 21, A-4202 Kirschschlag, Austria

(2000): A mechanistic link between parasite resistance and expression of a sexually selected trait in a damselfly. *Proceedings of the Royal Society Biological Sciences Series B* 267(1461): 2523-2527. (in English). ["This paper examines a field-based insect system in which a signal trait and an immune effector system responsible for parasite resistance rely on the same melanin-producing enzyme cascade (phenoloxidase, PO). Observations and experiments on males of the calopterygid damselfly *Calopteryx splendens xanthostoma* revealed that resistance to the prevalent parasite in the study system (a eugregarine protozoan infecting the mid-gut) was correlated with quantitative aspects of the sexually dimorphic melanized wingspot of males, a trait that is produced and fixed before the host comes into contact with the sporozoites of the parasite. Regulation of PO during experimental immune challenge showed that males with dark, homogenous melanin distribution in their wings showed no change in PO levels 24 h after challenge. By contrast males with lighter and/or more heterogenous melanin distribution in their wings tended to show higher PO levels 24 h after immune challenge. The changes in PO levels occur despite the lack of a relationship between wing-pigment distribution and the cellular encapsulation response. These results suggest a shared, limiting re may form the mechanistic basis of the trade-off between a condition-dependent signal trait and immune function in this system." 2205. Société française d'odonatologie. Groupe odonatologique Outre-mer (2000): Liste provisoire des odonates de la Nouvelle-Calédonie (Synthèse: Jean-Louis Dommaget). *Martinia* 16(3): 142-144. (in French). [Checklist (51 species) from New-Caledonia.] Address: Dommaget, J.-L., 7, rue Lamartine, F-78390 Bois-d'Arcy, France

2206. Sonntag, H. (2000): Erster Bodenständigkeitsnachweis von *Aeshna mixta* Latreille, 1805 für das Bundesland Tirol. *Anax*, Wien 3: 29-30. (in German with English summary). [Terfens, Tirol, Austria; 10 exuviae were collected between July 27 and August 19, 1998.] Address: Sonntag, H., Bahnhofstr. 2, A-6112 Wattens, Austria. E-mail: hes@tirol.wwf.at

2207. Soupir, C.A.; Brown, M.L.; Kallemeyn, L.W. (2000): Trophic ecology of largemouth bass and northern pike in allopatric and sympatric assemblages in northern boreal lakes. *Canadian Journal of Zoology* 78(10): 1759-1765. (in English). ["Largemouth bass (*Micropterus salmoides*) and northern pike (*Esox lucius*) are top predators in the food chain in most aquatic environments that they occupy; however, limited information exists on species interactions in the northern reaches of largemouth bass distribution. We investigated the seasonal food habits of allopatric and sympatric assemblages of largemouth bass and northern pike in six interior lakes within Voyageurs National Park, Minnesota. Percentages of empty stomachs were variable for largemouth bass (38-54%) and northern pike (34.7-66.7%).

Fishes (mainly yellow perch, *Perca flavescens*) comprised greater than 60% (mean percent mass, MPM) of the northern pike diet during all seasons in both allopatric and sympatric assemblages. Aquatic insects (primarily Odonata and Hemiptera) were important in the diets of largemouth bass in all communities (0.0-79.7 MPM). Although largemouth bass were observed in the diet of northern pike, largemouth bass apparently did not prey on northern pike. Seasonal differences were observed in the proportion of aquatic insects ($P = 0.010$) and fishes ($P = 0.023$) in the diets of northern pike and largemouth bass. Based on three food categories, jackknifed classifications correctly classified 77 and 92% of northern pike and largemouth bass values, respectively. Percent resource overlap values were biologically significant (greater than 60%) during at least one season in each sympatric assemblage, suggesting some diet overlap." 2208. Stav, G.; Kotler, B. P.; Blaustein, L. (2000): Direct and indirect effects of predatory dragonfly (*Anax imperator*) nymphs on green toad (*Bufo viridis*) tadpoles. *Israel Journal of Zoology* 46(2): 173. (in English). [Verbatim: "Artificial-pool experiments were conducted to assess the effects of predatory dragonfly (*Anax imperator*) nymphs on green toad (*Bufo viridis*) tadpoles. Six replicate pools were used for each of three treatment groups: (1) presence of free *Anax* nymphs (direct effects on mortality), (2) caged *Anax* (indirect effects on behavior, development, and individual growth rates), and (3) control (no *Anax*). Each pool consisted of 15 liters (10 cm depth) of water. After five days, 30 three-day-old tadpoles that had hatched from the same egg string were added. Caged *Anax* were fed with tadpoles three times a week. The experiments ran from 11 April through 4 August. Free *Anax* eliminated 90% of the tadpoles within two days and all of them within six days. Caged *Anax* had no effect on the spatial distribution of tadpoles. However, caged *Anax* caused tadpoles to metamorphose earlier and to a larger size (both statistically significant), and to attain a lighter color." Address: Stav, G., Life Science Department and Mitrani Center for Desert Ecology, Jacob Blaustein Institute for Desert Research, Ben-Gurion University of the Negev, Sede Boqer Campus, Beer Sheva, 84990 Israel

2209. Stav, G.; Blaustein, L.; Margalit, Y. (2000): Influence of nymphal *Anax imperator* (Odonata: Aeshnidae) on oviposition by the mosquito *Culiseta longiareolata* (Diptera: Culicidae) and community structure in temporary pools. *Journal of Vector Ecology* 25(2): 190-202. (in English). ["We assessed the overall (consumptive plus non-consumptive) and non-consumptive effects of nymphal *A. imperator* on experimental pool communities by comparing three treatments: (1) control (no *Anax*); (2) free *Anax* (*Anax* was not constrained); and (3) caged *Anax* (*Anax*, enclosed within a cage, could not consume prey outside the cages, but could possibly influence them via perceived risk of predation). Fewer egg rafts of the mosquito *Culiseta longiareolata* were found in the free *Anax* treatment compared to the other two treatments. There was no statistically significant difference in the number of egg rafts between control and caged *Anax* pools. Thus, while *Culiseta* females apparently oviposit fewer egg rafts in the presence of unconstrained *Anax*, they did not respond to predation risk from the caged *Anax*. Larval *Culiseta* densities were drastically reduced by free *Anax*; there

ties were drastically reduced by free *Anax*; there was nearly a 100% reduction in the number reaching metamorphosis (pupae) and a 100% reduction in emergence (pupal exuviae). There were no significant treatment effects on densities of crustaceans, *Daphnia magna* and *Heterocypris* sp., or on chironomid pupal exuviae. Ceratopogonid pupal abundance was higher in free *Anax* pools than in the other two treatments toward the end of the experiment. Free *Anax* caused a trophic cascade, presumably by strongly reducing the dominant periphyton grazer, *Culiseta* larvae; periphyton mass was greater in the free *Anax* treatment than in the control. However, there was no behavioral trophic cascade, i.e., no difference in periphyton abundance between the control and caged *Anax* treatment." (Authors)] Address: Stav, G., Institute for Desert Research, Ben-Gurion University, Sede Boqer Campus, 84990 Israel.

2210. Stiehler, H. (2000): 60 Jahre Naturschutzgebiet Döpe. Naturschutzarbeit in Mecklenburg-Vorpommern 43(1): 72-77. (in German). [*Leucorrhinia pectoralis*, *Ischnura elegans*, *I. pumilio*, *Lestes sponsa*, and *Sympetrum vulgatum* are communicated for the lake Döpe, Mecklenburg-Vorpommern, Germany] Address: Stiehler, H., Schweriner Str. 8, D-23972 Dorf Mecklenburg, Germany

2211. Stoks, R.; Knijf, G. de (2000): De Bruine korenbout (*Libellula fulva*) in Vlaanderen in 2000: hoop voor een met uitsterven bedreigd buitenbeentje? *Gomphus* 16(2): 131-138. (in Dutch with English and French summaries). ["*Libellula fulva* in Flanders in 2000: hope for a treathened outsider? The increase in the number of observations of the Scarce Chaser, *Libellula fulva*, in Flanders during the nineties was continued in 2000. More than 1.600 animals were seen at 13 different sites. In the region Noordoost Limburg there were three sites with only one solitary female and one site with about 100 animals. Very large (>100 individuals) populations were seen at the known sites in Klein-Brabant (Fort van Walem, Kleiputten van Niel, and Grote Wiel te Wintam). Surprisingly, more than 60% of the observations were concentrated outside the known sites in three populations in the Polders of the Scheldt (Waasland). A central population of more than 150 animals was present at the Rupelmondse Kreek. The other two populations of the Waasland were at Paviljoen in Bazel (more than 60 animals) and Steenbakkerij Steendorp (more than 40 animals). These populations together with the ones of Klein-Brabant constitute the region Rupel-Scheldepolders. The data of 2000 confirm the fact that *L. fulva* is a quite unusual 'Critically endangered' species as it can occur in large populations and shows a preference for habitats with fish. It is therefore not surprising that a re-analysis of the Red list status suggests that the species now should be considered 'Endangered' in Flanders." (Authors)] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

2212. Suhling, F.; Befeld, S.; Hausler, M.; Katur, K.; Lepkojus, S.; Mesleard, F. (2000): Effects of insecticide applications on macroinvertebrate density and biomass in rice-fields in the Rhone-delta, France. *Hydrobiologia* 431(1): 69-79. (in English). ["The density of 23 macroinvertebrate species and the total macroinvertebrate biomass were compared between rice-fields treated with lindane and diazinon in June and alphasmethine in Au-

gust and untreated controls. The macroinvertebrates could be divided into four groups: (1) Taxa, in which the densities were lower in the insecticide treatment in July and August than in the non-insecticide treatment. (2) The Culicidae which occurred in the insecticide treatment in significantly lower density in July, but in significantly higher density in August. (3) *Ischnura elegans* (Vander L.) which was found in July after the lindane application in significantly higher numbers in the insecticide treatments, but in significantly lower numbers in the insecticide treatment in August after the application of the pyrethroid. In these three groups, we assumed that direct effects due to the insecticides toxicity were the reason for the differences in density. (4) The fourth group included three taxa in which the densities were significantly higher in the insecticide treatment in July and August than in the control. For this, indirect effects due to reduced biotic interactions may be responsible. The biomass was higher in the insecticide treatments in July, mainly because of a high increase in gastropod density, during the rest of the season it was similar between treatments and controls." (Authors) Odonata treated are *Ischnura elegans*, *Orthetrum albistylum*, *O. cancellatum*, *Crocothemis erythraea*, and *Sympetrum fonscolombii*.] Address: Suhling F., Zool. Inst., TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

2213. Swanson, N.L.; Liss, W.J.; Ziller, J.S.; Wade, M.G.; Gresswell, R.E. (2000): Growth and diet of fish in Waldo Lake, Oregon. *Lake & Reservoir Management* 16(1-2): 133-143. (in English). ["Waldo Lake, located in the Oregon Cascades, is considered to be one of the most dilute lakes in the world. Even with low nutrient concentrations and sparse populations of zooplankton, introduced fish in the lake are large in size and in good condition when compared to fish from other lakes. This apparent anomaly is due to the availability of benthic macroinvertebrates. Taxa found in the stomach contents of fish captured in Waldo Lake consist primarily of Chironomidae larvae and pupae, Trichoptera larvae and pupae, amphipods, Ephemeroptera larvae, and Odonata larvae." 2214. Switzer, P.V.; Eason, P. K. (2000): Proximate constraints on intruder detection in the dragonfly *Perithemis tenera* (Odonata: Libellulidae): Effects of angle of approach and background. *Annals of the Entomological Society of America* 93(2): 333-339. (in English). ["The implications of insects' vision for territorial defense have been relatively little studied in the field. In the dragonfly *Perithemis tenera* Say we investigated whether either the angle at which an intruder was viewed by a territorial resident or the background against which it was viewed affected the detection of that intruder. Residents detected intruders at a greater distance if the intruders were directly in front of them; they also detected more intruders in front of them than from other angles. Intruders viewed against distant vegetation were detected more readily than were intruders against near vegetation. Residents detected more intruders viewed against distant vegetation than viewed against near vegetation; however, more intruders than expected were detected against near vegetation. The probability of detecting intruders depends on the angle at which they are viewed and the background behind them. Hence, there may be selection on territorial resi-

dents to adjust their orientation and space use to enhance their view of their territory and intruders."(Authors)] Address: Switzer, P.V., Eastern Illinois Univ., Dept Biol, Sci., Charleston IL 61920; USA. E-mail: cfpvs@eiu.edu

(male holotype: Florence Falls (13°04'S/130°45'E), in shade along small rainforest stream, Northern Territory, Australia, June 21st) is described, illustrated and compared with *Nososticta taracumbi*.] Address: Theischinger G., 2A Hammerley Road, Grays Point, NSW 2232, Australia

2216. Theischinger, G. (2000): Preliminary keys for the identification of larvae of the Australian Gomphides (Odonata). Cooperative Research Centre for Freshwater Ecology Identification Guide No. 28: I-III, 48pp. (in English). ["The descriptive information available on the larvae of the Australian Gomphides is presented. Keys are given for the identification of families, genera, subgenera and species. In this paper the classification of Australian gomphids as adopted by Watson (1991) and Theischinger (1998) is replaced by the classification proposed by Bechly (1996) [...] with Gomphides standing for Gomphidae, Lindeniidae for Ictinogomphinae and Gomphidae for Gomphinae. [...] Six gomphid genera, five subgenera and 39 species, generally based on adults only, have been described since 1854. Only much more recently some information on the larvae was presented. After the most recent comprehensive treatment of Australian gomphid larvae (Theischinger 1998) we now know the larvae of most species, but there are still large gaps in our knowledge. It is the main intention of this presentation to make possible or facilitate the identification of known larvae of Australian gomphid species. I have, however, strongly emphasised existing gaps in our knowledge in order to make it more interesting and easier for people from a wide range of activities to attempt to close some of them. [...] Measurements and descriptions are given from last instar larvae or from final instar exuviae. Most illustrations are given from final instar exuviae. As colouration of individuals may be variable in life due to specific conditions in the habitat and as colouration of preserved specimens may reflect the ways or methods of collection and preservation, colours are not given in the descriptions; they may range from pale greyish yellow to dark greyish brown. Pubescence that is rather strong in all taxa does not appear useful for diagnoses and is therefore omitted in illustrations and usually not mentioned or specified in descriptions. Smoothness or dentition of premental ligula and labial palps may to some degree be effected by conditions of habitat and food and possibly others. All diagnoses are made up in similar style facilitating comparison. Only the most reliable characters are used in keys and diagnoses. In spite of that the keys may be of limited use for identifying other than last instar larvae and exuviae." (Author) G. Theischinger presents information on the family level on taxonomy and diagnosis, and a checklist of the genera. On generic level information on taxonomy, diagnosis, general ecology, and a checklist of the species is given. Each species is keyed out, black-and-white drawings give optimal insight of morphological structures. On the species level information on dimensions, significant morphological structures, ecology, and distribution are compiled. These

attractive volume of the Odonata identification guide series (see OAS 2306) presents also a plate with colour photographs of nine species.] Address: Theischinger G., 2A Hammerley Road, Grays Point, NSW 2232, Australia. 2218. Tol, J. van (2000): The Odonata of Sulawesi and adjacent islands Part 5 The genus *Protosticta* Selys (Platystictidae). *Tijdschrift voor Entomologie* 143(2): 221-266. (in English) ["The type species of the genus *Protosticta* Selys, *P. simplicinervis* Selys, was described from Sulawesi (formerly Celebes, Indonesia). The present paper provides a revision of all Sulawesi species of the genus, and those of the adjacent island of Buton and the Sangihe Islands. Twelve species are recognized, three of which were previously known (*P. bivittata* Lieftinck, *P. gracilis* Kirby, and *P. simplicinervis*). One nominal species, *P. annulata* Fraser, appeared to be a synonym of *P. simplicinervis*. Consequently, nine species are described as new to science, viz *P. coomansi* (type locality: Palu: Lindu valley), *P. geijskesi* (type locality: NNE of Malili), *P. linduensis* (type locality: Polewali), *P. marenae* (type locality: Palu: Lindu valley near Gimpu), *P. maurenbrecheri* (type locality: NW of Palopo), *P. pariwonoi* (type locality: N of Ujung Pandang: Maros), *P. reslae* (type locality: Polewali), *P. rozendalorum* (type locality: Sangihe Islands), and *P. vanderstarrei* (type locality: Polewali). Characters of importance for species recognition are the thoracal and abdominal markings, and the structure of the prothorax and anal appendages in the male. Diagnostic characters of females include the structure of prothorax and anal appendages. The females of four species are unknown. The status of the genus *Protosticta* of the family Platystictidae is preliminarily discussed. Its high diversity in Sulawesi is in contrast with the complete absence of Platynemididae and Euphaeidae, and the virtual absence of the Protoneuridae from this island. Besides, various species as here recognized, show significant variation between populations. The morphological variation is clinal in some species (*P. coomansi*, *P. geijskesi*), presumably related to the geological history of the island." The meeting was also the charter meeting for the scheduled atlas of the Odonata of the Federal State Brandenburg, Germany.] Address: not stated

2223. Upson, S. (2000): Life history observations on *Sympetrum signiferum* in Arizona. *Argia* 12(4): 5-6. (in English). [The species was first recorded in early September, 1999 in Leslie Canyon National Wildlife Refuge. On this locality it was on the wing in August between November 2000 (see Flint 2000). Colouration during maturation period, habitat preferences in Arizona, and oviposition are described. Some additional Arizonan localities with records of the species are reported

(see Sibley, 2000).] Address: Upson, Sandy, PO Box, 1453 Bisbee, AZ 85603, USA

2224. Usseglio-Polatera, P.; Bournaud, M.; Richoux, P.; Tachet, H. (2000): Biological and ecological traits of benthic freshwater macroinvertebrates: relationships and definition of groups with similar traits. *Freshwater Biology* 43: 175-205. (in English). ["1. Relating species traits to habitat characteristics can provide important insights into the structure and functioning of stream communities. However, trade-offs among species traits make it difficult to predict accurately the functional diversity of freshwater communities. [...]. 2. We used multivariate analyses to examine separately the relationships among 11 biological traits and among 11 ecological traits of 472 benthic macroinvertebrate taxa (mainly genera). The main objective was to demonstrate (1) potential trade-offs among traits; (2) the importance of the different traits to separate systematic units or functional groupings; and (3) uniform functional groups of taxa that should allow a more effective use of macroinvertebrate biological and ecological traits. 3. We defined eight groups and 15 subgroups according to a biological trait ordination [...]. 4. Seven ecological groups and 13 ecological subgroups included organisms with combinations of traits which should be successively more adequate in habitats from the main channel to temporary waters, and from the crenon to the potamic sections of rivers, and to systems situated outside the river floodplain. [...]. 5. Monitoring and assessment tools for the management of water resources are generally more effective if they are based on a clear understanding of the mechanisms that lead to the presence or absence of species groups in the environment. We believe that groups with similar relationships among their species traits may be useful in developing tools that measure the functional diversity of communities. [...] Group d consisted of a homogeneous assemblage of medium to large-sized insects dominated by Odonata." (in Appendix 1, 25 European odonate genera are classified) "Genera were often semivoltine and had a long life cycle duration. They used a variety of reproductive techniques. Adults were strong fliers. As a result, the dispersal was usually aerial. Egg and larval diapause could be used as resistance strategies. Crawlers and engulferers were dominant in the larvae, and their food was mainly represented by macroinvertebrates." Landesamt für Wasserwirtschaft - Bericht 206/00*. Mainz: 113 pp. (in German). [Brooks and creeks in the low range mountain Hunsrück, Rheinland-Pfalz, Germany suffered strongly from acidification caused by air pollution. Chemical parameters indicate that acidification has slightly reduced in the past years. Compared with so-called reference running waters which are not acidified macrozoobenthos of acidified running waters indicate a species deficit of 65%. Abundance of *Cordulegaster boltonii* is low in acid and not acid creeks.] Address: not stated

2232. Wildermuth, H. (2000): Alternative Taktiken bei der Weibchensuche von *Boyeria irene* (Odonata: Aeshnidae). *Libellula* 19(3/4): 143-155. (in German with English summary). ["The flight behaviour of the males over water was studied at two mountain streams in southern France. Three flight styles were discriminated: cruise flight, territorial flight and search flight. All flight modes are described in detail and in association with the structural features of the habitat. Only the territorial and search flights were considered sexually motivated. Both tactics were restricted to the same oviposition and

rendezvous sites, these being distributed nonhomogeneously along the watercourse. The shift from one to the other flight mode may be caused by male density. It is suggested that *B. irene* recognizes the rendezvous by bright linear structures with dark cavities along their border. This view is supported by the observation of an obviously deceived male that searched intensely for females along the border of a dirt road with structures similar to those at streams." 2233. Wildermuth, H. (2000): Larvae of the Downy Emerald *Cordulia aenea* (L.) examine the space for eclosion with their hind-legs. *J. Br. Dragonfly Society* 16 (2): 59-62. (in English). ["The reactions to contact with the experimental obstacle during hind-leg circling were the same in all four larvae tested. None remained at the site but all descended and tried to find a new place. However, they did not return to the water but climbed up the same stick and repeated the procedure as before. Having found a new site for emergence, definite clinging and ecdysis ensued. No reaction was found when the pencil was held close to the larvae without physical contact. From the reactions of the larvae it is concluded that only physical contact of the circling hind-legs with the obstacle causes a larva to leave the site and search for a new one for ecdysis. Responses of larvae showed that visual cues were not dictating the behaviour observed. The findings support the hypothesis that an important function of the circling leg movements in emerging *C. aenea* larvae is to test the space around them for unhindered eclosion." (Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. E-mail: wildermuth@swissonline.ch

2234. Wimmer, W.; Winkel, W. (2000): Libellen (Odonata) in der Nestlingsnahrung des Trauerschnäppers *Ficedula hypoleuca* (Aves). *Libellula* 19(3/4): 241-246. (in German with English summary). ["The odonate component in the diet of Pied Flycatcher nestlings was examined during 2000 in an afforested area near Lingen / Emsland, NW Germany, by using the neck-ring method and collecting food-remains from the nests. The component amounted to 0.29 % (neck-ring method) and 0.57 % (food remains in nests). *Enallagma cyathigerum*, *Pyrrhosoma nymphula*, *Erythromma najas* and *Gomphus vulgatissimus* were recorded as imagines and *E. cyathigerum* and *Sympetrum flaveolum* as larvae." (in English with Chinese summary). [*Oligoaeschna pramoti* sp. nov., the second representative of the genus recorded from Thailand, is described, figured, and compared with a paratype male of *O. niisatoi*.] Address: Yeh Wen-Chi, Division of Forest Protection, Taiwan Forestry Research Institute, 53 Nan-Hai Rd., Taipei, Taiwan. E-mail: wcyeh@serv.tfri.gov.tw

2236. Yoshida, M. (2000): Predatory behavior of *Leucage magnifica* (Araneae: Tetragnathidae). *Acta Arachnologica* 49(2): 117-123. (in English). ["The predatory behaviour of *L. magnifica* was studied. This spe-

cies employed five predatory sequences: seize-pull out, bite-pull out, bite-wrap, wrap-bite, and wrap. Attack wrapping was used to subdue various types of prey such as grasshoppers, damselflies, ants and stinkbugs, which may be large and/or dangerous prey. Furthermore, living ants were more frequently immobilized by wrapping than dead ants. It suggests that attack wrapping is an effective method to immobilize large and/or dangerous prey." 2001

2237. Ak Libellen NRW (Menke, N.; Conze, K.-J.; Göcking, C.; Artmeyer, C.) (2001): Ergebnisse der landesweiten Libellenerfassung / Rasterkartierung in NRW von 1996 - 2000. AK Libellen in Nordrhein-Westfalen, c/o Conze, K.-J., LökPlan-Conze, Cordes & Kirst GmbH, Hedwigstr. 32b, D-59609 Anröchte, Germany. E-mail: lökplan@t-online.de: 79 pp. (in German). [Nordrhein-Westfalen, Germany; the results of the dragonfly survey of the mapping period 1996 to 2000 are presented on distribution maps. The distribution of 63 species is documented on the basis of 1/4 grid maps, in addition 10 species not traced in the mapping period are shortly discussed. They are briefly commented. The species are arranged in a tab. according to their grid frequency: *Ischnura elegans* occupies 71% of all grids, five species are only known from one locality in this federal state. This very useful up-to-date distribution atlas can be purchased for DM 10,- / Euro 5 from H.-J. Conze.] Address: see above

2238. Address, R. (2001): Obituary: Terrence de Fonseka (1919 - 2000). *Notul. odonatol.* 5(7): 95. (in English). [Born Sept. 6, 1919 in Kalutara, Sri Lanka, passed away March 21, 2000, Finchley, UK] Address: Address, R., 38 Capel Close, Whetstone, London, N20 0QU, UK

2239. Artiss, T. (2001): Structure and function of male genitalia in *Libellula*, *Ladona* and *Plathemis* (Anisoptera: Libellulidae). *Odonatologica* 30(1): 13-27. (in English). ["Male genitalia of 25 spp. are studied using scanning electron microscopy, and the structure of the fourth penile segment is described. [...] Species are categorized according to the morphology of the penis and inferred patterns of sperm removal. Type 1 taxa possess relatively large, broad, flat lateral lobes, and lack cornua, or possess cornua that are greatly reduced in size. These spp. are believed to displace sperm in the bursa copulatrix before depositing their own sperm, thereby gaining positional priority during oviposition. Type 2 spp. possess elongated lateral lobes and/or cornua. These taxa are believed to engage in a mixed strategy of sperm displacement and sperm removal. Optimization of these characters on a phylogeny of the 3 genera indicates that the Type 1 sperm displacement strategy is ancestral, and that the Type 2 strategy was subsequently derived within the majority of the *Libellula* s.s. taxa." (Author)] Address: Artiss, T, Lakeside School, 14050 1st Avenue NE, Seattle, WA 98125-3099, United States. E-mail: thomas.artiss@lakesideschool.org

66-67. (in English). [United Kingdom, *Orthetrum coerulescens*] Address: not stated

2241. Bang, C. (2001): Constructed wetlands: high-quality habitats for Odonata in cultivated landscapes. *International Journal of Odonatology* 4(1): 1-15. (in English). [This study has investigated the potential constructed wetlands (CW) have as habitat for freshwater organisms, exemplified by Odonata. "Four different CWs in southern Norway were investigated, and larval Odonata species composition was related to a wide range of environmental variables. The material was ordinated using Detrended Correspondence analysis (DCA) and Canonical Correspondence analysis (CCA). All the CWs had high nutrient values and high diversities of aquatic plants. Of the 11 Odonata species found, the richest CW contained 10 species. During the study, one of the CWs was exposed to diazinon (an insecticide). Sun exposure and nutrient content were the most important variables determining species composition. The species that dominated the wetlands were typically euryoecious species, indicating harsh living conditions. Despite the high nutrient content, the results clearly indicate that CWs have an obvious role in pond habitat creation, especially in areas managed according to pesticide-free management." (Author)] Address: Bang, C., Syverudveien 80, N-1430 As, Norway. E-mail: christoferbang@hotmail.com

2242. Belle, J. (2001): Two species added to the list of Balinese Odonata, Indonesia. *Notul. odonatol.* 5(7): 94. (in English). [Bali, Indonesia; *Agrionemys pygmaea*, *Tholymis tillarga*] Address: Belle, J., Onder de Beumkes 35, NL-6883 HC Velp, The Netherlands

2243. Beynon, T. (2001): My best day. *Atropos* 12: 36-37. (in English). [Report from a 'dragonfly day' in Chartley Moss, Staffordshire, UK. (see OAS 2244)] Address: Beynon, T.G.; 34 Church Lane, Checkley, Stoke-on-Trent, Staffordshire ST10 4NJ, UK

2244. Beynon, T.G. (2001): Colonization by White-faced Darter *Leucorrhinia dubia* (Vander Linden) of the East-West Ditch at Chartley Moss NNR, Staffordshire, with notes on its status at other pools. *J. Br. Dragonfly Soc.* 17(1): 20-30. (in English). ["*L. dubia* has bred for many years at two pools on Chartley Moss. [...] A rising lens of peat plugged Dead Pine Gulch some years ago, and this has gradually become vegetated so that the amount of free water is now minimal, and it is likely that the *L. dubia* population here will soon become extinct. [...] A significant recent development has been the colonization by *L. dubia* of the largest water body on the Moss, the East-West Ditch" (draining ditch constructed in the 18th century and maintained the following years). "[...] Fewer than ten adults were recorded annually between the mid 1980s and 1995. The population has increased rapidly since the first proof of breeding in 1995. About 850 adults emerged in 1998, and a careful census during emergence in 1999 produced a minimum of 826, with a probable population of c. 1,240. [...]". A series of 19 dams were constructed between 1986 and 1989 to reverse the drying out of the Moss. After damming, most sections gradually became colonized by Sphagnum moss to a varying extend. "The colonization increased very rapidly in the summers of 1998 and 1999, so that with few exceptions most now have more than 90 per cent cover. It is noticeable that those with almost complete semi-submerged Sphagnum produce

far more emerging adults of *L. dubia* than clearer sections [...]". Systematic counts of exuviae and habitat parameters (length, temperature, Sphagnum cover) per section are documented in tabs and discussed in detail.] Address: Beynon, T.G.; 34 Church Lane, Checkley, Stoke-on-Trent, Staffordshire ST10 4NJ, UK

2245. Bogunski, G. (2001): Zusammenfassung entomologischer Daten vom NSG "Jahnsgrüner Hochmoor" im Hartmannsdorfer Forst. Mitteilungen Sächsischer Entomologen 53: 11-18. (in German). [Sachsen, Germany; 19 odonate species from a devastated bog are listed; *Lestes virens vestalis*, *Coenagrion hastulatum*, *Aeshna juncea*, *Libellula quadrimaculata*, and *Leucorhinia dubia* are remains from the formerly typical odonate fauna of the bog.] Address: Bogunski, G., Gartenstr. 10, D-08141 Reinsdorf, Germany

[April 26, 2000, Lesbos, Greece; a black triangle on the synthorax is documented on a colour photo and discussed as a field identification character for general individuals of the species] Address: Bowers, J., 6 Ashwood Terrace, Leeds, West Yorkshire, L56 2EH, UK

2248. Bowman, N. (2001): Reports from Coastal Stations - 2000: Eccles-on-Sea, Norfolk. *Atropos* 12: 60-61. (in English). [United Kingdom; 3 odonate species are recorded] Address: not stated

2249. Brooks, S.J.; Jackson, K.A. (2001): The Odonata of Bioko, Republic of Equatorial Guinea, with the description of fan-shaped setae on early instar *Libellulidae* larvae. *Odonatologica* 30(1): 29-38. (in English). ["A checklist of 48 spp. recorded from the island of Bioko (3°30'N 8°40'E), based on historical records compiled by Dr Elliot Pinhey and augmented by a collection made in March-April 1999, is presented, together with notes on the distribution of the species on the island. The Odonata fauna apparently comprises 2 elements, an upland fauna which includes 6 spp. that only occur above 500 m, and a lowland fauna of 17 spp., none of which occurs above 500 m. A further 13 spp. have been found in both lowland and upland sites. There are insufficient published data on the remaining 13 spp. to assign them to either of these faunistic elements. In addition, unique fan-shaped setae on the dorsum of the head, thorax and abdomen of early instar libellulid larvae are described. These setae are thought to be mechano-receptors that are held above the sediment to detect the presence of prey and current flow while the larva remains buried." 2253. Busuttil, S. (2001): Red-veined Darters *Sympetrum fonscolombi* (Selys) at Dungeness RSPB Reserve (1993 to 2000). *Atropos* 12: 24-27. (in English). [2000 proved to be the year with highest abundance of *S. fonscolombii* in Dungeness Reserve, Kent, UK. The recent history of this species in the locality is outlined. In addition the habitat is described and conservation management measures are discussed. Additional records of the species are reported from a locality 30 km north-east of Dungeness: Samphire Hoe.] Address: Busuttil, S., Dungeness RSPB Reserve, Boulderwall Farm, Dungeness, Romney Marsh, Kent, UK

2254. Cham, S. (2001): The status of Small Red-eyed Damselfly *Erythromma viridulum* (Charpentier) in the British Isles. *Atropos* 12: 7-9. (in English). [In 1999 *E. viridulum* was discovered breeding in Essex, UK. In summer 2000 further discoveries provided the opportunity to follow the progress of colonisation. The new records are documented and mapped. In a figure the flight period of *Erythromma najas* is compared with that of *E. viridulum*.] Address: Cham, S., 45 Weltmore Road, Luton, Bedfordshire LU3 2TN, UK

2255. Chelmick, D.G. (2001): Larvae of the genus *Aeshna* Fabricius in Africa south of the Sahara (Anisoptera: Aeshnidae). *Odonatologica* 30(1): 39-47. (in English). ["9 species have been recorded from sub-Saharan Africa, of which only 5 species have been described as larvae. A more complete larval description of *A. scotias* Pinhey from Cameroon and a review of the current level of information on the larvae of the genus in the region, are provided here, and the known larvae are keyed." (Author) *Aeshna ellioti*, *A. rileyi*, *A. subpupillata*, *A. minuscula*] Address: Chelmick, D.G., 31 High Beech Lane, Haywards Heath, West Sussex, RH16 1SQ, UK. E-mail: david.chelmick@mdagroup.com

2256. Clancy, S. (2001): Reports from Coastal Stations - 2000: Dungeness area, Kent. *Atropos* 12: 55-56. (in English). [United Kingdom; *Anax parthenope*, *Sympetrum fonscolombii*] Address: not stated
2257. Clausnitzer, V. (2001): Notes on the species diversity of East African Odonata, with a checklist of species. *Odonatologica* 30(1): 49-66. (in English). ["Preliminary considerations concerning the species diversity of East African dragonflies and the problems of identifying and using such diversity figures are given. For a detailed approach the basic problem is lack of sufficient data in that area. A checklist of species recorded so far for East Africa is given. Looking at pure species number in relation to area, Uganda is definitely more important for dragonfly diversity than its eastern neighbouring countries. If taking endemism and taxonomic singularity into account, the coastal forests of Tanzania and Kenya are very important too." (Author)] Address: Clausnitzer, Viola, Liebenauer Str. 180, D-06110 Halle/Saale, Germany. E-mail: wesche@mail.uni-marburg.de
2258. Dewick, S. (2001): Problems at Small Red-eyed Damselfly *Erythromma viridulum* Site. *Atropos* 12: 74- (in English). [Verbatim: " In *Atropos* 9: 3-4 Richard Gerussi and I gave an account of our discovery of the first British colonies of Small Red-eyed Damselfly *Erythromma viridulum*. We were concerned about the vulnerability of the sites and explained that until such time as a foothold in this country appears more secure, the authors have decided to withhold information that could identify the existing localities. It is hoped that readers will understand and respect our decision. Acts of selfishness and stupidity are sadly not unknown in the world of insect recording, but nothing could have prepared me for what was to follow. From 30 July 2000, Curry Lane was invaded by in excess of 200 twitchers who had located a previously unknown colony at New House, Mill End, Bradwell. Our private lane just happened to be a convenient way to reach it! As if mass trespass was not enough, those approached reacted with rudeness and defiance, and bizarre messages appeared on the internet accusing us of obstructing a public footpath. Conservationists face an uphill struggle to convince many farmers to support wildlife the kind of behaviour seen at Bradwell does nothing to help our cause!"] Address: Stephen Dewick, Curry Farm, Bradwell-on-Sea, Southminster, Essex, CMO 7HL, UK
2259. Dewick, S. (2001): Reports from Coastal Stations - 2000: Bradwell-on-Sea, Essex. *Atropos* 12: 56-57. (in English). [United Kingdom; a list of 15 odonate species is communicated including *Brachytron pratense*. 19 specimens of *Sympetrum* were taken at light.] Address: not stated
2260. Di Domenico, M.; Carchini, G.; Samways, M.J.; Whiteley, G. (2001): Description of the last instar larva of *Chalcostephia flavifrons* Kirby, 1889 and comparison with other *Brachydiplactinae* (Anisoptera: Libellulidae). *Odonatologica* 30(1): 97-101. (in English). ["The morphology of this African sp. is illustrated and described. A comparison is made with other known *Brachydiplactinae*, the South American *Elga leptostyla* and *Nephepeltia phryne* and the African *Hemistigma albipuncta*. The group is a very heterogeneous one in terms of larval morphology." - chini
@utovrm.it
2261. Dijkstra, K.D.; Koese, B. (2001): Dragonflies of the Priyat National Park, Belarus (Odonata). *Opusc. zool. flumin.* 192: 1-20. (in English). ["Priyat National Park in Gomelskaya Oblast, southern Belarus was studied as a reference for conservation of river systems in Western Europe. A total of 43 odonate species is reported. *Sympecma paedisca*, *Coenagrion armatum*, *Ischnura pumilio*, *Pyrrhosoma nymphula*, *Aeshna subarctica*, *Anax imperator*, *Cordulegaster boltonii*, *Somatochlora arctica*, and *Leucorrhinia albifrons* are recorded from the Oblast for the first time. Records of " *Leucorrhinia pectoralis*, " *Lestes barbarus* and *Nehalennia speciosa* are also of interest. Information on ecology and larval habitats is provided for many spp. Early or mass emergence in relation to climate and habitat structure is discussed for *A. subarctica*, *N. speciosa*, *S. arctica* and other bog species. Peculiarities in habitat choice of *C. armatum*, *I. elegans*, and *P. nymphula* are also stipulated." (Authors) Of some interest is the observation that villagers in the area harvest *Stratiotes aloides* as pig fodder. *S. aloides* nearly exclusively is used by *Aeshna viridis* for egg deposition. This plant overgrows quite fast ditches, then becoming unsuitable as habitat for *A. viridis*. The villagers unintentionally maintain the larval biotops, which would otherwise disappear with progressing succession of the vegetation.] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl
2262. Dijkstra, K.-D.; Kalkman, V.J. (2001): Early spring records of Odonata from southern Turkey, with special reference to the sympatric occurrence of *Crocothemis erythraea* (Brullé) and *C. servilia* (Drury) (Anisoptera: Libellulidae). *Notul. odonatol.* 5(7): 85-88. (in English). [Odonata from eight localities - in most cases situated in the Silifke region (Göksu-Delta) - collected from 29 March to 9 April 1999 are presented. They are among the earliest ever published for Turkey. 22 species are recorded; the records of *Lestes macrostigma* and *Anax immaculifrons* are noteworthy. *Crocothemis erythraea* and *C. servilia* were found emerging from the same ditch; notes on their identification in teneral state and as exuviae are added.] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl
2263. Dijkstra, K.-D.; Cordero Rivera, A.; Andrés, J.A. (2001): Repeated predation of Odonata by the hornet *Vespa crabro* (Hymenoptera: Vespidae). *International Journal of Odonatology* 4(1): 17-21. (in English). ["Predation of aggregated, ovipositing tandems of *Sympetrum sanguineum* and *S. vulgatum* by the hornet *Vespa crabro* was observed in Belarus. The same species of hornet was seen killing territorial males and copulating females of *Calopteryx haemorrhoidalis* in Italy. Numerous remains of these odonates at the oviposition sites suggest that attacks occur frequently. A short review of vespid predation of Odonata is given. Species of the genera *Vespa* and *Vespula* have often been reported as predators of single, emerging and ovipositing odonates, taking prey as big as large *Aeshna* species. Odonata may form an important source of protein for *V. crabro* in parts of its range. Such predation may contribute strongly to odonate mortality locally. The disturbing effect may also disrupt opportunity for reproductive be-

haviour." (Authors)] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

2266. Gossum, H. van; Stoks, R.; De Bruyn, L. (2001): Discriminative mate choice in relation with female maturation in *Ischnura elegans* (Odonata: Coenagrionidae). *International Journal of Odonatology* 4(1): 83-91. (in English). ["It is often assumed that males do not choose among females because competition for partners is high and male mating costs are low. Nevertheless, this assumption does not always hold. In some species duration of copulation is long, possibly causing a limitation on the lifetime number of matings for males. In this case we expect males to discriminate among females differing in quality. We first discuss quality differences between immature and mature females. Second, we test whether males of the zygopteran *Ischnura elegans* discriminate between immature and mature females. The hypothesis was examined by performing binary choice experiments in small cages in three different populations. To examine possible mechanisms for discrimination we excluded behavioural differences in one of the two experiments by using dead females. The results show that males of *I. elegans* prefer mature to immature females and that this choice is probably based upon a difference in body coloration." (Authors)] Address: Gossum, H. van, Evolutionary Biology Group, University of Antwerp (RUCA), Groenenborgerlaan 171, B-2020 Antwerp, Belgium. E-mail: hvgossum@ruca.ua.ac.be

2267. Gossum, H. van; Stoks, R.; De Bruyn, L. (2001): Reversible frequency-dependent switches in male mate choice. *Proceedings of the Royal Society Biological Sciences Series B* 268(1462): 83-85. (in English). ["Current sexual-selection theories predict that mating should occur preferentially with the highest-quality partner, and assume that for distinguishing among potential mates the choosy sex applies an internal representation of the characteristics of the desired mate, i.e a template. Binary choice experiments were performed to test male mate choice between two different female colour morphs in the damselfly *Ischnura elegans*. Choice experiments were conducted before and after an habituation period, during which males were exposed to only one female colour morph. Given the choice between the two female morphs, males did exhibit a choice for the most recently experienced female morph. This is the first evidence for a reversible switch in mate choice in a frequency-dependent way. In contrast with previous studies on mate choice, template

formation in male *I. elegans* seems not to be based on quality. Switching mate choice in a frequency-dependent manner, choosing the most common morph, probably allows males to minimize their search efforts and to maximize fitness." 2268. Hämäläinen, M.; Karube, H. (2001): Two new species of Caloptera damselflies from southern Vietnam (Zygoptera: Chlorocyphidae, Euphaeidae). *Odonatologica* 30(2): 209-215. (in English). ["*Rhinocypha seducta* sp. n. (holotype male: southern Vietnam, Lam Dong prov., nr Di Linh, 26-IV-1998) and *Euphaea hirta* sp. n. (holotype male: southern Vietnam, Lam Dong prov., Bao Loc, 14-VI-1996) are described and illustrated, and their taxonomic status is discussed. The latter species co-occurs with *E. guerini* Rambur and *E. masoni* Selys." (Authors)] Address: Hämäläinen M., Dept Applied Zool., P.O.Box 27, FIN-00014 University of Helsinki, Finland; E-mail: matti.hamalainen@helsinki.fi

2269. Hunter, I. (2001): Reports from Coastal Stations - 2000: Elms Farm, Icklesham, East Sussex. *Atropos* 12: 53-54. (in English). [United Kingdom; *Aeshna juncea*, *Sympetrum flaveolum*, *S. danae*, *Libellula quadrimaculata*.] Address: not stated

2270. Inoue, K.; Yokota, H. (2001): *Somatochlora taiwana* spec. nov., a new dragonfly from Taiwan (Anisoptera: Corduliidae). *Odonatologica* 30(2): 217-221. (in English). ["The new sp. is described and illustrated from a single male (holotype): Taiwan, Hsinchu Hsien, Chienshih, nr Yuan Yang Lake, alt. 1670 m, 11-VIII-2000; to be deposited at Taiwan Forest Res. Inst., Taipei. It is compared with *S. dido* Needham." (Authors)] Address: Inoue, K., 5-9 Fuminosato 4-chome, Abenoku, Osaka 545, Japan

2271. Jenkins, D.K. (2001): Population studies of the Southern Damselfly *Coenagrion mercuriale* (Charpentier) in the New Forest. Part 8. Short range dispersal. *J. Br. Dragonfly Society* 17(1): 13-19. (in English). ["In the New Forest there is little evidence for establishment of new colonies over the past 50 years. The few new sites discovered are probably the result of more thorough coverage by recorders and are offset by a similar number of sites which have been lost through prolonged summer drought or habitat change. It has been established that *C. mercuriale* regularly move short distances along the same watercourse (Hopkins & Day, 1997), but are reluctant to pass sections of unsuitable habitat (Jenkins, 1998). Systematic attempts with marked insects to prove long distance dispersal have been disappointing. At Crockford in the New Forest, only two males have been recovered away from the marking area, both at distances of approximately 1km on, or near, the same stream (Hopkins & Day, 1997; Thompson & Purse, 1999). [...] Considering the high number of *C. mercuriale* marked, as well as the potential for dispersal arising from both weather conditions and site topography, it is quite remarkable that only one individual was confirmed as crossing the short distance between the ditches. This does, however, fit well with previous observations. [...] However, on 6 June 1986 and 12 June 1994, large numbers of male *C. mercuriale* were seen at distances of up to 0.5km west and east of Upper Crockford Stream respectively. Although this

might suggest a coordinated maiden flight and the possibility that most dispersal occurs at this stage, mass movement appears to be a rare phenomenon. At Rooks Bridge, a relatively high proportion of unmarked insects appeared each day, but none were found more than 3-4m from the water." (Author)] Address: Jenkins, D.K., 7 Lakewood Road, Ashurst, Southampton, SO40 7DH, UK

2272. Kemp, R.G.; Butler, S.G. (2001): Some dragonfly records from Phewa Tal, Pokhara, Nepal with notes on *Philoganga montana* (Selys) (Zygoptera: Amphipterygidae). *Notul. odonatol.* 5(7): 88-91. (in English). [Between the 22nd May and 27th May, 2000, dragonfly observations were made at the south-east end of the lake Phewa Tal, Pokhara, Nepal in the vicinity of the Fish Tail Lodge Hotel complex. Of the 20 species observed at the locality, *Gomphidia t-nigrum* is recorded for the first time from Nepal. *Philoganga montana* appears to be an exclusively arboreal insect during the adult stage. Observations on *Calicnemia nipalica*, *C. pulverulans*, *Epopththalmia frontalis* and *Macromia flavicolorata* are commented.] Address: Kemp, R.G., "Tree Tops" 5 Mailings Close, Ackleton, Wolverhampton, WV6 7WB, UK

2278. Marinov, M. (2001): Commented Bibliography of the Bulgarian fauna of the Odonata. IDF-Report 3(1/2): 17-45. (in English). [There are 108 years of history for Bulgarian odonatology. The first material was published by Hristovitch in 1892. Many scientists have since contributed to the understanding of the Bulgarian dragonfly fauna. A total of 135 articles dealing with the dragonfly fauna of Bulgaria were found during the literature survey. All papers are listed and - in some cases critically - annotated.] Address: Marinov, M., P.O. Box 134, BG-1000 Sofia, Bulgaria. E-mail: mgmarinov@yahoo.com

2279. Marinov, M. (2001): *Somatochlora borisi* spec. nov., a new European dragonfly species from Bulgaria (Anisoptera: Corduliidae). IDF-Report 3(1/2): 9-16. (in English). [*Somatochlora borisi* n. sp. is described and depicted. Short ecological and behavioural notes from the type locality are given. Holotype: 1 male, Deimin dere river (41°26'N 25°54'E) near the village of Byal Gradetz, Eastern Rhodopes mountain, S Bulgaria, 20 May 2000. Paratypes: 3 males, same locality, one 20 May 1999, one 20 May 2000 and one 22 June 2000. Holotype and paratypes are deposited in the National Museum of Natural History in Sofia. One paratype is deposited in the collection of Dr. H. Wildermuth, Rütli, Switzerland.] Address: Marinov, M., P.O. Box 134, BG-1000 Sofia, Bulgaria. E-mail: mgmarinov@yahoo.com

2280. Marinov, M. (2001): The genus *Somatochlora* Selys in Bulgaria. IDF-Report 3(1/2): 46-53. (in English). [With an IDF grant M. Marinov studied the distribution of the genus *Somatochlora* in Bulgaria by reviewing museums collections and conducting field work. The results of this study are published in this paper. The distribution of four of the seven members of the genus known to occur in Europe are listed in a tab, discussed, and mapped: *Somatochlora metallica*, *S. meridionalis*, *S. flavomaculata*, and *S. borisi*.] Address: Marinov, M., P.O. Box 134, BG-1000 Sofia, Bulgaria. E-mail: mgmarinov@yahoo.com

2281. Marinov, M. (2001): The *Orthetrum coerulescens* complex in Bulgaria (Odonata: Libellulidae). *International Journal of Odonatology* 4(1): 35-40. (in English). ["Although there are many records of *Orthetrum coerulescens* in Bulgaria, the presence of the nominotypical subspecies is doubtful. A critical analysis of all specimens available revealed that they belong either to *O. c. anceps* or to intermediate forms, but not to *O. c. coerulescens*. The latter taxon is therefore omitted from the Bulgarian species list, bringing the number of recorded species to 66." (Author)] Address: Marinov, M., P.O. Box 134, BG-1000 Sofia, Bulgaria. E-mail: mgmarinov@yahoo.com

2282. Martens, A. (2001): Oviposition of *Coenagrionemis reuniensis* (Fraser) in volcanic rock as an adaptation to an extreme running water habitat (Zygoptera: Coenagrionidae). *Odonatologica* 30(1): 103-109. (in English). ["The sp. inhabits streams and rivers in the mountain forests of the Indian Ocean of La Réunion. Because of heavy seasonal rainfalls and steep inclines, there are drastic changes of water level. As a consequence, no water plants, roots or wet driftwood at all are available for oviposition. The sp. seems to be well adapted to this habitat: females oviposit into wet soft and porous lava stones. The closely related *C. insularis* and *C. rufipes* inhabit streams and rivers on Mauritius, where there are less extreme conditions. Both spp. deposit eggs in plant tissue." (Author)] Address: Martens, A., Zool. Inst. TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. E-mail: andreas.martens@tu-bs.de
2283. Mauersberger, R. (2001): *Orthetrum brunneum* (Fonscolombe, 1837) und *Orthetrum coerulescens* (Fabricius, 1798) wieder im Nordosten Deutschlands (Odonata: Libellulidae). *Märkische entomologische Nachrichten* 3(1): 29-32. (in German with English summary). [Germany, Brandenburg, Lychen; *Orthetrum coerulescens* and *O. brunneum* - both rare in northeastern Germany - were observed as pioneer colonizers of a restored spring swamp. Also the well known pioneer species *Ischnura pumilio* and *Libellula depressa* co-occurred.] Address: Mauersberger, R., Waldstr. 4, D-16278 Steinhöfel, Germany
2284. May, M.L.; Corbet, P.S. (2001): Occurrence and taxonomic significance of a palpal spine in larvae of *Enallagma* and other genera (Odonata: Coenagrionidae). *International Journal of Odonatology* 4(1): 41-49. (in English). ["A small inconspicuous spine, first detected at the base of the distal-most seta on each labial palpus of early stadia of two species of *Enallagma*, is reported to occur in final-stadium (F-0) larvae of Palearctic and Nearctic *E. cyathigerum*, in F-0 of 31 other Nearctic species of *Enallagma* and in F-0 of three other coenagrionid genera among 11 inspected for this character. The spine is absent from F-0 of eight other coenagrionid genera, including *Coenagrion* and *Ischnura*. It is also lacking from F-0 of the two species of Afrotropical *Enallagma* that we examined, a discovery that suggests the latter may not be closely related to Nearctic and Palearctic species. In European populations such a spine occurs in the first few stadia of certain Coenagrion species but persists to F-0 only in *E. cyathigerum*. We re-emphasize the potential value of this spine as a means of distinguishing at least the last three stadia of *E. cyathigerum* from those of other coenagrionid genera in Europe, and very probably from *Coenagrion* and *Ischnura* everywhere." E-mail: Steve.Preddy@blueyonder.co.uk

2296. Ramírez, A.; Pringle, C.M. (2001): Spatial and temporal patterns of invertebrate drift in streams draining a Neotropical landscape. *Freshwater Biology* 46: 47-62. (in English). ["1. Invertebrate drift in streams draining a tropical landscape in Costa Rica was studied to assess differences in assemblage composition above and below a major gradient break in geomorphic land-

form and to assess temporal patterns of drift in lowland reaches below the gradient break. The gradient break (~ 50 m a.s.l.) is the point at which the foothills of the Costa Rican Cordillera Central (piedmont) merge with the Caribbean coastal plain (lowlands). 2. Spatial patterns were assessed along two streams by sampling drift over 24 h once a month for 3 months in both the piedmont (90 m a.s.l.) and lowlands (30 m a.s.l.). Temporal patterns of drift were assessed through monthly diel sampling of three lowland sites over 8-10 months, encompassing both 'dry' (< 400 mm precipitation per month, November to May) and wet (July to October) seasons. 3. Drift composition was insect dominated in piedmont sites and larval shrimp dominated in the lowlands. Percent similarity of assemblages between piedmont and lowland sites was low (range 26-43%) because of high larval shrimp densities in lowland versus piedmont sites. 4. Drift densities were higher during night than day, with peaks at sunset on all dates and at all sites. Diel patterns in drift agree with previous observations for the study area and support the 'risk of predation' hypothesis. 5. Analysis of monthly patterns in lowland sites showed high variability in drift densities; however, all major taxa were found every month. Overall, there was a trend for high invertebrate densities during the 'dry' season but these trends were not significant. 6. Observed changes in drift composition support the concept of river zonation, which predicts a change in community composition along the stream continuum due to geomorphic features. Drift at lowland sites below the gradient break was dominated by shrimps, which are linked to marine environments via their migratory behaviour." (Authors) Drift densities of Odonata are measured on the family level.] Address: Ramírez, A., Inst. Tropical Ecosystem Studies, Univ. of Puerto Rico, P.O. Box 363682, San Juan PR 00936-3682, Puerto Rico. E-mail: aramirez@sunites.upr.clu.edu

2297. Relyea, R. (2001): The relationship between predation risk and antipredator responses in larval anurans. *Ecology* 82(2): 541-554. (in English). ["Organisms that produce alternative, nondiscrete phenotypes in response to environmental conditions are expected to alter their phenotypes in relation to the degree of environmental change. This idea has been applied to the evolution of antipredator responses by prey, in which it has been hypothesized that prey should respond more strongly to predators that pose greater mortality risk. In a companion paper, I quantified predator-induced behavioral and morphological responses in six species of larval anurans across five different predator environments and found that these responses were prey- and predator-specific. In the present study, I addressed whether the responses were related to the level of predation risk posed by each of the predators. Within each prey species, I found that different predators posed different levels of predation risk; within each predator species, different prey species experienced different levels of risk. The differences in predation risk could be understood mechanistically after I quantified differences among predators in their ability to capture, handle, and consume prey and differences among prey in behavior and morphology. Using multivariate analyses, I found that predation risk had no significant effect on how a given prey responds to predators, although there were significant univariate behavioral effects; higher predation risk was related to greater decreases in activity and greater spatial avoidance. I also examined the relationship between risk and response across the six prey

species within a predator treatment and found that higher predation risk across species leads to greater decreases in activity in the presence of Umbra and greater increases in tail depth in the presence of Anax. Thus, while previous studies have found relationships between predation risk and prey response when focusing on relatively few species, few predators, and a single trait, this more powerful test using 30 predator-prey combinations and nine traits suggests that the relationship is not well supported. This finding arises from the fact that larval anurans, as well as many other taxa, exhibit predator- and prey-specific behavioral and morphological changes in response to predator- and prey-specific risk. " (Author)] Address: Relyea, R.A., Dept Biol. Sciences, University of Pittsburgh, Pittsburgh, Pennsylvania 15260, USA. E-mail: rarelyea@pitt.edu

2298. Ryazanova, G.I. (2001): One the reproduction tactics in the males of *Lestes sponsa* (Hansemann) (Zygoptera: Lestidae). *Notul. odonatol.* 5(7): 92-93. (in English). [The behaviour at the water of individually marked males of *L. sponsa* was observed in the floodplain of Borzhava river, Ukraine. Elements of territoriality and conservatism of individual reproductive tactics, despite a lasting absence of reproductive success, are demonstrated.] Address: Ryazanova, G.I., Department of Entomology, Faculty of Biology, Moscow State M.V. Lomonosov University, RUS-119899 Moscow, Russia

2299. Samways, M.J. (2001): *Aciagrion pinheyi* spec. nov. from South Africa (Zygoptera: Coenagrionidae). *Odonatologica* 30(1): 111-116. (in English). ["*Aciagrion* had until now not been recorded in South Africa. The new sp. from a pan in thick subtropical savanna is described, illustrated and compared with similar congeners. Holotype male, allotype female (in copula): South Africa, KwaZulu-Natal prov., Ndumo Game Reserve, 21-1-2000; deposited at SAM, Cape Town." 2300. Sherratt, T. (2001): The evolution of female-limited polymorphisms in damselflies: A signal detection model. *Ecology Letters* 4(1): 22-29. (in English). ["Female-limited intraspecific colour variation is a widely distributed trait within damselflies. Typically, one morph resembles the male (the andromorph) whereas one, or sometimes more, do not (the heteromorph(s)). While several selective explanations have been offered, such as decreased harassment by males balanced by predation or lack of mating success, field data indicate that andromorphs and heteromorphs mate at equal frequencies in the field, and survive equally well. In this paper, I use a signal detection model to characterize the properties of a new male-mimicry hypothesis, in which andromorphs are not only more similar to males, but are also encountered more by males. I show that this combination of frequency-dependent and frequency-independent factors readily combine to generate a balanced polymorphism. The model explains why morphs have similar mean mating frequencies, why the experimentally observed mating preferences of males vary between ponds, and why the frequency of andromorphs tends to rise with sex ratio." (Author)] Address: Sherratt, T.N., Department of Biological Sciences, Uni-

versity of Durham, South Road, Durham, DH1 3LE, UK. E-mail: T.N.Sherratt@durham.ac.uk

2301. Sirot, L. K.; Brockmann, H. J. (2001): Costs of sexual interactions to females in Rambur's forktail damselfly, *Ischnura ramburi* (Zygoptera: Coenagrionidae). *Animal Behaviour* 61(2): 415-424. (in English). ["Several species of damselflies, dragonflies and butterflies are characterized by a female-limited polymorphism in which one type of female, the andromorph, looks and behaves like males whereas the other type of female, the gynomorph, looks and behaves differently. Sexual conflict has been hypothesized to play a role in the maintenance of this polymorphism in that andromorphs may have an advantage over gynomorphs by avoiding costly sexual interactions through male mimicry. We tested for costs of sexual interactions to female *Ischnura ramburi* damselflies by comparing the success of singly mated females maintained with no males to the success of females maintained continuously with males at a 3:1 (male to female) operational sex ratio (OSR) and a 1:1 OSR. Our findings suggest that sexual interactions affect the two morphs differently. The time spent feeding, number of eggs laid and egg-laying rate of andromorphs were lower in the 3:1 OSR treatment than in the treatment with no males. Time spent feeding and number and rate of eggs laid by gynomorphs did not differ among treatments. Sexual conflict may be occurring between males and mated andromorphs because sexual interactions are associated with net costs to mated andromorphs whereas sexual interactions with mated andromorphs are beneficial to males because there is high last-male sperm precedence. Based on this experiment, andromorphs cannot be said to have an advantage over gynomorphs by avoiding costly sexual interactions because sexual interactions were not associated with net costs to gynomorphs." 2302. Smith, P.H. (2001): Diversity of dragonflies in dune ponds at Birkdale Sandhills, Sefton Coast, Merseyside. *J. Br. Dragonfly soc.* 17(1): 1-12. (in English). [11 of 16 odonate species known from this British locality breed in sand dune waterbodies. Of these, in 1994 and 1995 8 breeding species from a total of 13 observed species are analysed using different diversity indices, and counting maximum abundance. Dominant species are *Lestes sponsa* and *Enallagma cyathigerum*, *Sympetrum striolatum*, *Ischnura elegans*, and *Coenagrion puella* are fairly numerous, and the remaining eight species being relatively scarce. There is a positive relationship between the total numbers of individuals and the length of the margin at each pond. The ponds surveyed are assessed according positive and negative environmental factors.] Address: Smith, P.H., 2 Highfield Grove, Lostock Hall, Preston, Lancashire PR5 5YB, UK

2303. Spence, B. (2001): Reports from Coastal Stations - 2000: Spurn NNR, East Yorkshire. *Atropos* 12: 62-63. (in English). 2304. Stoks, R. (2001): Food stress and predator-induced stress shape developmental performance in a damselfly. *Oecologia* 127: 222-229. (in English). ["I stu-

died effects of stress factors like food shortage, non-lethal predator presence and autotomy on survival and larval performance (growth rate, development rate and developmental stability) of larvae of the damselfly *Lestes sponsa*. In a laboratory experiment, larvae were raised during their last two instars at two food levels (high or low) crossed with two levels of autotomy (caudal lamellae present or absent). These treatments were nested within three levels of predation risk (*Aeshna cyanea* absent, *Chironomus*-fed caged *Aeshna* or *Lestes*-fed caged *Aeshna*). The diet of the predator had no effects. The low food level and the presence of *Aeshna* independently increased mortality rates of *L. sponsa* larvae. The low food level, presence of a caged *Aeshna* and autotomy all independently reduced growth rate (mass and body size at day 40) and wing size at emergence, and the first two stress factors also reduced development rate. Regardless of predator presence and autotomy, all damselfly larvae consumed the food available. This indicated that the predator-induced stress effects were not due to reduced food uptake, but probably reflected lowered assimilation efficiency and/or a higher metabolic rate. Besides a low food level, the presence of caged *Aeshna* predator larvae and autotomy also increased hind wing asymmetry. This result demonstrated that predator-induced stress may reduce developmental stability in the prey." (Author)] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U. Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

2305. Tennessen, K.J. (2001): *Coryphaeschna huaorania* spec. nov. from central Ecuador with keys to all species in the genus (Odonata: Aeshnidae). *International Journal of Odonatology* 4(1): 71-81. (in English). ["*Coryphaeschna huaorania* sp. n. (holotype male: Ecuador, Morona Santiago Prov., pond 5 km N of Mendez jet., 6 Nov 1997; allotype female, same data; both to be deposited in FSCA, Gainesville, FL, USA) is described and compared with *C. amazonica*, *C. apeora*, and *C. perrensi*. The new species can be recognized by having 3 transverse rows of cells in the fork of Rs for a distance of 2 to 4 cells, and a combination of reddish frons without a dark spot, green thorax with small brown mesepisternal stripes, a reddish abdomen, and epiproct about half as long as the cerci. Separate keys are provided to males and females of the eight species currently recognized in the genus." (Author)] Address: Tennessen, K., 1949 Hickory Ave. Florence, AL 35630, USA. 2306. Theischinger, G. (2001): Preliminary keys for the identification of larvae of the Australian Synthemiidae, Gomphomacromiidae, Pseudocorduliidae, Macromiidae, and Austrocorduliidae (Odonata). Cooperative Research Centre for Freshwater Ecology Identification Guide No. 34: I-IV, 88pp. (in English). ["The more primitive Australian Libelluloidea were treated by Watson et al. (1991) under the corduliid subfamilies Synthemiinae, Gomphomacromiinae and Macromiinae. Hawking & Theischinger (1999), however, adopted for the above group of dragonflies a classification that Bechly (1996) based mainly on his own studies and on Carle (1995) and Lohmann (1996). The families Synthemiidae, Gomphomacromiidae, Pseudocorduliidae, Macromiidae and Austrocorduliidae in their present concepts are a significant portion of the Australian dragonfly fauna including 42 recognised species in 16 genera. Whereas Gomphomacromiidae, Pseudocorduliidae and Macro-

miidae each are represented in Australia by a single genus with two species, Synthemiidae and Austrocorduliidae are quite diverse, particularly at generic level. [...] It is the aim of this presentation to facilitate the identification of all known larvae of a group of Australian dragonflies whose identification up to now would have required a rather large number of papers, some of them containing misleading errors. There is also strong emphasis on the still existing gaps in our knowledge. To establish and confirm family identification, an updated version of the family key presented by Hawking & Theischinger (1999) is given at the beginning. Then there are, for each of the five families concerned, a taxonomic overview, a brief diagnosis and a key to genera and species followed by more detailed generic and specific treatments. Whereas the species lists given for each family are alphabetical, the more detailed treatments of genera and species are arranged in an order of detected similarity which may or may not reflect phylogenetic relationships. [...]. Measurements and descriptions are given from last instar larvae or from final instar exuviae. Most illustrations are given from final instar exuviae. As colouration of individuals may be variable in life due to specific conditions in the habitat and as colouration of preserved specimens may reflect the ways or methods of collection and preservation, colours are not given in the descriptions; [...] (Author)] Address: Theischinger G., 2A Hammerley Road, Grays Point, NSW 2232, Australia. 2307. Theischinger, G. (2001): Regions of taxonomic disjunction in Australian Odonata and other freshwater insects: Second addendum, with the description of *Austroaeschna unicornis pinheyi* ssp. nov. (Anisoptera: Aeshnidae). *Odonatologica* 30(1): 87-96. (in English). ["The information on taxonomic disjunction at the gap between the Paluma Range (ca 19°S) and Eugella (ca 21°S) of mostly species pairs of Odonata is updated and discussed. The holotype male of *A. u. pinheyi* ssp. n. comes from Queensland, Carnarvon Gorge (18/ 21-11-1990), deposited in ANIC, Canberra. *A. u. cooloola* Theischinger and *A. u. speciosa* Sjöstedt are appraised, respectively re-appraised, as distinct species." (Author)] Address: Theischinger G., 2A Hammerley Road, Grays Point, NSW 2232, Australia

2308. Tunmore, M. (2001): Reports from Coastal Stations - 2000: The Lizard, Cornwall. *Atropos* 12: 46-48. (in English). [United Kingdom; *Ischnura pumilio*, *Sympetrum fonscolombii*, and *S. striolatum* are communicated.] Address: Tunmore, M., 36 Tinker Lane, Meltham, Huddersfield, West Yorkshire HD7 3ES, UK

2309. Uzunov, Y.; Tzavkova, V.; Todorov, I.; Varadinova, E. (2001): The macrozoobenthic fauna of the Biosphere reserve Srebarna Lake in north-eastern Bulgaria. *Lauterbornia* 40: 43-51. (in English). ["The paper represents the results of two years regular observations on the species diversity of the benthic invertebrate communities of the Srebarna Lake - a Biosphere Reserve, World Natural Heritage Site and Ramsar Site of international importance, located on the Danube bank in north-eastern Bulgaria. All available faunistic information about the species content is associated with the data obtained in 1997-1999 as a part of a large monito-

ring program in developing a management plan of the reserve." 36 Odonata based on a survey of V. Beschovsky and M. Marinov are listed.] Address: Uzunov, Y., Central Laboratory of General Ecology, Bulgarian Academy of Sciences, 2 Gagarin Street, BG-1113 Sofia, Bulgaria

2310. Watts, P.C.; Thompson, D.J.; Kemp, S.J. (2001): A protocol for non-destructive extraction of DNA from odonates. *Odonatologica* 30(2): 223-226. (in English). ["Genetic methods are often utilised for the ecological study of odonate species. In many instances, especially from a conservation standpoint, it is desirable to employ a method of extracting DNA that does not affect the subsequent survival of the animal under investigation. Removal of part of an odonate leg has been demonstrated not to affect the subsequent reproductive success of the animal. Thus for odonates, a simple and quick method of extracting DNA from a portion of an odonate leg is presented that provides high yields of DNA suitable for PCR." (Authors)] Address: Thompson, D.J., Population Biology Research Group, School of Biological Sciences (Nicholson Building), University of Liverpool, P.O. Box 147, Liverpool, L69 3BX, UK. 2313. Wormwell, K. (2001): A very late record of Beautiful Demoiselle *Calopteryx virgo*. *Atropos* 13: 66. (in English). [8 and 12 October 2000, St. Levan, west Cornwall, UK] Address: Wormwell, K., 53 Cloughbane Drive, Ramsey, Isle of Man IM5 2BH, UK. E-mail: wormwell@mcb.net

2314. Yanoviak, S.R. (2001): Predation, resource availability, and community structure in Neotropical water-filled tree holes. *Oecologia* 126: 125-133. (in Eng-

lish). ["Predation and resource availability influence community structure in many aquatic ecosystems. Predators (odonates) and resources (leaf litter) were manipulated to determine their independent effects on macroorganism species richness, abundance, and composition in water-filled tree holes of Barro Colorado Island, Panama. Interactive effects of these factors were also investigated in artificial tree holes. Large odonates reduced species richness in natural tree holes, but did not significantly reduce macroorganism abundance. The presence of larvae of the mosquito *Culex urichii* and the ceratopogonid midge *Bezzia snowi* were negatively associated with the presence of large odonate larvae. In natural tree holes, leaf litter addition and removal respectively increased and decreased richness by c. 1 species relative to controls, and macroorganism abundance was greater in litter addition holes than in litter removal holes. Independent effects of predation showed similar patterns in artificial holes, but there was no predator x resource interaction, partly due to the short duration of the experiment. Predators grew faster when litter was abundant, and indirectly reduced litter degradation rates when resources were scarce in artificial holes. Both resource availability and predation influence species richness in water-filled tree holes, but act at different time scales; richness follows productivity (litter quantity) over a period of weeks, whereas effects of predation may span several months." (Author). *Megaloprepus coerulatus*] Address: Yanoviak, S.R., Evergreen State College, Lab I, Olympia, WA 98505, USA. E-mail: yanoviak@racsa.co.cr

1986. Orr, A.G. (1997): Odonate predation in Bornean treehole communities: some observations on predator density and prey diversity. H. Ulrich (ed.): Tropical biodiversity and systematics. Proceedings of the International Symposium on Biodiversity and Systematics in Tropical Ecosystems, Bonn, 1994. Zoologisches Forschungsinstitut und Museum Alexander König, Bonn, 1997: 223-227. (in English). ["Phytotelmata in Bornean mixed dipterocarp forest fall into several categories, the more common of which is the buttress or trunk pan. Such holes are often quite large (up to 10 litres) and are mostly filled nearly to the brim with a thick layer of leaf litter, under which is a large body of anoxic sludge. Despite apparently high rates of decomposition only a few (6-10) species make up the metazoan community, including up to three species of predatory odonate larvae; the Zygopteran *Pericnemis triangularis* (Coenagrionidae) and the Anisopterans *Lyriothemis cleis* (Libellulidae) and *Indaeschna grubaueri* (Aeshnidae). Odonates generally account for a relatively high proportion of the metazoan biomass, in some cases far exceeding the biomass of detritivores. This suggests that decomposition rates must be very high, and it is possible that high predation levels are responsible for suppressing diversity in the detritivore community." 1994. Rademacher, M. (1998): Bioökologische Untersuchungen zur Habitatpräferenz der Fledermaus-Azurjungfer (*Coenagrion pulchellum*). *Naturschutz am südlichen Oberrhein* 2: 119-128. (in German with English summary). ["In 1994 and 1995, waters in the southern and middle Upper Rhine valley serving as reproduction habitats for [...] *C. pulchellum* were studied. Vegetation maps, protocols of oviposition and emergence, and supplementary measurements of the morphology of the waters, physical and chemical parameters were employed to investigate the function of vegetation for occurrence and reproduction of the species. An experiment was conducted to document diurnal activity patterns. The results allow a detailed description of the species' preferred habitats within the study area. Threat factors and protective measures that should be

taken are discussed. In the study area, *C. pulchellum* colonizes mainly older still waters with well-developed water-plant vegetation. Oviposition and emergence sites of the examined waters can be divided into two types distinguished by their markedly different structure: A) Phytocoenoses characterized by water-plants with floating leaves (alliance *Nymphaeion*) mixed with reed and sedge vegetation (alliances *Phragmition* and *Magnocaricion*). B) Areas of waters with phytocoenoses of water-plants with floating leaves (alliance *Nymphaeion*), or containing other floating oviposition substrates, that are moderately shaded (maximum: 80 %) by overhanging woody vegetation." (Author)] Address: Rademacher, M., c/o Heidelberger Technology Center, Peter-Schumacher-Str. 8, 69181 Leimen, Germany

1995. Rademacher, M. (1998): Untersuchungen zum Schlupf- und Eiablagehabitat der Gemeinen Winterlibelle (*Sympecma fusca*) am südlichen und mittleren Oberrhein und mögliche Schutzmaßnahmen. *Naturschutz am südlichen Oberrhein* 2: 107-118. (in German with English summary). ["On 33 waters in the southern and middle Upper Rhine valley serving as reproduction habitats for *Sympecma fusca* oviposition sites and emergence sites were analyzed using standardized protocol forms. Oviposition and emergence occur in more or less extensive reed and sedge communities (alliances *Phragmition* and *Magnocaricion*) which are intensely mixed with water-plant communities. This vegetation has to be submerged from April/ May through July/ August and must have low coverages (<40 %) of emerged vegetation during the period of oviposition. The presence of a certain amount of dead or fresh plant material floating on the surface is a prerequisite for oviposition. The sites have to be well exposed to the sun during the whole day; shading by surrounding woody plants must not exceed 10 %. Compared to surrounding areas, the water temperature is markedly higher where oviposition takes place." (Author)] Address: Rademacher, M., c/o Heidelberger Technology Center, Peter-Schumacher-Str. 8, D-69181 Leimen, Germany

1997. Vogel, J. (1998): Das Dubringer Moor. *Staatliches Umweltfachamt Bautzen und Naturforschende Gesellschaft der Oberlausitz* (Hrsg.): 128 pp. (in German). [30 odonate species are listed from the bog of Dubringen, Saxonia, Germany. Population regression trends of some species are shortly outlined.] Address: Staatliches Umweltfachamt Bautzen, Postfach 1343, D-02603 Bautzen, Germany

1999

1998. D'Antonio, C. (1999): Nuovi reperti odontologici della provincia di Bergamo, Lombardia, Italia settentrionale (Odonata). *Opusc. zool. flum.* 173: 11-15. (in Italian with English summary). [So far only 4 odonate species were known from the province Bergamo, Italy. Here, an annotated provincial checklist of 30 spp. is pre-

sented. Most of these were evidenced at 23 localities in July-August 1997. The record of *Coenagrion pulchellum mediterraneum* (Schmidt) (2 males 1 female, Oltre di colle, alt. 1050 m; 9-VII-1997) is extending the northern limit of the ssp. range.] Address: D'Antonio, C., Via A. Falcone 386/b, I-80127 Napoli, Italy. E-mail: lindenia@freemail.it

1999. D'Antonio, C. (1999): Odonati della provincia di Brescia, Lombardia, Italia settentrionale (Odonata). *Opusc. zool. flum.* 173: 17-32. (in Italian with English summary). [An annotated checklist is presented of the 56 spp. hitherto known to occur in the province, based on literature and on previously unpublished material, brought together in 1997 from 46 localities. The species composition is biogeographically analysed. Also provided are concise comments on the occurrence of 15 spp., considered of particular regional interest. The complete regional bibliography is appended.] Address: D'Antonio, C., Via A. Falcone 386/b, I-80127 Napoli, Italy. E-mail: lindenia@freemail.it

2000. D'Antonio, C. (1999): Odonati italiani della collezione entomologica del Museo Civico di Scienze Naturali di Brescia (Odonata). *Opusc. zool. flum.* 173: 1-10. (in Italian with English summary). [53 spp. are listed along with the precise locality data and collection dates. *Aeshna juncea* is recorded from the province of Brescia for the first time since 1879. *Ophiogomphus cecilia* is new for the fauna of Brescia, *Somatochlora metallica* is new for that of the province of Mantova, and 20 spp. are added to the province of Cremona list. Records from the following Italian regions are dealt with: Emilia Romagna, Friuli Venezia Giulia, Liguria, Lombardia, Veneto, Sardegna, and Trentino Alto Adige. *Sympetrum fonsolombii* is listed from Corsica, France.] Address: D'Antonio, C., Via A. Falcone 386/b, I-80127 Napoli, Italy. E-mail: lindenia@freemail.it

2001. Federschmidt, A. (1999): Die Libellen der Taube und angrenzender Gräben auf dem Gebiet der Stadt Dessau. *Naturwiss. Beitr. Museum Dessau* 11: 66-73. (in German). [The River Taube (Dessau, Sachsen-Anhalt, Germany) and tributary ditches were surveyed for their dragonfly fauna. 27 species could be traced in 1995. 9 different stretches of the river including some ditches are assessed according to its species diversity. Records of *Orthetrum coerulescens*, *Ischnura pumilio*, *Calopteryx splendens*, and *Sympetrum pedemontanum* are of some regional interest.] Address: Federschmidt, A., LPR Landschaftsplanung Dr. Reichhoff GmbH, Außenstelle Magdeburg, Am Vogelgesang 2a, D-39124 Magdeburg, Germany

2002. Klop, E.; Hahn, T.; Kauth, M.; Engel, S.; Lastimoza, L.; Curio, L. (1999): Diet composition and food provisioning of the Visayan Tarictic Hornbill (*Penelopides panini panini*) during the breeding season. *Ökologie der Vögel* 21: 389-404. (in English with German summary). [Two nests of the Visayan Tarictic hornbill (Aves) on the Philippine island of Panay were monitored for a total of 465 hours, to reveal the diet composition both during the breeding season and in the course of the day. About 32 different fruit species were observed to be delivered by the male Tarictic during the nestling period, which comprise about 83% of the food items. Small insects like flies, ants and termites make up the biggest part of the invertebrate prey, whereas the vertebrate prey consisted mainly of lizards. Odonata are

among the food delivered, but the number of specimens was too small to be quantified.] Address: Curio, E.; Conservation Biology Unit, Faculty of Biology, Ruhr-Universität Bochum, D-44780 Bochum, Germany.

2003. Lange, L. (1999): Die Libellen der Wilstermarsch. *Bombus* 3(42/44): 172-176. (in German). [The odonate fauna of the marsh regions in Schleswig-Holstein, Germany is quite poorly known. Aim of the study was to make a significant contribution to close this gap of knowledge. Between 1996 and 1999 several standing water bodies were studied. A total of 33 species could be found, among them *Aeshna viridis*, a species of the European Fauna-Flora-Habitat-Directive. Influence of weather conditions in different years on the species composition of the region and the importance of selected water bodies as source habitats are outlined. Special attention is given to *Anax imperator*.] Address: Lange, L., Deichreihe 21, D-25599 Wewelsfleth, Germany

2004. Rademacher, M. (1999): Die Bedeutung von Kleingewässern in Kiesgruben für Libellen (Odonata) - Ein Fallbeispiel aus der südbadischen Trockenaue. *Ber. naturforsch. Gesell. Freiburg im Br.* 88/89: 185-222. (in German with English summary). [In a gravel pit northwest of Hartheim (Landkreis Breisgau-Hochschwarzwald, Baden-Württemberg, Germany) odonate "communities" in 22 small ponds and one gravel lake were studied from 1997 to 1999 and the results were compared with the species spectrum of 1 km along the Rhine River. Totally 32 species can be proved in the gravel pit area of which 24 species were indigenous (proof of reproduction by finding exuviae). Nearly 50% of the species are protected in Baden-Württemberg. Based on vegetation mapping four successional stages (Characeen-, Initial-, Accumulation- and Reed-Stage) were distinguished differing significantly in dragonfly species spectra. The highest species diversity was found in the accumulation-stage. A comparison with the shoreline of the river Rhine shows that many pioneer species of the ancient wild water meadow find important secondary habitats in gravel pits. The value of these secondary habitats for nature protection will be discussed and some maintenance measures for the gravel pit near Hartheim will be suggested." (Author) Finally some general proposals for dragonfly protection in gravel pits in the southern upper Rhine Valley are given.] Address: Rademacher, M., c/o Heidelberger Technology Center, Peter-Schumacher-Str. 8, 69181 Leimen, Germany

2005. Rademacher, M. (1999): Naturschutzwert von Baggerseen am Oberrhein. *Steinbruch und Sandgrube* 92(10): 6-11. (in German). [Presentation of some results of an intensive study of vegetation of the gravel pits in the upper Rhine floodplains, Germany. The importance of gravel pits for Odonata is shortly outlined. For more details see OAS 2004.] Address: Rademacher, M., c/o Heidelberger Technology Center, Peter-Schumacher-Str. 8, 69181 Leimen, Germany

2006. Rademacher, M. (1999): Naturschutzwert von Kies- und Sandrohböden im Bereich von Baggerseen der Oberrheinebene - Statusbericht. *Schriftenreihe der Umweltberatung im ISTE Baden-Württemberg* 2: 75-83. (in German). [M. Rademacher studied intensively in the past years vegetation and fauna - with special emphasis Odonata - of gravel pits. Results of his study, relevant for nature conservation measures, are outlined.

Odonata are discussed in terms of habitat requirements of *Sympecma fusca* and *Leucorrhinia caudalis*. Odonata demonstrate that the different aging stages of gravel pits have their own importance for different odonate coenocenes. In the case of *L. caudalis*, this extremely rare and threatened species stands for the stage of old gravel pits, often assessed as less important for nature conservation purposes.] Address: Rademacher, M., c/o Heidelberger Technology Center, Peter-Schumacher-Str. 8, 69181 Leimen, Germany

2000

2007. Anderson, N.; Barclay, M.; Menzies, I.S.; Page, K.; Prowse, A.D.; Swinney, I.F.; Willmott, K.J. (2000): Survey of Bookham Common: Fifty-eighth year: Progress report for 1999. *London Naturalist* 79: 177-186. (in English). [Anderson reports of two visits in July and August at two standing waters. The results, some more common odonate species in low abundance, are assessed as disappointing. It is supposed that fish have a significant negative impact on odonate fauna of the waters] Address: Anderson, N., 52 Beechwood Avenue, Greenford, Middlesex, UB6 9UB, UK

2008. Andres, J. A.; Sanchez-Guillen, R.A.; Cordero Rivera, A. (2000): Molecular evidence for selection on female color polymorphism in the damselfly *Ischnura graellsii*. *Evolution* 54(6): 2156-2161. (in English). ["The significance of female color polymorphism in Odonata remains controversial despite many field studies. The importance of random factors (founder effects, genetic drift and migration) versus selective forces for the maintenance of this polymorphism is still discussed. In this study, we specifically test whether the female color polymorphism of *Ischnura graellsii* (Odonata, Coenagrionidae) is under selection in the wild. We compared the degree of genetic differentiation based on RAPD markers (assumed to be neutral) with the degree of differentiation based on color alleles. Weir and Cockerham's theta values showed a significant degree of population differentiation for both sets of loci (RAPD and color alleles) but the estimated degree of population differentiation (theta) was significantly greater for the set of RAPD loci. This result shows that some sort of selection contributes to the maintenance of similar color morph frequencies across the studied populations. Our results combined with those of previous field studies suggest that at least in some *I. graellsii* populations, density-dependent mechanisms might help to prevent the loss of this polymorphism but cannot explain the similarity in morph frequencies among populations." (Authors)] Address: Andres, J. A., Animal Ecology, Ecology & Environmental Science, Umea University, SE 90187, Umea, Sweden. E-mail: jose.andres@eg.umu.se

2009. Arnold, A. (2000): Verbreitungsatlas der Libellen im Regierungsbezirk Leipzig. Veröffentlichungen des Naturkundemuseum Leipzig 19: 55-144. (in German with English summary). [More than 4400 data sets of odonatological records are compiled for the district Leipzig, situated in the west of Saxonia, Germany. 58 species could be traced. They are presented in a monographic way. Each species is discussed in most cases presenting interesting original material from the region or adjacent regions, e.g. reflections about colonisation and dispersal of the studied area by some spe-

cies (e.g. *Brachytron pratense*). Faunistic records are analyzed for the periods 1884-1945, 1946-1980, and 1981-1996, and presented in distribution maps. 12 additional species, occurring in neighbouring regions, are shortly discussed. The history of regional odonatological research is outlined, trends of development of populations, and the phenology of species are presented in some detail. This is a sound study with a lot of interesting material. Nevertheless it will be necessary to correct the chapter on *Coenagrion armatum*: we have to assume that this species never was represented in Saxonia (for details see Müller & Schorr, 2001: 41f.; **OAS 2160**).] Address: Arnold, A., Zur schönen Aussicht 25, D-04435 Schkeuditz, Germany

2010. Barker, J.J. (2000): Dragonfly Migration in the western Lake Ontario area in 1999. In: Cating, P.M., C.D. Jones & P. Pratt (Eds): *Ontario Odonata*, vol. 1. Toronto Entomologist's Association, Toronto, Ontario: 49-50. (in English). [Approximately 4000 dragonflies were recorded at two locations in the western Lake Ontario area in August and September 1999 during monitoring of hawk migration. The dominant *Anax junius* and *Tamea lacerata*, but *Pantala flavescens* and *P. hymenaea* were also present.] Address: Barker, J.J., 55-4101 Westminster Place, Mississauga, Ontario L4W 4X4, Canada

2011. Berrady, I.; Essafi, K.; Mathieu, J. (2000): Comparative physico-chemical and faunal studies of two thermal springbrooks near Sidi Harazem (Morocco). *Annales de Limnologie* 36(4): 261-274. (in English with French summary). ["The origin of the water of the two Sidi Harazem springs (Morocco), was found to be different. Environmental parameters made it possible to recognise three types of water: one issuing from a "cool spring", with lowest temperature (mean: 26.7°C), conductivity and chloride concentration; one issuing from the "hot spring" (mean: 31.7°C) with the highest temperature and high conductivity; and the one of the oued itself with into which both springs flow. This oued had the highest values of pH, conductivity, chlorides, and calcium. The interstitial fauna collected by means of artificial substrates was composed of both epigeal and stygobite species. Only the "cool spring" included stygobite species, the number of which generally decreased with depth." (Authors) "Odonata" are recorded on sampling sites of the "hot spring" upstream, but not at the "cools spring" or "cool stream".] Address: Mathieu, J., Laboratoire d'Hydrobiologie et Ecologie Souterraines, Université Claude Bernard Lyon I, ESA CNRS 5023, 43 Bd du 11 Novembre 1918, F-69622, Villeurbanne Cedex, France. [The odonate fauna of a petrol depot, used until 1991, and situated near Chemnitz, Saxonia, Germany, totals in 27 species. The results of the study - arranged according to the odonate dominance structure of the surveyed water bodies - are compiled in a tab., and shortly discussed. Some emphasis is given to the function and importance of short turf vegetation including heathlands as hunting area of *Lestes sponsa* and *L. virens*, as well as the genera *Aeshna* and *Sympetrum*.] Address: Eisermann, K., Carl-von-Ossietzky-Str. 213, D-09127 Chemnitz, Germany
- 2021.** Eterovick, P.C.; Sazima, I. (2000): Structure of an anuran community in a montane meadow in southeastern Brazil: Effects of seasonality, habitat, and predation. *Amphibia-Reptilia* 21(4): 439-461. (in English). ["In order to assess the main factors influencing its structure, an anuran community was studied from August 1996 to July 1997, in a 1200 m high rocky meadow site at the Serra do Cipo, Minas Gerais, Brasil, a region with markedly seasonal climate. The study site

included three temporary habitats: a stream, a puddle, and a swamp. Thirteen anuran species were recorded at the study site. Species of tadpoles differed in microhabitat as to their position in water column, annual occurrence period, and water flow in the occupied sites. Aquatic vegetation, depth and occupied habitat (stream, swamp, or puddle) were of secondary importance in telling species apart. Calling sites of males were distinguished based on occupied habitat and annual activity period. Most species started their reproductive activities at the onset of the rains, in an opportunistic way. Water availability in the habitat seems to be the most important factor affecting temporal distribution of reproductive activities in the anuran community. Competitive interactions could not be detected in the community. The most important tadpole predators recorded at the study site were belostomatid water bugs and dragonfly nymphs. Their abundance peaks occurred after those of tadpoles, as predicted for predator-prey populations with interconnected cycles. Mortality rates were high for tadpoles, and predation is the most likely cause. Differences recorded among species, considering time of occurrence, tadpole microhabitats, and male calling sites, may reflect distinct specific adaptations and preferences." (Authors)] Address: Eterovick, Paula Cabral, Departamento de Biologia Geral, Instituto de Ciencias Biologicas, Universidade Federal de Minas Gerais, 30161-970, Belo Horizonte, MG, Brazil. 2022. France, R. L.; Schlaepfer, M. A. (2000): 13C and 15N depletion in components of a foodweb from an ephemeral boreal wetland compared to boreal lakes: Putative evidence for microbial processes. *Hydrobiologia* 439: 1-6. (in English). ["Stable carbon and nitrogen isotope ratios were used to posit the relative importance of microbial processes on energy pathways in an ephemeral, humic boreal wetland compared to four clearwater lakes in northwestern Ontario, Canada. In addition to algae and dipteran larvae, odonate larvae were sampled as these latter organisms are known to predate indiscriminately on smaller invertebrates and are thus likely to have average isotope ratios reflective of their habitats. Similarities in delta13C and delta15N values between lake insect larvae and emerged adults suggested that littoral foodwebs in these oligotrophic lakes may rely to a considerable degree upon terrestrial carbon. Wetland insect larvae and algae were depleted in both 13C and 15N compared to biota in lakes Carbon isotope analysis implied a substantial presence of microbial respiration from decomposition in the humic wetland, whereas nitrogen isotope analysis suggested the prevalence of microbially modified nitrogen dynamics, including the possibility of N-fixation." (Authors)] Address: France, R. L., Graduate School of Design, Harvard University, 48 Quincy Street, Cambridge, MA, 02138 USA

2023. Gorb, S.N.; Kesel, A.; Berger, J. (2000): Microsculpture of the wing surface in Odonata: evidence for cuticular wax covering. *Arthropod Structure & Development* 29: 129-135. (in English). ["The insect wing membrane is usually covered by scales, hairs, and acanthae, which serve diverse functions, such as species-specific coloration pattern, decrease of wind resistance during flight or decrease of wing wettability. Representatives of Palaeoptera (Odonata and Ephemeroptera) have no hairy structures on the wing membrane, but both its sides are fine-sculptured. In this study,

the nature of the wing covering was studied using acoustic microscopy, scanning- and transmission electron microscopy followed by a variety of chemical treatments. It was shown that wing microsculptures are not cuticular outgrowths, but a wax covering, which is similar to pruinosity, which has been previously described in several odonate taxa. Data from scanning acoustic microscopy revealed that scratches on the wax covering have material density different from the surrounding material. Various functions of the wax covering are discussed." (Authors) Coenagrion puella, Pyrrhosoma nymphula, Aeshna cyanea] Address: Gorb, S., Max-Planck-Institut für Entwicklungsbiologie, Spemannstr. 35, D-72076 Tübingen, Germany. 2026. Hayes, P.A.; Maret, T.J. (2000): Wood frog and American toad tadpole behavioral responses to predators. *Journal of the Pennsylvania Academy of Science* 73 (Suppl.): 160. (in English). [Verbatim: "We examined the behavioral responses of tadpoles of wood frogs, *Rana sylvatica*, and American toads, *Bufo americanus* to the presence of bluegill sunfish, adult red-spotted newts, marbled salamander larvae, and dragonfly naiads. Groups of ten tadpoles of one species were placed into containers of water containing one large leaf as a hiding place and a wire cage into which a predator was added. The numbers of tadpoles moving and hiding under the leaf were counted before and after addition of a predator to the cage. Movement of wood frog tadpoles decreased in the presence of the newts and salamander larvae. Hiding by wood frog tadpoles increased in the presence of salamander larvae. Toad tadpoles, which are considered to be unpalatable to many vertebrates, showed no significant responses to presence of any predators. Wood frog tadpoles appear to respond adaptively to avoid predation by vertebrate predators they naturally encounter in temporary pond habitats."] Address: Hayes, P.A., Department of Biology, Shippensburg University, Shippensburg, PA, 17257 USA

2027. Hostettler, K. (2000): Neue Funde der Sibirischen Winterlibelle und der Gemeinen Keiljungfer (*Odonata*) im Gottlieber Ried und am Seerhein (Thurgau). *Mitt. thurg. naturf. Ges.* 56: 83-88. (in German). [In the "Gottlieber Ried" and along the "Tägerwilen See-Rhein", situated in the south of the Bodensee ("Lake Constanze"), Switzerland, 19 odonate species were recorded between 1985 and 1996 with *Ischnura pumilio* as an additional record in 2000. The reproduction habitat of *Sympecma paedisca* and its strategies to recognize suitable habitats are discussed in detail with special reference to factors as high waters. The regionally rare *Gomphus vulgatissimus* was found 21 May 1995.] Address: Hostettler, K., Schulstr. 7, CH-8590 Romanshorn, Switzerland

2028. Jones, C.D. (2000): Common Garter Snake (*Thamnophis sirtalis*) preying upon a teneral Black-tipped Darner (*Aeshna tuberculifer*) at Bat Lake, Algonquin Provincial Park, Ontario. In: Catling, P.M.; Jones, C.D.; Pratt, P. (Eds.): *Ontario Odonata*, vol. 1. Toronto Entomologists Association. ISBN 0-921631-22-7: 22-24. (in English). ["A review of the literature revealed that an observation of a Common Garter Snake [...] preying upon [...] *A. tuberculifer* is possibly the first unequivocal evidence of adult odonates as food items of garter snakes. Aspects of insects in the diet of garter snakes are discussed." (Author)] Address: Jones, C.D., Box 182, Lakefield, Ontario, K0L 2H0, Canada. E-mail: colin.jones@mnr.gov.on.ca

2029. Jones, C.D. (2000): New odonate records for Timiskaming District, Ontario. In: Cating, P.M., C.D. Jones & P. Pratt (Eds): *Ontario Odonata*, vol. 1. Toronto Entomologist's Association, Toronto, Ontario: 25-27. (in English). ["Sixteen new district records are reported for Timiskaming District, Ontario. A record of *Enallagma carunculatum* is a northern range extension. The rare species *Somatochlora incurvata* was discovered and the habitat described."] Address: Jones, C.D., Box 182, Lakefield, Ontario, K0L 2H0, Canada. E-mail: colin.jones@mnr.gov.on.ca

2030. Jones, C.D.; Holder, M.L. (2000): Additions to (and a deletion from) the Odonata list of Algonquin Provincial Park. In: Cating, P.M., C.D. Jones & P. Pratt (Eds): *Ontario Odonata*, vol. 1. Toronto Entomologist's Association, Toronto, Ontario: 13-17. (in English). ["Continued interest in the Odonata by Park Naturalists in Algonquin Provincial Park has led to the addition of 14 species (*Lestes forcipatus*, *Amphiagrion saucium*, *Coenagrion interrogatum*, *Enallagma carunculatum*, *E. cyathigerum*, *E. geminatum*, *Nehalennia gracilis*, *Epi-aeschna heros*, *Gomphaeschna firicillata*, *Arigomphus jurcifer*, *Somatochlora cingulata*, *Williamsonia fletcheri*, *Leucorrhinia intacta*, and *Nannothemis bella*) and the deletion of one (*Stylurus spiniceps*) from the Park's list since 1996. These changes are reported here along with annotations." (Authors)] Address: Jones, C.D., Box 182, Lakefield, Ontario, K0L 2H0, Canada

2031. Jones, C.D.; Michener, C.; Purdon, C.; Runtz, M.W.P. (2000): An annotated checklist of the Odonata of Renfrew County, Ontario. In: Cating, P.M., C.D. Jones & P. Pratt (Eds): *Ontario Odonata*, vol. 1. Toronto Entomologist's Association, Toronto, Ontario: 39-48. (in English). ["An annotated checklist of the Odonata of Renfrew County, Ontario is presented detailing the records for 93 species (26 Zygoptera, and 67 Anisoptera).

A list of an additional 36 species expected to occur in the county is also provided. This makes Renfrew the third in known diversity of approximately 50 Ontario counties and districts. Noteworthy species include *Gomphus vastus*, *Ophiogomphus anomalus*, *Stylurus spiniceps*, *S. notatus* and *Aeshna clepsydra*, the latter at or near to its northern limit." (Authors)] Address: Jones, C.D., Box 182, Lakefield, Ontario, K0L 2H0, Canada. E-mail: colin.jones@mnr.gov.on.ca

2032. Kalkman, V.; Dijkstra, K.D. (2000): The dragonflies of the Bialowieza area, Poland and Belarus (*Odonata*). *Opusc. zool. flumin* 185: 1-19. (in English). ["A synthesis of 942 records from the Bialowieza Forest and its surroundings, collected in 1983, 1990, 1993 and 1995-1999, is presented. Only 10% of them refer to Belarus, the rest being from Poland. A total of 49 spp was found. The fauna includes southern elements (*Sympecma fusca*, *Lestes barbarus*, *Erythromma viridulum*, *Ischnura pumilio*, *Anax imperator*, *Crocothemis erythraea*, *Orthetrum albisylum*, and *Sympetrum depressusculum*) and interesting northern and eastern spp (*Sympecma paedisca*, *Coenagrion armatum*, *C. hastulatum*, *C. lunulatum*, *Ophiogomphus cecilia*, *Epi-theca bimaculata*, *Somatochlora arctica*, *Sympetrum pedemontanum*, *Leucorrhinia albifrons*, *L. caudalis*, and *L. pectoralis*). Brief remarks are made about differences in habitat preference of spp between western and eastern Europe. It is postulated that *Pyrrhosoma nymphula* is restricted to running waters in the East. A short note on the subspecific status of *Somatochlora metallica* in northeastern Europe is added. It is concluded that specimens show a mix of features of the ssp. *metallica* and *abocanica* and that the recognition of the latter in the region by H. Lohmann (1994, *Notul. odonol.* 4: 39-40) is unjustified. The value of the area as a reference for conservation is discussed and conservation priorities are stressed." (Authors)] Address: Kalkman, V.J., Oude Rijnsburgerweg 28, NL-2342 BC Oegstgeest, The Netherlands. E-mail: kalkmann@naturalis.nnm.nl

2035. Kuhn, K. (2000): Untersuchungen zum Vorkommen der Helm-Azurjungfer (*Coenagrion mercuriale* Charpentier, 1840) im mittleren Mindeltal (Insecta, Odonata). Ber. naturf. Ges. Augsburg 59: 39-50. (in German). [Bavaria, Germany; the general amendment of regional running waters in the past 170 years, and the distribution of the species in Bavaria are outlined, and known regional records are compiled. The habitats of five populations of *C. mercuriale* are described in detail and the habitat requirements are analysed. The velocity and aquatic and riparian vegetation are of principal importance, while the quality of water is but rarely of any significance in habitat choice of *C. mercuriale* in this area. In addition, abundance and accompanying odonate species are dealt with.] Address: Kuhn, K., Ravensburgerstr. 7, D-86150 Augsburg

2036. Labeledzki, A. (2000): Dragonflies (Odonata) in the Bieszczady Mountains. In: Pawlowski, J. (Ed.): Osirodek Naukowy - Dydaktyczny Bieszczadzkiego Parku Narodowego. Monografie Bieszczadzkie VII. Bezkręgowce Bieszczadów Zachodnich ze Szczególnym uwzględnieniem Bielszczadzkiego Parku Narodowego Czesc. Ustrzyki Dolne: 157-163. (in Polish with English summary). ["Data from the literature and the results of contemporary studies indicate that the Bieszczady Mountains harbour 45 dragonfly species, which constitutes 62,5% of the native dragonfly fauna in Poland (72 species). In the Bieszczady National Park and its protection zone 30 dragonfly species have been identified. Among them there are 4 protected species (*Sympetma braueri* Bianchi, *Ophiogomphus cecilia* (Fourcroy), *Leucorrhinia albifrons* (Burmeister), *Leucorrhinia pectoralis* (Charpentier), of the total of 7 dragonfly species protected by law in Poland. In respect of the number of southern taxa, the BdnP is one of the richest national parks in Poland. In the Bieszczady fauna the most interesting and valuable dragonfly species are *Ophiogomphus cecilia*, *Aeshna affinis*, *Hemianax ephippiger*, *Cordulegaster bidentatus*, *Crocothemis erythraea*, *Tarnetrum fonscolombii*, *Leucorrhinia albifrons*, and *Leucorrhinia pectoralis*. Among the most endangered species one should reckon taxa connected with small water bodies (*O. cecilia*, *C. bidentatus*, and *O. coerulescens*) and acid bog waters (*S. braueri*, *L. albifrons*, and *L. pectoralis*) because these species can not develop in replacement sites. The best form of conservation of rare and critically endangered species in the Bieszczady National Park and its protection zone should be protection of their biotopes, as recommended by the European Commission of Nature and Natural Resources Conservation. Individual species protection does not produce satisfactory results, as exemplified by *O. cecilia* in Poland." (Author) *Sympetrum meridionale* is also listed; this record is of special faunistic interest in central Europe.] Address: Labeledzki, A., Akademia Rolnicza, Katedra Entomologii Lesnej, ull. Wojska Polskiego 71c, PL-60-625 Poznan, Poland. E-mail: andrzejlab@poczta.onet.pl

D'Antonio, Via A. Falcone 386/b, 1-80127 Napoli, Italy; E-mail: lindenia@freemail.it

2038. Lüderitz, V.; Pütter, S.; Heidecke, F.; Jüpner, R. (2000): Revitalisierung der Alten Elbe bei Magdeburg - ökologische und wasserwirtschaftliche Grundlagen. Abhandlungen und Berichte für Naturkunde, Magdeburg 23: 29-46. (in German with English summary). [A project for revitalisation of the old water course of river Elbe near Magdeburg, Sachsen-Anhalt, Germany is scheduled. An extensive study of biological and hydrological factors was realised including a survey of the Odonata. 38 species were traced including *Anaciaeschna isosceles*, *Aeshna viridis*, *Somatochlora flavomaculata*, *Leucorrhinia pectoralis*, and *Coenagrion lunulatum*. The species are arranged according to a classification of dragonflies in coenoses erected by J. Müller (1996).] Address: Heidecke, F., BUND Sachsen-Anhalt, Olvenstedter Str. 10, D-39108 Magdeburg, Germany

2039. Marden, J.H.; Rowan, B. (2000): Growth, differential survival, and shifting sex ratio of free-living *Libellula pulchella* (Odonata: Libellulidae) dragonflies during adult maturation. *Annals of the Entomological Society of America* 93(3): 452-458. (in English). ["We performed a mark-recapture study to determine rates of change in body mass during maturation of adult free-living *L. pulchella* dragonflies. We captured, weighed, marked, and released 444 individuals (278 females, 166 males) that were 0-5 d old, including 261 that had emerged on the day of initial capture. On subsequent days, we recaptured 87 individuals at least once, and 6 were recaptured more than once. Nearly all new emergents (mean mass = 272 mg) that were recaptured after 1 or 2 d had lost mass (mean change = -29 mg), whereas most individuals recaptured after 3 days had gained mass (mean change = 109 mg; mean rate = 18 mg/d). Individuals that were heavier at emergence were much more likely to gain mass and to be recaptured at ages >1 or 2 d, thus suggesting differential survivorship based on size at emergence. Average growth rates of gainers were as high as 57 mg/d over a 5-d period. The sex ratio of newly emerged adults was heavily biased toward females (61%), but males were significantly larger at emergence, were more successful at gaining mass, and the sex ratio of individuals that ultimately gained mass did not differ significantly from 1:1. New emergents had empty guts and minimal fat, and changes in fat and water content explained very little of the average decrease in body mass observed for most new emergents. Overall, our data suggest that *L. pulchella* dragonflies face severe energy stress during early adult maturation, which strongly affects their demography." (Authors)] Address: Marden, J.H., Dept Biol., Pennsylvania St. University, 208 Mueller Laboratory, University Park, PA 16802, USA

2040. McPeck, M.A. (2000): Predisposed to adapt? Clade-level differences in characters affecting swimming performance in damselflies. *Evolution* 54(6):

2072-2080. (in English). ["Previous studies have shown that two or three lineages of *Enallagma* damselflies, which historically co-existed with fish, recently invaded and adapted to living with large dragonfly predators in fishless waters. In adapting to live with these new predators, lineages shifted behaviorally to using swimming as an evasive tactic against attacking predators, evolved morphological features that made them faster swimmers, and evolved biochemical features to increase refueling strenuous activities like swimming. However, these habitat shifts have occurred in only one of the two primary clades within the genus in North America. Here, I show that clade-level differences exist among species in the ancestral, fish-lake habitat that should make habitat shifts easier to accomplish in the clade in which they have occurred. Specifically, fish-lake species in the clade in which habitat shifts occurred have much higher propensities to swim in the laboratory, swim faster when they do swim, and have higher mass-specific activities for arginine kinase than do species in the other primary clade, in which no extant species are found in fishless waters. These results are discussed in the context of the dynamics of founder events and the potential implications for community structure." (Authors)] Address: McPeck, M., Dept Biol. Sci., Dartmouth College, Hanover, New Hampshire 03755, USA. E-mail: mark.mcpeek@dartmouth.edu

2041. Oldham, M.J. (2000): Citrine Forktail (*Ischnura hastata*) in Ontario. In: Cating, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 1. Toronto Entomologist's Association, Toronto, Ontario: 7-9. (in English). [I. *hastata* "is reported from three sites in three SW Ontario counties (Kent, Essex, and Wellington) based on collections made in 1999. The three previous Ontario records are discussed and mapped and information is provided on habitat and identification." 2045. Pudwill, R. (2000): Kolonisation und Populationsdynamik von Libellen an neu angelegten Moorweihern (Odonata). Braunschweiger Naturk. Schr. 6(1): 57-67. (in German with English summary). ["The dragonfly fauna of a newly made acid and oligotrophic moor pond in Lower Saxony, Germany was investigated for 3 years. 25 species were recorded as adults, 16 of them as exuviae. The dragonfly fauna was a typical bog fauna. Characteristic species were: *Leucorrhinia dubia*, *Leucorrhinia rubicunda*, *Aeshna juncea*, and *Sympetrum danae*." (Author) Emergence patterns of *Anax imperator*, *Leucorrhinia dubia*, *L. rubicunda*, *Libellula quadrimaculata*, *Aeshna juncea*, and *Sympetrum danae* are documented in detail.] Address: Pudwill, R., Böttcherstr. 3, D-38518, Gifhorn, Germany

2046. Rademacher, M. (2000): Pilotprojekt "Konfliktarme Baggerseen". Ergebnisse und Erfahrungen am Beispiel der Region Oberrhein - Naturschutz-Asepkte. Beiträge der Akademie für Natur- und Umweltschutz Baden-Württemberg 29: 183-194. (in German). [Conflicts between excavation of gravel in the alluvium of River Rhine, Germany and succeeding use for different purposes are studied with special emphasize on nature conservation purposes. Different succession stadia of vegetation and odonate fauna in gravel pits and possibilities to maintain different old stadia are discussed.] Address: Rademacher, M., c/o Heidelberger Technology Center, Peter-Schumacher-Str. 8, D-69181 Leimen, Germany

2047. Rantala, M.J.; Koskimaki, J.; Taskinen, J.; Tynkkynen, K.; Suhonen, J. (2000): Immunocompetence, developmental stability and wingspot size in the damselfly *Calopteryx splendens* L.. Proc. of the Royal Society Biological Sciences Series B 267(1460): 2453-2457. (in English). ["*Calopteryx splendens* males exhibit a remarkable variation in wing pigmentation both within and between populations. In this study, we examined whether the wingspots of male *C. splendens* are related to male quality. We measured the nylon implant en-

capsulation rate for 85 males and found that males with larger wingspots had a faster encapsulation rate, indicating a better immunocompetence. We also found that the encapsulation rate was positively correlated with the density of haemocytes in the haemolymph. Another measurement of male quality, fluctuating asymmetry of wingspots, correlated negatively with the size of the wingspots. Males with asymmetrical wingspots also had lower encapsulation rates than more symmetrical males. Our results suggest that the size of wingspot is an indicator of male quality in *C. splendens*." (Authors)] Address: Rantala, M., Dept of Biological and Environmental Science, University of Jyväskylä, FIN-40351, Jyväskylä, Finland. E-mail: marrant@st.jyu.fi

2048. Salm, P. (2000): Methodentests zur Erfassung von Arten der Anhänge II, IV und V der FFH-Richtlinie. Schriftenreihe für Landschaftspflege und Naturschutz 68: 137-151. (in German with English summary). [Article 17 of the Fauna-Flora-Habitat Directive requires the member states to produce a report at six-year intervals concerning the implications of the required measures and their effects on the Annex I habitat types and on the Annex II species. Therefore, the Federal Agency for Nature Conservation at Bonn, Germany carried out a research project „Selection of parameters and tests of methods to record and evaluate the conservation status of species and habitat types according to the Habitats Directive". The aim of the project was to suggest how these reporting obligations should be implemented. The study of species from the Habitats Directive Annexes served for the development of a standardised method for the conservation-orientated implementation of the reporting obligations. An overview of the species studied is given in this paper; as an example a study on *Aeshna viridis* is presented.] Address: Salm, Petra, c/o Landschaftsökologisches Planungsbüro Stelzig, Aldegreverwall 1, D-59594 Soest, Germany

2049. Schnabel, H. (2000): Der Libellenbestand eines Naturschutzteiches am Stadtrand von Wittichenau. Veröff. Mus. Westlausitz Kamenz 22: 57-64. (in German). [Saxonia, Germany; after restoration of the standing water, between 1996 and 1998 22 odonate species could be observed.] Address: Schnabel, H., Keula 16, D-02997 Wittichenau, Germany

2050. Schoorl, J. W. (2000): Notes on Central Asian dragonflies (Insecta: Odonata). Zoologische Mededelingen (Leiden) 74: 205-213. (in English). ["New and old material from Central Asia is published. In total 38 species are recorded from various locations in this region. For the more interesting species notes and figures are provided. One probably new *Ischnura* species is briefly described, but not formally named. For a, possibly new, subspecies of *Sympetrum sinaiticum* Dumont, 1977, a short diagnosis with figures is provided." (Author) The material studied was collected in Turkmenistan, Tajikistan, Kirgizistan, and Uzbekistan. *Calopteryx orientalis*, *Sympecma fusca*, *S. gobica*, *S. paedisca*, *Lestes barbarus*, *Callaeschna microstigma*, *Cordulegaster insignis*, *Sympetrum striolatum*, *S. vulgatum*, and *S. sinaiticum* are commented more in detail, and partly illustrated. Of some interest are the records of *Onychogomphus forcipatus* in the eastern part of its range and of the very rare *Ladona pontica*.] Address: Schoorl, J. W., Jr., F Simonszstraat 86 II, 1017 TK, Amsterdam, The Netherlands

2051. Stoks, R.; Johansson, F. (2000): Trading off mortality risk against foraging effort in damselflies that differ in life cycle length. *Oikos* 91(3): 559-567. (in English). ["Life history theory predicts that size and age at emergence depend on the slope and shape of the relationship between mortality rate and foraging effort. Given the high expected foraging effort in obligate univoltine species compared with semivoltine species we expected a low slope and an increase in foraging effort in the presence of a predator for the former and the opposite pattern for the latter. We tested these predictions in two damselfly species of the univoltine genus *Lestes*, and the semi-voltine genus *Coenagrion* when confronted with perch. We determined for each of the four study species the relationships between mortality rate and foraging effort at an individual level. As expected by the different growth demands associated with differences in life cycle length, both *Lestes* species had a higher foraging effort than the two *Coenagrion* species in the absence as well as in the presence of perch. As a result, *lestids* also suffered a higher mortality rate. The slope of the regression between mortality rate and foraging effort was, as predicted, lower for *lestids* than for *coenagrionids*, for one species pair. Despite this, and opposite to our prediction, the *lestids* decreased foraging effort even more than *coenagrionids* in the presence of perch. We discuss these findings in the light of life history responses in species that differ in life cycle length." (Authors)] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be
