4125. Catling, P.M.; Carriere, S.; Johnson, D.; Fournier, M. (2004): *Dragonflies of the Northwest Territories, Canada: new records, ecological observations and a checklist*. *Argia* 16(1): 9-13. (in English). [oas 14: (1) New records for the Northwestern Territories (NWT) are: *Stylurus notatus*, *Somatochlora minor*, *Aeshna canadensis*, *Lestes forcipata*, and *Enallagma ebrium*. (2) *Aeshna eremita* consuming biting insects: Traversing an open bog, specimens of *A. eremita* flew in to glean mosquitos, deer flies, horse flies, and blackflies mostly from the top of the head or the shoulders of one of the authors. (3) *A. eremita* adapting foraging behaviour to specific prey: *A. eremita* was observed to prey on *Lestes disjunctus*. (4) *A. eremita* capturing and feeding on *A. juncea*: A female *A. eremita* preyed on a male *A. juncea*. (5) Hilltopping of *Lestes congener*: *L. congener* was found on the top of hills, no specimens could be traced at the pools located app. 200 m apart. (6): Birds feeding on dragonflies hit by cars: The numbers of dragonflies per mile killed by car collisions on a sunny day of July ist astimated to several hunderts. Of 110 species examined in a mile of a highway *Aeshna eremita* represented 60%, *A. juncea* 30%, and *A. interrupta lineata* 10%. The killed specimens were quickly devoured by birds as ravens and gulls. (7) Directional movement of *Aeshna* species: *Aeshna* sp. (in most cases *A. eremita*) "on average crossed one hundred meter of road every minute". (8) Dependence of endangered bird on dragonflies: "At certain times dragonflies make up to 80% of the food of endangered Whooping Cranes (*Grus americanus*) (9) Dragonfly outing a success: On 19 July 2003, the first NWT dragonfly outing was held at the Northern Frontier Visitors Centre, Yellowknife. Almost 100 people (Families, childrens etc.) participated. 13 odonate species were traced and demonstrated. (10) Dragonflies and biodiversity protection: The results of the NWT Biodiversity Action Plan (including 209 odonate species) are advertised to be published on <http://www.wildspecies.ca>. (11) Checklist of the dragonflies of the NWT: The checklist includes 40 species.] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, Ontario K0A 2P0, Canada. 4126. Cham, S.A. (2004): *Dragonflies of Bedfordshire*. Bedfordshire Natural History Society, Luton. ISBN 0-9506521-7-2: 145 pp. (in English). [Regional dragonfly books have a long lasting tradition in UK. To see the evolution of this kind of books, Steve Cham's book is a good example: starting in the 1970th as a kind of "handmade" regional fauna it developed to a highly professional designed book using the latest digital and mapping technology. Species distribution mapping of dragonflies is presented in a special, highly informative chapter. The book covers the usual introducing chapters as morphology and (regional) habitats. It informs on predators and field technics to survey Odonata. The phenology of species is documented in most impressive graphs, and dragonfly recording in Bedfordshire is outlined. The 32 Bedfordshire species are documented monographically giving information on distinctive features, habitat, the past and current distribution in Bedfordshire, conservation status, highly informative field notes, and the flight period. Excellent colour pictures of the species, sometimes larvae, and excellent maps of the species distribution in UK / Ireland and in Bedford-

shire provide highly welcome information. I am really impressed by this book. (Martin Schorr)] Address: Bedfordshire Natural History Society, Bedford Museum, Castle Lane, Bedford MK40 3XD, UK. Orders of the book should be directed to Peter Glenister: E-mail: PEGlenister@ukonline.co.uk. The book is priced £ 24.50.

4127. Cleary, D.F.R.; Mooers, A.O.; Eichhorn, K.A.O.; Tol, J. van; Jong, R. de; Menken, S.B.J. (2004): Diversity and community composition of butterflies and odonates in an ENSO-induced fire affected habitat mosaic: a case study from East Kalimantan, Indonesia. *Oikos* 105(2): 426-448. (in English). ["Little is known about the diversity of tropical animal communities in recently fire-affected environments. Here we assessed species richness, evenness, and community similarity of butterflies and odonates in landscapes located in unburned isolates and burned areas in a habitat mosaic that was severely affected by the 1997/98 ENSO (El Niño Southern Oscillation) event in east Kalimantan, Indonesian Borneo. In addition related community similarity to variation in geographic distance between sampling sites and the habitat/vegetation structure Species richness and evenness differed significantly among landscapes but there was no congruence between both taxa. The species richness of butterflies was, for example, highest in sites located in a very large unburned isolate whereas odonate species richness was highest in sites located in a small unburned isolate and once-burned forest. We also found substantial variation in the habitat/vegetation structure among landscapes but this was mainly due to variation between unburned and burned landscapes and variation among burned landscapes. Both distance and environment (habitat/vegetation) contributed substantially to explaining variation in the community similarity (beta diversity) of both taxa. The contribution of the environment was, however, mainly due to variation between unburned and burned landscapes, which contained very different assemblages of both taxa. Sites located in the burned forest contained assemblages that were intermediate between assemblages from sites in unburned forest and sites from a highly degraded slash-and-burn area indicating that the burned forest was probably recolonised by species from these disparate environments. We, furthermore, note that in contrast to species richness (alpha diversity) the patterns of community similarity (beta diversity) were highly congruent between both taxa. These results indicate that community-wide multivariate measures of beta diversity are more consistent among taxa and more reliable indicators of disturbance, such as ENSO-induced burning, than univariate measures." 4129. Corbet, P.S. (2004): Ballistic defaecation by anisopteran larvae (Odonata): a way to increase foraging success? *International Journal of Odonatology* 7(1): 25-32. (in English). ["The article considers the phenomenon of ballistic defaecation by odonate larvae, exhibited by certain Anisoptera but not by any Zygoptera, and explores two possibilities: (1) that ballistic defaecation in Anisoptera may correlate with increased foraging success (the 'Wudkevich Hypothesis') by distancing the prey's alarm pheromone, persisting in the pellet after defaecation, from the larva's ambush site; and (2) that its absence in Zygoptera may correlate with their much richer repertoire of intraspecific agonistic behaviour, perhaps reflecting the need to change, and compete for, ambush sites more often. Attention is drawn to kinds of information that could throw light on the Wudkevich Hypothesis and to the design of experiments that would sustain or refute it; and mention is made of the possible implications for larvae of Zygoptera of their ability to learn to modify their antipredation behaviour in response to chemical cues emitted by their predators or by injured conspecifics." 4131. De Block, M.; Stoks, R. (2004): Life-history variation in relation to time constraints in a damselfly. *Oecologia* 140(1): 68-75. (in English). ["Although variation within populations in plasticity to time constraints is expected with regard to hatching date, empirical studies are largely lacking. We studied life-history responses to time constraints manipulated by photoperiod and associated with hatching date in larvae of the damselfly *Lestes viridis* for two populations with a different hydroperiod. In a common garden experiment, early- and late-hatched larvae from both populations were reared at two photoperiods mimicking the start and the end of the egg-hatching season. In a reciprocal transplant experiment, early- and late-hatched larvae from both populations were reared in both ponds. In all these experiments, larvae were reared from egg hatching until adult emergence. Within both populations, larvae reared at the photoperiod indicating a late time point in the growing season, reduced development time to compensate

for their perceived shorter development period. Growth rate, however, did not respond to photoperiod, resulting in a lower mass at emergence. As expected, both in the laboratory and in the field, larvae from eggs that hatched later in the season generally had a shorter development time and a faster growth rate, resulting in a higher mass at emergence compared to early-hatched larvae. This may explain the intriguing seasonal increase in mass at emergence in this species, and affect the predictions of optimality models. None of these life-history responses differed between the two populations, despite clear differences in time constraints linked to hydroperiod, suggesting the robustness of the observed patterns. Given the ubiquity of asynchronous hatching in nature, and the adaptive value of the observed differences between early- and late-hatched larvae, we expect the effects of hatching date on life-history plasticity to be widespread." (2004): Fluctuations in chick diet of the Squacco Heron *Ardeola ralloides* in southern France: changes over the last 30 years. *Bird Study* 51(1): 69-75. (in English). ["Aims To determine the diet composition of chicks and its variations in 2000 and 2001. To look for any changes over the last 30 years. Methods: Chick regurgitates were analysed to determine which Order contributed most to the diet, by frequency and by biomass. Results: During 2000 and 2001 chick diet was dominated by insects (92% and 70% by biomass, respectively), mainly Coleoptera (60% and 41%) and Orthoptera (27% in both years). The dry mass of Orthoptera, Coleoptera adults, Odonata and amphibians differed significantly between breeding sites, months and years. The proportion of invertebrates (in biomass) increased from 36.5% in 1970 and 31% in 1971 to 95% in 2000 and 90% in 2001 whereas the proportion of amphibians decreased in the same time from 49% and 33% in 1970 and 1971 to 5.0% and 9.5% in 2000 and 2001, respectively. Conclusion: The proportion of prey types differed between colony sites and months. Major changes were found in the diet composition between the early 1970s and 2000s. The possible hypotheses for the observed differences are discussed." (Authors)] Address: Delord, K., Station Biologique Tour du Valat, Le Sambuc, F-13 200 Arles, France

4135. Eason, P.K.; Switzer, P.V. (2004): The costs of neighbors for a territorial dragonfly, *Perithemis tenera*.

Ethology 110(1): 37-47. (in English). ["Past researchers have often considered neighbors to be beneficial to territorial residents, particularly compared with non-neighbor conspecific competitors. However, neighbors have the potential to be costly to residents in terms of both defensive costs and lost resources. In this study, we assessed the relative costs of defending a mating territory against neighbors and non-neighbors for the dragonfly *Perithemis tenera*, comparing across males with different numbers of contiguous neighbors; we also examined the possibility that the presence of contiguous neighbors might reduce the detection of potential mates. When neighbors were present, residents experienced a greater total number of intrusions by males; this increase in intrusions was due to higher numbers of intrusions by neighbors, as the number of intrusions by non-neighbor males did not differ. Residents with immediately adjacent neighbors also made more sorties toward neighbors than did residents whose nearest neighbors territories were not immediately adjacent. Interestingly, although the number of visits by females did not vary with the presence of neighbors, residents with neighbors made fewer sorties toward females than did residents without neighbors. Our results suggest that defensive costs increased when neighbors were present, that residents with neighbors may have missed opportunities to acquire mates, and thus that living with neighbors can be costly in this species." ["For mate-searching species, the learned mate recognition (LMR) hypothesis assumes that sexual harassment favours signal variation among females, which exploits the receiver ability of males. The model predicts that coevolving males have responded to the female sexual foil by learning to recognize female variants as potential mates. I translate the LMR hypothesis into the language of signal detection theory to explain its novelty as a dynamic, coevolutionary, negative frequency-dependent selection model. Due to gene environment interactions, males cueing to the morph detected most often should generate positive but often asymmetrical, detection-dependent harassment towards females. Females are expected to sort to an ideal free distribution where harassment costs are equal. At equilibrium, morph fitness, but not necessarily morph frequency, is predicted to be equal. The LMR hypothesis is consistent with recent experimental data and the distribution of colour polymorphisms in the Odonata, predicts general conditions favouring variation in sexual signals, and provides a novel mechanism for speciation via sexual signalling." (2004): Evaluating exuvia collection as a management tool for the federally endangered Hine's emerald dragonfly, *Somatochlora hineana* Williamson (Odonata: Cordulidae). *Biological Conservation* 118(1): 15-20. (in English). ["Reliable population density estimates are crucial for monitoring endangered species. Many species are difficult to capture or range over large areas, making direct monitoring of populations through capture or observation extremely challenging. In such cases, indirect methods of assessing populations can be the only source of reliable information. We examined whether the discarded exoskeleton of the last larval instar (exuvia), left behind when dragonflies emerge into the adult stage, could be used to predict larval densities and provide life history information for the federally listed endangered, Hine's Emerald Dragonfly (*Somatochlora hineana*). Using standardized protocols, we collected exuvia within six 2 x 2 m plots in an ephemeral wetland in Door County, Wisconsin during spring and summer of 1999 and 2000. *S. hineana* is a "summer emerger", with more than 95% of the emergence occurring from late June until mid-July. Based on time of emergence and the flight period, adults appear to live a month or longer. The sex ratio at emergence did not differ significantly from a 1:1 ratio and emergence was synchronous between the sexes. Estimates of larval population density using exuvial data were similar to those obtained through intensive direct sampling for larvae. Exuvial collections provide a reliable estimate of larval population density, help link larval ecology to adult ecology and are a useful tool for assessing habitat suitability. Although sampling exuviae requires repeated searching on particular sites, less expertise and fewer people are required for this type of sampling, indicating that exuvial surveys can be a very effective tool for monitoring populations of endangered dragonflies." 4147. Johansson, F.; Suhling, F. (2004): Behaviour and growth of dragonfly larvae along a permanent to temporary water habitat gradient. *Ecological Entomology* 29(2): 196-202. (in English). ["1. Freshwaters form a gradient from small temporary waters to large permanent waters. Identifying and examining traits that restrict the distribution of species along this gradient are crucial to the understanding of community structure in these habitats. 2. Using dragonfly larvae species, differences in traits important for growth and survival were studied. 3. The traits were studied in a series of laboratory experiments using two pairs of dragonfly species that coexist in the Namibian semi-desert. One species pair was from the most temporary part of the water permanence gradient and the other species pair from an intermediate part of the gradient. 4. As predicted, activity, capture rate, and growth rate were significantly greater in the two temporary water species. Contrary to the prediction made in the work reported here, species differences in microhabitat selection were not related to the species' habitat origin. Cannibalism did not differ between species. 5. The results lend support to the hypothesis that selection has favoured certain combinations of trait values and that these traits are important for a successful life in temporary and permanent waters." 4148. Kéry, M.; Juillerat, L. (2004): Sex ratio estimation and survival analysis for *Orthetrum coerulescens* (Odonata, Libellulidae). *Canadian Journal of Zoology* 82(3): 399-406. (in English, with French summary). [oas 14 "There is controversy over whether uneven sex ratios observed in mature dragonfly populations are a mere artifact resulting from the higher observability of males. Previous studies have at best made indirect inference about sex ratios by analysis of survival or recapture rates. Here, we obtain direct estimates of sex ratio from capture recapture data based on the Cormack Jolly Seber model. We studied *O. coerulescens* at three sites in the Swiss Jura Mountains over an entire activity period. Recapture rates per 5-day interval were 3.5 times greater for males (0.67, SE 0.02) than for females (0.19, SE 0.02). At two sites, recapture rate increased over the season for males and was constant for females, and at one site it decreased with precipitation for both sexes. In addition, recapture rate was higher with higher temperature for males only. We found no evidence for higher male survival rates in any population. Survival per 5-day interval for both sexes was estimated to be 0.77 (95% CI 0.75 0.79) without significant si-

te- or time-specific variation. There were clear effects of temperature (positive) and precipitation (negative) on survival rate at two sites. Direct estimates of sex ratios were not significantly different from 1 for any time interval. Hence, the observed male-biased sex ratio in adult *O. coerulescens* was an artifact resulting from the better observability of males. The method presented in this paper is applicable to sex ratio estimation in any kind of animal." (Authors)] Address: Kéry, M., CEFE/CNRS, 1919 Route de Mende, F-34033 Montpellier, France. 4151. Lopau, W. (2004): Die Libellenfauna der Kykladen / Griechenland. *Naturkundliche Reiseberichte* 20: 59 pp. (in German). [The Kyklads, a group of islands in the central Aegean Sea in the Mediterranean Sea, are part of the territory of Greece. W. Lopau researched in 2002 extensively on the odonate fauna of the following islands: Anáfi, Ändros, Delos, Ios, Kea, Kimolos, Kithnos, Mikonos, Milos, Naxos, Páros, Santorini, Serifos, Sifnos, Siros, and Tinos. After a brief history of odonatological records referring to the Kyklads, the odonate fauna of each of the islands is documented considering old and new records. Each of the 29 taxa is commented in a monographic way, the distribution of the species is mapped, and a regional odonatological bibliography is added. This paper is an additional highly significant contribution of Wolfgang Lopau to the knowledge of the Greek and European odonate fauna.] Address: Orders: Kappes, W., Winsberggring 5, D-22525 Hamburg, Germany

4152. Marco, P. de; Cardoso Peixoto, P.E. (2004): Population dynamics of *Hetaerina rosea* Selys and its relationship to abiotic conditions (Zygoptera: Caloptery-

gidae). *Odonatologica* 33(1): 73-81. (in English). ["Aspects of population dynamics were tested against temperature, insolation and moisture. The monthly abundance of *H. rosea* was estimated utilizing a scan method based on 49 fixed areas in 30-min intervals from 0800 to 1700 h during the day. The daily male activity pattern is characterized by a sharp increase at 0900 h with continuous density until 1430 h, followed by a sharp decrease after 1600 h. A correlation between peak densities was observed during the year and high period of photoperiod and low evapotranspiration suggesting possible ways males can adjust their emergence periods to optimize water loss with longer reproduction periods of activities." 4153. McMillan, V.E.; Arnold, R.M. (2004): Oviposition behavior and substrate utilization by *Lestes* congener (Odonata: Lestidae). *International Journal of Odonatology* 7(1): 53-63. (in English). ["Here we describe tandem oviposition (contact guarding) in *L. congener* and the use of dry stems of the sedge *Eleocharis obtusa* as oviposition substrates at a pond in New York State. Pairs formed away from the pond, then flew to *Eleocharis* patches on dry land 0.5-3 m from the water's edge. Some copulations occurred at or near oviposition sites; these pairs began ovipositing immediately afterwards. Eggs were placed singly in a line of incisions down the length of the plant stem, and several to many different pairs might utilize a single stem over a period of time. However, less than 1 % of the surface area of such stems possessed incision scars, although, in regions of stems with a high density of incisions, some eggs were close enough to be touching. Lone males were present in small numbers at the pond, but male harassment of tandems was minimal and we observed no female take-overs. Some females remained to complete oviposition alone after being deserted by their mates. Lone females were most common in late afternoon, when few lone males remained at the pond and take-over risks were small." 4154. Medland, J. (2004): Reports from Coastal stations - 2003: Guernsey, Channel Islands. *Atropos* 21: 37-39. (in English). [Verbatim: It is 25 years since the last survey of Odonata in Guernsey. Prior to this the only list was compiled in 1892. The 1978 results indicated that only six species were present: *Calopteryx virgo*, *Ischnura elegans*, *Pyrrhosoma nymphula*, *Aeshna mixta*, *Anax imperator*, and *Sympetrum striolatum*. Since this time there has been a considerable reduction in suitable habitat with two large wetland areas being drained. It was feared that at least *C. splendens* and *I. elegans* had become extinct. It was against this rather bleak background that Barry Wells and I made an attempt to survey all possible sites to determine the current status of those species still remaining. A teneral *I. elegans* on 19 April was unusually early with the next record for the species not being until 25 May. Two fresh Emperor exuviae on 26 May were the forerunners of a synchronized emergence over the next 11 days totalling 44 individuals from a small garden pond. A male *Libellula depressa* at the same site on 7 June was the first record for Guernsey. On 13 June two new damselfly species

were found: *Enallagma cyathigerum* and *Erythromma viridulum*. The latter was the first record for the Channel Islands. Both these species were seen in modest numbers at several sites with ovipositing noted later in the summer. Hard work and perseverance paid off the following week with a small population of *Orthetrum cancellatum* being located at a west coast site. It later transpired that the species had been present but not reported in 2001. The same site was then visited on a regular basis and on 12 July single male *Anax parthenope* and *Sympetrum fonscolombei* were found and photographed. Two days previously a probable male Lesser Emperor had been seen at another site. Both these vagrants were new for the Channel Islands. *S. striolatum* and *A. mixta* were found to be widespread and present at all suitable sites. The last new species to be found was a single male *Chalcolestes viridis* on 10 August. Only one individual was seen at the site with all sightings from a small area of *Phragmites* and *Salix*. It was last reported on 20 September. Despite extensive searching there were no records of *C. splendens* and only a tantalising glimpse of a single 'red' damselfly. All in all a very productive and rewarding first year's effort. Habitat creation and improvement is planned with more mapping work to locate further sites. The excellent atlas work being done by our French colleagues in Manche, Normandy is a constant reminder of those species which could one day colonise the Island.] Address: not stated

4158. Nelson, B.; Thompson, R. (2004): The natural history of Ireland's dragonflies. The national Museums and Galleries of Northern Ireland. ISBN 0 900761 45 8: 454 pp. (in English). [In this comprehensive study of the Irish odonate fauna, the authors combine their knowledge and research based on twenty years of field studies with new information gleaned from an extensive four year study carried out by the Dragonfly Ireland Project. The book covers all aspects of dragonfly biology and ecology, and the history of odonatological research in Ireland. There are comprehensive accounts of all re-

sident and migrant species, an in-depth description of the major odonate habitats and a gallery section, illustrating and describing over fifty sites in detail. Additional chapters include information on how to study and how to photograph Odonata. There is an extensive bibliography listing all currently known publications on the subject. The highly informative text is written for the keen naturalist. In a monographic style each species is described and compared with similar species. Behaviour, habitat, life cycle, and distribution in Ireland are presented. All these facts are interpreted and critically discussed. This publication is lavishly illustrated throughout, with over 300 outstanding colour photographs of habitats, larvae, and adults of all resident and migrant species found in Ireland. This attractive book is sold for 30,- Euro and is worth its price. The book is a highly significant contribution to the knowledge of the European odonate fauna and should not be missing in any odonatological library. 4161. Petchey, O.L.; Downing, A.L.; Mittelbach, G.G.; Persson, L.; Steiner, C.F.; Warren, P.H.; Woodward, G. (2004): Species loss and the structure and functioning of multitrophic aquatic systems. *Oikos* 104(3): 467-478. (in English). ["Experiments and theory in single trophic level systems dominate biodiversity and ecosystem functioning research and recent debates. All natural ecosystems contain communities with multiple trophic levels, however, and this can have important effects on ecosystem structure and functioning. Furthermore, many experiments compare assembled communities, rather than examining loss of species directly. We identify three questions around which to organise an investigation of how species loss affects the structure and functioning of multitrophic systems. 1) What is the distribution of species richness among trophic levels; 2) from which trophic levels are species most often lost; and 3) does loss of species from different trophic levels influence ecosystem functioning differently? Our analyses show that: 1) Relatively few high-quality data are available concerning the distribution of species richness among trophic levels. A new data-set provides evidence of a decrease in species richness as trophic height increases. 2) Multiple lines of evidence indicate that species are lost from higher trophic levels more frequently than lower trophic levels. 3) A theoretical model suggests that both the structure of food webs (occurrence of omnivory and the distribution of species richness among trophic levels) and the trophic level from which species are lost determines the impact of species loss on ecosystem functioning, which can even vary in the

sign of the effect. These results indicate that, at least for aquatic systems, models of single trophic level ecosystems are insufficient for understanding the functional consequences of extinctions. Knowledge is required of food web structure, which species are likely to be lost, and also whether cascading extinctions will occur." 4162. Rantala, M.J.; Ilmonen, J.; Koskimäki, J.; Suhonen, J.; Tynkkynen, K. (2004): The macrophyte, *Stratiotes aloides*, protects larvae of dragonfly *Aeshna viridis* against fish predation. *Aquatic Ecology* 38(1): 77-82. (in English). ["Predation could be one force determining which contemporary species occupy a certain habitat. *Aeshna viridis* is an endangered dragonfly species with a larval distribution strongly associated with lakes where the water plant, water soldier, *Stratiotes aloides*, occurs. In this study, the larvae were almost exclusively found in patches of *S. aloides*. To study larval association with *S. aloides* further, we conducted a series of laboratory experiments. Behavioural experiments indicated that larvae preferred *S. aloides*. *Aeshna viridis* larvae were nocturnal and rather inactive. Larvae on *S. aloides* were less susceptible to predation by the perch, *Perca fluviatilis*, than larvae on another water plant, *Myriophyllum alterniflorum*. According to our study it seems that occurrence of *S. aloides* may limit the distribution of *A. viridis*, and the protection of refuges may be essential in planning the conservation of this endangered species." [Range extensions of *Anax imperator* and *Erythromma viridulum*; *Anaciaeschna isoceles* was included into the Danish Red List as vulnerable, but has made a significant comeback in the recent years; three localities for *Coenagrion armatum* are known; some new localities of the rare *C. lunulatum* have been discovered in 2003; second Danish record of *Sympetrum pedemontanum* in 2002 (west of Jutland); a migration of darters (*Sympetrum sanguineum*, *S. flaveolum*, *S. danae*) has been recorded in mid-August 2003 by a small lake in the centre of Copenhagen.] Address: Rasmussen, J., Stockholmsgade 13 I tv, 2100 Ø, Denmark

4164. Rehfeldt, G. (2004): Diel pattern of activity, mating, and flight behaviour in *Onychogomphus uncatus* (Odonata: Gomphidae). *International Journal of Odonatology* 7(1): 65-71. (in English). ["The behaviour of *O. uncatus*, including flight and mating activity, was studied at a fast-flowing irrigation canal. During the day, males perched in sections of the canal with a strong current and a turbulent water surface. During short flights, interactions with other con-specific and hetero-specific males occurred, particularly with *Orthetrum coerulescens*. Under conditions of high population density, the frequent occurrence and disturbances by this species often resulted in male *O. uncatus* leaving a particular section of the canal. In the late afternoon and evening, males concentrated on ground perches in the

vicinity of the water. The reproductive system of *O. uncatatus* was found to be 'encounter limited'. The operational sex ratio of imagines at the water was always strongly biased in favour of the males. Individual females were observed at the water during the morning and evening hours. Following pair formation there was a prolonged period of copulation away from the water. Most pair formations were observed in the morning and evening hours. They took place over water, and in the evening hours also away from the water." (Author)] Address: Rehfeldt, G., FasanenstraBe 3, D-38102 Braunschweig, Germany. E-mail: g.rehfeldt@tu-bs.de

Schmidt, E (2004): Die Alten Fahrten" des Dortmund-Ems-Kanals im Westmünsterland, ein spezifischer, wertvoller und gefährdeter anthropogener Stillwassertyp mit Auen-Charakter am Beispiel der Odonatenfauna - eine Aufgabe für den Naturschutz (Insecta, Odonata). Verh. Westd. Entomologentag 2002: 179-186. (in German). [Nordrhein-Westfalen, German; "Alte Fahrten" are remains of the former Dortmund-Ems-canal. Because they are linked with the new canal, they are influenced by the movement of water produced by the cargo ships using these new canals. The odonate fauna - 28 species could be recorded over a period of 10 years - is comparable with that of oxbows. Typical species are *Gomphus vulgatissimus*, *G. pulchellus*, and *Cercion lindenii*. Noteworthy species are the regional rare *Coenagrion pulchellum* and *Aeshna grandis*. *Crocothemis erythraea* was traced in 2002 and 2003.] Address: Schmidt, E., Coesfelder Str. 230, D-48249 Dülmen, Germany

4166. Smallshire, D.; Swash, A. (2004): Britain's Dragonflies. WildGuides. Old Basing. ISBN 1-903657-04-0: 168 pp. (in English). [This is a photographic guide to the Odonata of Britain and Ireland, covering all 57 species recorded and 10 potential vagrants. 55 full colour plates depict males, females, immatures and e.g. colour forms. These plates are produced using the latest digital image technology, combining (high quality!) colour pictures of different specimens against a common background. This looks quite "naturally", but I hesitate to say there is any advantage for identification of the species; to present the species in this way, is - of course - a matter of taste. I think, most of the plates are printed a little bit too dark. There are two particular strengths of the book: (1) the British species (imagines and larvae) are arranged in "picture tables" so that you can compare the species at a glance. Significant identification features are optically stressed in the accompanying text. (2) The colour plates are presenting pictures of immature stages which are missed in most of the European identification guides. The (optical) concept of this book is quite unusual; it is stressing on field identification of the species. And if you want to know what a dragonfly really is, look at page 5 of the book. The pricing of the book (£ 15,-) is fair. (Martin Schorr)] Address: WildGuides Parr House, 63 Hatch Lane, Old Basing, Hampshire RG24 7EB, United Kingdom. www.wildguides.co.uk

4167. Suhling, F.; Schütte, C.; Müller, O. (2004): *Nesiothemis farinosa*: description of the final stadium larva (Odonata: Libellulidae). International Journal of Odonatology 7(1): 73-78. (in English). ["A written description and illustrations of the final stadium larva of *Nesiothemis farinosa* are presented, based on larvae and exuviae collected in Namibia. The larvae were reared in the

laboratory until emergence. Additionally, information on larval microhabitat, behaviour and development is provided." (Authors)] Address: Suhling F., Inst. Geoökologie, TU Braunschweig, Langer Kamp 19c, D-38102 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

4168. Suutari, E.; Rantala, M.J.; Salmela, J.; Suhonen, J. (2004): Intraguild predation and interference competition on the endangered dragonfly *Aeshna viridis*. *Oecologia* 140(1): 135-139. (in English). ["We examined the effects of intraguild predation (IGP) and interference competition on an endangered dragonfly, *A. viridis*. *A. viridis* is rare in Europe due to the decrease in suitable habitats harboring the macrophyte *Stratiotes aloides* L. *Stratiotes* plants are the principal oviposition substrate for *A. viridis* females and protect the larvae of *A. viridis* from fish predation. In our study lakes *A. viridis* larvae are sympatric with larvae of *Aeshna grandis* and *Aeshna juncea*. The susceptibility of *A. viridis* larvae to IGP by similar-sized larvae of *A. grandis* and *A. juncea* was tested in a laboratory predation experiment. Microhabitat use of *A. viridis* and *A. grandis* was studied in the laboratory to determine the possible effects of interference competition on the spatial distribution of *A. viridis* larvae. Our results show that at least in laboratory conditions, *A. viridis* is susceptible to IGP and interference competition. In competition, *A. grandis* larvae dominated the middle and outer portion of *S. aloides* rosettes whereas *A. viridis* stayed in the inner parts. When *A. grandis* larvae were absent, *A. viridis* colonized the middle and outer parts of the rosettes. We conclude that asymmetric predation between odonate larvae of equal size can be intense, and that both IGP and interference competition affect *A. viridis*. Although natural habitat complexity diminishes their impact, these interactions may nevertheless influence the distribution of *A. viridis* in *S. aloides* waters and restrict its microhabitat use in *S. aloides* rosettes." 4169. Switzer P.V. (2004): Fighting behavior and prior residency advantage in the territorial dragonfly, *Perrithemis tenera*. *Ethology, Ecology & Evolution* 16(1): 71-89. (in English with Italian summary). ["Many factors, including residency status, body size, age, and energetic reserves, have been implicated as possibly determining the winner in animal contests. In this study I investigated which of these factors were correlated with the outcomes of naturally-occurring territorial contests between male amberwing dragonflies (*P. tenera*). Amberwing contests consist of non-contact interactions and are characterized by a series of distinct stages that represent different levels of escalation. Prior residents did tend to win, but interestingly this residency advantage only occurred in interactions that were not escalated. For both non-escalated and escalated interactions, body size (wing length) did not influence the outcome. Age was correlated with outcome for escalated interactions, with the younger of the pair tending to win. Winning males had also spent less time in male-male interactions both the day of the interaction and during their entire life, suggesting that energy reserves may also affect the outcome of contests. In contrast to escalated interactions, age and time spent in male-male interactions was not related to the outcome of non-escalated interactions. The difference between the two opponents' sizes, ages, and time spent in previous male-male inter-

reactions did not correlate with duration or escalation level of contests. These results suggest that non-escalated interactions may occur when intruders are simply assessing the quality of the site. Contests that do not escalate, and thus the prior residency advantage, are probably a result of the intruder not challenging for ownership because the value of the territory is too low." 4172. Tsubaki, Y.; Hooper, R.E. (2004): Effects of eugregarine parasites on adult longevity in the polymorphic damselfly *Mnais costalis* Selys. *Ecological Entomology* 29(3) : 361-366. (in English). ["1. The relationship between the abundance of midgut parasites (eugregarine trophozoites) and the survival of hosts (field-collected damselflies, *Mnais costalis*) was investigated under laboratory conditions. 2. Males of *M. costalis* are morphologically and behaviourally polymorphic, typically existing as clear-winged non-territorial sneaks and orange-winged territorial fighters (the latter are larger in size). The survival cost of eugregarine infection for the two morphs was compared. 3. Orange-winged males showed shorter longevity compared to clear-winged males when they were fed at levels lower than the natural feeding rate, or when they were deprived of food. In contrast, morph longevity did not differ when they were fed until satiation every day. 4. Within each morph, the survival of damselflies was negatively correlated with the parasite abundance except when damselflies were fed until satiation. 5. The results suggest that the abundance of eugregarine parasites exerts a substantial cost, which is associated with the maintenance of alternative mating strategies, together with the higher developmental cost and energy expenditure of the fighter morph." 4173. Vance-Chalcraft, H.D.; Soluk, D.A.; Ozburn, N. (2004): Is prey predation risk influenced more by increasing predator density or predator species richness in stream enclosures? *Oecologia* 139(1): 117-122. (in English). ["The direct lethal impacts and the indirect ef-

fects predators have on prey characteristics, such as behavior, have fitness consequences for the prey. Whether the level of predation risk that prey face in the presence of multiple predator species can be predicted from a null model that sums the risk from each predator species in isolation is unclear. In field enclosures, we tested whether the predation risk experienced by *Stenonema* mayfly larvae from a dragonfly larva (*Boyeria vinosa*) and a hellgrammite (*Corydalus cornutus*) together matched the predictions of the multiplicative risk model. We then compared whether any deviations from the models predictions were larger in the presence of two predator species than in the presence of an equivalent density of individuals from either predator species alone, to determine if unique effects arise for the prey in the presence of multiple predator species. We also determined if prey moved preferentially into predator-free refuge spaces or decreased their movement in the presence of predators. *Stenonema* risk of predation was reduced compared to the models prediction, but no unique multiple predator species effects were present because this risk reduction was comparable in magnitude to the level exhibited in the presence of each predator species alone. The prey did not move into predator-free refuge spaces in the presence of predators in the field enclosures. Thus, these predators appear to interfere interspecifically and intraspecifically, which may facilitate the coexistence of the predators and the prey." 4174. Vukusic, P.; Wootton, R.J.; Sambles, J.R. (2004): Remarkable iridescence in the hindwings of the damselfly *Neurobasis chinensis chinensis* (Linnaeus) (Zygoptera: Calopterygidae). *Proceedings of the Royal Society: Biological Sciences* 271(1539): 595-601. (in English). ["The bright green dorsal iridescence of the hindwings of *Neurobasis chinensis chinensis* males, very rare in Odonata, is known to play a significant role in their courtship behaviour. The mechanism responsible for such high contrast and spectrally pure colour has been investigated and found to be optical interference, producing structural colour from distinct laminations in the wing membrane cuticle. The ventral sides of these iridescent wings are dark brown in colour. In a single continuous membrane of wing cuticle, this is an effect that requires a specialized structure. It is accomplished through the presence of high optical absorption ($k = 0.13$) within two thick layers near the ventral surface of the wing, which leads to superior dorsal colour characteristics. By simultaneously fitting five sets of optical reflectivity and transmissivity spectra to theory, we were able to extract very accurate values of the complex refractive index for all three layer types present in the wing. The real parts of these are $n = 1.47, 1.68$ and 1.74 . Although there is often similarly significant dorsal and ventral colour contrast in other structurally coloured natural systems, very few system designs comprise only a single continuous membrane." 4175. Watanabe, M.; Matsuoka, H.; Taguchi, M. (2004): Habitat selection and population parameters of *Sympetrum infuscatum* (Selys) during sexual mature stages in a cool temperate zone of Japan (Anisoptera: Libellulidae). *Odonatologica* 33(2): 169-179. (In English) ["The mark-and-recapture method was used to

study the population parameters of sexually mature adult *S. infuscatum* in a forest-paddy field complex in the cool temperate zone of Japan. After emergence, they moved into the forest gaps, and they remained and fed exclusively in the forest gaps throughout their lives. Mature males captured outnumbered mature female on each sampling day in the paddy fields, but not in the gaps. However, the estimated daily numbers in both habitats and/or the whole survey area roughly indicated a 1:1 sex ratio. The estimated daily survival rates and daily immigrations showed that females were apt to stay in the forests, while males sometimes dispersed, though females in the paddy fields tended to have a long-range flight. In the morning, some of the paired couples flew to the paddy fields in tandem and oviposited on the wing; these were so-called flyers. The rest remained in the forests the entire day; these were designated as perchers. The forest gaps were thus important for the life cycle of this species both as feeding and roosting sites." 4176. Watts, P.C.; Wu, J.H.; Westgarth, C.; Thompson, D.J.; Kemp, S.J. (2004): A panel of microsatellite loci for the Southern Damselfly, *Coenagrion mercuriale* (Odonata: Coenagrionidae). *Conservation Genetics* 5 (1): 117-119. ["Of the 40 loci tested, 11 loci amplified spurious bands and 14 loci were monomorphic. We were able to develop, therefore, fifteen polymorphic loci that resolved distinct alleles within the expected size range. Numbers of alleles varied between 2 and 7 at the dinucleotide microsatellites and 2 and 6 at the trinucleotide loci (Table 1). Observed and expected heterozygosities varied between 0.233-0.732 and 0.291-0.799 respectively (Table 1. Three loci (LIST4-023, LIST4-030, LIST4-035), showed significant ($P < 0.05$) deviations from expected Hardy-Weinberg conditions, although these heterozygote deficits were all non-significant ($P > 0.05$) after correction for multiple testing. Only 4 of the 105 locus comparisons were ($P < 0.05$) out of linkage disequilibrium (LJST4-034-LIST4-002, $P = 0.043$; LIST4-037-UST4-002, $P = 0.030$; LIST4-058-LIST4-053, $P = 0.031$; LIST4-034-LIST4-060, $P = 0.031$). Given the large number of tests involved, however, these loci are probably not significantly linked but further samples are required to confirm this. We are presently using these loci to examine the genetic structure of the southern damselfly in the UK." (Authors)] Address: Watts, P.C., School of Biol. Scien., The Biosciences Building, Crown Street, University of Liverpool, Liverpool, L69 7ZB, UK. E-mail: p.c.watts@liv.ac.uk

4177. Watts, P.C.; Thompson, D.J.; Kemp, S.J. (2004): Cross-species amplification of microsatellite loci in some European zygopteran species (Odonata: Coenagrionidae). *International Journal of Odonatology* 7(1): 87-96. (in English). ["Microsatellites have been infrequently used for genetic analysis of odonate species. Here, we report four microsatellite loci that are polymorphic in *Coenagrion mercuriale*. Furthermore, we examine the success of cross-species amplification of a panel of 19 microsatellite loci that were developed from *C. mercuriale* in seven other European odonate species. PCR with microsatellite primers is more likely to be achieved in species that are closely related to the species used for marker isolation. Overall, 10 microsatellite loci amplified interpretable PCR products (seven

loci were variable) in both *C. puella* and *C. pulchellum*, whilst two loci were variable in *Ischnura elegans*. These markers should facilitate genetic research into these zygopteran species." (Authors)] Address: Watts, P.C., School of Biological Sciences, The Biosciences Building, Crown Street, University of Liverpool, Liverpool L69 7ZB, UK. E-mail: p.c.watts@liv.ac.uk.

4180. Worthen, W.B.; Gregory, S.; Felten, J.; Hutton, M.J. (2004): Larval habitat associations of *Progomphus obscurus* at two spatial scales (Odonata: Gomphidae). *International Journal of Odonatology* 7(1): 97-109. (in English). ["*P. obscurus* is one of the most abundant dragonflies in South Carolina, USA. We collected dragonfly larvae from 127 sites in the Enoree River and nine of its tributaries, and correlated the abundance of *P. obscurus* larvae with physical and chemical characteristics of these streams. As expected for this burrowing species, larval abundance varied among streams and was significantly correlated with mean silica concentrations and the proportion of sandy-bottom sites in these streams. We also examined habitat associations on a smaller spatial scale. We sampled *P. obscurus* larvae by kick-seine from fine sand, coarse sand, and pebble sediment types in five sites in the Enoree River basin. Larvae were collected, preserved in 75% EtOH, and their body lengths were measured. Sediment samples were collected and Ro-tapped, and mean particle size was calculated. Larvae were present in a greater fraction of the 'fine sand' samples than 'pebble' samples. In addition, abundance was inversely correlated with mean particle size. Mean larvae size was weakly correlated with mean particle size, and inversely correlated with larval abundance. This species is associated with sandy-bottom streams and fine sandy sediments within streams. Changes in sediment characteristics resulting from channelization, increased flooding, and increased stream flow could change sediment composition and impact the abundance of this common dragonfly species." 4181. Haarstad, J. (1997): The dragonflies of selected eastern Minnesota rivers. Report submitted to the Minnesota Department of Natural Resources: 83 pp. (in English). ["During the summer of 1992 I visited 25 rivers and streams in eastern Minnesota collecting dragonfly exuviae and adults. Streams visited in the Northeast were the Gooseberry (1 site), Baptism (3 sites), Manitou (1 site), Temperance (4 sites), Cascade (2 sites), Stony (1 site), Kawishwi (1 site), and St. Louis (3 sites). Streams visited in Eastcentral Minnesota were the St. Croix (12 sites), Kettle (5 sites), Snake (7 sites), Crooked Creek (1 site), Little Sand (1 site), Sand (2 sites), Rock Creek (1 site), Sunrise (1 site), Groundhouse (1 site), Ann (1 site), and Rum (2 sites). Streams visited in the Southeast were the Cannon (4 sites), Zumbro (5 sites), Whitewater (2 sites), Root (8 sites) and Mississippi (5 sites). A total of 33 species of riverine dragonflies were collected. Species of Gomphidae included Hagenius brevistylus, Dromogomphus spinosus, Ophiogomphus earolus, O. colubrinus, O. howei, O. rupinsulensis, x O. sabrinus, Hylogomphus adelphus, H. viridifrons, Gomphus externus, G. fraternus, G. lineatifrons, G. vastus, G. ventricosus, Gomphus exilis, G. graslinellus, G. lividus, G. quadricolor, G. spicatus, Ariogomphus cornutus, Stylurus amnicola, S. notatus, and S. spiniceps. Species of Aeshnidae included Anax junius, Aeshna umbrosa, Basiaeshna janata, Boyeria grafi-ana, and B. vinosa. Species of Cordulegastridae included Cordulegaster maculata and C. obliqua. Species of Macromiidae included Didymops transversa and Macromia illinoensis. Species of Corduliidae included Cordulia shurtleffi, Epicordulia princeps, Epitheca canis, E. spinigera, Neurocordulia yamaskenensis, Somatochlora minor, and S. elongata. Libellulidae (primarily Plathemis lydia, Libellula pulchella, L. luctuosa) were noted but generally not collected since most occur abundantly at ponds and marshes. Also noted was the presence of the damselflies Calopteryx aequabilis, C. maculata, and Hetaerina americana." 4185. Kosterin, O.E. (1998): Important findings of the dragonfly (Odonata) fauna of the Dahurian Nature Reserve and its environs. Problems of Entomology in Russian. Theses for XI Congress of Russian Entomological Society, Sanct-Petersburg, 1998 - Vol. 1): 210-211. (in Russian). [Verbatim: "Until recently the odonofauna of the steppen Transbaikalia was insufficiently studied. (Gorb et al., 1996) reported on a finding of 17 species in the Dahurian Nature Reserve (an extreme south of the Chita Province), of which *Aeshna serrata* Hag. found much more easterly of its previous easternmost finding on the Baikal longitude. In summer 1995-1996 in the same region we managed to find 30 species. Two localities were studied: the Onon River valley in the environs of the village Nizhnii Tsasuchei (the steppen zone but with an unique pine forest) and Torei Lakes (the dry steppe zone). In both localities 19 species were found: *Lestes dryas*, *L. sponsa*., *Sympetma paedisca*, *Coenagrion armatum*, *C. ecornutum*, *C. lanceolatum*, *C. lunulatum*, *Erythromma najas*, *Enallagma cyathigerum risi* Schmidt, *Ischnura elegans*, *Aeshna mixta*, *A. serrata*, *Pantala flavescens*, *Leucorrhinia intermedia*, *Libellula quadrimaculata*, *Sympetrum danae*, *S. flaveolum*, *S. (vulgatum) imitans*., *S. pedemontanum*. 10 species were found only in the Onon valley: *Cercion v-nigrum*, *Coenagrion glaciale*, *Aeshna crenata*, *A. juncea*, *Ophiogomphus spinicornis*, *Anisogomphus maacki*, *Stylurus flavipes*, *Epithea bimaculata*, *Somatochlora graeseri*, *S. (metallica) exuberata*. Only one species, *Anax parthenope*, was recorded in the Torei Lakes depression (lake Nizhnii Mukei); besides, *Sympetrum depressiusculum* was reported for this depression (Gorb et al., 1996) but not found by us. The odonofauna of the Onon valley is much more rich thanks to a diversity of intrazonal biotopes and the river presence while the Torei Lakes depression, bearing only more or less mineralized lakes, is poor of species. Unexpected are the findings of two Manshurian species, *C. v-nigrum* and *A. maacki*, known earlier no west of Blagoveshchensk (Malikova, 1995). Thus, they penetrate along the Onon valley to the steppen Transbaikalia and, probably, inhabit all the Amur River basin. Proved is the presence in Transbaikalia of southern species *P. flavescens*, which was reported earlier for the village Pokrovka at the Shilka and Argun' Rivers junction (Selys Longchamps, 1887), and *A. parthenope*, which has been observed visually by B.F. Belyshev (1973) at Lake Gusinoe. A Chinese-Mongolian species *O. spinicornis* is hereby for the first time reliably reported for Russia. Analysis of collections revealed that this species inhabit also the southern coast of Baikal and the northern Ubsu-Nur Hollow in the southern Tuva Republic. The author expresses his gratitude to V.A. Brinikh, a Director of the State Nature Reserve "Dauriskii" for a great help in work and to E.I. Malikova (Blagoveshchensk) for valuable consulting."] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. 4186. Lotzing, K. (1998): Ergebnisse von Bestandserfassungen zur Libellen-Fauna (Odonata) in ausgewählten Biotopen am Südrand der Magdeburger Börde. Abh. Ber. Mus. Naturk. Magdeburg 20: 19-35. (in German). [Alt-Landkreis Staßfurt, Sachsen-Anhalt, Germa-

ny; a total of 36 odonate species resulting from collection made between 1970 to 1995 is documented in a table and briefly discussed.] Address: Lotzing, K., Am Hollschen Bruch 4c, D.39435 Unseburg, Germany

4187. Resetarits, W.J. (1998): Differential vulnerability of *Hyla chrysoscelis* eggs and hatchlings to larval insect predators. Journal of Herpetology. 32(3): 440-443. (in English). [Analysis of variance revealed a highly significant effect of treatments on the survival of *Hyla* tadpoles. Mean tadpole survival was 97.5% in the predator-free controls, but was reduced to 62.5% with dragonfly naiads (*Pachydiplax longipennis*) and to 0.84% with dytiscid larvae (*Ilybius* sp.). Tukey's procedure showed that both the dragonfly and dytiscid treatments were significantly different from the controls, and that the dytiscid treatment was significantly different from the dragonfly treatment. Dragonfly naiads and dytiscid larvae were both significant predators of newly hatched *Hyla* tadpoles in the experiment, but the predation rate by dytiscid larvae was much greater than that of dragonfly naiads. There was also a highly significant effect of treatments on the survival of *Hyla* eggs. Mean egg survival was 97% in the controls and 89% in the dragonfly treatment, but was reduced to only 16% in the presence of dytiscid larvae. In contrast to the results for tadpoles, the control and dragonfly treatments were not significantly different from each other, but the dytiscid treatment was significantly different from both the dragonfly treatment and the control. Therefore, only dytiscid larvae were important predators on the eggs of *H. chrysoscelis*.] Address: Resetarits, W.J., Jr., Cent. Aquatic Ecol., Illinois Nat. History Survey, 607 E. 4191. Bulet, P.; Hetru, C.; Dimarcq, J.-L.; Hoffmann, D. (1999): Antimicrobial peptides in insects; structure and function. *Developmental and Comparative Immunology* 23: 329-344. (in English). ["Antimicrobial peptides appear to be ubiquitous and multipotent components of the innate immune defense arsenal used by both prokaryotic and eukaryotic organisms. During the past 15 years a multitude of these peptides have been isolated largely from insects. In spite of great differences in size, amino acid composition and structure, most of the antimicrobial peptides from insects can be grouped into one of three categories. The largest category in number contains peptides with intramolecular disulfide bonds forming hairpin-like β -sheets or α -helical β -sheet mixed structures. The second most important group is composed of peptides forming amphipathic α -helices. The third group comprises peptides with an overrepresentation in proline and/or glycine residues. In general, the insect antimicrobial peptides have a broad range of activity and are not cytotoxic. Despite a wealth of information on structural requirements for their antimicrobial activity, the mode of action of these peptides is not yet fully understood. However, some data suggest the existence of two types of mode of action: 1. through peptide-lipid interaction or 2. through receptor-mediated recognition processes. This review presents the main results obtained during the last four years in the field of antimicrobial peptides from insects with a special focus on the proline-rich and cysteine-rich peptides." (1999): Unique steephead stream segments in southwest Georgia: invertebrate diversity and biomonitoring. *Proceedings of the 1999 Georgia Water Resources Conference*, held March 30-31, 1999, at University of Georgia. Kathryn J. Hatcher, editor, Institute of Ecology, The University of Georgia, Athens, Georgia: 4 pp. (in English). ["The steephead streams we studied are springfed, relatively high gradient, and have greater substrate diversity than is typical of most Coastal Plain streams. The study objectives were: 1) to describe the physical characteristics of the streams and quantify the seasonal biodiversity in several streams draining managed forestlands, and 2) test and adapt rapid bioassessment methods. Our results show these streams to have high invertebrate diversity throughout the year with the highest occurring in winter and early spring. The streams and their valleys had a regionally unique assemblage of plants and animals. Bioassessment values indicated water quality to be fair to good when sampling with the fixed area modified Hess sampler and good to excellent when sampling multiple habitats using a D-frame kicknet. The values were calculated using the rapid assessment methods adapted by Save-Our-Stream (SOS) and the Hilsenhoff Family Biotic Index (FBI). The results of the bioassessment values indicate that the streamside management zones (SMZs) implemented in these areas of silvicultural activity are effective in maintaining adequate water quality standards and supporting diverse and abundant aquatic life." (Authors). *Calopterygidae*, *Cordulegasteridae*, and *Gomphidae* are listed in table 1. The total density of individuals / m² was 699 in summer, 322 in winter, and 361 in early spring] Address: Entekin, Sally, Jones Ecological Research Center, Rte 2 Box 2324, Newton, GA 31770, USA.

4197. Goodyear, K.L.; McNeill, S. (1999): Bioaccumulation of heavy metals by aquatic macro-invertebrates of different feeding guilds: a review. *The Science of the Total Environment* 229: 1-19. (in English). ["The available literature on heavy metal bioaccumulation by freshwater macro-invertebrates has been analysed. A very uneven data distribution was found. Ephemeroptera and Diptera are the most commonly investigated orders of insect larvae, whilst many orders are not represented at all. The collector/gatherer and predator feeding guilds are more frequently investigated than other guilds. Furthermore, Zn, Cu, Pb and Cd are the most intensively researched heavy metals, and only infrequent investigations of other metals are documented. Relationships between metal concentrations in the animals and levels in sediments and waters were determined from the pooled data for three feeding guilds. No one relationship represents how each metal interacts within the feeding guilds. Each of the four metals Zn, Cu, Pb and Cd displays a unique relationship between metal concentrations in sediments or waters with those in individual feeding guilds of macro-invertebrates, indica-

ting the relative importance of different sources of metals to the different feeding types. Biomagnification of Zn, Cu, Pb and Cd has been demonstrated not to occur between these guilds." 4202. Leslie, H.A.; Pavluk, T.I.; bij de Vaate, A.; Kraak, M.H.S. (1999): Triad Assessment of the Impact of Chromium Contamination on Benthic Macroinvertebrates in the Chusovaya River (Urals, Russia). *Archives of Environmental Contamination and Toxicology* 37(2): 182-189. (in English). ["The impact of chromium (Cr) contamination on the benthic macroinvertebrate community (including "Odonata") of the Chusovaya River in the Ural Mountains of Russia was assessed using a triad approach. The triad consisted of chemical analysis of the contamination in various environmental compartments, examination of the benthic macroinvertebrate community structure, and analysis of ecotoxicological effects on the caddisfly *Hydropsyche pellucidula* (Trichoptera). Chemical analyses of water, sediments, and detritus indicated that the main contaminant present was indeed Cr and that the level of the Cr contamination near the point source, a severely polluted dead tributary, was extremely high: Downstream Cr concentrations were about 450 times higher in water and 25 times higher in sediments compared with a clean reference site upstream. The contamination at the mouth of the tributary was even more severe: 800 times more Cr in water and 50 times more Cr in sediments. Benthic macroinvertebrate community structure was

studied using artificial substrates colonized in situ. Lower species richness was observed at the downstream site compared with the upstream site. Larvae of *H. pellucidula* collected from the contaminated site on the river bioaccumulated large amounts of Cr and exhibited physical abnormalities. The incidence of tracheal gill damage was significantly higher than at a reference site on the nearby Reshotka River, as was the incidence of discoloration of the anal papillae of these animals. The application of a triad demonstrated that the observed extreme Cr contamination had an adverse effect on aquatic life in the Chusovaya River, both at the community level (reduced diversity) and at the level of individuals (sublethal effects on surviving individuals)." 4203. Linhart, J. (1999): Phytophilous macrofauna in the *Stratiotes aloides* vegetation of the Lake Lukie, Poland. *Acta Universitatis Palackianae olomucensis, Facultas Rerum naturalium, Biologica* 37: 67-76. (in English). ["On 14th July 1999, a small tentative investigation into the composition of phytophilous macrofauna in the *Stratiotes aloides* vegetation was conducted in the Lake Lukie, Poland. Altogether 22 main (33 recognized) invertebrate taxa were found. Out of these, only 7 taxa represented more than 1 % share on the total abundance - Chironomidae, Cladocera, Oligochaeta, Cyclopoida, Trichoptera, Isopoda and Gastropoda; chironomid larvae being by far the most abundant (almost 72 % of the total abundance). Representatives of groups Hydroida, Bivalvia, Hirudinea, Araneida, Hydrachnellae, Ostracoda, Anisoptera, Ceratopogonidae, Ephydriidae, Stratiomyidae and Coleoptera were found only occasionally (2-16 individuals per m²). The total abundance of phytophilous macroinvertebrates (> 300 µm) was estimated to be 8,328 ind. m² for epiphytic invertebrates and 11,800 ind. m² for all animals (including mining Chironomidae). An interesting feature was an enormous infection of *S. aloides* leaves by the mining chironomid larvae. These miners comprised about 40 % of all chironomid larvae found in the samples. I have estimated a number of mining Chironomidae in 1 plant to be 579 on average (15.6 ind.gn1 plant dry weight). It has been suggested that the quadrat sampling method underestimated numbers of highly active animals dwelling in macrovegetation - Cladocera, Copepoda, predators (Odonata, Heteroptera, Coleoptera)." distics was originally developed as a method of analysis of the present-day diversity pattern, and some problems are arising when it is applied to the palaeontological record. The most important difficulties are connected with 1. the different time scales (phylogenetic scale in cladistics, geological or physical scales in palaeontology where neither paraphyletic taxa nor chronotaxa can be excluded accurately); and 2. the different basic levels for establishment of terminal branches (the single present-day level in cladistics and numerous successive levels in palaeontology). Both modified versions of cladistics and complementary methods have to be developed to describe fossil biodiversity in an adequate manner." 4221. Kampa, E.; Artemiadou, V.; Lazaridou-Dimitriadou, M. (2000): Ecological quality of the River Axios (N. Greece) during spring and summer, 1997. *Belgian Journal of Zoology* 130 (supplement 1): 21-27. (in English). ["This study examines the applicability of five European biotic indices combined with the measurements of physicochemical parameters in order to determine the water quality at ten sites along the Greek part of the river Axios during the high flow (spring) and low flow season (summer) in 1997. The river Axios is situated in northern Greece, west of the city of Thessaloniki. [...] The Greek part of the river Axios receives mainly agricultural runoff but also urban sewage and industrial wastes." Physicochemical parameters were measured in situ. The benthic macroinvertebrates - including Odonata -, sampled with the 3 min kick/sweep method, were identified to the lowest possible taxonomic level, but not documented in this paper. "The faunal composition was typical of a lowland river, i.e. the zoobenthos was not very diverse. The quality of the water was influenced by human activities during both seasons. The deterioration in water quality during spring was due to excess suspended solids of diffuse agricultural origin, and during summer was due to organic pollution. Lower discharge and impoundment accentuated this deterioration. Overall, changes in physicochemical parameters were in agreement with the results of the biological data, despite their instant nature. However, some problems arose with regard to the applicability of the European biotic indices, thus emphasizing the need to develop a Greek Biotic Index." (Authors)] Address: Lazaridou-Dimitriadou Maria, Dept. of Zoology, School of Biology, Aristotle University of Thessaloniki, 54006 Thessaloniki, Greece. E-mail: mlazarid@bio.auth.gr

4235. Beutel, R.G.; Gorb, S.N. (2001): Ultrastructure of attachment specializations of hexapods (Arthropoda): evolutionary patterns inferred from a revised ordinal phylogeny. J. Zool. Syst. Evol. Research 39: 177-207. (in English with German summary). ["Attachment devices of representatives of most higher taxa of hexapods were examined. Short descriptions of tibial, tarsal and pretarsal adhesive structures for each order are presented. In their evolution, hexapods have developed two distinctly different mechanisms to attach themselves to a variety of substrates: hairy surfaces and smooth Pelexible pads. The Pelexible properties of pad material guarantees a maximal contact with surfaces, regardless of

the microsculpture. These highly specialized structures are not restricted to one particular area of the leg. They may be located on different parts, such as claws, derivatives of the pretarsus, tarsal apex, tarsomeres, or tibia. The 10 characters of the two alternative designs of attachment devices (smooth and hairy) were coded and analysed together with a data matrix containing 105 additional morphological characters of different stages and body parts. The analysis demonstrates, that similar structures (arolium, euplantulae, hairy tarsomeres) have evolved independently in several lineages. Nevertheless, some of them support monophyletic groups (e.g. Embioptera + Dermaptera; Dictyoptera + Phasmatodea + Grylloblattodea + Orthoptera; Dictyoptera + Phasmatodea; Hymenoptera + Mecoptera; Neuropterida + Strepsiptera + Coleoptera). Other structures such as claw pads (Ephemeroptera), balloon-shaped ever-sible pads (Thysanoptera), or fossulae spongiosae (Reduviidae) are unique for larger or smaller monophyletic units. It is plausible to assume that the evolution of Pight and the correlated necessity to cling to vegetation or other substrates was a major trigger for the evolution of adhesive structures. Groups with a potential to evolve a great variety of designs of adhesive pads are Hemiptera and Diptera. Even though characters of the adhesive pads are strongly subject to selection, they can provide phylogenetic information. The results of the cladistic analyses are largely congruent with current hypotheses of hexapod phylogeny. A sister-group relationship between Diplura and Insecta and between Zygentoma (excl. Tricholepidion) and Pterygota is confirmed. Plecoptera are probably the sistergroup of the remaining Neoptera. Dermaptera are the sistergroup of Embioptera and Dictyoptera the sistergroup of Phasmatodea. Paurometabola excl. Dermaptera + Embioptera are monophyletic. A sistergroup relationship between Zoraptera and a clade comprising Paraneoptera + Endopterygota is only supported by weak evidence. Coleoptera + Strepsiptera are the sistergroup of Neuropterida and Hymenoptera the sistergroup of Mecoptera." (Authors) *Enallagma cyathigerum*, *Lestes barbarus*, *Anax imperator*] Address: Gorb, S., Max-Planck-Institut für Entwicklungsbiologie, Spemannstr. 35, D-72076 Tübingen, Germany. 4245. Martin, M. (2001): Environmental monitoring in Baden-Württemberg with special reference to biocoenotic trend-monitoring of macrozoobenthos in rivers and methodical requirements for evaluation of long-term biocoenotic changes. Aquatic Ecology 35(2): 159-171. ["Biomonitoring methods from a comprehensive study of man-made impacts on urban and on the near-natural environment are presented. Part of the environmental monitoring in Baden-Württemberg is a biocoenotic trend-monitoring project on macrozoobenthos in running waters which has resulted in a database enabling long-term trend assessment of biocoenosis in diverse rivers and streams in the future. About 561 species of

macrozoobenthos have been recorded (21 species for the first time in Baden-Württemberg). Data are analysed for different purposes: methodological requirements for aquatic trend-biomonitoring, status of endangerment according to the Red Data Book, and first assessment of faunistic long-term changes in the River Rhine. Calculation of cumulative species numbers over number of samples offers sampling success and therefore represents a good way to show how sure or complete results of a given faunistic approach are at a given time. One sample provides less than 25% of the fauna recorded within a three years period of quarterly inspections. To collect the main fraction (90%) of species, it takes 3 years of quarterly collections if all species recorded only once during the whole period are neglected. Several rare species were recorded within the project. 34% of mayflies, stoneflies and caddisflies are endangered. The River Rhine and its changes in faunal composition within the last century is the example to illustrate the principle of biocoenotic trend-monitoring. The more recent samples of the macrobenthic fauna of the River Rhine indicate an improved quality and diversity because of improved water quality. Several species, indicative of good water quality have returned, and invasion of neozoans is still high, too. However, with respect to extinct species of macrozoobenthos, especially stoneflies, mayflies and caddisflies, mentioned by former authors, there is still a marked absence of indigenous species in the River Rhine." 4247. Reels, G.T. (2001): Two Hong Kong endemics sunk at Wutongshan. Porcupine 23: 5- (in English). [*Sinosticta ogatai* and *Drepanosticta hongkongensis* (Platystictidae) previously only known from Hong Kong have been discovered on the slopes of Wutongshan in Shenzhen. Both were found in good numbers in wooded ravines on the north-facing slopes of the 944 m mountain, just over the border from Sha Tau Kok, during a field visit on 16-17 May.2001.] Address: not stated

4248. Smallshire, D. (2001): A warning for those "bitten by the bug"! Dragonfly News 40: 14- (in English). [Verbatim: Thankfully, we often hear of people who get bitten metaphorically by the dragonfly 'bug', but here is a tale of the unfortunate consequences of being literally bitten by a dragonfly. Those who have handled our larger dragonflies will be well aware that an adult in the hand will often try to nip a finger if it comes close enough. A BDS member (who will remain nameless!) at the Smallhanger field meeting in July was curious about how strong such a bite would be. When the chance came to try out the mandibles of a Golden-ringed Dragonfly held by another member, a finger was proffered. The bite was obviously more painful than expected, because the finger was withdrawn sharply but unfortunately, and to everyone's horror, the dragonfly's head came with it! I've never heard of this happening

me with it! I've never heard of this happening before, but to avoid a repeat I suggest that anyone desperate for a quick nip should ensure that both mandibles and legs are allowed to connect with the same finger!] Address: Dave Smallshire, 8 Twindle Beer, Chudleigh, Newton Abbot, TQ13 OJP, UK

4249. Smallshire, D. (2001): Criteria for proof of breeding in dragonflies. *Dragonfly News* 39: 17-18. (in English). [Suggested categories: Confirmed breeding: exuvia or newly emerged adult; probable breeding: larva, ovipositing female, or copulating pair (Zygoptera only); present: all other records.] Address: Smallshire, D., 8 Twindle Beer, Chudleigh, Newton Abbot, TQ13 OJP, UK

4250. Staniczek, A. H. (2001): Der Larvenkopf von *Oniscigaster wakefieldi* McLachlan, 1873 (Insecta: Ephemeroptera: Onscigastridae). Dissertation, Fakultät für Biologie, Eberhard-Karls-Universität Tübingen. 165 pp. (in German, with English summary). [The larval head of the New Zealand mayfly *Oniscigaster wakefieldi* is investigated, a mayfly which is thought of as plesiomorphic in many respects. Based on a broad comparison with other mayfly species, it is aimed to reconstruct the groundplan of the larval head of mayflies. Emphasis is laid on the anatomy and functional morphology of the larval mouthparts and the homologization of their muscles. The results indicate the presence of an anterior articulation complex of the mandible that is made up of two points of mandibular attachment to the cranium in the groundplan of Ephemeroptera. These attachment points are compared with the condition in the relic silverfish *Tricholepidion gertschi* and other *Zygentoma*. It is shown that in the *Zygentoma* there is a similar articulation complex present. This correspondence is regarded as a groundplan character of *Dicondylia*. The character transformation from the monocondylous mandibles of *Ectognatha* to the dicondylous mandible of *Odonata* and *Neoptera* is interpreted in its functional and phylogenetic context. The alterations of the mandible and its muscles are correlated with changes in the construction and position of the anterior tentorial arms and the lateral cranium. None of the investigated mandibles show traces of segmentation. Thus the hypothesis of a tripartite telognathic mandible in the groundplan of insects is rejected. The fused galeolacinia of mayfly larvae is compared to the ones of the *Odonata*. The different ways of interpretation of these results are discussed. The findings of this study, together with all previously discussed characters, are used for a phylogenetic analysis to unravel the phylogenetic affinities between the three basal groups of the *Pterygota* (Ephemeroptera, *Odonata*, *Neoptera*). The data point to a sistergroup relationship between the Ephemeroptera and all other pterygote insects, the *Metapterygota*. kationsdatum: 07.11.2001] Address: <http://w210.ub.uni-tuebingen.de/dbt/volltexte/2001/310/>

4251. Steffens, W.P. (2001): Status Survey for *Ophiogomphus anomalus* Harvey, and early-season dragonfly inventory of western Superior National Forest Rivers. Submitted to: Superior National Forest and Minnesota DNR Natural Heritage and Nongame Research Program: 12 pp. (in English). [Status surveys for the Special Concern dragonfly, *Ophiogomphus anomalus*, were conducted on selected rivers in northeastern Minnesota, along with an inventory of other early-season river dragonflies. *Ophiogomphus anomalus* were confirmed on the upper St. Louis River in St. Louis County, but no

new occurrences were found. Additional evidence of developmental abnormalities in northern Minnesota dragonfly larvae was found at several locations.] Address: <http://www.dnr.state.mn.us/ecologicalservices/nongame/projects/researchreports/abstracts/insects/steffens-2001.html>

4252. Taylor, G.K. (2001): Mechanics and aerodynamics of insect flight control. *Biol. Rev.* 76: 449-471. (in English). [Insects have evolved sophisticated flight control mechanisms permitting a remarkable range of manoeuvres. Here, I present a qualitative analysis of insect flight control from the perspective of flight mechanics, drawing upon both the neurophysiology and biomechanics literatures. The current literature does not permit a formal, quantitative analysis of flight control, because the aerodynamic force systems that biologists have measured have rarely been complete and the position of the centre of gravity has only been recorded in a few studies. Treating the two best-known insect orders (*Diptera* and *Orthoptera*) separately from other insects, I discuss the control mechanisms of different insects in detail. Recent experimental studies suggest that the helicopter model of flight control proposed for *Drosophila* spp. may be better thought of as a facultative strategy for flight control, rather than the fixed (albeit selected) constraint that it is usually interpreted to be. On the other hand, the so-called 'constant-lift reaction' of locusts appears not to be a reflex for maintaining constant lift at varying angles of attack, as is usually assumed, but rather a mechanism to restore the insect to pitch equilibrium following a disturbance. Differences in the kinematic control mechanisms used by the various insect orders are related to differences in the arrangement of the wings, the construction of the flight motor and the unsteady mechanisms of lift production that are used. Since the evolution of insect flight control is likely to have paralleled the evolutionary re-orientation of these unsteady aerodynamic mechanisms, taxonomic differences in the kinematics of control could provide an assay of the relative importance of different unsteady mechanisms. Although the control kinematics vary widely between orders, the number of degrees of freedom that different insects can control will always be limited by the number of independent control inputs that they use. Control of the moments about all three axes (as used by most conventional aircraft) has only been proven for larger flies and dragonflies, but is likely to be widespread in insects given the number of independent control inputs available to them. Unlike in conventional aircraft, however, insects' control inputs are likely to be highly non-orthogonal, and this will tend to complicate the neural processing required to separate the various motions.] Address: Taylor, G., Department of Zoology, Oxford University, South Parks Road, Oxford, OX1 3PS, UK. Holotype male: El Salvador, Quebrada Piedra de Afilar, 5.5 km S of Tacuba, 19-IV-1986; deposited at FSCA, Gainesville/FL, USA.] Address: Hellebuyck, V.J., 1277 Lincoln St., Sherbrooke, QC, J1H2H8, Canada

4265. Hellmund, M.; Hellmund, W. (2002): Erster Nachweis von Kleinlibellen-Eiogen (Insecta, Zygoptera, Lestidae) in der mitteleozänen Braunkohle des ehemaligen Tagebaues Mücheln, Bfd. Neumark-Nrd (Geiseltal, Sachsen-Anhalt, Deutschland). *Hallesches Jahrb. Geowiss., Reihe B*, 24: 47-55. (in German, with English summary). ["In May 2001 geological and paleontological research was done in the opencast pit Mücheln, Neumark-Nord. During this effort egg-sets of fossil damselflies (Zygoptera, Lestidae) were found in the (?) Upper Middle Eocene brown coal (= MP 13) of the Geiseltal, the first record in this famous site ever found. In contrast to earlier treated specimens originating from the Messel pit near Darmstadt, whose sediments belong stratigraphically to the Lower Middle Eocene (= MP 11), the described new specimen is around 2.5 mio. a younger. The producer of the Geiseltal egg-sets presumably is a member of the family Lestidae, whereas the Messel specimens were made by individuals of the family Coenagrionidae, respectively Platycnemidae. [...] It is striking that the recently found egg-sets are the only evidence for the entire order Zygoptera over decades of collecting in the pits of the Geiseltal district. Corresponding larva or imagines were never observed. This fact may be due to biostratigraphical reasons on the one hand, but also because of the fact that such filigree and small objects may have been overlooked on the dark substratum during fossil excavations. It has to be underlined once more that the endophytic reproductive strategy of certain damselflies is at least successfully practised since the Paleogene until today. A lot of analogs can be observed in the recent Odonatafauna." (Authors) Egg sets of the recent *Lestes virens*, *L. sponsa*, and *Chalcolestes viridis* in the Köln-Bonn region, Nordrhein-Westfalen, Germany are illustrated in detail.] Address: Hellmund, M., Martin-Luther-Universität Halle-Wittenberg, Inst. Geol. Wiss. und Geiseltalmuseum, Domstr. 5, D-06108 Halle/Saale, Germany. E-mail: hellmund@geologie.uni-halle.de

4266. Hellmund, M.; Hellmund, W. (2002): Neufunde und Ergänzungen zur Fortpflanzungsbiologie fossiler Kleinlibellen (Insecta, Odonata, Zygoptera). *Stuttgarter Beiträge zur Naturkunde (B)* 319: 1-26. (in German, with English summary). ["A specimen from the Lower Miocene of Berzdorf (Lusatia, Saxony) was recently discovered during field work in an open coal mine. The other specimens described and figured here have also a Lower Miocene Age (MN5) and originate from the locality Randecker Maar (Southwest Germany). In both sites, Berzdorf and Randecker Maar, the fossil egg-sets are the only evidence for the presence of the Suborder Zygoptera in the fossil insect fauna, due to biostratigraphical reasons. Because of the rapid decomposition of such filigree animals after death, they rarely become fossil. For the first time, egg-sets of the „Lestid Type"

are documented in a monocotyledon leaf. A detailed overview of the hitherto published specimens of fossil egg-sets is compiled." (Authors)] Address: Hellmund, M., Martin-Luther-Universität Halle-Wittenberg, Inst. Geol. Wiss. und Geiseltalmuseum, Domstr. 5, D-06108 Halle/Saale, Germany. E-mail: hellmund@geologie.uni-halle.de

4267. Ishimoda-Takagi, T.; Nakamura, Y.; Takamori, H. (2002): On the tropomyosin isoforms contained in odonate muscles. *Zoological Science (Tokyo)* 19(12): 1436. (in English). [Verbatim: We have investigated heterogeneity of muscle tropomyosin obtained from various species of insects to understand generality of insect tropomyosin isoforms. However, we did not investigate yet tropomyosin obtained from Odonata, which is one of phylogenetically primitive insect and of which wing-beat depends on the action of both direct and indirect flight muscles. In the present study, we examined tropomyosin isoforms included in muscles of 4 species of the odonate, *Anax nigrofasciatus*, *Orthetrum albistylum*, *Pantala flavescens*, and *Calopteryx japonica*. Four to five kinds of tropomyosin isoforms were detected electrophoretically in each species. One kind of tropomyosin isoforms were detected exclusively in the flight muscles of all species. We also examined tropomyosin isoforms included in the larvae of *A. nigrofasciatus* and *C. japonica*. However, the flight muscle specific-isoform was not detected in the larval muscles of both species.] Address: Ishimoda-Takagi, T., Department of Biology, Tokyo Gakugei University, Koganei, Tokyo, 184-8501, Japan

4269. Kadoorie Farm and Botanic Garden (in collaboration with Shenzhen Fairy Lake Botanical Garden. The National Forest Park Office of Shenzhen Special Economic Zone Government) (2002): Report of a Rapid Biodiversity Assessment at Wutongshan National Forest Park, Shenzhen Special Economic Zone, China, 16 to 17 May 2001. *South China Forest Biodiversity Survey Report Series* 11: 20 pp. (in English). [Verbatim: Dragonflies. 17 dragonfly species were recorded (tab. 6). The stream at Xiaowutongshan, with more gentle flow and smaller rocks, yielded more species than the cascade-boulder stream at Dawutongshan. Table 6. Dragonflies recorded in Shenzhen Wutongshan National Forest Park on 16-17 May 2001. Sequence follows Schorr et al. (2001a, 2001b). Species 1. *Mnais mneume* 2. *Neurobasis chinensis* 3. *Rhinocypha perforata* 4. *Philloganga vetusta* 5. *Euphaea decorata* 6. *Agriomorpha fusca* 7. *Drepanosticta hongkongensis* 8. *Sinosticta ogatai* 9. *Coelliccia cyanomelas* 10. *Copera marginipes* 11. *Leptogomphus elegans* 12. *Hydrobasileus croceus* 13. *Orthetrum glaucum* 14. *Orthetrum triangulare* 15. *Tramea virginia* 16. *Trithemis aurora* 17. *Zygonyx iris* The most interesting findings were the records of *Drepanosticta hongkongensis* and *Sinosticta ogatai*. These two species of global conservation concern (Fellowes et al., in press) were previously thought to be endemic to Hong Kong (Reels, 2001). *Mnais mneume*, *Philloganga vetusta*, *Agriomorpha fusca* and *Leptogomphus elegans* are globally restricted, and known from a limited

number of sites in Hong Kong (Fellowes et al., in press), but do not appear to be highly restricted within South China. *Zygonyx iris* is also of potential global concern, due to its narrow global range. All dragonfly and damselfly species found in this survey have been recorded in Hong Kong. (Fellowes, J.R., Lau, M.W.N., Dudgeon, D., Reels, G.T., Ades, G.W.J., Carey, G.J., Chan, B.P.L., Kendrick, R.C., Lee K.S., Leven, M.R., Wilson, K.D.P. and Yu Y.T., in press. Wild animals to watch: terrestrial and freshwater fauna of conservation concern in Hong Kong. Memoirs of the Hong Kong Natural History Society 25.)] Address: www.kfbg.org.hk/download/No11Wutongshan0501Web.pdf

4270. Khaliq, A. (2002): Potential of dragonflies as bio-control agents of insect pests of rice. In: Kumar, A. (Ed.): Current trends in odonatology. Daya Publishing House. Delhi. ISBN 81-7035-274-6: 1-26. (in English). ["The feeding capacity of 11 dragonfly species on some insect pests of rice in a day (10 hours) was determined by forced feeding. The adults consumed [...] on yellow stem borers, white stem borers, hairy caterpillars, rice skippers, white-backed planthoppers, white leafhoppers, green leafhoppers, rice bugs, cicadellid leafhoppers and grasshoppers (*Oxya* spp.) respectively in 10 hours. The females of all the species proved to be the most voracious feeders as compared with their males, *Orthetrum sabina* was most voracious feeder followed by *O. prunosum neglectum*, *O. triangulare triangulare*, *O. glaucum*, *Crocothemis seivillia*, *O. erythraea*, *Pantala flavescens*, *Palpopleura sexmaculata sexmaculata*, *Sympetrum commixum*, *Acisoma panorpoides panorpoides* and *Trithemis festiva*. The population density of dragonflies was maximum from middle of August to the end of September. However, it was at peak from last week of August to 3rd week of September. The population then declined as the crop matured and the pest population become low. The studies on the seasonal abundance of insect pests of rice, namely rice skippers, grasshoppers, green leafhoppers, white leaf hoppers, hairy caterpillars, rice bugs, rice stem boms and *Poophilus* species were conducted at four localities, i.e. Hajeera, Mandhole, Harighale, and Banipasari during the crop season 1996-97. The population of rice skippers and grasshoppers was somewhat higher than other insect pests. However, the population of different insect pests was higher from the 2nd week of August to the 4th week of September. The population then decreased afterwards as the crop matured. The efforts were made to evaluate the feeding potential of dragonflies in the field cages. They did not show any activity and interest in their prey due to their captivity. In view of this dragonfly attitude, the relationship between the population of dragonflies and insect pests of rice was observed by the multiple linear regression equation. The statistical analysis revealed that the dragonflies had negative regression coefficient with the population density of all the insect pests. It indicated that the pest population was decreased with the corresponding increase in dragonflies population. However, their feeding behaviour was not similar at all the localities but differed from locality to locality." 4274. Kumar, A. (2002): Ecology of larval odonates in lentic freshwater ecosystems. In: Kumar, A. (Ed.): Current trends in odonatology. Daya Publishing House. Delhi. ISBN 81-7035-274-6: 115-150. (in English). [Wetlands of Santal Pargana, India; "The present investigation deals with the seasonality, species diversity, richness of species and secondary productivity of larval odonates as well as the various abiotic factors of the surroundings from January to December, 2000. The anisopteran larvae showed trimodal peaks whereas zygopteran larvae exhibited bimodal in their seasonality during the period of study. The species diversity varied between 0.332 to 1.918 bits and between 0.672 and 1.902 bits in anisopteran and zygopteran larvae respectively. The biomass of the larvae was recorded maximum in September (0.553 g/haul) whereas minimum was in April (0.212 g/haul). The net growth of the population varied between 0.0087 g. dry wt./cub. met. /day to 0.0005 g.dry wt./cub.met/day having positive growth in the population. The product moment correlation coefficient for biomass of larval population with different abiotic factors of water were also computed and dissolved oxygen (DO) showed marked correlation with the biomass of the Odonata larvae ($r=0.898$; $p>0.05$)."] (Author)] Address: Kumar, A., Northern Regional Stn., Zool. Daya Publishing House. Delhi. ISBN 81-7035-274-6: 189-206. (in English). ["The present article elaborates the structure of respiratory

organs and oxygen uptake by dragonfly larvae in freshwater ecosystems. Gills were found in branchial chamber which have filled the maximum posterior part of the abdominal cavity. The rectal gills were observed in six rows and recorded their tracheal supply from four to six main longitudinal tracheal trunks. The oxygen consumption by the 3rd and 5th instar nymphs of dragonfly was also estimated and found that oxygen uptake was directly dependent upon the body size and age group of the larvae. The average oxygen uptake (mlO₂/larvae/hr.) was 0.0112 ± 0.0015 for 3rd instar larvae whereas it was 0.0160 ± 0.0020 for 5th instar larvae. It was also observed that the 5th instar larvae utilized about 0.0048 ml O₂/individual/hr. more oxygen than the 3rd instar larvae." (Author)] Address: Kumar, A., Northern Regional Stn., Zool. Surv. Daya Publishing House. Delhi. ISBN 81-7035-274-6: 329-356. (in English). ["The present investigation has been made on the systematics, faunistic composition, and community structure and biomass estimation of zygopteran larvae.

During the present observation, altogether 22 species belonging to 9 genera under 4 families were recorded. The maximum production of the larvae was found in summer and monsoon months when positive increase in biomass was recorded. The maximum production rate was recorded in October (0.060 g/cub m/day) and minimum (0.004 g/cub m/day) in January. It was also found that the production of these larvae is governed by complex extrinsic and intrinsic physical, chemical and biological factors discussed in the text." (Author) Larvae of the following species are illustrated: *Elatoneura campioni*, *Copera marginipes*, *Pseudagrion rubriceps*, *P. laidlawi*, *Ceriagrion coromandelianum*, *Ischnura aurora*, *I. senegalensis*, *Rhodischnura nursei*, *Agriocnemis pygmaea*, *Bayadera indica*, *Neurobasis chinensis*, and *Rhinocypha unimaculata*.] Address: Kumari, Poonam, Dept of Zoology, S.G. 4284. Liljaniemi, P.; Vuori, K.-M.; Ilyashuk, B.; Luotonen, H. (2002): Habitat characteristics and macroinvertebrate assemblages in boreal forest streams: relations to catchment silvicultural activities. *Hydrobiologia* 474: 239-251. (in English). ["We compared the stream habitat characteristics and macroinvertebrate assemblages of boreal headwater streams in both the Finnish and the Russian parts of a single river basin, the Koitajoki River. Over the last 50 years, the Finnish side of the catchment has been managed using modern forestry techniques, whereas Russian side has remained nearly unexploited and is near to its natural state. Differences in silvicultural activities were observed to contribute to differences in habitat structure. The channel habitats were in fairly natural state in the Russian reference streams, whereas the impacted Finnish sites were cleared and straightened. In comparison with the impacted channels, the abundance of coarse woody debris (CWD) was 10-100-fold higher in the reference streams. Implications on the forestry-induced deterioration of water quality were also observed. On the contrary, only small differences in macroinvertebrate assemblages were detected. Despite the lower amount of retentive structures (CWD), significantly higher relative abundance of shredders was observed in the forestry-impacted streams. Otherwise the zoobenthic communities were quite similar in the two subcatchments. [...]" No reference to the Odonata is made in the main text. In an appendix, 4 odonate species are listed: *Calopteryx virgo*, *Cordulegaster boltonii*, and *Somatochlora metallica* from both countries, *Platycnemis pennipes* from Finland only.] Address: Liljaniemi, P., Dept Biol. & Envir. ASEAN Review of Biodiversity and Environmental Conservation (ARBEC) July-September 2002: 8 pp. (in English). ["The macroinvertebrate community of the fast flowing rivers of the Crocker Range Park examined consists mainly of insects. All the six rivers surveyed demonstrated excellent water quality. The assemblages of taxa reported from the study sites are considered as that typical of the macroinvertebrate fauna in tropical rivers. Out of the existing ten orders of insects that contain aquatic species, a total of 7 orders of aquatic insect species were encountered in the rivers surveyed. These are Ephemeroptera, Odonata, Plecoptera, Hemiptera, Coleoptera, Trichoptera and Diptera. In addition to these insects, the hexapodan Collembola was also encountered. The overall macroinvertebrate density ranges from 71 to 303 individuals per 1m sq and all sampling sites were found to sustain at least three groups of taxa with the exception of Sg. Tikolud, which only contains the dipteran chironomids. The dipteran chironomid fauna was dominant and found at all stations and forms the highest density of up to 250 individuals per m² in Sg. Tandulu and Balayo." (Authors)] Address: www.arbec.com.my/pdf/art12julysep02.pdf

4287. Mancinelli, G.; Costantini, M.L.; Rossi, L. (2002): Cascading effects of predatory fish exclusion on the detritus-based food web of a lake littoral zone (Lake Vico, central Italy). *Oecologia* 133: 402-411. (in English). ["An enclosure experiment was carried out in the reed-dominated littoral zone of a volcanic lake (Lake Vico, central Italy) to test whether the impact of predatory fish on benthic invertebrates cascades on fungal colonisation and breakdown of leaf detritus. The abundance, biomass, and Shannon diversity index of the invertebrate assemblage colonising *Phragmites australis* leaf packs placed inside: (1) full-exclosure cages, (2) cages allowing access only to small-sized fish predators, and (3) cageless controls, were monitored over a 45-day period together with the mass loss and associated fungal biomass of leaf packs. The species composition of the fungal assemblage was further assessed at the end of the manipulation. In general, invertebrate predators did not show any significant response to fish exclusion, either on a trophic guild or on a single taxon level. In contrast, the exclusion of large predatory fish induced a diverse spectrum of changes in the abundance and population size-structure of dominant detritivore taxa, ultimately increasing the biomass and Shannon diversity index of the whole detritivorous guild. These changes corresponded with significant variations in leaf detritus decay rates as well as in the biomass and assemblage structure of associated fungal colonisers. Our experimental findings provide evidence that in Lake Vico effects of fish predators on invertebrate detritivores influence the fungal conditioning and breakdown of the detrital substrate. We conclude that in lacustrine littoral zones predator-driven constraints may structure lower trophic levels of detritus-based food webs and affect the decomposition of leaf detritus originated from the riparian vegetation." (Authors) The biomass of "Odonata ssp (larval stages)" totalled to 0,66%.] Address: Rossi, L., Department of Genetics and Molecular Biology, Ecology Area, University of Rome "La Sapienza", Via dei Sardi 70, I-00185 Rome, Italy. e-mail: loreto.rossi@uniroma1.it

4288. Michal, A., (2002): Feeding ecology of Central European bat community. IXth European Bat Research Symposium Le Havre 26-30 August 2002: 22- (in English). ["Trophic ecology of 16 bat species living sympatrically in SE Czech Republic was studied by means of faecal analysis of netted animals. Food supply was studied using a light trap, sweeping and beating. The collected material enabled to assess main foraging strategies of bats, detailed seasonal dynamics of trophic niches and their overlaps in sympatry, foraging success of particular species etc. *E. serotinus*, *E. nilssonii*, *M. brandtii*, *M. mystacinus*, *M. daubentonii*, *N. leisleri*, *N. noctula* and *P. pipistrellus* s.l. can be classified as aerial hawkers, while *M. myotis* is a ground gleaner. Some food items (Odonata and Ephemeroptera larvae) in the diet of *M. daubentonii* indicate the use of water-surface gleaning. *M. nattereri*, *M. emarginatus*, *M. bechsteini*, *P. auritus* and *P. austriacus* are foliage gleaners. Two species do not fit well in any of these groups and their

groups and their strategies can be called slow hawking (*B. barbastellus*) or slow hawking/hovering/gleaning (*R. hipposideros*). Comparing food supply and the diets of bats, we can state opportunistic foraging of most species in the frame of their morphological and echolocation constraints. On the other hand, a trend of selectivity was found in several species which preferred hunting of relatively big species of Lepidoptera in summer, although small species distinctly prevailed in the food supply. Considerable differences were recorded in the foraging success rate, flying activity and weight changes between *P. auritus* and *M. daubentonii* - representatives of the groups applying different foraging strategies - foliage gleaning and aerial hawking. Compared to *M. daubentonii*, *P. auritus* is able to forage more effectively very early in the spring and late in the autumn, it shows higher flying activity during these periods and its weight grows earlier in spring." 4290. Neumann, M.; Dudgeon, D. (2002): The impact of agricultural runoff on stream benthos in Hong Kong, China. *Water Research* 36: 3103-3109. (in English). ["We investigated three small streams in the New Territories of Hong Kong, China. In each stream, we compared the benthic macroinvertebrate fauna of one site immediately upstream of an area of agricultural land (market gardening) with a second site immediately downstream. Each pair of sites was <300m apart. Samples were taken at the end of the dry season (March 2000) and again (April 2000) just after heavy rainfall had caused runoff from the fields. The total number of taxa at the downstream sites was the same as that in the upstream sites in March. In April, the total taxon richness was lower at the downstream localities although this difference was statistically significant in only one stream. The acute toxic effect of runoff became clearer when focusing on the group of sensitive benthic fauna. The grouping was done by ranking the relatively physiological tolerance to organotoxins following the relevant literature (*Bull. Environ. Contam. Toxicol.* 67 (2001) 360). All streams showed a significant downstream decrease in the number of sensitive taxa in April, while in two of three streams the number of relatively tolerant taxa increased. Ordination (by n-MDS) confirmed this pattern. It revealed a marked temporal trend in all streams resulting from a decrease of sensitive taxa downstream that was not apparent at the upstream sites. The size of the observed effects varied among streams, and may have reflected differences in the composition of the agricultural runoff." 4297. Ring, S.; Kraus, F. B.; Schierwater, B.; Hadrys, H. (2002): Evolutionary ecology and genetic diversity measures in dragonflies. *Poster, Deutsche Zoologische Gesellschaft 2002*: (in English). ["Results and discussion: The microsatellite analysis for *O. coerulescens* revealed 5 private alleles exclusively present in the CdV population. These alleles were lost after the dredging and a significant mode shift in allele frequencies took place which is typical for bottleneck situations (Fig. 1, Levins 1970; Luikart et al. 1998). Despite considerable gene flow between populations the alleles could not be recovered by the surrounding subpopulations (F-statistic). Due to the fact that the CdV population recovered very fast (2 generations) this cryptic loss of genetic diversity will remain undetected by traditional monitoring techniques. Sequence data for *C. splendens* and *C. haemorrhoidalis* populations on the contrary showed no to very little (<0.5%) intraspecific genetic diversity despite a broader geographic scale including various geographic phenotypes (Tab. 1). On the supposed subspecies level sequence divergence was also minimal, whereas depending on the marker a genetic variation of up to 15.7% could be detected among species (Fig. 2). The genetic homogeneity of all 3 markers tested is not congruent with data for other species and opposes our expectation based on the high number of geographical phenotypes within this family compared to other Odonata groups (Vogler & DeSalle 1994, Watanabe & Chiba 2001). The postglacial recolonization hypothesis presents a possible explanation for the low sequence divergence on the intraspecific and subspecies level suggesting recent habitat shifts and rapid radiation of the European *Calopteryx* clade (Hewitt 1993)."] (Authors)] Address: Ring, Sabine, ITZ, Ecology & Evolution, TiHo Hannover, Bünteweg 17d, 30559 Hannover, Germany. (Ed.): *Current trends in odonatology*. Daya Publishing House. Delhi. ISBN 81-7035-274-6: 315-328. (in English). ["The present article deals with the seasonal variations in the energy contents, productivity in terms of g/m²/month/year, food and feeding biology and foraging ratio (FR) of *Mesogomphus lineatus* Selys, *Cordulegaster* sp. (Anisoptera: Odonata) and *Ischnura* sp. (Zygoptera : Odonata) of a fish pond of Bhagalpur (Bihar, India). The maximum calorific values of *M. lineatus*"]

tus Selys and Cordulegaster sp. (5.487 ± 0.003 Kcal/g dry weight and 5.430 ± 0.00 Kcal/g ash-free dry weight) was recorded in September. However, the minimum calorific value (4.133 ± 0.09 Kcal/g dry weight) was recorded in January. The calorific values of *Ischnura* sp. (3.706 ± 0.032 Kcal/g dry weight and 3.470 ± 0.034 Kcal/g ash-free weight) was measured. It was investigated that the calorific values of these larvae varied from instar to instar, month to month and upon the physiological state of the animals. The annual productivity was measured as 2.414g dry wt/cub. met/year with monthly productivity being 0.210 g dry wt/cub. met/month. The gut content analysis of the larval odonates revealed that the Rotifera, Cladocera, Rhizopoda and aquatic insects form the maximum percentage of food items in *Ischnura* sp. but in *M. lineatus* Selys and *Cordulegaster* sp. Rhizopoda were recorded in very small quantity and other food items such as Rotifera, Cladocera, Copepoda, aquatic insects and other animal tissues were found in maximum percentage in the foregut. Due to the utilization of food present at various trophic levels of the food chains, they have regulatory impact in the management of the aquatic ecosystems as well as their mere presence indicates healthy and non-contaminated environments." 4300. Stirpari, N. de L.; Henry, R. (2002): The invertebrate colonization during decomposition of *Eichhornia azurea* KUNTH in a lateral lake in the mouth zone of Paranapanema River into Jurumirim Reservoir (Sao Paulo, Brazil). *Braz. J. Biol.* 62(2): 293-310. (in English with Portuguese summary). ["The invertebrate colonization during decomposition of *Eichhornia azurea* was observed in a lateral lake in the mouth zone of Paranapanema River into Jurumirim Reservoir in two periods of the year. The litter bags method was used for measuring the decomposition rate as well as to evaluate the invertebrates colonization. Forty-two litter bags, measuring 15 - 20 cm in size and 2 mm mesh net, were incubated in situ. Six litter bags (three for colonization and three for decomposition measurements) were removed after the 1st, 3rd, 7th, 14th, 28th, 56th and 72nd days of incubation. After each day, the material was carefully cleaned for detritus removal and invertebrate (including Odonata) sampling. The biological material was fixed with 4% formaline and then sorted and identified. The remaining plant material was dried in an oven (at 60°C) and weighed. A fast material loss occurred during the first 24 hours and the decomposition rate was higher during the rainy season than in the dry season. A peak on invertebrate density (110 ind.g.DW 1) on the remaining detritus of *Eichhornia azurea* was recorded in the 56th day of dry season, when the polyphenol concentration of plant detritus was 0.57 UDO.g.DW 1. In the rainy season, higher density was found in the 28th day of incubation, when the polyphenol concentration was 4.36 UDO.g.DW 1. Apparently, the reduction in the

polyphenol concentration was followed by an increase in invertebrate densities. The majority of the species observed in the detritus belongs to the collector group that was dominant after the 7th and 14th days in the rainy and dry seasons, respectively." Daya Publishing House. Delhi. ISBN 81-7035-274-6: 255-272. (in English). ["The territoriality and reproductive behaviour of *A. pygmaea* has been studied in detail in a perennial pond "Dalpat Sagar", Jagdalpur Bastar District, Madhya Pradesh, India. The territoriality is strongly demonstrated by some of the males. Males copulate both isochromatic and heterochromatic forms of females with equal consideration. Precopulatory courtship display is present and brief 4 to 7 Sec (mean: 4.2, N = 9). Intramale sperm translocation has occurred only after the seizure of the female and lasted for 12-18 Sec (mean : 15.35, N = 8). The copulatory wheel was formed during the perched condition; and stage I lasted for 20 to 42 min (mean: 28.05 N =14). While stage II lasted for 2 to 6 min (mean: 4.75, N = 14). The oviposition is endophytic and performed both in tandem and female alone. Behavioural comparisons at various levels have been drawn with the other members of the family Coenagrionidae." 4307. Anderson, A.R.; Petranka, J.W. (2003): Odonate predator does not affect hatching time or morphology of embryos of two amphibians. *Journal of Herpetology* 37(1): 65-71. (in English). ["Many larval amphibians respond to predators by developing broad tail fins that increase maneuverability and reduce predation risk. Recent evidence also indicates that amphibian embryos may adaptively alter their time at hatching in the presence of a predator, but the generality of this phenomenon is unknown. We examined whether embryos of the Wood Frog (*Rana sylvatica*) and Spotted Salamander (*Ambystoma maculatum*) would alter hatching time, hatching synchrony, or body morphology in the presence of a larval predator. Using a 2 × 2 factorial design, we exposed developing embryos to four experimental treatments that varied in predation risk: unfed *Anax junius* (an odonate predator), fed *A. junius*, conspecific larvae, or water. Response variables were central tendency (mean or median) and variation (CV or range) for hatch time and developmental stage and four linear body dimensions that were used to detect changes in morphology. Effect sizes were small (< 0.36), and none of the response variables differed significantly among treatments, suggesting that embryos of these species do not respond strongly to the presence of a predator. This and other studies indicate that the response of

amphibian embryos to predators varies both within and between taxa, although the adaptive significance of such variation is poorly resolved. We discuss the possible roles of developmental constraints and natural selection in explaining the lack of strong responses of *Rana* and *Ambystoma* embryos to a dangerous larval predator." 4308. Ballantyne, A.P.; Brett, M.T.; Schindler, D.E. (2003): The importance of dietary phosphorus and highly unsaturated fatty acids for sockeye (*Oncorhynchus nerka*) growth in Lake Washington a bioenergetics approach. *Can. J. Fish. Aquat. Sci.* 60: 12-22. (in English). ["Juvenile sockeye salmon (*Oncorhynchus nerka*) in Lake Washington experience very high growth rates, but the mechanisms regulating their growth rates are poorly understood. The potential for food quality limitation of growth was tested using a coupled bioenergetics and mass balance model. Sockeye and zooplankton prey species were analyzed for their fatty acid composition. Ratios of phosphorus to carbon (P:C) for both sockeye and zooplankton were obtained from the literature. Based on sockeye stomach contents and zooplankton weights, diets of zooplankton biomass were calculated and monthly values of specific fatty acids and P:C ratios in the diet were derived. An increase in highly unsaturated fatty acids, especially in the liver, was observed with increased fork length up to smoltification size, with a subsequent decrease in smolts and kokanee. Measurements of docosahexaenoic (DHA) in daphnids were significantly lower than in cyclopoids. Model predictions suggest that sockeye are not limited by the availability of phosphorus or eicosapentaenoic acid (EPA) in their diet but may experience limited growth because of DHA deficiencies. Thus, the ability and efficiency of sockeye at elongating 18:3 ω 3, 18:4 ω 3, and EPA to DHA may be of critical importance to lacustrine growth and production. ... Eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) contents (% total fatty acids) of various freshwater and marine prey taxa of salmonids (revised from Higgs et al. 1995 and references therein). Odonata: 9.4%." (Authors); Address: Ballantyne, A.P. Department of Civil and Environmental Engineering, University of Washington, Seattle, WA 98195, USA. 4312. Bojsen, B.H.; Jacobsen, D. (2003): Effects of deforestation on macroinvertebrate diversity and assemblage structure in Ecuadorian Amazon streams. *Archiv für Hydrobiologie* 158(3): 317-342. (in English). ["The effects of deforestation on stream macroinvertebrate faunas were studied at twelve sites located in an area of fragmented rainforest in the Ecuadorian Amazon. The most pronounced changes in habitat characteristics with reduced riparian canopy cover were a reduced amount of litter detritus on the streambed and an increased periphyton biomass. Alpha diversity decreased with the degree of deforestation. Beta diversity was also lower in deforested than forested sites, indicating that macroinvertebrate composition among the forested sites were more heterogeneous than among the deforested sites. Total macroinvertebrate density increased with decreasing canopy cover, and with increasing periphyton biomass. The relative density of Ptilodactylidae, Tanypodinae, Euthyplociidae, Libellulidae and Megapodagrionidae were positively related with either canopy cover or litter detritus. A marked effect on the trophic structure of the macroinvertebrate fauna was found. The relative density of collectors decreased with canopy cover and the amount of litter detritus, while the relative density of predators increased. Shredder abundance was low and unrelated with canopy cover. Temporal variability in the macroinvertebrate data were greater in the deforested sites than in the forested sites. Using two-way indicator species analysis (TWINSPAN) and principal components analysis (PCA) riparian canopy cover was found important structuring the macroinvertebrate assemblages. Litter detritus associated with particulate organic material was the main variable related with the PCA ordination axes." 4315. Clausnitzer, V. (2003): Odonata of African humid forests - a review. *Cimbebasia* 18: 173-190. (in English). ["In this review, distribution patterns and diversity of dragonflies are discussed in respect to the geological and climatic history of African forests. The review focuses primarily on the humid forests of eastern Africa, but equally applies elsewhere in Africa. The ecology of forest dragonflies, which is as diverse as the broad spectrum of aquatic habitats in the forests, is outlined. The need for further research on all topics related to the ecology of forest dragonflies is stressed. Forest dragonflies are most often stenotopic and highly sensitive to habitat disturbance and have a high potential as indicator species. The conservation of African humid forests is discussed and possible steps towards their protection proposed." (Author)] Address: Clausnitzer, Viola, Liebenauer Str. 180, D-06110 Halle/Saale, Germany. E-mail: violacl@gmx.de

4316. Corbet, P.S. (2003): A positive correlation between photoperiod and development rate in summer species of Odonata could help to make emergence date appropriate to latitude: a testable hypothesis 1. *J. entomol. soc. Brit. Columbia* 100: 3-17. (in English). ["In the western Nearctic and the Palearctic Regions several species of Odonata occur, without evident gaps in distribution, from latitude 50° N northwards to the Arctic Circle (66°30' N) and beyond. The decline in incident solar radiation along this latitude gradient does not appear to be reflected, as might be expected, in progressively later emergence, despite the progress of metamorphosis being dependent on ambient temperature. On the contrary, reports indicate that, in some species, northernmost populations may emerge at least as early as, and sometimes even earlier than, more southerly populations, suggesting that some mechanism exists that enables larval developmental rate to compensate for latitude. Reported responses by late-stadium larvae to photoperiod, placed in the context of seasonal changes of photoperiod at different latitudes, make it plausible to postulate the existence of a single, fixed response to photoperiod that would continuously adjust

developmental rate to latitude, at least between 50° and 70° N. In Odonata such a response, to be effective, would be confined to species possessing a Type-2 or Type-3 life cycle, in which more than one stadium precedes metamorphosis in spring or early summer. The hypothesis proposed here does not invoke genetic heterogeneity of response in populations at different latitudes, such as has been detected in certain other insects. The response predicted by the hypothesis may complement, rather than substitute for, other mechanisms of seasonal regulation. Steps are described by which the hypothesis could be tested in Odonata." (Author)] Address: Corbet, P.S., Crean Mill, Crean, St Buryan, Cornwall, TR19 6HA, UK. E-mail: pscorbet@creanmill.u-net.com

4317. Corbet, P.S. (2003): Ecological perspectives of African Odonata. *Cimbebasia* 18: 167-172. (in English). ["The distribution and seasonal ecology of African Odonata are determined by the habitats available and their seasonal continuity, which in turn reflect seasonal patterns of rainfall. Rainfall within the tropics is determined by the periodic passage of the Inter-Tropical Convergence Zone; at Africa's northern and southern extremities the climate is Mediterranean. Life cycles of African Odonata reveal two dichotomies: temperate versus tropical, and regulated versus unregulated. Examples are provided of life-cycle strategies of species occupying temporary waters in the tropics. Hypotheses regarding their method of dispersal and dry-season survival are reviewed, and ways are suggested whereby useful information about their seasonal ecology may be obtained." (Author)] Address: Corbet, P.S., Crean Mill, Crean, St Buryan, Cornwall, TR19 6HA, UK. E-mail: pscorbet@creanmill.u-net.com

4318. Córdoba-Aguilar, A.; Uhia, E.; Cordero Rivera, A. (2003): Sperm competition in Odonata (Insecta): the evolution of female sperm storage and rival's sperm displacement. *Journal of Zoology, London* 261: 381-398. (in English). ["Odonates are well known for the ability of the males to displace sperm stored in the female's spermstorage organs during copulation. By this means, copulating males are able to increase their fertilization success. This ability has been used as an example to illustrate a conflict of interests between the sexes in which males have evolved sperm-displacement mechanisms whilst females have presumably evolved means to avoid sperm displacement. The present review has four aims: (1) to describe the copulatory mechanisms used during sperm displacement; (2) to analyse the causes of sperm usage patterns; (3) to discuss this information using current hypotheses on conflict between the sexes; (4) to illuminate topics for further research. Four copulatory mechanisms are described: sperm removal (physical withdrawal of stored sperm), sperm repositioning ('pushing') of rival sperm to sites where its use will be least likely), female sensory stimulation to induce sperm ejection, and sperm flushing (displacement of sperm using the copulating male's sperm). Sperm-precedence studies in Odonata are scarce and their values vary considerably between species. In those species in which sperm-displacement is incomplete, the last copulating male obtains a high but variable short-term fertilization success which decreases with time. Some male and female factors affecting sperm precedence patterns are mentioned: (1) male variation in genital morphology; (2) duration of copulation influenced by the male (the lon-

ger the copulation, the more stored sperm displaced); (3) adaptations of the sperm-storage organs that allow the female to manipulate the sperm she has received (i.e. avoiding sperm displacement, re-distributing sperm masses, favouring sperm located in certain sites and ejecting sperm after copulation). We suggest that male and female odonates have co-evolved at the level of genital function with the control of stored sperm as the focus of the conflict. The benefits for males in this co-evolution lie in maximizing their fertilization success. However, it is not clear what females obtain from storing sperm and making it unreachable during sperm displacement. Two hypothetical benefits that females may obtain for which some evidence has been gathered are genetic diversity and viability genes. It is finally suggested that odonates can become excellent subjects of study for testing current ideas related to sexual conflict and speciation processes through sexual selection." (Authors)] Address: Cordoba-Aguilar, A., Centro de Investigaciones Biologicas, Universidad Autonoma del Estado de Hidalgo, Apdo. P. 69-1, Plaza Juarez, Pachuca, Hidalgo 42001, Mexico E-mail: acordoba@uah.reduaeh.mx

4319. Cross, W.F.; Benstead, J.P.; Rosemond, A.D.; Wallace, J.B. (2003): Consumer-resource stoichiometry in detritus-based streams. *Ecology Letters* 6: 721-732. (in English). ["Stoichiometric relationships between consumers and resources in detritus-based ecosystems have received little attention, despite the importance of detritus in most food webs. We analysed carbon (C), nitrogen (N), and phosphorus (P) content of invertebrate consumers (including *Lanthus* sp.), and basal food resources in two forested headwater streams (one reference and the other nutrient-enriched). We found large elemental imbalances between consumers and food resources compared with living plant-based systems, particularly in regard to P content, which were reduced with enrichment. Enrichment significantly increased nutrient content of food resources (consistent with uptake of N and P by detritus-associated microbes). P content of some invertebrates also increased in the enriched vs. reference stream, suggesting deviation from strict homeostasis. Nutrient content varied significantly among invertebrate functional feeding groups, orders and, to some extent, size classes. Future application of stoichiometric theory to detritus-based systems should consider the potential for relatively large consumer-resource elemental imbalances and P storage by insect consumers." 4321. De Celis, J.F.; Diaz-Benjumea, F.J. (2003): Developmental basis for vein pattern variations in insect wings. *Int. J. Dev. Biol.* 47: 653-663. (in English). ["The

venation patterns characteristics of different insect orders and of families belonging to the same order possess enormous variation in vein number, position and differentiation. Although the developmental basis of changes in vein patterns during evolution is entirely unknown, the identification of the genes and developmental processes involved in *Drosophila* vein pattern formation facilitates the elaboration of construction rules. It is thus possible to identify the likely changes which may constitute a source of pattern variation during evolution. In this review, we discuss how actual patterns of venation could be accounted for by modifications in different Pterygota of a common set of developmental operations. We argue that the individual specification of each vein and the modular structure of the regulatory regions of the key genes identified in *Drosophila* offer candidate entry points for pattern modifications affecting individual veins or interveins independently. Assuming a general conservation of the processes involved in different species, the transitions between different patterns may require few changes in the regulatory gene networks involved." restoration measures rehabilitate fauna diversity in raised bogs? A comparative study on aquatic macroinvertebrates. *Wetlands Ecology and Management* 11(6): 447-459. (in English). ["To assess whether raised bog restoration measures contribute to the conservation and restoration of the fauna diversity, macroinvertebrate species assemblages were compared between water bodies created by rewetting measures and water bodies which have not been subject to restoration measures, but are remnants of former peat cuttings and trenches used for buckwheat culture in the past. The restoration sites were inhabited by characteristic raised bog species and rare species, but their numbers were higher at the remnant sites not affected by restoration management. A considerable number of characteristic and rare fauna species were only found at the remnant sites. The remnant sites included considerably more variation in macroinvertebrate species assemblages and had a higher cumulative species richness. The number of characteristic macroinvertebrate species was not clearly related to the presence of a characteristic raised bog vegetation. In restoration sites numbers of rare and characteristic species per site tended to increase with the time elapsed after rewetting. However, restoration measures will not automatically result in restoration of a more or less complete macroinvertebrate species spectrum, as restoration measures have so far resulted in habitats for only a limited number of the characteristic species. When planning restoration measures, it is recommended to protect the populations of rare and characteristic species present in the area, as these populations may become the sources for colonization of rewetted sites. Safeguarding habitat diversity during the restoration process and restoration of different elements of the habitat diversity of complete raised bog systems will result in the characteristic fauna diversity being conserved and restored more successfully." (Authors) *Ceriatrion tenellum* and *Coenagrion lunulatum* are listed in tab. 4.] Address: Duinen, G.-J.A. van, Bargerveen Foundation, University of Nijmegen, The Netherlands Department of Environmental Studies, University of Nijmegen, The Netherlands. 4328. Geraeds, R.P.G. (2003): The river Roer offers perspectives for dragonflies of running water. *Natuurhistorisch Maandblad* 92: 223-227. (in Dutch with English summary). ["The river Roer houses populations of seven species of dragonfly associated with running water, viz. *Calopteryx splendens*, *Platynemis penni-*

pes, *Cercion lindenii*, *Gomphus vulgatissimus*, *G. pulchellus*, *Stylurus flavipes*, and *Ophiogomphus cecilia*. This makes the river Roer unique in the Netherlands. The most important causes of this variety of dragonflies are the improved water quality, morphology and natural dynamics of the Dutch Roer basin. Unlike the German situation, the river Roer is allowed to meander in most of its Dutch basin. This has resulted in a great morphological variety, providing suitable habitats for dragonfly larvae. It is expected that the circumstances for dragonflies of running water will further improve. The policy of the "Roer en Over-maas" water board aims at further improvement of the water quality and preservation of the unique meandering character of the river Roer. In addition, the Ministry of Agriculture, Nature Management and Fisheries has initiated a procedure to designate the valley of the river Roer as a special conservation area under the EU Habitat Directive." (Authors)] Address: Geraeds, R.P.G., Julianalaan 46, NL-6042 JH Roermond, The Netherlands

4329. Geske, C. (2003): Die Tier- und Pflanzenarten der Anhänge II und IV der Fauna-Flora-Habitat-Richtlinie in Hessen - Rechtliche Vorgaben, Rahmenbedingungen und Stand der Umsetzung in Hessen. Jahrbuch Naturschutz in Hessen 8: 115-123. (in German). [This paper is of some interest, for the odonate fauna of Hessen, Germany is known quite bad. It contains unpublished records of *Coenagrion mercuriale*, *Ophiogomphus cecilia*, and *Leucorrhinia pectoralis*, and outlines current activities for mapping these species in Hessen.] Address: Geske, C., Hess. 4330. Glupov, V.V.; Kryukova, N.A.; Khodyrev, V.P.; Sokolova, Yu.Ya (2003): Endocytobionts of haemocytes of *Aeshna juncea* L. dragonfly (Odonata). Eurasian entomological journal 2: 131-132. ["In haemocytes of *Aeshna juncea* dragonfly larvae endocytobionts were found. After haemocyte monolayer staining endocytobionts were visualized in light microscope as dark-red inclusions contrasting to the surrounding haemocyte cytoplasm being blue in colour. EM analysis showed that the most of endocytobionts are look elongate in shape. An infected haemocytes contain microorganisms are surrounded by multilayer envelopes, residing in a special compartments very often, but not always filled with homogenous matrix. Presumably, these compartments represent the sites of bacteria multiplication, since several bacteria can be usually recognized within each vacuoles. Great number of coated vesicles, multivesicular bodies and an empty membrane profiles can be observed in the area of the cell being occupied by endosymbionts indicating the participation of host cell lysosomal system in the formation of endosymbiont-containing compartment. It is stated that only plasmatocytes and, sometimes, granulocytes bear endocytobionts of dragonfly haemocytes. The isolated microorganisms were identified as bacteria of the genus *Pseudomonas*. The number of dragonfly larvae containing *Pseudomonas* bacteria reached 73-78% of the whole population in natural water basins of Novosibirsk region in 1997. Water temperature rising up to 28°C in laboratory experiment caused to the mortality increasing of the infected larvae up to the 73-79%, whether mortality of the uninfected larvae population did not exceed the 5-7%. Analysis of the fresh cadaverous and alive insects shows big amount of *Pseudomonas* bacteria inside the hae-

mocytes and the lymph. Laboratory experiments proved that the occurrence of *Pseudomonas* does not depend on such reactions of the larvae cellular response as encapsulation. We suppose that the bacteria of the genus *Pseudomonas* are the normal bacterial endocommensals, which could be pathogenic under a certain stress factor(s), and influence on the regulation of population dynamics of the hosts." 4336. Hammer, J.; Linke, R. (2003): Assessments of the impacts of dams on the DuPage River. The Conservation Foundation, Naperville: 48 pp. (in English). [Illinois, USA. "Over the last fifteen years The Conservation Foundation and others have worked hard to improve and protect the quality of the DuPage River watershed. Many improvements have been seen both in water quality and the increased level of awareness people have for the river and river issues. Many more people view the river as an important part of the ecosystem and amenity in their community. Although great strides have been made, there is still much to do to meet the water quality goals of the Clean Water Act of fishable and swimmable. Some of the greatest constituents of concern are nutrients, sediment and habitat alteration. Dams can increase the impacts of all three, with the greatest consequences to aquatic habitat. This study has collected data that indicates that dams on the DuPage River are a significant contributor to the overall degradation of native aquatic species and their habitat. Water quality sampling performed as part of the study indicates that these low-head dams probably do not significantly exacerbate the existing, system-wide water quality problems of the DuPage River. As discussed in Sections 2 through 5 of this report, three of the five dams within the study area do not provide any useful function other than they maintain a flat water pool and create the sound of rushing water, both of which are usually considered attractive to many people visiting the public areas around these dams. Moreover, all of the dams (the ones at Channahon and Hammel Woods in particular) create an elevated safety hazard to the people using the river, be it for fishing, swimming, or boating. Dam owners and local decision makers should actively consider options to address these safety and ecological concerns so that the safety of the general public and patrons to these facilities is improved and the health of the watershed's natural resources are preserved.

The next four sections of the report are organized into separate assessment reports for each of the four dams included in this study. Information on potential alternatives, their benefits, drawbacks and associated costs has been included to provide decision makers and stakeholders with as much site-specific information as possible to make the most informed decision as to how to manage the dams to ensure a safe and healthy future for residents, visitors and the river." (Authors) 14 odonate taxa are listed in table 1.9. <http://www.theconservationfoundation.org/tcf/wp/assessmentofdupageriverdams.pdf>] Address: The Conservation Foundation, 10S404 Knoch Knolls Road, Naperville, IL 60565, USA

4337. Hermans, J.T.; Maanen, B. van (2003): Dragonflies of the Beegerheide area: survey findings from 2001 to 2002. *Natuurhistorisch Maandblad* 92: 126-133. (in Dutch with English summary). ["The adult dragonfly fauna of all the moorland pools of the Beegerheide area was monitored by the first author throughout the period from 1984 to 2001. In addition, eleven pools were examined for dragonfly larvae by the Limburg Water Authority in 2002. In 2001, 27 species of dragonfly were observed in the area, while the total number of species observed between 1984 and 2001 is 35. The status of the Beegerheide dragonflies is surveyed in table II. Fifteen species are regarded as wanderers or irregular guests, nineteen species are permanent inhabitants and one species (*Coenagrion lunulatum*) seems to have disappeared. The most common dragonflies of the Beegerheide are *Lestes vrens*, *Enallagma cyathigerum*, *Pyrrhosoma nymphula*, *Anax imperator*, *Libellula quadrimaculata*, and *Sympetrum danae*. Adults of *Lestes sponsa* and *Coenagrion puella* were also common, but their larvae were rather rare, suggesting the existence of very local, larger populations from which the adults disperse. *Ceragrion tenellum* was rediscovered as larvae at two locations in 2001 and four in 2002. Larvae of *Aeshna juncea* were still found in the area, although no adults were seen in 2001. A very interesting finding was that of larva of *Leucorrhinia pectoralis*. In addition, the larvae survey revealed several 'new' reproductive sites of *Lestes viridis*, *C. tenellum*, *Sympetrum sanguineum*, and *Leucorrhinia dubia*. There were no great shifts in the dragonfly species composition between 1984 and 2001, (table II) The pools at the Beegerheide area are very important for several species of dragonfly, and pool restoration measures taken during the last five years have had a favourable effect on the dragonfly fauna. The activities were implemented on a small scale to achieve greater habitat diversity by saving parts of the vegetation structure, especially at peat fens. It is essential that this process is continued to maintain the area's characteristic dragonfly community." (Authors)] Address: Hermans, J.T.; Hertestraat 21, NL-6067 ER Linne, The Netherlands

It is lavishly illustrated throughout, with excellent colour photographs of Wen-Kuei (Taiwan). The presented information covers the usual subjects as eating and being eaten, cleaning, mating, larval growth, emergence etc.] Address: Thomson Gale, World Headquarters, 27500 Drake Road, Farmington Hills, MI 48331, USA

4341. Jansen, W.; Tham, J.; Koch, M. (2003): Die aquatische Invertebratenfauna des Moorkomplexes Wurzacher Ried (Landkreis Ravensburg): Biodiversität, habitatspezifische Artengemeinschaften, Rote-Liste-Status und Zielarten-Konzeption. Stuttgarter Beiträge zur Naturkunde, Serie A (Biologie) 655: 1-19. (in German with English summary). ["Between 1991 and 1996 we collected aquatic macroinvertebrates (MIB) from 28 water bodies within the Wurzacher Ried", a south German bog and fen complex of 17 km² area that has been awarded the European Diploma for nature reserves. In this baseline study, we documented 581 species of MIB. The three orders Trichoptera, Coleoptera, and Diptera, with more than 120 species each, contributed substantially to the biodiversity among the MIB. The relatively high proportion of specialized bog species among the Trichoptera (12%), the Coleoptera (21 %), and the Odonata (23%) is indicative of the generally natural state of the Wurzacher Ried. In addition to most of the bog specialists, numerous other endangered species were identified, resulting in a relatively high proportion of Red Data book species to the total number of species found. For Gastropoda and Odonata, this proportion amounted to 42 % and 58 %, respectively. The six types of water bodies differentiated in this study based on their water chemistry and vegetation (raised bog, acid transitional fen, neutral transitional fen, fen, bog forest, and streams) showed typical MIB communities that could be distinguished taxonomically at both the order and species level. Within each of the six types of water bodies we found further community differences that mainly correlated with structural features as, for example, the area of the open water. Based on our findings and literature data, we identified target/indicator species to facilitate the evaluation of future changes in the aquatic habitats of the Wurzacher Ried." 4349. Lamberigts, M. (2003): Diatoms, macroinvertebrates and water quality of the Beegderheide moorland pools. *Natuurhistorisch Maandblad* 92: 112-125. (in Dutch with English summary). ["The Beegderheide nature reserve was originally a sand dune landscape, and includes over thirty moorland pools. Eutrophication and natural succession have resulted in the pools being choked by vegetation. Various restoration measures have recently been successfully implemented: organic sediment has been removed and the borders of the pools have been restructured. The Limburg Water Authority has been monitoring the Beegderheide moorland pools since 1987 as part of its water quality survey. The

article outlines the changes in water chemistry found in these studies, particularly relating to the pH, nutrient status and buffer capacity of a number of soft-water moorland pools in the Beegderheide. The restoration measures have improved the environmental conditions and yielded favourable changes in animal and plant communities. Recovery of the specific, valuable circumstances found in moorland pools seems to have been successful, and the restoration measures have resulted in greater habitat diversity. The macroinvertebrate community proved to be species-rich, with many rare species characteristic of peat bogs. During the first year after the completion of the restoration, the relatively rich diatom flora indicated disturbance, some nutrient enrichment and a somewhat increased calcium buffering. In the following year, the diatom community in most of the pools became very poor in terms of species as well as numbers, with species indicating acid and nutrient-poor conditions abundant in some of the pools. The system seems to be lacking in buffer capacity. Acidification is to be expected in these areas, where acid deposition is high and the catchment soil is poor in lime and other easily dissolved minerals that provide a buffer against acid precipitation. The effects of future changes should be followed by continued chemical and biological monitoring, which should help to finetune the restoration activities to prevent further acidification." (Author) 19 odonate species including *Ceriagrion tenellum*, *Leucorrhinia rubicunda* and *L. pectoralis* are listed.] Address: Lamberigts, Monique, Barend van Maanen & Bert Pex, Zuiveringschap Limburg, Postbus 314, 6040 AH Roermond

4350. Legrand, J. (2003): Sur le genre malgache *Isomma*, I. hieroglyphicum Selys, male, female, larve et description d'une nouvelle espece (Odonata, Anisoptera, Gomphidae, Phyllogomphinae). *Revue française d'entomologie (N.S.)* 25(1): 43-54. (in French, with English summary). ["The genus *Isomma* has been described by Selys on a single female from Madagascar. Later he described the male on a specimen belonging to Rene Martin whose collection is preserved in MNHN Paris. Till now only a few specimens were known and the genus was erroneously placed among Gomphinae. The genus and the first species, *I. hieroglyphicum*, are redescribed and illustrated [...]. A new species, *Isomma elouardi*, also from Madagascar, is described.] Address: Legrand, J., 10, rue du Chemin de fer, F-94110 Arcueil, France

4351. Martens, K. (Ed.); [Dumont, H.J.] (2003): Bibliography of Henri J. Dumont. *Hydrobiologia* 500(1-3): 1-21. (in English). [The bibliography lists 349 publications, including some 80 odonatological papers. As far as I could trace, only two odonatological titles are missing: Dumont, H. (1996): The dragonfly fauna of the Caspian Basin. *Selysia* 24(1): 9-10, and Dumont, H.J. (2003): Odonata from the Republic of Mongolia and from the Autonomous Region of Inner Mongolia. *International Journal of Odonatology* 6(2): 127-146.] Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. Ledeganckstraat 35, B-9000 Gent, Belgium. E-mail: Henri.Dumont@rug.ac.be

4352. Meuris, L. (2003): Na zeer lange afwezigheid terug *Glassnijder* (*Brachytron pratense*) in de Damvallei. *Gomphus* 19(2): (in Dutch, with English and French summaries). ["*Brachytron pratense* back in the Damvallei after a long absence. On June 19th 2002 a perching

male *B. pratense* has been reported from the peat-bogs of the Damvallei (Laarne, East-Flanders, Belgium). The previous observation dates from 73 years back. In other marshy areas along the Flemish section of the river Scheldt, there have also been some recent observations of the Hairy Dragonfly. It seems that *Brachytron* numbers are increasing in the Scheldt Valley. A similar tendency has recently become apparent in the neighbouring regions of France, Germany and the Netherlands. In this specific case, the observed *Brachytron* probably was a wanderer. Its origin remains uncertain. To establish any populations in the Flemish Scheldt Valley, one should search for exuviae in the areas surrounding the recent observations." (Author)] Address: Meuris, L., August Van Bockxstaelestraat 7, 9050 Gent, Belgium. E-mail: Luc.meuris@pandora.be

4354. Mizutani, A.; Chahl, J.S.; Srinivasan, M.V. (2003): Insect behaviour: Motion camouflage in dragonflies. *Nature* 423, vom 5. Juni 2003: 604. (in English). ["Most animals can skilfully conceal themselves when stationary, but they may become apparent as soon as they move. Here we use stereo cameras to reconstruct the movements in three dimensions of dragonflies (*Hemianax papuensis*), and show that these insects actively use motion camouflage to disguise themselves as stationary during territorial aerial manoeuvres. Deployment of this sophisticated technique by the oldest airborne predator tricks the victim's retina into perceiving the stalker as stationary even while it darts about in pursuit." (Authors)] Address: Mizutani, Akiko, Centre for Visual Science, Research School of Biological Sciences, Australian National University, PO Box 475, Canberra, ACT 2601, Australia. 4357. O'Grady, E.W.; May, M.L. (2003): A phylogenetic reassessment of the subfamilies of Coenagrionidae (Odonata: Zygoptera). *Journal of Natural History* 37 (23): 2807-2834. (in English). ["We reanalyzed subfamily divisions of Coenagrionidae phylogenetically using morphological characters. Characters historically and currently used to divide Coenagrionidae, as well as previously unpublished characters, were carefully defined or redefined and coded. Many characters traditionally used in coenagrionoid taxonomy were found to be continuously distributed rather than falling into discrete states. Nevertheless, it is just these characters on which most subfamily distinctions are based, we regarded it as essential to try to assess their effects in phylogenetic analysis. Therefore, character states for continuously distributed morphometric characters were determined using a clustering algorithm. We also present trees that exclude these characters, however. Cladistic analysis indicates that, of the existing subfamilies, only the apophyletic Agriocnemidinae is monophyletic. Shortest trees were markedly shorter than ones in which all current subfamilies were constrained to be monophyletic. Cladistic analysis using characters of Davies and Tobin (1984) and Fraser (1957) alone to define subfamilies resulted in poorer resolution and failed to support monophyly of any of the current subfamilies, as did alternative character weightings. Even a phenetic comparison using discriminant analysis failed to support the existing taxonomy. Our phylogeny suggests the existence of several possible clades within Coenagrionidae, but none are strongly supported by bootstrap analysis or decay index values. Coenagrionidae as a whole is polyphyletic in our shortest trees, although trees supporting a monophyletic Coenagrionidae are only slightly longer. We conclude that subfamilies should not be recognized within Coenagrionidae until well-supported subdivisions are demonstrated." 4365. Sane, S.P. (2003): Review: The aerodynamics of insect flight. *The Journal of Experimental Biology* 206: 4191-4208. (in English). ["The flight of insects has fascinated physicists and biologists for more than a century. Yet, until recently, researchers were unable to rigorously quantify the complex wing motions of flapping insects or measure the forces and flows around their wings. However, recent developments in high-speed videography and tools for computational and mechanical modeling have allowed researchers to make rapid progress in advancing our understanding of insect flight. These mechanical and computational fluid dynamic models, combined with modern flow visualization techniques, have revealed that the fluid dynamic phenomena underlying flapping flight are different from those of non-flapping, 2-D wings on which most previous models were based. In particular, even at high angles of attack, a prominent leading edge vortex remains stably attached on the insect wing and does not shed into an unsteady wake, as would be expected from non-flapping 2-D wings. Its presence greatly enhances the forces generated by the wing, thus enabling

insects to hover or maneuver. In addition, flight forces are further enhanced by other mechanisms acting during changes in angle of attack, especially at stroke reversal, the mutual interaction of the two wings at dorsal stroke reversal or wing wake interactions following stroke reversal. This progress has enabled the development of simple analytical and empirical models that allow us to calculate the instantaneous forces on flapping insect wings more accurately than was previously possible. It also promises to foster new and exciting multidisciplinary collaborations between physicists who seek to explain the phenomenology, biologists who seek to understand its relevance to insect physiology and evolution, and engineers who are inspired to build micro-robotic insects using these principles. This review covers the basic physical principles underlying flapping flight in insects, results of recent experiments concerning the aerodynamics of insect flight, as well as the different approaches used to model these phenomena." (Author) Odonata are referred on several opportunities.] Address: Sane, Sanjay P., Department of Biology, University of Washington, Seattle, WA 98195, USA. E-mail: sane@u.washington.edu

4366. Solem, J. (2003): You should have seen the one that got away! *Argia* 15(4): 27. (in English). [Verbatim: On a hot summer day, my husband, Bob, fellow enthusiast June Tveekrem, and I spent an afternoon visiting reservoir sites for odonates. At Pigtail boat landing on Triadelphia Reservoir in central Maryland, we were getting our gear assembled and checking out nearby odes when two young men with fishing rods came over and inquired what we were catching. Bob explained our quest; men we started down the path while they stayed in the parking lot to fish. We had not gone more than 100 yards when we heard yelling: "I've got one." "Do you want to see it?" "It's a big one!" After debating briefly how they could have actually caught a dragonfly when they didn't have a net, we started back, moving swiftly with Bob in the lead. When June and I arrived, Bob was kneeling on the ground extracting something from under his net. It was a female *Nasiaeschna pentacantha*. How had it been captured? As one fisherman dangled his lure over the water, the dragonfly zoomed up and grabbed the artificial 3 inch yellow minnow. (Talk about her eyes being bigger than her stomach!) The young man flipped the lure back on shore with the dragonfly still clinging to it. When Bob came up, the odonate and the lure were still on the ground so he clapped a net over them. It was the first female of the species we had had in hand so June took numerous photos, and the proud young man asked us to take his picture with the dragonfly and the lure. Eventually, we set the odonate on a shrub; later, when we returned, she was gone. Not only was this one of our most intriguing odonate experiences, but August 19 was also a new late date for the species for most part of the state.] Address: not stated

4367. Terzani, F.; Marconi, A. (2003): Descrizione della femmina di *Agriocnemis angustirami* Pinhey, 1974 e qualche osservazione sul maschio. (*Insecta*, Odonata, Coenagrionidae). *Quaderno di studi e notizie di storia naturale della Romagna* 17(Suppl.): 1-4. (in Italian with English summary). [Sierra Leone; a female - taken in copula - is described and illustrated for the first time. In addition, some descriptive notes on, and figures of the male are provided.] Address: Terzani, F., Mus. - 4368.** Van de Meutter, F. (2003): 150 jaar libellengeschiedenis in de Maten (Genk): een reis doorheen de tijd. *Gomphus* 19(2): 79-89. (in Dutch, with English and French summaries). ["150 years of history of Odonata in de Maten (Genk, Belgium): a travel through time. Based on data spanning the past 150 years, we make a reconstruction of the history of the dragonfly fauna of the nature reserve 'de Maten' (Genk). These data were compared with data of the present dragonfly community. During the studied period of 150 years, 54 species of dragonflies were recorded in the reserve of which 18 have gone extinct by now. Recently, another 3 species succeeded in colonizing 'de Maten'. These 3 species presumably are not very choosy in their habitat requirements. Finally, the present status of some red-list species that still occur in de Maten is discussed." (Author) The locality once inhabited such species as *Nehalennia speciosa* and *Oxygastra curtisii*.] Address: Van de Meutter, F., Arthur De Greefstraat 36, 3000 Leuven, Belgium. E-mail: frank.vandemeutter@bio.kuleuven.ac.be
- 4369.** Van Lieshout, F.; Peelers, E.; Franken, R.; Kuiper, R. (2003): The river Allier as an ecological reference for the "Border Meuse"? *Natuurhistorisch Maandblad* 92: 10-16. (in Dutch with English summary). ["An ecological comparison was made between the section of the river Meuse that forms the border between the Netherlands and Belgium (the so-called "Border Meuse") and the Allier River in France, in order to assess the suitability of the river Allier as a reference for the ecological recovery to be expected in the Border Meuse after the implementation of the current reconstruction plans. Special attention was given to the macroinvertebrate community and its functional aspects, such as preference for flowing water and feeding ecology. The macroinvertebrate community in the Allier was found to include more families requiring good water quality. Furthermore, the Border Meuse community included only a few of the typical families with a preference for flowing water. Possible explanations for these differences are the lack of suitable habitats and the poor water quality in the Border Meuse. The Border Meuse community also includes very few sediment-inhibiting detritivores. This might be caused by the poor condition of the sediment, which is contaminated with heavy metals and organic micropollutants. Finally, several exotic species" - including *Dikerogammarus villosus*; see OAS 3686 for its negative effects on Odonata - "were found to have colonised the Border Meuse, which might have a dramatic effect on the native macroinvertebrate community. A comparison of the present data with historical data on the Border Meuse indicated that many species that prefer flowing water have disappeared, and that there used to be far more detritivores as well. The present study, along with previous research on the Border Meuse, revealed a number of bottlenecks for ecological recovery. The first is the poor water quality, but as water quality is improving, this may not be too serious. The second problem is the lack of habitat diversity, and the third is the unnatural discharge variations caused by the dam at Lixhe in Belgium. New bottlenecks identified by the present study are the polluted sediment and the presence of exotic species. Since the reconstruction project does not address these two impediments, they may undermine the expected ecological recovery of the Border Meuse." (Authors) While in the Allier "*Calopterygidae*" and "*Gomphidae*" are present, these taxa are not represented in the Border Meuse. Only "other Odonata" taxa are represented in both rivers.] Address: Floor van Lieshout, Edwin Peelers & Rob Franken, Waenigen Universiteit Leerstoelgroep Aquatische Ecologie en Waterkwaliteitsbeheer, Postbus 8080, 6700 DD Wageningen, The Netherlands
- 4370.** Vanreusel, W.; Cortens, J. (2003): Uitzonderlijk vroege waarnemingen van de Gewone bronibel (*Cordulegaster boltonii*). *Gomphus* 19(2): 51-54. (in Dutch, with English and French summaries). ["Exceptionally early recordings of the Golden-ringed dragonfly {*Cordulegaster boltonii*}. During fieldwork in the East of Flanders, we observed *Cordulegaster boltonii* on different locations in the National Park "Hoge Kempen". Several recordings were done early in the year. In 2003, the earliest observation was on May 7. This is more than 3 weeks before the earliest known recording in Belgium, Germany and the Netherlands. This is exceptional since the phenology of dragonflies is usually relatively constant. It could be interesting to pay more attention to this species in spring." (Authors)] Address: Vanreusel, W., & Cortens, Joeri, Onderzoeksgroep Dierenecologie, Universiteit Antwerpen, Campus Drie Eiken, Universiteitsplein 1, 2610 Wilrijk, Belgia. - 4372.** Westermann, K. (2003): Erster Bodenständigkeitsnachweis der Pokaljungfer (*Cercion lindenii*) für den höheren Schwarzwald. *Naturschutz am südlichen Oberrhein* 4(1): 87-88. (in German, with English summary). [Germany, Baden-Württemberg. "In the year 2003, *C. lindenii* emerged successfully in the Black Forest near St. Märgen (county of Breisgau-Hochschwarzwald) at 845 m a.s.l. The emergence site is the highest one known in Baden-Württemberg and in Germany. Most likely, the water does not support an autochthonous population but is being recolonised by migrating individuals stemming from the Upper Rhine Valley." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de
- 4373.** Westermann, K. (2003): Schlüpfabundanz und Schlüpfhabitat des Frühen Schilffjägers (*Brachytron pratense*) im Naturschutzgebiet Rheinniederung Wyhl-Weisweil. *Naturschutz am südlichen Oberrhein* 4(1): 99-112. (German, with English summary) [Germany. "In the nature reserve 'Rheinniederung Wyhl-Weisweil' (county of Emmendingen, Baden-Württemberg) with a total area of 1350 ha, exuviae of *B. pratense* were collected quantitatively as far as possible. At least 48 waters were inhabited by the species, with a total count of at least 400 freshly emerged imagoes. The highest abundances found were 39 exuviae/100m resp. 21 exu-

viae/50 m of water body length. Five waters yielded more than 50% and 15 waters more than 75% of all exuviae recorded. The population as a whole appears to be stable, supported by a few densely populated waters and a multitude of waters with medium or low abundances. *B. pratense* is common along spring fed waters ("Gießen"), ground water fed ponds, oxbows, excavated pools and backwaters of the Rhine river. All of these water types are stagnant or only slowly flowing and have extended zones of shallow water - these are probably the crucial habitat factors. The abundances of exuviae rise with the width of the zones of shallow water. Very shallow waters prone to sporadic desiccation are avoided. The habitat used for emergence and its usage during the process of emergence are described in detail." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

4374. Westermann, K. (2003): Zum Schlüpfsubstrat der Gebänderten Prachtlibelle (*Calopteryx splendens*) an südbadischen Altrheinen. *Naturschutz am südlichen Oberrhein* 4(1): 95-98. (in German, with English summary). [Germany, Baden-Württemberg; "Larvae *C. splendens* preferred several reed species for emergence. Shrubs thriving along the shoreline were used only sporadically. In most cases the imagoes emerged on the lower surface or on the edges of the substrate. Accordingly, the angle between larva and the horizontal line ranged from 90° to 180°. On a bridge made of concrete with a rough surface, the ceiling (180°) was clearly preferred over diagonal parts of the bridge. Vertical pillars and foundations, however, were usually avoided." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

4375. Westermann, K. (2003): Zum Status der Großen Königlibelle (*Anax imperator*) im höheren Schwarzwald. *Naturschutz am südlichen Oberrhein* 4(1): 81-85. (in German, with English summary). [Germany, Baden-Württemberg. "Hitherto, useful data about occurrences of *A. imperator* in higher elevations of the Black Forest were very scarce. Successful reproduction was shown for the species in a pond at 830 m a.s.l. during two years, and, in the year 2003, in two ponds at 900 and 915 m a.s.l., respectively. In three more ponds at altitudes of up to 944 m a.s.l., ovipositions were observed. *A. imperator* was found almost exclusively in ponds with turbid or humic water, in which the water temperatures climb markedly during the summer. The waters were furnished with dense vegetation made up of floating-leaved aquatic macrophytes or at least with low reed vegetation." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

4376. Westermann, K. (2003): Zur Konkurrenz zwischen der Pokaljungfer (*Cercion lindenii*) und der Hufeisen-Azurjungfer (*Coenagrion puella*) an Altrheinen bei Weisweil (Landkreis Emmendingen). *Naturschutz am südlichen Oberrhein* 4(1): 91-94. (in German, with English summary). [Germany, Baden-Württemberg. "The once predominant damselfly species *C. puella* has become much less abundant in the backwaters of the Rhine river following the immigration of another Coenagrionid species, *C. lindenii*, which has established very large populations over the course of one or two decades. In backwaters which remain cool during the

summer or which are shallow, as well as in small water bodies, *C. lindenii* has remained scarce so that *C. puella* could maintain its original population sizes. A collapse of the *C. lindenii* populations following a major flood event led to a significant rise in the population sizes of *C. puella*. The data presented here support the hypothesis brought forward repeatedly that *C. puella* has become largely replaced by *C. lindenii* in many waters of the Upper Rhine valley in southern Baden." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. E-mail: fosor@t-online.de

4380. Wootton, R.J.; Herbert, R.C.; Young, P.G.; Evans, K.E. (2003): Approaches to the structural modelling of insect wings. *Philosophical Transactions: Biological Sciences* 358(1437): 1577-1587. (in English). ["Insect wings lack internal muscles, and the orderly, necessary deformations which they undergo in flight and folding are in part remotely controlled, in part encoded in their structure. This factor is crucial in understanding their complex, extremely varied morphology. Models have proved particularly useful in clarifying the facilitation and control of wing deformation. Their development has followed a logical sequence from conceptual models through physical and simple analytical to numerical models. All have value provided their limitations are realized and constant comparisons made with the properties and mechanical behaviour of real wings. Numerical modelling by the finite element method is by far the most time-consuming approach, but has real potential in analysing the adaptive significance of structural details and interpreting evolutionary trends. Published examples are used to review the strengths and weak-

nesses of each category of model, and a summary is given of new work using finite element modelling to investigate the vibration properties and response to impact of hawkmoth wings." (Authors) The paper contains references to Odonata.] Address: Wootton, R.J., School of Biol. Sciences, University of Exeter, Hatherly Laboratories, Prince of Wales Road, Exeter EX4 4PS, UK

4381. Zakaria, T. (2003): CIA used dragonfly, catfish as spy gadget models. *Argia* 15(4): 27. (in English). [Verbatim from *Argia* 15(4): 27: "CIA USED DRAGONFLY, CATFISH AS SPY GADGET MODELS from the web. Original article by Tabassum Zakaria (from Reuters, article appeared 28 Oct 2003) LANGLEY, Va. (Reuters) - The CIA once built a mechanical dragonfly to carry a listening device but found small gusts of wind knocked it off course so it was never used in a spy operation. The agency also tested a 24-inch-long rubber robot catfish named "Charlie" capable of swimming inconspicuously among other fish and whose mission remains secret. Charlie and the dragonfly were among spy gadgets displayed at CIA headquarters in an exhibit to mark the 40th anniversary of the Directorate of Science and Technology. It is not open to the public. "Charlie's mission is still classified, we can't talk about it," Toni Hiley, curator of the CIA museum, told Reuters on a tour of the exhibit "All we can say is he's our work on aquatic robotic technologies." After seeing the life-like "insectothopter," Hiley jokes that she cannot look at a dragonfly the same way anymore. In the 1970s the CIA had developed a miniature listening device that needed a delivery system, so the agency's scientists looked at building a bumblebee to carry it. They found, however, that the bumblebee was erratic in flight, so the idea was scrapped. An amateur entomologist on the project then suggested a dragonfly and a prototype was built that became the first flight of an insect-sized machine, Hiley said. A laser beam steered the dragonfly and a watchmaker on the project crafted a miniature oscillating engine so that the wings beat, and the fuel bladder carried liquid propellant. Despite such ingenuity, the project team lost control over the dragonfly in even a gentle wind. "You watch them in nature, they'll catch a breeze and ride with it. We, of course, needed it to fly to a target. So they were never deployed operationally, but this is a one-of-a-kind piece," Hiley said."]

4382. Abro, A. (2004): The female seminal receptacle and accessory glands in *Pyrrhosoma nymphula* (Sulzer) (Zygoptera: Coenagrionidae). *Odonatologica* 33(3): 237-244. (in English). ["Sperm, transmitted to the female as individual filamentous cells suspended in a liquid medium, are discharged into a thick-walled pouch, the receptaculum seminis, on the dorsum of the vaginal canal. Spermatozoa soon appear concentrated in a single, smaller, pear-shaped accessory sac, the spermatheca, attached to the receptaculum-vagina junction. Particular cells in the wall of the accessory sac secrete a material that is thought to be added to the sperm concentrate. The purpose of the accessory sac is to serve as a store of spermatozoa for use in fertilization. A pair of posterior accessory glands has each an efferent duct that opens into the distal region of the vaginal canal; these ducts are provided with an elaborate muscular

apparatus probably serving as a pump; in fresh material, efferently directed peristaltic waves have been observed. The glands are presumed to contribute to the investment of the eggs. The apical domains of the glandular epithelial cells contain intraplasmic assemblages of multiplying bacteroids. They are likely to be transferred to the ooplasm and thereby transmitted to a new generation." 4383. Apodaca, C.K.; Chapman, L.J. (2004): Adult Zygoptera of Kibale National Park, Uganda: habitat associations and seasonal occurrence. *Odonatologica* 33(2): 129-146. (in English). ["In this study, a 10-month survey of four aquatic sites in Kibale National Park, Uganda was used to quantify seasonal and spatial variation in both limnological features of the sites and adult damselfly assemblage structure. Of the 4 limnological characters measured dissolved oxygen was the most variable among sites, ranging from an average of 1.01 mg l⁻¹ in the interior of the Rwembaita Swamp (a papyrus-dominated wetland) to 6.71 mg l⁻¹ in an inflowing tributary of the swamp. Species richness was similar among sites and did not correlate with dissolved oxygen concentration. However, site was a significant predictor of occurrence for some spp. This suggests that site effects are important, and that a combination of site-specific environmental characters may underlie the observed distributional patterns. Seasonal fluctuation in rainfall was not a good predictor of Zygoptera activity. Several species were active in both the wet and dry seasons. Surprisingly, adult *Proischnura subfurcatum* were detected year-round in the hypoxic waters of the Rwembaita (papyrus) Swamp and did not occur at any other sites in the larval or adult phase, suggesting that this species is a swamp specialist." (Authors)] Address: Apodaca, C.K., Fairbanks Fish and Wildlife Field Office, 101 12th Ave., Box 17, Room 222, Fairbanks, AK 99701-6236, USA. E-mail: ChrissyApodaca@fws.gov

4384. Apodaca, C.K.; Chapman, L.J. (2004): Larval damselflies in extreme environments: behavioral and physiological response to hypoxic stress. *Journal of Insect Physiology* 50(9): 767-775. (in English). ["The extensive papyrus (*Cyperus papyrus*) swamps of East and Central Africa form a habitat of great ecological importance due to their extent, the extreme and chronic hypoxia of the interior swamp, and the unique assemblages of water-breathing insects that characterize these communities, including zygopteran (damselfly) larvae. The major goal of this study was to quantify physiological and behavioral responses of gilled and gill-less damselfly larvae of a papyrus swamp specialist, *Proischnura subfurcatum*, to low-oxygen conditions. Gill autotomization was common in *P. subfurcatum* of the Rwembaita Swamp in Kibale National Park, Uganda, with one to three gills missing from 56% of the specimens surveyed. We examined behavioral (ventilation activity and vertical migration) and physiological (metabolic rate) response to hypoxia in gilled and gill-less *P. subfurcatum*. Behavioral response to progressive hypoxia indicated that gill-less individuals rely more on use of wing sheaths (lifting and spreading) than gilled *P. subfurcatum* larvae. However, both morphs migrated to the surface to gain contact with atmospheric air under extreme hypoxia. On average, the rate of oxygen consumption of gill-less individuals was 51% lower than that of gilled individuals. This observed metabolic de-

pression in gill-less *P. subfurcatum* may be attributed to the loss of major respiratory appendages. However, the apparent ability of both gilled and gill-less individuals to maintain their metabolic rates to a similar critical tension suggests other mechanisms may compensate for loss of gills, though not enough to mediate metabolic depression." (Authors)] Address: Apodaca, Christine, Fairbanks Fish and Wildlife Field Office, 101 12th Avenue, Box 17, Room 222, Fairbanks, AK 99701-6236, USA. E-mail: chrissyapodaca@fws.gov

4385. Artiss, T. (2004): Phylogeography of a facultatively migratory dragonfly, *Libellula quadrimaculata* (Odonata: Anisoptera). *Hydrobiologia* 515(1-3): 225-234. (in English). ["The biogeography of a widely distributed dragonfly (*Libellula quadrimaculata*) was examined via a phylogenetic analysis of 416 bp of the mitochondrial cytochrome oxidase I subunit (COI). Phylogenetic analyses under parsimony and minimum evolution produced trees with similar topologies, and revealed strong support for three clades corresponding to populations in Asia, Europe and North America. However, resolution was poor within clades, and genetic distances between populations within continents was quite low (1.2%). Several populations of this species are known to engage in periodic mass migrations, and it is possible that introgression from gene flow due to the mobility of this species has obscured phylogenetic patterns within continents. I was unable to test for phylogenetic patterns coincident with historical glacial refugia given the lack of phylogenetic patterns within continents. However, given that some sequence divergence was observed between populations within continents, it is possible that phylogenetic patterns exist, and subsequent studies should make use of larger data sets, and molecular data from faster evolving genes. Despite the propensity for periodic, short distance migrations in *L. quadrimaculata*, gene flow appears to be limited and does not influence the phylogenetic relationships of populations between continents." 4386. Assis, J.C.F. de; Carvalho, A.L.; Nessimian, J.L. (2004): Composição e preferência por microhabitat de imaturos de Odonata (Insecta) em um trecho de baixada do Rio Ubatiba, Maricá-RJ, Brasil. *Rev. Bras. entomol.* 48(2): 273-282. (in Portuguese, with English summary). ["Composition and microhabitat preferences of Odonata (Insecta) immatures in a lowland section of the Rio Ubatiba, Maricá-RJ, Brazil. Monthly sampling was held from May, 1999 to May, 2000 in the Rio Ubatiba, a lowland river situated at Maricá district, Rio de Janeiro State, Brazil. Seven different substrates were collected along fifty meters. A total of 1,279 larvae of Odonata were collected and identified in 27 species, belonging to five families. The most numerous species were *Acanthagrion lancea* (Selys, 1876), *Hetaerina auripennis* (Burmeister, 1839), *Micrathyrina hesperis* Ris, 1911 and *Telabasis filiola* (Perty, 1834). The greatest number of individuals were found in "riparian plants in depositional areas". In general, the species recorded showed habitat preferences: *Dythemis multipunctata* Kirby, 1894, *Erythrodiplax* sp., *M. hesperis*, *T. filiola*, *A. lancea*, *Erythemis* sp., *Coryphaeschna adnexa* (Hagen, 1861) and *H. auripennis* seem to prefer organic substrates and *Brechmorhoga* sp., *B. praecox* (Hagen, 1969) and *Progomphus complicatus* Selys, 1854, inorganic substrates." 4388. Baber, J.M.; Fleishman, E.; Babbitt, K.; Tarr, T. (2004): The relationship between wetland hydroperiod and nestedness patterns in assemblages of larval amphibians and predatory macroinvertebrates. *Oikos* 107(1): 16-27. (in English). ["Assemblages exhibit nested distributional patterns if the species found in species-poor locations also occur in progressively richer locations. We investigated patterns of nestedness in assemblages of larval amphibians and predatory macroinvertebrates in 42 isolated freshwater wetlands in southern New Hampshire, USA. These wetlands varied markedly in hydroperiod and we predicted that nestedness would be relatively weak because changes in disturbance processes (the relative threat of desiccation and predation) along the hydroperiod gradient often generate distinct assemblages. Contrary to expectations we found that both amphibian and macroinvertebrate assemblages were strongly nested not only with respect to species richness but also with respect to hydroperiod and wetland size, which were positively correlated. We attribute our results to the increased colonization rates and decreased extinction rates associated with increasing hydroperiod, and to concomitant increases in wetland size, habitat heterogeneity / complexity, and possibly water temperature. Moreover, the impact of predatory fishes on species richness and composition of amphibians and macroinvertebrates was relatively minor. We found that amphibians had a significantly lower degree of nestedness than macroinvertebrates, suggesting that a higher proportion of amphibian species found in species-poor assemblages was unlikely to occur in species-rich assemblages of amphibians (e.g. wood frogs and spotted salamanders). The degree of nestedness appeared to be influenced primarily by hydroperiod and wetland size for amphibians, whereas nestedness of macroinvertebrates was influenced by unknown factors (possibly water temperature) in addition to hydroperiod and wetland size. The high degrees of nestedness observed in amphibian and macroinvertebrate assemblages imply that protection of larger, more permanent wetlands may be more important for conserving native biological diversity than protection of smaller, non-permanent wetlands. However, non-permanent wetlands are used by several species of conservation concern that often do not occur in larger and more permanent wetlands." 4389. Baranowska, A.; Zawal, A. (2004): Dragonflies (Odonata) of the Binowskie Lake in the Szczeciński Landscape Park. *Parki Narodowe i Rezerваты Przyrody* 23: 111-120. (in Polish with English summary). [Between 1999 - 2000, a total of 34 dragonfly species were collected. *Calopteryx splendens*, *Lestes dryas*, and *Sympteryx danae* were represented by adults only, and were regarded as immigrants. "The odonate fauna

of the area comprises primarily of eurytopic species with *Enallagma cyathigerum* (dominant) and *Ischnura elegans*, *Erythromma najas*, *Coenagrion pulchellum*, *C. puella*, and *Platycnemis pennipes* (subdominants), the most abundant species, which contributed together to more than 70% of the collection. Due to a high habitat complexity, *Platycnemis pennipes*, a rheophile species occurring also in lentic waters with abundant vegetation, and *Orthetrum cancellatum*, inhabiting mainly extensive lentic areas with poor vegetation, were quite frequent. There were also species such as *Lestes sponsa*, *L. virens*, *Coenagrion hastulatum*, *Aeshna juncea*, *Somatochlora flavomaculata*, and *Libellula fulva*, that are associated with peat bogs and/or dystrophic habitats. The first three of the above listed species inhabited exclusively sites in a peaty cove (stations 7 and 8)(Table 1). The sites located on a small beach (stations 9 and 10) provided a single larva of *Anax imperator* (an Ethiopian - Mediterranean species) and a single larva of *Aeshna viridis* (a protected species, associated with *Stratiotes aloides*)." 4393. Bedjanic, M. (2004): Odonata fauna of Sri Lanka: research state and threat status. *International Journal of Odonatology* 7(2): 279-294. (in English). ["Altogether 116 odonate species are known from Sri Lanka. The level of endemism is high - 53 taxa or 45.7% are confined to the island. The Chlorocyphidae, Euphaeidae, Protoneuridae, Platystictidae, Gomphidae and Corduliidae consist of almost exclusively endemic taxa. The odonate fauna of Sri Lanka is still insufficiently

known. Knowledge on distribution, biology and taxonomy of adults and especially larval forms is very poor. An assessment of threat status showed that it is very endangered due to habitat destruction. A list of 47 endangered odonate taxa has been compiled. It consists of exclusively endemic taxa and comprises more than 80% of described species confined to the island. Altogether 20 species are preliminary put in the IUCN categories 'extinct' (EX) and 'critically endangered' (CR) and are urgently proposed for inclusion in the IUCN Red List. Future Odonatological research priorities and recommendations are given. Special attention should be devoted to the work dealing with taxonomy of larval forms and adults. Serious faunistic mapping should cover the whole island and should be focused on still preserved areas. Simultaneously also the research of biology of selected species and research of seasonal phenology of adult Odonata should be carried out. Effective nature conservation measures in declared protected areas as well as the establishment of new protected areas and corridors in the Wet zone is of biggest importance for effective long-term preservation of a rich endemic fauna and flora of Sri Lanka, including odonates." 4396. Benstead, J.P.; Pringle, C.M. (2004): Deforestation alters the resource base and biomass of endemic stream insects in eastern Madagascar. *Freshwater Biology* 49: 490-501. (in English). ["1. Rainforest streams in eastern Madagascar have species-rich and diverse endemic insect communities, while streams in deforested areas have relatively depauperate assemblages dominated by collector-gatherer taxa. We sampled a suite of benthic insects and their food resources in three primary rainforest streams within Ranomafana National Park in eastern Madagascar and three agriculture streams in the park's deforested peripheral zone. We analysed gut contents and combined biomass and stable isotope data to examine stream community responses to deforestation in the region, which is a threatened and globally important hotspot for freshwater biodiversity. 2. Gut analyses showed that most taxa depended largely on amorphous detritus, obtained either from biofilms (collector-gatherers) or from seston (microfilterers). Despite different resource availability in forest versus agriculture streams, diets of each taxon did not differ between stream types, suggesting inflexible feeding modes. Carbon sources for forest stream insects were difficult to discern using $\delta^{13}C$. However, in agriculture streams dependence on terrestrial carbon sources was low relative to algal sources. Most insect taxa with $\delta^{13}C$ similar to terrestrial carbon sources (e.g. the stonefly *Madenemura*, the caddisfly *Chimarra* sp. and *Simulium* blackflies) were absent or present at lower biomass in agriculture streams relative to forest streams. Conversely, collector-gatherers (*Afroptilum* mayflies) relied on algal carbon sources and had much higher biomass in agriculture streams. 3. Our analyses indicate that a few collector-gatherer species (mostly Ephemeroptera) can take advantage of increased primary production in biofilms and consequently dominate biomass in streams affected by deforestation. In contrast, many forest stream insects (especially those in the orders Plecoptera, Trichoptera and Diptera) depend on terrestrial carbon sources (i.e. seston and leaf litter), are unable to track resource availability and consequently decline in streams draining deforested landscapes. These forest-specialists are often micro-endemic and particularly vulnerable to deforestation. 4. The use of consumer biomass data in stable isotope research can help detect population-level responses to shifts in basal resources caused by anthropogenic change. We also suggest that restoration of vegetated riparian zones in eastern Madagascar and elsewhere could mitigate the deleterious effects of deforestation on sensitive, endemic stream taxa that are dependent on terrestrial carbon sources." (Authors) *Libellula* sp. is listed in table 2.] Address: Benstead, J.P., The Ecosystems Center, Marine Biological Laboratory, Woods Hole, Massachusetts 02543, MA, U.S.A. E-mail: jbenstead@mbl.edu

4397. Berger, C. (2004): *Dragonflies*. Stackpole Books. ISBN 0-8117-2971-0: 134 pp. (in English). [This field guide focuses not on the species descriptions, but in the introductory material, which covers slightly more than half of the entire (thoroughly treated and illustrated) book. Beginning with life history, Cynthia Berger continues with chapters on flight, territoriality, mating, oviposition, prey capture, thermal regulation, migration, construction of a dragonfly pond, etc.. The remainder of the book is devoted to the identification of 27 odonates from eastern US, four Zygoptera and 23 Anisoptera. The author aims to facilitate identification of the more common species encountered in the eastern US, it is

not intended to provide a complete identification key. Each of the 27 species has a page or two, an attractive colored picture, and discussion of habitat and behaviour. The species provided should facilitate to recognize any odonate at least at the family level. The author finishes with a list of useful books, contact addresses, organizations, web sites, and field equipment. This is an easy to read introduction in Odonata which will help many people to get more closely interested in dragonflies. (Martin Schorr)] Address: Stackpole books, 5067 Ritter Rd, Mechanicsburg, PA 17055-6921, USA. www.stackpolebooks.com

4398. Bernard, R.; Ivinskis, P. (2004): *Orthetrum brunneum*, a new species in Lithuania. *Acta Zoologica Lituonica* 14(3): 31-36. (in English, with Lithuanian summary). [*O. brunneum*, "was recorded in two localities in the years 2001-2003. The northernmost position of these localities, probably of the whole species' range, is shown and discussed with reference to climate-related changes in the range and numbers of this species and some other species. The habitat is described and discussed in comparison with the data from central Europe. The establishing of more permanent populations of *O. brunneum* in these latitudes is questionable; its occurrence in Lithuania seems to be dependent on allochthonous nomadic individuals." 4399. Béthoux, O.; Galtier, J.; Nel, A. (2004): Earliest evidence of insect endophytic oviposition. *Palaios* 19 (4): 408-413. (in English) ["The knowledge of fossil plant-insect interactions is almost entirely restricted to evidences of feeding behavior. Records of endophytic oviposition are relatively scarce, with previous earliest reports from the Middle to the early Late Triassic. Nevertheless, several Paleozoic insect taxa have been suspected of this reproductive behavior, but without any direct evidence. Specimens of *Calamites cistii* (Sphenophyta; Pennsylvanian, France) are described showing endophytic cavities, located in the outer cortex of the stem, a tissue that is rarely preserved. This new record shifts the appearance of this behavior back 60 Ma. Possible tracemakers are representatives of the Odonoptera (Odonata and related extinct taxa), Palaeodictyopteroidea (extinct palaeopterous orders), and Archaeorthoptera (Orthoptera and related extinct orders). The antiquity of the insect endophytic oviposition behavior suggests that it could have been important during the emergence and diversification of the insect group." (Authors)] Nel, A., Lab. Ent.. 4400. Beukema, J.J. (2004): Recognition of conspecific females by males of *Calopteryx haemorrhoidalis* (Vander Linden) (Zygoptera: Calopterygidae). *Odonatologica* 33(2): 147-156. (in English). ["Males of calopterygid damselflies appear to court females of other (related, sympatric) species only rarely. Apparently, females of this group bear species-specific characteristics that release sexual behaviour in conspecific males only. Sympatric *Calopteryx* species usually differ conspicuously in pigmentation (colour, transparency, darkness) of their wings. Female *C. haemorrhoidalis* differ from all other European species by the presence of a dark distal zone in the hindwings. - The relative value of various

(manipulated) sets of female wings for elicitation of male courtship was assessed using choice experiments. *C. haemorrhoidalis* males did not court wingless females of their own species nor did they court conspecific females with wings of the sympatric *C. xanthostoma*. However, the presence of a single wing of a conspecific female was sufficient to elicit courtship behaviour. Choices between 2 female models (presented simultaneously to territorial male individuals) revealed that the presence of a contrasting dark zone was an important distinguishing characteristic, whereas too high a transparency (a single wing as opposed to a set of 2 or 4 wings pressed against each other) greatly diminished the value of a model. The need for the presence of a dark zone will be effective in precluding courtship of females of other sympatric species. The need for sufficiently low transparency will put a check on courtship attempts of immature females." (Author)] Address: Beukema, J.J., Royal Netherlands Institute for Sea Research, P.O. 4411. Boyero, L.; Bosch, J. (2004): Multiscale spatial variation of stone recolonization by macroinvertebrates in a Costa Rican stream. *Journal of Tropical Ecology* 20: 85-95. (in English). ["The process of stone recolonization by macroinvertebrates was studied at different spatial scales in a stream in Costa Rica. A hierarchical design was used with riffles nested into reaches, and individual stones nested into riffles. Macroinvertebrate abundance and taxon richness varied at riffle scale, although patterns of variation seemed to change with

time of recolonization, and taxonomic composition varied mostly at reach scale. Patterns of variation of background communities and macroinvertebrate drift at different spatial scales suggest that the contribution of these two sources of colonists to stone recolonization depends on spatial scale. Macroinvertebrate abundance was related to local environmental variables during recolonization, but taxon richness was related to the local environment only in the very first stage of the process. The need for explicitly determining the appropriate spatial scale in the study of substrate recolonization is emphasized." (Authors) "Zygoptera" are listed in Appendix 1 and 2.] Address: Boyero, L., Museo Nacional de Ciencias Naturales (CSIC), José Gutiérrez Abascal 2, 28006 Madrid, Spain. E-mail: luz@mncn.csic.es

4413. Braune, E. (2004): Dispersal of Namibian dragonflies: Population dynamics in a changing landscape. Abstracts: 5th International Symposium on Tropical Biology. SATELLITE EVENTS: 6th International Symposium on the Chrysomelidae; Workshop on African Odonata (Edited by Bernhard A. Huber); Zoologisches Forschungsinstitut und Museum Alexander König, Adenauerallee 160, 53113 Bonn, Germany: 142. (in English). [Verbatim: In the arid and semi-arid regions of western Namibia water is one of the most limiting and limited resources for biodiversity. Climate change is supposed to increase the problems rising from water deficiency. Due to their aquatic/terrestrial life cycle dragonflies may serve as indicator organisms for changes in the water balance, as they are affected through loss of potential habitats. I developed a model for the prediction of the dispersal of Odonata. The model incorporates a population dynamic model based on extended Leslie matrices. The development rates and the survival rates are mainly dependent on the available food in the aquatic habitat. Inter- and intraspecific competition between the larval stages as a mechanism of density dependent population regulation is also included in the model. The model reproduces population dynamic patterns which are typical for tropical-centered dragonflies. The population dynamic model is embedded in a landscape model developed for three regions (in the biomes Namib desert, Nama karoo and tree and shrub savanna). The spatial realisations are grid-based models with extensions of 50*50 km with a cell size of 1 km². Three different landscape parameters, representing the different habitat preferences of the modelled species *Pantala flavescens*, *Crocothemis erythraea* and *Paragomphus* sp., are used to describe the landscape: presence of water, aquatic vegetation diversity and riverbeds as guidelines. These parameters were gained using both GIS Information and expert knowledge. Different scenarios describing the effects of climate change are realised by dynamic modelling of the landscape parameters. With this model it is possible to simulate reactions of dragonfly populations on landscape changes due to water shortage and to investigate which landscape requirements must be met to avoid regional

extinction.] Address: Braune, E., Institute of Geocology, TU Braunschweig, Langer Kamp 19c, 38106 Braunschweig, Germany. E-mail: e.braune@tu-bs.de

4417. Brockhaus, T. (2004): Interspezifische Konkurrenz zwischen *Sympetrum fonscolombii* und *Orthetrum cancellatum* in Mitteleuropa? (Odonata: Libellulidae). *Libellula* 23(1/2): 77-86. (in German, with English summary). ["In 2003, both spp. were observed as common at the pond 'Beuthenteich' (district Stollberg/Erzgebirge, Saxony, Germany). Apart from imaginal records, also larvae of both spp. were sampled. The head widths of 80 larvae of *O. cancellatum* were measured. For seven larvae of *S. fonscolombii* the total length, the head widths and the number of abdominal segments covered by the wing cases were determined. A larva of *S. fonscolombii*, found on 31 August 2003, was damaged partially by predation. The developmental cycles of both species are discussed under the aspect of interspecific competition of the larvae. It is suggested that in 2003 the sp. had three imaginal and two larval generations. However, one can also suggest a retarded development of *S. fonscolombii* because of the presence and the predatory or competitive effect of larger *O. cancellatum*"]

tum larvae in higher densities." (Author)] Address: Brockhaus, T., An der Morgensonne 5, D-09387 Jahnsdorf, Germany. E-mail: T.Brockhaus@t-online.de

4418. Brooks, S.; Lewington, R. (2004): Field Guide to the Dragonflies and Damselflies of Great Britain and Ireland. British Wildlife Publishing. Revised edition. ISBN 0 9531399 0 5: 160pp. (in English). [This latest edition of this popular field guide in Britain (first published in 1997) includes minor revisions to the text, but more significantly the addition of two species recently added to the British list: *Lestes barbarus* and *Chalcolestes viridis*. This book covers a wide range of topics; there is a sound introduction to the life history of the Odonata and their ecology, and also a section on good dragonfly sites throughout Britain and (to a lesser degree) Ireland, selected by people with local experience. About two thirds of the book comprises an identification guide, which includes a short section on larvae. Richard Lewington's artwork is of outstanding high quality, with illustrations typically showing the male and female in dorsal view, with one additional lateral view. Clearly distinct colour forms are also illustrated, and close up views show critical structural features where these are of help to species identification. A small-scale map illustrates the distribution of each species. The text to accompany the illustrations covers identification features, ecology and conservation aspects. Mark Tunmore writes in *Atropos* 22 (2004: 55): "The crisp and detailed illustrations combined with authoritative text ensure that it remains an essential publication for British Odonata enthusiasts." And more than this, it is of high interest for the odonatologists on the European continent too, especially due to its illustrations of all the *Anax* species. As happened in France last year, *Anax junius* can be expected in every western European country, and you should not miss it. 4423. Bulankova, E.; David, S. (2004): Die Verbreitung der in den Anhängen II und IV der FFH-Richtlinie aufgeführten Libellen in der Slowakei und ihr ökologischer Status (Odonata). *Libellula* 22(3/4) (2003): 127-138. (in German with English summary). [“In Annex II and IV 16 dragonflies species are included, 8 of which have been recorded in Slovakia: *Coenagrion mercuriale*, *C. ornatum*, *Leucorrhinia albifrons*, *L. pectoralis*, *Ophiogomphus cecilia*, *Gomphus flavipes*, *Sympecma paedisca*, *Cordulegaster heros*. Records of *C. mercuriale* and *L. albifrons* are of historical interest and in the Red List of plants and animals of Slovakia these species are therefore included in the category "Extinct". Records of the "Endangered" species *S. paedisca*, *L. pectoralis* and *O. cecilia* are still made at present. The "Vulnerable" species *C. ornatum* and *G. flavipes* have been recorded in the recent years in Slovakia too. Large populations of *G. flavipes* were found in the Maly Dunaj River (Danube River basin) and its occurrence was confirmed in the River Morava (March River basin) also. Some new localities of the occurrence of the species *Coenagrion ornatum* are in the Danube River basin too. The newest findings of the threatened species *Cordulegaster heros*, which was not included into the Check list of Odonata of Slovakia until now, is important from the european point of view. Our findings indicate the natural character of some biotopes in Slovakia and their high faunistic value.” (Authors)] Address: Bulankova, Eva, Institute of Ecology, Faculty of Natural Sciences, Comenius University, Mlynská dolina B-II, SK-84215 Bratislava., Slovakia; E-mail: Bulankova@nic.fns.uniba.sk

4424. Buss, D.F.; Baptista, D.F.; Nessimian, J.L.; Engler, M. (2004): Substrate specificity, environmental degradation and disturbance structuring macroinvertebrate assemblages in neotropical streams. *Hydrobiologia* 518: 179-188. (in English). [“Structure and composition of benthic macroinvertebrate assemblages were investigated in seven sampling sites with a gradient of environmental integrity and water quality conditions. Composite samples of the four most representative substrates were collected in order to characterize the riffle-pool dynamic in each sampling site. Spatial and temporal variability of macroinvertebrate assemblages were analyzed at two scales: using substrates and grouping samples for comparing sampling sites. Distri-

bution of macroinvertebrates was influenced primarily by substrate type, but also by environmental integrity, water quality and sampling period. Species occurrence was highly dependent on substrate type. At local spatial scale, environmental degradation measured by the Riparian Channel Environmental Inventory and water chemistry were the determinants of assemblage patterns. We evaluated to which extent the substrates were influenced by environmental integrity and water chemistry, and we found that degradation influenced significantly the macroinvertebrate fauna on the four substrate types, although they were not responding to the same variables. Our results show that qualitatively communities were not influenced by seasonal changes, but abundance was stochastically dependent on rainfall." (Authors) On the genus level, seven odonate taxa are listed in table 2 as dwellers of pool litter.] Address: Buss, D.F., Laboratório de Avaliação e Promoção da Saúde Ambiental, Departamento de Biologia, IOC, FIOCRUZ, Av. 4428. Carchini, G.; Pacione, T.; Tanzilli, C.; Di Domenico, M.; Solimini, A. (2004): Temporal variation of an Odonata species assemblage (Rome, Italy). *Odonatologica* 33(2): 157-168 (in English) ["The Castel Porziano estate is a well preserved coastal Mediterranean woodland, rich in still bodies of water, where odonatological studies have been taking place since the 1950s. Adult

Odonata were recorded for the entire estate in 1997 and 1998 (March-Nov.; 2 checks each month). 1,838 adults (22 species) were marked, to assess their movements. The results showed that in 1997-1998 a total of 31 species were present. This number is very close to the number (29) recorded up to 1976. Variation in species assemblage in 16 ponds was observed from 1997 to 1998. Although the overall species similarity was preserved, the number of species for each pond and the number of ponds inhabited by each species significantly increased from 1997 to 1998. In regard to the adult movements, 251 marked individuals of 13 species were re-sighted only at the same ponds where they had been marked and 30 individuals of 6 species were sighted at different ponds. Among the latter, the majority moved within a range of a few hundred metres, but some individuals were able to fly quite far, e.g. 2.7 km (*Coenagrion puella*) and 5.8 km (*Libellula depressa*). It is concluded that the assemblage variation for the entire estate was small, varying more on a decennial than on an annual scale, but for a single pond variation is wider on both time scales. The quick recolonization among ponds, due to the adult's movements, appears to be the cause of greater stability at meso-scale rather than at local scale." 4430. Cattin Blandenier, M.-F. (2004): Food web ecology: models and application to conservation. Thèse présentée à la Faculté des Sciences de l'Université de Neuchâtel pour l'obtention du grade de Docteur ès sciences: 127 pp. (in English with French summary). ["Food webs are descriptions of who eats whom in an ecosystem. We propose here two different approaches to this topic. Firstly, we describe an empirical study applied to the management of fens of the Grande Caricaie (on the south bank of Lake Neuchâtel), a site of high value for nature conservation in Switzerland. Secondly, we introduce a new model explaining food-web structure, the nested-hierarchy model, which solves major problems encountered with former models. Nearly 90% of the fenlands in Switzerland have been lost during the last century. They harbour a high number of endangered species. Presently, they are threatened by brushwood encroachment and terrestrialisation due to water regulation and draining. Mowing is a commonly used management technique to prevent this succession. This management practice is beneficial for floristic diversity, but its effects on arthropods are less well known. Here, we use two different complementary approaches to

study the effect of mowing on two types of wet meadows. Firstly, we evaluate the impact of management by means of the comparison of a control and a two-year-old mown area. The results indicate that mowing reduces the less mobile spiders and species linked to litter or dead reeds, including rare species. Secondly, in order to measure the impact of mowing on the ecosystem structure and functioning, we adopt a food-web approach in the same wet meadows. Our results demonstrate that mowing has different consequences depending on the trophic group and level. It increases the total number of taxa, an increase particularly beneficial to species of the first trophic level. The impact on the third trophic level is hardly perceivable, because of the dominance of generalist feeders in this level. Intermediate species and particularly herbivores show the strongest change: mowing results in a shift towards more generalist herbivores and detritivores to the detriment of specialized species. This could be a particularly undesirable consequence of management. In the second part, we introduce the nested-hierarchy model, which describes foodweb structure. Though extremely complex and variable, their structure possesses basic regularities. Until now, two models have been devised for the description of trophic interactions within a natural community. Both are essentially based upon the concept of ecological niche, with the consumers organized along a single niche dimension, e.g., prey size. Unfortunately, they fail to describe adequately recent high-quality data. We propose here a new model built on the hypothesis that any species diet is the consequence of phylogenetic constraints and adaptation. Simple rules incorporating both concepts yield food webs whose structure is very close to real data. Consumers are organized in groups forming a nested hierarchy, which better reflects the complexity and multidimensionality of most natural systems. Our nested-hierarchy model emphasizes the role of phylogenetic constraints in food webs. It is an important element to be considered in the actual context of decrease in biodiversity. The relative impacts of taxonomy and adaptation in the reaction of ecosystems to species losses remains to be determined." (Author)] Address: www.unine.ch/biblio/bc/theses_pdf/these_CattinMF.pdf

- 4441.** Clausnitzer, V. (2004): Dragonflies in East Africa's coastal forests and Eastern Arc Mts indicators of habitat health and landscape history. Abstracts: 5th International Symposium on Tropical Biology. SATELLITE EVENTS: 6th International Symposium on the Chrysomelidae; Workshop on African Odonata (Edited by Bernhard A. Huber); Zoologisches Forschungsinstitut und Museum Alexander König, Adenauerallee 160, 53113 Bonn, Germany: 143. (in English). [Verbatim: The species diversity and the level of endemism in dragonflies from East Africa's coastal forests and the Eastern Arc Mts is very high. Many of the forest specialists are stenotopic, highly sensitive to habitat disturbance and confined to the coastal zone. Some of these species are relicts, indicating the former connection to central and west Africa and even to the Neotropics. Once a more or less continuous forest belt from southern Somalia to northern Natal, today's remaining coastal forests consist of highly isolated and often very tiny forest fragments. The effects of these habitat fragmentations will be briefly shown on the species community level and on the population level. With increasing forest destruction the alpha-diversity increases locally, while the beta-diversity decreases with the disappearance of the forest specialists. Most colonisers of disturbed habitats are eurytopic species, which are common and widely distributed all over Africa. The impacts of habitat fragmentation on the population level will be shown for a very ancient inhabitant of the coastal and Eastern Arc forests: *Coryphagrion grandis*, a giant damselfly and the only extant member in Africa of a family with otherwise neotropical distribution. This species is highly specialised and heavily reliant on a long-term habitat stability. The ongoing habitat destruction has already resulted in genetically isolated populations.] Address: Clausnitzer, Viola, Liebenauer Str. 180, D-06110 Halle/Saale, Germany. E-mail: violacl@gmx.de

(2004): Diversity and community composition of butterflies and odonates in an ENSO-induced fire affected habitat mosaic: a case study from East Kalimantan, Indonesia. *Oikos* 105: 426-446. (in English). ["Little is known about the diversity of tropical animal communities in recently fireaffected environments. Here we assessed species richness, evenness, and community similarity of butterflies and odonates in landscapes located in unburned isolates and burned areas in a habitat mosaic that was severely affected by the 1997/98 ENSO (El Nino Southern Oscillation) event in east Kalimantan, Indonesian Borneo. In addition related community similarity to variation in geographic distance between sampling sites and the habitat/vegetation structure Species richness and evenness differed significantly among landscapes but there was no congruence between both taxa. The species richness of butterflies was, for example, highest in sites located in a very large unburned isolate whereas odonate species richness was highest in sites located in a small unburned isolate and once-burned forest. We also found substantial variation in the habitat/vegetation structure among landscapes but this was mainly due to variation between unburned and burned landscapes and variation among burned landscapes. Both distance and environment (habitat/vegetation) contributed substantially to explaining variation in the community similarity (beta diversity) of both taxa. The contribution of the environment was, however, mainly due to variation between unburned and burned landscapes, which contained very different assemblages of both taxa. Sites located in the burned forest contained assemblages that were intermediate between assemblages from sites in unburned forest and sites from a highly degraded slash-and-burn area indicating that the burned forest was probably recolonised by species from these disparate environments. We, furthermore, note that in contrast to species richness (alpha diversity) the patterns of community similarity (beta diversity) were highly congruent between both taxa. These results indicate that community-wide multivariate measures of beta diversity are more consistent among taxa and more reliable indicators of disturbance, such as ENSO-induced burning, than univariate measures." as space permits. Philip Corbet's reply is further proof that entomologists never really retire: Philip S. Corbet, Crean Mill, St Buryan, Cornwall, UK I left Canada, for a position in New Zealand, in 1974 and moved to UK in 1980. I retired from my position as Professor of Zoology and Head of the Department of Biological Sciences, University of Dundee in 1986. From then until 1996 I was given an Honorary Faculty position at the University of Edinburgh where I wrote a book *Dragonflies. Behaviour and Ecology of Odonata*, published by Cornell University Press and Harley Books (UK) in 1999. Since 1996 I have been living in an 18th Century converted mill house, the grounds of which I share with 15 species of butterfly and 11 species of dragonfly, the latter being encouraged to breed there by the presence of a pond and stream. My house is in West Cornwall, not far from Land's End where the climate is markedly milder than most of the British Isles. I devote my spare time to work for the Worldwide Dragonfly Association, travelling, and writing up (unpublished) work on mosquitoes, caddisflies and dragonflies. I also collaborate on joint research projects on dragonflies and mosquitoes. I work in a voluntary capacity for the Cornwall Wildlife Trust, serving on Council and the Executive, and chairing the Conservation Strategy Committee.] Address: Corbet, P.S., Crean Mill, Crean, St Buryan, Cornwall, TR19 6HA, UK. 4446. Córdoba-Aguilar, A.; Siva-Jothy, M.T. (2004): Sperm displacement ability in *Calopteryx haemorrhoidalis* (Vander Linden): male and female roles, male limits in performance, and female neural control (Zygoptera: Calopterygidae). *Odonatologica* 33(3): 245-252. (in English). ["During copulation, *C. haemorrhoidalis* males displace the sperm of rivals stored by the female. During displacement, sperm stored in 2 spermathecae are ejected by the female as a consequence of male genitalic stimulation: the aedeagus distorts 2 vaginal plates in which mechanoreceptive sensilla are embedded. The sensilla control spermathecal sperm release and a wider aedeagus displaces more sperm. There is variation between females in their sensillum number which might also affect sperm displacement rate. The role of sensillum number and aedeagal width in sperm displacement variation in copulations whose duration was controlled was investigated. Results indicated that only aedeagal width could predict sperm displacement variation. The neural communication between the vaginal plates and both spermathecae was also examined. Previous observations suggested a "lateral" control of sperm ejection between each vaginal plate and its corresponding spermatheca. This was corroborated by stimulating the mechanoreceptive sensilla of females that underwent different surgical treatments: only those females whose vaginal plate nerves were cut, showed no volumetric decline in sperm in the corresponding spermatheca. Finally, the effect of copula duration (number of aedeagal copulatory movements) on sperm ejection was experimentally examined. In natural conditions, males perform approximately 50 aedeagal movements during copulation. There was no difference in sperm volumes between the pairs of females that were subjected to 50 and 80 aedeagal movements of stimulation using the same aedeagus. These results help to understand the nature of the spermathecal sperm displacement mechanism in this species." 4448. D'Amico, F.; Darblade, S.; Avignon, S.; Blanc-Manel, S.; Ormerod, S.J. (2004): Odonates as indicators of shallow lake restoration by liming: Comparing adult and larval responses. *Restoration ecology* 12(3): 439-446. ["Odonate assemblages were compared between replicate sets of shallow lakes that had been created and acidified by open-cast mining across a large area (2,451 ha) of southwest France (Arjuzanx, Landes); one set of lakes (n = 5) was experimentally restored by liming with calcium carbonate, whereas another group (n = 5) was left as untreated reference lakes. Both odonate adults and exuviae were sampled bimonthly during May August 1998. Elevated turbidity and conductivity in limed lakes were the only physicochemical measures differing between restored and reference lakes, because deacidification occurred naturally, even in reference lakes during the 17 years after the onset of restoration. Restoration by liming can apparently lead to effects on lake turbidity that might be considered adverse. Twenty-four and 19 odonate species occurred among adults and exuviae, respectively, but there were no significant differences in richness between restored and reference sites. However, significantly, more exuviae were collected from the reference sites (588 vs. 180), where exuvial diversity and rank abundance indicated more evenly structured assemblages than those in restored lakes. Ordination showed that adult assemblages differed significantly between restored and reference lakes, and varied highly significantly with lake turbidity. This effect occurred because a small group of generally scarce adults were characteristic of reference sites (*Chalcolestes viridis*, *Lestes virens*, *Cordulia aenae*, *Leucorrhinia albifrons*, and *Sympetrum sanguineum*). Exuviae of these same species were less abundant at restored sites, but exuvial assemblages overall did not discriminate between restored and reference lakes. We conclude that lake restoration by liming can reduce diversity and larval numbers among odonates and subtly affects adult assemblages. In this case study, adult assemblages discriminated best between the lake types involved in the experiment, but important additional information arose from exuvial abundance and structure. This study indicates that natural recovery processes after acidification in formerly open-cast areas rather than chemical intervention through liming might lead to preferable conservation outcomes." - 4449.** De Block, M.; Stoks, R. (2004): Life history responses depend on timing of cannibalism in a damselfly. *Freshwater Biology* 49(6): 775-786. (in English). ["1. Cannibalism has often been suggested as an important mechanism to reach the necessary developmental stage and size before a critical time horizon is reached, but this role has been largely unexplored. We studied effects of cannibalism on the life history of the damselfly *Lestes viridis* under combinations of a time constraint (by manipulating the perceived time available in the growth season) and a biotic constraint (density). 2. Larvae had a faster development and growth rate when reared at high time stress (late photoperiod). They also had a higher growth rate and mass at emergence when cannibalism occurred (density 2 and 4). Cannibalism occurred earlier at higher density. Accelerated life history responses (faster development and growth rate) and a higher mass at emergence were dependent upon the timing of cannibalism. Responses were more pronounced or only present if cannibalism occurred early in the larval period. 3. Our data suggest that cannibalism may not only act as a lifeboat mechanism by enabling cannibals to survive detrimental ecological conditions, but may also act as a compensatory mechanism to keep life history variables near-optimal at life history transitions, even under sub-optimal conditions." - 4455.** Dijkstra, K.-D.; Clausnitzer, V. (2004): Critical species of Odonata in Madagascar. *International Journal of Odonatology* 7(2): 219-228. (in English). ["Madagascar has approximately 175 species of Odonata. Of the Anisoptera ca 60% is endemic and of the Zygoptera almost 95%. The endemic species can roughly be separated into 'new endemics' that are probably recent arrivals from the African mainland and 'old endemics'. The latter group includes many members of the families Megapodagrionidae, Platycnemididae and Corduliidae, which are much more diverse here than on the African continent. Many of these species belong to endemic genera and appear to be restricted to rainforest habitat. The rate of deforestation on Madagascar is alarming, and therefore the majority of 'old endemics' is potentially threatened. One hundred and eleven species, 64% of the fauna, are listed as being of primary concern and

their conservation status needs to be assessed immediately. Research on Madagascar's Odonata is urgently needed in all aspects from basic inventories and systematic work to studies on ecology, biogeography and conservation related issues." 4456. Dijkstra, K.-D.; Vick, G.S. (2004): Critical species of Odonata in western Africa. *International Journal of Odonatology* 7(2): 229-238. (in English). ["Western Africa - defined as the tropical area from Cameroon westwards - probably has the richest odonate fauna in Africa, particularly the region of (and around) the Cameroon highlands. This region is home to many relict and endemic species, such as the continent's only representatives of the families Amphipterygidae and Perilestidae. Previous selections of threatened West African Odonata have been arbitrary because it is impossible to differentiate between species that are genuinely endangered and those which are simply data-deficient. Many listed species just appear to be difficult to record or have been taxonomically confused; some 'endangered species' have already dissolved into synonymy. A revised and probably more complete selection of species requiring attention is provided, but because the source data is so scanty it remains subjective. Species in Gomphidae and Corduliidae are not included, as the knowledge of their taxonomy and distribution is particularly problematic at present. Many listed species may prove to be of minor concern once more research in the field and in the museum has been done. It is argued that if rainforest reserves (existing in most nations discussed) are maintained, the great majority of West Africa's unique Odonata will be protected. Although most rare species are probably stenotopic rainforest inhabitants, open landscapes also harbour a rich and potentially endangered odonate fauna." 4461. Dumont, H.J. (2004): Dragonflies from Azerbaijan. *Zoology in the Middle East* 31: 87-92. (in English, with German summary). ["Thirty-two species of dragonflies were recorded from Azerbaijan in late spring 2002. We estimate the true species richness to be about 45-50 species. Several of these are first records for the Caucasus region or for the Eastern Caucasus subregion. Two forms of *Calopteryx splendens* were found, separated by the valley of the lower Kura, of which only *C. splendens intermedia* occurs in the so-called southern and lower Kura. *C. s. orientalis* occurs on rivers that drain the Talysh hills directly to the Caspian, but there is some phenotypic evidence of hybridization with *intermedia* south-west of the Kura, where the lower River Vilescay approaches rather close to the Kura. A few species are salt-tolerant and may be outliers from populations further north and east. Others are derived from Iran. Two members of the *Coenagrion puella* group are recorded; they occur within 50 km of each other, so that Azerbaijan is part of the zone where the two meet. A blue male of *Aeshna cyanea* is recorded. This may be the first case in Odonata of a rare point mutation that causes wild-type green animals to occur in a blue form." (Author) colour mutation] Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. Ledeganckstraat 35, B-9000 Gent, Belgium. E-mail: Henri.Dumont@rug.ac.be

4462. Dunkle, S.W. (2004): Critical species of Odonata in North America. *International Journal of Odonatology* 7(2): 149-162. (in English). ["Of the approximately

439 species of Odonata known from North America, north of Mexico, comments on 25 species (6%) of conservation concern are given. Species deemed to be under the most threat are *Ischnura gemina*, *Gomphus sandrius*, *Ophiogomphus australis*, *Stylurus potulentus*, and *Libellula jesseana*. Two other species not under threat, *Neurocordulia michaeli* and *Somatochlora brevicincta*, are briefly discussed because of their conservation interest. Some geographical clumping of species under threat is discussed, in southeastern Arizona, coastal New England, and the central Gulf of Mexico Coast." 4463. Dunkley, J. (2004): Four-spotted Chaser *Libellula quadrimaculata* form *praenubia*. *Atropos* 23: 56. (in English). [Billing gravel pit, Northamptonshire, UK, without date.] Address: Dunkley, J., 10 Stonelea Road, Sywell, Northampton, NN6 0AZ, UK

4464. Dyatlova, E.S. (2004): New records of *Cercion lindenii* (Odonata, Coenagrionidae) in the basins of lower Danube, Dniestr and Dnieper Rivers in the south of Ukraine. *Vestnik zoologii* 38(5): 10. (in English). [Verbatim: Detailed information on *Cercion lindenii* (Selys, 1840) was given in the second edition of "The Dragonflies of Europe" by R. R. Askew (2004). On the territory of the former USSR this Mediterranean species is known from Caucasian Black Sea coast and, probably, from Armenia (Popova, 1953). Akromovski (1975) recorded rare local population in the Armenian river Metsamor (Kalkman et al, 2004). Three specimens of *C. lindenii* were firstly recorded for Ukrainian fauna by R. S. Pavlyuk (1981) in the lower Danube (Odessa province, the vicinity of Vilko). The scarce earlier data on the regional occurrence of *C. lindenii* in the lower Danube were confirmed later (Gorb, Ermolenko, 1996) in SW Ukraine, Danube delta, Odessa Province, Kilijsky District, Primorskoje village. The species was included into Ukrainian Red Book (1994) with the status of 1st category of conservation. Our investigations showed that *C. lindenii* occur much wider in Danube delta and was firstly found in the basins of other rivers (lower Dniestr and Dnieper delta). There are following new records of *C. lindenii* in the Ukraine. Odessa Province, Bolgrad District, lake Yalpug, near Vinogradovka village. 13.07.03, 2 males. Odessa Province, Ismail District, Ismail city, near "Krepost", little pond near the Danube shore. 17.07.03, female. Odessa Province, Belyaevsky District, Mayaki village, lower Dniestr river. 12.06.04, male (teneral). Cherson Province, Golopristansky District, surroundings of village Staraya Zbur'evka, zaliv "Zbur'evskij Kut". 1.08.04, male; 2.08.04, female. Cherson Province, Golopristansky District, surroundings of Golaya Pristan', Dnieper delta, Konkra River, Belogradj Island. 3.08.04, 3 males; 4.08.04, 2 female and 8 males (7 mature and 1 teneral). Active mating of damselflies was observed in this period. Hie tandems and single individuals were found above the water surface and on the semi-aquatic plants.] Address: Dyatlova, Elena, French Boulevard 37, apt 3, Odessa, Ukraine

4465. Dyatlova, E.S. (2004): The first record of *Coenagrion scitulum* (Odonata, Coenagrionidae) in the south-western part of Ukraine. *Vestnik zoologii* 38(5): 10. (in English). [Verbatim: *C. scitulum* is a common species in the Mediterranean region of Europe and

North Africa, extending from Spain (north-east) and Morocco to the Middle East. It is local in central Europe and very rare in the north (Askew, 2004). It can be found near ditches, dykes, weedy eutrophic ponds, small streams and frequently in water with a slight flow (Boulard, 1981). In the Ukraine it was recorded only from Crimea by a few records (Bartenev, 1912). One male (16.06.2004) and one female (18.06.2004) of this species were firstly found in the coastal part of Odessa (north-western part of the Black Sea). The distribution of this rare species in the Ukraine is much wider than it was known before.] Address: Dyatlova, Elena, French Boulevard 37, apt 3, Odessa, Ukraine

4466. Ellzey, K.D. (2004): First state record of *Gomphus militaris* in Louisiana. *Argia* 16(2): 24. (in English). [USA, Louisiana, 18-V-2004.] Address: Ellzey, K.D., 3416 Gum Springs Loop. Hornbeck, LA 71439, USA

4468. Frolich-Strong, K.; Robinson, G. (2004): Odonate communities of acidic Adirondack Mountain lakes. *Journal of the North American Benthological Society* 23(4): 839-852. (in English). ["New York State's fauna is exceptionally rich in odonates (dragonflies and damselflies), whose lengthy aquatic larval phases render them susceptible to effects of lake acidification, including the loss of fish. We used a collection of benthic macroinvertebrate samples taken by the Adirondack Lakes Survey Corporation to compare odonate communities in 460 lakes. Half were from the Adirondack Mountains, where acid neutralizing capacity (ANC) is low (mean ANC = 108.0 µg/L) and Al concentrations are high (mean Al = 111.61 µg/L), and half were from the Lower Hudson Valley, where ANC is significantly higher (mean ANC = 554.6 µg/L) and Al is significantly lower (mean Al = 0.049 µg/L). Many more lakes in the Adirondack lakes were fishless (52) compared to the lower Hudson (3), and the pH in Adirondack fishless lakes was an order of magnitude lower than the pH of Adirondack lakes with fish. Ninety-nine odonate taxa were identified (86 to species). In Adirondack samples, co-occurrence patterns were correlated with presence or absence of insectivorous fish and with acidic waters. Similar patterns were not apparent in Lower Hudson Valley samples. In Adirondack samples, richness of common taxa (found in 20 lakes) was higher in lakes with fish than in lakes without fish, regardless of pH. Loss of fish may enhance the top predator role of large larval dragonflies, causing change in odonate community structure, an interpretation consistent with previous research. Acidification of Adirondack lakes appears to promote a nonrandom subset of possible odonate communities, with negative implications for regional diversity." (Authors)] Address: Frolich Strong, Karen, Conservation and Policy, Department of Biological Sciences, State University of New York at Albany, 1400 Washington Avenue, Albany, New York 12222 USA

4469. Gäde, G.; Marco, H.G. (2004): Adipokinetic hormones in Odonata are group-specifically distributed. Abstracts: 5th International Symposium on Tropical Biology. SATELLITE EVENTS: 6th International Symposi-

um on the Chrysomelidae; Workshop on African Odonata (Edited by Bernhard A. Huber); Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 160, 53113 Bonn, Germany: 33. (in English). [Verbatim: "Peptides that regulate the level of circulating metabolites in energy metabolism of insects are synthesized in intrinsic neurosecretory cells of the corpora cardiaca. These neuropeptides have 8 to 10 amino acid residues, function as hormones and are named according to the specific metabolites that are affected when the neurohormone is injected into the insect or upon the stimulus of flight: i.e. adipokinetic (elicits elevation of diacylglycerols), hypertrehalosaemic (increases trehalose), and/or hyperprolinaemic (elevates proline levels). It is known that Odonata use lipids during flight and they, therefore, show an adipokinetic response to the specific hormones in the corpora cardiaca. In the current study, the adipokinetic hormone (AKH) was isolated and structurally characterized from various families of Odonata occurring in South Africa; some representatives from Europe, North America and Japan were also included. Sequences were compared to ascertain whether a specific pattern existed across families. All members from various zygopteran families, viz. Calopterygidae, Lestidae, Synlestidae, Chlorocyphidae, Platycnemididae and Coenagrionidae contain the same peptide, denoted Psi-AKH (sequence: pEVNFTPGWamide). The living fossil, the Japanese anisozygopteran species *Epiophlebia superstes*, contains the peptide denoted Ani-AKH (sequence differs from Psi-AKH: S5 instead of T5, and S7 instead of G7). Ani-AKH is also found in the anisopteran families Aeshnidae, Cordulegastridae and Corduliidae. In the anisopteran families Gomphidae and Libellulidae the main AKH peptide is Lia-AKH (sequence is similar to Psi-AKH: S7 instead of G7). Curiously, in one species of Libellulidae, the N. American *Erythemis simplicicollis*, a variant of Lia-AKH was sequenced containing a conservative L2 exchange instead of V2." 4470. García, G.; Dijkstra, K.D. (2004): Odonata collected in the Ankarafantsika National Park, Madagascar. IDF-Report 6: 7-22. (in English). ["Records of 33 species of Odonata from Ankarafantsika National Park are presented. Four additional species have been reported in the literature. Nineteen species are recorded from the site for the first time. The site is the largest remaining block of dry forest in Madagascar's Western Region. While 80% of Madagascar Odonata species are endemic, only 40% of the species recorded in Ankarafantsika is endemic. Moreover, the endemics recorded are mostly common throughout the island. The dry forests are thus of relatively little importance for Madagascar's diversity of Odonata." (Authors)] Address: García, G., Durrell Wildlife Conservation Trust, Les Augres Manor, Trinity, Jersey JE35BP, Channel Islands, UK, gerardo.garcia@durrell.org

4471. Garrison, R.W.; Ellenrieder, N. von (2004): *Orthemis sibylla*, a junior synonym of *O. ambirufa* (Odonata: Libellulidae). International Journal of Odonatology 7(3): 467-470. (in English). ["*Orthemis sibylla* is shown to be a junior synonym of *O. ambirufa*, based on a comparison of the holotype male of *O. ambirufa* with voucher specimens in the UMMZ identified as *O. sibylla* by Ris and specimens of this species from French

Guiana and Venezuela in the RWG collection. Diagnostic characters of the male holotype of *O. ambirufa* are illustrated, and compared with those of *O. lev* is." 4472. Gerhard, A.; Janssens de Bisthoven, L.; Soares, A.M.V.M (2004): Macroinvertebrate response to acid mine drainage: community metrics and on-line behavioural toxicity bioassay. Environmental Pollution 130: 263-274. (in English). [Portugal. "The hypothesis is tested that toxicity of acid mine drainage can be detected by a selection of existing macroinvertebrate community and bioindicator metrics supplemented by toxicity tests with the local mosquitofish *Gambusia holbrooki* Girard and the shrimp *Atyaephyra desmaresti* Millet. The behavioural responses of *A. desmaresti* to acid mine drainage were recorded in the Multispecies Freshwater Biomonitor, based on behaviour and survival as parameters. Bioassessment methods were based on community diversity, structure, function, and bioindicators and supplemented by chemical analysis (temperature, pH, metals). The Biological Monitoring Working Party adapted for the Iberian Peninsula, the number of predators (Coleoptera, Hemiptera) and the number of Ephemeroptera and Trichoptera taxa differentiated the sites well. The on-line toxicity test revealed pH-dependent acute toxicity of the acid mine drainage for the shrimp (LC50-48 h: pH-AMD=5.8) and a pH-dependent decrease in locomotory activity with the lowest-observed-response-times (LORTs) within 5 h of exposure. Shrimp were more sensitive to acid mine drainage than fish (LC50-48 h: pH-AMD=4.9). A new multimetric index combining toxicity testing and bioassessment methods is proposed." (Author) Some Odonata are listed on the genus or family level including "*Epitheca* sp." for Portugal which is more than questionable.] Address: Gerhardt, A., LimCo International, An der Aa 5, D-49477 Ibbenbüren, Germany. 4473. Gibbs, K. E.; Bradeen, B.; Boland, D. (2004): Spatial and Temporal Segregation Among Six Species of Coexisting *Ophiogomphus* (Odonata: Gomphidae) in the Aroostook River, Maine. Northeastern Naturalist 11(3): 295-312. (in English). ["Spatial and temporal segregation of six coexisting species of *Ophiogomphus* (*O. anomalus*, *O. aspersus*, *O. carolus*, *O. howei*, *O. mainensis*, and *O. rupinsulensis*) were studied in a 137.7 km reach of the Aroostook River in northern Maine. Collections of exuviae showed that *O. mainensis* was most abundant and dominated the assemblage at sites in the upper reaches of the study area and was in low numbers and percent of total *Ophiogomphus* at sites in the lower reaches of the study area. *Ophiogomphus rupinsulensis* was most abundant and dominated the assemblage at sites in the lower reaches of the study area but was absent or in low numbers and percent of total *Ophiogomphus* at sites in the upper reaches. *Ophiogomphus anomalus* and *O. carolus* were present at all sites and *O. anomalus* was generally more abundant and made up a higher percent of the total *Ophiogomphus* spp. than *O. carolus*. *Ophiogomphus howei* and *O. aspersus* were present at only a few sites in low abundance and percent of the total *Ophiogomphus*. Several species of *Ophiogomphus* coexisted as larvae in 0.20 m² areas of the substrate. There was little evi-

dence of temporal segregation among the six species. All species had short seasonal emergence periods in June. Diel emergence was during the morning and early afternoon. Timing of seasonal and diel emergence either differed little or not at all among the six species. Species that we were able to identify in all larval stages (*O. mainensis*, *O. anomalus*, and *O. howei*) were present in a wide range of instars on all sampling dates (May to October) suggesting overlapping generations and multivoltine life histories. In all six species, some larvae remained in the final instar for almost a year before emerging as adults." (Authors)] Address: Gibbs, K. Elizabeth

4478. Gunzburger, M.S.; Travis, J. (2004): Evaluating predation pressure on green treefrog larvae across a habitat gradient. *Oecologia* 140(3): 422-429. (in English). ["The effect of a predator on the abundance of a prey species depends upon the predators abundance

and its ability to capture that prey. The objectives of this research were to evaluate the community structure of predators of green treefrog (*Hyla cinerea*) tadpoles across habitat types and evaluate the effectiveness of individual predators on *H. cinerea* tadpoles. Correspondence and cluster analyses of predator frequencies across 23 aquatic habitats indicated that the majority of variance in predator communities was due to a division between permanent and temporary habitats. Experimental work demonstrated that survival of the smallest *H. cinerea* tadpoles was significantly lower than survival of medium and large tadpoles with the most effective predators, indicating that *H. cinerea* tadpoles attain a refuge from predation at larger body sizes. We combined the effectiveness of predators in experiments with the abundance of each predator species from the predator community survey to demonstrate that predation pressure on *H. cinerea* tadpoles is higher in temporary ponds. This pattern may explain in part why this species generally breeds successfully only in permanent habitats. It also confirms that discussions about an increasing gradient of predation pressure from temporary to permanent aquatic habitats should be restricted to individual prey species for which such a gradient has been demonstrated." (Authors) *Anax junius* and *Traema lacerata* were the most effective predators on *H. cinerea*.] Address: Gunzburger, Margaret S., Department of Biological Science, Florida State University, Tallahassee, FL 32306-1100, USA. 4493. Inoue, K. (2004): Critical species of Odonata in Japan. *International Journal of Odonatology* 7(2): 311-324. (in English). ["Japan is a small country but ranges from the subtropical to the subarctic zone. Every year during spring to autumn, many typhoons bring tropical taxa, which occasionally establish in Japan. Up to now, 215 odonate taxa have been recorded, 34 of which are regarded as critical species. Intensive research on Odonata -supported by identification guides - has been carried out mainly after 1945. The current IUCN Red List does not sufficiently reflect present knowledge of the threat status of Odonata in Japan. Therefore changes for an updated global Red List are suggested and explained. The most critical sites are situated in suburban areas and in the isolated islands; the latter host many endemics. Conservation priorities and recommendations are stated and the importance of publicity is stressed. The Division of Nature Conservation of the Japanese Society for Odonatology is currently very active, and it is expected that the activity of all 15 committees will even increase in the future. The so-called "Dragonfly Citizen Summit" has been carried out every year since 1990. With this festival the number of dragonfly lovers has increased remarkably, and the knowledge and consent on conservation of Odonata and their habitats have made a good progress." 4501. Kalkman, V.J.; Pelt, G.J. van; Dumont, H.J.; Haritonov, A.Yu.; Taily, M. (2004): Critical species of Odonata in Turkey, Iran and the Caucasus. *International Journal of Odonatology* 7(2): 325-339. (in English). ["An overview is given of the present knowledge and current research on the Odonata fauna of Turkey, Iran, and the Caucasus. The occurrence of endemic taxa and of rare and possibly threatened species is discussed. The use of water from various aquatic habitats is reviewed in order to gain insight in existing and potential problems, and a number of conservation measures are proposed.

The creation of a few protected key areas for vulnerable species is considered to be the most effective measurement at short notice. Taking our restricted knowledge into account, it is concluded that only a general increase in the awareness of the necessity to deal with environmental problems, both with governmental organisations as well as with the public in the countries involved, may help solving problems regarding aquatic habitats." (Authors)] Address: Kalkman, V.J., Oude Rijnburgerweg 28, NL-2342 BC Oegstgeest, The Netherlands. E-mail: Kalkman@naturalis.nnm.nl

4502. Kalkman, V.J.; Lopau, W.; Pelt, G.J. van (2004): Hitherto unpublished records of dragonflies from Turkey (Odonata). *Libellula Suppl.* 5: 65-166. (in English, with German and Turk summaries). ["Over 2000 records of 84 of the 96 species of Odonata known to occur in Turkey are presented. Many of the records were gathered during the last decades by entomologists from western Europe. Records based on material present in the collections of Naturalis (formerly the Rijksmuseum voor Natuurlijke Historie), Leiden, The Netherlands (RMNH), the Zoologisch Museum Amsterdam, The Netherlands (ZMAN), and the Natural History Museum, London, UK (NHM) are also included." In a personal account he emphasises the importance of collections for documenting and studying biodiversity in Canada.] Address: Kenner, R.D., c/o Spencer Entomological Museum, University of British Columbia, Vancouver, BC, V6T 1Z4. Canada. E-mail: kenner@zoology.ubc.ca

4507. Khrokalo L.A. (2004): Special composition and ecological peculiarities of dragonflies (Insecta, Odonata) of the northeastern Ukraine.. Thesis, candidate of biological sciences in speciality 03.00.16 - ecology. - Kyiv National Taras Shevchenko University, Kyiv: 19 pp. (in Ukrainian, with Russian and English summaries). [Verbatim: This work is the first complex study of the dragonflies of northeastern part of Ukraine. 56 dragonflies species (including 55 ones in imaginal, 43 in larval phases) have been recorded for the area of research. Complete list of the northeastern Ukraine consists of 62 species including 6 ones reported by previous investigators only (Artobolewski, 1927a; Rodzyanko, 1895; Sharlemani & Artobolewski, 1915; Sheshchurak & Padalko, 1996; Gorb, 1991a; Gorb, 1996a). This number composes 85 % of all dragonflies species of the Ukrainian fauna. We separated the groups of the most rare (9), rare (15), common (19) and frequent (13) species according to the numbers of the specimens in our collection. 2 species (*Chalcolestes parvidens* and *Sympetrum depressiusculum*) have been first recorded for whole area of research, 18 species for Sumy, 2 species for Chernigiv, and 5 species for Cherkasy regions. "The most northern point of occurrence in the UKraine has been established for *Crocothemis erythraea*, and most eastern point for *Sympetrum pedemontanum*. The species have been divided into six seasonal groups by terms of flying periods and peculiarities of life cycles: 1) species, which overwinter in imago (2 species); 2) spring species (9); 3) spring-summer species (14); 4) summer species (7); 5) summer-autumn species (16); 6) transeasonal species (7). More precise definitions of the terms of flying periods in the UKraine have been given for 12 species (*Chalcolestes parvidens*, *Sympetrum fasca*, *Coenagrion armatum*, *Erythromma viridulum*, *Aeshna qffinis*, *Anaciaeschna isosceles*, *Anax imperator*, *Gomphus vulgatissimus*, *Cordulia aenea*, *Orthetrum albistylum*, *Sympetrum meridionale*, *Leucorrhinia rubicunda*). The analysis of seasonal distribution between the 10-day periods of months has been made for number of flying species. The beginning of fly period was registered in the second 10-day period of April; the number of flying species increased deeply during May-June; the maximum (42 species) was recorded in the middle of July; the ending of flying period was observed in the second 10-day period of October. The biotopic distribution of dragonflies larvae from 43 species on waterbodies of 18 types has been studied. The greatest number of the species showed euritopic, the smaller number stenotopic. *Calopteryx virgo*, *C. splendens*, *Stylurus flavipes*, *Gomphus vulgatissimus* were found in rivers and springs only (obligate reophyllic species). *Leucorrhinia*-species were found in lentic lakes and puddles and thus they are typical stagnophyllic forms. *Lestidae* and *Sympetrum* (*Libellulidae*) species adapted to existing in periodic waterbodies owing

to peculiarities of life cycles. The greatest species diversity (21 ones) was registered in rivers. Per one species were found in dystrophic creek of pond and open parts of reservoirs only. The analysis of the degree of similarities shown the existing of a few groups of biotopes. Stagnat dystrophic waterbodies and oligotrophic bogs complexes were separated deeply from flowing and stagnatic eutrophic waterbodies. The later were divided into complexes of periodic and permanent waterbodies. Special composition of anthropogenic waterbodies were very diversified due to variations of condition. Protection and conservation of the rare and endangered species are very actual today. The changes of the list of the dragonflies in Red Data book of Ukraine have been proposed. The finding of *Coenagrion mercuriale* in the Ukraine was not established and thus this species must be excepted from Red Data book. *Calopteryx virgo* and *Anax imperator* must be excepted too because a real risk of extinction of these species in the wild now and in near future isn't facing. The consideration of the five new species-candidates (*Nehalennia speciosa*, *Coenagrion lunulatum*, *Ophiogomphus cecilia*, *Cordulegaster bidentata*, *Leucorrhinia albifrons*) for making of a new list of the next edition of Red Data book of Ukraine have been proposed.] Address: Khrokalo, L.A., Dept Zool., Fac. Biol., Shevchenko Univ., Volodymirska 64, UKR-01033 Kiev, Ukraine

4508. Kitching, D. (2004): News from Cheshire. *Darter* 21: 8-9. (in English). ["[...] Following the major pollution incident and consequent fish kill on the River Dee in late 2000 there were concerns that the population of the Club-tailed Dragonfly *Gomphus vulgatissimus* would have suffered too. Searching for exuviae in late May 2001 soon showed that the lack of fish may well have reduced Odonate mortality as hundreds of exuviae were found rather than the usual few. Since then the population appears to have returned to the previous level. [...]". A lot of additional notes refering to different species are provided.] Address: Kitching, D., 84 Broken Cross, Macclesfield, Cheshire, SK11 8TZ, UK. E-mail: davidk@broccross.co.uk

4509. Kitt, M.; Reder, G. (2004): Gehäuftes Auftreten der Zierlichen Moosjungfer (*Leucorrhinia caudalis* Charpentier, 1840) am pfälzischen Oberrhein. *Fauna und Flora in Rheinland-Pfalz* 10(2): 493-507. (in German, with English summary). [New records of the very rare *L. caudalis* in Rhinland-Palatinate, Germany are documented in detail. In most cases, the species could be found at gravel pits or oxbows in the alluvium of the River Rhine. A few old records are included, including a previously unpublished first record for Hessia.] Address: Reder, Gerd, Am Pfortengarten 37, D-67592 Flörsheim-Dalsheim, Germany. [Bavaria, Germany; This paper, directed to a more general in nature interested readership, outlines a few species of special aesthetic interest, and illustrates the contribution with two beautiful pictures of dragonflies.] Address: Koppmann, M., c/o Naturpark Nördlicher Oberpfälzer Wald, Stadtplatz 38, D-92660 Neustadt an der Waldnaab, Germany. E-mail: MKoppmann@neustadt.de

4512. Koskimäki, J.; Rantala, M.J.; Taskinen, J.; Tynkkynen, K.; Suhonen, J. (2004): Immunocompetence and resource holding potential in the damselfly, *Calopteryx virgo* L.. *Behavioral Ecology* 15(1): 169-173. (in English). ["It is generally believed that resource holding potential reliably reflects male quality, but empirical evidence showing this is scarce. Here we show that the outcome of male-male competition may predict male immunocompetence in the territorial damselfly, *C. virgo*. We staged contests between 27 pairs of males and found that winners of the contests showed higher immunocompetence, measured as encapsulation response, compared with that of losers. Furthermore, the winners had larger fat reserves. We also collected 29 males that had not been used in staged contests, and found that in these males encapsulation response correlated positively with an individual's fat reserves. Both immunocompetence and resource holding potential seem to depend on energy reserves, suggesting a trade-off between parasite resistance and energetically costly territorial behavior. The results suggest that the outcome of male-male contest can be used to predict male quality in terms of immune defense." (Authors)] Address: Taskinen, J., Institute of Applied Biotechnology, University of Kuopio, Box 1627, FIN-70211 Kuopio, Finland. E-mail: jouni.taskinen@uku.fi

4513. Kosterin, O.E.; Malikova, E.I.; Haritonov, A.Yu. (2004): Critical species of Odonata in the Asian part of the former USSR and the Republic of Mongolia. *International Journal of Odonatology* 7(2): 341-370. (in English). ["The region covered is briefly defined and characterized as relatively little disturbed. A survey of relevant Odonatological literature, including local Red Lists, is given, along with current scientific activity. Sixteen species are indicated, which deserve special attention, one of them, *Ischnura aralensis*, being the only strict endemic in the region. Some isolated populations deserving protection are indicated. Regions important for odonate protection are listed, including parts of the Russian Far East in which threatened Chinese populations find a northern refuge. Measures taken for nature protection in the countries considered are also discussed." (Authors)] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. 4517. Lajeunesse, J.M.; Forbes, M.; Smith, B. (2004): Species and sex biases in ectoparasitism of dragonflies by mites. *Oikos* 106(3): 501-508. (in English). ["An important problem in understanding the evolution of parasite host range is determining the extent to which parasite fitness varies among host species and the factors affecting that fitness variation. We present a detailed investigation on the patterns of host use and successful parasitism of two dragonfly species by the ectoparasitic water mite, *Limnochares americana* Lundblad. In our field surveys, we found both species biases and sex biases in parasitism by mites, which appear explained by differences in exposure. Differential habitat use by dragonflies helped explain male biases in parasitism in both host species, but was not useful in explaining species biases in parasitism. Species biases in parasitism may be explained by more subtle variation in habitat use not explored in this study, or perhaps by differences in timing of emergence, as we found for the two dragonfly species. Despite species differences in parasitism in nature, we found that mites attached equally successfully to both dragonfly species during experimental infestations. However, mites failed to engorge more often on the dragonfly species less often used as a host in nature. This host species also was more likely to have dead mites in natural infestations as compared to the other host species, which was more often and more heavily parasitized. Our results are consistent with previous research suggesting parasites are less successful on less often used hosts. Such research has

implications for understanding determinants of host range for animal parasites." (Authors)] Address: Forbes, M.R., Dept of Biology, Carleton University, 587 Tory Building, 1125 Colonel By Drive, Ottawa, ON K1S 5B6, Canada. E-mail: mforbes@ccs.carleton.ca

4524. Marden, J.H.; Cobb, J.R. (2004): Territorial and mating success of dragonflies that vary in muscle power output and presence of gregarine gut parasites. *Animal Behaviour* 68(4): 857-865. (in English). ["Competition for mating territories in libellulid dragonflies involves aerial contests that require high levels of exertion and locomotor performance. Here we test the hypothesis that success of male *Libellula pulchella* dragonflies in territoriality and mating is affected by muscle contractile performance, and we examine how gregarine gut parasites affect muscle performance, energy reserves and territorial behaviour of their hosts. At a pond where gregarine parasites are rare, long-term territorial and mating success of males showed a significant positive association with muscle power output. At a nearby pond that had a much higher incidence and intensity of gregarine parasitism, there was no relationship between muscle performance and short-term territorial success. Instead, males assorted themselves into aggressive territory holders and submissive satellites, with the large majority of territory holders having no parasites and nearly all of the satellites parasitized. Unparasitized males showed a tight positive relationship between muscle power and fat content, which suggests that they use a known phenotypic adjustment in muscle contractile performance to allow the energy consumption rate of the flight muscles to match the rate at which energy can be mobilized from storage pools. Parasitized dragonflies showed a small decrease in average fat content and a marked change in the relationship between fat content and muscle power output. The apparent loss of the ability to match muscle contractility to the size of the energy storage pool in parasitized dragonflies suggests that gregarines may have systemic effects on signalling pathways and energy homeostasis. By indirectly choosing males that had successfully competed for territories, females consistently mated with physiologically or immunologically superior males despite large between-pond differences in male behaviour and the incidence and intensity of parasitic infection." 4526. Marquis, O.; Saglio, P.; Neveu, A. (2004): Effects of predators and conspecific chemical cues on the swimming activity of *Rana temporaria* and *Bufo bufo* tadpoles. *Archiv für Hydrobiologie* 160(2) : 153-170. (in English). ["Behavioural observations were performed in

an olfactometer to examine the effects of chemical stimuli from predators and conspecifics on the swimming activity of two larval anurans, the common frog, *Rana temporaria*, and the common toad, *Bufo bufo*. Both species of tadpoles showed a slight but non significant reduction in swimming behaviour when confronted to chemical cues from starved sympatric predators (larval spotted salamander, *Salamandra salamandra*; larval dragonfly, *Anax imperator*). In contrast, test solutions from starved *Astacus leptodactylus*, a recently introduced predator, produced no change at all in behaviour. As a whole, significant results indicate that indirect chemical signals resulting from the preying activity of the predator are mainly used for the chemical assessment of predation risk by tadpoles. Swimming activity of *R. temporaria* and *B. bufo* tadpoles was also found to be significantly decreased in response to chemical cues released by crushed conspecifics, or by *A. leptodactylus* within the day following ingestion of conspecific tadpoles. Our results suggest that the presence of conspecific alarm substances in water and predators' waste products play a pre-eminent role in the chemical detection of predators by these larval anurans." 4533. McKee, D.; Harvey, I.; Sherratt, T.N. (2004): Behaviour of male coenagrionid damselflies towards conspecific females at the water's edge (Zygoptera: Coenagrionidae). *Odonatologica* 33(3): 271-278. ["The behaviour of male *Coenagrion puella* and *Xanthocnemis zealandica* towards conspecific andromorph and gynomorph females was studied at breeding ponds in the U.K. and in New Zealand respectively. As expected, male attention directed towards copulation wheels (*C. puella*) did not depend on whether the wheel contained an andromorph or a gynomorph. Similarly, male attention directed towards tandem pairs (*C. puella* and *X. zealandica*) did not depend on whether the tandem contained an andromorph or a gynomorph. When individual andromorph and gynomorph females (*C. puella* and *X. zealandica*) were released at the water's edge they experienced similar levels of attention from males. By contrast, males (*X. zealandica*) formed significantly more tandems with gynomorphs tethered at the water's edge than with tethered andromorphs. The observations suggest that males readily identify and intercept conspecific ♀♀ at the water's edge, particularly when in motion, and that andromorphs and gynomorphs are equally susceptible to ♂ attention. Behaviour of males towards tethered females may be atypical compared to that recorded under more natural conditions." 4534. McPeck, M.A. (2004): The growth/predation risk trade-off: So what is the mechanism? *The American Naturalist* 163(5) (E-article): E88-E111. (in English) ["Among damselflies in natural lakes, *Ischnura* species grow faster than coexisting *Enallagma* species, but *Enallagma* species have higher survival under predation than *Ischnura* species. This growth/predation risk trade-off apparently allows these taxa to coexist in ponds and lakes across the Holarctic. However, laboratory studies presented here show that the mechanism assumed by most theoretical and empirical studies to mediate this

trade-off, namely activity simultaneously modulating foraging returns and predation risk, does not operate in this system. *Ischnura verticalis* larvae were more active than larvae of *Enallagma* species in a short-term behavioral experiment, which explains why *Ischnura* experiences greater mortality from predation. However, this greater activity did not translate into higher feeding rates. *Ischnura verticalis* and *Enallagma* species ate comparable amounts of food in both the short-term behavioral experiment and a longer feeding and digestion experiment. In spite of no difference in the amount of food ingested or assimilated, *I. verticalis* larvae grew faster than *Enallagma* larvae because they were better able to physiologically convert assimilated food into their own biomass in the presence of mortality threats. From these studies we understand the phenotypic mechanisms determining the antagonistic patterns of relative growth and survival between these two genera, but why these patterns exist remains unclear." - 4539.** Mikolajewski, D.J.; Johansson, F.; Brodin, T. (2004): Condition-dependent behaviour among damselfly populations. *Canadian Journal of Zoology* 82: 653-659. (in English). ["Body condition is predicted to influence behaviours such as activity, which in turn affects energy gain and survival. In this study we investigated (i) whether populations of the damselfly *Lestes sponsa* (Hansemann, 1823) differ in body condition and activity among lakes, and (ii) which body condition factors affect behaviour. We estimated last instar larval behaviour (measured as activity), body condition (measured as size, body mass, muscle mass, fat content, and time to emergence), and fish presence/absence in eight lakes. Body condition of larvae differed among lakes but the presence/absence of fish in lakes had no effect on body condition. Activity did not differ among lakes and was not affected by the presence/absence of fish in lakes. Activity was negatively related to size, body mass, muscle mass, and fat content, and positively related with time to emergence, suggesting that final-instar larvae in good condition are favouring development over growth to emerge earlier. This study highlights the importance of differences in condition among populations and among individuals." - 4540.** Mikolajewski, D.J.; Johansson, F. (2004): Morphological and behavioral defenses in dragonfly larvae: trait compensation and cospecialization. *Behavioral Ecology* 15(4): 614-620. (in English). ["Many animals have two basic traits for avoiding being killed by a predator: behavioral modification and morphological defense. We examined the relationship between antipredator behavior and morphological defense in larvae of three closely related dragonfly species within the genus *Leucorrhinia* (*L. albifrons*, *L. dubia*, *L. rubicunda*). The three species differ with regard to their morphological defense as expressed in the length of the larval abdominal spines. Results showed that longer abdominal spines provided protection against an attacking fish predator (perch) because the probability of being rejected after an attack was significantly higher in the species with the longest abdominal spines. In contrast to other studies, the species with the strongest morphological defense did not show the least behavioral predator avoidance. Instead, the species with intermediate morphological defense showed the least predator behavioral avoidance. The results suggest that the *Leucorrhinia* system is a mixture of trait cospecialization (a positive correlation between antipredator behavior and morphological defense) and trait compensation (a negative correlation between antipredator behavior and morphological defense). Differences in the relationship between morphological and behavioral defense between species might be related to abundance patterns of the three species in lakes with and without fish predators." (2004): Mistakes in sexual recognition among sympatric Zygoptera vary with the time of day and color morphism (Odonata: Coenagrionidae). *International Journal of Odonatology* 7(3): 471-491. (in English). ["In odonates, female specific color polymorphisms appear to be an evolutionary response to sexual harassment, but we know little about the decision rules males use when searching for variable females. For two sympatric species of *Enallagma*, we measured male responses to live female variants under field conditions, early and later in the day. In the morning, when the operational sex ratio was the most male-biased and female density the lowest, males of the polymorphic *E. civile* did not discriminate among conspecific female morphs, and reacted sexually to the andromorphic females of *E. aspersum*, a monomorphic species. Then, male *E. aspersum* did not favor conspecific females over *E. civile* morphs. Both morph types were more confusing for males than were conspecific male signals. However, after 13:00 h, males of both species made few mistakes, and *E. civile* males reacted sexually relatively less often to conspecific andromorphs, the minority morph in this population. The changes in a male's sexual response suggested that they cued to female-specific traits when females were scarce, increasing their detection of potential mates at the expense of making mistakes with heterospecific females. When females of both species were more abundant, a male's behavior was consistent with cueing to morph-specific features. Analyses of comparative data suggested that for several genera, males of polymorphic species were more likely to mistake heterospecific females as mates than males of monomorphic congeners. Our results best support the learned mate recognition hypothesis for the evolution and maintenance of female-specific polymorphisms." (Authors)] Address: Fincke, O.M., Dept Zool., Univ. (2004): The wetland plant and macroinvertebrate assemblages of temporary ponds in England and Wales. *Biological Conservation* 120(2): 265-282. (in English). ["The biodiversity value of Northern European temporary ponds has been little recognised, and there are many gaps in our understanding of their ecology. This study investigated the wetland (including aquatic) plant and macroinvertebrate assemblages, and the physico-chemical characteristics of 71 temporary ponds in semi-natural habitats. Temporary ponds supported on average 17 (SD ± 8) wetland plant and 25 (SD ± 10) macroinvertebrate species. Over 75% of temporary ponds supported at least one uncommon (local, nationally scarce or Red Data Book) species. The number of uncommon wetland plant species and total number of macroinvertebrate species were both positively correlated with the total number of wetland plant species (richness), but there was no correlation between the number of uncommon and common macroinvertebrate species. Almost three-quarters of temporary ponds supported at least one nationally scarce macroinvertebrate and 8% supported at least one nationally scarce plant across a wide range of physico-chemical characteristics. The main environmental factor influencing the composition of temporary pond communities was water chemistry, particularly pH and alkalinity. The occurrence of facultative as well as obligate temporary pond species suggested that this habitat may play an important role in the interchange of species between waterbodies at the landscape scale." 4554. Ocon, C.S.; Rodrigues Capítulo, A. (2004): Presence and abundance of Ephemeroptera and other sensitive macroinvertebrates in relation with habitat conditions in pampean streams (Buenos Aires, Argentina). *Archiv für Hydrobiologie* 159(4) : 473-487. (in English) ["The objective of this work was to analyse the presence and abundance of Ephemeroptera and other sensitive invertebrates in two streams in the pampean area of Argentina, which have different ecological conditions. Juan Blanco stream is a pristine system and a reference site for the area while Buñirigo stream is affected by industrial effluents coming from food industries and tanneries. Biological and physico-chemical samples were taken seasonally from each stream over two years at two sites (upstream and downstream). DO, conductivity, pH, BOD, COD, heavy metals (Pb, Cr, Cu, Cd, Zn and Hg) and nutrients were measured and biotic indices were applied to determine water quality. Among the Ephemeroptera, *Caenis cf. argentina* (Caenidae) and *Callibaetis cf. fasciatus* (Baetidae) were the dominant species with maximum densities in Juan Blanco

stream. Other macroinvertebrates found in the study area and considered sensitive were *Magellomyia bruchina* (Trichoptera, Limnephilidae), *Campsurus major* (Ephemeroptera, Polymitarcyidae), *Rhinoaeschna bonariensis* and *Micrathyrina dydima* (Odonata Anisoptera) and *Diplodon delodontus delodontus* (Pelecypoda, Hyriidae) recorded at low number in Buñirigo downstream. The abundance of individuals for each species can be correlated with water quality variations in the study sites. Certain parameters like pH can influence the distribution patterns of *C. cf. fasciatus*. (Authors)] Address: Rodrigues Capitulo, A., Instituto de Limnología "Raúl A. 4556. Orr, A.G. (2004): Critical species of Odonata in Malaysia, Indonesia, Singapore and Brunei. *International Journal of Odonatology* 7(2): 371-384. (in English). ["Malaysia, Brunei and the Indonesian archipelago comprise a total land area of ca 1.84 million km² including ca 13,000 islands, lying entirely within the tropics. The region is bisected by Wallace's line and supports a rich Oriental fauna to the west (Sundaland) and mainly Australian elements to the east. Taxonomic studies throughout the region were greatly advanced in the first part of the last century by M.A. Lieftinck especially, but many areas remain totally unexplored. Present knowledge suggests ca 700 species occur in the region of which ca 500 are endemic. Many species are known from limited material, often a single specimen or a type series from a poorly defined locality. It is certain that many are highly stenotopic and sometimes occur naturally at low abundance. The most critical habitats are mixed-dipterocarp terra firma forests and fresh-water swamp forests, both of which exhibit high a and /? diversity and harbour a majority of stenotopic species. However all potentially critical species must presently be classified as data deficient. On present knowledge it is not possible to recommend specific action against any species or habitat. No red listings are appropriate. There is an acute need for baseline data, especially from Central Borneo. Wholesale, unregulated habitat destruction for short-term profit poses the gravest threat to the region. Formerly well-studied areas such as Java are in urgent need of reassessment." (Author)] Address: Orr, A.G., Cooperative Research Centre for Tropical Rainforest Ecology and Management, Environmental Sciences, Griffith University, Nathan, Q 4111, Australia. E-mail: agorr@universal.net.au

4557. Orr, A.G. (2004): Territorial behaviour associated with feeding in both sexes of the tropical zygopteran, *Libellago hyalina* (Odonata: Chlorocyphidae). *International Journal of Odonatology* 7(3): 493-504. (in English). ["Territorial behaviour associated with adult odonate feeding in a Bornean rain forest under-storey is described and its underlying causes are analysed. Immature males and females of all ages of *Libellago hyalina* defended perches along a narrow trail in kerangas forest, concentrating especially around patches of sunlight. Throughout the day there was displacement of individuals as the illuminated areas moved and population levels of foragers increased, with maximal density

from 13:00 -15:00 h, but territorial success which followed physical combat could not be associated with size, sex or age. Foraging rates were also highest in this period but peaked clearly at 14:00 h. Both foraging attack rates and attack success were higher in sun patches than in shaded territories. Potential prey, mostly small Diptera < 4 mm length, were more abundant along the trail than in the surrounding forest, but were not concentrated in sunlight. It is suggested that, against the dark backdrop of the forest under-storey, prey became much more visible in sunlight, and were more easily detected and more easily captured, hence sites near sun patches were strongly contested. This behaviour constitutes a hitherto undescribed foraging strategy, which may be characterized as follows: "increasing capture success by concentrating in situations where prey visibility is enhanced by overhead sunlight against a dark background." It is suggested this strategy may be common in tropical rain forest, home to a majority of Odonata species." (Author)] Address: Orr, A.G., Cooperative Research Centre for Tropical Rainforest Ecology and Management, Environmental Sciences, Griffith University, Nathan, Q 4111, Australia. E-mail: agorr@universal.net.au

4558. Ott, J. (2004): Die Libellenfauna des unteren Moosalbtales bei Trippstadt/Pfalz - Ergebnisse eines 6-jährigen Monitorings. *Fauna und Flora in Rheinland-Pfalz* 10(2): 581-602. (in German, with English summary). ["Between 1999 and 2004 the dragonfly fauna of the 'Moosalbtal' near Trippstadt / Palatinate was investigated as part of an ecological monitoring programme. In total 22 species were recorded during this period, some of the species belonging to the federal and national Red Lists of endangered species. Some typical species of running waters are remarkable. The area must be seen in connection with other wetland biotopes in the near vicinity and the whole Palatinate. The real value of a site for nature conservation can only be recognised by longterm monitoring of at least several years and these kinds of studies should be carried out more often." (Authors)] Address: Ott, J., Friedhofstr. 28, D-67705 Trippstadt, Germany. E-mail: L.U.P.O.GmbH@t-online.de

4559. Ott, J. (2004): S7.6 - Dragonflies as indicators for climatic changes - consequences for biodiversity and nature protection [ore 15.15]. *Società Italiana di Ecologia - XIV Congresso Nazionale in collaborazione con la European Section of the Society for Conservation Biology Università degli Studi di Siena. Conservazione e gestione degli ecosistemi. Programma e riassunti del XIV Congresso SItE* Editors: Carlo Gaggi, Valentina Nicolardi e Stefania Santoni Siena, Centro Didattico ale Scotte», 4-6 ottobre 2004: 26. (in English). [Verbatim: Climatic changes are meanwhile regarded as one of the main causes for species extinction and this process is still ongoing. Dragonflies were among the first taxonomic groups reacting on climatic changes: already about 15 years ago the first observations on changes in the distribution patterns of single species were made in Germany and Europe. Meanwhile northward expansions of mediterranean species to northern Europe, as well as invasions from African species into southern european countries are reported in lots of cases. Also the colonisation of biotopes in higher altitudes are documented and changes in the behaviour and in life history parameters (univoltine to bivoltine) are observed. Whereas the invasions of these southern species into the

north until recently was increasing the biodiversity in total, now also the first negative effects could be registered as the changes in the abiotic conditions of the waters - together with changes in dominance structures - could harm the coenosis of the waters (e.g. moorland biotopes) in the long term and will lead to a general change of the biocoenosis. Here the actual changes within the ecology and distribution of dragonfly species on the European level are shown and the negative effects on stenoeicous species (like *Leucorrhinia dubia*, *Somatochlora arctica* etc.) and consequences on protection measurements (e.g. landscape planning or the implementation of biotope webs according to the EC habitats directive) are pointed out] Address: Ott, J., Friedhofstr. 28, D-67705 Trippstadt, Germany. 4564. Parr, A.; Knijf, G. de; Wasscher, M. (2004): Recent appearances of the Lesser Emperor *Anax parthenope* (Selys) in north-western Europe. *J. Br. Dragonfly Soc.* 20(1): 5-16. (in English). ["For much of the 20th century, *A. parthenope* was a considerable rarity in north-western Europe. In 1983, the first individuals for 100 years were noticed in Belgium, and by the mid 1990s the species had also started to appear in The Netherlands, and Britain. Records from all of these countries are now annual, with no fewer than 33 individuals reported from the region during 1999. This paper details and analyses the occurrences of *A. parthenope*

in north-western Europe during recent years, and relates them to records of the species in other parts of northern Europe. The distribution of *A. parthenope* currently seems to be undergoing significant modification, possibly as a result of climate change. Most records in north-western Europe are apparently still of immigrants, though successful breeding was recorded in Britain during 1999 and could easily have been overlooked elsewhere. Reports from north-western Europe span a time period from late May to early September, with the greatest number of individuals appearing in July. Meteorological evidence suggests that many migratory events have a likely origin in Iberia or other regions surrounding the western Mediterranean." 4565. Parr, A.J. (2004): Migrant and dispersive dragonflies in Britain during 2003. *J. Br. Dragonfly Society* 20(2): 42-50. (in English). ["With a fine and hot summer and record high temperatures for the UK in August, it was no surprise that 2003 turned out to be an excellent year for dragonflies. As far as migrant and dispersive species were concerned there were many highlights. Several records were received of 'resident' species in very unusual locations, possibly in part due to the extreme weather providing favourable conditions for dispersal. Of the more traditional migrants, *Sympetrum flaveolum* reappeared in low numbers after an absence of three years, and *S. fonscolombii* and more especially *Anax parthenope* had a good year. However, the main theme was one of continuing range expansions. Following the first record for Britain during 2002, *Lestes barbarus* was again observed in eastern England, with single individuals seen at two sites. There was also a record of a possible *S. pedemontanum*. On a more local scale, several British residents continued their expansion northwards, and Scotland recorded at least two 'firsts' (*A. imperator* and *Libellula depressa*) during the course of the year." 4566. Parr, A.J. (2004): Odonata Records Committee Update. *Atropos* 22: 60. (in English). [Four additional 2003 records of *Anax parthenope* have been accepted by the committee, totalling the British records of the species to 16 in 2003. A claimed sighting of a female *Aeshna affinis* was not accepted.] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St. Edmunds, Suffolk IP29 5BX, UK. E-mail: Adrian.parr@bbsrc.ac.uk

4567. Paulson, D.R. (2004): Critical species of Odonata in the Neotropics. *International Journal of Odonatology* 7(2): 163-188. (in English). ["This report summarizes progress that has been made during the past five years toward the understanding of Neotropical Odonata. It also presents a list of critical species and sites, threats to Odonata conservation in the region, and priorities for further research. This region, the richest in the world for Odonata, must be a focus of intense research and conservation efforts." (Author)] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dpaulson@ups.edu

4568. Paulson, D.R. (2004): Why do some zygopterans (Odonata) perch with open wings? *International Journal of Odonatology* 7(3): 505-515. (in English).

["Zygoptera show two perching modes, one with wings closed and one with wings open. These perching modes are distributed unequally through the suborder; most Zygoptera perch with closed wings, but species in 43 genera of eight families at least occasionally - in most cases usually - perch with open wings. Alternative hypotheses to explain this dichotomy are assessed. The dichotomy does not seem to be explicable by the Phylogenetic Inertia Hypothesis (PIH), the Wing Display Hypothesis (WDH), or the Thermoregulation Hypothesis (TH). I propose a hypothesis that the opening position used by some zygopterans facilitates either more rapid takeoff or quicker orientation toward flying prey: the Quick Takeoff Hypothesis (QTH). That opening species usually take flying prey furnishes support for the QTH, although many closedwing species also take flying prey. However, as most zygopterans perch with closed wings, that behavior needs explanation too, and I propose a hypothesis that perching with wings spread may make a zygopteran more conspicuous to predators and thus may be disadvantageous: the Shiny Wing Hypothesis (SWH). Larger species are less at risk of predation than smaller species, open wings in shade should be less conspicuous than in sunlight, and the majority of zygopterans with open wings are large tropical shade perchers, furnishing support for the SWH." (Author)] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dpaulson@ups.edu

4569. Pelt, G.J. van (2004): New records of dragonflies from Turkey (Odonata). *Libellula Suppl.* 5: 3-38. (in English, with German and Turk summaries). ["Material of 60 species of Odonata from numerous localities on the mainland of Turkey (collected in 1993, 1996, 1997, 1998, 1999, 2001) is reported upon. A list of taxa is provided, and a complete list of localities is presented. The material is preserved in the collection of the RMNH, Leiden, The Netherlands. Remarks on distribution and taxonomy are restricted to major issues, pending an overview of the odonatofauna of Turkey." This colour, blending with the green of the emergence substract (stems of *Eleocharis* sp.), is said to be a perfect camouflage.] Address: not stated

4574. Prum, R.O.; Cole, J.A.; Torres, R.H. (2004): Blue integumentary structural colours in dragonflies (Odonata) are not produced by incoherent Tyndall scattering. *Journal of Experimental Biology* 207: 3999-4009. (in English). ["For nearly 80 years, the non-iridescent, blue, integumentary structural colours of dragonflies and damselflies (Odonata) have been attributed to incoherent Tyndall or Rayleigh scattering. We investigated the production of the integumentary structural colours of a damselfly the familiar bluet, *Enallagma civile* (Coenagrionidae) and a dragonfly the common green darner, *Anax junius* (Aeshnidae) using fibre optic spectrophotometry and transmission electron microscopy (TEM). The reflectance spectra of both species showed discrete reflectance peaks of 30% reflectance at 475 and 460 nm, respectively. These structural colours are produced by light scattering from closely packed arrays of spheres in the endoplasmic reticulum of box-shaped epidermal pigment cells underlying the cuticle. The observed reflectance spectra do not conform to the inverse fourth power relationship predicted for Tyndall / Rayleigh scattering. Two-dimensional (2-D) Fourier analysis of the TEM images of the colour-producing arrays reveals ring-shaped distributions of Fourier power at intermediate spatial frequencies, documenting a quasiperiodic nanostructure. The nanostructured Fourier power spectra falsify the assumption of spatial independence of scatterers that is required for incoherent scattering. Radial averages of the Fourier power spectrum indicate that the spheres are substantially nanostructured at the appropriate spatial scale to produce visible colours by

coherent scattering. However, the spatial periodicity of the arrays is apparently too large to produce the observed colour by coherent scattering. The nanospheres could have expanded substantially (50%) during preparation for TEM. Alternatively, coherent light scattering could be occurring both from the surfaces and from structures at the centre of the spheres. These arrays of colour-producing spheres within pigment cells have convergently evolved at least 11-14 times independently within the Odonata. Structural colouration from arrays in living cells has also fostered the convergent evolution of temperature-dependent colour change in numerous odonate lineages." 4584. Sahlén, G.; Bernard, R.; Cordero Rivera, A.; Ketelaar, R.; Suhling, F. (2004): Critical species of Odonata in Europe. *International Journal of Odonatology* 7(2): 385-398. (in English). ["The status of the odonate fauna of Europe is fairly well known, but the current I-UCN Red List presents only six species out of ca 130, two of which are actually out of danger today. In this paper we propose a tentative list of 22 possibly declining or threatened species in the region. For the majority, reliable data of population size and possible decline is still lacking. Also 17 endemic species are listed, most occurring in the two centres of endemism in the area: the south-eastern (mountains and islands) and the western Mediterranean. These species should receive extra attention in future updates of the world Red List due to their limited distribution. The extreme variation in biomes and the human exploitation of habitats make con-

ervation planning complicated in Europe. Within the EU, the FFH directive is a working tool aiding conservation. However, the species included do not fully correspond to those on the current Red List, nor to those discussed in this paper. We believe that future conservation efforts should focus on the most valuable and threatened habitats in each sub-region. Active conservation measures could be implemented on a European scale, provided that research will establish a solid ground for such measures." 4588. Sawabe, K.; Ueda, T.; Higashi, K.; Lee, S.-M. (2004): Genetic identity of Japanese *Sympetrum frequens* and Korean *Sympetrum depressiusculum* inferred from mitochondrial 16S rRNA sequences (Odonata: Libellulidae). *International Journal of Odonatology* 7(3): 517-527. (in English). ["The Japanese endemic *Sympetrum frequens* is considered as the insular vicariant of *S. depressiusculum*, widely distributed in the Eurasian Continent. In Korea, morphologically intermediate specimens have been collected, mixed with typical *S. depressiusculum*. The taxonomical status of these two species is thus questionable. To clarify their status, sequencing of mitochondrial 16S ribosomal RNA (rRNA) was performed on 77 specimens of *Sympetrum* species collected from Korea and Japan. The pairwise differences between 378 nucleotides of *S. frequens* and *S. depressiusculum*, including the intermediate type, revealed only minor differences (< 0.5%, average 0.48%).

The neighbor-joining phylogenetic tree indicated that all *S. frequens* and *S. depressiusculum* form one clade, suggesting that they pertain to a single species. The tree also suggests that the *S. frequens* population from Hokkaido is different from all other populations." 4589. Schenk, K.; Suhling, F.; Martens, A. (2004): Egg distribution, mate-guarding intensity and offspring characteristics in dragonflies (Odonata). *Animal Behaviour* 68 : 599-606. (in English). ["We studied how egg size, larval size and egg development time are related to oviposition site selection and mate guarding in a dragonfly assemblage of the Namib desert. Species that oviposited mainly in tandem flight (*Pantala flavescens* and *Sympetrum fonscolombii*) spread their eggs over several ponds, which we interpreted as spatial risk spreading. Other species (*Orthetrum chrysostigma*, *Trithemis kirbyi*, *T. annulata*, and *Crocothemis erythraea*) performed noncontact guarding and localized their eggs, usually in a single pond, which we interpreted as distinct habitat selection. Because long oviposition durations increase the risk of disruption by rival males, we predicted that in species that localize their eggs to a distinct oviposition habitat the largest-laid eggs of a clutch should be the largest, indicating high quality. Species that perform risk spreading should distribute large eggs randomly over all oviposition sites. We tested our hypothesis at artificial ponds using experimental manipulations of oviposition. In *O. chrysostigma* and *T. kirbyi*, egg size and larval size decreased significantly with order of laying, and the time to hatch was randomly distributed. As predicted, within the clutches of *P. flavescens* and *S. fonscolombii*, egg size was randomly distributed over a clutch and we found no trend of decrease in larval size or increase in the time to hatch in relation to order of laying." 4590. Schenk, K. (2004): Relation between egg distribution, mate guarding intensity, and offspring conditions in dragonflies (Odonata). Abstracts: 5th International Symposium on Tropical Biology. SATELLITE EVENTS: 6th International Symposium on the Chrysomelidae; Workshop on African Odonata (Edited by Bernhard A. Huber); Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 160, 53113 Bonn, Germany: 144- (in English). [Verbatim: How is egg size, larval size, and egg development time related to oviposition site selection and mate guarding in dragonflies? My behaviour studies showed species that oviposited mainly in tandem flight spread their eggs over several ponds (spatial risk spreading). Other species performed non-contact guarding and localised their eggs usually in a single pond only (distinct habitat selection). The longer females oviposited at one place the higher the risk caused by disruption by males or increasing predation. Therefore, I proposed that in species which layed their eggs into a distinct oviposition habitat, the eggs of a clutch laid first should be the largest, which I interpret as indicator for high condition. Species that perform risk spreading should distribute large eggs randomly over all oviposition sites. The hypothesis was tested and confirmed at artificial ponds in Namibia and Germany using experimental manipulations of oviposition.] Address: Schenk, Kamilla, Zoologisches Institut, Abtei-

(2004): Beobachtung einer Schabrackenlibelle - *Hemianax ephippiger* (Burmeister, 1839) - am Eich-Gimbsheimer Altrhein (Rheinessen, Rheinland-Pfalz). *Fauna und Flora in Rheinland-Pfalz* 10(2): 699-702. ["On May 4th 2003 a male imago of *Anax ephippiger* was recorded at the 'Meerwasser', a shallow pool with an extensive *Phragmites* reedbed belonging to the 'Eich-Gimbsheimer Altrhein', an oxbow lake of the Rhine river near the city of Worms (Rhinessen, Rhineland-Palatinate, Germany). Since there had been strong winds on the days before, it seems possible, that the specimen had been drifted by these winds. It is the second documented record of *A. ephippiger* in Rhineland-Palatinate where the species has been classified as an irregular immigrant." (Author)]. Address: Schlotmann, F., Bahnhofstr. 22a, D-55256 Harxheim, Germany.

4593. Schlumprecht, H.; Strätz, C.; Potrykus, W.; Frobel, K. (2004): Libellenverbreitung und wasserwirtschaftliche Renaturierungsmaßnahmen im oberen Maintal. Vorher-Nachher-Vergleich anhand einer Rasterkartierung. *Naturschutz und Landschaftsplanung* 36(8): 277-284. (in German with English summary). ["In the Upper Main Valley (Upper Frankonia, Bavaria) since 1991 many restoration projects have been planned and carried out by the local water authority. They included a survey of the dragonfly fauna which was compared to a former survey of FROBEL (1997; investigations from 1979 to 1993). The study investigated all water bodies in 61 squares of 1 km², covering the 51 km reach of the Upper Main. Applied methods comprised the determination of adults by sight or caught by net, collection of exuviae, and mapping dragonflies from the shore or by canoeing. Several species classified as very rare ten years ago, like *Gomphus vulgatissimus* and *G. pulchellus*, were now found as adults or exuviae in more than 50 % of all plots, mostly in river restoration areas. Furthermore, typical species of rivers and streams such as *Onychogomphus forcipatus* and *Calopteryx virgo* have considerably increased their regional distribution (covering 36 or 20 % of all plots). This is also true for *Orthetrum brunneum*, *Brachytron pratense*, *Anax parthenope* and *Erythromma viridulum*. For the first time *Crocothemis erythraea*, *Cercion lindenii*, *Sympetrum fonscolombii*, *Onychogomphus forcipatus* and *Ophiogomphus cecilia* (listed in the EU Habitat Directive, Annex II) were identified in 2003 in the Upper Main valley. Reasons for the increased distribution and abundance of the species characteristic for natural or near-natural rivers and streams are presumably the creation of new habitats like gravel banks, cut-off meanders, coves, ponds and shallow water zones and the widening of rivers sections which took place in 21 river restoration projects of the local water authority. On

the other hand, some species declined or vanished in the survey area. Ten years ago these species were rare (i. e. they were only found in 1 to 3 plots), namely *Aeshna juncea*, *Coenagrion lunulatum*, *Lestes virens*, *L. barbarus*, *Leucorrhinia dubia*, *L. pectoralis*, *Sympetrum pedemontanum* and *Somatochlora flavomaculata*. Some of these species can be classified from their preferred habitats as bog species (i. e. species of meso- or dystrophic habitats) or from their geographical distribution as boreomontane species. At the same time, thermophilic or mediterranean species increased, such as *Crocothemis erythraea*." (2004): Veränderung der Artenzusammensetzung und erhöhte Abwanderung bei Libellen durch die Mahd der Uferwiesen zweier Fließgewässer (Odonata). *Libellula* 23(1/2): 1-43. (in German, with English summary). ["Change of species composition and increased migration rate of dragonflies due to cutting of adjacent meadows of two running waters (Odonata) At a lowland brook and a meadow ditch near Freiburg (Baden-Wuerttemberg, Germany), before cutting of adjacent meadows the damselfly assemblage at the brook comprised about 1100 individuals. During the day 89% and over night 50% of them stayed in the herbaceous, richly structured meadows up to >60 m from the bank. The ditch assemblage with about 350 individuals was found in the surrounding, monotonously structured tall oat grass meadow mainly near the water. Directly after cutting, the meadows along the brook and the ditch were almost free of damselflies, whereas the anisopteran *Orthetrum coerulescens* was still found in similar densities as before. As a result of cutting, the damselfly numbers of the brook decreased to 50% and that of the ditch to 32 %. Due to cutting, sex ratio and ratio of mature and immature damselflies changed at the brook as well as species composition and dominance relationships within the assemblages at the ditch. In the further surrounding, abundance in particular of females and numbers of flights away from the waters increased shortly after cutting. The study underlines the great importance of terrestrial habitats for dragonfly assemblages. Notes for practical nature conservation are given." 4609. Suhling, F.; Schenk, K.; Padeffke, T.; Martens, A. (2004): A field study of larval development in a dragonfly assemblage in African desert ponds (Odonata). *Hydrobiologia* 528: 75-85. (in English). ["Aquatic animals distributed along a habitat-permanence gradient (HPG), differ in life history (Wellborn et al., 1996. *Annual Review of Ecology and Systematics* 27: 337-363). Dragonflies that occur in hot arid regions often occur in temporary waters and consequently perform direct and rapid development. Dragonfly species of the Namibian desert do differ in their selection of habitats along the HPG and therefore may also differ in life cycle. Here, we attempt to monitor colonisation, larval growth and emergence in a temporary pond of known history. We studied the development of dragonfly species that laid eggs in artificial ponds constructed by us in March 2001. The assemblage consisted of species that originate from different habitats along the HPG. To obtain data on larval development we took samples from the ponds at 10-day intervals. Most species showed rapid development. By regressing the maximum sizes attained by larvae on each sampling date against time we estimated growth rates for five species and were there-

by able to estimate that total duration of development from oviposition to emergence ranged between 38 and 70 days. Observation of first oviposition and first emergence for three of these species corroborated our estimates based on growth rate. Of few species, which laid eggs in the ponds no larvae or adults were found. For some this may have been the result of predation whereas others may not have grown fast enough to emerge before the ponds dried up. Our results indicate that dragonflies cannot recognise whether a pond will retain water long enough for full larval development and oviposit in waters that will not allow larval development." 4610. Suhling, F.; Martens, A.; Marais, E. (2004): Critical species of Odonata in southwestern Africa. *International Journal of Odonatology* 7(2): 263-277. (in English). ["In this report we review the conservation status of Odonata of southwestern Africa, viz Angola, Botswana, Namibia, Zambia and Zimbabwe. In total, 287 species have been recorded of which three have been previously listed by IUCN. We consider 60 species mainly because of their endemism in the region. The majority of the species have to be categorised as 'data deficient' according to IUCN regulations. The most important freshwater habitats in the region are the extensive swamps in the Kalahari basin, such as the Okavango Delta, the Caprivi swamps and the swamps along the courses of the middle Zambezi system, which host a unique odonate community. The most important threats for species in the region include overuse of water, construction of dams in the large rivers and deforestation. We strongly recommend extensive research on the Angolan and Zambian odonate faunas, which appear to be the richest in the regions, although they are poorly investigated." (Authors)] Address: Suhling F., Inst. Geoökologie, TU Braunschweig, Langer Kamp 19c, D-38102 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

4611. Suhling, F.; Schütte, C.; Martens, A. (2004): Habitat selection, ecological traits and regional distribution pattern of dragonflies in arid Namibia. *Zoologisches Forschungsinstitut, und Museum Alexander Koenig, Adenauerallee 160, 53113 Bonn, Germany. 5th International Symposium on Tropical Biology: 145.* (in English). [Verbatim: Freshwaters can be classified into types with respect to the extent of drying they experience. While temporary waters limit the distribution of taxa due to harsh physical conditions (drying), perennial waters limit distribution of taxa through biotic factors. Hence, species occurring in different types of freshwaters along the gradient should differ in ecological traits, e.g. behaviour and life history. We studied adult habitat selection and behavioural and life history traits of larvae of 11 species of Namibian dragonflies. We hypothesised that species selecting different habitats along the gradient in Namibia should differ in traits studied. Three groups were identified: (1) species confined to perennial springbrooks, (2) species occurring mainly at large perennial lakes, and (3) species occurring at several types of habitats. Experimental studies revealed that perennial water species grow slower and are less active than temporary water species. The latter is normally interpreted as adaptation against large predators. Slow growth is a trade-off, which prevents species of developing in temporary waters. Because in arid Namibia perennial

freshwaters are limited we expected that species specialised to such freshwaters are rare, whereas species able to develop in temporary waters should be widespread. We produced distribution maps based on data of museum collections and own sample data, which revealed that species of type (1) and (2) are limited in distribution, while species of type (3) are widespread in the country.] Address: Suhling F., Inst. ["[...] Females arriving at the breeding site with a full clutch of eggs to lay are bound to be harassed by males until they enter tandem. The same females leaving the breeding site with no mature eggs to lay signal to males that they are not worth mating with and males believe them. Females might like to persuade males to leave them alone when they approach the breeding site, but invariably they do not. Why are they able to do it on the way out, but not on the way in? The answer would seem to be that they have an honest signal on the way out, a signal to males
- the way out, a signal to males with which they are unable to convey false information, an honest signal. When leaving a breeding site, female coenagrionid damselflies, if approached by males, bend their abdomens down outrageously, at an angle close to ninety degrees. Males seem to get the message that these females are not worth chasing. Females are quite unable to do this when they approach a breeding site because their abdomens are completely full of mature eggs such that it is impossible to bend them at such angles. So bending the abdomen at such an angle is an honest signal because it is impossible to cheat on this signal. The abdomen can only be bent to such a large extent when it is empty of mature eggs." - 4624.** Tiemann, J.S.; Gillette, D.P.; Wildhaber, M.L.; Edds, D.R. (2004): Effects of Lowhead Dams on Riffle-Dwelling Fishes and Macroinvertebrates in a Midwestern River. *Transactions of the American Fisheries Society* 133: 705-717. (in English). ["Many studies have assessed the effects of large dams on fishes and macroinvertebrates, but few have examined the effects of lowhead dams. We sampled fishes, macroinvertebrates, habitat, and physicochemistry monthly from November 2000 to October 2001 at eight gravel bar sites centered around two lowhead dams on the Neosho River, Kansas. Sites included a reference site and a treatment site both upstream and downstream from each dam. Multivariate analysis of variance indicated that habitat, but not physicochemistry, varied immediately upstream and downstream from the dams, with resultant effects on macroinvertebrate and fish assemblages. Compared with reference sites, upstream treatment sites were deeper and had lower velocities and downstream treatment sites were shallower and had higher velocities; both upstream and downstream treatment sites had greater substrate compaction than reference sites. Macroinvertebrate richness did not differ among site ty-

pes, but abundance was lowest at downstream treatment sites and evenness was lowest at upstream treatment sites. Fish species richness did not differ among site types, but abundance was highest at downstream reference sites and evenness was highest at upstream sites. [...] Although limited to one system during a 1-year period, this study suggests that the effects of lowhead dams on fishes, macroinvertebrates, and habitat are similar to those reported for larger dams, providing important considerations for riverine ecosystem conservation efforts." (Authors) *Lestidae* and *Gomphidae* are listed in tab. 2] Address: Tiemann, J., Illinois Natural History Survey, Center for Biodiversity, Champaign, Illinois 61820, USA. 4625. Tofilski, A. (2004): DrawWing, a program for numerical description of insect wings. *Journal of Insect Science* 4(17): 5pp. (in English). ["There is usually a pattern of veins on an insect wing. This pattern is species-specific and is used taxonomically.[...] A tool is presented that enables automatic identification of vein junctions. An image of an insect wing is used to determine the wing outline and veins. The vein skeleton is obtained using a thinning algorithm. Bezier splines are fitted to both the wing outline and the vein skeleton. The splines are saved in an encapsulated postscript file. Another output file in text format contains the coordinates of vein junctions. Both the program and its source code are available under GNU General Public License at [www.cyfkr.edu.pl/~rotofilsk/drawing.html]. The program presented in this paper automatically provides a numerical description of an insect wing. It converts an image of an insect wing to a list of coordinates of vein junctions, and a wing diagram that can be used as an illustration. Coordinates of the vein junctions extracted by the program from wing images were used successfully to discriminate between males of *Dolichovespula sylvestris* and *Dolichovespula saxonica*." (Author) A wing of *Aeshna juncea* is demonstrated.] Address: Available online: insectscience.org/4.17

4632. Tynkkynen, K.; Rantala, M.J.; Suhonen, J. (2004): Interspecific aggression and character displacement in the damselfly *Calopteryx splendens*. *Journal of Evolutionary Biology* 17(4): 759-767. (in English) ["Problems in species recognition are thought to affect the evolution of secondary sexual characters mainly through avoidance of maladaptive hybridization. Another, but much less studied avenue for the evolution of sexual characters due to species recognition problems is through interspecific aggression. In the damselfly, *Calopteryx splendens*, males have pigmented wing spots as a sexual character. Large-spotted males resemble males of another species, *Calopteryx virgo*, causing potential problems in species recognition. In this study, we investigate whether there is character displacement in wing spot size and whether interspecific aggression could cause this pattern. We found first that wing spot size of *C. splendens* in populations decreased with increasing relative abundance of *C. virgo*. Secondly, *C. virgo* males were more aggressive towards large- than small-spotted *C. splendens* males. Thirdly, in interspecific contests *C. virgo* males had better territory holding ability than *C. splendens* males. These results suggest that interspecific aggression may have caused character displacement in wing spot size of *C. splendens*, because the intensity of aggression towards large-spotted males is likely to increase with relative abundance of *C. virgo* males. Thus, interspecific aggression may be an evolutionarily significant force that is able to cause divergence in secondary sexual characters." (Authors)] Rantala, M.J., University of Jy-

väskylä, Department of Biological and Environmental Science, P.O. Box 35, FIN-40014, University of Jyväskylä, Finland; Current address: Department of Biology, University of California, Riverside, CA 92521, USA. E-mail: marrant@st.jyu.fi

4633. Tyrrell, M. (2004): Group oviposition behaviour in the Brown Hawker *Aeshna grandis* (L.). *J. Br. Dragonfly Society* 20(2): 79. (in English). ["... a group of six to eight female *A. grandis* were observed swarming around a partially submerged wooden pallet. The pallet had been present at this site for at least six months and was used as a stand by fishermen. It became clear that the females were ovipositing as a group into the submerged sections of the pallet. Despite the weather, which would not generally have allowed much activity, the hawkers were highly active, competing for space to oviposit on the pallet. A similar observation was made on 18 July 2004 at Ditchford Lakes and Meadows. Again this was during a warm (21°C), humid, but overcast afternoon. This time, activity was centred on a partially submerged broken tree trunk. It appeared that at all points where the trunk entered the water, a female *A. grandis* was ovipositing just above the water level. There were many other females swarming around and perching on nearby branches, as if waiting their turn. When one female flew away, her oviposition site was immediately taken up by one of the waiting females. This carried on for several minutes until the group broke up and dispersed. ..." 4634. Tyrrell, M.; Brayshaw, S. (2004): Population expansion of the Hairy Dragonfly *Brachytron pratense* (Müller) and other breeding dragonflies of the Nene Valley in Northamptonshire. *J. Br. Dragonfly Society* 20(2): 51-60. (in English). ["The River Nene valley is the primary habitat for Odonata in Northamptonshire, hosting breeding populations of 18 of the 19 resident species. A series of gravel pits, many of which are managed nature reserves, have created excellent habitats for these typical lowland species. The data from the survey reported on in this paper has been included in a report to English Nature to support the case for expansion of the Nene Valley SSSI suite with the recommendation that some pits are designated as SSSI based purely on their assemblages of dragonflies. Following an apparent decline since the 1950s, *B. pratense* is now firmly established as a breeding species in the Nene Valley gravel pits, and breeds in fishing pits, country parks, dykes and managed nature reserves. The main dispersal route into the valley appears to have been along the River Nene corridor from the Cambridgeshire gravel pits located to the north-east. The expansion during the early 1990s coincided with a general range expansion in southern England. The Hairy Dragonfly appears absent from the newer heavily commercial pits, such as Billing Aquadrome south of Northampton, where the leisure uses of the pits may be incompatible with wildlife management, and from those pits with an open aspect such as those found in the Northampton, Hardingstone and Clifford Hill areas. Confirmed breeding is concentrated to the east of Northampton, with only occasional sightings to the west. Breeding sites in Northamptonshire are associated with moderately dense emergent vegetation, floating decaying plant debris, shallow water margins and the presence of Common Club-rush, Bulrush, sedges, Reed Canary-grass and Reed Sweet-grass. Ditchford Lakes and

grass. Ditchford Lakes and Meadows Nature Reserve is the primary breeding site, based on the number of exuviae collected. Breeding has been proven at one site away from the Nene Valley gravel pits and with regular sightings at others, the indications are that the Hairy Dragonfly continues to expand its range in the county, and may soon be recorded at other suitable habitats." 4635. Uéda, T. (2004): How do the Japanese see Dragonflies. Kyoto University Press. ISBN 4-87698-638-X: 505 pp. (in Japanese). [Translation by Naoya Ishizawa: "Uéda, Tetsuyuki: Prologue. While environmental problems aggravate, instead of the Western-like view on nature which conquers nature, the Japanese view on nature attracts attention. Surely, as we love the beauties of nature and enjoy the sound of crickets, Japanese people have lived identifying ourselves with nature. We also produced the peculiar art, which describes nature in haiku poem. However, on the other hand foreigners are disgusted that there is no country, which has been destroying nature of Japan so much. Is the Japanese view on nature surely the one, which brings about coexistence with nature? It is indicated that the Japanese view on nature is so much idealistic that the Japanese do not know the real nature. For example, a raccoon dog, popular to us, is the one that appears in folklore and literature, and we know little about it as a creature. Consequently, concerning management of wild animals, we react only emotionally; saying that killing it is pitiless. Thus our view on nature seems to be much inconsistent and confused. This seems to bring on destruction of culture as well as nature. Therefore, I tried to deal with the problem of the Japanese view on nature, with which we don't deal directly everyday, moreover, to review it thoroughly through the eyes on insects. Because I thought that the essential thing can be seen in the way of coming in contact with such trifles, smallness, and in a sense, peculiarity. Fortunately, I could organize the project supported by the Nissan Science Foundation; How do the Japanese see dragonflies?: A study on the Japanese view of nature. Various experts such as literary persons, linguists, sociologists, artists as well as ecologists reviewed our world through the eyes of insects besides their own works, and held a meeting once every year. This book was accomplished based on the result of the project. My specialty is animal ecology, and I have been studying particularly the behaviours of dragonflies and their life history. I never thought that I began such research till several years before. For these ten years I have been studying *Sympetrum frequens* that is famous of migration to highlands in summer, and I came to suspect that *S. frequens* might be not only an insect but also a scenery that was brought about in the course of interaction between human being and nature. I don't know what made me think so, however, such emotion is only noise for a natural scientist. But the more I endeavor to understand *S. frequens*, the larger my emotion was strengthened. Probably it may be related to the present day situation when rice fields of the main habitat of *S. frequens* have been devastated. Probably I could see it through *akatombo*: *S. frequens*, that agricultural devastation is that of the scenery, that has been suggested concerning the importance of neighbouring nature. Another chance of starting this research was brought about by a big incident. That was Great Hanshin Earthquake. There was a report, which was a relief among a lot of miserable

news. It was a newspaper report that the lives of a couple buried under debris had been supported by the song of "aka-tombo". The report said that only the song of "aka-tombo" that the wife sang was the support of the effort for the life of the husband. At the news I wondered deeply what of the song of "aka-tombo" had produced the effort for life. As you know, the song of "aka-tombo" is none to summon up people's courage. The song might have remembered the couple of the hills and rivers where they had lived in their childhood and might have made them want to live again in such a world. Or there may be another deep meaning. Anyway, it might have been the very thing that I wanted to understand the background of the "aka-tombo" through the word of "scenery". At such time I happened to be invited to a meeting of a research by Yuma, Masahide, Center for Ecological Research, Kyoto University, one of the member of this project. The meeting was the one of a small group for the large theme: General research of Stable Society- Kyoto International Seminar hosted by Foundation of Kyoto Seminar House, presided by Yokoyama, Toshio and others, Institute for Research in Humanities, Kyoto University. This was the group beyond the domain of learning. The theme at that time was "Things break out, continue/ on the mediation", which were like the spells for scientists. Then, in January 1997, two years after the earthquake, I made a presentation on "Change from insects to the scenery in S. frequens" at the seminar house in the cedar forest slightly covered with snow at Miyama-cho, Kyoto-fu. At the meeting I met Prof. Chung, Kwang of Korean University, who said that there had been the word of scenery, however, at present it is not used. His words were so much impressive, then, I decided to review seriously the scenery. Thus this research project started with many participants as well as Prof. Chung. However, without continuous support by Nissan Science Foundation in 1997, from 1999 to 2002 we could not have completed this project, and I express my cordial thanks to the staffs of the foundation. Part I focuses on dragonflies and I will introduce how the Japanese see dragonflies, with the views of Koreans, Chinese and Taiwanese. Part II was the selected results of researches on the Japanese views on nature from various aspects. The above mentioned presentation at "The General Research on the Stable Society", which became the start of this project, is carried in the introduction as it was.

4636. Utzeri, C.; Ercoli, C (2004): Distribution by unpaired males prolongs postcopulatory guarding duration in the damselfly *Lestes virens* (Charpentier) (Zygoptera: Lestidae). *Odonatologica* 33(3): 291-301. (in English). ["In *L. virens*, the tandem post-copulatory guarding varies from some minutes to more than 4 hours and appears correlated to the time of the day and disturbance by unpaired males. Using a multiple regression analysis, with guarding duration as the dependent variable and time of day, temperature and disturbance as the independent variables, it is shown that only disturbance significantly explains the model. An experimental test, in which early-occurring tandem males were not disturbed, while late-occurring ones were disturbed (a reverse situation of what happens in the field), showed that the latter kept their ovipositing females for significantly longer times than the former. The capability of males of varying guarding duration accordingly to the density of solitary males allows them to invest more or less time for guarding, according to the actual risk of losing sperm precedence." 4637. Van Buskirk, J.; Aschwanden, J., Buckelmüller, I.; Reolon, S.; Rüttiman, S. (2004): Bold tail coloration protects tadpoles from dragonfly strikes. *Copeia*, 2004(3): 599-602. (in English). ["Some amphibian larvae develop brightly colored or black tail fins when reared in ponds with predaceous insects. The conspicuous tail has been proposed to lure predator strikes toward the tail and away from the more vulnerable head/body region. We tested this hypothesis by presenting model tadpoles that differed only in coloration to *Aeshna* dragonfly larvae. The models had either a dark body and pale tail, a dark spot in the middle of the tail, or a dark spot near the tip of the tail. Almost all models with plain tails were struck on the head/body, whereas those with dark spots in the tail were struck significantly more often on the tail. Because living tadpoles survive better when attacked on the tail than on the head, our results show that tail coloration can protect tadpoles from predators at close range." 4638. Van de Meutter, F.; Stoks, R.; De Meester, L (2004): Behavioral linkage of pelagic prey and littoral predators: microhabitat selection by *Daphnia* induced by damselfly larvae. *Oikos* 107(2): 265-272. (in English). ["Only recently ecologists started treating the

previously separately considered benthic, littoral and pelagic zones of lake ecosystems as closely connected compartments. Here we study a link between organisms belonging to a different compartment - namely the pelagic and the littoral - through behavior in a series of laboratory experiments. Waterfleas of the genus *Daphnia* are inhabitants of the pelagic zone and suffer a high predation pressure from syntopic vertebrate predators (mainly fish). Presumably to escape this predation, they sometimes migrate in the day to the littoral to seek refuge within macrophytes and return to the pelagic at night. Zygopterans from the genus *Ischnura* do commonly co-occur in ponds with *Daphnia* and are known as opportunistic predators of *Daphnia*. In two initial experiments in microcosms in the lab we showed that *Ischnura* larvae are littoral predators strongly associated with macrophytes. Although we found that predation rates of individual *Ischnura* larvae on *Daphnia* are approximately 1.5 fold lower in macrophytes compared to open water, total predation from *Ischnura* on *Daphnia* per unit area is tenfold higher within macrophytes than in open water, making the open water a safer place for *Daphnia* with regard to *Ischnura* predation. In a third microcosm experiment we monitored horizontal distribution of *Daphnia* in the absence, presence and odor only of *Ischnura* larvae. After 2 hours, on average 10% less *Daphnia* remained within the vegetation when *Ischnura* larvae or only their odor were present compared to when *Ischnura* or their odor were absent. We interpret this as a behavioral anti-predation response of *Daphnia* to the presence of *Ischnura* larvae that seems primarily chemically mediated. The observed horizontal migration of the pelagic prey driven by the littoral predator may couple both lake compartments and may interact with the predator-prey relationships within the pelagic." 4641. Ward, L.; Mill, P.J. (2004): Distribution of the Banded Demoiselle *Calopteryx splendens* (Harris) in northern England: an example of range expansion? *J. Br. Dragonfly Society* 20(2): 61-69. (in English). ["... In the north-east of England, comparison of the current distribution of *C. splendens* [...] with earlier distribution maps [...] shows that its area of occurrence appears to have increased considerably since 1961. However, when recorder effort is taken into account, most or all of the increase up to 1990 can be accounted for by the increase in the number of 10km squares for which odonate records in general have been received. By then,

21 % of the 10km squares in the 100km squares with the O.S. grid letters SE and NZ (which cover most of Yorkshire, Durham and Northumberland) had *C. splendens* records compared to an overall coverage of 94 per cent. The increase in *C. splendens* to 34 % of these squares since 1990 appears to reflect a real increase in the area of occupancy by this species in the north-east of England. ..."] (Authors)] Address: Ward, Louise, Mill, P.J., School of Biology, University of Leeds, Leeds LS2 9JT, UK

4642. Warfe, D.M.; Barmuta, L.A. (2004): Habitat structural complexity mediates the foraging success of multiple predator species. *Oecologia* 141(1): 171-178. (in English). ["We investigated the role of freshwater macrophytes as refuge by testing the hypothesis that predators capture fewer prey in more dense and structurally complex habitats. We also tested the hypothesis that habitat structure not only affects the prey-capture success of a single predator in isolation, but also the effectiveness of two predators combined, particularly if it mediates interactions between the predators. We conducted a fully crossed four-factorial laboratory experiment using artificial plants to determine the separate quantitative (density) and qualitative (shape) components of macrophyte structure on the prey-capture success of a predatory damselfly, *Ischnura heterosticta tasmanica*, and the southern pygmy perch, *Nannoperca australis*. Contrary to our expectations, macrophyte density had no effect on the prey-capture success of either predator, but both predators were significantly less effective in the structurally complex *Myriophyllum* analogue than in the structurally simpler *Triglochin* and *Eleocharis* analogues. Furthermore, the greater structural complexity of *Myriophyllum* amplified the impact of the negative interaction between the predators on prey numbers; the habitat use by damselfly larvae in response to the presence of southern pygmy perch meant they captured less prey in *Myriophyllum*. These results demonstrate habitat structure can influence multiple predator effects, and support the mechanism of increased prey refuge in more structurally complex macrophytes." 4643. Watanabe, M.; Mimura, Y. (2004): Diurnal changes in perching sites and low mobility of adult *Mortonagrion hirosei* *Asahina* inhabiting understory of dense reed community (Zygoptera: Coenagrionidae). *Odonatologica* 33(3): 303-313. (in English). ["Shifts between perching sites, the flying behaviour as well as reproductive behaviour of adults were observed. All marked individuals inhabiting the dense reed community floor were followed from sunrise to sunset. Simultaneous observation was carried out by approximately 20 researchers. Every adult, sexually immature and mature, perched at 20 cm above the water surface within the reed community. For immature adults, about 120 flight activities were performed per day. The accumulated length of the movement was 9 m per day. When matured, the number of flight activities increased two-fold and the total length of the movement was 27 m per day. Although this species is a percher, showing little movement, increased flight activity by mature individuals caused encounters between individuals, hovering face-to-face. Few tandem flights were observed and females oviposi-

ted alone. The behaviour traits of this species at low light intensity are discussed." (Authors)] Address: Watanabe, M., Institute of Biological Sciences, University of Tsukuba, Tsukuba, Ibaraki 305-8572, Japan. E-mail: watanabe@kankyo.envr.tsukuba.ac.jp

4644. Watts, P.C.; Rouquette, J.R.; Saccheri, I.J.; Kemp, S.J.; Thompson, R.J. (2004): Molecular and ecological evidence for small-scale isolation by distance in an endangered damselfly, *Coenagrion mercuriale*. *Molecular Ecology* 13: 2931-2945. (in English). ["*C. mercuriale* is one of Europe 's most threatened damselflies and is listed in the European Habitats directive. We combined an intensive mark-release-recapture (MRR) study with a microsatellite-based genetic analysis for *C. mercuriale* from the Itchen Valley, UK, as part of an effort to understand the dispersal characteristics of this protected species. MRR data indicate that adult damselflies are highly sedentary, with only a low frequency of inter-patch movement that is predominantly to neighbouring sites. This restricted dispersal leads to significant genetic differentiation throughout most of the Itchen Valley, except between areas of continuous habitat, and isolation by distance (IBD), even though the core populations are separated by less than 10 km. An urban area separating some sites had a strong effect on the spatial genetic structure. Average pairwise relatedness between individual damselflies is positive at short distances, reflecting fine-scale genetic clustering and IBD both within- and between-habitat patches. Damselflies from a fragmented habitat have higher average kinship than those from a large continuous population, probably because of poorer dispersal and localized breeding in the former. Although indirect estimates of gene flow must be interpreted with caution, it is encouraging that our results indicate that the spatial pattern of genetic variation matches closely with that expected from direct observations of movement. These data are further discussed with respect to possible barriers to dispersal within the study site and the ecology and conservation of *C. mercuriale*. To our knowledge, this is the first report of fine-scale genetic structuring in any zygopteran species." 4646. Weekers, P.H.H.; Dumont, H.J. (2004): A molecular study of the relationship between the coenagrionid genera *Erythromma* and *Cercion*, with the creation of *Paracercion* gen. nov. for the east Asiatic "*Cercion*" (*Zygoptera*: *Coenagrionidae*). *Odonatologica* 33(2): 181-188. ["The ribosomal DNA genes (18S, 5.8S) and internal transcribed spacers (ITS1, ITS2) of 5 representatives of "*Cercion*" occurring in East Asia were examined and compared with west-palaearctic "*Cercion*" *lindenii*, *Erythromma najas* (2 populations), *E. viridulum*, some true *Coenagrion* species, and with *Enallagma* and *Ischnura* as outgroups. The molecular phylogenetic tree confirms the position of *H. Heidemann* & *R. Seidenbusch* (1993, *Die Libellenlarven Deutschlands und Frankreichs*, Bauer, Keltern) that *Cercion lindenii* belongs in *Erythromma*, and consequently, the binomen *Erythromma lindenii* is accepted. Regarding the "orien-

tal" group for which, under the new situation, the name *Cercion* is no longer available, the genus name *Paracercion* gen. n. is introduced. This is supported by molecular evidence and by some morphological traits. A morphological basis for setting apart the new genus from *Erythromma* is thus achieved, but its delimitation from *Coenagrion* remains to be defined." 4647. Westermann, K. (2004): Ausbreitungsversuche von *Lestes viridis* in den Schwarzwald - ein Beitrag zur Arealausweitung und Höhenverbreitung (*Odonata*: *Lestidae*). *Libellula* 22(3/4) (2003): 87-105. (in German with English summary). ["In the winters from 2000/2001 through 2002/2003, I examined shrubs and trees at 104 standing waters in the southern and south-western central Black Forest for traces of *Lestes viridis* egg clutches. All study sites were located higher than 700 m a.s.l. and had a size of at least 300 m². Approximately 120 traces of egg clutches were recorded at 31 different localities, the highest of which was at 1 109 m a.s.l. Prior to this study, only seven records of imagines existed for the study area and in rare cases involved observations of oviposition behaviour. As very few traces of egg clutches were found at certain sites, they can probably be attributed to either one or only a few females. Only rarely were these traces of egg clutches fresh; instead they were usually at least several years old. Therefore, in contrast to the number of findings, it is unlikely that the species succeeded in establishing permanent populations at any one of the localities. Instead, a permanent, low-level immigration of individuals from the Rhine Valley into the study area appears to take place. However, during the exceptionally hot summer of 2003, F-0 exuviae and emerging imagines were found at three localities at 845 and 900 m a.s.l., respectively. These results describe the status of *L. viridis* at higher elevations in the Black Forest and illuminate mechanisms of both immigration into mountainous terrain and range expansion." 4649. Wilson, H. (2004): Perching orientation of sea-side dragonflies (*Erythrodiplax berenice*) in a Maine salt marsh. *Argia* 15(4): 14. (in English). ["[...] On five dates in 2002, I made opportunistic observations on the orientation of perched *E. berenice* with respect to the wind direction. On each occasion, the wind was either from the northeast or southwest so that a significant fetch resulted. Wind speeds varied from 5 to 10 miles per hour on each day. When I found a perched *E. berenice*, I recorded the quadrant in which its head was directed relative to the wind. For a southwesterly wind, a dragonfly with its head oriented between south and east was scored as upwind. Similarly, a dragonfly oriented between north and west was scored as downwind. Dragonflies oriented between east and north or between west and south were scored as lateral to the

south were scored as lateral to the wind. Some observations were made from upwind, others downwind and yet others lateral, eliminating any possible bias in direction of my presence on the orientation of the dragonflies. If the perching orientations were randomly distributed, one would expect a ratio of 1:1:2 for upwind, downwind and lateral orientations. The upwind and downwind orientations each include 90° of the compass and the lateral orientation includes 180° of the compass. The observed distribution is statistically different from random by a chi-square test ($X^2 = 19.32$, $p < 0.001$). A reasonable hypothesis for the preference of orienting into the wind is the generation of lift when *E. berenice* takes flight. If this hypothesis is true, one can draw a parallel with birds that engage in dynamic soaring over the ocean. Albatrosses and other procellariiform birds have mastered this technique in which the birds glide downwind until they lose attitude, then turn into the wind to generate lift and then turn again to continue downwind. One must be cautious in developing this analogy too far because odonate flight is much more difficult to model than albatross flight. Aside from twice as many wings, odonate wings deform in complex ways to accomplish flight. Nevertheless, for a weak flier like *E. berenice*, perching into the wind may provide a source of lift when the dragonflies take flight." 4653. Worthen, W.B.; Patrick, E.R. (2004): Competitive interactions affect perch-height preferences of three Odonata taxa (Coenagrionidae, Libellulidae). *International Journal of Odonatology* 7(3): 529-541. (in English). [Co-occurring odonate species often perch at different heights. We studied the effects of interspecific and intraspecific interactions on perch-height selection by *Perithemis tenera*, *Pachydiplax longipennis*, and *Enallagma* spp. by creating artificial perch stations and comparing perch selection when species perched alone or together. We also compared the frequency of perch-height use in the presence or absence of *P. tenera* and *P. longipennis* decoys (dead mounted specimens). When species perched alone, *Enallagma* spp. preferred low perches, *P. tenera* intermediate perches, and *P. longipennis* tall perches. This correlated with body mass; larger species used taller perches. Intraspecific responses to decoys were species specific; *P. tenera* showed an aggressive positive response to the presence of a conspecific decoy, whereas *P. longipennis* avoided conspecific decoys by shifting to lower perches. Interspecific effects were more consistent. The presence of living or decoy *P. tenera* at a station caused *Enallagma* to shift to lower perches. Likewise, the presence of living or decoy *P. longipennis* at a station caused *P. tenera* to shift to lower perches. Reciprocal effects were insignificant. These interactions were defined as interference competition because, in the decoy trials, perch-height shifts occurred although all four perches were available to visitors. We conclude that asymmetrical competition contributes to perch-height selection among these species." (Authors)] Address: Worthen, W.B., Dept of Biology, Furman University, Greenville, SC 29613 USA. 4655. Fincke, O.M.; Yanoviak, S.P.; Hanschu, R.D. (1997): Predation by odonate depresses mosquito abundance in water-filled tree holes in Panama. *Oecologia* 112: 244-253. (in English). ["In the lowland moist forest of Barro Colorado Island (BCI), Panama, larvae of four common species of odonates, a mosquito, and a tadpole are the major predators in water-filled tree holes. Mosquito larvae are their most common prey. Holes colonized naturally by predators and prey had lower densities of mosquitoes if odonates were present than if they were absent. Using artificial tree holes placed in the field, we tested the effects of odonates on their mosquito prey while controlling for the quantity and species of predator, hole volume, and nutrient input. In large and small holes with low nutrient input, odonates depressed the number of mosquitoes present and the number that survived to pupation. Increasing nutrient input (and consequently, mosquito abundance) to abnormally high levels dampened the effect of predation when odonates were relatively small. However, the predators grew faster with higher nutrients, and large larvae in all three genera reduced the number of mosquitoes surviving to pupation, even though the abundance of mosquito larvae remained high. Size-selective predation by the odonates is a likely explanation for this result; large mosquito larvae were less abundant in the predator treatment than in the controls. Because species assemblages were similar between natural and artificial tree holes, our results suggest that odonates are keystone species in tree holes on BCI, where they are the most common large predators." 4656. Gorb, S.N. (1997): Porous channels in the cuticle of the head-arrester system in dragon/damselflies (Insecta: Odonata). *Microscopy Research and Technique* 37: 583-591. (in English). ["The ultrastructure of the porous channels (PC) of the postcervical sclerite (SPC), which provides additional head fixation to the neck in adult odonates, was studied using TEM and high resolution SEM microscopy. Single chitin-protein microfibrils, about 0.14 μm thick, are arranged into channels with cylinder-like shapes. The axial rod of the chitin fiber (0.04 μm thick) is located in the center of the cylinder. The orientation of the axial rods was three-dimensionally demonstrated after dissolving the protein cover with NaOH. The PCs are arranged vertically to the surface and pass from the epidermal cells through

all the cuticular layers to the surface of the cuticle. In the exo- and endocuticle, the PCs are usually oval in cross-section and about 0.3 μm thick. In the endocuticle, the cross-sectional area of the PCs varies widely, from 0.01-0.15 μm^2 . The shape of the PC is determined by the macromolecular organization of the chitin-protein microfibrils: the long axis of the channel is orientated parallel to the axis of the preferred orientation of the cuticular microfibrils. The microfibrils tend to follow the line of the channel very closely. In fractures orientated perpendicular to the surface, the PC resembles a ribbon-like construction, which was clearly demonstrated by casts. The strongly parallel orientation of PCs in the deep layers of the cuticle changes within the microtrichia (MT), and they begin to be curved. Numerous PCs pass through the microtrichium, and most of them end on its side wall. PCs usually contain channel filaments about 0.09 μm thick. Usually, a single channel contained one filament, but channels located in the deep layers of the endocuticle have from one to five single filaments. The filaments were observed in the intact cuticle and in the cuticle enzymatically treated with chitinase, while in the cuticle treated with NaOH filaments were absent. The porous channel system of the odonate arrester is interpreted as a device transporting adhesive excretions from the epidermal cells to the cuticular surface." 4658. Watanasit, S. (1997): Sperm displacement in the damselfly, *Xanthagrion erythroneurum* (Zygoptera: Coenagrionidae) - Variance in female sperm count and genital morphology. *J. Sci. Soc. Thailand* 23: 115-122. (in English). ["Sperm competition was examined in the non-territorial damselfly, *Xanthagrion erythroneurum* in a small freshwater lake (Forrestdale Lake reserve), which is close to city Perth, Western Australia. Mating pairs were collected along the shores of lake in 3 categories: precopula, interrupted copula and postcopula. Evidence of sperm removal in *X. erythroneurum* was found from two sources: counts of the number of sperm and penis / female genitalia morphology. Females captured during copulation had fewer sperm in their stora-

ge organ than pre- and post-copula females. These results suggest that male *X. erythroneurum* can remove rival sperm from a female's storage organ during copulation. The morphology of the penis shows that the distal appendage of the penis is a recurved flap-like structure covered with small spines. These structures suggest that the male scoops sperm from the bursa copulatrix before or during deposition of its own sperm. After removing the sperm from the previous matings, new sperm is discharged through a channel which opens on the tip of penis." 4659. Watanasit, S. (1997): Size and mating success in a non-territorial damselfly *Xanthagrion erythroneurum* (Zygoptera: Coenagrionidae). *J. Sci. Soc. Thailand* 23: 61-74. (in English) ["Flight activity and reproductive behaviour of the damselfly *Xanthagrion erythroneurum* (Zygoptera: Coenagrionidae) was observed over a 2 year period (1989-1990). Marked insects were censused hourly between 0900 -1600 hs each day for 6 weeks in each year where, in addition to presence or absence, records were made of individual behaviour including mating and oviposition. Evidence for male-male behaviour was tested using models of both sexes. All observations and experiments were conducted at a focal pond close to Perth, Western Australia. Sex ratios of damselflies visiting the pond were male biased; males tended to arrive at the pond ahead of females. Sexual maturity, as indicated by the first attempts to mate were measured for both sexes. Both sexes matured within 8 days from emergence. Daily survival rate was estimated by the number of times individuals returned to the focal pond. Conservative estimates of survival were 80% for males and 70% for females. Males showed no signs of agonistic behaviour either towards other flying or perched males or towards the models of either sex. *X. erythroneurum* showed no signs of territorial behaviour. Mating behaviour involved males intercepting perched or flying females. Pairs adopted the tandem and wheel positions typical of all odonates. Oviposition immediately followed mating. Males remained with the submerged females or on the surface of the water close to the submerged female. Females remained underwater for an average of 35 mins. On emergence other males attempted to copulate with the female, adopting the tandem position for several minutes. No successful copulations were observed and males released the previously mated female within minutes. Although age had a significant effect on mating success, size (head width and wing length) of adult males and females had no effect on mating success. Both males and females close to 7 days post-emergence had the greatest chance of mating." 4662. Horner, P. (Ed.) (1998): Wildlife survey in freshwater ecosystems and adjoining terrestrial habitats on Melville Island, Northern Territory. Magnt Research Report No. 1. ISSN 1444-8939 PRINT. ISSN 1447-1981 ONLINE: 56 pp. ["Islands, comprising Bathurst and Melville Islands to the north of Darwin, Northern Territory, are of high natural and cultural significance. Separated by a narrow, fast-flowing strait, these large continental islands are approximately 70 kilometres from the mainland and are inhabited by the Tiwi people. Compared to the adjacent mainland, they include mostly pristine habitat, relatively undisturbed by European settlement and the effects of introduced plants and animals. This report presents the results of a two week field survey (3-17 October 1996) of wildlife in freshwater ecosystems on Melville Island. At the initial planning stage of the project it was intended to carry out surveys of freshwater ecosystems on both Islands, however, a funding reduction restricted field work to the larger Melville Island only. Conducted in collaboration with Aboriginal custodians, the survey aimed to assess wildlife associated with freshwater ecosystems, including the fauna occurring in the various terrestrial habitats bordering the creeks and streams on Melville Island. Results of the survey contribute to the assessment, conservation, documentation and management of the Tiwi Islands natural values, and also provide baseline data for the determination of faunal distributional patterns. Voucher specimens of most species recorded are lodged in the scientific reference collections of the Museum and Art Gallery of the Northern Territory (NTM). From the targeted faunal groups, the survey recorded 187 species on Melville Island. These were composed of 80+ aquatic insects, 49 fishes, 10 amphibians, 31 reptiles and 17 mammals. Results of particular interest include that 26 species of aquatic insects were either new or could not be identified to species with certainty. An as yet undescribed odonate (dragonfly) is the first record for the genus *Huonia* in Australia. The freshwater fish survey determined that the two drainage systems on the island (north and south) support different fish faunas, and terapontids (grunters) common elsewhere in the Northern Territory, appear to be absent from the Island. The terrestrial vertebrate survey recorded the Fawn Antechinus (a mouse-like marsupial) from the Tiwi Islands for the first time, and that colour forms of some tree snakes differed from local mainland forms and are biogeographically significant. These results indicate that the fauna of the Tiwi Islands contains many species of conservation significance. The brevity of the survey (13 days) and the inaccessibility of many potential collecting sites, means that the species lists given are incomplete. Further sur-

vey work, on both Bathurst and Melville Islands, will greatly contribute to knowledge of the Tiwi Islands natural resources." Odonata on pages 10-14.]

["*Archilestes grandis* has undergone extensive range expansion during this century. *A. grandis* has been documented in a wide variety of aquatic habitats often with varying degrees of degradation or contamination, and biotic indices for this species based on relative water quality tolerances tend to vary widely. Water quality data for *A. grandis* habitats is limited, particularly in the northeast. We evaluated various water quality parameters at three man-made aquatic habitats in central New Jersey that support *A. grandis*. These evaluations and those of others suggest that *A. grandis* is very tolerant of water conditions generally considered "poor" by conventional water quality indices; this apparent tolerance of *A. grandis* to degraded water quality may explain its recent range expansion. The occurrence of this species in habitats generally depauperate in other, less tolerant odonate and other macroinvertebrate species may be a useful indicator of "poor" water quality in biotic "index" systems. Moreover, the facility with which the adult odonate community of an aquatic system can be characterized suggests, as other investigators of odonates have proposed, that "odonate metrics" would be ideal for the rapid biological assessment of such ecosystems." 4668. Haubruge, E.; Arnaud, L.; Mignon, J.; Gage, M.J.G. (1999): Fertilization by proxy: rival sperm removal and translocation in a beetle. Proc. R. Soc. Lond. B 266: 1183-1187. (in English). ["Competition between different males' sperm for the fertilization of ova has led to the evolution of a diversity of characters in male reproductive behaviour, physiology and morphology. Males may increase sperm competition success either by enhancing the success of their own sperm or by negating or eliminating the success of rival sperm. Here, we find that in the flour beetle *Tribolium castaneum*, the second male to mate gains fertilization precedence over previous males' sperm and fertilizes approximately two-thirds of the eggs. It is not known what mechanism underlies this pattern of last-male sperm precedence; however, the elongate tubules of the female sperm storage organ may encourage a 'last-in, first-out' sperm use sequence. Here we present an additional or alternative mechanism of sperm precedence whereby previously deposited sperm are removed from the female tract by the mating male's genitalia. In addition to providing evidence for sperm removal in *T. castaneum*, we also show that removed, non-self sperm may be translocated back into the reproductive tracts of new, previously unmated females, where the translocated sperm go on to gain significant fertilization success. We found that, in 45 out of 204 crosses, sperm translocation occurred and in these 45 crosses over half of the offspring were sired by spermatozoa which had been translocated between females on the male genitalia. In the natural environment of stored food, reproductively active *T. castaneum* adults aggregate in dense mating populations where copulation is frequent (we show in three naturally occurring population densities that copula duration and intermating intervals across three subsequent matings average 1-2min). Selection upon males to remove rival sperm may have resulted in counter-selection upon spermatozoa to survive removal and be translocated into new females where they go on to fertilize in significant numbers." gonfly watchers, and a checklist of the California odonate species.] Address: Azalea Creek Publishing, 308 Bloomfield Rd, Sebastopol, CA 5472-5161, USA

4670. Bortolotti, G.R.; Tella, J.L.; Forero, M.G.; Dawson, R.D.; Negro, J.J. (2000): Genetics, local environment and health as factors in uencing plasma carotenoids in wild American kestrels (*Falco sparverius*). Proceedings of the Royal Socociety, London B 267: 1433-1438. (in English). ["Carotenoids are important as pigments for bright coloration of animals, and as physiologically active compounds with a wide array of health-related functions. Carotenoid-dependent coloration may have evolved as a signal to conspecifics; however, factors that may limit availability of carotenoids are poorly known. We investigated how the acquisition of carotenoids may be constrained by availability in the environment, diet, genetic make-up and health status of wild American kestrels. Plasma concentrations of siblings at the time of fledging showed a high degree of resemblance; however, a crossfostering experiment revealed that variance was largely explained by nest of rearing, rather than nest of origin, thus indicating a low genetic component. A multivariate analysis of attributes of nestlings (sex, size, plasma proteins, immune function), parental reproduction (laying date, clutch size) and rearing conditions (brood size, size hierarchy, nestling mortality) showed only a small significant effect of leucocyte differentials on carotenoid concentrations of nestlings. A strong environmental effect on plasma carotenoids was demonstrated by levels of adult kestrels being correlated within mated pairs, and having a significant association with the abundance of voles, the primary prey species, per territory. [...] A total of 5195 prey items was observed, 5070 of which could be identified to some taxonomic level. The major components as a percentage by number (and biomass) of all prey delivered were 10.4 (47.6) small mammals, 63.5 (21.5) dragonflies 3.1 (12.8) birds, 6.4 (9.3) fogs, and 5.4 (1.8) grasshoppers (Orthoptera)." (Authors)] Address: Dept of Biology, University of Saskatchewan, 112 Science Place, Saskatoon, Saskatchewan, Canada S7N 5E2. E-mail: bortolotti@sask.usask.ca

4671. Brooks, K.M. (2000): Migration of polycyclic aromatic hydrocarbons (PAH) from new and used railway crossties into ballast and adjacent wetland environments. American Wood-Preservers Association 96th Annual Meeting: 34 pp. (in English). ["In 1996, an electric utility replaced weathered creosote treated railway ties with newly treated ties as part of a routine maintenance operation on a railway spur carrying coal through a wetland into a power generating facility. The wetland was considered important habitat to *Somatochlora hiemana* an endangered dragonfly. The US Fish and Wildlife Service considered the creosote treated railway ties a threat to this endangered dragonfly and required the utility to replace the treated wood ties with steel ties and to conduct a study to determine the potential risks to wetland environments associated with the use of creosote treated railway ties. Because there are many sources of polycyclic aromatic hydrocarbons associated with all forms of transportation, particularly railway lines carrying coal, a mesocosm study was used to determine the rate at which creosote derived PAH moves from treated ties into railway ballast and then into adjacent wetlands. This study included three cells containing newly treated ties, weathered (old) ties, and untreated red oak ties as a control. The mesocosms replicated

conditions, including the wetland's hydrology, found along the actual right-of-way. Concentrations of PAH were monitored quarterly in mesocosm ballast at distances of 5, 20 and 30 cm from the faces of all three types of railway ties and in sediments at distances of 0.0, 0.5 and 0.75 meters from the toe of the ballast for 555 days. The mesocosms were constructed without significant PAH contamination. Creosote was observed migrating from the newly treated ties into adjacent ballast to a distance of at least 30 cm during the summer of the first year following construction. A similar pulse of PAH was not observed in the weathered tie mesocosm. It appeared that this pulse of PAH was associated with warm ambient air temperatures experienced during July and August at the site and with solar insolation that may have significantly increased surface temperatures on the black colored ties, which act as a black body. Concentrations of PAH adjacent to the newly treated ties declined rapidly to low levels during the fall of the first year. This decline was likely associated with photochemical degradation in the dry ballast environment. A second pulse of PAH was not observed in any of the mesocosms during the second summer of monitoring and ballast concentrations remained low throughout the remainder of the study. Sediment concentrations of PAH remained low until near the end of the study when a small increase in sediment PAH was observed in the new tie mesocosm. The increase in sediment PAH attributable to the creosote treated railway ties was approximately 0.3 mg/g, which was equal to the observed atmospheric PAH deposition observed in this area. However, the observed increases were not statistically significant as a function of Distance, Treatment or Day of the study. Polycyclic aromatic hydrocarbons appeared to have migrated vertically downward to a depth of approximately 60 cm in the ballast. At the end of the study, the observed SPAH concentration was less than 0.85 mg SPAH/g dry ballast at any depth. PAH were detected in one of 16 water samples. Those samples were collected on the final day of the study. However the PAH concentrations were very low and an assessment using the sum of toxic units approach indicated that none of the samples approached concentrations associated with biological stress. Likewise, the PAH concentrations observed in the two most contaminated wetland sediment samples were not predicted to be stressful using the newly developed consensus sediment benchmark methodology of Swartz (1999). No adverse biological effects to even the most sensitive organisms were predicted at the PAH concentrations observed in wetland sediments during this study." 4674. García-Berthou, E.; Moreno-Amich, R. (2000): Food of introduced pumpkinseed sunfish: ontogenetic diet shift and seasonal variation. *Journal of Fish Biology* 57: 29-40. (in English). ["The pumpkinseed sunfish *Lepomis gibbosus* introduced into Lake Banyoles (Spain) were predominantly littoral but there was a tendency of large fish to use deeper zones. Their diet was dominated by littoral macrobenthos, particularly amphipods (*Echinogammarus* sp.). There was ontogenetic variation in the diet, with small young-of-the-year (LF<4 cm) feeding on several littoral microcrustaceans, especially the cladoceran *Ceriodaphnia reticulata*, whereas larger fish shifted to a freshwater shrimp (*Atyaephyra desmaresti*), snails and damselfly larvae. Seasonal variation in diet was linked to resource availability, with consumption of fish eggs and plant debris in spring and summer. In autumn, pumpkinseeds were partially zooplanktivores, preying on the cladoceran *Daphnia longispina*. The diet of pumpkinseeds in Lake Banyoles and other Iberian populations shows less molluscivory than North American populations. The potential ecological impact of this successful exotic species involves mainly predation on fish eggs and molluscs." (Authors) Odonate larvae total to 2.9% of number, 6.5% of biomass, and 18.2% in frequency of occurrence in the diet of *L. gibbosus*.] Address: García-Berthou, E., Departament de Ciències Ambientals and Institut d'Ecologia Aquàtica, Universitat de Girona, E-17071 Girona, Catalonia, Spain. 4675. Gaskin, B.; Bass, D. (2000): Macroinvertebrates collected from seven Oklahoma springs. *Proc. Okla. Acad. Sci.* 80: 17-23. ["We collected macroinvertebrates, measured physicochemical conditions, and visually observed the microhabitats of seven springs located across Oklahoma. Fifty-four species were collected from the seven springs. No single taxon was found in all seven sites and only four species were observed in over half of the sites. This indicates that many of the macroinvertebrates occurring in these springs are not truly spring invertebrates, but are local species able to exist in these environments. The number of taxa collected was directly related to the various microhabitats present and the concentration of dissolved oxygen. Based on the macroinvertebrate community, Sorensen's similarity coefficient revealed that Boiling Springs and Big Spring were most similar, with both containing abundant microhabitats. Desperado Spring and Cattlewash Spring were least similar, having a large difference in dissolved oxygen concentrations. Four of the seven springs were sampled previously. Only 17% of macroinvertebrate species had been previously recorded from a particular site, indicating that a large turnover of species occurs in

these spring habitats." (Authors) Anax junius and additional five taxa on the genus level are listed in table 2.] Address: Bass, D., Department of Biology, University of Central Oklahoma, Edmond, OK 73034

4676. Hall, O.R.; Wallace, B.; Eggert, S.L. (2000): Organic matter flow in stream food webs with reduced detrital resource base. *Ecology* 81(12): 3445-3463. (in English). ["Food webs based on flows of organic matter were developed for two small streams to examine food web response to a large reduction in detrital inputs. At the study site, Coweeta Hydrologic Laboratory in the southern Appalachians, leaf litter inputs and associated microbial assemblages are the main energy source for food webs in headwater streams. We eliminated leaf litter inputs to one stream using a net placed over the first 180 m of stream from its origin. Food webs based on flow of organic matter were developed for a reference stream and the litter-excluded stream for two months, July and December of year 1 of the litter exclusion, to examine effects of leaf litter exclusion on the trophic base of the food web, size distribution of flows, predator-prey interactions, and trophic structure. Flows (mg AFDM-m22-d21; AFDM 5 ash-free dry mass) were estimated using gut content analyses for detritus and prey items, coupled with secondary production estimates. We used a whole-stream $\delta^{13}\text{C}$ tracer method to estimate assimilation of bacteria by invertebrates. The food webs encompassed most (84-91%) of invertebrate secondary production, but 30% of the estimated total links. The primary sources of organic matter for the food web in the reference stream were leaf tissue, bacterial carbon, and animal prey, with 25-30% of total secondary production derived from each. In-stream primary production led to 1% of invertebrate secondary production. A higher fraction of food web production in the litter-excluded stream was derived from wood. Magnitudes of detrital flows were lower in the litter-excluded stream, and some taxa were missing compared to the reference stream. The fraction of predator ingestion approached 100% of total secondary production for both streams, but this predation was distributed diffusely among several taxa. Flows to predators were fewer and smaller in the litter-excluded stream, yet these flows had higher per-biomass consumption coefficients, suggesting stronger interactions among the remaining common taxa. These food webs enabled us to examine interactions among taxa in the streams; hence, we found responses of the stream ecosystem to litter exclusion that we would not have considered had we only measured changes in invertebrate population sizes or system-level changes in organic matter flow." (Authors) The paper contains notes on Odonata.] Address: Hall, R.O., Institute of Ecology, University of Georgia, Athens, Georgia 30602 USA. E-mail: bhall@uwoyo.edu

4677. Kazancı, N.; Dügel, M. (2000): An evaluation of the water quality of Yuvarlakçay stream, in the Köyceğiz-Dalyan protected area, SW Turkey. *Turkish Journal of Zoology* 24: 69-80. (in English, with Turkish summary). ["The longitudinal and seasonal distribution of macroinvertebrates and the physical and chemical variables of Yuvarlak Stream in the Köyceğiz-Dalyan Protected Area in South-Western Turkey were studied between April 1992 and April 1993. The diversity, frequency, dominance, abundance and similarity of macroinvertebrates through the year were recorded. In addition, the Belgian Biotic Index was used as a biological criterion for the assessment of water quality for the first

time in Turkey. According to the physico-chemical variables and the distribution of benthic macroinvertebrates, continuous slight and moderate organic pollution exists in the stream. The monitoring of the water quality of Yuvarlakçay Stream is also necessary for the protection of water quality in meromictic Lake Köyceğiz." (Authors) Odonate taxa are treated on the genus level, including "Ophiogomphus".] Address: Kazanci, N., Department of Biology, Faculty of Science, Hacettepe University, Beytepe, Ankara, Turkey

4681. Shieh, S.-H.; Yang, P.-S. (2000): Community structure and functional organization of aquatic insects in an agricultural mountain stream of Taiwan: 1985-1986 and 1995-1996. *Zoological Studies* 39(3): 191-202. (in English, with Chinese summary). ["Changes in stream water and habitat quality of Chichiawan Stream, which flows through Wulin Farm in central Taiwan, were examined using community structure and functional organization of aquatic insects at 4 sites in 1985-1986 and 1995-1996. Long-term records of water chemistry for the study area indicate that water quality in 1995-1996 had not degraded as compared with data in 1987-1988. It was found that there were significant differences in the number of taxa and number of individuals per sample unit for samples at all sites combined between 1985-1986 and 1995-1996. In general, the number of taxa and number of individuals per sample unit were

higher in 1985-1986 than in 1995-1996 at the 4 sites. Higher relative abundances of *Baetis* spp., *Rhithrogena* ample, *Cincticostella fusca*, and *Uenoa taiwanensis* were found in 1985-1986 compared to 1995-1996, suggesting that the substrate quality of the stream had deteriorated at sites located in agricultural areas. Similar results were found between the taxonomic and functional feeding group analyses when the percentage similarity analysis was used. The functional organization and community composition of aquatic insects at sites 1 and 2 in 1995-1996 were similar to those at site 4 in 1985-1986. Site 4 is located downstream of the confluence between Chichiawan Stream and Yousheng Stream where the stream watershed has been developed for agricultural land use. Principal component analysis indicated that, in addition to the substrate quality of the stream, water temperature, dissolved oxygen, conductivity, and ammonia were the most important physico-chemical variables shaping the aquatic insect community structure in the study stream reach. The study sites in agricultural areas had poorer stream water and habitat quality. The raw cropping of orchards and vegetable farms greatly increased soil erosion and suspended solids inputs to the stream which may have been harmful to the aquatic insect communities." (Authors) In table 2 (relative composition of total aquatic insect fauna in %), *Lanthus* sp. and *Sieboldius deflexus* represent the Odonata, which are very rare in the stream samples.] Address: Ping-Shih Yang, Department of Entomology, National Taiwan University, Taipei, Taiwan 106, R.O.C. 4684. Edwards, J.S.; Thornton, I.W.B. (2001): Colonization of an island volcano, Long Island, Papua New

Guinea, and an emergent island, Motmot, in its caldera lake. VI. The pioneer arthropod community of Motmot. *Journal of Biogeography* 28: 1379-1388. (in English). [Aim: To evaluate the arthropod community of Motmot in relation to primary colonization of young volcanic surfaces. Location: Motmot, an island in Lake Wisdom which occupies the caldera of Long Island, Papua New Guinea. Methods: Arthropod sampling by means of pit-fall, water and tube traps, fallout collectors, and hand collecting. Results: At least 35 species of arthropod were collected in 6 days between 23 June and 3 July 1999. Lycosid spiders and ants dominated in all areas. The predator± scavenger arthropod population is largely or entirely dependent on allochthonous input of aquatic insects from the surrounding lake. Main conclusions: Major changes in the arthropod fauna since the pioneer surveys of Ball and his colleagues in the 1970s are the loss of a strand flotsam community as the island has eroded to form a predominantly cliffed coastline. Ant and spider diversity has increased. The current colonists include a number of widespread 'tramp' species sensu Diamond." (Authors) The following Odonata have been observed. *Xiphagrion cyanomelas* (1969, 1999), *Orthetrum sabina* (1999), *Pantala flavescens* (1999), and *Tramea liberata* (1969, 1971, 1972, 1999). *Xiphagrion* was collected from spider webs, 125 specimens of *P. flavescens* emerged in a 1m² "of the surface of a low cliff about 1,5 m above lake level".] Address: John S. 4690. Wells R.D.S.; Clayton, J.S. (2001): Ecological impacts of water net (*Hydrodictyon reticulatum*) in Lake Aniwhenua, New Zealand. *New Zealand Journal of Ecology* 25(2): 55-63. (in English). ["The ecological impacts of *Hydrodictyon reticulatum* blooms (1989-94) were studied at Lake Aniwhenua (a constructed lake) in North Island, New Zealand by collating fish, invertebrate and macrophyte data collected towards the end of a four year bloom period and following its decline. *Hydrodictyon reticulatum* had some localised impacts on the biota of the lake. Some macrophyte beds were smothered to the extent that they collapsed and disappeared, and dense compacted accumulations of *H. reticulatum* caused localised anoxic conditions while it decayed. However, fish and some invertebrates in the lake benefited from the *H. reticulatum* blooms. High numbers of *Ceriodaphnia* sp. (maximum, 5.5 x 10⁴ m⁻²) were recorded amongst *H. reticulatum*, and gastropods were exceptionally abundant, the most common being *Potamopyrgus antipodarum* (maximum, 1.8 x 10⁵ m⁻²). *Hydrodictyon reticulatum* was consumed by three species of common gastropods in experimental trials, with *Austropeplea tomentosa* consuming up to 1.3 g dry weight *H. reticulatum* g⁻¹, live weight of snail day⁻¹. Gastropods comprised the major portion of the diet of *Oncorhynchus mykiss* in Lake Aniwhenua during and after the *H. reticulatum* bloom. A marked peak in sports fishing (with exceptional sizes and numbers of fish caught) coincided with the period of *H. reticulatum* blooms and the abundant invertebrate food source associated with the blooms." (Authors) *Procordulia grayi* was only recorded after the bloom of *H. reticulatum*. Zygoptera indet. were recorded during both periods.] Address: Wells, R.D.S., National Institute of Water and Atmospheric Research, P.O. Box 11 115, Hamilton, New Zealand. E-mail: r.wells@niwa.cri.nz

(in English). ["A unified understanding of >390 Myr of insect evolution requires insight into their origin. Molecular clocks are widely applied for evolutionary dating, but clocks for the class Insecta have remained elusive. We now define a robust nucleotide and amino acid mitochondrial molecular clock encompassing five insect orders, including the Blattaria (cockroaches), Orthoptera (crickets and locusts), Hemiptera (true bugs), Diptera, and Lepidoptera (butterflies and moths). Calibration of the clock using one of the earliest, most extensive fossil records for insects (the early ancestors of extant Blattaria) was congruent with all available insect fossils, with biogeographic history, with the Cambrian explosion, and with independent dating estimates from Lepidopteran families. In addition, dates obtained from both nucleotide and amino acid clocks were congruent with each other. Of particular interest to vector biology is the early date of

the emergence of triatomine bugs (99.8-93.5 MYA), coincident with the formation of the South American continent during the breakup of Gondwanaland. More generally, we reveal the insects arising from a common ancestor with the Anostraca (fairy shrimps) at around the Silurian-Ordovician boundary (434.2-421.1 MYA) coinciding with the earliest plant megafossil. We explore Tilyard's theory proposing that the terrestrial transition of the aquatic arthropod ancestor to the insects is associated with a particular plant group (early vascular plants). The major output of the study is a comprehensive series of dates for deep-branching points within insect evolution that can act as calibration points for further dating studies within insect families and genera." (in English). [Verbatim: Coastal ecosystems worldwide face increased nutrient enrichment from shoreline and watershed development and atmospheric pollution. Our research formed part of a larger study by the US Geological Survey of the relationship between watershed development and ecosystem integrity within a small estuary dominated by the submerged macrophyte *Ruppia maritima* (widgeon grass) in Acadia National Park, Maine. We used a stable isotope approach to characterize the natural faunal community of the estuary and to determine the response of dominant estuarine consumers to nutrient enrichment using existing *in situ* experimental mesocosms. The estuarine faunal community is dominated by brackish water invertebrates including midge larvae (Chironomidae), oligochaetes, damselfly larvae (*Enallagma* sp.), amphipods (*Gammarus* sp.), ostracods, and water boatmen (*Trichocorixa* sp.), and fish (*Fundulus* sp.). Experimental nutrient additions changed the community

of primary producers, with losses of *R. maritima* and increases in epiphytic and planktonic algae. Although increased nutrients did not significantly alter total invertebrate abundance and diversity, higher nutrient mesocosms had reduced densities of chironomids and greater densities of oligochaetes. Assessment of food web structure using stable isotopes showed a dependence of consumers on epiphytic algae and terrestrial detrital pools under both natural and enriched conditions. *R. maritima* and epiphytic algae were more enriched in $\delta^{15}\text{N}$ and *R. maritima* was more depleted in $\delta^{13}\text{C}$ in the enriched mesocosms. Experimental nutrient loading altered the composition and structure of the natural community in this estuary.] Address: Keats, Rachel, University of Maine-Orono, Orono, ME USA

4704. Moan, J.L.; Marks, J.C.; Williamson, C.; Leroy, C.J. (2002): The effect of elevated atmospheric CO_2 on in-stream cottonwood decomposition and detritivore assemblages. *Ecological Society of America Annual Meeting* s 87: 215. (in English). [Verbatim: Leaf litter is an important allochthonous energy source for stream ecosystems. It has been shown in previous studies that elevated atmospheric CO_2 can reduce leaf litter quality by increasing C:N ratios. We studied how elevated atmospheric CO_2 affects in-stream decomposition and detritivore assemblages. In this experiment, leaves from two species of cottonwoods, *Populus fremontii* and *P. angustifolia*, grown in greenhouse chambers under elevated and ambient CO_2 were collected and placed in litterbags in Beaver Creek, Arizona. Leaves grown in elevated CO_2 showed a significantly slower decomposition than those grown in ambient conditions during the first harvest (7 days), but not for subsequent harvests. Significantly slower decomposition was observed for *P. angustifolia* for all four harvests. This suggests that although atmospheric CO_2 may have an effect on early stages of leaf litter decomposition, three species has a greater overall effect. Over time, invertebrate abundance paralleled decomposition rates with significantly more invertebrates found on *P. fremontii* leaves over *P. angustifolia*. Invertebrate species richness increased in all treatments over time and the invertebrate assemblage shifted from dominance by chironomids to increased abundances of caddisflies and odonates.] Address: Moan, Jaina, Northern Arizona University, Flagstaff, AZ USA

4705. Rodrigues da Silva, E.; Jaffe, K. (2002): Expanded food choice as a possible factor in the evolution of sociality of Vespidae (Hymenoptera). *Sociobiology* 39(1): 1-12. (in English). ["A recent theory suggests that economic considerations are more important than genetic ones in the emergence and maintenance of social behavior. Evolution of social behavior in wasps, thus, could be based on the development of worker castes, which increase the efficiency of brood care and energy use of the colony. If so, social wasps should collect a larger range of prey, favoring polyethism, as social behavior should increase the adaptive value of social spe-

cies among wasps by increasing the range of prey accessible. We explored the literature and showed that the Eumeninae, which are mostly solitary, draw prey from significantly fewer orders of arthropods than wasps in the subfamily Vespinae and Polistinae, which are mainly social, supporting the hypothesis that social behavior may have emerged as a more efficient way to feed and care for the young by opening a wider range of food sources, increasing the amount of food and quality of care provided to the young. Two alternative explanations of this data are also discussed." (Authors) Odonata are listed as prey for several species of Vespinae and Polistes wasps.] Address: Rodrigues da Silva, E., UNESP, Instituto de Biociências, Departamento de Zoologia, C.P. 199, Rio Claro, Brazil. 4706. Schoeppner, N.M.; Relyea, R.A. (2002): You are what you eat: How prey discriminate among predator diets. Ecological Society of America Annual Meeting s 87: 258. (in English). [Verbatim: The evolution of predator-induced plasticity requires reliable environmental cues that convey information about predation risk. Many aquatic organisms rely on chemical cues (produced during predation events) for making phenotypic decisions and these cues differ when predators consume different prey diets. It has been hypothesized that prey should exhibit strong anti-predator responses when predators consume closely-related species but weak responses when predators consume distantly-related species (termed the "phylogenetic hypothesis"). However, tests of this hypothesis typically only include the extreme end points predators eating prey from the same species or prey from a different phylum. We reared three tadpole species (*Hyla versicolor*, *Rana sylvatica*, and *Rana catesbeiana*) in the presence of caged dragonflies (*Anax junius*) fed one of ten diets and quantified tadpole activity. The diets spanned a range of phylogenetic relatedness to include different species, different genera, different families, different orders, and different phyla. We found that while all three tadpole species could discriminate among predator diets, there was poor support for the phylogenetic hypothesis. The more distantly-related diets did not consistently produce weaker responses than the more closely-related diets in the target species. These results suggest that the chemical cues released during the predation event provides specific information about the species being consumed and that the recognition of this signal by other species is not determined solely by phylogenetic relatedness.] Address: Relyea, R.A., Dept Biol. 4708. Srivastava, D.S. (2002): Trophic diversity, habitat complexity and ecosystem function: Complex linkages in bromeliad insect communities. Ecological Society of America Annual Meeting s 87: 272. (in English). [Verbatim: Biodiversity loss often begins at the top level of food webs and flows down, causing concomitant loss of trophic levels. Furthermore, biodiversity loss is frequently caused by habitat changes (i.e. change in amount, type, or heterogeneity). Therefore, two questions are key to understanding the effects of species loss

on ecosystem functions: (1) What is the effect of trophic diversity on ecosystem function? (2) How does trophic diversity interact with habitat changes to affect ecosystem function? These questions were examined using an aquatic insect food web in Costa Rican bromeliads. Bromeliads trap both water and detritus, and this detritus is consumed by larvae of many insect species. The rate of detrital processing by insects was examined as a critical ecosystem function for this system. All detritivore insects are preyed upon by nymphs of a single damselfly species. I examined detrital processing in bromeliads with and without this predatory trophic level. Bromeliads also vary substantially in structure, with high structural complexity (many bromeliad leaves dividing up a volume of water) or lower degrees of complexity (fewer bromeliad leaves per volume of water). The linkages between trophic diversity, habitat complexity and ecosystem function are surprisingly complex in this system. High habitat complexity decreases foraging efficiency of the detritivores (reducing detrital processing), but also reduces predation rates by damselfly nymphs, which indirectly increases detrital processing. Whether not these two effects cancel each other out depends on the equilibrium abundance of insects; that is the relative rate at which insects pupate and leave the bromeliad versus the rate at which new insects enter the bromeliad through oviposition. Increasing habitat size dampens these effects of habitat complexity.] Address: Srivastava, Diane, Dept of Zoology, University of British Columbia, 6270 University Boulevard, Vancouver, B.C., Canada V6T 1Z4. 4709. Sunahara, T.; Ishizaka, K.; Mogi, M. (2002): Habitat size: a factor determining the opportunity for encounters between mosquito larvae and aquatic predators. Journal of Vector Ecology 27(1): 8-20. (in English). ["Occurrence patterns of mosquito immatures and insect predators in containers of various sizes were surveyed in summer (June-July) and autumn (September) of 1998 in a rural area of Saga, southwestern Japan. Mosquitoes were categorized into three types in relation to habitat size. First, *Aedes* (*Stegomyia*) spp. and *Tripteroides bambusa* occurred mostly in small containers of < 0.1 m². Second, *Ae. japonicus* and *Culex kyotoensis* occurred in larger container sizes, compared with the first group. Third, *Cx. tritaeniorhynchus* and *Anopheles sinensis* occurred in rice fields in summer and in large containers in the autumn. Predators such as Notonectidae, Anisoptera nymphs, and *Chaoborus* sp. and a predaceous mosquito *Cx. halifaxii* occurred mainly in large (D0.1 m²) containers. The mosquitoes of the third group showed similarities with predators in the occurrence of each habitat type, and they frequently co-occurred with predators. The mosquitoes of the first group showed less similarity with predators in habitat type preference, and they rarely co-occurred with predators. The second group mosquitoes showed intermediate patterns of the first and the third groups." 4710. Vance, H.D.; Soluk, D.A. (2002): Evaluating the prevalence of non-additivity for multiple predator species in aquatic systems. Ecological Society of America Annual Meeting s 87: 288. (in English). [Verbatim: Understanding whether the consumption rates of two different predator species in isolation can be summed together to predict the consumption rate when those

predator species are present simultaneously has widespread implications. Some studies have shown that the observed consumption rates match the predictions of a null model of additivity (an additive outcome) while other studies show that the observed and predicted values differ dramatically (a non-additive outcome). We address the question of how prevalent additive interactions are in comparison to non-additive interactions and discuss when additivity and non-additivity may occur. We measured the consumption of mayfly larvae (*Isonychia* sp.) under conditions of varying predator density and species composition in artificial stream tanks. Two predatory invertebrates, dragonfly larvae (*Boyeria vinosa*) and hellgrammites (*Corydalus cornutus*), and two fish, greenside darters (*Etheostoma blennioides*) and creek chubs (*Semotilus atromaculatus*) were used. The consumption of every two-predator species combination was monitored in the same controlled experimental conditions. Out of six interspecific combinations of two predator species, only one combination demonstrated even a trend toward non-additivity. The low occurrence of non-additivity observed in this study suggests the possibility that predicting the outcome of multiple predator species interactions may be easier than previously thought.] Address: Vance, Heather, University of Illinois, Urbana, IL USA

4711. Ackerman, J.; Galloway, T.D. (2003): Odonata larvae in urban retention ponds in Winnipeg, Manitoba, Canada. *Proceedings of the Entomological Society of Manitoba* 59: 5-15. (in English). ["We assessed the diversity of Odonata larvae in retention ponds, a prevalent but unexplored aquatic habitat in many cities. Ten storm water retention ponds in Winnipeg were sampled for larval Odonata during the 2001 summer season. Twenty-two species were collected. Six species were common in four or more ponds: *Anax junius*, *Sympetrum costiferum*, *Lestes unguiculatus*, *Enallagma hageni*, *E. ebrium* and *E. civile*. Of the other species found, only one specimen each of 10 species was collected. There appeared to be fewer species and fewer individuals of each species in ponds where vegetation control practices had been applied. No juvenile Odonata were found in ponds where carp were present. *Anax junius* was most abundant in ponds with emergent vegetation. However, in one pond where there had been no vegetation control and where there was no emergent vegetation, the greatest number of species was collected." (Authors)] Address: Ackerman, J., 500 Camden Place, Winnipeg, Manitoba, Canada R3G 2V7. E-mail: joeackerman@hotmail.com

4712. Adelman, T.L.; Bialek, W.; Olberg, R.M. (2003): The information content of receptive fields. *Neuron* 40(4): 823-833. (in English). ["The nervous system must observe a complex world and produce appropriate, sometimes complex, behavioral responses. In contrast to this complexity, neural responses are often characterized through very simple descriptions such as receptive fields or tuning curves. Do these characterizations adequately reflect the true dimensionality reduction that takes place in the nervous system, or are they merely convenient oversimplifications? Here we address this question for the target-selective descending neurons (TSDNs) of the dragonfly (*Aeshna canadensis*).

Using extracellular multielectrode recordings of a population of TSDNs, we quantify the completeness of the receptive field description of these cells and conclude that the information in independent instantaneous position and velocity receptive fields accounts for 70%-90% of the total information in single spikes. Thus, we demonstrate that this simple receptive field model is close to a complete description of the features in the stimulus that evoke TSDN response." 4713. Adeniyi, A.A.; Idowu, A.B.; Okedeyi, O.O. (2003): Levels of cadmium, chromium and lead in dumpsites soil, earthworm (*Lybrodrius violaceous*), housefly (*Musca domestica*) and dragon fly (*Libellula luctosa*). *Pakistan Journal of Scientific & Industrial Research* 46(6): 452-456. (in English). ["Chemical analyses of cadmium, chromium and lead in dumpsites soil, earthworm (*Lybrodrius violaceous*), housefly (*Musca domestica*) and *Libellula luctosa* were performed by atomic absorption spectrophotometry to estimate the degree of metal pollution in two Lagos dumpsites located at Iba Housing Estate (dumpsite A) and Soluos along LASU - Isheri road (dumpsite B). Soil pH and moisture content were also determined. Chromium was not detected (ND) in most of the samples except in the soil samples whose mean and standard deviation (SD) were 0.43 +/- 0.37 µg/g and 0.23 +/- 0.37 µg/g, respectively for dumpsites A and B, and the earthworm samples harvested from dumpsite B (1.00 +/- 1.41 µg/g). The cadmium levels were 4.00 +/- 3.16 µg/g and 7.50 +/- 6.37 µg/g for earthworm; 2.86 +/- 1.43 µg/g and 4.29 +/- 3.74 µg/g for housefly, 0.75 +/- 1.26 µg/g and 1.25 +/- 0.95 µg/g for dragonfly, respectively for dumpsites A and B. However, the concentration of lead in the invertebrates were, 130.00 +/- 112.58 µg/g and 105.75 +/- 94.44 µg/g for earthworm; 145.71 +/- 101.87 µg/g and 225.71 +/- 79.31 µg/g for housefly; 165.00 +/- 69.78 µg/g and 85.00 +/- 69.73 µg/g for dragonfly respectively for dumpsites A and B. Cadmium and lead levels were found to be higher in the invertebrates harvested from the dumpsites than those collected from the non-dumpsites. The non-dumpsite values for cadmium were 1.24 +/- 0.94 µg/g, 0.45 +/- 0.56 µg/g and 0.38 +/- 0.14 µg/g for earthworm, housefly and dragonfly, respectively. Similarly, the non-dumpsite lead levels for earthworm, housefly and dragonfly were 23.12 +/- 10.11 µg/g, 20.75 +/- 11.85 µg/g and 33.62 +/- 14.95 µg/g, respectively." 4714. Albertoni, E.F.; Palma-Silva, C.; de Assis Esteves, F. (2003): Natural diet of three species of shrimp in a tropical coastal lagoon. *Brazilian Archives of Biology & Technology* 46(3): 395-403. (in English). ["The gut content of 495 specimens of *Farfantepenaeus brasiliensis*, 131 of *F. paulensis* (Penaeidae) and 102 of *Macrobrachium acanthurus* (Palaemonidae) were analyzed to establish the composition of their diets. *F. brasiliensis* had as the most important feeding items in its diet larvae of Chironomidae, Polychaeta and *Heleobia australis* (Mollusca). For *F. paulensis*, the most important items were the same as for *F. brasiliensis*, but the order of importance of *H. australis* and Polychaeta was inverted. *M. acanthurus* had detritus as the most important item, followed by Chironomidae larvae, Odonata

nymphs, and fragments of the macroalgae *Chara*. The results showed that the three species were omnivorous, with a varied diet including both components of macrofauna of benthos and associated to the macroalgae *Chara* and plant fragments and detritus." 4715. Asaithambi, M.; Manickavasagam, S. (2003): Effect of habitat manipulation on population density of odonates in paddy ecosystem. *Entomon* 28(2): 147-152. (in English). ["Trials were conducted in a Paddy field to study the effect of habitat manipulation on the population density of odonates. The field was divided into direct sown and transplanted paddy and each was further subdivided into weeded and anweeded plots. Population of both damselfly and dragonfly naiads were counted in one m² in each plot. Results revealed that the direct sown paddy plot harboured more damselfly population than transplanted paddy plot while the dragonfly population was high in transplanted plot than in direct sown plot. Odonate population increased gradually with monsoon and declined during dry weather." 4716. Bazzanti, M.; Della Bella, V.; Seminara, M. (2003): Factors affecting macroinvertebrate communities in astatic ponds in central Italy. *Journal of Freshwater Ecology* 18(4): 537-548. (in English). ["Twenty astatic ponds near Rome were studied in order to define the relationships between physicochemical variables and macroinvertebrate communities. The main abiotic factor differentiating the ponds was the annual hydrologic cycle. Depth, surface area, and sand percentages in the sediment were higher in permanent ponds, whereas silt+clay content was higher in temporary ones. No difference was recorded in pH, conductivity and oxygen content in the water or organic matter in the sediments between the two pond types. Three main ecological assemblages were distinguished: a) generalist taxa common to both pond types; b) taxa associated with and adapted to temporary ponds; and c) taxa which seemed to prefer permanent ponds. Overall, there was no relationship between number of taxa and surface area, except for Odonata and aquatic macrophytes. A positive correlation was observed between number of macrophyte species and macroinvertebrate taxa richness, and particularly of odonates and chironomids, suggesting that an increase in aquatic vegetation species leads to an increase in microhabitats and suitable food, substrate, and/or refuge from predators. Odonata seemed also to prefer more stable and sunny ponds." (Authors)] Address: Bazzanti, M., Dept. Animal & Human Biology, Univ. "La Sapienza", viale dell'Universita 32, 00185, Rome, Italy. 4717. Bohonak, A.J.; Jenkins, D.G. (2003): Ecological and evolutionary significance of dispersal by freshwater invertebrates. *Ecology Letters* 6: 783-796. (in English). ["Traditional expectations for how widely and how often freshwater invertebrates disperse differ from empirical data. Freshwater invertebrates have been characterized as frequent, widespread dispersers, particularly those that are transported passively. Our re-

view finds that this characterization may describe the potential for dispersal in some taxa, but it is not an accurate generalization for actual dispersal rates. High variance among habitats and taxonomic groups is a consistent theme. Advances in population genetics may help resolve these issues, but underlying assumptions should be carefully tested. Further, even unbiased estimates of gene flow may not equate with individual movement, because not all dispersers survive and reproduce. Some freshwater invertebrates may exist in classic Levins metapopulations. However, other species fit into a broader metapopulation definition, where temporal dispersal via diapause is functionally equivalent to spatial dispersal. In the latter case, local extinctions and rescue effects may be rare or absent. Finally, limited dispersal rates in many taxa suggest that theories of freshwater community assembly and structure can be made more robust by integrating dispersal and local processes as joint, contingent regulators. Recent research on freshwater invertebrate dispersal has substantially advanced our basic and applied understanding of freshwaters, as well as evolutionary ecology in general." 4720. Campbell, L.M.; Hecky, R.E.; Wandera, S.B. (2003): Stable Isotope Analyses of food web structure and fish diet in Napoleon and Winam Gulfs, Lake Victoria, East Africa. *J. Great Lakes Res.* 29 (Supplement 2):

243-257. (in English). ["The food web structures in Napoleon and Winam gulfs, Lake Victoria, were characterized using stable nitrogen and carbon isotope analyses. Similar biota in Napoleon Gulf had significantly lighter $\delta^{15}\text{N}$ values and heavier $\delta^{13}\text{C}$ values than similar biota in Winam Gulf, indicating different basal isotopic values. In both gulfs, Nile perch (*Lates niloticus*) was the top trophic predator while Nile tilapia (*Oreochromis niloticus*) was littoral and feeding at lower trophic levels. *Rastrineobola argentea* and *Yssichromis laparograma* had surprisingly high $\delta^{15}\text{N}$ values, close to those of Nile perch, which were not consistent with the high isotopic values of their assumed zooplankton prey. *Caridina nilotica*, a freshwater shrimp, had a wide range of $\delta^{13}\text{C}$ values but low $\delta^{15}\text{N}$ values, consistent with their appearance in nearly all habitants in the lake, and their presence in the stomachs of most fish species. Nile perch showed an increase in $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ values with size, signifying that piscivory increases and their dietary reliance on invertebrates decreases as they mature. Stable isotope values for Napoleon Gulf biota which were adjusted for different basal values were not statistically different from those of Winam Gulf biota, suggesting that stable carbon and nitrogen isotopes fractionate consistently through trophic transfers in Lake Victoria. The stable isotope data illustrate a short food web, with the top predator Nile perch feeding on a restricted set of fish and macroinvertebrate species (including Odonata), including its own young." 4721. Chahl, J.; Thakoor, S.; Le Bouffant, N.; Stange, G.; Srinivasan, M.V.; Hine, B.; Zornetzer, S. (2003): Bioinspired engineering of exploration systems: A horizon sensor/attitude reference system based on the dragonfly ocelli for Mars exploration applications. *Journal of Robotic Systems* 20(1): 35-42. (in English). ["Bio-inspired engineering of exploration systems (BEES) is a fast emerging new discipline. It focuses on distilling the principles found in successful, nature-tested mechanisms of specific crucial functions that are hard to accomplish by conventional methods, but are accomplished rather deftly in nature by biological organisms. The intent is not just to mimic operational mechanisms found in a specific biological organism but to imbibe the salient principles from a variety of diverse organisms for the desired crucial function. Thereby, we can build exploration systems that have specific capabilities endowed beyond nature, as they will possess a mix of the best nature-tested mechanisms for each particular function. Insects (for example, honey bees and dragonflies) cope remarkably well with their world, despite possessing a brain that carries less than 0.01% as many neurons as ours does. Although most insects have immobile eyes, fixed focus optics, and lack stereo vision, they use a number of ingenious strategies for perceiving their world in three dimensions and navigating successfully in it. We are distilling some of these insect-inspired strategies for utilizing optical cues to obtain unique solutions to navigation, hazard avoidance, altitude hold, stable flight, terrain following, and smooth deployment of payload. Such functionality can enable access to otherwise unreachable exploration sites for much sought-after data. A BEES approach to developing autonomous flight systems, particularly in small scale, can thus have a tremendous impact on autonomous airborne navigation of these biomorphic flyers particularly for

planetary exploration missions, for example, to Mars which offer unique challenges due to its thin atmosphere, low gravity, and lack of magnetic field. Incorporating these success strategies of bioinspired navigation into biomorphic sensors such as the horizon sensor described herein fulfills for the first time the requirements of a variety of potential future Mars exploration applications described in this paper. Specifically we have obtained lightweight (6 g), low power (<40 mW), and robust autonomous horizon sensing for flight stabilization based on distilling the principles of the dragonfly ocelli. Such levels of miniaturization of navigation sensors are essential to enable biomorphic microflyers (<1 kg) that can be deployed in large numbers for distributed measurements. In this paper we present the first experimental test results of a biomorphic flyer platform with an embedded biomorphic ocellus (the dragonfly-inspired horizon sensor/attitude reference system). These results from the novel hardware implementation of a horizon sensor demonstrate the advantage of our approach in adapting principles proven successful in nature to accomplish navigation for Mars exploration." 4722. Chase, J.M. (2003): Strong and weak trophic cascades along a productivity gradient. *Oikos* 101: 187-195. (in English). ["Variation in the strengths of predator effects, although commonly observed in natural communities, and predicted from theoretical models, remains poorly understood in the study of food web interactions and community structure. In this study, I first showed that prey species in benthic pond food webs were highly variable in their susceptibility to predators. Some were vulnerable throughout their lives, whereas others were vulnerable as juveniles, but able to grow to a size-refuge. Next, I showed that herbivore and predator abundance increased along a natural productivity gradient among 29 ponds, and herbivore species composition shifted from dominance by vulnerable to dominance by invulnerable herbivore species along this gradient. However, there was a considerable amount of variation both in herbivore biomass and composition at intermediate productivity; some were dominated by small species and others by larger species. Finally, in situ enclosure experiments, I found that predator effects were strong and cascaded to plants in a low productivity pond and in an intermediate productivity pond dominated by small herbivore species. Alternatively, in a high productivity pond and in an intermediate productivity pond dominated by larger herbivores, I found that predator effects on prey biomass were weak, and did not cascade to plants." 4723. Chessman, B.C. (2003): New sensitivity grades for Australian river macroinvertebrates. *Marine and Freshwater Research* 54: 95-103. (in English). ["The SIGNAL biotic index for river macroinvertebrates, originally developed and tested in eastern Australia, was revised for application to the entire continent. Macroinvertebrate survey data from the National River Health Program were used to set grade numbers between 1 and

10 to represent the water-quality sensitivities of 210 taxa (including the Odonata on the family level). Grades were assigned at the taxonomic levels customarily used by government agencies (predominantly family level) and by community groups (mainly order). A new index version using these grades, SIGNAL2, was correlated with water temperature, turbidity, electrical conductivity, alkalinity, pH, dissolved oxygen, total nitrogen and total phosphorus. Because of natural spatial variation in water quality, index scores need to be interpreted in a local context or against site-specific predictions generated by the Australian River Assessment System (AUSRIVAS)." 4724. Combes, S.A.; Daniel, T.L. (2003): Flexural stiffness in insect wings I. Scaling and the influence of wing venation. *Journal Experimental Biology* 206: 2979-2987. (in English). ["During flight, many insect wings undergo dramatic deformations that are controlled largely by the architecture of the wing. The pattern of supporting veins in wings varies widely among insect orders and families, but the functional significance of phylogenetic trends in wing venation remains unknown, and measurements of the mechanical properties of wings are rare. In this study, we address the relationship between venation pattern and wing flexibility by measuring the flexural stiffness of wings (in both the spanwise and chordwise directions) and quantifying wing venation in 16 insect species from six orders (including *Aeshna multicolor*, *Pachydiplax longipennis*, *Letes* sp., *Ischnura* sp.). These measurements show that spanwise flexural stiffness scales strongly with the cube of wing span, whereas chordwise flexural stiffness scales with the square of chord length. Wing size accounts for over 95% of the variability in measured flexural stiffness; the residuals of this relationship are small and uncorrelated with standardized independent contrasts of wing venation characters. In all species tested, spanwise flexural stiffness is 1-2 orders of magnitude larger than chordwise flexural stiffness. A finite element model of an insect wing demonstrates that leading edge veins are crucial in generating this spanwise chordwise anisotropy." 4725. Crumrine, P.W. (2003): Examining the role of size structure on intraguild predation in larval odonates. *Ecological Society of America Annual Meeting* s. [cdrom] 88: 76. (in English). [Verbatim: The direction and intensity of intraguild predation (IGP) interactions are heavily influenced by size differences among interacting species. Asymmetric IGP is common when IG predators are larger than IG prey, and many empirical studies on IGP include predators with these relative size relationships. In addition to size differences between species, individuals in most natural populations of predators and prey vary in size, but few studies specifically test how size variation within species influences IGP interactions. The aim of this study was to investigate how IG predator size structure influences the survival and behavior of IG prey and shared prey. I tested for these effects in a larval odonate system by exposing shared prey (*Ischnura verticalis*) to the presence or absence of IG prey (*Pachydiplax longipennis*) and two size classes of IG predators (small or large *Anax junius*) in a 2x2x2

factorial design. Both size classes of *A. junius* significantly decreased *I. verticalis* survival and activity level, but there were no significant effects of *P. longipennis* on *I. verticalis* survival or behavior. *P. longipennis* responded differently to the two size classes of *A. junius*. *P. longipennis* survival was significantly lower when exposed to only the large size class of *A. junius*, and *P. longipennis* also decreased their activity level in the presence of large *A. junius*. Survival of the small size class of *A. junius* was also lower in the presence of large *A. junius*. These results demonstrate that different size classes of IG predators can impose varying levels of risk on IG prey and shared prey, but these effects depend on the assemblage of predators in the system. Within-species size structure adds significant complexity to IGP interactions, and studies incorporating this feature should provide a more complete understanding of how IGP influences community structure] Address: Crumrine, P.W., University of Kentucky, Lexington, KY, USA USA

4726. Gaines, K.H. (2003): Does size really matter? Factors affecting larval odonate diversity patterns in a desert sinkhole complex. *Ecological Society of America Annual Meeting* s. 88. August 3 - 8, 2003. Savannah International Trade & Convention Center, Savannah, Georgia: 116-117. (in English). [Verbatim: The Bitter Lake National Wildlife Refuge in southeastern New Mexico contains an unusual ecological mosaic consisting of desert scrub and grassland surrounding dozens of saline water-filled sinkholes of varying sizes, geomorphologies, and water chemistries. Nearly one hundred species of adult dragonflies and damselflies (Order Odonata) have been collected on the refuge, representing the highest diversity of odonates in the state of New Mexico. In order to characterize the distribution and diversity patterns exhibited by the breeding odonate population, thousands of exuviae (final instar larval exoskeletons) were periodically collected at over thirty sinkholes in 2000, 2001, and 2002. Multivariate analyses of sinkhole dimensions and water quality data revealed that while larger sinkholes did tend to support more diverse larval odonate communities, average winter salinity levels explained nearly 70% of the variation observed in species diversity, as species with broad larval salinity tolerances successfully bred in most sinkholes visited by adults regardless of sinkhole size. In contrast to predictions of island biogeography theory, this study suggests that in certain cases, individual species characteristics (e.g. larval stenotopy) may have a far greater influence on community diversity patterns than does habitat patch size.] Address: Gaines, Karen H., University of New Mexico-Albuquerque, Albuquerque, NM, USA. E-mail: kgaines@unm.edu

4727. Gassmann, D. (2003): Phylogeny and distribution of the Philippine damselfly subgenus *Risioconemis* (*Igneocnemis*) *Hämäläinen* (Odonata: Platycnemididae). Fritz (ed.): Abstracts of the 6th Annual Congress of the Gesellschaft für Biologische Systematik (GfBS, Society for Biological Systematics). *Org. Divers. Evol.* 3, Electr. Suppl. 17: 20. (in English). [Verbatim: *Risioconemis* Cowley, 1934 is the largest genus of the zygopteran subfamily Calicnemiinae in the Indo-Pacific region. The group is endemic to the Philippines, except for the Sulu Archipelago and the Palawan island chain. Members of the group are confined to small, clear creeks in shady rainforest environment, occurring from lowland up to mid-montane forest. Two subgenera with-

in the genus *Risioenemis* are currently recognized: *Risioenemis* Cowley, 1934 s. str., and *Igneocnemis* Hämäläinen, 1991. A revision of the subgenus *Risioenemis* was presented by Hämäläinen (1991). Mainly based on the large Roland A. Müller collection from the Philippines, which is now housed by the Natural History Museum in Leiden, a complete taxonomic revision of the subgenus *Igneocnemis* has recently been completed by Gassmann & Hämäläinen (2002). In total, 20 species of sg. *Igneocnemis* have been recognized, of which five were newly described. Several putative synapomorphies of *Igneocnemis* species point to the monophyly of the group. However, the monophyly of the whole genus, i.e. *Risioenemis* Cowley sensu lato, is less certain. Within the scope of a phylogenetic-biogeographical study on the Indo-Pacific Platycnemididae, the phylogeny of the *Igneocnemis* species was reconstructed based on morphological characters. The distribution patterns of the species can be explained by Tertiary island arc connections as well as by the existence of larger islands during the Pleistocene. References: Gassmann, D. & Hämäläinen, M. (2002): A revision of the Philippine subgenus *Risioenemis* (*Igneocnemis*) Hämäläinen (Odonata: Platycnemididae). *Tijdschr. Entomol.* 145: 213-266. Hämäläinen, M. (1991): The Philippine genus *Risioenemis* Cowley (Zygoptera: Platycnemididae). 1. Subgenus *Risioenemis*. *Odonatologica* 20: 151-194.] Address: Gassmann, D., Inst. Biol. International Commission on Zoological Nomenclature (2003): Liochelidae Fet & Bechly, 2001 (1879) (Scorpiones): Adopted as a valid substitute name for Ischnuridae Simon, 1879 in order to remove homonymy with Ischnurinae Fraser, 1957 (Insecta, Odonata). *Bull. Zoological Nomenclature* 60(2): 159-161. (in English). ["The Commission has ruled that the scorpion family name LIOCHELIDAE Fet & Bechly, 2001 (1879) is to have precedence over ISCHNURIDAE Simon, 1879, which is a homonym of the widely used damselfly name ISCHNURINAE Fraser, 1957 (Odonata). The type genus of LIOCHELIDAE is Liocheles Sundevall, 1833, which is in wide use as the valid senior subjective synonym of the long abandoned name Ischnurus C.L. Koch, 1837 (the type genus of ISCHNURIDAE Simon, 1879). ISCHNURINAE Fraser, 1957 is not to be rejected despite being a junior homonym of ISCHNURIDAE Simon, 1879." (Author)] Address: International Commission on Zoological Nomenclature, Natural History Museum, Cromwell Road, London, SW7 5BD, UK

4735. Jacobsen, D. (2003): Altitudinal changes in diversity of macroinvertebrates from small streams in the Ecuadorian Andes. *Archiv für Hydrobiologie* 158(2): 145-167. (in English). ["Altitudinal patterns in diversity of macroinvertebrate families at different spatial scales (stone, stream and altitude) were studied by collecting stone samples from six streams at each of the three altitudes: lowlands (400 m), midlands (2000 m) and highlands (3800 m), in the equatorial Andes of Ecuador. Stream sites were characterised by a number of physico-chemical parameters and the fauna by several indices of richness, diversity and evenness. A MDS ordination on the composition of the fauna clearly separated the streams in three groups according to altitude. The invertebrate fauna was dominated by insects, mainly Ephemeroptera, Trichoptera and Diptera at all three altitudes. Odonata and Hemiptera were relatively rich in lowland streams, scarcely present in the midland streams and absent in the highland streams (as was the case for the less diverse orders Lepidoptera and Megaloptera). Four of the five measures of stream diversity correlated significantly with altitude and temperature. In addition, seven environmental parameters were correlated with one or more of the diversity measures. Of these parameters, stream width, riparian vegetation cover and coarse detritus cover were inter-correlated with altitude and temperature. With the effect of altitude removed, the number of families, the Jack-knife richness estimate and the evenness were positively correlated with an index of physical stream stability. The effect of region (altitude) explained more of total variability in family richness than that among streams within regions. The mean number of families was 8.2, 4.9 and 4.1 per stone, 26.5, 19 and 13.3 per locality (stream), and 44, 37 and 27 per region at the three alti-

tudes, respectively. Thus, both local and regional richness decreased approximately linearly with increasing altitude. In contrast, beta diversity (taxon turnover among streams) increased with altitude. The higher richness in the lowland streams appeared at the smallest spatial scale (stone), and was therefore not due to higher betadiversity among stones within streams. Local richness was nearly linearly related to regional richness, indicating non-saturated local communities, even in lowland streams." (Author)] Address: Jacobsen, D., Freshwater Biological Laboratory, University of Copenhagen, Helsingorsgade 51, DK-3400, Hillerod, Denmark. E-mail: Djacobsen@zi.ku.dk

4736. Johnson, E.B.; Bierzychudek, P.; Whiteman, H.H. (2003): Potential of prey size and type to affect foraging asymmetries in tiger salamander (*Ambystoma tigrinum nebulosum*) larvae. *Canadian Journal of Zoology* 81(10): 1726-1735. (in English). ["Although competitive interactions within predator populations are known to depend on their size structure, we understand less about how these interactions are influenced by prey characteristics. Most studies of such interactions for *A. tigrinum nebulosum* larvae have used small zooplankton prey. We investigate the potential of exploitation and interference competition to influence the success of tiger salamander larvae feeding on relatively large prey, mayfly and damselfly larvae. We measured salamander foraging efficiency for a range of salamander and prey sizes and observed aggression levels of salamanders of varying size housed together. Exploitative foraging efficiency (captures per attempts) increased with salamander size but was better predicted by relative prey size (prey size as a percentage of salamander snout-vent length) than by salamander size alone; it also depended significantly on prey type. Aggression (interference) levels were higher when prey were present, and larger salamanders were more aggressive than smaller ones but did not consume more mayfly prey. Our results suggest that investigating the environmental conditions, particularly the prey characteristics, that influence size-based competitive advantages will lead to a better understanding of predator population dynamics.] Address: Johnson, E.B., 524 W. 122nd Street, No. 4D, New York, NY, 10027, USA. 4737. Johnson, J.B.; Saenz, D.; Adams, C.K.; Conner, R.N. (2003): The influence of predator threat on the timing of a life-history switch point: Predator-induced hatching in the southern leopard frog (*Rana sphenoccephala*). *Canadian Journal of Zoology* 81(9): 1608-1613. (in English). ["We tested the hypotheses that potential egg predators, crayfish *Procambarus nigrocinctus* and dytiscid *Cybister* sp. larvae, would accelerate the timing of hatching and that a larval predator, dragonfly naiad *Anax junius*, would delay hatching in the southern leopard frog (*Rana sphenoccephala*). We also tested the hypothesis that differences in response would be proportional to predator lethality. Our results indicate that our hypotheses were partially supported. The presence of an efficient egg predator (crayfish) induces hatching faster than a less efficient predator (dytiscid larvae). However, the presence of a larval predator (naiads) did not delay hatching. Eggs that developed in the presence of egg predators produced hatchlings that were shorter (total length) than those reared in the presence of larval predators or those reared in the absence of predators. We suggest that earlier hatching

times should decrease vulnerability to egg predators but result in shorter hatchlings." (Authors)] Address: Johnson, J.B., Department of Biology, Stephen F. Austin State University, Nacogdoches, TX, 75961, USA. E-mail: frogjinn@hotmail.com

4738. Jones, C.D. (2003): NHIC participates in the national Odonata assessment workshop. Ontario Natural Heritage Information Centre-Newsletter 8(1): 5-6. (in English). [Winnipeg, Canada, 9-X-2002; this is a brief report on the current situation on mapping the Odonata of Ontario and on assessing the current status of Odonata in their areas.] Address: Jones, C.D., Box 182, Lakefield, Ontario, K0L 2H0, Canada. 4739. Kirti, J.S.; Singh, A. (2003): Significance of male genitalic structures for differentiating three species of *Trithemis* Brauer (Libellulidae: Anisoptera: Odonata) occurring in India. *Geobios (Jodhpur)* 30(4): 259-264. (in English). [Male accessory genital structures of *Trithemis pallidinervis*, *T. aurora*, and *T. festiva* are described, illustrated and keyed.] Address: Kirti, J.S., Dept of Zoology, Punjabi University, Patiala, 147002, India

4740. Küry, D. (2003): Wirbellosen-Gemeinschaften der Gewässer Wildensteins. *Mitteilungen der Naturforschenden Gesellschaften Beider Basel* 7: 205-219. (in German, with English summary). ["To evaluate the success of the landscape restorations in the Wildenstein region (canton of Basel-Landschaft) the initial quality of the running and standing waters was assessed. Physico-chemical parameters showed a rather high quality of the brooks but eutrophic to hypertrophic conditions in ponds. Most of the 68 macrozoobenthos taxa in the brooks lived in the Wildensteinerbach (59 taxa) while in the Sormattbächli only 37 taxa were observed. The difference was explained with differing substrate conditions. A total of 45 macrozoobenthos taxa were determined in the ponds: 36 taxa in the Luxmatt ponds and 24 taxa in the Wildenstein pond. Compared to other ponds which are important for conservation, Luxmatt and Wildenstein ponds were poor in taxa. This could be explained with their small areas, the short period since their construction and the presence of fish populations. In both, running and standing waters, 11 species figured in the red lists of Switzerland and Southern Germany, respectively. The enhancement of habitat diversity in running waters and the reduction of the nutrients input in the ponds shall improve the conditions of the macroinvertebrate communities. A monitoring based on the present investigation will estimate the effect of the management to extensivate the farming and forestry." (Authors) The taxa lists include Odonata.] Address: Küry, D., Life Science AG, Greifengasse 7, CH-4058, Basel, Switzerland

4741. Legrand, J. (2003): Les odonates du Nimba et de sa région. *Mem. Mus. natn. Hist. nat.* 190: 231-310. (in French with English summary). [127 species from the Mimba region (Africa: Guinée, Côte d'Ivoire, Liberia) are treated. The (re)descriptions or descriptive notes, and the information on their ecology and distribution are provided. No endemics were encountered in the area (Guinea, Ivory Coast, Liberia), but some species seem to be located only in the slopes of the Nimba mountain. The following species are illustrated: *Gomphidia gamblesi*, *Diastatomma gamblesi*, *Chlorocnemis rossii*, *C. flavipennis*, *Microgomphus jannyae*, *Onychogomphus*

quirkii, *Paragomphus kiautai*, *P. tournieri*, *Phyllogomphus moundi*, and *Tragomomphus christinae*. *Chlorocnemis nubilipennis rossii* Pinhey, 1969 got species rank *C. rossii* Pinhey, 1969.] Address: Legrand, J., 10, rue du Chemin de fer, F-94110 Arcueil, France

4742. Mackenzie, R.A.; Kaster, J.L. (2003): A preservative-free emergent trap for the isotopic and elemental analysis of emergent insects from a wetland system. *Great Lakes Entomologist* 35(1), Spring-Summer 2002 (2003): 47-51. (in English). ["This study reports a cost-effective, live emergent trap designed for the preservative-free use in both biogeochemical and ecological analyses of emerging insects. The trap proved to be advantageous in several ways. First, the simple design made the trap time-efficient since it was easy to set-up, change, and maintain. Second, live sampling not only provided uncontaminated organisms for elemental and stable isotopic analyses, it minimized disfigurement. This resulted in rapid and easy handling, as well as identification, of adult insects. Finally, trap avoidance by ephemeropterans and odonates, a common problem encountered in the literature, was minimal and organisms from both insect orders were successfully collected." (Authors)] Address: The Center for Great Lakes Studies at the WATER Institute, University of Wisconsin-Milwaukee, 600 E. Greenfield Ave., Milwaukee, WI, 53204, USA

4743. Marden, J.H.; Thomas, M.A. (2003): Rowing locomotion by a stonefly that possesses the ancestral pterygote condition of co-occurring wings and abdominal gills. *Biological Journal of the Linnean Society* 79(2): 341-349. (in English). ["A leading hypothesis for the origin of insect wings is that they evolved from thoracic gills that were serial homologues of the abdominal gills present in fossil pterygotes and in the nymphs of some modern mayflies, damselflies and stoneflies. Co-occurrence of thoracic wings and abdominal gills is the primitive condition for fossil pterygote insects, whereas the winged stage of modern insects almost exclusively lacks abdominal gills. Here we examine the locomotor behaviour and gill morphology of a stonefly, *Diamphipnopsis samali* (Plecoptera), which retains abdominal gills in the winged adult stage. This species can fly, but also uses its forewings as oars to accomplish rowing locomotion along the surface of water. The abdominal gills are in contact with both air and water during rowing, and their elaborately folded surface suggests an ability to contribute to gas-exchange. *D. samali* nymphs also have behaviours that place them in locations where their gills are exposed to air; they forage at night at the stream margin and within bubble curtains in rapids. These traits may exemplify an early pterygote condition in which gill and protowing function overlapped in an amphibious setting during a transition from aquatic to aerial locomotion and gas exchange. Rowing locomotion provides a novel and mechanically intermediate stage for the wings-from-gills and surface-skimming hypotheses for the origin of insect wings and flight." 4744. Martinez, J. C. (2003): Habitat specificity and population genetics of three dragonfly larvae in fragmented landscapes. *Ecological Society of America Annual Meeting s. [cd-rom]* 88: 219. (in English). [Verbatim: While anthropogenic land use change is a major

component of environmental change and often results in fragmentation of habitat into isolated remnant patches, habitat specialization is another important mechanism that may lead to population patchiness. My research investigates the sensitivity to extinction by fragmentation in three dragonfly species with differing degrees of habitat specialization, a habitat generalist (*Libellula quadrimaculata*), intermediate habitat specialist (*Somatochlora williamsoni*), and habitat specialist (*Somatochlora tenebrosa*). This is based on principal component analysis using multiple habitat variables. I combine population genetics, ecology, and a modeling approach to gain a more complete understanding of species' sensitivity to extinction by fragmentation. My study species appear to exhibit metapopulation dynamics in the field. Preliminary results of my metapopulation model reveal that when female adults disperse into demes at low population densities, they provide a rescue effect because female immigrants carry thousands of potential eggs with them. On the other hand, male adult dispersal may generally contribute more to gene flow between demes because of their ability to mate with multiple females (pre-mating dispersal model). Preliminary population genetic results for the intermediate habitat specialist revealed no population subdivision on a spatial scale of 300 miles when allozymes were used as molecular markers.] Address: Martinez, Jeannette C., Dept. of Ecology, Evolution and Behavior, University of Minnesota, 100 Ecology, Saint Paul, MN, USA

4745. Pacheco-Flores, C.; Deloya, C.; Cortes-Genchi, P. (2003): Lista de nombres de insectos en lengua Tlapaneca de la "Region de la Montana", Guerrero, Mexico (Arthropoda: Insecta). *Folia Entomologica Mexicana* 42(3): 309-320. (in Spanish, with English summary). ["During the period between September 2000 and January 2001, a collection of insects was performed on herbaceous vegetation, shrubs and trees, in coffee plantations, excrement of different animals, ant detritus (*Atta mexicana* Smith, Hymenoptera: Formicidae), dead wood and public illumination; additionally, some people that was infested by ectoparasites was examined in the localities of Malinaltepec, Acatepec, Iliatenco, and Aseradero, at the "Mountain Region" of the State of Guerrero, Mexico. All the insects obtained were presented to some native people of the region asking their name in Tlapaneco language, the meaning of the name and their importance. By this method, a total of 41 names for the adults (Dyctioptera (1), Orthoptera (2), Hemiptera (2), Odonata (1), Diptera (3), Lepidoptera (1), Siphonaptera (1), Anoplura (1), Hymenoptera (15) and Coleoptera (14)), and only nine names for immature stages of Lepidoptera, Coleoptera and Anoplura, as used in Tlapaneco, were achieved. The results presented includes the Spanish common name, the Tlapaneco name, the meaning of the word, and the known importance for this people of type of each insect. Some species of Coleoptera Melolonthidae, Scarabaeidae and Passalidae, were taxonomically determined to specific level." 4747. Rasmussen, N.L.; Bidwell, J.R. (2003): Influence of fish introduction on the sex ratio and size of damselfly larvae of the *Enallagma* complex. *Proc. Okla. Acad. Sci.* 83: 100-101. [Verbatim: Ponds and wetlands are often stocked with fish as a way to improve their perceived recreational value. The influence of such stocking on resident invertebrates in these systems has not been extensively investigated, although fish predation could significantly change community structure. A previous laboratory study that examined the effects of sex on the behavior of larvae of a damselfly (*Ischnura verticalis*) indicated that male larvae spent more time moving and moved greater distances than did females which could result in differential susceptibility to capture. This could have serious implications for damselfly populations subjected to predation by introduced fish, since skewed sex ratios could severely impact population viability. The purpose of this study was to determine if damselfly larvae belonging to the *Enallagma* complex exhibit differential susceptibility to fish predation between males and females. Damselfly exuviae were sampled approximately every 48 h from mid-May to mid-September from a quarter-acre pond both before and after the addition of green sunfish (*Lepomis cyanellus*). A second quarter-acre pond that remained fishless was similarly sampled. Emergence structures constructed of window screen were placed in each pond and exuviae found on these screens were collected and sorted. For approximately every 4th sampling date, all exuviae of individuals belonging to the *Enallagma* complex were sexed and their head capsule width was measured. From these samples, it was determined that between 30 and 60 individuals had to be examined in order to get a sex ratio representative of the population. The average head capsule size of the damselfly larvae was reduced after the addition of fish, with a greater decrease apparent in female larvae. However, no significant difference in sex ratio was apparent. Laboratory studies will seek to more specifically characterize any sex-specific differences in susceptibility to predation that may exist in this particular genus. Results such as these may prove useful in the management of aquatic habitats, since the introduction of fish to a previously fishless system may reduce effective population sizes and threaten the viability of some damselfly populations.] Address: Rasmussen, N.L., Department of Zoology, Oklahoma State University, Stillwater, OK 74078

4748. Ren, D. (2003): A new hemeroscopid dragonfly from the Lower Cretaceous of Northeast China (Odonata: Hemeroscopidae). *Acta Entomologica Sinica* 46(5): 622-628. (in Chinese). ["[...] *Abrohmeroscopus mengi* gen. et sp. nov., of the family Hemeroscopidae Pritykina, 1977, from the Lower Cretaceous Jiufotang Formation, Liaoning Province, Northeastern China, is

described and illustrated. This new genus is rather similar to *Hemeroscopus Pritykina*, 1977, but differs from the latter in the following characters: (1) hindwing anal loop is smaller, only with 6-7 cells (plesiomorphy); (2) Rspl is absent (plesiomorphy); (3) the hindwing vein CuAa is curved and has five distinct posterior branches (plesiomorphy); (4) the forewing MP is not shortened, reaching the posterior wing margin slightly beyond the level of the nodus (plesiomorphy); (5) pterostigmata more distinctly braced (plesiomorphy); (6) the hindwing area between MP and CuAa is narrow, with only one row of cells near the discoidal triangle (plesiomorphy). This is the oldest fossil record of the Hemeroscopidae in China." (Authors)] Address: Department of Biology, Capital Normal University, Beijing, 100037, China. E-mail: rendongprof@yahoo.com.cn

4750. Rose, J.S. (2003): Ecology of exotic dragonfly species in different native assemblages. *Ecological Society of America Annual Meeting* 88: 286-287. (in English). [Verbatim: To determine whether exotic species express the same ecology under different ecological contexts or whether these contexts alter their ecology, the ecological niches of dragonfly species were quantified in three bioregions: the Everglades of south Florida, the Lower Rio Grande Valley of south Texas, and the main islands of the Hawaiian archipelago. Florida and Texas each possess many more species of dragonflies than Hawai'i, and have many more types of predators and prey as well. Some dragonfly species are indigenous to all three regions, but most to one or two; a few species occur as nonnatives in two regions, or are native in one but have invaded another. Several species in Texas appear to use shaded and dry habitats more extensively than conspecifics in Florida. In Hawai'i neither indigenous nor exotic species appear to express wider niches than their conspecifics in Texas and Florida, nor is niche overlap among species in Hawai'i perceptibly lower. However, populations of some species do appear to express different ecological niches between two or three of these regions. Nonnative species occur predominantly in altered or artificial habitats in Florida and Hawai'i; Texas has only one invading

species, which occurs in apparently undisturbed habitat.] Address: Rose, J.S., Duke University, Durham, NC, USA

4756. Soares, C.M.; Hayashi, C.; Reidel, A. (2003): Predacao de pos-larvas de curimba (*Prochilodus lineatus*, Valenciennes, 1836) por larvas de Odonata (Pantala, Fabricius, 1798) em diferentes tamanhos. *Acta Scientiarum Biological Sciences* 25(1): 95-100. (in Portuguese, with English summary). ["Predation of *Prochilodus lineatus* (Valenciennes, 1836) post-larvae by dragonfly (Pantala, Fabricius, 1978) fry in different development phases. The aim of this experiment was to evaluate the predation of dragonfly (*Pantala* sp.) fry in different development phases by the *Prochilodus lineatus* post-larvae (Characiformes, Prochilodontidae). Fifty-four dragonfly fry were distributed among eight length groups (2.54, 3.89, 6.37, 9.67, 10.98, 12.81, 18.50 e 24.50 mm), then they were also distributed among 27 aquarium (1.0 L), with constant illumination by fluorescent lamps (40 watts), and two dragonfly fry of similar size were put in each experimental unit. The *P. lineatus* post-larvae (Lt: 6.20+/-0.22 mm and Wt: 0.91 mg). 15 *P. lineatus* post-larvae were distributed in each aquarium (18:00h), each three-hour-interval (21.00, 0.00, 3.00, 6.00, 9.00, 12.00, 15.00 and 18.00h), the live post-larvae were counted and the dead ones were replaced. The physical and chemical parameters pH, dissolved oxygen, electric conductivity and temperature was measured in the beginning and in the end of the experiment, the average values of these ones were 7.83+/-1.11, 6.57+/-1.23 mg/L, 212.71+/-3.93 μ S/cm and 27.19+/-0.27°C, respectively. A quadratic effect of the dragonfly fry size on the total number of *P. lineatus* post-larvae eaten with maximum point with dragonfly larvae of 24.46mm. was observed. And a decrease in the number of post larvae eaten in time of the experimental period was also observed. It may be concluded that there was an increase in the number of *P. lineatus* post-larvae eaten with a size increase of dragonfly fry." (Authors)] Address: Soares, C.M. Dept Biol. Programa Posgrad Ecol. Ambientes Aquaticos Cont, Univ. Estadual Maringa, Av Colombo 5790, BR-87020900, Maringa, Parana, Brazil. E-mail: cmssoares@uem.br

4757. Stein, K.J.; Mitchell, J.C.; Smith, E.P.; Waldon, J.L. (2003): Trophic level distribution of ephemeral pool insects: Uniformity among pools. *Journal of Freshwater Ecology* 18(4): 549-556. (in English). ["We collected aquatic insects from three types of ephemeral pools (grassland, road, and woodland) in attempt to determine the trophic structure and trophic level distribution of insect communities. Each specimen was assigned to one of several trophic levels including carnivore, detritivore, herbivore, or some combination of these. Trophic level proportions were then compared for all pool classes; six of seven trophic level proportions were the same (P<0.05: except herbivores, P=0.01) in the following order of occurrence: 1) carnivores, 2) camivo-

re/detritivores, 3) detritivores, 4) detritivore/herbivores, 5) herbivores, 6) herbivore/carnivores, and 7) herbivore/detritivores. Carnivores (64.1%) and carnivore/detritivores (13.6%) accounted for 77.7% of the total insects; these consisted of odonates, dytiscids, and notonectids (58.1%), with gerrids, belostomatids, nepids, and naucorids, comprising an additional 19%. The near uniform distribution of trophic level proportion rankings found among pools regardless of surrounding habitat was independent of pool size and longevity and indicated baseline similarity. Although ephemeral pools are known for being transitory, with respect to trophic levels, they may be more ecologically stable than is implied by their name." 4758. Sukhacheva, G.A.; Krukova, N.A.; Glupov, V.V. (2003): On the roles of morphological and biochemical criteria in species identification: An example of dragonfly larvae of the genus *Aeshna*. *Biology Bulletin of the Russian Academy of Sciences* 30(1) : 63-68. (in English). ["Dragonflies belong to the group of organisms with numerous well-differentiated species-specific characters at the adult stage, on the one hand, and a significantly smaller number or even the absence of such characters at the early ontogenetic stages. An example of the genus *Aeshna* is used to show difficulties in revealing morphological and biochemical characters allowing identification of larval dragonflies belonging to closely related species of the family. Distinct morphometric characters can be found only in late-instar larvae. The presence of species-specific proteins in the homogenates of thoracic muscles provides the possibility of using biochemical tests for species identification of larvae. Infestation by parasites has no effects on the biochemical parameters studied. Species identification of the early-instar dragonfly larvae is still problematic." 4760. Takahara, T.; Kohmatsu, Y.; Maruyama, A.; Yamaoka, R. (2003): Effects of fish chemical cues on tadpole survival. *Ecological Research* 18(6): 793-796. (in English). ["The indirect effects of goldfish chemical cues on tadpole survival and predation by other predators (e.g. dragonfly nymph and crayfish) were tested in a field experiment. Fish chemical cues were found to affect tadpole survival when dragonfly nymphs were present. In contrast, this indirect effect was not detected in the presence of crayfish. The results from the present study found that predators, even without predation, can affect the predatory efficiency of other predators, and that the degree of such an indirect effect may differ among the foraging strategies of predators." 4762. Tolonen, K.T.; Hämäläinen, H.; Holopainen, I.J.; Mikkonen, K.; Karjalainen, J. (2003): Body size and substrate association of littoral insects in relation to vegetation structure. *Hydrobiologia* 499: 179-190. (in English). ["Variation in substrate association types and maximum size of aquatic insects were studied in a vegetated littoral zone of three lake basins. The basins differed from each other in trophic status, biomass of benthivorous fish, and abundance of macrophytes. Four types of substrate association - swimmers, crawlers, semisessiles and burrowers, respectively - were assumed to represent decreasing vulnerability to fish predators. Large-sized species were also hypothesised to be more vulnerable to fish predators. The distributions of species traits were examined in relation to vegetation density. Inferring from "predation hypothesis" opposite selection pressures on the species traits were expected along the vegetation density. Dense macrophyte beds were thought to be dominated by invertebrate predators and open water by fish predators, since the predation efficiency of fish decreases in complex environments. In the case of invertebrate predator domination, large size and higher activity should be favoured traits among the prey species. Distribution patterns of modes of the two studied traits were explored separately for predatory and non-predatory insects. As expected, swimmers and large-sized crawlers were characteristic of the insect assemblages of dense macrophyte beds. The densities of Odonata, Corixidae, Dytiscidae, Ephemeroptera and Sialidae were higher among macrophytes than in open water, where these insect taxa were possibly depleted by fish. On the other hand, the small-sized and fairly immobile Chironomidae were the most abundant group in open water. These results support the existence of a predator transition zone among littoral vegetation, ranging from domination of invertebrate predation among the dense beds to that of fish predation in open water." 4763. Tryjanowski, P.; Karg, M.K.; Karg, J. (2003): Diet composition and prey choice by the red-backed shrike *Lanius collurio* in western Poland. *Belgian Journal of Zoology* 133(2): 157-162. (in English). ["We investigated diet and prey choice in a population of *L. collurio* living in an intensively used farmland (W Poland). Diet was estimated by three methods: collars in nestlings, and pellets and prey remains in larders. Insects, mainly Coleoptera, Hymenoptera and Orthoptera con-

stituted 97.7% of the diet, with a total of 4392 prey items identified from all samples. However, during rainy and cold days vertebrates formed an important component (up to 26.5% by biomass) of the food of the red-backed shrike. Food preference - expressed in relation to availability - was estimated for five arthropod taxa. Hymenoptera, Orthoptera and Coleoptera were more preferred prey. Heteroptera and "other invertebrates", included mainly flies, dragonflies and spiders were less preferred. For rational management of the red-backed shrike in farmland, we suggest that places with available prey (in appropriate densities), small vegetation patches and perches suited to low-expenditure hunting strategy, should be preserved, as well as established." 4765. van Huis, A. (2003): Insects as food in sub-Saharan Africa. *Insect Science & its Application* 23(3): 163-185. (in English). ["Data on insects as food in sub-Saharan Africa were collected by reviewing the literature and conducting interviews in a number of African countries. A list of about 250 edible insect species from Africa was compiled. Of these, 78 percent are Lepidoptera (30%), Orthoptera (29%) and Coleoptera (19%), and 22 percent Isoptera, Homoptera, Hymenoptera, Heteroptera, Diptera and Odonata. Insects are rich in protein, vitamins and minerals, and a good source of iron and B-vitamins. Examples of insects being toxic are given, but often traditional methods are used to remove the poison. Whether or not insects are eaten depends not only on taste and nutritional value, but also on customs, ethnic preferences or prohibitions. The harvesting of insects is often done by women. The way of collecting depends on insects' behaviour. For example, inactivity at low temperatures enables easy catching of locusts and grasshoppers in the morning. Night flyers (termites, some grasshoppers) can be lured into traps by light and some insects like palm weevils can be attracted to artificially created breeding sites. Some species (crickets, cicadas) can be located by the sound they make. A number of tools are used to facilitate capturing such as glue, sticks, nets and baskets. Because most insects are only seasonally available, preservation by drying is often practised. Some examples of how to prepare them as food are given from important insect groups. To manage insects in the interest of food security more attention should be given to environmentally sustainable harvesting methods. They should be made better available throughout the year by developing im-

proved conservation methods or by farming this minilivestock. Considering the economic, nutritional and ecological advantages of this traditional food source, its promotion deserves more attention both from national governments and assistance programmes." 4767. Whiting, M.F.; Bradler, S.; Maxwell, T. (2003): Loss and recovery of wings in stick insects. *Nature* 421: 264-267. (in English). ["The evolution of wings was the central adaptation allowing insects to escape predators, exploit scattered resources, and disperse into new niches, resulting in radiations into vast numbers of species. Despite the presumed evolutionary advantages associated with full-sized wings (macroptery), nearly all pterygote (winged) orders have many partially winged (brachypterous) or wingless (apterous) lineages, and some entire orders are secondarily wingless (for example, fleas, lice, grylloblattids and mantophasmatids), with about 5% of extant pterygote species being flightless. Thousands of independent transitions from a winged form to winglessness have occurred during the course of insect evolution; however, an evolutionary reversal from a flightless to a volant form has never been demonstrated clearly for any pterygote lineage. Such a reversal is considered highly unlikely because complex interactions between nerves, muscles, sclerites and wing foils are required to accommodate flight. Here we show that stick insects (order Phasmatodea) diversified as wingless insects and that wings were derived secondarily, perhaps on many occasions. These results suggest that wing developmental pathways are conserved in wingless phasmids, and that reevolution of wings has had an unrecognized role in insect diversification." (Authors) *Argia vivida* and *Ophiogomphus severus* have been used as outgroup species for the phylogenetic study of the Phasmatodea.] Address: Whiting, M.F., Department of Integrative Biology, Brigham Young University, Provo, Utah, 84602, USA

4768. Wishart, M (2003): A Comparative Phylogeographic Approach Toward Defining Functional Units for the Conservation of Biodiversity in Lotic Ecosystems. Thesis, Australian School of Environmental Studies, Griffith University: XVII, 165 pp. (in English). ["The conservation of lotic ecosystems has historically focused on maintaining the structural properties and processes of river systems, considered as surrogates for the protection of biological diversity. However, the geological structure of the catchment unit and the hierarchical, longitudinal nature of the rivers that drain them impose a number of potential barriers to dispersal. This creates a mosaic of aquatic islands within a terrestrial

landscape. As such the protection of biodiversity and biological processes requires considerations that extend beyond the catchment unit. Understanding the extent to which barriers limit the movement of individuals is important in developing an integrated approach toward conservation of river systems. It is also important in understanding the role of dispersal in the process of species formation and population structure. While catchment units represent the logical social, economic and often political scale upon which to manage water resources they are increasingly being defined as the appropriate functional unit for the conservation and management of freshwater ecosystems. The aim was to determine the extent to which catchment units represent the appropriate scale for the conservation of lotic biodiversity. This was done by examining the effect of catchment units on the distribution of genetic variation and population structure in four aquatic taxa among streams in the south-western Cape, South Africa. All four taxa are part of the ancient paleoendemic Gondwanaland fauna characteristic of the Cape region and reflect relative differences in dispersal. The taxa were the freshwater fish, *Galaxias zebratus* (Teleostei: Galaxiidae); the net-winged midge *Elporia barnardi* (Diptera: Blephariceridae), which given its specialised morphology and specific habitat requirements has a very limited potential for dispersal; the stonefly *Aphanicercia capensis* (Plecoptera: Notonemouridae), a species with intermediate dispersal; and the widely distributed dragonfly *Aeshna subpupillata*, with the potential for wide dispersal. Allozyme electrophoresis and direct sequencing of a fragment of the cytochrome oxidase subunit 1 (COI) region of the mitochondrial DNA were used to examine genetic structuring within and among streams in two discontinuous mountain ranges. F statistics were calculated from allele frequencies derived from allozyme electrophoresis as a measure of population subdivision and population trees constructed. Nucleotide diversity and levels of divergence were calculated among mtDNA sequence data. Genetic distance, and the relationship among haplotypes, was examined using neighbour-joining trees and an analysis of molecular variance in order to determine the effect of catchment units on dispersal, the distribution of genetic variation and population structure. Low levels of allozyme variability were observed in all four taxa, with no variable loci resolved for the stonefly *A. capensis*. Significant population structure among all sites in the two ranges in *G. zebratus*, *E. barnardi* and *A. subpupillata* highlights the effect of discontinuous habitat (~ 0.70 , 0.39 ± 0.10 and 0.03 ± 0.01 respectively), while FST values among streams on Table Mountain reflect differences in the dispersal potential of the three species (~ 0.70 , 0.23 ± 0.04 and 0 respectively). Population trees for the Cape galaxiid *G. zebratus* and the net-winged midge *E. barnardi* revealed two highly divergent groups (Genetic Identity = 0.41 and 0.73 respectively). Both reflect poor dispersal potential, with the pattern among *G. zebratus* reflecting a pattern of connectivity between ancient drainages during periods of lower sea levels. Mitochondrial DNA data obtained from the COI region similarly revealed two highly divergent clades in populations of the Cape galaxiid *G. zebratus* ($\sim 7\%$), the netwinged midge *E. barnardi* ($\sim 5\%$) and the stonefly *A. capensis* ($\sim 7\%$). Additional data derived from the cytochrome b region for *G. zebratus* revealed five highly divergent clades from across the species range (from 7 to 17%). Congruence between monophyletic clades and catchment units in *G. zebratus* and *E. barnardi*, along with an analysis of the

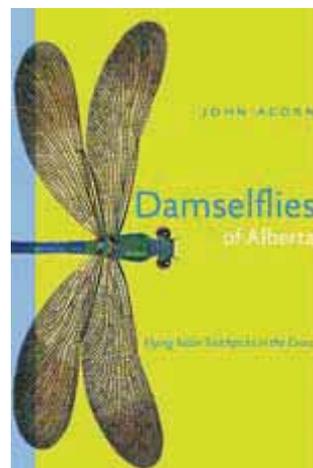

distribution of genetic variation, suggest movement is confined to within the catchment. In contrast, the distribution of haplotypes and genetic variation in *A. capensis* and *A. subpupillata* suggests movement beyond the catchment boundary. Similarities in the degree of divergence in *A. capensis* and *E. barnardi* indicate a vicariant event around 3-4 MYBP, coinciding with the erosion of the land bridge between Table Mountain and the Tottentot's Holland. Divergence among *G. zebratus*, *A. capensis* and *E. barnardi* suggests the presence of more than a single species in all three taxa. The distribution and patterns of genetic variation reflected among these taxa show general congruence with dispersal potential, thus having two important implications for conservation practices in lotic systems. The monophyletic nature of some taxa confirm the suitability of catchment based initiatives, but also suggest that current water resources developments, such as inter-basin water transfers, have the potential to undermine the evolutionary processes important in species formation. By providing a conduit for the transfer of individuals between geologically separated catchments and historically isolated populations they also provide an avenue for gene flow between genetically discrete populations, thus undermining the generation of biodiversity. For other more mobile species, the distribution of genetic variation and pattern of population sub-division indicates the effective population covers a wide geographic range such that catchment units may not represent the appropriate scale for conservation of the aquatic fauna. Results for *A. subpupillata* and *A. capensis* suggest that efforts aimed at conserving the fauna of riverine ecosystems should move beyond individual catchment considerations to incorporate reserve designs and management strategies that cover and incorporate a number of adjacent catchments. Such areas or management plans should be replicated and spread through identified phylogeographic regions. In conclusion, it is important to note that despite efforts to select taxonomically well resolved taxa, the results have revealed a number of discrete, highly divergent, genetic units in the Cape galaxiid *G. zebratus*, the net-winged midge *E. barnardi* and the stonefly *A. capensis*. The monophyletic nature and degree of sequence divergence among these units reflect populations that have experienced long periods of isolation. The levels of sequence divergence are comparable to those observed among recognized species, including the highest levels of mtDNA divergence ever recorded for an intra-specific comparison within any fish species. The results contribute to an increasing body of knowledge that recognizes the aquatic fauna of the Cape fynbos region as having a uniquely high degree of endemism, containing a large amount of as yet undescribed variation at the morphological and genetic level." Ecological Society of America Annual Meeting Abstracts. 88: 368. (in English). [Verbatim: Deforestation potentially alters the distribution and abundance of phytotelmata and their resident fauna. We surveyed phytotelm habitats along a deforestation gradient near Iquitos, Peru, as part of a larger study of arbovirus ecology. Mean phytotelm density was greater in cultivated areas ("chacra"; 174 ± 33 SD per hectare) than in secondary forest

("purma"; 28 ± 36) and primary forest ("bosque"; 25 ± 17). Fallen leaves and plant axils were the most abundant microhabitats present at all sites. Half (47%) of the colonizable microhabitats contained macroinvertebrates and mosquitoes were the most abundant occupants. In addition to the microhabitat survey, replicated phytotelm analogs (water-filled bamboo sections) were placed along the gradient and destructively sampled every two weeks. Mean species richness (ca. 3 per bamboo) and abundance (ca. 50) were similar among chacra, purma and bosque. *Trichoprosopon digitatum* was the most abundant macroinvertebrate in the bamboo sections across all sites. However, species composition of top predators differed, with *Toxorhynchites* spp. occurring more often in chacra and odonates exclusively inhabiting bosque. These differences may have cascading effects on the abundance and composition of mosquito prey along the deforestation gradient.] Address: Yanoviak, S.P., Florida Medical Entomology Lab, University of Florida, Vero Beach, FL, USA.

4770. Zhou, C.-f.; Zhou, K.-y. (2003): Status of phylogenetic research on the Palaeoptera (Insecta, Pterygota). *Acta Zootaxonomica Sinica* 28(2): 192-195. (in Chinese, with English summary). ["The phylogenetic position of the Palaeoptera in the Hexapoda and the relationship of this group with the Neoptera has been debated for a long time. There are three main point of view on this issue: Palaeoptera (= Ephemeroptera + Odonata) + Neoptera, Ephemeroptera + (Odonata + Neoptera), or Odonata + (Ephemeroptera + Neoptera). The first formula is supported by morphological, fossil and some molecular evidence. The second depends more on morphological characters, while the last is based on the least evidence. Finding more insects, discovering better fossils, and sequencing more genes and mitochondrial genomes may resolve this long debate." 4772. Aguirre-Leon, G.; Aquino-Cruz, O. (2004): Hábitos alimentarios de *Kinosternon herrerae* Stejneger 1925 (Testudines: Kinosternidae) en el Centro de Veracruz, Mexico. *Acta Zoológica Mexicana* (n.s.) 20(3): 83-98. (in Spanish, with English summary). ["The feeding habits of Herrera's mud turtle (*Kinosternon herrerae*) were studied from October 1999 through September 2000 in the southern limits of its range, in streams near Xalapa, Veracruz. Turtles were captured by hand and using baited traps, and stomach contents were flushed with water from 48 adults. Frequency of occurrence, numeric frequency, and volume percentage of 21 food items found by examination of stomach contents showed that this turtle primarily consumed decapod crustaceans (*Procambarus* sp.), animal material, plant material, adult anurans (*Eleutherodactylus* sp. *Rana* sp., and *Bufo marinus*), *Ficus* sp. fruits, dragonfly larvae, and anuran tadpoles. These turtles are omnivorous, but ingested a higher proportion of animal material than plant (females 92% vs. 52%; males 85.7% vs. 52.4%). *Kinosternon herrerae* is a generalist feeder throughout all seasons showing an opportunistic response in the exploitation of some food items such as anuran eggs. Trophic diversity of both sexes varied among seasons (Herrera's diversity index: 2.77 to 16.65 for females, and 3.3 to 15.24 for males), yet females showed some seasonal diet specialization during summer, and males during spring and winter, when trophic diversity values were lower for each sex. Diet similarity between males and females were measured using the simplified Morisita index was higher in summer and winter (0.67 and 0.66) compared to spring and fall (0.60 and 0.55), suggesting some seasonal resource partitioning takes place between males and females in this species." 4773. Anonymus (2004): New Conservation Status for the Dragonflies of Canada. *The Reeder* 12(3): 5. (in English). [Verbatim: The Manitoba Conservation Data Centre (MBCDC) gathers and stores information on Manitoba's plants and animals. It is part of a network that maintains information about the diversity of species in North and South America. The MBCDC has developed lists of plants, animals, and plant communities found in Manitoba. It assigns each species or community a conservation status rank. This is based on how rare the species or community is in Manitoba. It then collects detailed information on where each is found. Recently, the National General Status Working Group (NGSWG) produced new ranks for dragonflies and damselflies in Canada. The new report (Wild Species 2005) includes ranks for the same species reviewed in Wild Species 2000. Approximately 5,000 species have been added. This includes vascular plants, freshwater mussels, crayfish, tiger beetles, and marine fishes. An attempt is being made to include more invertebrates in the list. Manitoba Conservation has been helping the NGSWG prepare their Wild Species reports. The NGSWG Web site (www.wildspecies.ca) allows you to view and search the general status ranks for each province and territory and for Canada as a whole. The general status of each of the 209 species of dragonflies and damselflies (odonates) in Canada was included in the new report. Over the past few decades, hundreds of volunteers have been studying, collecting and identifying species

been studying, collecting and identifying species of dragonflies and damselflies. Results of their work were used in these assessments. This illustrates how dedicated naturalists can make a significant contribution to increase the existing knowledge about a group of species. It is noteworthy that this assessment of Canada's odonata also engaged experts from other countries - making it an international conservation effort. The dragonflies and the damselflies together make up the order odonata. The odonata are ancient and distinctive insects. They have many primitive insect features, such as unspecialized chewing mouthparts. They also have specialized body parts reflecting their way of hunting and feeding. For example, their eyes have up to 25,000 lenses that give them nearly 360-degree vision. While they beat their wings only up to 30 times per second (other insects can beat their wings more than 1,000 times per second), they have been clocked flying at more than 50 kilometres per hour and can make a 90-degree turn at full speed.] Address: Dr. James R. Duncan, Manager, Biodiversity Conservation Section, Wildlife and Ecosystem Protection Branch, Canada. E-mail: jduncan@gov.mb.ca

4774. Bass, D. (2004): Diurnal stream drift of benthic macroinvertebrates on the small Oceanic Island of Dominica, West Indies. *Caribbean Journal of Science* 40 (2): 245-252. (in English). ["An investigation was conducted to determine if invertebrate drift occurred in streams of small oceanic islands. Two nets were placed 14-15 May 2001 in midstream of the Check Hall River on the Caribbean island of Dominica. Each net was checked and its contents were emptied every three hours for a 24-hour period. Results of this study indicate that only some invertebrates are undergoing drift. Although the number of taxa present in those samples did not vary much during the 24-hour study, the number of individuals found in the samples collected during darkness was approximately four times higher than in the daylight samples, indicating diel periodicity. Common taxa captured in drift samples included Baetidae, Leptohyphes, Smicridea cariba, and Simulium. Because freshwater benthic populations on small oceanic islands are difficult to establish, they often occur in low numbers, possibly resulting in little competition for resources. In this situation, drift is greatly reduced because it is not necessary to seek other resources. The production compensation model suggests that organisms occurring in the drift represent the excess production of that population. Alternatively, tropical streams are frequently low in nutrients and unable to support large populations. This may lead to increased competition for the limited resources and that may cause invertebrates to drift to locate new resources. Losses of invertebrates through downstream drift may be balanced via upstream movement by others in the population. Further studies addressing these hypotheses are necessary to completely explain the invertebrate drift observed in this stream on Dominica." (Author) The samples include *Argia concinna*.] Address: Biology Department, University of Central Oklahoma, Edmond, Oklahoma, USA 73034. E-mail: dbass@ucok.edu

4775. Berra, E.; Forcella, M.; Giacchini, R.; Marziali, L.; Rossaro, B.; Parenti, P. (2004): Evaluation of enzyme biomarkers in freshwater invertebrates from Taro and Ticino river, Italy. *Annales de Limnologie* 40(3): 169-180. (in English). ["Benthic macroinvertebrates are an essential component of freshwater environments.

The ecotoxicological risk of benthic communities, estimated through the assay of biochemical markers, can be used as an early warning signal for environment alterations. In this work the activities of a number of enzymes, regarded as potential biomarker of exposure to pollutants (catalase, acetylcholinesterase, glutathione-S-transferase) was determined in homogenates of whole organisms. Specimens were collected in the rivers Taro and Ticino, northern Italy, in stony bottom reaches in five and three stations respectively. The orders of aquatic Insects Diptera, Plecoptera, Odonata, Ephemeroptera and Trichoptera, the Crustacea Amphipoda, and Annelida Oligochaeta were examined. Additional enzymes, such as NADP-dependent malate dehydrogenase, isocitric dehydrogenase, glucose-6-phosphate dehydrogenase, alcohol dehydrogenase, and lactate dehydrogenase were considered in the study. Results emphasize significant differences among taxa concerning the specific activity of most enzymes." 4776. Biggs, K. (2004): Common dragonflies of the Southwest. Azalea Creek Publishing, Sebastopol: 160 pp. (in English). [121 common odonate species represented in the six southwestern US states north of Mexico are pictured and briefly described. In addition brief notes on habitat, phenology, and distribution are given. A checklist includes all known regional species.] Address: Azalea Creek Publishing, 308 Bloomfield Rd., Sebastopol, CA 95472. azalea@sonic.net

4777. Bönsel, A. (2004): Hinweise zur Verbreitung von *Epitheca bimaculata* CHARPENTIER, 1825 (Odonata) und zu ökologischen Habitatparametern in der nordostdeutschen Jungmoränenlandschaft. Entomologische Nachrichten und Berichte 48(3/4): 191-198. (in German, with English summary). ["In 2000 to 2003, 86 lakes of different sizes in the young moraine landscape of north-eastern Germany were checked for occurrences of *E. bimaculata*. 32 waters proved to be inhabited by the species, which was autochthonous in 28 of the water bodies. Autochthonous occurrence of 19 additional species of dragonflies in the same lakes was proven. The most common species was *Brachytron pratense*, occurring in 94% of the waters, followed by *Cordulia aenea*, *Coenagrion pulchellum*, *Erythromma najas*, and *Orthetrum cancellatum*, each occurring in more than 50% of the waters. Waters with an average water surface of 9,62 ha and an average depth of 2,92 m were preferred. 89% of the waters were not thermally stratified, 46% were polytrophic, 40% eutrophic and 14% mesotrophic. In all waters submerged structures were present, in 82% of the waters consisting of the stalks of *Nuphar lutea* and *Nymphaea alba*. Calcium contents was strikingly high in all waters, with an average content of 68,79 mg/l. In the study area, negative influences such as destruction of submerged vegetation caused by air-borne acids were buffered by Ca-, Mg- and K-ions in historical as well as in recent times. Therefore, the young moraine landscape of northeastern Germany can also in future be regarded as the recent core area of *Epitheca bimaculata*." 4778. Brenden, T.; Murphy, B.R. (2004): Experimental assessment of age-0 largemouth bass and juvenile

bluegill competition in a small impoundment in Virginia. North American Journal of Fisheries Management 24(3): 1058-1070. (in English). ["Previous research has found that early ontogenetic stages of largemouth bass *Micropterus salmoides* and bluegills *Lepomis macrochirus* may compete for food resources in small impoundments in northern-latitudes. We experimentally assessed whether competition also might occur in a southern-latitude system by stocking fish allopatrically and sympatrically in 1.0-m³ cages within a small impoundment in Virginia and monitoring fish growth and diets. Although growth was not significantly different between bluegills stocked with and without largemouth bass, largemouth bass grew significantly larger when stocked alone than when stocked with bluegills. Although bluegills maintained similar diets in terms of sizes, numbers, and types of items consumed, largemouth bass stocked alone consumed fewer but larger items than those stocked with bluegills. Further, largemouth bass consumed higher volumetric proportions of Diptera larvae and Odonata nymphs when stocked alone than when stocked with bluegills. Of these two items, only Diptera larvae constituted a large portion of bluegill diets. Competition between largemouth bass and bluegills apparently occurs in both southern- and northern-latitude small impoundments. Competition with bluegills may result in a competitive juvenile bottleneck for largemouth bass in regions where overwinter mortality is size related, which could affect management (i.e., stocking, establishing harvest regulations) of small-impoundment fisheries." 4780. Brockhaus, T. (2004): Interspezifische Konkurrenz zwischen *Sympetrum fonscolombii* und *Orthetrum cancellatum* in Mitteleuropa? (Odonata: Libellulidae). Libellula 23(1-2): 77-86. (in German, with English summary). ["In 2003, both spp. were observed as common at the pond 'Beuthenteich' (district Stollberg/Erzgebirge, Saxony, Germany). Apart from imaginal records, also larvae of both spp. were sampled. The head widths of 80 larvae of *O. cancellatum* were measured. For seven larvae of *S. fonscolombii* the total length, the head widths and the number of abdominal segments covered by the wing cases were determined. A larva of *S. fonscolombii*, found on 31 August 2003, was damaged partially by predation. The developmental cycles of both species are discussed under the aspect of interspecific competition of the larvae. It is suggested that in 2003 the sp. had three imaginal and two larval generations. However, one can also suggest a retarded development of *S. fonscolombii* because of the presence and the predatory or competitive effect of larger *O. cancellatum* larvae in higher densities." (Author)] Address: Brockhaus, T., An der Morgensonne 5, D-09387 Jahnsdorf, Germany. E-mail: T.Brockhaus@t-online.de

4781. Brodin, T.; Johansson, F. (2004): Conflicting selection pressures on the growth/predation risk trade-off in a damselfly. Ecology 85(11): 2927-2932. (in Eng-

lish). ["Activity is an important behavioral trait that in most animals mediates a trade-off between obtaining food for growth and avoiding predation. Active individuals usually experience a higher encounter rate with food items and predators and, as a consequence, grow faster and suffer higher predation pressure than less active individuals. We investigated how predator-induced mortality and growth of the damselfly *Coenagrion hastulatum* depend on activity at the level of the genotype. Larvae from six different *C. hastulatum* families were reared in two different predator treatments: predator present or absent. Families differed in activity, and active families grew to a significantly larger size than less-active families. Within families there was a plastic response to predators. Larvae reared without predators were more active and grew larger than larvae reared with a non-lethal predator. In the presence of a lethal predator the active families experienced higher mortality than the less active families. The results illustrate that the growth/predation-risk trade-off was mediated by activity and clearly show a cost of antipredator behavior. They also suggest that variation in activity level might be genetically regulated and could explain why *C. hastulatum* are abundant in aquatic systems both with and without potential predators." 4784. Buczyński, P. (2004): The dragonflies (Odonata) of Polesie National Park and its protection zone: new data and the summary of studies conducted in the years 1985-2003. *Parki Narodowe i Rezerваты Przyrody* 23: 381-394. (in Polish, with English summary). [New records of 43 species are given from Polesie National Park situated north of Lublin, Poland. "Ophiogomphus cecilia and *Libellula fulva* are new for the park. Odonatological studies conducted in the years 1985-2003 are summed up. The park was studied very well and data about the protection zone are rich but incomplete. Among 56 species found in general, 52 occurred in the park. 9 species protected by law (of 15), 8 from national Red list (of 16), 8 from regional Red list (of 15), one species from the Red list of IUCN (of 1), 6 from annexes of Bern Convention and Habitats Directive (of 7) were found. The dragonfly communities of lakes, fens, peat bogs, small water bodies and ponds were the most valuable. The fauna of rivers was highly impacted due to the river regulations. Despite anthropogenic changes of the environment it can be concluded

that the current situation of the dragonfly fauna is still very good. This is the result of good preservation of some habitats and traditional use of many changed habitats: extensive agriculture, hand peat exploitation and fish breeding. Therefore, the conservation of dragonflies demands the setback of changes in natural habitats (mainly eutrophication and falling of ground water level) as well as the continuation of traditional use in habitats that are transformed or created by man." (Author) Records of the following species are briefly discussed: *Coenagrion armatum*, *Nehalennia speciosa*, *Gomphus vulgatissimus*, *Leucorrhinia albifrons*, and *L. caudalis*.] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. 4786. Buden, D.W. (2004): The Odonata of Pakin, Ant, Mokil, and Pingelap atolls, Eastern Caroline Islands, Micronesia. *Micronesica* 37(1): 145-155. (in English). ["Seven species of Odonata are recorded from among Pakin, Ant, Mokil, and Pingelap atolls, Eastern Caroline Islands, Micronesia - one Zygoptera (damselfly), *Ischnura aurora*; and six Anisoptera (dragonflies), including *Anax guttatus*, *Agrionoptera sanguinolenta*, *Diplacodes bipunctata*, *Pantala flavescens*, *Tholymis tillarga*, and *Tamea transmarina*. None is endemic to the islands, but *A. sanguinolenta* is known to breed only in Chuuk and Pohnpei states, east-central Micronesia; the six others are widely distributed in Oceania and the Indo-Australian region, and in some cases well beyond. The largest number of species recorded on any one of the four atolls is five each on Mokil and Pingelap-six each if unconfirmed records of *A. guttatus* are accepted. Multiple surveys on Ant and Pingelap atolls reveal differences in species composition on the two atolls, but no marked seasonal variations. Evidence of breeding was obtained for all but the two least common species (*I. aurora* and *D. bipunctata*) and data suggest that breeding occurs year-round." - 4789.** Caldwell, J.P.; de Araujo, M. C. (2004): Historical and ecological factors influence survivorship in two clades of phytotelm-breeding frogs (Anura: Bufonidae, Dendrobatidae). *Miscellaneous Publications Museum of Zoology University of Michigan* 193: 11-21. (in English). ["Throughout Amazonia, Brazil nut trees (*Lecythidaceae*, *Bertholletia excelsa*) produce a grapefruit-sized fruit with a thick, woody pericarp that is functionally indehiscent; each fruit contains 25 or more seeds (Brazil nuts). After falling to the ground, the fruit capsules are chewed open and emptied of their seeds by agoutis (genus *Dasyprocta*). The empty capsules remain on the forest floor and fill with rainwater. Five Amazonian frog species in two clades, Dendrobatidae and Bufonidae, and two insects with predaceous larvae use Brazil nut capsules for some aspects of reproduction. These small microhabitats lack some kinds of predators (fish) but have others (insects) and can have limited food and low oxygen levels. Interactions among tadpoles and insect larvae and the possible effects of food limitation and anoxia were studied at three sites in Brazil. *Bufo castaneoticus* deposits clutches of eggs that are small compared to most other species in the genus (mean number of eggs: 178 at one locality and 234 at another locality). Survivorship of eggs of *Bufo castaneoticus* at all sites was low. Mean volume of water in the capsules at two localities was 110.9 ml and 132.4 ml; thus, eggs and larvae are crowded, presumably leading to anoxia, especially in the absence of rainfall. An experiment in which tadpoles were raised with and without food revealed that metamorphosis does not occur in unfed tadpoles; thus, food limitation may decrease growth and survivorship. Damselfly larvae occur significantly more frequently with tadpoles of *Bufo* than in all capsules in the samples. These factors appear to provide a competitive release for *Bufo* tadpoles; reduction of tadpole density may increase the probability that some individuals will survive. If they are the first colonizers, the predaceous tadpoles of *Dendrobates* can eliminate predators from the capsules. More basal clades of dendrobatids have detritivorous tadpoles that are not capable of eliminating predators from the capsules. Although they primarily use small forest pools and stream edges for tadpole deposition, tadpoles of *Allobates femoralis* and *Colostethus* sp. were transported occasionally to Brazil nut capsules, where their survivorship was low compared to *Dendrobates*. The propensity of individuals in basal clades for depositing some tadpoles in phytotelmata may have led in part to the evolution of use of phytotelmata by the derived *Dendrobates* once a predaceous tadpole evolved. Occasional deposition of tadpoles in phytotelmata by basal dendrobatids may represent a transitional step from obligate tadpole deposition in forest streams or pools to facultative phytotelm tadpole deposition to obligate phytotelm deposition (*Dendrobates*)."] Address: Caldwell, Janalee, Sam Noble Oklahoma Museum Nat Hist, Univ Oklahoma, Norman, OK, 73072, USA. - 4790.** Callisto, M.; Goulart, M.; Medeiros, A.O.; Moreno, P.; Rosa, C.A. (2004): Diversity assessment of benthic macroinvertebrates, yeasts, and microbiological indicators along a longitudinal gradient in Serra do Cipó, Brazil. *Braz. J. Biol.* 64(4): 743-755. (in English, with Portuguese abstract). ["The main goals of this study were: 1) to evaluate the structure, diversity, and functional trophic group composition of benthic macroinvertebrate communities; 2) to characterize water quality in the headwaters of the Doce river watershed, based on physical, chemical, and biological parameters (benthic macroinvertebrates, fecal coliforms, heterotrophic bacteria, and yeasts); and 3) to contribute to the knowledge of the structure and function of longitudinal gradients in lotic ecosystems in Brazil. A total of 60 benthic macroinvertebrate taxa were identified, the dominant group being the aquatic insects, with 50 families distributed in 8 orders. The dry period presented higher values of taxonomic richness and total density of benthic macroinvertebrates. A decreasing gradient was observed in these variable values from the 3rd order stretch down to the 6th order stretch. The highest Shannon-Wiener diversity values were found in the rainy period in the 3rd order stretches, which presented well-developed riparian forest. Besides the 3rd order stretches, the Pielou evenness index values were also high in the 6th order stretch. The collectors, together with the scrapers, predominated in the benthic macroinvertebrate communities in all river stretches, except in the 2nd, 4th, and 5th order stretches in the rainy period, where communities were dominated by filterers. The shredders and predators presented low densities for all river stretches. All microbiological variables presented low levels. Due to the high counts of heterotrophic bacteria and coliforms, the studied river stretches presented inadequate potability but adequate balneability levels. The results suggest that the structure, diversity, and composition of the benthic macroinvertebrate communities are influenced by the trophic resource availability, seasonality, and sediment heterogeneity. The microbiological results of this study allow inferring that the waters from Serra do Cipó have excellent potential for recreational use and as future sources of water for human consumption." (Authors) The list of taxa includes Odonata on the family level.] Address: Callisto, M., Laboratório de Ecologia de Bentos, Departamento de Biologia Geral, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, C.P. 486, CEP 30161-970, Belo Horizonte, MG, Brazil, e-mail: callisto@icb.ufmg.br
- 4791.** Cammaerts, R. (2004): Taxonomic studies on African Gomphidae (Odonata, Anisoptera) 2. A revision of the genus *Neurogomphus* Karsch, with the description of some larvae. *Belgian Jour. Entom.* 6(1): 91-239. (in English). ["A revision of the genus *Neurogomphus* is presented. 17 species and two distinct subspecies are recognised, i.e. *N. fuscifrons* Karsch, 1890, *N. agilis* (Martin, 1908), *N. martinus* (Lacroix, 1921), *N. uelensis* Schouteden, 1934, *N. vicinus* Schouteden, 1934, *N.*

wittei Schouteden, 1934, *N. chapini* (Klots, 1944), *N. featheri* Pinhey, 1967, *N. pallidus* Cammaerts, 1967, *N. pinheyi* Cammaerts, 1968, *N. angustisigna* Pinhey, 1971, *N. alius* sp. n., *N. paenulensis* sp. n., *N. cocytius* sp. n., *N. zambeziensis* sp. n., *N. carlcooki* sp. n., *N. chapini lamtoensis* subsp. n., *N. dissimilis* sp. n. and *N. dissimilis malawiensis* subsp. n. The genus is divided into two subgenera, of which *Mastigogomphus* (type-species: *Oxygomphus chapini* Klots, 1944) is new. Of the former described species, all but one (*Karschiogomphus ghesquierei* Schouteden, 1934) remain valid, but their names were often erroneously applied to unrelated taxa. Synonymy lists give evidence of this great amount of confusion. Nevertheless, the accurate status of five of the taxa here recognised as well as of some females (*N. sp. cf. zambeziensis* from Tanzania and sp. indet. A, B, C, D) awaits further collecting of material. Generic larval characters are specified for the first time and the larvae of some species are described, among others that of *N. alius* as well as the supposed larvae of *N. cocytius*, *N. zambeziensis* and *N. featheri*. Information about the biology of the larvae is reviewed." (Author)] Address: Cammaerts, R., Serv. Syst. and Ecol. Anim., Free Univ. Brussels, CP 160-13,50 Av FD Roosevelt, B-1050, Brussels, Belgium. 4792. Chapman, L.J.; Schneider, R.J.; Apodaca, C.; Chapman, C.A. (2004): Respiratory ecology of macroinvertebrates in a swamp river system of East Africa. *Biotropica* 36 (4): 572-585. (in English). ["Hypoxia (oxygen scarcity) is widespread in tropical freshwaters, particularly in dense swamps, and may be an important factor structuring benthic macroinvertebrate communities. Macroinvertebrates show a diversity of respiratory modes ranging from atmospheric breathing to tracheal gill breathing, and these adaptations affect their ability to use hypoxic water. The objectives of this study were to (a) describe the benthic macroinvertebrate community from ten swamp and river sites in Kibale National Park, Uganda, (b) determine the degree to which dissolved oxygen explains variation in abundance of respiratory groups (taxa with a similar respiratory mode) among sites, and (c) test for significant seasonal variation in the abundance of the numerically dominant respiratory groups. Macroinvertebrates from monthly collections over a two-year period were identified to the lowest taxonomic level necessary to place them in functional respiratory groups. Across all sites, both the relative and absolute abundance of atmospheric breathers (e.g., pulmonate snails and nepids) and mantle/ctenidia breathers (primarily fingernail clams) were negatively correlated with dissolved oxygen, while the abundance of tracheal gill breathers (e.g., anisopterans and zygopterans) was positively correlated with dissolved oxygen. We did not detect significant seasonal trends in catch per unit effort of numerically dominant respiratory groups. Dissolved oxygen concentration was a good predictor of the abundance of some respiratory groups and may be a key factor in maintaining the structure and diversity of these assemblages." (Authors) Address: Chapman, Lauren J., Department of Zoology, University of Florida, Gainesville, Florida 32611, USA. E-mail: lauren.chapman@mcgill.ca

4793. Chovanec, A.; Waringer, J.; Raab, R.; Laister, G. (2004): Lateral connectivity of a fragmented large river system: assessment on a macroscale by dragonfly surveys (Insecta: Odonata). *Aquatic Conservation: Ma-*

rine & Freshwater Ecosystems 14(2): 163-178. (in English). ["1. The ecological status of floodplain areas along the Austrian section of the Danube was assessed by an approach based on dragonfly surveys. Although this river section contains a relatively high portion of the river-type-specific alluvial floodplain areas, most of them are influenced by river regulation and damming. 2. A key element of the assessment procedure, which is oriented towards the new EC Water Framework Directive, is the Odonate Habitat Index. 3. Classification of ecological status is based on the comparison between the status quo and reference conditions derived from a historical situation minimally influenced by human activities. 4. Data from 408 sites from 14 investigation areas were used. Ten of the 14 areas were ranked in class II (good ecological status) within the five-tiered system, which is the level of ecological status targeted in the directive. One area corresponds to the reference condition (class I, high ecological status), and three areas do not meet the quality objective (class III, moderate ecological status). A total of 49 species were found along the whole section, which represents 82% of the river-type-specific reference list." 4794. Clausnitzer, V. (2004): Diversity and species composition of Odonata as indicators of biotope quality of East African rain forests and their replacement communities. Project ID: 01 LC 0025 (BIOTA AFRICA E07) 01.05.2001-30.04.2004: 2 pp. (in English). [Verbatim: The principal aim of this project is a comparative study of ecology, diversity and biogeography of dragonflies (Insecta: Odonata) in primary, secondary and fragmented rain forests and different wetland habitats in East Africa. To achieve this an identification key for the dragonflies of eastern Africa is prepared and distribution data as well as data on species specific habitat requirements are collected. These will be used for further applied studies, e.g. the development of indicator systems for environmental disturbances. Results: Utilising both, aquatic and terrestrial habitats, the large, predominantly diurnal dragonflies, who can be readily observed and in most cases easily identified in the field, can contribute much to the evaluation of environmental quality. They are known to be very sensitive to structural habitat quality and thus can be a valuable tool to evaluate landscape degradation and have been used as indicator species. The amphibious larvae of dragonflies are critical in regard to water quality and aquatic morphology of streams. The adults are sensitive to habitat structure and are excellent indicators of river disturbance, e.g. changes in habitat structure. Within this project a throughout inventory of East African dragonflies in various habitats and the collection of species specific ecological data is aimed at. Current activities: Data collection has been started in different areas in Kenya, Uganda and Tanzania. In most areas visited, new records for the could be made and a lot of data on various ecological aspects could be collected. The PhD student John Joseph Kisakye, (Makerere University, Kampala, funded through the BIOTA programme) works on dragonflies in different forests. In cooperation with a GEF project in southern Tanzania it is planned to have Master's projects on the impact of habitat degradation on dragonflies from 2002. Coastal forests in Kenya: During the last year coastal forests of Kenya were surveyed to a large extend. Coastal forests are listed as important areas in terms of conservation for East Africa [1]

and are a major centre of endemism in Africa [2, 3]. Coastal forest areas of Kenya and Tanzania are the primary habitat for a number of highly localised dragonfly species (endemics and/or of unique taxonomy). Detailed studies were carried out on the ecology of the two dendrolimnetic species *Coryphagrion grandis* and *Hadrothemis scabrifrons*. Dragonfly communities relative to different habitat types from indigenous forests to cultivated landscapes were described. Most of the forest species are confined to coastal forests of East Africa, being stenotopic and highly sensitive to disturbance. With increasing habitat disturbance eurytopic species which are common and widely distributed in Africa colonise the habitats. The species assemblages between different habitat types (stream, swamp, pool) in the disturbed landscape are identical, the beta-diversity being very low, although the diversity of single localities may increase after habitat disturbances. Publicity work: Species check-lists for several National Parks and other protected areas of Kenya have been prepared and were presented to the corresponding authorities. Information boards on the local dragonflies were prepared for some visitor centres (Saiwa Swamp NP, Mt. Elgon NP, Arabuke Sokoke Forest, Nairobi NP). For 2002 a small dragonfly workshop is planned in the Institute of Environmental and Natural Resources, Makerere University, Kampala. Cooperations: Dragonflies are included in a Wildlife Conservation Society (WCS) project in Tanzania "Southern Highlands Conservation Programme" and in a DANIDA funded project on IBA fs in Uganda. Within all projects national reference collections are build up and local scientists trained. First negotiations have started with Ethiopia to include dragonflies in a planned inventory of insects. Together with BIOTA S08 species assemblages in arid habitats, colonisation strategies in seasonal habitats and population genetics of species with a panafrikan distribution and different dispersal types are comparatively studied. Odonatologists working in Africa are linked through the recently started PHAON (Pinhey's Heritage African Odonata Network), which proves to be an excellent tool to exchange views and data, discuss results and present projects. In cooperation with other scientists an atlas for African Odonata and a mapping programme are long term aims. Publications The identification key of East African dragonflies will be published in 2002 or 2003. A regional report on dragonflies of Eastern Africa for the IUCN Odonata Specialist Group has been recently prepared. At least one new species waits for description, while a number of other projects need more field work. Following recent manuscripts could be finished: Clausnitzer, V. 2001a. 4795. Clopton, R.E. (2004): *Calyxocephalus karyopera* g. nov., sp. nov. (Eugregarinorida: Actinocephalidae: Aactinocephalinae) from the Ebony Jewelwing Damselfly *Calopteryx maculata* (Zygoptera: Calopterygidae) in Southeast Nebraska, U.S.A.: Implications for mechanical prey-vector stabilization of exogenous gregarine development. *Comparative Parasitology* 71(2): 141-153. (in English). ["*Calyxocephalus karyopera* g. nov., sp. nov. (Apicomplexa: Eugregarinorida: Actinocephalidae: Actinocephalinae) is described from *C. maculata* collected along Turkey Creek in Johnson County, Nebraska, U.S.A. *Calyxocephalus* gen. n. is distinguished by the form of the epimerite complex: a terminal thick disk or linearly crateriform sucker with a distal apopetalus calyx of petaloid lobes and a short intercalating diamerite (less than half of the total holdfast length). The epimerite complex is conspicuous until association and syzygy. Association occurs immediately before syzygy and is cephalolateral and biassociative. Gametocysts are spherical with a Conspicuous hyaline coat. Lacking conspicuous sporoducts they dehisce by simple rupture. Oocysts are axially symmetric, hexagonal dipyramidic in shape with slight polar truncations, bearing, 6 equatorial Spines, 1 at each equatorial vertex and 6 terminal spines obliquely inserted at each pole, 1 at each vertex created by polar truncation. The ecology of the *C. karyopera*-*C. maculata* host-parasite system provides a mechanism for mechanical prey-vector Stabilization of exogenous gregarine development and isolation." 4797. Cothran, R. (2004): Precopulatory mate guarding affects predation risk in two freshwater amphipod species. *Animal Behaviour* 68(5): 1133-1138. (in English). ["Contact mate guarding may increase predation risk in the presence of active, size-selective predators by increasing the apparent size or decreasing the escape ability of an individual. These same characteristics may, however, make paired individuals less vulnerable to sit-and-wait, non-size-selective predators. Because the costs and benefits associated with mate guarding are likely to depend on local ecological conditions, species or populations should vary in the duration of the guarding phase. In this study, I investigate whether precopulatory mate guarding increases an individual's pre-

dition risk for two freshwater amphipod species within the *Hyalella azteca* species complex that experience different predators. When larval dragonflies, *Anax junius* and *Tramea lacerata*, were used as predators in laboratory trials, single, unpaired individuals were more likely to be consumed than paired individuals. Conversely, predatory fish consumed paired females more often than single females. Therefore, the short precopulatory mate guarding duration observed in the species that co-occurs with predatory fish may be due to habitat-specific, predator-driven costs associated with precopulatory mate guarding. Furthermore, the predation cost associated with precopula was greater for females than males when predatory fish were used as predators, implying that intersexual conflict over the duration of the guarding period may be more intense for the species that co-occurs with predatory fish." 4798. Cowell, B.C.; Remley, A.H.; Lynch, D.M. (2004): Seasonal changes in the distribution and abundance of benthic invertebrates in six headwater streams in central Florida. *Hydrobiologia* 522(1-3): 99-115. (in English). ["Seasonal variations in invertebrate assemblages at two sites (upstream and downstream) on six central Florida headwater streams were compared by sampling at quarterly intervals with core and dip net samplers. Two of the streams were reclaimed following phosphate mining (app. 6 yr prior to this study), two received runoff from mined lands, and two were disturbed by agriculture and/or residential developments. Physical and chemical characteristics of the reclaimed streams differed markedly from those of the non-reclaimed streams; principal differences between the streams were in current velocity, percent organic matter (POM), Mn, conductivity and alkalinity. Annual mean densities of meiofauna and smaller macrofauna for the 12 stream sites ranged from 20 896 to 175 212 m² and the mean for all sites was 56 492 m² reclaimed streams and one of the streams influenced by agriculture had annual means of less than 40 000 m²- to 5-fold lower than the other streams. Fall and winter core densities were 2.4-fold greater than those for spring or summer when drought and low dissolved oxygen prevailed. Meiofauna comprised 68-91% of the core sample invertebrates in reclaimed streams but only 43-62% in the non-reclaimed streams; principal functional groups were: gathering collectors -61.5%, predators -19.3% and filtering collectors -15%. The taxonomic composition of the reclaimed streams was predominated by crustaceans (60-71%) while chironomids and annelids were more abundant (71-92%) in the non-reclaimed streams. Dip net sampling added 21 larger macrofauna species (Odonata, Hemiptera and Coleoptera) to our list of taxa, producing a total of 209 species. Species richness and diversity (H' and N2) indices were lower in the reclaimed streams, but evenness was more variable. The Czekanowski-Dice-Sorensen similarity index showed that the reclaimed stream sites were quite similar to each other, but differed markedly from the other stream types; there was large variation both within and between seasons. For central Florida headwater streams, drought appears to have a larger influence on invertebrates than the type of land use, however this relationship should be confirmed using streams of similar hydrology." 4800. De Block, M.; Stoks, R. (2004): Cannibalism-mediated life history plasticity to combined time and food stress. *Oikos* 106: 587-597. (in English). ["There is increasing awareness that combinations of biotic and time stress interact in shaping life history plasticity. Despite being widespread and abundant, the role of cannibalism in linking both types of constraints to life history plasticity has been largely neglected. Moreover, no studies disentangled direct (due to the extra meal) and indirect (due to the elimination of the competitor) life history effects of cannibalism, and little is known about their differential dependency on these constraints. We studied effects of cannibalism on the life history of the damselfly *Lestes viridis* under combinations of time stress (by manipulating the perceived time available in the growth season) and food stress. We reared larvae per two and disentangled direct and indirect effects of cannibalism by preventing cannibalism in half of the cups and by manipulating the per capita food increase after cannibalism. Cannibalism was more frequent under both time stress and food stress and our results show it may help cannibals to compensate for the negative effects of these constraints imposed on life history. Both direct and indirect benefits of cannibalism (increased development and growth rates, larger mass at emergence) were dependent on the timing of cannibalism, being more pronounced or only present when cannibalism occurred early. Moreover, we found that the ecological constraints (time stress and food stress) also differentially shaped some of the direct and indirect effects. Given the differential context-dependency of direct and indirect effects and the fact that direct and indirect life history effects may be both important in shaping life history, disentangling these effects is critical to mechanistically understand under which conditions cannibalism is expected to be adaptive or not." 4805. Echols, K.R.; Tillitt, D.E.; Nichols, J.W.; Se-cord, A.L.; McCarty, J.P. (2004): Accumulation of PCB congeners in nestling tree swallows (*Tachycineta bicolor*) on the Hudson River, New York. Environmental Science & Technology 38(23): 6240-6246. (in English). ["Tree swallows were used as a sentinel species to monitor the contamination and bioavailability of polychlorinated biphenyls (PCBs) in the Hudson River watershed. Several tree swallow nest box colonies around and downstream from Hudson Falls, NY were studied. Tree swallow eggs, adults, and 5-, 10-, and 15-day-old nestlings were collected and analyzed for 103 PCB congeners. Emergent insects collected by net (primarily Odonata) or as a food bolus (primarily Diptera) taken from the mouths of adult tree swallows returning to the nest were analyzed in the same manner. Total PCB concentrations (wet weight) in eggs from two contaminated sites ranged from 9000 to 25 000 ng/g and accumulated to 32 000 and 96 000 ng/g in 15-day-old nestling at two contaminated sites. The congener patterns of PCBs in eggs, nestlings, and adults were compared to those found in emergent insects (Odonata and Diptera) using principal components analysis. The PCB patterns of the biota differed from that of Aroclor technical mixtures. PCB patterns in adult tree swallows were similar to those in eggs, while the patterns in dietary insects were similar to nestling tree swallows. Uptake rate constants were determined for tree swallow nestlings and compared between the two contaminated sites. The estimated PCB congener uptake rate constants were 0.008-0.02 d⁻¹ based on uptake in nestlings until day 15 post-hatch. The rate constants were comparable between the two study areas and may be used to predict nestling contamination at other locations. Our studies confirm

the utility of nestling tree swallows to evaluate localized PCB contamination." (Authors)] Address: Tillitt, D.E., Columbia Environm. Res. Ctr., US Geol. Survey, 4200 New Haven Rd, Columbia, MO, 65201, USA. E-mail: dtillitt@usgs.gov

4806. Englund, R.A.; Arakaki, K. (2004): Rapid Biological Inventories of Streams in the Ala Wai Watershed, Oahu Island, Hawai'i. Final Report prepared for: Oceanit Laboratories, Inc., 1001 Bishop Street, ASB Tower 2970, Honolulu, Hawai'i 96813, USA. Contribution No. 2004-007 to the Hawaii Biological Survey: 16 pp. (in English). [...] With a few notable exceptions, the aquatic macrofauna found within the Ala Wai watershed was comprised largely of invasive alien species. Except in the highest reaches of the Ala Wai watershed, aquatic habitats were found to be highly disturbed; this was a result of the effects of urbanization that includes stream diversions and miles of concrete channelization. The worst form of channelization found during these surveys was the flat-bottom concrete lined channels such as those found in lower Pälolo Stream, where stream temperatures were increased by 23° F because of channelization. No native aquatic species were found in concrete-lined stream channels. A complete loss of channel heterogeneity and riparian vegetation cover result in increased water temperatures that are lethal to native species. [...] (Authors) 6 (invasive) odonate species are listed.] Address: <http://hbs.bishopmuseum.org/pdf/alawai.pdf>

4807. Fenoglio, S.; Bo, T.; Cucco, M. (2004): Small-scale macroinvertebrate distribution in a riffle of a neotropical rainforest stream (Rio Bartola, Nicaragua). Caribbean Journal of Science 40(2): 253-257. (in English). ["Streams are highly heterogeneous environments in which habitat characteristics vary drastically over small distances, but little information is available in this context about Neotropical systems. In this work, we analyse the relationship between taxonomical composition and functional organization of stream benthic communities and some environmental variables in a single riffle of the Rio Bartola, Nicaragua. Current velocity, position in the streambed, and substratum composition evidently influence invertebrate density and taxonomical richness. We investigate the functional organisation of the communities, reporting that collectors are the most represented functional feeding group, while shredders are almost absent." (Authors) Four odonata taxa are listed on the genus level.] Address: University of Eastern Piedmont, Via Cavour 84 I-15100 Alessandria, Italy. E-mail: fenoglio@unipmn.it

4808. Fleck, G. (2004): La larve du genre *Cyanothemis* Ris, 1915 (Odonata: Anisoptera: Libellulidae). Consequences phylogénétiques. Ann. Soc. Ent. France 40 (1): 51-58. (in French, with English summary). ["The larva of the genus *Cyanothemis* Ris, 1915 is described and illustrated for the first time. The comparison of the larva and adult of *Cyanothemis* with those of *Lepthemis* Hagen, 1861 and *Rhodothemis* Ris, 1911 suggests that these three genera are closely related, filling a phylogenetic gap which nearly goes back a century. The genus *Acisoma* Rambur, 1842, even if more derived, has to be considered as belonging to the clade (*Cyanothemis* + *Lepthemis* + *Rhodothemis*). The genera *Nannophya* Rambur, 1842 and *Nannothemis* Brauer, 1868, put traditionally into *Brachydiplacinae* and not into *Sympetrinae*, could be the adelphotaxa of the clade

(Acisoma + Cyanothemis + Lephthernis + Rhodothemis). Studying wing venation in systematics and phylogeny was till now preponderant, but seems to be limited for the Libellulidae." (Author)] Address: Fleck, G., Lab. Ent.. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: fleck@mnhn.fr

4809. Fleck G.; Bechly G.; Martínez-Delclòs X.; Jarzembowski E. A.; Nel A. (2004): A revision of the Upper Jurassic-Lower Cretaceous dragonfly family Tarsophlebiidae, with a discussion on the phylogenetic positions of the Tarsophlebiidae and Sieblosiidae (Insecta, Odonoptera, Panodonata). *Geodiversitas* 26(1): 33-60. (in English with French summary). ["The Upper Jurassic-Lower Cretaceous dragonfly family Tarsophlebiidae is revised. The type species of the type genus Tarsophlebia Hagen, 1866, *T. eximia* (Hagen, 1862) from the Upper Jurassic Solnhofen Limestones, is redescribed, including important new information on its head, legs, wings, anal appendages and male secondary genital apparatus. The type specimen of Tarsophlebiopsis mayi Tillyard, 1923 is regarded as an aberrant or unusually preserved Tarsophlebia eximia. One new species of Tarsophlebia and three new species of Turanophlebia are described, i.e. Tarsophlebia minor n. sp., Turanophlebia anglicana n. sp., T. mongolica n. sp., and T. vitimensis n. sp. A new combination is proposed for Turanophlebia neckini (Martynov, 1927) n. comb. The phylogenetic relationships of the Mesozoic Tarsophlebiidae are discussed on the basis of new body and wing venation characters. The present analysis supports a rather derived position for the Tarsophlebiidae, as sister group of the the Epiproctophora rather than of (Zygoptera + Epiproctophora). Also, through the present discussion, the Oligo-Miocene family Sieblosiidae seems to be more closely related to the Epiproctophora than to the Zygoptera. But the present study and previous analyses suffer of the lack of informations concerning the more inclusive groups of Odonoptera, viz. Protozygoptera, Triadophlebiomorpha, Protanisoptera, etc. The significance of the tarsophlebiid secondary male genital apparatus for the reconstruction of the evolution of odonate copulation is discussed." (Authors)] Address: Fleck, G., Lab. Ent.. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: fleck@mnhn.fr

4810. Forbes, M.R.; Muma, K.E.; Smith, B.P. (2004): Recapture of male and female dragonflies in relation to parasitism by mites, time of season, wing length and wing cell symmetry. *Experimental and Applied Acarology* 34(1-2): 79-93. (in English). ["For aquatic mites parasitic on dragonflies, completion of their life cycle depends on their being returned to appropriate water bodies by their hosts, after completion of engorgement. We examined whether differences among hosts in timing of emergence or phenotypic attributes might affect their probability of return to an emergence pond, and hence success of mites. Parasitized males and females of the dragonfly *Sympetrum obtrusum* (Hagen) did not differ in overall recapture rates. Females that had wing cell symmetry and emerged early were more likely to be recaptured than females that emerged later or had wing cell asymmetry, but there were no consistent relations between these variables and parasitism by mites. No such relations between wing cell asymmetry, emergence date, and recapture likelihood were found for males. Using randomization tests, we found that mean intensities of *Arrenurus planus* (Marshall) mites at host emergence were the same for recaptured females and fema-

les not recaptured; however, males that were recaptured had lower mean intensities of mites at emergence than males not recaptured. Further, mature females carried more mites than mature males, and the latter had fewer mites than newly emerged males not recaptured. Biases in detachment of engorging mites do not explain the differences in parasitism between mature males and females, nor the differences in mite numbers between mature males and newly emerged males that were not recaptured. Rather, heavily parasitized males appear to disperse or die and are not recaptured, which should have implications for dispersal of mites and fitness of male hosts." 4811. Freitag, H. (2004): Composition and longitudinal patterns of aquatic insect emergence in small rivers of Palawan Island, the Philippines. *Inter. Rev. Hydrobiol.* 89(4): 375-391. (in English). ["This study presents the first emergence trap samples from streams in the Philippines and Greater Sunda. Aquatic insect emergence from two small rivers and longitudinal patterns including estuaries are compared. A decline of total emergence towards estuaries was observed, affecting all major orders. Diptera, namely Chironomidae, dominated all sites. High abundances in Ceratopogonidae, Odonata, and Coleoptera were found, compared to other emergence studies from tropical and temperate latitudes. Ephemeroptera displayed a highly variable contribution to the emergence from Palawan as well as in other comparative studies either supported by the appropriate conditions for certain functional groups or limited by environmental variables such as pH. Trichoptera are likely to tolerate a wider range of environmental conditions and they are consequently able to fill further niches where Ephemeroptera are under-represented. Except for scarce abundances of Plecoptera observed in this and other studies from the tropics, no substantial differences in emergence composition at order level existed between temperate and tropical rivers, however, with a remarkable local variation. Components of riparian and non-aquatic insects and non-emergent fauna contributing to the collections are discussed based on trap features. [...] Odonata occurred at all sites apart from estuaries in low numbers. The highest numbers were found at PR1 (98 a -1 m -2), and CR3 (73 a -1 m -2). *Rhinocypha humeralis* SELYS, 1873 (Chlorocyphidae) was frequent in the middle course (CR3, CR4) of the CR while *Prodasineura palawana* LIEFTINCK, 1948 (Protoneuridae) was dominant in the site PR1. A third species, *Coelliccia* sp. (Platycnemididae) was trapped once at CR1 (Table 2)." (Author)] Address: Freitag, H., Martin-Luther-University Halle-Wittenberg, Institute of Zoology, D-06099 Halle, Germany. 4812. Gade, G.; Auerswald, L.; Predel, R.; Marco, H.G. (2004): Substrate usage and its regulation during flight and swimming in the backswimmer, *Notonecta glauca*. *Physiological Entomology* 29(1): 84-93. (in English). ["The metabolites that are generally used by insects during exercise are present in quite different concentrations in the haemolymph of the backswimmer *N. glauca* L. Lipids are most abundant (between 10 and 20

mg/mL), whereas carbohydrates (2-3 mg/mL) and proline (approximately 1 mg/mL) are at very low concentrations. Injection of an extract of conspecific corpora cardiaca causes pronounced hyperlipaemia in the backswimmer. A neuropeptide with the same effect was isolated from the corpora cardiaca in a single high-performance liquid chromatography (HPLC) step; the primary sequence was deduced from mass spectrometric measurements (matrix-assisted laser desorption/ionization-time of flight and electrospray quadrupole time-of-flight mass spectrometry) of whole corpora cardiaca, and the mass was confirmed in the HPLC fraction that had adipokinetic activity. The biologically active octapeptide has the sequence pGlu-Val-Asn-Phe-Ser-Pro-Ser-Trp amide, which was characterized previously from the corpora cardiaca of *Anax imperator*, and denoted Anaim-adipokinetic hormone (AKH). The synthetic Anaim-AKH peptide causes lipid mobilization when injected at a dose of 1 pmol into *N. glauca*. When other synthetic AKH members that occur in Hemiptera are injected into *N. glauca* at the same dose, the hyperlipaemic responses are significantly lower than after injection of Anaim-AKH. Because only lipids increase upon activity, such as continuous swimming for 1 h or during a 1-h rest period after a 3-min flight episode in the laboratory, it is assumed that Anaim-AKH serves as a true adipokinetic hormone in the backswimmer during bouts of natural swimming and flight." (Authors)] Address: Gade, G., Zoology Dept, Univ. of Cape Town, Rondebosch, 7701, South Africa. E-mail: ggade@botzoo.uct.ac.za

4813. Geraeds, R.P.G.; Schaik, V.A. van (2004): The dragonfly *Onychogomphus forcipatus*, a new species for the Netherlands? Findings of a few exuvia along the river Roer. *Naturhistorisch Maandblad* 93: 33-35. (in Dutch, with English summary). ["During a dragonfly survey along the river Roer, four exuviae of *Onychogomphus forcipatus* were found at three locations along the river Roer. The first exuvium was found on 5 July, south of Melick. The second and third exuviae were found on 12 July, west of Melick, both in the same location. The fourth was found on 9 August, also south of Melick. *Onychogomphus forcipatus* is not regarded as a native species in the Netherlands. There were only two reliable observations in the Netherlands in the 20th century, viz., in 1947 and 1995. Observations of this species along the river Roer in 2000 and the new findings of the three exuviae in 2003 show that *O. forcipatus* may have established itself along the river Roer. Since the larvae take three years to develop, it is likely that the larvae that emerged in 2003 are the offspring of the animals observed in 2000." (Authors)] Address: Geraeds, R.P.G., Julianalaan 46, NL-6042 JH Roermond, The Netherlands

4814. Gewecke, M.; Odendahl, A. (2004): Der Bewegungsapparat der Antennen des Großen Blaupfeils *Orthetrum cancellatum* (Odonata: Libellulidae). *Entomologia Generalis* 27(2): 73-86. (in German, with English summary). ["The antenna of *O. cancellatum* is composed of 6 segments, scapus, pedicellus, and 4 segments of the flagellum. Only the two proximal ones can be moved actively by muscles. The axis of the caput-scapus-joint and the axis of the scapus-pedicellus-joint are nearly parallel with each other. Thus the antenna can be moved above the frontal rim of the compound eye, forward-down or backward-up. The pedicellus-flagellum-joint is as like a socket joint passively movable in all directions. During flight the relatively stiff flagellum

is pushed backward by the head wind. These movements can be perceived by the organ of Johnston within the pedicellus. The muscles and sense organs of the antenna are innervated by the antennal nerve, originating from the deutocerebrum." (Authors)] Address: Gewecke, M., Inst. Zool. Abt. Neurphysiol., Univ. Hamburg, Martin-Luther-King Platz 3, D-20146, Hamburg, Germany

4815. Gossum, H. van; Stoks, R.; De Bruyn, L. (2004): Conspicuous body coloration and predation risk in damselflies: are andromorphs easier to detect than gynomorphs? *Belg. J. Zool.*, 134(2/1): 37-40. (in English). ["The coexistence of multiple female colour morphs in damselflies remains poorly understood. Typically, one of the female morphs is coloured like the male (andromorph), while the other morphs are not (gynomorphs). Andromorphs, by resembling males, are thought to benefit from avoiding male harassment. Some authors have proposed that this benefit is offset by a higher probability of detection for andromorphs compared to gynomorphs owing to differences in body colouration. We experimentally tested detectabilities of the different female colour morphs using human observers as model predators. In contrast to expectation, detection probabilities for andromorphs and gynomorphs were equal. We discuss the use of survival probabilities to test for differences in predation rate between female morphs and consider whether human predators are representative models for the natural predator guild of the studied damselfly." (Authors)] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

4816. Gossum, H.V.; Adriaens, T.; Dumont, H.; Stoks, R. (2004): Sex- and morph-specific predation risk: Colour or behaviour dependency? *Eur. J. Entomol.* 101(3): 373-377. (in English). ["The coexistence of discrete morphs within a species, with one morph more conspicuous than the other(s) is often thought to result from both sexual selection and predation. In many damselflies, sexual dimorphism occurs jointly with multiple female colour morphs. Typically, one morph is coloured like the male (andromorph), while the other(s) is not (gynomorph(s)). The mechanisms contributing to the maintenance of such female polymorphism in damselflies remain poorly understood, especially the role of predation. We tested the detectability of two different female colour morphs of the damselfly, *Enallagma cyathigerum*, using human observers as model predators; andromorphs were detected more frequently than gynomorphs. Field data on mortality of males and the two different female morphs due to predation or drowning were also collected, and these observations support morph-specific mortality. In natural populations predation risk was higher in males than females; gynomorphs, however, were more prone to predation than andromorphs. Differences in behaviour between morphs, rather than colour, may explain this result." 4817. Groenendijk, D. (2004): Dragonflies and damselflies in Dutch limestone quarries. *Naturhistorisch Maandblad* 93: 95-99. (in Dutch, with English summary). ["Marl pits in the province of Limburg are of great entomological importance. Their sheltered situation and

the continuing marl-stone extraction provide a special dynamic and warm habitat. So far, 37 dragonfly species have been recorded in these quarries, many of them relatively rare in the rest of the Netherlands. Most of these are species characteristic of poorly vegetated seepage areas or have a southern distribution. Reproduction of *Sympecma fusca*, *Cercion lindenii*, and *Crocothemis erythraea* has been observed in pools with a rich vegetation, while *Ischnura pumilio*, *Orthetrum brunneum*, and *Orthetrum coerulescens* were found to reproduce in seepage areas with shallow ponds and small streams. Most of the recorded dragonfly species need the dynamic situation found in these quarries. Conserving this special habitat and its fauna requires a tailored approach, involving the maintenance of geomorphological and hydrological processes after marl-stone extraction ends." 4818. Hachmöller, B.; Kneis, P.; Schrack, M.; Stolzenburg, U. (2004): Ein neuer Nachweis der Vogel-Azurjungfer (*Coenagrion ornatum* Selys, 1850) in Sachsen. *Mitteilungen Sächsischer Entomologen* 69: 10-12. (in German). [Germany, Sachsen, east of Meißen, August 2004; the species inhabited two ditches. Habitat and co-occurring odonate species are described.] Address: Hachmöller, B., Staatliches Umweltfachamt Radebeul, Wasastr. 50, D-01445 Radebeul, Germany.

4819. Hämäläinen, M. (2004): Caloptera damselflies from Fujian (China), with description of a new species and taxonomic notes (Zygoptera: Calopterygoidea). *Odonatologica* 33(4): 371-398. (in English). ["Based on literature records and the examination of an extensive Odonata collection made in Fujian in 1930-1940's (now in RMNH, Leiden), 21 species of Caloptera (Calopterygoidea) are recognized as occurring in Fujian province in eastern China. The Fujian Caloptera material (ca. 860 specimens of 18 species) in RMNH is enumerated. The following taxonomic decisions are presented: *Caliphaea nitens* Navas, 1934 is removed from synonymy with *Bayadera melanopteryx* Ris, 1912(!) and ranked as a valid species, distinct from *C. consimilis* McLachlan, 1894. The lectotype of *Vestalis smaragdina* Selys, 1879 is designated. *Vestalis velata* Ris, 1912 (syn. *V. virens* Needham, 1930) is ranked as a good species, while the "hyaline winged form of *V. smaragdina velata*" (sensu Asahina, 1977) is described as a new sp. *Vestalis venusta* sp. n. *Bayadera continentalis* Asahina, 1973 from Fujian and *B. ishigakiana* Asahina, 1964 from the Ryukyus are treated as full sp. and not as ssp. of *B. brevicauda* Fraser, 1928 from Taiwan. *Bayadera melania* Navas, 1934 is synonymized with *B. melanopteryx* Ris, 1912. Some preliminary taxonomic comments (to be discussed in detail elsewhere) are presented: *Calopteryx grandaeva* Selys, 1853 is a probable synonym of *C. atrata* Selys, 1853, whereas *C. atrocyana* (Fraser, 1935) is a good sp. *Matrona basilaris* Selys, 1853 and *M. nigripectus* Selys, 1879 appear to be distinct sp. *Mnais tenuis* Oguma, 1913 and *M. andersoni* McLachlan in Selys, 1873 are also better treated as separate sp. Faunistic notes include: *Libellago lineata* (Burmeister, 1839) is recorded from Fujian province for the first time. Old records of *Psolodesmus mandarinus* McLachlan, 1870 and *Euphaea compar* McLachlan, 1870 (synonym of *E. formosa* Hagen in Selys, 1869) from Amoy Island near the Fujian coast are considered doubtful." 4820. Hayashi, F.; Dobata, S.; Futahashi, R. (2004): Macro- and microscale distribution patterns of two closely related Japanese *Mnais* species inferred from nuclear ribosomal DNA, its sequences and morphology (Zygoptera: Calopterygidae). *Odonatologica* 33(4): 399-412. (in English). ["Much variation occurs in morphology and colouration among individuals of Japanese *Mnais* species. It has been noted that 2 groups of *Mnais* often cohabit a stream in western Japan. There is, however, no clear morphological difference in male appendages and penis between the 2 groups, and this makes it difficult to determine their taxonomic status. In this study, to clarify the relationships between the sympatric species on both small (along a stream) and large (across Japan) geographic scales, sequences of the internal transcribed spacers 1 and 2 (ITS 1 and 2) of nuclear ribosomal DNA are compared. Base substitutions occurred at 4 sites of 223 bps of the ITS1 region, and by their combinations, the four sequence types could be distinguished among a total of 800 individuals. In the ITS2 region (total 411 bps including 5.8S rRNA region), all examined individuals had the same sequence. The geographical distribution of each ITS1 sequence type and morphological data of wings and a pterostigma suggest that Japanese *Mnais* includes 2 distinct species, *M. strigata* Selys, 1853 and *M. costalis* Selys, 1869. Their distribution ranges overlap widely in western Japan, where *M. strigata* is usually found at smaller and upper streams than *M. costalis*." 4826. Herberholz, J.; Sen, M.M.; Edwards, D.H. (2004): Escape behavior and escape circuit activation in juvenile crayfish during prey-predator interactions. *Journal of Experimental Biology* 207(11): 1855-1863. (in English). ["The neural systems that control escape behavior have been studied intensively in several animals, including mollusks, fish and crayfish. Surprisingly little is known, however, about the activation and the utilization of escape circuits during prey-predator interactions. To complement the physiological and anatomical studies with a necessary behavioral equivalent, we investigated encounters between juvenile crayfish and large dragonfly nymphs in freely behaving animals using a combination of high-speed video-recordings and measurements of electric field potentials. During attacks, dragonfly nymphs rapidly extended their labium, equipped with short, sharp palps, to capture small crayfish. Crayfish responded to the tactile stimulus by activating neural escape circuits to generate tail-flips directed away from the predator. Tail-flips were the sole defense mechanism in response to an attack and every single strike was answered by tail-flip escape behavior. Crayfish used all three known types of escape tail-flips during the interactions with the dragonfly nymphs. Tail-flips generated by activity in the giant neurons were predominantly observed to trigger the initial escape responses to an attack, but non-giant mediated tail-flips were often generated to attempt escape after capture. Attacks to the front of the crayfish triggered tail-flips mediated either by the medial giant neuron or by non-giant circuitry, whereas attacks to the rear always elicited tail-flips mediated by the lateral giant neuron. Overall, tail flipping was found to be a successful behavior in preventing predation, and only a small percentage of crayfish were killed and consumed." 4827. Hilfert-Rüppell, D (2004): Optimierung des Fortpflanzungsverhaltens: wichtige Einflussgrößen auf Territorialität und auf Paarungen von europäischen Prachtlibellenmännchen (Odonata: Zygoptera). Dissertation TU Braunschweig; <http://opus.tu-bs.de/opus/volltexte/2004/567/>: 216 pp. (in German, with English summary). ["The aim of this study was to find out, which influences contribute to the variability and optimisation of the reproductive behaviour of *C. splendens splendens* in Germany and in Southern France as well of *C. haemorrhoidalis* in Southern France. This approach allowed for the detection of variation in reproductive behaviour among species and geographic regions. In my experiments, the main determinant for the reproductive behaviour was success through copulations. Males left their territories after a unsuccessful predation attempt by

frogs or waterspiders, when they had become territorial only shortly before the attack. Males showed more site fidelity when they had courted or copulated with a female in their territory before the attack, probably because of the higher resource value. Males with or without copulation did not differ in their morphology. The amount of success of males to form a mating wheel from a tandem correlated positively with preceding courtship. After copulations, males showed more territorial flights and displayed versus other males more often. In enclosure-experiments males with an early copulation experience achieved a higher number of further copulations, while male quality (fat, size, wingspot) did not differ significantly between males with or without mating. Northern *Calopteryx splendens splendens* showed a more frequently alternative reproductive behaviour (ARB) than the southern ones. Winner of fights did not differ in their morphology from losers. The experiment showed a significant effect of preceding copulations on duration and outcome of male-male fights. Contests between the same opponents were determined more quickly after a mating than without mating experience. Males which had previously lost a fight won the contest with the same opponent after a copulation in significantly more cases." 4828. Holroyd, P.A.; Bown, T.M.; Schankler, D.M. (2004): *Auroralestes*, gen. nov., a replacement name for *Eolestes* Bown and Schankler, 1982, a preoccupied name. *Journal of Vertebrate Paleontology* 24(4): 979. (in English). [Verbatim: A recent internet search revealed the homonymy of the generic name *Eolestes*, proposed by Bown and Schankler (1982:52) for the early Eocene erinaceid lipotyphlan *Eolestes simpsoni* (Bown, 1979). The erinaceid species was first described by Bown (1979:61) as *Leipsanolestes simpsoni*, and Bown and Schankler (1982) assigned it to a new genus. The generic name *Eolestes* was erected by Cockerell (1940: 104) for an Eocene dragonfly from the Florissant Formation of Colorado, *Eolestes synthetica* (Order Odonata). The generic name *Eolestes* is preoccupied, and we therefore propose the replacement name *Auroralestes* (based on the root *Aurora*, goddess of the dawn) for the erinaceid genus, giving *Auroralestes simpsoni* for *Eolestes simpsoni*. reviews." (Authors)] Address: Holusa, O., Muzeum Beskyd, prirodovedné oddeleni, Zámecké námesti 1264, CZ-738 01 Frydek-Mistek. E-mail: holusao@post.cz

4830. Hunger, H. (2004): Naturschutzorientierte, GIS-gestützte Untersuchungen zur Bestandssituation der Libellenarten *Coenagrion mercuriale*, *Leucorrhinia pectoralis* und *Ophiogomphus cecilia* (Anhang II FFH-Richtlinie) in Baden-Württemberg. Dissertation zur Erlangung des Grades des Doktors der Naturwissenschaften am Institut für Naturschutz und Umweltbildung (INU) der Hochschule Vechta. Dragonfly Research 2. ISSN 1438-034X. IX, 229 pp, Anlagen. (in German, with English summary) ["In the thesis, I focus on the current condition and trends of all known populations of *C. mercuriale*, *L. pectoralis*, and *O. cecilia* in Baden-Württemberg (southwestern Germany). These 3 Odonata species are protected under European law (listed in annex II of the habitats directive). Vector- and raster-based GIS methods play an important role in the analysis of the data. A synoptic discussion of the results leads to concrete recommendations for action plans for protection of the species. As a starting point, all accessible data on the species occurrences and population sizes were compiled and digitised. To gain additional insight into certain aspects of *C. mercuriale* population biology, field experiments were carried out using a unique method of marking the animals with UV ink and searching for them at night with a portable black light lamp. The recapture rate was 35% (140 out of 305 specimens), however, only 11 animals had moved away from the place where they had been marked. The maximum distance of their movement was 300 m. The longest period between marking and last recapture was 16 days. In three instances, marked individuals were found in copula at night. Employing the Lincoln index, the results of mark-recapture experiments showed that the actual population size was 2 to 2.5 times higher than the numbers estimated by conventional field methods. The sex ratio of animals marked was 713 males : 152 females (82:18). The recapture rate on the fifth day after marking was significantly lower for females (3%) than for males (11%). The hypothesis that fertilized females emigrate more frequently than males and thus play a key role in colonization and recolonization events is discussed. The results confirm empirical knowledge that, in the study area, *C. mercuriale* shows only very little tendency to emigrate from its home waters. In the GIS-based habitat model for *C. mercuriale*, a groundwater model and land use data for the Upper Rhine valley were employed. A preference analysis was used to detect "high density areas" with a positive electivity index and a statistically significant χ^2 deviation measure, in which the species occurs at an elevated frequency. In the natural geographic region "Freiburger Bucht" (214 km²) "high density regions" lay within grassland in which the groundwater table was 2 m or less below the surface, and within farmland where the groundwater table was 1 m or less below the surface. In the "Offenburger Rheinebene" (851 km²) they lay within grassland in which the groundwater table was 1,5 m or less below the surface; farmland, even in areas with high groundwater levels, was not to be classified as a "high density region" probably due to the predominance of corn fields. These model results were very plausible. Additional data analyses demonstrated that the model cannot be used for the adjacent natural geographic regions because these have different landscape-related characteristics. The raster-based dispersal model for *C. mercuriale*

took into consideration: on the species level, biological information (dispersal behaviour); on the patch level, information on the size of the subpopulations (emigration rate); and on the landscape level, information on the quality and spatial configuration of the matrix (definition of the cost surface). Land use data and a slope model were incorporated into the design of the cost surface. The model output allowed for a differentiated interpretation of the degree of isolation between individual subpopulations. An "optimistic scenario" (few large metapopulations) was contrasted with a "neutral scenario" (distinct size reduction and fragmentation of the metapopulations). By combining the "high density areas" of the habitat model with the dispersal model zones for *C. mercuriale*, three "suitability classes" were calculated. They indicate where measures for the stabilisation of the metapopulations are most urgent and, at the same time, promising. To document the habitats of *L. pectoralis*, biotypes were mapped in the most significant areas with species occurrences in Upper Swabia (prealpine region of South-Germany). A comparison between digital aerial photographs from 1996 and 2001 allowed the detection of habitat changes caused by vegetative succession. In order to model the long distance dispersal of *L. pectoralis*, the slope model was used as a cost surface. The possible role of cost paths as migration routes was discussed. A "cost distance matrix" was calculated to quantify the spatial relationship between the individual areas occupied by the species. For *O. cecilia*, a series of measurements taken from a data catalogue of the Landesanstalt für Umweltschutz Baden-Württemberg revealed that in many bodies of flowing water the water quality has markedly improved throughout the past two decades. This circumstance, combined with intensified search efforts and possibly climatic factors has probably led to an increase in the number of known populations during the last few years. Metapopulation structure and trends in the overall population size are described in detail in the chapter, "Current status of the studied Odonata species and recommendations for their protection". In addition, concrete recommendations for the species protection, the implementation of the monitoring programmes, and the compilation of the reports regulated by the habitats directive are given. The thesis ends with a discussion of methods, focusing on the applied approach and the GIS methods used. I conclude that, given careful planning and data evaluation, advanced GIS models, such as habitat and dispersal models, are generally of high value for issues of nature conservation." (Author) Address: Hunger, H., Institut für Naturschutz und Landschaftsanalyse (INULA), August-Ganther-Straße 16, D-79117 Freiburg, Germany. E-mail: Holger.Hunger@inula.de

[town of Gera, Thuringia, Germany; compilation of, in most cases prior 1997-data, including some recent records of *Leucorrhinia dubia*, *L. rubicunda*, *Aeshna affinis*, and *Coenagrion lunulatum*.] Address: Jänicke, M., Am Tonteich 4, D-07607 Eisenberg, Germany

4832. Jergentz, S.; Mugni, H.; Bonetto, C.; Schulz, R. (2004): Runoff-related endosulfan contamination and aquatic macroinvertebrate response in rural basins near Buenos Aires, Argentina. Archives of Environmental

Contamination & Toxicology 46(3): 345-352. (in English). ["Information in the open literature about the fate and effects of pesticides in small streams from agricultural areas of Argentina is very rare. The objective of the present work was to study the pesticide contamination and potential biological effects in basins that have undergone intense agricultural activity, mainly related to the cultivation of soybeans. Three streams (Maguire, Helves, and Horqueta) with a low-flow discharge (0.1 and 0.2 m³/s) in March close to the city of Arrecifes were studied during the period of maximum insecticide application, between February and April 2001. Various sampling devices were installed to trap suspended: particles, runoff, and floodwater plus sediment throughout the study period. The suspended-particle samples were analyzed for the insecticides endosulfan (END), chlorpyrifos, and cypermethrin. Water chemistry and the macroinvertebrate communities were assessed on four occasions and the organismic drift was measured continuously. Following a 184-mm rainfall on March 1, 2001, beta-endosulfan concentrations up to 318 and 43 µg/kg were measured from suspended-particle samples from Horqueta and Helves, respectively. No END contamination was detected in Maguire. Chlorpyrifos and cypermethrin were not detected in any of the streams. A significant decrease in the average macroinvertebrate species density was observed in Horqueta (from 12.8±0.5 to 9±0.7 species; ANOVA, p<0.05) and Helves (from 10.8±1.7 to 3.3±1.3 species; p<0.001) following the same rainfall event at the beginning of March, while the species density in Maguire remained constant at 7.9±0.3 species. The runoff primarily reduced species abundances of Odonata and Ephemeroptera significantly (p<0.01) in Horqueta and Helves but not in Maguire. A greater drift of Smicridae (Trichoptera) and Ephemeroptera occurred in Helves and Horqueta during this runoff event, while no changes in the macroinvertebrate drift were detectable in Maguire. This study highlights the potential pesticide effects on macroinvertebrate communities in Argentinian rural streams. It is suggested that a small wetland area formed by Maguire between the agriculturally used catchment and the sampling site contributes to the absence of contamination and effects at this site." 4835. Kadoya, T.; Suda, Shin-ichi; Washitani, I. (2004): Dragonfly species richness on man-made ponds: effects of pond size and pond age on newly established assemblages. *Ecological Research* 19(5): 461-467. (in English). ["We studied the abundance and species richness of adult dragonflies in 11 artificial ponds which were recently established (within 2 years). We found that the adult dragonfly assemblage patterns were influenced by pond size as well as pond age. The species richness was positively correlated with the pond size, which was because the distributional patterns of species were significantly nested according to pond area. The species richness was highly correlated with pond age in association with the vegetation cover within ponds. It was suggested that the species richness was enhanced by the increasing immigration rate of species which favor well-vegetated ponds." (Authors)] Address: Kadoya, T., Dept Ecosyst. Studies, Inst. 4839. Keskinen, E. (2004): Post-embryonic growth and fine-structural organization of arthropod photoreceptors A study involving selected species of insects and crustaceans. Oulu University Press; ISBN 951-42-7560-8 (PDF) <http://herkules.oulu.fi/isbn9514275608/>: 64 pp. (in English). [Arthropod photoreceptors are versatile sense organs. Any investigation of these organs has to consider that their structure and functional limitations at the moment of fixation depend on many factors: species, sex, developmental and nutritional state of the animal, time of day and ambient light. The microscopic image of an arthropod photoreceptor is always a sample frozen in time and space. Quite often publications on arthropod photoreceptors only provide the name of the species studied, but nothing beyond that. At least the developmental status of the study animals ought to be noted, possibly even the sex and body size. Forty publications on insect and 54 on crustacean photoreceptors were checked for the information that was given about the investigated animals: Out of these papers 40% provide only information on the name of the studied species and nothing else. The aim of this thesis, thus, was to investigate, to what extent the developmental state and the sex of the animal as well as the ambient light conditions affect the structure of the eye of a given species. Five species of arthropods were chosen: (a) the semi-terrestrial isopod *Ligia exotica* and two aquatic Branchiuran fishlice, *Argulus foliaceus* and *A. coregoni*, to represent the Crustacea, and (b) the stick insect *Carausius morosus* and the spittle bug *Philaenus spumarius*, both terrestrial, to represent the Insecta. The addition of new ommatidia was studied in a paper on *L. exotica*, which also dealt with the site of newly added ommatidia. It was found that all of these species had two sessile, large compound eyes firmly positioned on their heads (but fishlouse compound eyes were bathed in haemocoelic liquid). In all species, the compound eye was found to be of the apposition type. The gross structural organization of the ommatidia stayed approximately the same during the whole postembryonic development. Lateral ocelli of the *A. coregoni* nauplius eye changed from elongated to spherical between the metanauplius and the 8th stage pre-adult. The sex of the specimens was not found to affect the structure of the eye. In all species, it turned out that the larger the animal and hence the eye, the better its sensitivity. The addition of new ommatidia in the *L. exotica* compound eye was concluded to take place in the anterior and ventral marginal areas of the eye." 4842. Kohnert, S.; Perry, S.F.; Schmitz, A. (2004): Morphometric analysis of the larval branchial chamber in the dragonfly *Aeshna cyanea* Müller (Insecta, Odonata, Anisoptera). *Journal of Morphology* 261(1): 81-91. (in English). ["The aquatic larvae of anisopteran dragonflies possess tracheal gills located in the rectum. Using stereological methods, we estimated the morphometric diffusing capacity for oxygen across the gill epithelium, i.e., from rectal water to the gill tracheoles, in the larvae of *Aeshna cyanea*. A 271-mg larva has a total branchial surface area of app. 12 cm². Tracheoles make up 6% of the epithelial volume of the gills; the harmonic mean thickness of the water-tracheolar diffusion barrier is 0.27 m and consists mainly of cuticle. The calculated DMO₂ is 23.0 l min⁻¹ g⁻¹ kPa⁻¹, which, using published values for oxygen consumption in a similar species, would result in a mean driving pressure of 0.2 kPa at rest and 1.3 kPa during activity. Since these driving pressures are similar to those reported for other arthropods, we conclude that the DMO₂ of the gill is not rate-limiting for aerobic metabolism in *Aeshna cyanea* larvae." 4843. LaFiandra, E.M.; Babbitt, K.J. (2004): Predator induced phenotypic plasticity in the pinewoods tree frog, *Hyla femoralis*: Necessary cues and the cost of development. *Oecologia* 138(3): 350-359. (in English). ["Predator-induced defenses can result from non-contact cues associated with the presence of a feeding predator; however, the nature of the predator cue has not been determined. We tested the role of two non-contact cues, metabolites of digestion of conspecific prey released by the predator and alarm pheromones released by attacked conspecific prey, in the development of inducible defenses by exposing pinewoods tree frog (*Hyla femoralis*) tadpoles to non-lethal dragonfly (*Anax junius*) larvae fed either inside experimental bins or removed from the bins for feeding to eliminate alarm pheromones. The costs associated with the development of the induced morphology were also investigated by providing the tadpoles with two food levels intended to provide adequate or growth limiting resources. The generalized morphological response of *H. femoralis* tadpoles to predators included the development of bo-

dies and tails that were both deeper and shorter, smaller overall body size, and increased orange tail fin coloration and black tail outline. Metabolites of digestion were sufficient to initiate development of inducible defenses; however, the combination of metabolites and alarm cue resulted in a greater response. Furthermore, growth and development were slowed in tadpoles that expressed the induced morphology; however, this growth cost was insufficient to preclude the development of the induced morphology when food resources were low. These results indicate that two aspects of the indirect predator cue work together to trigger a morphological anti-predator response." 4844. Lam, E. (2004): Damselflies of the Northeast. A comprehensive identification guide to the damselflies of the Northeast, from Canada to Virginia. ISBN 6-9754015-0-5: 96 pp. (in English). [This book covers 69 species and subspecies, more than half of all North American damselflies north of Mexico. Introductory chapters are devoted to damselfly anatomy, behaviour, life cycle, identification and sampling methods. More than 300 detailed paintings, drawings and photos, range maps, and advice to similar species enable a competent identification of the species, even without the usual binomic keys which are omitted in this book. This is an absolutely lovely book, and it deserves to be in the library of anyone interested in worldwide Odonata. (Martin Schorr)] Address: Biodiversity Books, P.O. Box 353, Eastchester, NY 10709, U.S.A.

4845. Lambert, T.D.; Howard, J.; Plant, A.; Soffe, S.; Roberts, A. (2004): Mechanisms and significance of reduced activity and responsiveness in resting frog tadpoles. *Journal of Experimental Biology* 207(7): 1113-1125. (in English). ["Hatchling *Xenopus laevis* tadpoles spend most of their time attached to objects or the water surface by mucus secreted by a gland on the head. While attached, swimming activity and responsiveness to swim-initiating stimuli are reduced over long periods of time. We have investigated the mechanisms and significance of this apparent long-term inhibition. In behavioural experiments we show, firstly, that innervation of the cement gland and GABAA-mediated inhibition are necessary for attachment to reduce responsiveness, and secondly, that denervation of the cement gland increases tadpole activity and increases their predation by damselfly nymphs (Zygoptera). To investigate the neuronal pathway from the cement gland to GABAA inhibition, we have devised an immobilized, inverted tadpole preparation where a weight attached to the mucus simulates the force as it hangs. Simulated attachment reduces responsiveness and spontaneous fictive swimming activity. We have recorded the activity and responses of trigeminal neurons innervating the cement gland. They are spontaneously active and simulating attachment results in a sustained increase in this activity. We propose that hanging from a mucus strand increases firing in cement gland afferents. This leads to tonic GABA inhibition that reduces tadpole activity and responses, and leads to fewer attacks by predators." (Authors)] Address: Lambert, T., Inst. Physiol., Univ. Hohenheim, Garbenstr 30, D-70593, Stuttgart, Germany. E-mail: lambert@uni-hohenheim.de

4846. Laurila, A.; Jarvi-Laturi, M.; Pakkasmaa, S. Merila, J. (2004): Temporal variation in predation risk: stage-dependency, graded responses and fitness costs in tadpole antipredator defences. *Oikos* 107(1): 90-99. (in English). ["Temporal variation in predation risk may be an important determinant of prey antipredator behaviours. According to the risk allocation hypothesis, the strongest antipredator behaviours are expected when periods of high risk are short and infrequent. We tested this prediction in a laboratory experiment where common frog *Rana temporaria* tadpoles were raised from early larval stages until metamorphosis. We manipulated the time a predatory Aeshna dragonfly larva was present and recorded behavioural responses (activity) of the tadpoles at three different time points during the tadpoles' development. We also investigated how tadpole shape, size and age at metamorphosis were affected by temporal variation in predation risk. We found that during the two first time points activity was always lowest in the constant high-risk situation. However, antipredator response in the two treatments with brief high-risk situation increased as tadpoles developed, and by the third time point, when the tadpoles were close to metamorphosis, activity was as low as in the constant high-risk situation. Exposure to chemical cues of a predation event tended to reduce activity during the first time period, but caused no response later on. Induced morphological changes (deeper tail and shorter relative body length) were graded the response being stronger as the time spent in the proximity of predator increased. Tadpoles in the brief risk and chemical cue treatments showed intermediate responses. Modification of life history was only found in the constant high-risk treatment in which tadpoles had longer larval period and larger metamorphic size. Our results indicate that both behavioural and morphological defences were sensitive to temporal variation in predation risk, but behaviour did not respond in the manner predicted by the risk allocation model. We discuss the roles of concentration of predator chemical cues and prey stage-dependency in determining these responses." (Authors)] Address: Evolutionary Biol. Ctr. Dept Populat. (in English). ["The factors that determine contest outcomes among territorial male animals are complex and much debated. This study investigated how breeding resource availability and body size influence territorial contests of *Hetaerina miniata*.

In our marked population, some males were territory owners while others were part of a wanderer contingent. Male territoriality was not correlated with availability of oviposition substrate. We predicted that territory owners would have an advantage in disputes. Removal experiments demonstrated that owners won significantly more territorial contests than did wanderers, and whereas males were significantly larger than females, male territorial status did not depend on body size. However contest outcome was not based solely on ownership because experimentally removed individuals regained their territories from new owners (intruders). We suggest that intrinsic resource holding potential based on other morphological and physiological factors, such as energy reserves, may govern male competitive ability." 4852. Macías, M.; Green, A.J.; Sánchez, M.I. (2004): The diet of the Glossy Ibis during the breeding season in Doñana, Southwest Spain. *Waterbirds* 27(2): 234-239. (in English). ["We present the first detailed study of the diet of Glossy Ibis (*Plegadis falcinellus*) in Europe, from an expanding breeding colony in Doñana, southwest Spain. In 2000, fecal samples, mainly from adults, were collected from 15 nests. In 2001, 36 regurgitates were collected, mainly from large chicks. Fecal contents were dominated by aquatic beetles and dragonfly larvae, which were present in 100% and 93% of samples respectively. Regurgitates contained mainly aquatic beetles (41% by aggregate percent, mainly *Cybister* spp.), dragonfly larvae (29%, mainly *Sympetrum fonscolombii*, *Aeshna mixta*, and *Anax imperator*), Sharp-ribbed Salamanders (*Pleurodeles waltii*, 12%) and Carp (*Cyprinus carpio*, 7%). The absence of vertebrate and

other hard remains from feces was presumably due to their excretion in pellets. Thus fecal analysis is not a suitable method to investigate the food of the Glossy Ibis. The results suggest that there may be no major difference in the diet of breeding adults and their chicks, and that the recent increase in numbers of this ibis in Doñana is not explained by the abundance of introduced Red-swamp Crayfish (*Procambarus clarkii*) in the breeding area." 4853. Maezono, Y.; Miyashita, T. (2004): Impact of exotic fish removal on native communities in farm ponds. *Ecological Research* 19(3): 263-267. (in English). ["Introduced largemouth bass (*Micropterus salmoides* spp.) and bluegill (*Lepomis macrochirus* spp.) are thought to threaten native aquatic organisms worldwide and hence their eradication has recently begun in Japan. Our previous studies suggested that the removal of largemouth bass increases native fish, shrimp, dragonflies, and exotic crayfish, but decreases macrophytes. To test this prediction, we removed the exotic fishes by draining farm ponds and compared the numbers of these organisms before and after the drain, as well as between drained and undrained ponds. The number of dragonfly *Pseudothemis zonata*, crayfish, shrimp, and goby increased rapidly after the drain, but the coverage of macrophyte declined. The reduction in macrophyte is assumed to be caused by increased herbivory by crayfish. The number of exuviae of damselfly *Cerion calamorum* and the total number of species of odonate also decreased after the drain. These decreases can be due to the reduction of macrophyte because reduced odonate species are known to use macrophytes as oviposition sites. Therefore, the removal of largemouth bass has a potential to cause negative effects on some native organisms. We propose that reduction of exotic crayfish should be considered when eradicating the exotic fishes." (Authors)] Address: Maezono, Y., Sch. Agr. and Life Sci. Lab. Biodivers. 4855. Mantel, S.K.; Salas, M.; Dudgeon, D. (2004): Foodweb structure in a tropical Asian forest stream. *Journal of the North American Benthological Society* 23(4): 728-755. (in English). ["A food web based on the gut contents of consumers (invertebrates and fishes) in pools of Tai Po Kau Forest Stream (TPKFS), Hong Kong (southern China), indicated the importance of periphyton and fine organic particles; coarse particulate organic matter was a less important food source despite its higher relative abundance in this shaded hillstream. Stable isotope analysis of consumer tissues was undertaken to confirm this result. IsoSource software was used to model n-isotope and >n + 1-sources, so that the relative contribution of the potential food sources could be determined. Results of an IsoSource mixed model of $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ stable isotope signatures

of primary consumers generally supported evidence from gut content analyses about the importance of autochthonous resources. Inconsistencies between the results of gut content analysis and isotope signatures of consumer tissues occurred in a few cases but could be explained either by small sample size or the wide range of feasible solutions provided by the isotopic mixed model. Both techniques were needed to resolve the trophic position of omnivores. For instance, the gut contents of balitorid loaches indicated that they were primarily herbivorous but their stable isotope signatures revealed a significant dependence on animal food. Considerable overlap in the diets of predatory fishes and invertebrates (odonates, perlid stoneflies, palaemonid shrimps) was confirmed by both gut contents and stable isotope analyses. This finding, along with a lack of intraguild predation, resulted in a short mean and maximum food-chain length, high links per species, and high connectance for the TPKFS food web when compared with literature reports of other stream food webs. Periods of spate-induced disturbance during the wet season and limited algal productivity in TPKFS might also have contributed to the short food chains. Inconsistent levels of resolution for different taxonomic groups within the food web may have generated artefacts of low linkage complexity, high predator-prey ratio, and a small number of basal and intermediate species, a pattern that has been confirmed for stream food webs elsewhere. Our study is the first example of a food web based on complementary analyses of gut contents and stable isotope signatures for any tropical stream. This combined approach is recommended for future studies of food webs, especially in habitats where omnivores are an important component of the community." (2004): Bio-control of mosquito vector with special reference to dragon fly nymph *Aeschna* [sic]. *Journal of Experimental Zoology, India* 7(2): 353-355. (in English). ["Population regulation in mosquitoes can be extremely complex. Therefore there is a need to control the mosquito more effectively using environmental measures. Over forty different biocontrol agents on mosquito have been recorded till now and among them fishes, insects and parasites show promising results. The present paper reports the use of a dragonfly nymph in mosquito control programme." (Authors)] Address: Mishra, P.K., Dept Zool., JH Govt PG Coll, Betul, 460001, India

4868. Motta, R.L.; Uieda, V.S. (2004): diet and trophic groups of an aquatic insect community in a tropical stream. *Braz. J. Biol.* 64(4): 809-817. (in English, with Portuguese abstract). ["The diet and trophic groups of an assemblage of aquatic insects were studied in a tropical stream. Genera of the orders Ephemeroptera, Odonata, Plecoptera, Lepidoptera, and Hemiptera showed feeding specialization. Others, such as Trichoptera, Coleoptera, and Diptera, showed great diet variation with genera of different trophic groups. Seasonal variation of insect diet, evident only for some genera of the orders Trichoptera, Lepidoptera, Coleoptera, and Diptera, was due to the differences observed in community composition and to generalist habits of these genera. However, the seasonal comparison of trophic groups showed no significant statistical differences. The great importance of organic matter, a non-limited resource, in the diet of Ribeirão do Atalho aquatic insects may be the explanation for the trophic stability in this community organization." (Authors) Odonata are treated on the genus level.] Address: Uieda, Virginia S., Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, C.P. 510, CEP 18618-000, Botucatu, SP, Brazil

- 4874.** Ocharán, F.J.; Torralba Burrial, A. (2004): La relación entre los odonatos y la altitud: el caso de Asturias (norte de España) y la península Ibérica (Odonata). *Boletín de la Sociedad Entomológica Aragonesa* 35: 103-116. (in Spanish with English summary). [The trade-off "between the distribution of Odonata and altitude is studied for Asturias (northern Spain), by means of profiles of corrected frequencies, and is compared with bibliographical data for the rest of the Iberian Peninsula and other areas. Decreasing species richness of Odonata with increasing altitude across an altitude gradient is the general pattern. However, some species are limited to high altitude (*Sympetrum flaveolum*) or have a predominantly high-altitude distribution range (*Aeshna juncea*, *Lestes dryas*, *Lestes sponsa*). Other species live only at very low altitude (like the thermophilic *Crocothemis erythraea*) or predominantly in low areas (*Calopteryx haemorrhoidalis asturica*, *Orthetrum cancellatum*, *Onychogomphus uncatus*). Some species have a wide altitudinal range which covers the whole altitude gradient (*Pyrrhosoma nymphula*, *Coenagrion puella*, *Enallagma cyathigerum*, *Cordulegaster boltonii*, *Sympetrum striolatum*), and others seem to follow this pattern too (*Ischnura graellsii*, *Aeshna cyanea*). Habitat preferences and the relationship of some environmental factors with the altitude and the distribution of Odonata in Asturias are discussed, especially the differences with the altitudinal data known for the Iberian Peninsula. *Calopteryx virgo meridionalis* seems indifferent to altitude between 0 and 1000 m, where it disappears, thus it is not a montane species. The implications of the presence of *Aeshna juncea* at a low altitude pond (230 m above sea level) are discussed." - 4875.** Olowo, J.P.; Chapman, L.J.; Chapman, C.A.; Ogutu-Ohwayo, R. (2004): The distribution and feeding ecology of the characid *Brycinus sadleri* in Lake Nabugabo, Uganda: implications for persistence with Nile perch (*Lates niloticus*). *African Journal of Aquatic Science* 29(1): 13-23. (in English). ["Coincident with a rapid increase in numbers of introduced predatory Nile perch (*Lates niloticus*) in lakes Victoria, Kyoga, and Nabugabo of east Africa was a dramatic decline in populations of many native fishes. However, a few species, including the characid *Brycinus sadleri*, have shown remarkable resilience. This study examined how the distribution and foraging behaviour of *B. sadleri* in Lake Nabugabo may facilitate their persistence with Nile perch. Both *B. sadleri* and Nile perch were most abundant in exposed areas offshore (20m) as opposed to wetland areas. However, we found evidence for a strong diel shift in activity and modest changes in the habitat use of *B. sadleri* that may contribute to persistence with Nile perch. In general, *B. sadleri* actively foraged during the daylight hours and remained quiet during the night. Nile perch began foraging during the early evening and were more active during the night than during the day. By early morning the proportion of full stomachs in Nile perch was low, though there was evidence of a low level of feeding activity during the day. Stomach contents of *Brycinus sadleri* indicated a shift from surface to benthic feeding as light levels increased, which appears to decrease their susceptibility to predation by Nile perch during the daylight hours." (Authors) The diet includes also Odonata.] Address: Chapman, Laureem, Department of Zoology, University of Florida, Gainesville, Florida 32611, United States of America. E-mail: lchapman@zoo.ufl.edu

4878. Parris, M.J.; Davis, A.; Collins, J.P. (2004): Single-host pathogen effects on mortality and behavioral responses to predators in salamanders (Urodela: Ambystomatidae). *Canadian Journal of Zoology* 82(9): 1477-1483. (in English, with French summary). ["Pathogens can alter host behavior and affect the outcome of predator-prey interactions. Acute phase responses of hosts (e.g., a change in activity level or behavioral fever) often signal an infection, but the ecological consequences of host behavioral changes largely are unexplored, particularly for directly transmitted (i.e., single-host) pathogens. We performed three experiments to test the hypothesis that a pathogen, *Ambystoma tigrinum* virus (ATV), alters host behavior of Sonoran tiger salamanders (*Ambystoma tigrinum* *stebbinsi* Lowe, 1954) and enhances predation. In the first experiment, salamander larvae exposed to ATV experienced 48% lower mortality from dragonfly *Anax junius* (Drury, 1773) larvae than those in controls. Second, uninfected and infected larvae exposed to the nonlethal (caged) presence of predators did not significantly differ in their distance from the predator. Infected salamanders significantly increased their activity level relative to those in controls in predator-free conditions. Finally, ATV-infected larvae preferred significantly warmer temperatures than uninfected larvae, but larvae reared at the thermal maximum for the virus all died. High host activity level yet retention of effective antipredator responses likely benefits ATV because this single-host pathogen relies on host survival for transmission. Preference for warmer temperatures may be associated with the host response to pathogens and may help fight infection."] (Authors)] Address: Parris, M., Dept Biol., Memphis State Univ., Memphis, TN, 38152, USA. 4884. Polhemus, D.A.; Englund, R.A.; Allen, G.R. (2004): Freshwater Biotas of New Guinea and Nearby Islands: Analysis of Endemism, Richness, and Threats. Final Report Prepared for: Conservation International, Washington, D.C. Bishop Museum Technical Report 31, Contribution No. 2004-004 to the Pacific Biological Survey: II, 62 pp. ["Effective conservation of regional biotas requires accurate information on the distribution, endemism, local richness, and taxonomic composition of species assemblages across multiple geographic scales. This is especially true in the Melanesian region, which contains ten percent of the world's biota on its numerous islands scattered across thousands of kilometers between Fiji and the Moluccas. Although certain important biotic components within this region, such as birds, have been reasonably surveyed, many others,

particularly freshwater organisms, remain poorly understood. To this end, a systematic survey program for freshwater fishes and invertebrates on New Guinea and nearby islands was undertaken over the last 10 years, involving an array of research organizations with long-standing interests in Melanesia, including the Bishop Museum, Smithsonian Institution, the Indonesian science ministry (LIPI), the Papua New Guinea National Museum and Gallery, and Conservation International. This work has also been augmented by partnerships with private sector entities operating in the region, most notably Chevron Niugini and P. T. Freeport Indonesia. These surveys have revealed previously unsuspected levels of species richness and endemism among New Guinea freshwater organisms, and the remarkable number of new species discovered during these surveys has also highlighted the fact that similar knowledge gaps and potentially similar levels of undocumented freshwater biodiversity remain through much of the rest of Melanesia beyond New Guinea. To the extent that they are now understood, Melanesian freshwater biotas appear to be characterized by foci of high endemism clustered around tectonic provinces within individual large islands, such as New Guinea, or on geologically allied groups of smaller islands, such as the Louisiades and Solomons. In lotic systems, such as streams and rivers, this endemism frequently displays a marked turnover in species elements along the length of individual catchments, linked to segregation of individual species by altitude, water temperature, substrate, bed profile and terminal reach salinity gradients. By contrast, lentic systems often harbor suites of localized endemic species centered around individual lakes or wetland complexes. Although known in a broad sense based on scattered collections made during the past 200 years and distributed among major museums, freshwater biotas of islands in the Melanesian region remain for the most part under-surveyed and poorly characterized taxonomically. Although the overall condition of freshwater ecosystems in the New Guinea region is currently excellent, there are obvious threats to the biota that tend to manifest themselves on local rather than regional scales. These threats may be grouped into three general categories: 1.) physical alteration of habitat; 2.) utilization of biotic resources, and 3.) invasive species. Threats from habitat alteration to freshwater ecosystems include but are not limited to industrial logging, shifting cultivation, oil palm plantations, mining, petroleum development, and hydroelectric schemes. Utilization of biotic resources such as the live aquarium fish trade or the harvest of native fish for food are deemed a much lower threat. While invasive species have not yet caused large-scale perturbations to freshwater systems they are a looming threat that is becoming increasingly problematic." (Authors) Numerous colour pictures of Odonata are included.] Address: www.bishopmuseum.org/research/pbs/pdf/ci-png.pdf

4885. Popova, O.N. (2004): Intraspecific taxonomy of *Sympetrum pedemontanum* (Müller, 1766) (Anisoptera: Libellulidae). *Odonatologica* 32(2): 207-216. (in English). ["An analysis of a large series of specimens from Eurasia showed a strong morphological variability. It is of an individual, modificatory, or clinal nature, rather than a geographical one. Thus, 2 continental subspecies, *S. p. intermedium* Belyshev, 1955 and *S. p. kurentzovi* Bely., 1956, should be suppressed as they cannot be defined by any taxonomically significant differences. The insular subspecies, *S. p. elatum*, inhabiting

Sakhalin, the Kurile and the Japanese islands, however, can be separated. It is concluded that *S. pedemontanum* has only 2 subspecies: continental *S. p. pedemontanum* and the insular *S. p. elatum*." (Author) The author outlines the correct authorship of the taxon being Müller, 1766, and not Allioni, 1766.] Address: Popova, O.N., Institut Sistemati i Zkologii Zhivotnykh, 630091 Novosibirsk, Ul. 4887. Reborá, M.; Piersanti, S., Gaino, E.; (2004): Visual and mechanical cues used for prey detection by the larva of *Libellula depressa* (Odonata Libellulidae). *Ethology, Ecology & Evolution* 16(2): 133-144. (in English). ["Cues used for the detection of prey by the larva of *Libellula depressa* (Odonata Libellulidae) were investigated. Nymphs (alive and recently dead) of the mayfly *Cloeon dipterum* (Ephemeroptera Baetidae) and dummies were used as prey models. The responses of the larva to stimulations of different kinds and intensity, in different areas around the body, were tested in the laboratory in six different behavioural experiments. From the statistical analysis of the data (Pearson Chi-square and one-way ANOVA) it emerged that: (i) chemical cues seem not to be involved in the detection of the prey or, if they are involved, they are negligible in comparison with other kinds of stimuli; (ii) the larva of *L. depressa* utilizes mechanical and visual cues for the release of the predatory labial strike, and either one of these cues is effective for labial strike elicitation; (iii) mechanical stimuli have a predominant role in predation; (iv) the larva of *L. depressa* can rely on a non-contact mechanical sense for the detection of the prey. The importance of mechanical and visual cues is discussed in relation to the pond bed habitat of this species." (Authors)] Address: Gaino, E., Univ. Perugia, Dipartimento Biol. 4890. Robinson, B.A. (2004): An Inventory of Aquatic Macroinvertebrates and Calculation of Selected Biotic Indices for the U.S. Army Atterbury Reserve Forces Training Area near Edinburgh, Indiana, September 2000 August 2002. Prepared in cooperation with the Indiana Army National Guard, Scientific Investigations Report 2004-5010, U.S. Department of the Interior, U.S. Geological Survey: 19 pp. (in English). ["At the request of the Indiana Army National Guard Environmental Protection Office, macroinvertebrate samples were collected by the USGS at 16 sites within the Camp Atterbury study area between September 2000 and August 2002. The data were combined, and duplicate and ambiguous taxa were removed to develop an inventory of macroinvertebrates in the streams at Camp Atterbury. This inventory and the taxonomic list produced for each site provide base-line data to evaluate environmental changes if future macroinvertebrate samples are collected at Camp Atterbury or if physical changes are made within or upstream from the study area. In this inventory, 173 distinct taxa have been identified; of those, 156 distinct taxa are from the Phylum Arthropoda. The orders with the greatest number of identified distinct taxa are Diptera, Coleoptera, Ephemeroptera, and Trichoptera. One of the species identified in the Camp Atterbury samples was *Cordulegaster maculata* Selys (a twin-spotted spiketail dragonfly). This species, while not listed as endangered or threatened at the State or Federal level, is recognized by IDNR as being rare enough to warrant special concern (Indiana Department of Natural Resources, 2002). Three biotic indices were calculated to evaluate what the macroinvertebrate data may indicate regarding surface-water-quality conditions at Camp Atterbury the Ephemeroptera, Plecoptera, Trichoptera Richness Index; the Hilsenhoff Biotic Index; and the Invertebrate Community Index. The composition of the macroinvertebrate community at a site is used in these indices to provide insight regarding surface-water quality. The Ephemeroptera, Plecoptera, Trichoptera Richness Index is a measure of the abundance of these three pollution-sensitive insect orders within a sample. The EPT values calculated for the macroinvertebrate samples collected at Camp Atterbury range from 5 to 15, with more than 75 percent of the values within the range of 7 to 11. The lowest value of 5 came from a qualitative sample collected at site A4 in 2002. This low value could be taken as an indicator of degraded water quality at this site compared to the other sites. At site A4, however, a Surber sample collected in 2000 produced an EPT value of 11, and a duplicate sample collected in 2002 produced an EPT value of 10. Therefore, the low value generated from the 2002 qualitative sample at site A4 seems to have resulted from natural variation within the macroinvertebrate community or the sampling and analysis process and may not be a true indicator of poor water quality. The Hilsenhoff Biotic Index evaluates surface-water quality at a site, using pollution-tolerance values of individual taxa identified in a sample. For Camp Atterbury, Hilsenhoff Biotic Index scores were calculated for the three artificial-substrate samples collected in 2002. Samples collected at sites A5 and B2 indicated fair water quality, whereas the sample collected at site B3 indicated poor water quality. The Invertebrate Community Index was developed to aid in the evaluation of surface-water-quality conditions at sites where artificial-substrate and qualitative macroinvertebrate samples have been collected. This index was applied to evaluate environmental conditions at the three sites where artificial-substrate samples were col-

lected in 2002. Results derived from samples collected at sites A5 and B2 indicate good water quality, whereas the Invertebrate Community Index score calculated for site B3 placed water quality between the good and fair categories. The Hilsenhoff Biotic Index score and the Invertebrate Community Index score calculated for site B3 indicate that water-quality conditions are slightly degraded. The calculated scores, however, simply may reflect the relatively small drainage area of this site compared to other sampling sites in the study area and that flow periodically approaches zero." (Author) 9 odonate taxa are listed in table 2] Address: <http://water.usgs.gov/pubs/sir/2004/5010/sir20045010.pdf>

4891. Rodrigo Fonseca, A.; Moreno Sanches, N.; Moisés Quintilhiano, D.; da Fonseca, M.C.; da Silva, E.S. (2004): Levantamento de espécies de Odonata associadas à tanques de piscicultura e efeito de *Bacillus thuringiensis* var. *israelensis* sobre ninfas de *Pantala flavescens* (Fabricius, 1798) (Odonata: Libellulidae). *Acta Scientiarum. Biological Sciences* Maringá 26(1): 25-29. (in Portuguese, with English summary). ["Odonata species survey associated with pisculture tanks and *Bacillus thuringiensis* var. *israelensis* effect on *P. flavescens* (Fabricius, 1798) nymphs. Several pisculture stations that deal with fingerlings or ornamental fishes rearing have presented some problems with larvae preying, post-larvae and fingerlings by Odonata Order insect nymphs. Thus, the aim of this work was to survey the Odonata species present in fish-raising tanks in two towns of the Midwest region of Minas Gerais, and also to evaluate the effect of *Bacillus thuringiensis* var. *Barjac israelensis* on *Pantala flavescens* nymphs (Fabricius, 1798) (Odonata: Libellulidae). Fortnightly collections were performed over a three month period. The adult insects were captured with entomological nets and the nymphs with fine mesh sieves, coupled to wooden handles. The captured nymphs were taken to the laboratory where they were individualized in 2L plastic foam boxes and sealed in its upper extremity with tulle. Soon after the adults emergence, they were killed, packed into envelopes and sent to be identified. The laboratory experiments were conducted in an acclimatized room at $25 \pm 2^\circ\text{C}$, RH of $70 \pm 10\%$ and 12-hour photophase. Second instar *P. flavescens* nymphs were packed individually into plastic foam boxes containing 500mL of chlorine free water each one. When they were in the third, fifth and seventh instars, they were treated with *B. thuringiensis* var. *israelensis* through the microbial product Vectobac® in granulate formulation. The product was directly applied to the rearing container water at the concentration denoted for the control of culicidae larvae, two superior concentrations, two inferior and also another one, where the product was not applied. The evaluations were done at 24, 48 and 72 hours after the product application, recording the dead insects number in each treatment. In both experiments, the nymphs were fed with Culicidae larvae and new-born fishes of the species *Poecilia cf. vivipara* Schneider, 1801. The following species were identified: *Ischnura fluvialis* Selys, 1876; *Aphylla theodorina* (Navas, 1933); *Brachymesia furcata* (Hagen, 1861); *Erythrodiplax fusca* (Rambur, 1842); *Miathyria marcella* (Selys, 1857); *Micrathyria almeidai* Santos, 1945; *Micrathyria hesperis* Ris, 1911; *Orthemis discolor* (Burmeister, 1839); *Perithemis moorma* Kirby, 1889 and *P. flavescens*. There were no significant microbial product effects on the studied species." (Authors)] Address: Rodrigo Fonseca, A., Fundação Educacional de Divinópolis Funedi, Universidade Esta-

dual de Minas Gerais, Centro de Pós-graduação e Pesquisa, Campus Universitário, s/nº, Jardim Belvedere II, 35500-970, Divinópolis, Minas Gerais, Brasil. E-mail alysson@funedi.edu.br

4892. Rödel, M.-O.; Rudolf, V.H.W.; Frohshammer, S.; Linsenmair, K.E. (2004): Life history of a West African tree-hole breeding frog, *Phrynobatrachus guineensis*, Guibe & Lamotte, 1961 (Amphibia: Anura: Petropedetidae). *Miscellaneous Publications Museum of Zoology University of Michigan* 193: 31-44. (in English). ["This article is based on field data gathered through the years 1999 to 2002 in Tai National Park, Ivory Coast. From May 2000 to September 2002 we monitored breeding sites on a nearly daily basis. In total we have 49,818 data sets covering 89 natural and 57 artificial breeding sites. *P. guineensis* occurs in primary rainforest and reproduces in water-filled tree-holes, fruit capsules and snail shells. Density of potentially suitable tree-holes ranged between 0 and 167 tree-holes per hectare in different parts of the forest. Breeding sites showed a clumped distribution and were situated exclusively in drier parts of the forest. Highest density of breeding sites used through a particular period was 23 per hectare. Water volume of oviposition sites ranged from 4 to 900 ml. Based on mark-recapture data, we calculated a mean population size of 49 reproducing males in an area of approximately five hectares. Breeding activity was highest during the rainy seasons and close to zero during drier parts of the year. Adult males had a total reproductive period of about one month. The longest interval from first to last capture was 193 days for a male, and 130 days for a female. Only 2.3% of known frogs survived the long dry season of about three months. Most males stayed only for a single day at a particular breeding site. The longest period that a male continuously remained at a breeding site was 23 days. We observed turnover rates of up to 75% in use of breeding sites between successive rainy seasons. Most often, only single males occupied a breeding site. However, occasionally up to six males shared the same hole. Territorial behavior was rarely observed among males. Adult frogs did not provide parental care. Mean clutch size was 18.7 eggs. Tadpoles hatched after five days, and larval development ranged from 15 to 28 days (mean 20.6 days). Mean tadpole density was 0.6 tadpoles/ml; the highest density was two tadpole s/ml. Mean tadpole mortality was 44.7%. Predation and desiccation accounted each for about one quarter of the mortality, the remainder was for unknown reasons. The presence of aquatic predators prevent *P. guineensis* from using larger tree-holes that are less prone to desiccation. When fly and dragonfly larvae were present, tadpole mortality raised to 75-100% per tree-hole." (Authors)] Address: Rödel, M.-L., Dept Anim. Ecol. & Trop. Biol. Bioctr., Univ. ["The strength of selection on immune function in wild populations has only been examined in a few vertebrate species. We report the results from a study measuring selection on a key insect immune enzyme, phenoloxidase (PO), in a wild population of the damselfly *Calopteryx xanthostoma*. We followed individually marked males from the pre-

reproductive adult phase and recorded their lifetime mating success. We found positive selection on PO activity in response to an immune insult, but no selection on wing-spot quality, a trait actively displayed to females during courtship. We suggest that positive selection on PO activity in the year of study may be explained by annual fluctuations in parasite loads." 4894. Rolff, J.; Meutter, F. van de; Stoks, R. (2004): Time constraints decouple age and size at maturity and physiological traits. *American naturalist* 164(4): 559-565. (in English). ["Life-history theory predicts changes in age and size at maturity in response to constraints in animals with complex life cycles. A critical underlying assumption is that only these traits are optimized during ontogeny. However, it is not clear how altered life histories mechanistically translate into survival and fecundity. Here we present data from damselflies reared from egg to adult under day lengths mimicking the start or end (time constrained) of the season at high and low food level. These data show that an important component of immunity is suppressed under time-constrained development as well as under low food conditions and that fat storage is affected only by food availability. Intriguingly, the physiological responses are partly decoupled from age and size at maturity, which indicates that the predictive value of traits such as age and size at maturity might well be restricted." 4895. Rowe, R.J. (2004): Agonistic behaviour in final-instar larvae of *Episynlestes cristatus*, *Synlestes tropicus* and *Chorismagrion risi* (Odonata: Synlestidae), and relationships within the 'Lestioidea'. *Australian Journal of Zoology* 52(2): 169-181. (in English). ["Larval agonistic displays are reported from three sympatric synlestid damselflies: *Episynlestes cristatus*, *Synlestes tropicus* and *Chorismagrion risi*. There were strong similarities between the species in the observed displays. Repertoires of all three species contained elements otherwise known only from larval Lestidae (conventionally interpreted as a member of the sister group to the Synlestidae). In night-time observations under infrared illumination different displays, some similar to those of coenagrionids, occurred. On the basis of similarities in larval displays I conclude that *Chorismagrion risi*, regarded on adult characters as an enigmatic form, is a member of the Synlestidae and that the Synlestidae and Lestidae are closely allied." 4898. Samways, M.J.; Taylor, S. (2004): Impacts of invasive alien plants on Red-Listed South African dragonflies (Odonata). *South African Journal of Science* 100(1): 78-80. (in English). ["This paper gives an overview of the threats to dragonflies (including damselflies) (Odonata), globally and nationally Red-Listed by the IUCN, in South Africa. All the globally Red-Listed species are endemic to South Africa. Invasive alien plants, especially Australian Acacia trees along water-courses, are by far the most important threat to these endemic species. Removal of the invasive alien trees is likely to increase considerably the prospects for the long-term survival of these species. In contrast, the nationally Red-Listed species that are not globally Red-Listed are threatened overall more by natural vagaries of weather than by invasive alien plants." 4900. Schilder, R.; Marden, J.H. (2004): A hierarchical analysis of the scaling of force and power production by dragonfly flight motors. *Journal of Experimental Biology* 207(5): 767-776. (in English). ["Maximum isometric force output by single muscles has long been known to be proportional to muscle mass^{0.67}, i.e. to muscle cross-sectional area. However, locomotion often requires a different muscle contraction regime than that used under isometric conditions. Moreover, lever mechanisms generally affect the force outputs of muscle-limb linkages, which is one reason why the scaling of net force output by intact musculoskeletal systems can differ from mass^{0.67}. Indeed, several studies have demonstrated that force output by intact musculoskeletal systems and non-biological systems is proportional to motor mass^{1.0}. Here we trace the mechanisms that cause dragonflies to achieve a change from muscle mass^{0.67} scaling of maximum force output by single flight muscles to mass^{1.0} scaling of dynamic force output by the intact dragonfly flight motor. In eight species of dragonflies, tetanic force output by the basalar muscle during isometric contraction scaled as muscle mass-

0.67. Mean force output by the basalar muscle under dynamic conditions (workloops) that simulated in vivo maximum musculoskeletal performance was proportional to muscle mass^{0.83}, a significant increase in the scaling exponent over that of maximum isometric force output. The dynamic performance of the basalar muscle and the anatomy of its lever, consisting of the second moment of area of the forewing (d_2) and the distance between the muscle apodeme and the wing fulcrum (d_1), were used to analyze net force output by the integrated muscle-lever system (Find). The scaling of d_2 conformed closely to the expected value from geometric similarity (proportional to muscle mass^{0.31}), whereas d_1 scaled as muscle mass^{0.54}, a significant increase over the expected value from geometric similarity. Find scaled as muscle mass^{1.036}, and this scaling exponent was not significantly different from unity or from the scaling exponent relating maximum load-lifting by flying dragonflies to their thorax mass. Thus, the combined effect of a change in the scaling of force output by the muscle during dynamic contraction compared to that during isometric contraction and the departure from geometric similarity of one of the two lever arm lengths provides an explanation for how mass^{1.0} scaling of force output by the intact musculoskeletal system is accomplished. We also show that maximum muscle mass-specific net work and power output available scale as mass^{0.43} and mass^{0.24}, respectively." 4901. Schilder, R.; Marden, J. (2004): Diabetic Dragonflies: hyperglycaemia and insulin response differences in *L. pulchella* dragonflies suffering from a protozoan gut parasite. *FASEB Journal* 18(4-5): Abst. 452.3.. (in English). ["We study the effects of a protozoan (gregarine) gut parasite on protein expression, metabolism and locomotory performance of *Libellula pulchella* dragonflies. Freshly caught parasitized *L. pulchella* males show significantly higher hemolymph glucose levels. This hyperglycaemia can also be induced in healthy individuals by exposing them to gregarine excretory / secretory (E/S) products. Our current working hypothesis is that the hyperglycaemia is induced by an immune-response driven insulin resistance in the flight muscles. Western blot analyses of p38-mitogen activated kinase (p38 MAPK), a protein involved in cell signaling during inflammatory responses of the immune system, show that it is chronically phosphorylated in flight muscles of parasitized individuals. Chronic activation of p38-MAPK has been shown to negatively affect insulin function in vertebrate skeletal muscle. Healthy dragonflies injected with insulin show a significant decrease in hemolymph glucose levels, while insulin treated parasitized individuals show a significant increase in hemolymph glucose levels. While the exact nature of the proposed insulin resistance needs further exploration, this host-parasite interaction shows a potential to become a model system to study possible causes and effects of type II diabetic phenotypes caused by inflammation." 4905. Sharifi, M.; Hemmati, Z. (2004): Variation in the diet of Mehely's Horseshoe Bat, *Rhinolophus mehelyi*, in three contrasting environments in western Iran. *Zoology in the Middle East* 33: 65-72. (in English). ["The diet of *R. mehelyi* was investigated through analysis of droppings collected from three maternity roosts in northern Zagros, mid-Zagros and the northern Mesopotamian plain. Moths (Lepidoptera) dominated in all areas (34.9-69.5% volume). The second most important food items in the northern Mesopotamian plain and the mid-Zagros are beetles (Coleoptera, 12.6-28.2% volume), while in northern Zagros Homoptera (16% volume) are

the next important food items. The diet of *R. mehelyi* in northern Zagros is characterized by a low proportion of Coleoptera (10%) and the presence of more diverse prey species (12 categories). In the northern Mesopotamian plain and in mid-Zagros, the food items consist mainly of lepidopteran and coleopteran species with fewer additional prey species. Species groups occurring only in the diet of Mehely's Horseshoe Bat in the northern Zagros are Odonata, Trichoptera, Dictyoptera and Acarina." (Authors)] Address: Sharifi, M., Fac. Sci Dept Biol., Razi Univ, Kermanshah, 67149, Iran. E-mail: sharifimozafar@hotmail.com]

4906. Shukla, A. N.; Shrivastava, S. (2004): Species diversity of macrozoobenthos: A tool for monitoring water pollution of Gandhisagar Reservoir, M.P., India. *Biological Memoirs* 30(1): 7-13. (in English). ["Limnological studies on Gandhisagar Reservoir (GSR) were undertaken during July 2001 to June 2003. Species diversity index of macrozoobenthos was applied for the monitoring of water pollution of the reservoir. Total 109 species of macrozoobenthos (including Odonata) were recorded. The number, however, varied at different study sites. The order of decrease in diversity index was Dam > Rampura > Basai. Further, it gradually decreased from shallower zone to deeper profundal zone. Low macrozoobenthic diversity was observed during rainy season, which may be due to pollution inputs of run-off water and a decline in dissolved oxygen and transparency. The diversity index was greater in summer months, which may be attributed to the breeding season in nutrient rich and oxygenated habitats. Thus, GSR may be designated as beta-mesosaprobic as it exhibits fluctuating pattern a feature of moderately polluted water." (Authors)] Address: Sch. Studies Zool. Limnol. and Environm. Biol. 4907. Simaika, J.P.; Cannings, R.A. (2004): *Lestes disjunctus* Selys and *L. forcipatus* Rambur (Odonata: Lestidae): Some Solutions for Identification. *J. Entomol. Soc. Brit. Columbia* 101: 131-139. (in English). ["Five species of the damselfly genus *Lestes* live in British Columbia, Canada, and of these, *Lestes forcipatus* Rambur and *L. disjunctus* Selys are the most similar and most difficult to separate morphologically. Females can be readily distinguished by the size of the ovipositor, but males are difficult to separate. In British Columbia, *L. disjunctus* is the more common, widespread and familiar species. Before 1998, *L. forcipatus* specimens were mistaken for those of *L. disjunctus* because the former is primarily an eastern North American species and because most *Lestes* species are usually identified using male characters. With the discovery that *L. forcipatus* is part of the western fauna, an evaluation of the relative status of the two species in British Columbia is necessary. The best method for separating the two species uses the length of the anterior lamina (part of the secondary genitalia) as a unique character or as part of ratios using other measurements. In addition, in at least western North America, *L. forcipatus* males are more pruinose than those of *L. disjunctus*, especially on the thorax. Identification using the pruinoscence pattern was tested in the field and is recommended as a simple and accurate method for western North America. Soaking Odonata specimens in acetone, a common technique used to preserve colours, damages surface pruinoscence and should not be used to preserve mature, pruinose adults, including those of *Lestes* spe-

cies. To identify *L. disjunctus* and *L. forcipatus* males treated in acetone, it may be necessary to calculate ratios based on various character measurements. Future research should investigate spatial and temporal differences between the species, as well as modes of interspecific communication." 4908. Sohni, V.; Finch, O.-D. (2004): Die Libellen eines regenerierten Restmoores in Nordwestdeutschland (Insecta: Odonata). *Drosera* 2004: 119-135. (in German, with English summary). ["Dragonflies of a regenerated bog relict in northwest Germany (Insecta: Odonata) We examined the odonate assemblages of 11 water systems situated within a protected remnant peat bog in the north-eastern part of Cloppenburg district, Lower Saxony in summer 2001. A total of 30 species was recorded, representing half of the species known to occur between the rivers Ems and Weser. 13 species (45%) are listed in the Red Data Books of either Germany and/or Lower Saxony. Two species, *Ceriagrion tenellum* and *Aeschna subarctica*, are listed as endangered, with the former being confirmed to reproduce within the study site. Species richness at the water systems ranged from 5 to 18 species per system. Besides high densities of eurytopic species like *Lestes sponsa* and *Pyrrosoma nymphula*, we found some stenotopic species confined to acidic bogs occurring in lower numbers. The number of bog specialists found in our study area is in concordance with the situation of other bogs in early stages of regeneration. Regeneration of the investigated bog was initiated by measures in 1988. Subsequent measures like the sealing of drainages increased the ratio of bog specialists vs. generalist species in the study area. The occurrence of *Ceriagrion tenellum* and *Aeschna subarctica* justifies taking measures in the future." 4909. Storfer, A.; White, C. (2004): Phenotypically plastic responses of larval tiger salamanders, *Ambystoma tigrinum*, to different predators. *Journal of Herpetology* 38(4): 612-615. (in English). ["Studies of prey responses to different predators are needed to investigate costs and benefits of particular antipredator responses and to unravel community-level effects on phenotypic plasticity. We reared laboratory-bred larvae of Arizona Tiger Salamanders, *Ambystoma tigrinum nebulosum* with either of two common predators, diving beetle larvae (*Dytiscus* sp.) or dragonfly naiads (*Anax junius*). Relative to controls, salamander larvae in both predator treatments had shorter snout-vent lengths and deeper tails; these differences may be related to increased swimming ability. In addition, larvae reared with dragonfly naiads had shorter tails than those reared with diving beetle larvae, possibly in response to different predator foraging strategies or differences in strength of selection imposed by each. Salamander larvae from predator treatments weighed less than controls, with salamanders reared with dragonflies weighing the least. This suggests that salamanders respond more strongly to dragonfly naiads than diving beetles and that dragonflies may be a more important predator. Thus, salamander larvae may distinguish between different predators, highlighting the utility of studying effects of multiple predators on phenotypic plasticity of prey." 4910. Strobbe, F.; Stoks, R. (2004): Life history reaction norms to time constraints in a damselfly: differential effects on size and mass. *Biological Journal of the Linnean Society* 83(2): 187-196. (in English). ["Optimality models predict that, under a time constraint, organisms should accelerate development, and preferably so by increasing growth rate, to keep size at emergence constant. Unfortunately, most tests did neglect genetic constraints and interchanged mass with body size which may explain mixed support for some of the models' predictions. We imposed time constraints on full sibling larvae of the damselfly *Enallagma cyathigerum* by manipulating day length regimes. Under a time constraint, larval development and growth rate based on size indeed were faster. This made it possible to keep size at emergence constant, despite the shorter development time. Interestingly, under a time constraint, growth rate based on mass was not increased and larvae had a lower mass at emergence. We see two reasons for this difference between body mass and size. First, size is fixed at emergence, while mass can still increase in many insects. Secondly, genetic constraints may have contributed to different responses for size and mass. In general, our results strongly suggest discriminating between size and mass when testing life history responses." 4911. Strong, K.F.; Robinson, G. (2004): Odonate communities of acidic Adirondack Mountain lakes. *Journal of the North American Benthological Society* 23 (4): 839-852. (in English). ["New York State's fauna is exceptionally rich in odonates, whose lengthy aquatic larval phases render them susceptible to effects of lake acidification, including the loss of fish. We used a collection of benthic macroinvertebrate samples taken by the Adirondack Lakes Survey Corporation to compare odonate communities in 460 lakes. Half were from the Adirondack Mountains, where acid neutralizing capacity (ANC) is low (mean ANC = 108.0 µg/L) and Al concentrations are high (mean Al = 111.61 µg/L), and half were from the Lower Hudson Valley, where ANC is significantly higher (mean ANC = 554.6 µg/L) and Al is significantly lower (mean Al = 0.049 µg/L). Many more lakes in the Adirondack lakes were fishless (52) compared to the lower Hudson (3), and the pH in Adirondack fishless lakes was an order of magnitude lower than the pH of Adirondack lakes with fish. Ninety-nine odonate taxa were identified (86 to species). In Adirondack samples, co-occurrence patterns were correlated with presence or absence of insectivorous fish and with acidic waters. Similar patterns were not apparent in Lower Hudson Valley samples. In Adirondack samples, richness of common taxa (found in 20 lakes) was higher in lakes with fish than in lakes without fish, regardless of pH. Loss of fish may enhance the top predator role of large larval dragonflies, causing change in odonate community structure, an interpretation consistent with previous research. Acidification of Adirondack lakes appears to promote a nonrandom subset of possible odonate communities, with negative implications for regional diversity." of Biological Sciences, State University of New York at Albany, 1400 Washington Avenue, Albany, New York 12222 USA. E-mail: klstrong@gw.dec.state.ny.us

4912. Sun, M.; Lan, S. (2004): A computational study of the aerodynamic forces and power requirements of dragonfly (*Aeshna juncea*) hovering. *Journal of Experimental Biology* 207(11): 1887-1901. (in English). ["Aerodynamic force generation and mechanical power requirements of a dragonfly (*A. juncea*) in hovering flight are studied. The method of numerically solving the Navier-Stokes equations in moving overset grids is used. When the midstroke angles of attack in the downstroke and the upstroke are set to 52degree and 8degree, respectively (these values are close to those observed), the mean vertical force equals the insect weight, and the mean thrust is approximately zero. There are two large vertical force peaks in one flapping cycle. One is in the first half of the cycle, which is mainly due to the hindwings in their downstroke; the other is in the second half of the cycle, which is mainly due to the forewings in their downstroke. Hovering with a large stroke plane angle (52degree), the dragonfly uses drag as a major source for its weight-supporting force (approximately 65% of the total vertical force is contributed by the drag and 35% by the lift of the wings). The vertical force coefficient of a wing is twice as large as the quasi-steady value. The interaction between the fore- and hindwings is not very strong and is detrimental to the vertical force generation. Compared with the case of a single wing in the same motion, the interaction effect reduces the vertical forces on the fore- and hindwings by 14% and 16%, respectively, of that of the corresponding single wing. The large vertical force is due to the unsteady flow effects. The mechanism of the unsteady force is that in each downstroke of the hindwing or the forewing, a new vortex ring containing downward momentum is generated, giving an upward force. The body-mass-specific power is 37 W kg⁻¹, which is mainly contributed by the aerodynamic power." (Authors)] Address: Sun, M., Inst. Fluid Mech., Beijing Univ. 4913. Svensson, E.; Kristoffersen, L.; Oskarsson, K.; Bensch, S. (2004): Molecular population divergence and sexual selection on morphology in the banded demoiselle (*Calopteryx splendens*). *Heredity* 93: 423-433. (in English). ["The importance of sexual selection in population divergence is of much interest, mainly because it is thought to cause reproductive isolation and hence could lead to speciation. Sexually selected traits have been hypothesized to diverge faster between populations than other traits, presumably because of differences in the strength, mechanism or dynamics of selection. We investigated this by quantifying population divergence in eight morphological characters in 12 south Swedish populations of a sexually dimorphic damselfly, the banded demoiselle (*Calopteryx splendens*). The morphological characters included a secondary sexual character, the male melanized wing spot, which has an important function in both inter- and intrasexual selection. In addition, we investigated molecular population divergence, revealed by amplified fragment length polymorphism (AFLP) analysis. Molecular population divergence was highly significant among these Northern European populations (overall $F_{st}=0.054$; pairwise population F_{st} 's ranged from ~0 to 0.13). We found evi-

dence for isolation-by-distance ($r=0.70$) for the molecular markers and a significant correlation between molecular and phenotypic population divergence ($r=0.39$). One interpretation is that population divergence for the AFLP loci are affected by genetic drift, but is also indirectly influenced by selection, due to linkage with loci for the phenotypic traits. Field estimates of sexual and natural selection from two of the populations revealed fairly strong sexual selection on wing spot length, indicating that this trait has the potential to rapidly diverge, provided that variation is heritable and the observed selection is chronic." 4917. Teplitsky, C.; Plenet, S.; Joly, P.; (2004): Hierarchical responses of tadpoles to multiple predators. *Ecology* 85(10): 2888-2894. (in English). ["The impact of multiple factors on the expression of phenotypic plasticity has been poorly studied. The simultaneous presence of factors inducing diverging responses may result either in a trade-off between the responses or in a hierarchy of responses. Inducible defenses offer a suitable model to investigate these alternatives. Inducible defenses evolve in response to variability in predation risk. Here, we investigated the impact of the nonlethal

presence of both pursuing (fish, *Gasterosteus aculeatus*) and sit-and-wait (dragonfly larvae, *Aeshna cyanea*) predators on tadpole morphology in two frogs (*Rana dalmatina* and *R. ridibunda*). Predation tests showed that *Aeshna* were the more dangerous of the two predators for the tadpoles of both species. In both species, induced responses differed according to predator type. In the presence of fish, tadpoles invested in both tail muscle depth and tail length. In the presence of dragonfly larvae, the investment was made in tail fin depth. When faced with the two types of predators simultaneously, the response was similar to that expressed in the presence of *Aeshna* alone, suggesting a hierarchy of response according to predation risk. Such a hierarchy of response could result from selection against the phenotype induced by the other predator" (Authors)] Address: Teplitsky, Celine, Dept Populat Biol, Evolut Biol Ctr, Norbyvagen 18D, SE-75236, Uppsala, Sweden. 4918. Tessier, C.; Cattaneo, A.; Pinel-Alloul, B.; Galanti, G. (2004): Biomass, composition and size structure of invertebrate communities associated to different types of aquatic vegetation during summer in Lago di Candia (Italy). *J. Limnol.* 63(2): 190-198. (in English). ["We compared the biomass, taxonomic composition, and size distribution of invertebrates (including Odonata) associated to emergent (*Schoenoplectus lacustris*), submerged (*Myriophyllum spicatum*), and floating leaved (*Trapa natans*) vegetation at two depths (surface and water column) during summer in Lago di Candia, Italy. Invertebrate biomass was positively related to epiphyton biomass (Chl-a). *M. spicatum* supported higher invertebrate biomass per unit of plant weight than *S. lacustris* whereas *T. natans* was somewhat intermediate. Depth did not affect invertebrate biomass significantly. Surface sections of *M. spicatum* and *T. natans* supported invertebrate communities with similar taxonomic composition dominated by oligochaetes and ostracods. Large hirudineans and gastropods characterized the communities on the water column sections of *M. spicatum*. *S. lacustris* and the water column sections of *T. natans* (composed of stems and aquatic roots) were supporting invertebrate communities dominated by copepod nauplii and lacking large organisms. Changes in aquatic vegetation in Lago di Candia following harvesting of *T. natans* and removal of submerged vegetation by the invasion of the rodent coypu (*Miocastor coypus*) may affect the invertebrate biomass of its littoral zone." (Authors)] Address: Cattaneo, Antonia, Département de Sciences Biologiques, Université de Montréal, C.P. 6128, succursale Centre Ville, Montréal, Québec, Canada H3C 3J7. 4919. Theischinger, G. (2004): Affinities and status of some genus-group taxa in Australian Gomphidae (Anisoptera). *Odonatologica* 33(4): 413-421. (in English). ["Relevant and mainly structural characters of *Austrogomphus* s. str., *Austroepigomphus* Fraser, *Pleio-gomphus* Watson, *Xerogomphus* Watson and *Zephyrogomphus* Watson, all considered by J.A.L. Watson (1991, *Invertebr. Taxon.* 5: 289-441) as subgenera of *Austrogomphus* Selys, are described and illustrated. On the basis of this information it is suggested that *Austroepigomphus* and *Zephyrogomphus* should be elevated to generic rank, that *Pleio-gomphus* should keep its position as a subgenus of *Austrogomphus*, and that *Xerogomphus* should be regarded as a subgenus of *Austroepigomphus*. Some morphological details of the

previously undescribed male of what is now *Zephyrogomphus longipositor* (Watson) are given." (Author)] Address: Theischinger G., 2A Hammerley Road, Grays Point, NSW 2232, Australia

4920. Thomas, A.L.R.; Bompfrey, R.J. (2004): Dragonfly flight: free-flight and tethered flow visualizations reveal a diverse array of unsteady lift-generating mechanisms, controlled primarily via angle of attack. *Journal of Experimental Biology* 207: 4299-4323. (in English). ["Here we show, by qualitative free- and tethered-flight flow visualization, that dragonflies fly by using unsteady aerodynamic mechanisms to generate high-lift, leading-edge vortices. In normal free flight, dragonflies use counterstroking kinematics, with a leading-edge vortex (LEV) on the forewing downstroke, attached flow on the forewing upstroke, and attached flow on the hindwing throughout. Accelerating dragonflies switch to in-phase wing-beats with highly separated downstroke flows, with a single LEV attached across both the fore- and hindwings. We use smoke visualizations to distinguish between the three simplest local analytical solutions of the Navier Stokes equations yielding flow separation resulting in a LEV. The LEV is an open U-shaped separation, continuous across the thorax, running parallel to the wing leading edge and inflecting at the tips to form wingtip vortices. Air spirals in to a free-slip critical point over the centreline as the LEV grows. Spanwise flow is not a dominant feature of the flow field spanwise flows sometimes run from wingtip to centreline, or vice versa depending on the degree of sideslip. LEV formation always coincides with rapid increases in angle of attack, and the smoke visualizations clearly show the formation of LEVs whenever a rapid increase in angle of attack occurs. There is no discrete starting vortex. Instead, a shear layer forms behind the trailing edge whenever the wing is at a non-zero angle of attack, and rolls up, under Kelvin Helmholtz instability, into a series of transverse vortices with circulation of opposite sign to the circulation around the wing and LEV. The flow fields produced by dragonflies differ qualitatively from those published for mechanical models of dragonflies, fruitflies and hawkmoths, which preclude natural wing interactions. However, controlled parametric experiments show that, provided the Strouhal number is appropriate and the natural interaction between left and right wings can occur, even a simple plunging plate can reproduce the detailed features of the flow seen in dragonflies. In our models, and in dragonflies, it appears that stability of the LEV is achieved by a general mechanism whereby flapping kinematics are configured so that a LEV would be expected to form naturally over the wing and remain attached for the duration of the stroke. However, the actual formation and shedding of the LEV is controlled by wing angle of attack, which dragonflies can vary through both extremes, from zero up to a range that leads to immediate flow separation at any time during a wing stroke." 4927. Trockur, B. (2004): Untersuchungen zur Habitatwahl von *Epitheca bimaculata* CHARPENTIER 1825. Dissertation zur Erlangung des Grades des Doktors der Naturwissenschaften am Institut für Naturschutz und Umweltbildung (INU) der Hochschule Vechta Dragonfly Research 2. ISSN 1438-034X: 291 pp. (in German, with English summary). ["The dissertation focuses on the

habitat selection of the Two-spotted Dragonfly *E. bimaculata* (Corduliidae). Important aspects of the chapter dealing with the faunistical-ecological and phenological data base are: comparison of the study sites in the Central Valley of the River Saar (esp. bayous, ponds) and the biosphere reserve Schorfheide-Chorin (small lakes), increase in the amount of newly detected occurrences in both study regions owing to an optimised and intensified search strategy, characteristics as a typical spring species (start of emergence in the first half of May) with a short emergence period and a flight period until the end of June/beginning of July, and relations between emergence and flight period and weather characteristics. The females select submersed habitat elements near the water surface in the open water of the breeding sites (floating leaf of plants such as *Nuphar lutea*, large areas with submersed plants, e.g. *Myriophyllum* spp., *Ceratophyllum* spp. and *Elodea canadensis*, reeds standing in the water, or woody debris) for the deposition of the egg strings containing more than 1,000 eggs. The analysis of the oviposition sites shows marked differences between the stem habitats. In several cases a repeated neighbouring, thus double concentrated oviposition took place and frequently it was observed on the edges of submersed vegetation just below the water surface. These parts of the water bodies used as oviposition sites are also primary triggers of habitat selection for mature males, because in most cases these males ready for reproduction use the same habitat elements for orientation within the territories, which are sometimes continuously occupied for several hours. Perching behaviour and thus habitat selection of the males can be influenced by strong wind, shadow by groves at the shoreline, or the presence of other dragonflies which occupy perching sites in a similar way and are dominant over *Epitheca*. The lack of an exact congruence of perching and oviposition sites is discussed as well as the potential correlation between differences in niche specialisation between younger and older larvae. Also, the frequently observed orientation of territorial males towards the edges of submersed vegetation is discussed. The behaviour in larval stages 1-3 is, above all, characterized by the selection of submersed, vertical habitat elements located near the water surface. Some weeks older larval stages switch to a predominantly or at least partially benthic and night-active life style. Special interest was paid to the documentation and analysis of emergence sites, and on habitat selection of the F-0-larvae, as indicated by the sites where the exuviae were found. For this purpose, quantitative, spatially precise documentation data taken over many years at the biggest population in the Saarland, the analysis of accumulations of exuviae (amount and extent), correlations between the finding sites of the exuviae and various habitat elements (positive correlation with *Nuphar lutea*) and the depth of the water bodies (negative to the maximal depth), and changes over the course of the six intensive study years are used. In addition to the comparison with other stem habitats, emergence substrates, distance from the shoreline and height of the emergence sites are treated. The duration of the larval period of usually two or three years was deduced from the analysis of potential sibling pools, the characteristics of pools of exuviae found within very short distance of each other, and the often both highly stenotope and synchronized behaviour of the emergent F-0-larvae are taken into account as well. In a comprehensive, synecological synopsis, different hypotheses about the ecological requirements of the

species are developed and discussed. In this context, the population ecological view of the known occurrences in reference to the mobility and dispersal ability is taken into consideration. Aspects of stenotopy and synchronisation are evaluated and compared with other species. The observed behaviour and the habitat selection are related to the visually identifiable habitat factors. The role of potentially effective ultimate factors in the water body is discussed. The availability of vertical habitat element near the surface and the ecological conditions in the fish dominated biocoenosis are found to be the most important factors. The negative biotopes and the observed effects of changes or systematic manipulations of the habitat configuration at some occurrences are included into these considerations. The special role of fish and the ecological adaptation of the *Epitheca* larvae to the fish-dominated biotope, the ecological comparison and the syntopy with *Leucorrhinia caudalis* and *Cordulia aenea* are discussed in the context of the synecological demands of the species. Subsequently, a new classification, exceeding the common classification of the occurrences in stem-, secondary- and male-habitats, is proposed, and the different metapopulation levels and a promising search strategy are discussed. In a separate chapter about aspects of nature conservation, the current classification in the Red List of Germany (endangered), the proposal to include the species in a nation-wide monitoring programme, the high diversity of dragonflies at the *Epitheca* waters, the function as an indicator species, the coexistence with other species, threat factors and components of the management of the species and a protection concept are treated." (Author)] Address: Trockur, B., Schulstr. 4, D-66636 Tholey-Scheuern, Germany. E-mail: Bernd-Trockur@gmx.de

4928. Ueda, T.; Kinoshita, E.; Ishihara, K. (2004): Habitat use by the Tiny Dragonfly, *Nannophya pygmaea* RAMBUR, and conservation of its habitat in a hillside marsh. *Japanese Journal of Conservation Ecology* 9: 25-36. (in Japanese, with English summary). ["To propose conservation plans for *N. pygmaea*, we investigated its habitat use in a paddy field at the bottom of a valley in the hill country around Kanazawa City, Ishikawa Prefecture, Japan. The field, which had an area of 1200 m² and was located at the top of a terraced paddy field, was plowed every spring but was not used for rice cultivation. There were four plant communities, corresponding to varying water levels on the ground, which was plowed annually. One of the four communities, which included annual plants, extended along the spring-fed hillside outside of the plowed area. Mature males primarily occupied Communities 1 and 2, and immature males and females were distributed in other terrestrial parts. The distribution of mature males was relatively similar, especially in Community 2, across the years investigated. Although emergence occurred in Community 2 every year, in Community 1, it was observed in 2002, but not in 2001 and may not in 2003. This yearly difference corresponded to the precipitation observed during the previous summer. Thus, the emergence from Community 1 may reflect larval survival, which probably depended on the degree and length of the dry period in relation to precipitation. Individuals that seemed to have dispersed from the paddy population were seen in several fallow fields up to 1.5 km away from the paddy. Based on these results, we considered *N. pygmaea* to be an opportunistic species that has adapted to small temporary marshes. We propose a con-

servation plan for *N. pygmaea* that incorporates creating biotope networks by plowing abandoned paddy fields." (Authors)] Address: Ueda, T., Ishikawa Agricultural College, Suematsu, Nonouchi, Ishikawa Pref., 921, Japan. E-mail: ueda@ishikawa-c.ac.jp

4929. Uzarski, D.G.; Burton, T.M.; Genet, J.A. (2004): Validation and performance of an invertebrate index of biotic integrity for Lakes Huron and Michigan fringing wetlands during a period of lake level decline. *Aquatic Ecosystem Health & Management* 7(2): 269-288. (in English). ["Our goal was to develop an invertebrate-based index of biotic integrity that was robust to water level fluctuations and applied to broad classes of lacustrine wetlands across wave-exposure gradients. Our objectives were to evaluate the performance and test the robustness of our preliminary index (e.g., Burton et al., 1999) at a range of water levels, eliminate any problems with the index of biotic integrity, remove the preliminary status, test the index on similar wetlands of Lake Michigan, and establish stressor: ecological-response relationships. Twenty-two sites, both open- and protected-fringing lacustrine marshes of Lake Huron and Michigan were selected for study. Correspondence analysis and Mann-Whitney U tests were used to test the robustness of existing metrics and search for additional metrics. Wilcoxon Signed Rank tests were used to determine if metrics were responding to inter-annual water level fluctuation. Principal components analysis and Pearson correlations were used to establish stressor: ecological response relationships. Analyses confirmed the utility of most of the metrics suggested in our preliminary index, but we recommended several improvements. With improvements, the index was able to place all sites in a comparable order of disturbance that we placed them a priori based on adjacent landuse/landcover, limnological parameters and observed disturbances. The improved index worked very well from 1998 through 2001 despite the substantial decreases in lake level over this time-period. Analyses of 2001 data collected from similar fringing wetlands along the northern shore of Lake Michigan suggested that the index could also be used for fringing wetlands of northern Lake Michigan. We are confident that our index is ready for implementation as a tool for agencies to use in assessing wetland condition for Lakes Huron and Michigan fringing wetlands." (Authors) The index includes Odonata. 4932. von der Ohe, P.C.; Liess, M. (2004): Relative sensitivity distribution of aquatic invertebrates to organic and metal compounds. *Environmental Toxicology & Chemistry* 23(1): 150-156. (in English). ["In the field, a multitude of species can be exposed to numerous toxicants; thus, the sensitivity of individual species to particular toxicants must be known to predict effects and to analyze changes in species composition. For most species, no information about their toxicant sensitivity is available. To address this limitation, we have grouped the available information to assign sensitivities to aquatic invertebrate taxa relative to *Daphnia magna*. With respect to organic compounds, most taxa of the orders Anisoptera, Basommatophora, Coleoptera, Decapoda, Diptera, Ephemeroptera, Eulamellibranchiata, Heteroptera, Hirudinea, Isopoda, Oligochaeta, Prosobranchia, Trichoptera, Tricladida, and Zygoptera are less sensitive than *D. magna*. Some taxa of the Amphipoda, Plecoptera, and Cladocera (other than *D. magna*) are significantly more sensitive. For organic compounds, approximately 22% of the investigated taxa were more sensitive than *D. magna*. Most taxa of the orders Amphipoda, Basommatophora, Diptera, Ephemeroptera, Eulamellibranchiata, Heteroptera, Isopoda, Oligochaeta, and Tricladida are significantly less sensitive than *D. magna* to metal compounds. The taxa belonging to the Crustacea, with the exception of the order Isopoda, are much more sensitive. For metal compounds, approximately 30% of the investigated taxa were more sensitive than *D. magna*. Hence, *D. magna* is among the most sensitive taxa regarding both groups of toxicants. The sensitivities for several taxa are listed, and use of the relative sensitivity distribution to link toxicant effects in mesocosm studies and field investigations is discussed." (Authors)] Address: Dept Chemical Ecotoxicology, UFZ Centre for Environmental Research, Permoserstr. 15, 04318, Leipzig, Germany. E-mail: peter.vonderohe@ufz.de

4933. Wakakuwa, M.; Ozaki, K.; Arikawa, K. (2004): Immunohistochemical localization of Papilio RBP in the eye of butterflies. *Journal of Experimental Biology* 207 (9): 1479-1486. (in English). ["We recently identified a novel retinoid binding protein, Papilio RBP, in the soluble fraction of the eye homogenate of the butterfly *Papilio xuthus*, and demonstrated that the protein is involved in the visual cycle. We now have localized the protein in the Papilio eye by light and electron microscopic immunohistochemistry using a monospecific antiserum produced against artificially expressed Papilio RBP. We found strong immunoreactivity in the primary as well as secondary pigment cells and in the tracheal cells. The pigment cells have long been regarded as an

important site of the visual cycle, and this view is further supported by the present result. Interestingly, the cytoplasm and nuclei of these cells were equally labeled, indicating that the protein exists in both the cytoplasm and the nucleus. We conducted a survey for the existence of the Papilio RBP-like proteins in other insects including several species of butterflies, dragonflies, cicadas, grasshoppers and honeybees. Anti-Papilio RBP immunoreactivity was confirmed in the proteins isolated only from butterflies belonging to the superfamily Papilionoidea and not from other species. In all insects tested, however, fluorescing proteins were clearly detected, suggesting that these insects also have similar retinol-binding proteins." (Authors)] Address: Arikawa, K., Grad. Sch. 4934. Wang, Z.J. (2004): The role of drag in insect hovering. *Journal of Experimental Biology* 207(23): 4147-4155. (in English). ["Studies of insect flight have focused on aerodynamic lift, both in quasi-steady and unsteady regimes. This is partly influenced by the choice of hovering motions along a horizontal stroke plane, where aerodynamic drag makes no contribution to the vertical force. In contrast, some of the best hoverers - dragonflies and hoverflies - employ inclined stroke planes, where the drag in the down- and upstrokes does not cancel each other. Here, computation of an idealized dragonfly wing motion shows that a dragonfly uses drag to support about three quarters of its weight. This can explain an anomalous factor of four in previous estimates of dragonfly lift coefficients, where drag was assumed to be small. To investigate force generation and energy cost of hovering flight using different combination of lift and drag, I study a family of wing motion parameterized by the inclined angle of the stroke plane. The lift-to-drag ratio is no longer a measure of efficiency, except in the case of horizontal stroke plane. In addition, because the flow is highly stalled, lift and drag are of comparable magnitude, and the aerodynamic efficiency is roughly the same up to an inclined angle about 60degree, which curiously agrees with the angle observed in dragonfly flight. Finally, the lessons from this special family of wing motion suggests a strategy for improving efficiency of normal hovering, and a unifying view of different wing motions employed by insects." 4938. Xylander, W.E.R.; Bender, J. (2004): Animal species and zoocoenoses of former open cast lignite mines in Eastern Germany - Aspects of mining, reclamation and conservation. *Peckiana* 3: 155-165. (in English). ["The importance of lignite mine sites for conservation in eastern Germany is considered on the basis of zoological data from terrestrial and aquatic habitats. This importance results from high species richness (e. g. dragonflies, carabid beetles) in few cases, but chiefly from secondary habitats for endangered xerophilic and psammophilic species that occur mainly on sites of early successional stages (e.g. amphibia, reptilia, birds, grasshoppers). These species (many of which are listed in the national or federal Red Data books) have become extinct in other areas due to prevention of landscape dynamics, whereas the impacts of lignite mining constitute the dynamics these species need; this is the major importance of mine sites for conservation. Dynamics, however, stops when mining activity finishes and succession proceeds; succession leads to habitat changes, resulting in many cases in the extinction of the most valuable species for conservations whereas others - less important from a conservational point of view - come up; zoological examples are given for this process. On the other hand reclamation and post-mining activities themselves may have impacts on valuable habitats and species. How reclamation is done and what targets are finally realised depend on different types of decisions; the motivation and consequences for conservation of such decisions are discussed." 4939. Yamauchi, M.M.; Miya, M.U.; Nishida, M. (2004): Use of a PCR-based approach for sequencing whole mitochondrial genomes of insects: two examples (cockroach and dragonfly) based on the method developed for decapod crustaceans. *Insect Molecular Biology* 13(4): 435-442. (in English). ["Recent development of a PCR-based approach for sequencing vertebrate mitochondrial genomes has attracted much attention as being more rapid and economical than traditional methods using cloned mtDNA and primer walking. Such a method has not been available for insect mitochondrial genomes, despite widespread use of them for the molecular phylogenetic, biogeographical and population genetic markers. A recently developed PCR-based approach for sequencing whole mitochondrial genomes of decapod crustaceans, which included the design of

many versatile PCR primers for the latter, was applied with the same primers sets to mitochondrial genomes of two insects, smokybrown cockroach *Periplaneta fuliginosa* (Serville, 1839) and skimmer dragonfly *Orthetrum triangulare melania* (Selys, 1883). Almost the entire region of the two mitochondrial genomes was successfully sequenced. Features of the two mitochondrial genomes are described and the usefulness of this PCR-based approach for sequencing insect mitochondrial genomes demonstrated." ["As well as being one of the most densely populated areas on Earth, Hong Kong also has the highest percentage of protected areas (38% of the 1098 km² land area) of any administrative region in the Asia Pacific. Overlay of field records from a biodiversity survey of eight taxa (amphibians, reptiles, mammals, breeding birds, ants, butterflies, dragonflies and rare vascular plants) in 1 km grid squares with protected areas indicated that over half of the 623 species of conservation concern (globally, regionally, or locally restricted species) were under-represented. Ants, butterflies and reptiles were most poorly represented. The hotspots of different taxa also received differing levels of protection. Hong Kong's protected areas are biased towards high-altitude habitats, so the under-represented species are mostly associated with the lowland habitats (freshwater wetlands, abandoned agriculture and feng shui woods). Since the restricted species are scattered and the hotspots of different taxa do not overlap, a large protected area network will be required to represent all species. This indicates the challenge that will be encountered in the conservation of many other parts of Asia that support burgeoning human populations, and where landscapes are increasingly human-dominated." 4943. Yurewicz, K.L. (2004): A growth/mortality trade-off in larval salamanders and the coexistence of intraguild predators and prey. *Oecologia* 138(1): 102-111. (in English). ["Behavioral and morphological traits often influence a key trade-off between resource acquisition and vulnerability to predation, and understanding trait differences between species can provide critical insight into their interactions with other species and their distributions. Such an approach should enhance our understanding of the criteria for coexistence between species that can interact through both competition and predation (i.e. intraguild predators and prey). I conducted a common garden experiment that revealed strong differences between three guild members (larval salamanders *Ambystoma laterale*, *A. maculatum*, and *A. tigrinum*) in behavior, morphology, and growth in the presence and absence of a shared top predator (the larval dragonfly *Anax longipes*). All three species also reduced their activity and modified their tail fin depth, tail muscle length, and body length in response to non-lethal *Anax*. Species that act as intraguild predators were more active and could grow faster than their intraguild prey species, but they also suffered higher mortality in laboratory predation trials with *Anax*. I also used survey data from natural communities to compare the distribution of *Ambystoma* species between ponds differing in abiotic characteristics and predatory invertebrate assemblages. An intraguild prey species (*A. maculatum*) was found more reliably, occurred at higher densities, and was more likely to persist late into the larval period in ponds with more diverse invertebrate predator assemblages. Taken together, these results indicate that top predators such as *Anax* may play an important role in influencing intraguild interactions among *Ambystoma* and ultimately their local distribution patterns." 4948. Anonymus (2005): Wild Corner. Porcupine 32: 25. (in English). [The feature "Wild Corner" presents some interesting sightings in Hong Kong. The following observations on Odonata are presented: "Pseudagrion microcephalum laying eggs at a rehabilitated freshwater pond of Mai Po Nature Reserve. One *Macrodiplax cora* was seen at Luk Keng marsh (near mangrove) on 29 September, and both sexes of this species were seen at Mai Po throughout October. *Gynacantha subinterrupta* was seen at Mai Po on 10 November and 5 December (both were male individuals)."]

4949. Block, M. De; Stoks, R (2005): Pond drying and hatching date shape the tradeoff between age and size at emergence in a damselfly. *Oikos* 108(3): 485-494. (in English). ["The trade off between age and size at emergence, which plays a central role in life history theory, is hypothesized to be more pronounced under stressful conditions, especially when these conditions are combined. Empirical evidence for this is equivocal. We tested the hypothesis by imposing combinations of two types of time stress (pond drying and late hatching date) in larvae of the damselfly *Lestes viridis*. Larvae from a temporary pond and a permanent pond population were reared in outdoor tubs from egg hatching until emergence. Unexpectedly, larvae did not accelerate their life history in response to simulation of pond drying. Instead, larvae reared in temporary tubs generally had a slower development and growth than larvae reared in permanent tubs. Probably deteriorating growth conditions in temporary tubs associated with higher densities and lower food levels caused this pattern. In agreement with a higher time stress in late hatched larvae, they generally had faster development and growth than larvae that hatched early in the season. Drying regime and hatching date shaped the covariation pattern between age and size at emergence, but the tradeoff was only apparent when time stress was relaxed. The tradeoff between age and size at emergence was only present in early hatched larvae, especially in permanent tubs (lowest time stress). Conversely, in late hatched larvae there was a strongly negative relationship between age and size at emergence, especially in temporary tubs (highest time stress). Our results support an alternative hypothesis that deteriorating growth conditions (i.e. pond drying) may decouple the tradeoff under time stress. The absence of a tradeoff in more time-stressed late hatched larvae can be explained by their higher intrinsic growth rates, independent of deteriorating growth conditions. We hypothesize that the pattern of less clear tradeoffs under the imposed types of time stress may be general." 4951. Bönsel, A. (2005): Ökologische Analyse der Libellen- und Heuschreckentaxozönosen (Odonata & Saltatoria) in nordostdeutschen Regenmooren und deren Umgebung - als Grundlage zur Entwicklung von Landschaftsplanungszielen. *Rostocker Materialien für Landschaftsplanung und Raumentwicklung* 6: 129 pp. (in German, with English summary). ["The first hypothesis, that in the beginning of the 21st century, disturbed rain bogs in the young moraine landscape of North-Eastern Germany are more rich in structures and species than the surrounding cultivated landscape, could be verified in this ecological analysis. 96 sites were sampled for dragonflies, 46% of which were located in rain bogs and 54 % in the surrounding cultivated landscape. Sampling for grasshoppers was conducted at 76 sites, 41 % in rain bogs and 59 % in the surrounding landscape. 37 vegetation types were mapped, on average 12 of these

occurred in rain bogs and 16 in the surrounding cultivated landscape. Disturbed rain bogs are structure-rich habitats with a closely interlocking mosaic of different ecological conditions. 35 species of dragonflies with altogether 6318 individuals, and 21 species of grasshoppers with altogether 4486 individuals could be proven. In disturbed rain bogs, more species and, above all, more individuals of dragonflies and grasshoppers were found than in the surrounding landscape. A comparison of diversity values between disturbed rain bogs and the surrounding landscape using the SHANNON-WEAVER-Index didn't show significant differences for dragonflies and grasshoppers. A comparison of larger landscape units with such indices was not of additional value, since species and individuals were not homogeneously distributed in space. No species of dragonflies or grasshoppers could be assigned to a single category of dominance over all sampling sites; the same is true for species' constancy. Frequent high abundances of individuals were reached only by highly constant species, and mainly in disturbed rain bogs. Species turnover was higher for dragonflies and grasshoppers in the surrounding landscape than in rain bogs in both years of the study, though only for dragonflies the difference was significant. Species turnover in 73 years was calculated and structural diversity was compared between historical and actual times using the work of RABELER (1931) on the „Göldenitzer Moor". In this disturbed rain bog, RABELER counted 16 vegetation types, whereas in this study 23 vegetation types were found. This difference can be used to explain species turnover rates of 32 % in dragonflies and 61 % in grasshoppers. It became clear, that today man is the dominating ecological factor, determining species richness and species poverty in the young moraine landscape of North-Eastern Germany. By extensive agrarian land use, he creates extensive landscapes poor of species and individuals, whereas in originally species-poor rain bogs, he creates habitats rich in species and individuals by changing intensities of disturbance. Most species of dragonflies showed highest abundances in eutrophic waters, grasshoppers in oligotrophic sites, and both taxa in sites with moderate disturbance intensity. It is assumed, that under those conditions interlocking of ecological conditions is optimal for all ontogenetic stages. Coincidences between presence of dragonflies or grasshoppers and vegetation type or other ecological factors could not be proven for any species, this verifying the second hypothesis. For verification of the third hypothesis, saying that species diversity on terrestrial islands such as disturbed rain bogs is less determined by area, but by duration of existence of preferred conditions and by presence of constant species with high abundances, this work gives clear indications. Abundant species might be decimated by predators and/or parasites, thereby enabling their existence. Intraspecific competition causes dismigration of numerous individuals, though resources do not have to be depleted. Specialized species can unfold undisturbed in such habitats and fill their niches completely, therefore disabling even ubiquitous species to invade them. According to the latest amendment of the Federal Law of Nature Conservation, landscape planning was assigned two completely new functions. An European network of protected areas is to be developed for sustainable conservation of Middle-European biodiversity by planning. Based on data from environmental observation, a report on the success of the employed means is to be delivered in regular intervals. From the results of this work can be derived, that

conservation of biodiversity is not necessarily combined with the development of a network of protected areas. The actual sense of the network should be understood as development of a net of ecotope mosaics, an interlocking of different ecological conditions, micro- and mesoclimata, different trophic level and disturbance intensities that are representative for a landscape unit. In future, instead of rare species and vegetation types, sites with high abundances of constant species should be criteria for conservation areas or linking biotopes. The widespread habit of focussing on rare species should be changed, since most rare species have always been rare - rareness is a natural evolutionary phenomenon. In future, landscape planning should try to link its aims with those of other planning disciplines, in order to e.g. integrate moderate disturbances within different landscape units. Overall structures with moderate disturbances occurring at regular intervals could be created by provision of areas at transition zones between different forms of land use. For those, landscape planning could develop specific measures of maintenance and development in accordance with edaphic conditions and in coordination with land owners and -users. By a restriction of planning to specific measures of revitalisation for the small number of conservation areas, and otherwise allowing succession, high costs for the maintenance of decentred conservation areas could be avoided. Extended hydrological buffer zones around intact and revitalized rain bogs lead to permanently high water levels, creating a mosaic of different stages of succession and thereby enabling existence of numerous species and, particularly, individuals. If Middle-European biodiversity is to be preserved, landscape planning will have to concentrate on area-wide measures in the long term, since this diversity is a product of land use in the Middle-European cultivated landscape. Agricultural politics and agrarian legislation will have to be altered fundamentally for realization of these aims; otherwise agriculture will stay the evident originator for losses of habitat- and species diversity." ["Species distributional limits may coincide with hard dispersal barriers or physiological thresholds along environmental gradients, but they may also be influenced by species interactions. We explore a number of models of interspecific interactions that lead to (sometimes abrupt) distribution limits in the presence and absence of environmental gradients. We find that gradients in competitive ability can lead to spatial segregation of competitors into distinct ranges, but that spatial movement tends to broaden the region of sympatry between the two species, and that Allee effects tend to sharpen these boundaries. We generalize these simple models to include metapopulation dynamics and other types of interactions including predator/prey and host-parasite interactions. We derive conditions for range limits in each case. We also consider models that include coevolution and gene flow and find that character displacement along environmental gradients can

lead to stable parapatric distributions. We conclude that it is essential to consider coevolved species interactions as a potential mechanism limiting species distributions, particularly when barriers to dispersal are weak and environmental gradients are gradual." 4955. Clausnitzer, V.; Dijkstra, K.-D. (2005): The dragonflies (Odonata) of Ethiopia, with notes on the status of endemic taxa and the description of a new species. *Entomologische Zeitschrift* 115(3): 117-130. (in English, with German summary). ["In March 2004 the authors undertook a survey of Odonata in the highlands of central and southwest Ethiopia, as well as along some Rift Valley lakes. The endemic species were the main target, as almost no information other than descriptions existed. Some type localities were visited, as were other habitats, to gather information on the species' distribution, habitat requirements and conservation status. 29 sites were sampled and 69 species recorded. Of 11 known endemics, 9 were found, all at sites other than their type localities. One new species assumed to be endemic was found, and is described as *Paragomphus crenigomphoides* sp. nov. A revised checklist of Ethiopian Odonata is presented: 96 species have been reliably recorded. *Ischnura hilli* Pinhey, 1964 and *Enallagma caputavis* Terzani & Carletti, 1998 are considered synonyms of *I. abyssinica* Martin, 1907 and *Pseudagrion niloticum* Dumont, 1978 respectively. The taxonomy and nomenclature of an undescribed *Aeshna* species (near *A. meruensis* Sjöstedt, 1909 and *A. yemenensis* Waterston, 1985), *Notogomphus ruppeli* (Selys, 1857) (frequently spelt as *N. rueppeli*) and *Orthetrum kollmannspergeri* Buchholz, 1995 (probably confused with Asian *O. taeniolum* (Schneider, 1845)) are discussed. Ethiopia's odonate fauna is compared with that of other East African highlands: It is impoverished (especially forest species) but rich in endemics." - 4957.** Cordoba-Aguilar, A. (2005): Possible coevolution of male and female genital form and function in a calopterygid damselfly. *Journal of Evolutionary Biology* 18(1): 132-137. (in English). ["In this paper some evolutionary changes of genitalia in the damselfly *Calopteryx haemorrhoidalis* are investigated by determining their current and past function. *Calopteryx haemorrhoidalis* males stimulate females by aedeagal frictioning on a set of vaginal sensilla. The aedeagus is considerably variable and positively correlates with volumes of ejected sperm from the spermatheca. Interestingly, females show a significantly reduced sensillum number compared with other family members. Here I explore whether there existed directional selection for aedeagal width at its evolutionary onset; and whether the sensillum reduction evolved to make sperm ejection less effective. Using *C. haemorrhoidalis* aedeagi in females whose species retained the ancestral conditions (no stimulatory ability and large sensillum numbers), *Hetaerina cruentata* and *C. xanthostoma*, my results corroborated these assumptions: variation in aedeagal width inversely correlated with sperm ejection rate while sperm ejection was higher in species with high sensillum numbers. A suggested coevolutionary interpretation of these results in *C. haemorrhoidalis* is that aedeagal width was favoured which was followed by a sensillum reduction." - 4958.** De Block, M.; Stoks, R. (2005): Fitness effects from egg to reproduction: bridging the life history transition. *Ecology* 86(1): 185-197. (in English). ["Although complex life cycles are widespread, we know little about how constraints in the larval stage influence adult fitness. Most models assume a tight coupling of larval conditions and adult fitness through size and timing of the life history transition. However, there are few empirical tests of this assumption. We combined an experimental manipulation of larval environment with a subsequent study of adult fitness, measured as lifetime mating success. Individuals of the damselfly *Lestes viridis* were followed from the egg stage to adult reproduction and death. Under time constraints, emergence occurred earlier, but in late-hatched larvae, this did not result in a lower size. Under nutritional constraints, emergence occurred later, and size was reduced. Variation in survival to maturity was better explained by larval constraints than by emergence traits, whereas both larval constraints and emergence traits explained variation in life-

time mating success. Sexes reacted differently to larval constraints, and the coupling of larval constraints to adult fitness also was sex specific. Our results indicate that larval constraints do not necessarily carry over to adult fitness through size and timing of transition, and that carryover effects may be sex specific. This may explain the existence of hidden costs that become visible after maturation and may explain part of the unexplained variation in selection studies on adults." 4960. Dmitriew, C.; Rowe, L. (2005): Resource limitation, predation risk and compensatory growth in a damselfly. *Oecologia* 142(1): 150-154. (in English). ["Periods of poor nutrition during early development may have negative fitness consequences in subsequent periods of ontogeny. In insects, suppression of growth and developmental rate during the larval stage are likely to affect size and timing of maturity, which in turn may lead to reduced reproductive success or survivorship. In light of these costs, individuals may achieve compensatory growth via behavioural or physiological mechanisms following food limitation. In this study, we examined the effects of a temporary period of food restriction on subsequent growth and age and size at maturity in the larval damselfly *Ischnura verticalis*. We also asked whether this temporary period of reduced nutrition affected subsequent foraging behaviour under predation risk. *I. verticalis* larvae exposed to a temporary food shortage suffered from a reduced growth rate during this period relative to a control group that was fed ad libitum. However, increased growth rates later in development ensured that adult body size measurements (head and pronotum widths) did not differ between the treatments upon emergence. In contrast, adult dry mass did not catch up to that of the controls, indicating that the increased growth rates for size dimensions occur at the cost of similar gains in mass. Predators reduced foraging effort of larvae, but this reduction did not differ between control larvae and those previously exposed to poor nutrition." 4961. Ellenrieder, N. von; Garrison, R.W. (2005): Case 3294: *Gynacantha Rambur, 1842* and *Triacanthagyna Selys, 1883* (Insecta, Odonata): proposed conservation of usage by designation of *Gynacantha nervosa Rambur, 1842* as the type species of *Gynacantha*. *Bulletin of Zoological Nomenclature* 62(1): ?. (in English). ["The purpose of this application, under Article 70.2 of the Code, is to conserve the accustomed usage of the names *Gynacantha Rambur, 1842* and *Triacanthagyna Selys, 1883* for two genera of aeshnid dragonflies. The names are objective synonyms but are currently in use for two distinct groups of species. It is proposed that *Gynacantha nervosa Rambur, 1842* should be designated as the type species of *Gynacantha* to conserve the accustomed usage of these two

generic names." (Authors)] Address: Ellenrieder, Natalie von, Instituto de Limnología "Dr. Raúl A. Ringuelet", C.C. 712, AR-1900, La Plata, Argentina. E-mail: ellenr@ilpla.edu.ar

4962. Erös, T.; Schmera, D.; Cser, B.; Csabai, Z.; Murány, D. (2005): Composition of macroinvertebrate assemblages in two submontane streams - The influence of stream order and riffle-pool structure. *Acta Biol. Debr. Oecol. Hung* 13: 85-94. (in Hungarian, with English summary). ["We examined the seasonal assemblage composition and biomass pattern of macroinvertebrate assemblages in two streams of the Börzsöny mountain in riffle and pool habitat types. Clear similarities and differences in species composition were found between riffles and pools. Biomass values showed significant differences between seasons. Biomass was higher in the second order stream in between stream comparisons and in riffles in between riffle-pool comparisons, although these differences were not significant in each season. Composition based on mass percentage was determined largely by Ephemeroptera, Trichoptera, Amphipoda, Coleoptera, Chironomidae, and other Diptera groups, showing large differences between seasons and habitat types. Multivariate analyses showed that riffle-pool habitat structure predominantly determined the similarity of the assemblages based on mass percentage, however seasonal and between stream differences also contributed to differences in assemblage composition." 4963. Foote, L.A.; Rice, C.L. (2005): Odonates as biological indicators of grazing effects on Canadian prairie wetlands. *Ecological Entomology* 30(3): 273-283. (in English). ["1. Aquatic macro-invertebrates have frequently been used as biological indicators in lotic environments but much less commonly so in lentic habitats. Dragonflies and damselflies (Order Odonata) satisfy most selection criteria for lentic bioindicators of grazing impacts. 2. Intensive cattle grazing affects most of the Canadian prairie pothole region but the effects of grazing on wetlands are poorly understood. 3. Here the vegetation structure and invertebrate community composition of 27 prairie potholes in Alberta, Canada were studied and compared. Wetlands were evenly divided into three treatments of different grazing regimes. 4. Removal of emergent vegetation by cattle grazing decreased odonate abundance and reproductive effort. Shorter *Scirpus acutus* stems resulted in significantly fewer damselflies (Suborder Zygoptera) and lower reproductive efforts. 5. Overall odonate diversity was affected by the height of key plant species, highlighting the importance of the vegetation structure of both emergent vegetation for breeding and adjacent upland vegetation for nocturnal roosts. Wetland vegetation structure was more important than vegetation composition to the life history of odonates. 6. Wetland water quality parameters of nitrogen, phosphorus, total dissolved solids (TDS), and chlorophyll-a concentration did not change due to the presence of grazing cattle at wetlands so water quality influences were rejected as mechanisms of change. 7. Larval odonate diversity and abundance was positively correlated with overall aquatic macro-invertebrate diversity and abundance, hence it was concluded that the larval odonate community can be an accurate bioindicator of intactness and diversity

of overall aquatic macro-invertebrate communities in Canadian prairie wetlands." (Authors)] Address: Lee Foote, A., Department of Renewable Resources, GSB 7-51, University of Alberta, Edmonton, Alberta T6G 2H1, Canada. E-mail: lee.foote@ualberta.ca

4964. Grimaldi, D.; Engel, M.S. (2005): Evolution of the Insects. Cambridge University Press. ISBN-13 978-0-521-82149-0 hardback: (in English). [Chapter 6 (pp 173-187) relates to the Odonatoptera.]

4965. Gysels, F.G.M.; Stoks, R (2005): Threat-sensitive responses to predator attacks in a damselfly. *Ethology* 111(4): 411-423. (in English). ["The threat sensitivity hypothesis predicts that prey species assess and adjust their behaviour flexibly in accordance with the magnitude of the threat imposed by a predator. We tested this hypothesis with regard to escape behavior and thanatosis (feigning of death to escape predation) in larvae of the damselfly *Ischnura elegans*. We manipulated the perceived predation threat of the larvae by changing three factors: lamellae autotomy (an escape strategy where animals sacrifice a body part when grasped by a predator; lamellae present or absent), kairomone type (odors released by predators; control, dragonfly kairomones or fish kairomones), and population of origin (fishpond or fishless pond). We demonstrated that thanatosis increased survival both when confronted with dragonfly and fish predators. We could show, for the first time, costs of past autotomy to be predator-dependent: larvae without lamellae suffered higher predation mortality but only in the presence of a dragonfly predator and not in the presence of a fish predator. This is in accordance with the observed reduced escape speed of larvae after autotomy, which may affect escape probability toward dragonfly predators but not to the very fast fish predators. Unexpectedly, kairomone type did not affect the escape response of the larvae. In accordance with the threat sensitivity hypothesis, after an unsuccessful attack, larvae without lamellae had a higher frequency to enter thanatosis than larvae with lamellae and larvae from the fishpond showed longer thanatosis durations than larvae from the fishless pond. Consistent with the hypothesis, the reaction of the larvae to a simulated attack depended jointly on lamellae status and population. In fishless ponds, larvae with lamellae swam away more frequently than larvae without lamellae; in fishponds both groups almost never swam away and relied mostly upon immobility. Given the obvious benefits of adaptively varying escape responses we hypothesize this threat sensitivity to be widespread. Moreover, we argue that former inconsistencies between studies with regard to escape behavior may have been partly because of such adaptive variation." (Authors)] Address: Gysels, Freya; Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

4966. Hernandez, K.M.; Reece, B.A.; McIntyre, N.E. (2005): Effects of anthropogenic land used on Odonata (dragonflies and damselflies) in Playas of the Southern High Plains. International Association of Landscape Ecology Annual Symposium (US-IALE). March 12-16, 2005 in Syracuse, New York. <http://iale.esf.edu/pdfs/IALEProgram2005.03.11.pdf>: 93. (in English). [Verbatim: Playas are ephemeral wetlands that are the only source of freshwater on the Southern High Plains, making them of vital importance to aquatic and amphibious

animals. Playas are also highly threatened from anthropogenic land use (chiefly agriculture, which decreases hydroperiod through increased sedimentation). We are examining the ecology of odonates in playas that differ in surrounding land use (cropland vs. grassland). Preliminary analyses of odonate diversity have revealed a high degree of overlap between cropland and grassland playas (not surprising in a highly mobile taxon). There appears to be a threshold playa size that supports maximal odonate richness, which may reflect a tradeoff between water depth and emergent vegetation that is required for oviposition. Since agriculture effectively reduces playa depth, this tradeoff may be mitigated, which has important implications for odonate community structure in the Southern High Plains.] Address: Hernandez, Kyle M. , Howard Hughes Medical Institute, Dept of Biological Sciences, Lubbock, Texas, 79409-3131, USA. 4970. Leipelt, K.G. (2005): Behavioural differences in response to current: implications for the longitudinal distribution of stream odonates. *Archiv für Hydrobiologie* 163(1): 81-100. (in English). ["Different longitudinal distribution patterns occur in closely related running water species. However, the mechanisms that underlie this phenomenon are poorly studied. In European Cordulegaster species (Odonata) two different longitudinal distribution patterns occur: species like *C. bidentata* and *C. insignis* are limited to springs and springbrooks, whereas species like *C. boltonii* and *C. picta* are less restricted and occur from springs to larger streams and rivulets. To find an explanation for these patterns, expe-

periments in artificial streams were carried out to reveal differences in larval response to current between species of the two types. Larval *C. bidentata* and *C. insignis* showed a higher proneness to drift compared to *C. boltonii* and *C. picta*. Furthermore, *C. bidentata* and *C. insignis* avoided renewed drifting after a forced drift event less effectively and, exposed to strong current, travelled longer distances. It is concluded that, compared to the other pair of species, the behavioural traits of *C. bidentata* and *C. insignis* are less effective to withstand strong hydraulic stress, which restricts the distribution of these species to habitats with low discharge and current velocity, namely springs and springbrooks." 4971. Lencioni, F.A.A. (2005): Damselflies of Brazil. 1 - Non-Coenagrionidae families. 332 pp. (in Bilingual in English and Portuguese). ["The book begins with an introductory chapter containing illustrations of all diagnostic characters, collection, preservation techniques, and identification keys for families and genera. Each species account includes original literature citation, synonymies, references to described larvae, and diagnostic illustrations, usually of the caudal appendages and/or wing scans. The last chapter includes an extensive, up-to-date bibliography and glossary. More than 1000 diagnostic illustrations (of which almost 300 are original) for the 153 species of non-Coenagrionidae species are included which should make identification of the damselfly fauna of Brazil considerably easier than was previously possible." The species are treated in a monographic style containing the following items: Data on Original description; data on imago (if male and female are described); type locality; where the types are housed; synonymy; distribution in South America; distribution in Brazil; data on larvae (described or not and where); data on revision. The glossary includes 156 entries in English and Portuguese (in Portuguese with the English word or expression) and the bibliography refers to app. 120 papers. This publication is available from the author and is priced US \$ 60 plus shipping.] Address: Lencioni, F.A.A., Rua dos Ferroviários 55, Jardim Mesquita, BR-12300-000, Jacarei, S.P., Brazil. 4972. Maes, D.; Van Dyck, H. (2005): Habitat quality and biodiversity indicator performances of a threatened butterfly versus a multispecies group for wet heathlands in Belgium. *Biological Conservation* 123(2): 177-187. (in English). ["We analyzed whether a single species (i.e., the threatened Alcon Blue butterfly *Maculinea alcon*) was a useful indicator for the quality and area of wet heathlands in Belgium. During a survey of 18 wet *Erica tetralix* heathlands, we identified 624 species from 20 different taxonomic groups. Sites with the single indicator species *M. alcon* were significantly richer in typical wet heathland species and in Red List species but did not show significant differences in biotope quality (i.e., the number of different typical wet heathland biotope attributes) than sites without. In addition, we used a multispecies indicator approach including a group of nine species from five different taxonomic groups (each two birds, dragonflies, butterflies, vascular plants, and one grasshopper). High quality sites (5-9 species from the multispecies indicator group present) tended to ha-

ve more Red list species than low quality sites (0-4 species from the multispecies indicator group present) but did not expose differences in overall species richness, typical wet heathland species or in biotope quality. The number of species in this umbrella group, however, was positively correlated with both the diversity of typical wet heathland species and with biotope quality. Furthermore, the complementary information of the species in the multispecies indicator group usefully signalled distinctions in biotope area and configuration, vulnerability to fragmentation, eutrophication, desiccation and contained species of different trophic levels; this was not the case for *M. alcon* as a single indicator species. We discuss the use of a single indicator and of a multispecies group as conservation umbrella and advocate a much wider use of combined knowledge from different taxonomic groups in conservation planning and evaluation." 4973. Maes, D.; Bauwens, D.; Bruyn, L. de; Anselin, A.; Vermeersch, G.; Landuyt, W. van; Knijf, G. de; Gilbert, M. (2005): Species richness coincidence: conservation strategies based on predictive modelling. *Biodiversity and Conservation* 14: 1345-1364. (in English). ["The present-day geographic distribution of individual species of five taxonomic groups (plants, dragonflies, butterflies, herpetofauna, and breeding birds) is relatively well-known on a small scale (5x5 km squares) in Flanders (north Belgium). These data allow identification of areas with a high diversity within each of the species groups. However, differences in mapping intensity and coverage hamper straightforward comparisons of species-rich areas among the taxonomic groups. To overcome this problem, we modelled the species richness of each taxonomic group separately using various environmental characteristics as predictor variables (area of different land use types, biotope diversity, topographic and climatic features). We applied forward stepwise multiple regression to build the models, using a subset of well-surveyed squares. A separate set of equally well-surveyed squares was used to test the predictions of the models. The coincidence of geographic areas with high predicted species richness was remarkably high among the four faunal groups, but much lower between plants and each of the four faunal groups. Thus, the four investigated faunal groups can be used as relatively good indicator taxa for one another in Flanders, at least for their within-group species diversity. A mean predicted species diversity per mapping square was also estimated by averaging the standardized predicted species richness over the five taxonomic groups, to locate the regions that were predicted as being the most species-rich for all five investigated taxonomic groups together. Finally, the applicability of predictive modelling in nature conservation policy both in Flanders and in other regions is discussed." 4974. Mastrantuono, L.; Mancinelli, T. (2005): Littoral invertebrates associated with aquatic plants and bioassessment of ecological status in Lake Bracciano (Central Italy). *J. Limnol.*, 64(1): 43-53. (in English) ["Lake Bracciano is a large and deep volcanic lake which plays

an unquestionable role for drawing water source and for fishing and recreational activities. The existence of a project aimed at increasing the amount of water drawn from the lake suggested the advisability of undertaking an ecological analysis of the invertebrate community associated with aquatic plants in order to obtain a detailed knowledge of its composition, biodiversity and quantitative structure, and to provide a set of basic and essential information for defining the ecological status in the littoral zone and for future bioassessments in the lake ecosystem. A good water quality, approaching oligotrophy, was evidenced both from data on aquatic vegetation, which showed the extensive colonization of Charales (down to a depth of about 20 m), and from faunal parameters such as high species richness and diversity values, presence and abundance of bioindicator taxa (mainly cladocerans and gastropods), abundances of total fauna. Nevertheless, a considerable disappearance of the reed thicket due to the intense shore management for recreational purposes have negatively influenced the colonization of the more shallow and productive waters, so evidencing a negative trend of the littoral quality." (Authors) The checklist of species includes *Erythromma lindenii* and *Trithemis annulata*.] Address: Mastrantuono, Luciana, Dept. of Animal and Human Biology, Univ. "La Sapienza", Viale dell'Università 32, 00185 Rome, Italy. E-mail: luciana.mastrantuono@uniroma1.it

4975. Mauersberger, R.; Bauhaus, S.; Salm, P. (2005): Zum Vorkommen der Grünen Mosaikjungfer (*Aeshna viridis* Eversmann) im Nordosten Brandenburgs (Odonata: Aeshnidae). *Naturschutz und Landschaftspflege in Brandenburg* 14(1): 17-24. (in German). [60 sites with *A. viridis* have been found between 1987 and 2003 in a region of 3500 km² situated in Brandenburg, Germany. The habitats are characterised in detail. A rare exception of an oviposition in *Sparganium emersum* is described and discussed.] Address: Mauersberger, R., Bahnhofstr. 24, D-17268 Templin, Germany. 4976. Mauffrey, B.; Beaton, G. (2005): The distribution of dragonflies and damselflies (Odonata) in Georgia. *Bulletin of American Odonatology* 9(2): 21-66. (in English). ["We present a list of 173 odonate taxa (170 species) from Georgia, USA. Four taxa are newly added to the state list: *Calopteryx amata*, *Argia fumipennis violacea*, *Enallagma caecum*, and *Gomphus australis*. Several species listed in recent publications are removed from the list: *Lestes forcipatus*, *Gomphus crassus*, *G. septima*, *Cordulegaster diastatops*, *Epitheca spinigera*, *Erythrodiplax umbrata*, *Ladona exusta*, and *Libellula jesseana*. Synonyms and unsupportable older species records are discussed." (Authors)] Address: Beaton, G., 320 Willow Glen Drive, Marietta, GA 30068, USA. E-mail: giffbeaton@mindspring.com

4977. Mikolajewski, D.J.; Brodin, T.; Johansson, F.; Joop, G. (2005): Phenotypic plasticity in gender specific life-history: effects of food availability and predation. *Oikos* 110: 91-100. (in English). ["If environmental conditions vary, plasticity in life-history traits is predicted. A recent model indicates that males and females should differ in life-history traits, because sexes differ in optimal attributes depending on species ecology. In this study we test the impact of two biotic factors in combination (presence/absence of predators and low/high

food level) on gender specific life-history traits in the damselfly *Coenagrion puella* (Odonata). Results show that predator presence and low food density decreased activity in both sexes. Additionally, individuals with less food grew more slowly, emerged later, remained smaller and had a higher mortality. At low food densities, however, and in contrast to former investigations, individuals from treatments with predator presence were the same size or larger than individuals without predators. Gender had a strong impact on larval activity and life-history traits and sexes differed in development. Females were less active and took longer to complete development, but emerged at a larger size, weight and fat content. This study highlights the importance of gender specific approaches in life-history research." (Authors)] Address: Johansson, F., Dept of Ecology & Environmental Sci., Animal Ecol. Group, Umea Univ., 90187 Limed, Sweden. E-mail: frank.johansson@eg.umu.se

4978. Nel, A.; Petrulevicius, J.F.; Gentilini, G.; Martínez-Delclòs, X. (2005): Phylogenetic analysis of the Cenozoic family Sieblosiidae (Insecta: Odonata), with description of new taxa from Russia, Italy and France. *Geobios* 38(2): 219-233. (in English with French summary). ["We describe the following Sieblosiidae: an unnamed gen. and sp. A from the Miocene of Italy, *Miostenolestes zherikhini* nov. gen., nov. sp., *Paraoligolestes stavropolensis* nov. sp., *Stenolestes fasciata* nov. sp. (all from the Miocene of North Caucasus), *Stenolestes (?) adygeianensis* nov. sp. (Oligocene of North Caucasus), and *Stenolestes cerestensis* nov. sp. (Oligocene of France). The genus *Sieblosia* Handlirsch, 1906 is restored. A new phylogenetic analysis of the Sieblosiidae is proposed. The two taxa gen. and sp. A and *Oligolestes* fall in most inclusive positions in the same clade with the Sieblosiidae. Within the Sieblosiidae sensu stricto, the two clades (*Paraoligolestes* + *Parastenolestes* + *Stenolestes*) and (*Parastenolestes* + *Stenolestes*) are the best supported. The family Sieblosiidae seems to be restricted to the Oligocene-Miocene of Europe." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. 4980. Opper, S. (2005): Odonata of the Crater Mountain Wildlife Management Area, Papua New Guinea. *IDF-Report* 7: 1-28. (in English, with German summary). ["The odonate fauna of Papua New Guinea (PNG) is species rich but poorly studied. Geographic ranges, ecology, and thus conservation status of many species are unknown. In this study I provide an inventory of two sites within the largest formally protected forest area in PNG, the Crater Mountain Wildlife Management Area. I sampled odonates for a total of 112 days in a pristine forest site and for 36 days in a traditional garden village, and worked with local communities to increase the awareness of dragonflies in the area. I found a total of 78 species (60 Zygoptera, 18 Anisoptera) from 13 families, including at least six currently undescribed spe-

cies. The pristine rainforest hosted more species (61) than the village (37), and a longer sampling period was required to reach an approximately equal level of the total species richness. I calculated species accumulation curves for both areas and found that 100 sampling days were required in the pristine forest, whereas 35 sampling days appeared sufficient in the modified forest. More than two-thirds of all species recorded in the pristine forest were observed in less than half of all the sampling sessions, indicating that species might be both rare and occur only during certain times of the year. The number of species recorded per sampling session indicated some seasonality in the odonate fauna of the pristine forest, which should be considered in future studies. The study suggests that modification of tropical rainforests will lead to a loss of species richness. Conservation of odonates in PNG is therefore dependent on the preservation of primary rainforests, which requires the education of native people living in these areas. Dragonflies were well known among local people inhabiting the study area, but did not play a major role in their culture. More work on dragonflies is needed to describe the diversity of the PNG odonate fauna." (Author)] Address: Opiel, S., Wildlife Conservation Society, PO Box 277, Goroka, EHP, Papua New Guinea. 4986. Purse, B.V.; Thompson, D.J. (2005): Lifetime mating success in a marginal population of a damselfly, *Coenagrion mercuriale*. *Animal Behaviour* 69(6): 1303-1315. (in English). ["In scrambling species, where males obtain matings by actively searching for females, the timing and location of mating may be more important to females than choice of males based on phenotype. Since their activity rates are constrained by climate, variation in lifetime reproductive success in marginal populations of scrambling insects may be governed primarily by stochastic processes, limiting the role of selection. Using multivariate analysis, we examined activity patterns and lifetime mating success (LMS) in a marginal British population of *Coenagrion mercuriale*, a rare, scrambling damselfly, versus that in a core population of a similarly sized scrambling congeneric. Time spent at the breeding site and mating efficiency were the most important factors explaining variation (<75% correct predictions) in LMS in both species, whereas body size, age, and day of entry to the mature population were unimportant. This suggests that LMS in these scrambling species is governed by sexual and natural selection as well as stochastic processes such as weather. However, in *C. mercuriale*, daily mating and activity rates were highly constrained by poor environmental conditions (and increased with sunlight and temperature). Breeding site visits were so curtailed that an equal distribution of LMS between the sexes was observed. Selection in marginal populations of *C. mercuriale* may operate upon traits that confer endurance ability in poor environmental conditions rather than body size, life span or age. Climatic variation across species' ranges will in turn generate geographical variation in mating behaviour, in the intensity of sexual selection and the type of traits selected." 4987. Reels, G. (2005): Book reviews: Field Guide to the Dragonflies of Hong Kong 2nd Edition. by Keith D.P. Wilson, 383 pages, softcover. Cosmos Books Ltd, Hong Kong, 2004. *Porcupine* 32: 20-21. [Verbatim: The first edition of this landmark field guide, which appeared in the shops late last year, went completely unremarked in *Porcupine*! That is unfortunate, since this book, now in its second edition, has set a new standard for field guides of the local fauna. The author, Keith Wilson, worked in Hong Kong for the Agriculture, Conservation and Fisheries Department from 1991 until 2003, and it is under the auspices of AFCD that this fine field guide has been published. The book was written in collabora-

tion with AFCD's Dragonfly Working Group, whose survey work has resulted in four new species records for Hong Kong, including one undescribed gomphid, since its establishment in 2001. However, no-one should be under any doubt that this book is first and foremost the result of one man's efforts. Wilson's first book on the subject (Hong Kong Dragonflies) was published in 1995 and listed 102 species for the territory. It was a truly ground-breaking work, with no local antecedents, but its large, floppy landscape format, coupled with the fact that species descriptions rarely appeared on the same page as their photographs, made it confoundingly unwieldy, and hopeless as a field guide. This was followed in 2002 by the mystifyingly pointless Hong Kong Flying Colour: Dragonflies booklet - another AFCD collaboration (and I beseech them not to repeat it) - which contained photographs of most Hong Kong species, but no text. The peril of producing this kind of anti-information, with no clues on habitat associations or diagnostic features of particular species, was brought sharply into relief for me when I reviewed the results of a dragonfly survey conducted in a disturbed lowland pond and marsh mosaic by an environmental consultant who had made his identifications from the photographs in Flying Colour: many dragonflies look superficially similar, and the hapless consultant had included several stream specialists and many other highly improbable species in his impressive-looking but tragically flawed list. Fortunately, such calamitous failures of identification should now be a thing of the past, as anybody armed with Field Guide to the Dragonflies of Hong Kong, and a good dose of common sense, ought to be capable of making a decent fist of putting a name to most dragonflies they encounter in Hong Kong. An impressive total of 112 species has now been recorded in the SAR, and all of them are illustrated in this 2nd edition. Good, clear photographs of adult males and females are provided in most cases, along with useful information on distinguishing features, biometrics, habitat and distribution. This information is backed up with excellent, user-friendly keys to adults at sub-order, family, genus and species levels. There is also a handy pull-out photo index, a check-list, and a section on additional species which could be expected to occur locally. The layout is compact and attractive. Best of all, it fits easily into a field bag. One could wish for a more robust, hard-back production, and a less cursory treatment of the larvae, but otherwise this has all that one might reasonably ask of a field guide to adult dragonflies.]

4988. Reinhardt, R. (2005): 1. Ergänzung zu: Reinhardt, R. & Klausnitzer, B. (2002): Bibliographie über Sachsens Insekten - ein 300jähriger Überblick. Mitteilungen Sächsischer Entomologen 57: 1-182. 4989. Relyea, R.A. (2005): The impact of insecticides and herbicides on the biodiversity and productivity of aquatic communities. *Ecological Applications* 15(2): 618-627. (in English). ["Pesticides constitute a major anthropogenic addition to natural communities. In aquatic communities, a great majority of pesticide impacts are determined from single-species experiments conducted under laboratory conditions. Although this is an

essential protocol to rapidly identify the direct impacts of pesticides on organisms, it prevents an assessment of direct and indirect pesticide effects on organisms embedded in their natural ecological contexts. In this study, I examined the impact of four globally common pesticides (two insecticides, carbaryl [Sevin] and malathion; two herbicides, glyphosate [Roundup] and 2,4-D) on the biodiversity of aquatic communities containing algae and 25 species of animals. Species richness was reduced by 15% with Sevin, 30% with malathion, and 22% with Roundup, whereas 2,4-D had no effect. Both insecticides reduced zooplankton diversity by eliminating cladocerans but not copepods (the latter increased in abundance). The insecticides also reduced the diversity and biomass of predatory insects (including *Anax junius*) and had an apparent indirect positive effect on several species of tadpoles, but had no effect on snails. The two herbicides had no effects on zooplankton, insect predators, or snails. Moreover, the herbicide 2,4-D had no effect on tadpoles. However, Roundup completely eliminated two species of tadpoles and nearly exterminated a third species, resulting in a 70% decline in the species richness of tadpoles. This study represents one of the most extensive experimental investigations of pesticide effects on aquatic communities and offers a comprehensive perspective on the impacts of pesticides when nontarget organisms are examined under ecologically relevant conditions." (Author)] Address: Relyea, R.A., Dept Biol. Sciences, University of Pittsburgh, Pittsburgh, Pennsylvania 15260, USA. E-mail: rarelyea@pitt.edu

4990. Robb, T.; Forbes, M.R. (2005): On understanding seasonal increases in damselfly defence and resistance against ectoparasitic mites. *Ecological Entomology* 30(3): 334-341. (in English). ["1. Defence against parasites and pathogens can be essential, yet not all hosts respond similarly to parasitic challenge. Environmental conditions are thought to explain variation in host responses to parasites. 2. *Lestes forcipatus* damselflies emerging later in the season have shown higher resistance to the mite, *Arrenurus planus*, than hosts emerging earlier. This study was undertaken to determine whether variation in environmental temperatures characteristic of early vs. late emergence times, degree or costs of mite parasitism, and/or size of newly emerged adults could explain seasonal variation in defence and resistance to ectoparasitic mites. 3. In this study damselflies from early vs. late emergence groups differed in size at emergence and mite intensity. In general, early hosts were larger and had more mites than later hosts. However only experimental temperatures experienced by damselflies at emergence influenced defence and resistance against mites and not host size or degree of parasitism. 4. More specifically, hosts from early and late emergence groups did not differ in defence and resistance when held at the same temperatures in incubators. Housing at a high temperature, indicative of later in the season, was associated with higher defence and resistance for damselflies from both early and late emergence groups. 5. These results indicate that daily temperatures in relation to emergence timing can account for seasonal increases in resistance for this temperate insect. Seasonal increases in resistance may be expected for other temperate insect-parasite associations and should have important implications for the phenology of parasites and for seasonal variation in parasite-mediated selection." 4991. Rouquette, J.R.; Thompson, D.J. (2005): Habitat associations of the endangered damselfly, *Coenagrion mercuriale*, in a water meadow ditch system in southern England. *Biological Conservation* 123(2): 225-235. (in English). ["[...] We obtained estimates of density of mature adult *C. mercuriale* during an intensive mark-release-recapture study over 7.65 km of a water meadow ditch network in the Itchen Valley, Hampshire. Detailed habitat information was also collected, including a variety of physical variables, and data about the in-channel and bankside vegetation. *C. mercuriale* density and movement were analysed in relation to habitat variables and local population size using Generalized Linear Models. Mean adjacent population density was the single most important factor determining density. However the species was also associated with a number of habitat features, the most important of which were: a channel substrate consisting primarily of silt, wide underwater ledges (berms), in-channel emergent dicots, and bankside monocots. The presence of trees was negatively associated with damselfly density. Mean net lifetime movement was greatest from sections with low density, with smaller than average berms, and with deeper water. The causes and consequences of these findings are discussed in relation to the conservation and management of this rare species." 4994. Suhling, F.; Sahlén, G.; Kasperski, J.; Gaedecke, D. (2005): Behavioural and life history traits in temporary and perennial waters: comparisons among three pairs of sibling dragonfly species. *Oikos* 108: 609-617. (in English). ["Identifying and examining traits that influence the distribution of species is crucial to the understanding of community structure. Theory predicts that traits should differ between species that live in temporary and permanent waters because of differing major environmental variables; viz drying out and predator presence, respectively. Species, however, will also be influenced by their evolutionary history, i.e. by the traits of their common ancestors. We studied differences in life history and behaviour traits in a series of laboratory experiments using pairs of dragonfly species out of

three genera of Namibian Libellulidae with one species from each type of habitat. As predicted, growth rates were significantly higher in the temporary water species compared to the permanent water species. Activity and foraging, in contrast, differed between the genera, but did not differ between the habitat types. Hence, our study implies that the behavioural traits are influenced by phylogenetic inertia rather than by the habitat variables, while growth rate is adapted to the habitat. We argue that in all three genera one species has diverged recently from a sister species that lives in the original habitat of the genus, which may be temporary waters in *Crocothemis* and in *Orthetrum*, and permanent waters in *Trithemis*. The behavioural traits may therefore be less well adapted. Rapid growth may be the more relevant trait because it is crucial to survival in temporary waters." (Authors)] Address: Suhling F., Inst. 4996. Teplitsky, C.; Plenet, S.; Lena, J.-P.; Mermet, N.; Malet, E.; Joly, P. (2005): Escape behaviour and ultimate causes of specific induced defences in an anuran tadpole. *Journal of Evolutionary Biology* 18(1): 180-190. (in English). ["Induced defences, such as the predator avoidance morphologies in amphibians, result from spatial or temporal variability in predation risk. One important component of this variability should be the difference in hunting strategies between predators. However, little is known about how specific and effective induced defences are to different types of predators. We analysed the impact of both pursuing (fish, *Gasterosteus aculeatus*) and sit-and-wait (dragonfly, *Aeshna cyanea*) predators on tadpole (*Rana dalmatina*) morphology and performance (viz locomotive performance and growth rate). We also investigated the potential benefits of the predator-induced phenotype in the presence of fish predators. Both predators induced deeper tail fins in tadpoles exposed to threat of predation, and stickleback presence also induced longer tails and deeper tail muscles. Morphological and behavioural differences resulted in better escape ability of stickleback-induced tadpoles, leading to improved survival in the face of stickleback predation. These results clearly indicate that specific morphological responses to different types of predators have evolved in *R. dalmatina*. The specific morphologies suggest low correlations between the traits involved in the defence. Independence of traits allows prey species to fine-tune their response according to current predation risk, so that the benefit of the defence can be maximal." 4998. Tuno, N.; Okeka, W.; Minakawa, N.; Takagi, M.; Guiyun, Y. (2005): Survivorship of *Anopheles gambiae sensu stricto* (Diptera: Culicidae) larvae in western Kenya highland forest. *J. Med. Entomol.* 42(3): 270-277. (in English). ["The western Kenya highland has been experiencing dramatic landuse changes in the past three decades. Landuse change has been hypothesized to be one of the mechanisms for malaria epidemics in African highlands because it can alter the physical and chemical characteristics of mosquito breeding habitats. One important landuse change in western Kenya highland is deforestation. The current study examined the effects of forestation or deforestation on the survivorship of *Anopheles gambiae* larvae and colonization of other aquatic insects in larval habitats in Kakamega forest (elevation 1,500 - 1,700 m above sea level), western Kenya. We found that the survivorship of *An. gambiae* larvae was reduced from 55 to 57% in habitats fully exposed to sunlight (open habitats) to 1 - 2% in habitats with full forest canopy coverage (forest habitats) and partial canopy coverage (forest edge habitats) in two out of three trials. The average daily water temperature of the open habitats was app. 3 - 3.4 C higher than the forest habitats. Insect species in the orders of Diptera, Coleoptera, and Odonata colonized the larval habitats, but the three habitat types differed greatly in the animal assemblage. Canonical correspondence analysis found that water temperature and amount of leaf litter were the significant variables associated with animal assemblages. Redundancy analysis revealed that openness and the presence of predatory animals were significantly related to *An. gambiae* survivorship. This result suggests that deforestation facilitates the survival of the immature stage of *An. gambiae* in the highland." 4999. Uhía, E.; Cordero Rivera, A. (2005): Male damselflies detect female mating status: importance for postcopulatory sexual selection. *Animal Behaviour* 69 (4): 797-804. (in English). ["The existence of postcopulatory sexual selection is now clearly established in many animal species. In Odonates, males remove sperm during copulation from the bursa copulatrix and (when physically accessible) from the spermatheca. We used these model organisms to test the relative importance of sperm competition and cryptic female choice for copulation duration in laboratory experiments. If long copulations evolved only because of sperm competition, males should prolong copulation with previously mated females, and use this extra time to remove/displace the stored sperm. In species without a spermatheca (or when it is physically inaccessible), copulation duration should be similar in mated and virgin females. The cryptic female choice hypothesis predicts that copulations should be prolonged (acting as copulatory courtship) when males cannot physically remove sperm from the spermatheca but not if females do not have a spermatheca. We found that male damselflies can detect the mating status of females probably using chemical sensilla in their genitalia. Copulation duration with mated females was almost twice as long as with virgins in species with a spermatheca, but this behaviour was probably not the result of sperm competition, because in our model species, males could not remove sperm from this organ. The duration of copulation did not inc-

rease in species without a spermatheca. We conclude that even in odonates, where sperm removal is widespread, females have retained control over sperm reserves in their spermatheca(e), and males prolong copulation with mated females to elicit rival sperm ejection and/or to induce females to use their sperm in fertilization." 5000. Van de Meutter, F.; Stoks, R.; De Meester, L. (2005): Spatial avoidance of littoral and pelagic invertebrate predators by *Daphnia*. *Oecologia* 142: 489-499. (in English). ["Studies on spatial avoidance behaviour of predators by prey often ignored the fact that prey typically face multiple predators which themselves interact and show a spatial pattern in abundance and predation rates (PRs). In a series of laboratory experiments, we investigated predation risk (PRI) and horizontal migration of the cladoceran *Daphnia magna* between open water and vegetation in response to two important invertebrate predators with a contrasting spatial distribution: pelagic *Chaoborus* and vegetation-associated *Ischnura*. As expected, PRI by *Chaoborus* was higher in open water due to higher numbers and higher PRs of *Chaoborus*, while for *Ischnura*, PRI was highest in the vegetation due to higher densities, despite lower PRs of *Ischnura*. In accordance with this, *Daphnia* moved into the vegetation in the presence of the pelagic *Chaoborus* alone. In the presence of *Ischnura* alone, however, *Daphnia* showed no response. We hypothesize this may be the result of a constitutive behaviour of *Daphnia* to avoid pelagic fish, which impedes a response to the open water. In the combined predator treatment, *Daphnia* migrated to the open water zone. The increased risk of predation in the vegetation, due to a facilitating effect of *Chaoborus* on *Ischnura* PRs is believed to have caused this migration of the *Daphnia*. This response of *Daphnia* declined through time and *Daphnia* moved toward the vegetation. A decline in the activity of the *Ischnura* larvae through time may have switched the risk balance in favour of the vegetation environment." 5002. Ward, L.; Mill, P.J. (2005): Habitat factors influencing the presence of adult *Calopteryx splendens* (Odonata: Zygoptera). *European Journal of Entomology* 102(1): 47-51. (in English). ["1. In Great Britain the distribution of the riverine damselfly *C. splendens* is predominantly southern. However, the last decade has seen records of the species in previously unoccupied areas in the northeast of England, prompting speculation regarding northward range expansion. The current study is the first to quantify the physical features of the habitat that influence the presence of *C. splendens*. 2. A field survey was carried out on the physical characteristics of habitat supporting *C. splendens* along a secti-

on of the River Wharfe, West Yorkshire, U.K. Adult *C. splendens* were marked uniquely for individual identification in order to assess the occurrence of the species within different habitat patches of the study area. 3. A multiple logistic regression was used to identify the significant habitat variables in explaining the occurrence of adult *C. splendens*. 4. The most important habitat factor in determining the presence of *C. splendens* was the height of the vegetation at the edge of the river. Significant negative relationships were found between the presence of *C. splendens* and tree coverage along the bank, and between its presence and increased bank height. 5. The distribution of *C. splendens* is affected by the natural physical features of the habitat, anthropogenic disturbance and the behaviour of the species itself. 6. The importance of quantitative habitat data in species conservation, particularly with regard to range expansion, is discussed." (Authors)] Address: Mill, P., School of Biol., L.C. 5003. Wendzonka, J. (2005): Klucz do oznaczania dorosłych wazek (Odonata) Polski. Odonatrix 1, Suppl. 1: 1-26. (in Polish, with English summary). ["Identification key to the imagines of Polish dragonflies (Odonata). - The present study is a part of the project "The Atlas of distribution of dragonflies (Odonata) in Poland". It contains a key for the identification of 75 dragonfly species of which 72 ones were recorded from the area of Poland. *Coenagrion mercuriale* and *Gomphus pulchellus* were mistakenly recorded in Poland in the past, however, together with *Lestes macrostigma* they are really possible to find. Thanks to the simple structure of the key, as well as the right selection of features and notations, it is easy to use for people without experience in this field. This publication is first of all directed to them." (Author)] Address: Wendzonka, J., ul. Palacza 18B/326,60-241 Poznań, Poland. E-mail: wendzonka@wp.pl

5004. Wildermuth, H. (2005): Dragonflies of the mont Ventoux region, Provence, France (Odonata). Opusc. zool. flumin. 220: 1-12. (in English). ["An annotated list of 32 species is presented, comprising records of adults, exuviae or larvae, made in July 2000 and 2003 and in June 2004 at 16 localities in a 600 km² area N of Mont Ventoux. The dragonfly fauna of this mountainous region, characterized by large forests, vineyards and other agricultural land, comprises chiefly spp. of running waters: Along with *Onychogomphus forcipatus*, *O. uncatatus*, and *Cordulegaster boltonii*, which all develop in the few source-fed brooks and permanent rivers, *Boyeria irene* is of major importance. Most species typical for stagnant water bodies, such as *Enallagma cyathigerum*, *Anax imperator*, and *Crocothemis erythraea*, breed in a single large fish pond used for angling. *Ceragrion tenellum*, *Libellula fulva*, and *Sympetrum pedemontanum* are of special interest for this region, where stagnant waters are mostly present as man-made irrigation tanks and small reservoirs that are scattered over the area." 5005. Wildermuth, H.; Gonseth, Y.; Maibach, A. (Hrsg) (2005): Odonata. Die Libellen der Schweiz. Fauna Helvetica 12. ISBN 2-88414-024-7: 398 pp. (in German). [This is a sophisticated and very well balanced book on the Swiss odonate fauna, which treats 84 spe-

cies and discusses additional taxa. It is a tribute to the famous Swiss artist and odonatogogist Paul André Robert, who's unpublished wonderful and detailed paintings of dragonflies are used for illustration (species, not painted by Robert are added using painting from Askew's book on the European Odonata). A brief and very readable introduction into the biology of Odonata is followed by brief characterisations of the habitats. A focus is set on the distribution of the species, which are mapped, and the turn over of species distribution. All species are treated in a monographic way highlighting the general and Swiss distribution, development of populations, emergence and phenology, habitats of imagines and larvae, threat, and conservation measures. The book is closed by an extensive odonatalogical bibliography and the list of contributors. A French edition of the book is also available. This book is a must in every odonatalogical library, even if you don't read German or French. 5006. Baker, R.L.; Smith, B.P. (1997): Conflict between antipredator and antiparasite behaviour in larval damselflies. *Oecologia* 109: 622-628. (in English). ["Larval damselflies resist infestation by parasitic larval mites by exhibiting behaviours such as grooming, crawling, swimming, and striking at host-seeking mites. Larval damselflies are known to increase time spent in these behaviours in the presence of mites but reduce time spent in these behaviours in the presence of fish predators. The presence of both fish and larval mites presents an obvious conflict: a larval damselfly may actively avoid parasitism by mites, thus increasing its risk of predation, or it may reduce its activity when fish are present, thus increasing its risk of parasitism. We analysed the behaviour of larval *Ischnura verticalis* in an experiment where we crossed presence and absence of fish with presence and absence of larval mites. Presence of mites induced a large increase in activity of larval *I. verticalis* but fish had no effect and there were no interpretable interactions between effects of mites and fish. Subsequent experiments indicated that larval *I. verticalis* in the presence of both mites and fish were more likely to be attacked and killed by fish than those exposed only to fish. The high activity level of *I. verticalis* larvae in the presence of both fish and mites may suggest that costs of parasitism are high, or that under field conditions it is rare for larvae to be in the immediate presence of both fish predators and potentially parasitic mites." (1999): Landscape approaches in ecotoxicology. *Aspects of Applied Biology* 53 (Challenges in Applied Population Biology): 227-234. (in English). ["A mark-recapture study of odonates was conducted in Cheshire, UK to estimate the degree to which odonate populations at ponds were connected by dispersal. The probability of individuals of each species moving between ponds declined exponentially with the distance between ponds. Using these relationships, we parameterised a simple simulation model, which indicated that the odonate populations around some ponds ("keystone ponds") could be much more important than others in mediating the recovery of odonates after exposure to a toxic agrochemical. On the basis of this result we quantified the attributes of every pond above 10 m² in both Cheshire and County Durham, using a GIS of Ordnance Survey 1:25000 scale digital vector map data. By incorporating the observed dispersal characteristics into this GIS, we have developed a tool which is capable of estimating the rate of odonate colonisation of any pond in these counties, hence their ability to recover from a toxic perturbation." 5016. Kalbfus, W.; Kopf, W.; Seitz, G.; Butz, L. (2000): Report on the investigations of the rivers Szamos and Theiß (Hungary) after the cyanide accident. Instructed by the Bavarian State Ministry for Regional Development and Environmental Affairs. www.bayern.de/LFW/aktuelles/neuesausdemlfw/ungarn/UngarnBerichtenglisch3.pdf: 14 pp. (in English, with German summary). ["The accident on 30th of January 2000 in the AURUL goldmine near Baia Mare (Romania) caused an extraordinary decrease of the fish-fauna in the Hungarian rivers Szamos and Tisza accompanied by high economic losses. It is, however, not an easy task to assess the ecological dimension of environmental damage. The first impression implied that all life in the rivers has been extinguished by cyanide, which is extremely toxic. However about 1 month after the disaster this hypothesis could not be confirmed by the Bavarian expert group. The zoological investigation of the underwater fauna revealed living macro- and microorganisms, which were typical for these river sites. It can be assumed that these organisms survived the pollution and did not re-populate the river bottom from tributaries. The conditions of oxygen-saturation in the river Tisza indicate the existence of physiologically active phytoplankton. The water samples and the sediments of river Szamos and river Tisza had a specific ecotoxic potential. No acute toxic effect to bacteria, algae and the crustacean *Daphnia* (zooplankton, fish-fodder) could be detected. However the growth of macrophyte was proved to be strongly inhibited by the samples originated from river Szamos. The concentration of heavy metals in the water samples as well as in the sediments indicate a contamination at high to at least very high concentrations in the river Szamos, which had an effect on the downstream river Tisza. Residues of cyanides could not be detected. The analysis of some persistent organic chemicals in the sediment indicates, that Szamos and Tisza are not polluted by these substances." (Authors) The study includes notes on Odonata.] Address: Bayer. Landesamt für Wasserwirtschaft, Kaulbachstr. 37, D-80539 München, Germany

5017. Lemly, A.D.; King, R.S. (2000): An insect-bacteria bioindicator for assessing detrimental nutrient enrichment in wetlands. *Wetlands* 20(1): 91-100. (in English). ["Field and laboratory studies were conducted to evaluate the use of bacterial growth on aquatic insects as a metric for determining the existence of nutrient impacts in wetlands. Results from field investigations indicated that elevated concentrations of nitrate and phosphate were associated with growth of filamentous bacteria on insect body surfaces and that there were significantly fewer mayflies (Ephemeroptera) in the nutrient-enriched wetland. Laboratory investigations confirmed a strong linkage between bacterial growth and reduced survival of mayflies. Survival was examined for individuals with bacterial infestation ranging

from 0% to 60% body coverage. A threshold for catastrophic mortality was present at about the 25% level of coverage; there were very few survivors above that level. Based on these findings, the diagnostic endpoint for the bioindicator is 25% body coverage by bacterial growth, a level that signifies major differences in insect populations in the field and is also easy to detect visually. This study provides evidence that the insect-bacteria bioindicator is a reliable tool for assessing nutrient impacts on wetland macroinvertebrate communities. The bioindicator could be useful in the development of a Wetland Bioassessment Protocol." (Authors) Bacterial growth on Odonata is documented in table 1. 5018. Nikoh, N.; Fukatsu, T. (2000): Interkingdom host jumping underground: Phylogenetic analysis of entomoparasitic fungi of the genus *Cordyceps*. *Mol. Biol. Evol.* 17(4): 629-638. (in English). ["Most members of the ascomycetous genus *Cordyceps* are endoparasitic fungi of insects and other arthropods, but about 20 of the 300 described species are parasitic to hart's truffles, *Elaphomyces* spp. In order to understand the evolution of host specificity and the process of interkingdom host jumping in *Cordyceps*, we investigated the phylogenetic relationships of 22 representatives, including 4 truffle parasites and 18 insect parasites, based on nuclear and mitochondrial rDNA sequences. Five monophyletic groups were identified in both nuclear and mitochondrial phylogenies. In three of the five clades, the members utilized hosts from the same insect group, suggesting that the endoparasite-host connections have been conserved to some extent. On the other hand, it was also shown that major host shifts between distantly related insects must have occurred repeatedly. Notably, phylogenetic analyses strongly suggested that parasites of hart s truffles originated from parasites of cicada nymphs during the evolution of the *Cordyceps*. The common habitats of cicada nymphs and hart s truffles, deep underground and associated with tree roots, suggest that the interkingdom host jumping from Animalia to Fungi might have been promoted by the overlapping ecological niche of the unrelated hosts. This finding provides an impressive case of a drastic host shift in favor of the host habitat hypothesis." (Author) The paper has a passing reference to the Odonata.] Address: Fukatsu, T., National Institute of Bioscience and Human-Technology, Agency of Industrial Science and Technology, Tsukuba, 305-8566, Japan. 5027. Jordan, S.D. (2001): Molecular Systematics and Phylogeography of Hawaii's Megalagrion damselflies. Ph.D. University of Connecticut. Advisor: Dr. Chris Simon: 108 pp. (in English). [I have used mitochondrial and nuclear DNA sequence data to explore the phylogenetic relationships of species in Hawaii's marvelous Megalagrion damselfly radiation. These damselflies occupy a wide diversity of habitats. Results indicated that Megalagrion species relationships agree with some hypotheses of previous workers. In particular the monophyly of several species groups was supported by the molecular data, and traditional taxonomy appears to be adequate. However, molecular data also contradicted and clarified the established notions in several key ways. First, two sequential bursts of evolution may have been responsible for the some of the remarkable ecological diversity in the genus. Analysis of mitochondrial DNA under a local molecular clock suggested that these rapid speciation events coincided with the emerging availability of suitable habitats on Kauai and Oahu. Second, the traditional problematic phylogenetic placement of several species is probably due to the rapid pace of the radiation that produced these species, leaving few informative characters on key internal branches. The phylogeography of the species *M. xanthomelas* and *M. pacificum* was explored using mitochondrial sequence data from 157 individual damselflies. I sought to understand the demographic and historical processes responsible for the current distribution of genetic variation in these two species, and found that current patterns of female genetic diversity correspond to Pleistocene island connections. Finally, I evaluated the usefulness of three different methods for performing Nested Clade Analysis (NCA), with reference to real and theoretical examples. Data from Hawaiian damselflies indicate that Method 2 NCA is susceptible to problems when population sample sizes are small or unbalanced, and when hypothesized population boundaries vary." 5028. László, F.; Csányi, B.; Literáthy, P. (2001): Cyanide and heavy metal accidental pollution in the

Tisza River basin: Consequences on water quality monitoring and assessment. *Proceeding MTM-III - Accidental pollution in the Tisza River Basin: 65-70.* (in English). ["An accidental industrial spill of high cyanide concentration, originating - due to dike failure from a storage pond of a mining company in Baia Mare (Romania) caused disastrous pollution on 30 January 2000. The total volume of the accidental spill was approximately 100 000 m³ containing around 100 tons of cyanide. [...] On the 10th of March 2000 another serious accident occurred in the upper Tisza region in Romania. Bursting the dike of a storage pond caused the discharge of 20 000 tons of ore slurry containing high concentration of lead, copper and zinc. [...] Since the cyanide pollution has passed the Hungarian part of the river Tisza, we have found live specimens of all macro-invertebrate taxa recorded previously in the given sections. These results so far show that some of the macro-invertebrate fauna of the river Szamos and Tisza has survived the cyanide pollution. Characteristic surviving species include [...] larvae of river Odonata species (*Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Stylurus flavipes*, *Platycnemis pennipes*, *Calopteryx splendens*) [...].] Address: László, F., Water Resources Research Centre Plc. (VITUKI), H-1095 Budapest, Kvaszay J. út 1., Hungary

(2001): Breakdown rates and macroinvertebrate colonisation of alder (*Alnus glutinosa*) leaves in an acid lake (Lake Orta, N Italy), before, during and after a liming intervention. *J. Limnol.* 60(1): 127-133. (in English). [The effectiveness of the liming intervention on Lake Orta, the speed of leaves decay and of colonisation processes by macrobenthonic fauna were studied on alder leaves (*A. glutinosa*) placed on the bottom of the lake and recovered after appropriate time intervals. Experiments were performed at two sites (North and South) and two depths (-3 and 18 m), during three successive winters: 1988-1989 (pre-liming), 1989-1990 (liming), 1990-1991 (post-liming). Two main results emerged: 1) alder leaves, which are known to have a medium to high decaying speed in a number of aquatic environments, behave in Lake Orta as a low speed species. Decaying processes in the three years are significantly different only in station N3, where the mean breakdown rate in 1988-1989 is more than twice that measured in the two subsequent winters. 2) The species richness of colonising benthic fauna is low: the community is made up almost exclusively of Chironomidae, which form 70 to 100% of the whole population; among them, the genus *Phenopsectra* is always present, while *Tanytarsus* was collected only during the first year and in the less deep sampling sites. The mean population abundances were higher before liming." (Authors) The list of taxa includes "Coenagion sp.".] Address: Dipartimento di Biologia Evoluzionistica Sperimentale, Università degli Studi di Bologna, Via Selmi 3, 40126 Bologna, Italy. Cordulegasteridae). *Quad. Studi Star. nat. Romagna* 16 (Suppl.): 1-4. (in Italian with English summary). [Abdominal segments 8-10 of adult *C. trinacriae* and *C. b. boltonii* are figured and compared.] Address: Carletti, B., Viale Raffaello Sanzio 5, 1-50124 Firenze, Italy

5037. da Rosa, I.; Canavero, A.; Maneyro, R.; Naya, D.E.; Camargo, A. (2002): Diet of four sympatric anuran species in a temperate environment. *Bol. Soc. Zool., Uruguay* 13: 12-20. (in English with Spanish summary). [The diet of four sympatric anurans species was studied, from October 1998 to November 1999, in a temperate Neotropical environment (Espinass Stream, Maldonado, Uruguay). A total of 387 individuals were collected and their stomach prey content, examined (186 *Physalaemus gracilis*, 88 *Leptodactylus ocellatus*, 96 *Hyla p. pulchella* and 17 *Bufo gr. granulosus*). The main prey items were: coleopterans, spiders and acari for *L. ocellatus*; dipterans, spiders, coleopterans, hemipterans, and acari for *H. p. pulchella*; formicids for *B. gr. granulosus*; and collembolans, acari and formicids for *P. gracilis*. *Leptodactylus ocellatus* and *H. p. pulchella* showed the highest diet amplitude, *P. gracilis* occupied a middle position, and *B. gr. granulosus* presented the lowest diet amplitude value. According to prey items attributes, a Sit-and-wait foraging strategy is proposed for *L. ocellatus* and *H. p. pulchella*, and an active capture strategy for *B. gr. granulosus*. Seasonal analysis indicated that, except for *P. gracilis*, all the other predator species increased their diet richness during the cold season, mainly because each predator included new preys. This result, probably related to seasonal changes in prey availability, may indicate that species trophic behavior change along the year, and so, do not allow to locate a species in fixed place between generalist and specialist extremes." Odonata were captured by *L. ocellatus* and *H. p. pulchella* during the cold season.] Address: da Rosa, Inés, Section Zoología Vertebrados, Facultad de Ciencias, Universidad de la República, I-gua 4225, CP 11400, Montevideo, Uruguay, ines@fcien.edu.uy

sone, NW Italy). *Hydrobiologia* 474: 125-130. (in English). ["Macroinvertebrates continuously redistribute themselves in the riverbed. A knowledge of the colonization mechanisms and movement patterns is very important for an understanding of processes of restoration of lotic environments, particularly of inland waters with severe pollution. We tested the colonization patterns of stream macroinvertebrates in the Visone River, a tributary of the highly contaminated Bormida River (NW Italy). We placed six groups of traps in the riverbed, each group consisting of three traps: the C trap allowed colonization from all directions, while the D and U traps allowed access only from downstream and upstream respectively. The C traps were the most colonized substrates, both in number of individuals and taxa. The U traps were more colonized than the D traps, demonstrating the great importance of movements directed downstream. We report data on taxonomic and seasonal differences in the colonization process." (Authors) Appendix 1 documents the occurrence of Odonata (e.g. *Boyeria irene*, *Cordulegaster boltonii*, *Calopteryx splendens*) in the traps.] Address: Fenoglio, S., University of Eastern Piedmont, Dept. Sciences and Adv. Tech., via Cavour 84, 15100 Alessandria, Italy. E-mail: fenoglio@unipmn.it

sity of Massachusetts Boston, USA. E-mail: fred.saintours@umb.edu

5050. Sudo, S.; Tsuyuki, K. (2002): Biomechanics of flying insects and air flows. *Nagare* 21(2): 142-152. (in Japanese, with English translation of the title and figures). [<http://www.nagare.or.jp/nagare/21-2/21-2-t05.pdf>

The following translation of Odonata-related issues was made by Naoya Ishizawa: Introduction This report deals with the relation of biomechanics of flying insects, Odonata, Hymenoptera and Diptera to air flows, concentrating our aims on their wing morphology and wing beating based on authors' experience.

Symbols: c: wing span; f: Hz; fi: wing beat frequency; L: body length; l: wing length; m: body mass; P (f): power of components of wing beat frequency; S: wing area; t: time; u, v, w: speed components of each direction of x, y, z; V: three dimensions composite speed; x, y, z: frame of reference.

Devices of experiments and Methods 2.1 Microobservation of wing morphology of insects by a scanning electron microscope and a non-contact three dimensional curved surface measurement 2.2 Measurement of wing beating of insects Thoracic skeleton vibration was measured by an optical displacement detector and FFT analyzer. Wing movement in free flying insects was analyzed on three dimensions by two high-speed video cameras, synchronous device, recorders, motion grabber, monitors and personal computers. The frame of reference of x, y, x and the space of measurement had been set numerically, then insects were released in it and their free flying was analyzed. Wing beat sounds of free flying hymenopteran insects were measured by a noise-meter and frequencies and wave of the signals were analyzed through FFT analyzer. 2.3 Air flows around insects were measured with a wind tunnel (wind speed was available within 0.5-10m/sec.) and three dimensional PIV system. The test section was 200 mm*300mm made of transparent acrylic resin.

Flying organs of insects Fig. 3 shows the cross sections of costae of the forewing of *Sympetrum infuscatum*. The costae at the basal part were developed well in the direction of up and downward, due to that the power operates chiefly up and downward at the basal part in wing beating. The costae so far from the nodus toward the wing tip stick out sharply forward. This is due to the faster wing speed at the tip and decreases air resistance. Thus, costae of dragonflies are most suitable forms for cope with the power that works at each of them. Fig. 4 shows the three dimensions of upper and down side of the wing of *Sympetrum frequens*. The height of the wing surface was larger at the basal part of the wing. Roles of the wave structure of the wing were increase of strength, shock absorber and lowering of fluid resistance. The posterior edge of the wing curve toward underside at the cross section and has a camber, and the characteristic seems to be common among insects. The height difference between the basal part and the wing tip suggests that at the former rigidity works high and at the latter flexibility works most, and this brings the wings deformed easily. There are many micro spines on the wing membrane of Diptera. The spines seem to tilt toward the air flows that were generated on the surface of the wing, and have a role of libretti. In Odonata, such spines exist on wing veins, but not on the membrane. 4. Wing beat and the wing beat frequency 4.2 Wing beat frequency The wing beat frequency of *Vespa simillima xanthoptera* was 105 Hz. Valensi number $Va=S?/v=Strouhal\ number* Reynolds$

number, ($?=2\pi fi$) and kinematic viscosity of the air. It is clear that Valensi number is proportional to the body length. The equation of wing beat frequency is shown below; $fi=Km-1/6$, K is a parameter valuable by insects. 4.3 Wing beat Fig. 12 shows the trajectories of fluttering wing tips in *S. infuscatum*. It is generally known that trajectory of wing tips of insects draws the character of 8, however, especially insects of Odonata, Hymenoptera and Diptera shows remarkable diversity of the trajectory. Fig. 14 shows the composite speed and its equation is shown below; $V=(u^2+v^2+w^2)$ Wing beat of insects has a function of complicated controlling with deformation of wings. 5. Air flows around wingbeating insects We measured the changes of air speed produced by wing-beat and the changes of wingbeat at the basal part synchronously, putting a live dragonfly in a stationary air speed, which made the dragonfly beat wings. Fig. 16 shows the range of wing beat?, changes of air speed u and correlation coefficient between them $Ru?$ in *Sympetrum kunkeli* that was fluttering in the stationary air flow ($U0=1.75m/sec$). In nature, dragonflies do not always flutter in flight, they fly with repeating fluttering and gliding alternatively. Fig. 17 shows wingbeat of *Pantala flavescens* in the air flow of 2.1m/sec. It fluttered 14-15 times during 0.5-0.6sec. and glided for 0.3-0.4 sec. Speed vector in fluttering *Crocothemis servilia mariannae*, body length $L=46.6$ mm, examined with PIV system is shown in Fig. 18. The measuring points were set at 14 mm (nodus) from the basal part of left wings. The forewing is stroking downward, with the hindwing reaching the bottom. Fig. 18 (a) suggests that large speed upward air flow is a lift and the wave of speed vector backward shows the change of speed produced by fluttering. Fig. 18 (b) shows speed vector of upward stroking of wings. Thus, it is cleared that dragonflies fly with their wings deformed, changing angles of wing stroking and the phase of wing beat of fore and hind wings.] Address: Sudo, S., Faculty of Systems Science and Technology, Akita Prefectural University, Yurihonjo 015-0055 Japan. - 5055.** Hodgkison, S.; Hero, J.-M. (2003): Seasonal, sexual and ontogenetic variations in the diet of the 'declining' frogs *Litoria nannotis*, *Litoria rheocola* and *Nyctimystes dayi*. *Wildlife Research* 30(4): 345-354. (in English). ["Faecal analyses were used to investigate the diets of the endangered frogs *Litoria nannotis*, *L. rheocola* and *Nyctimystes dayi* in Tully Gorge, North Queensland. Comparisons of diet and food availability indicate that these species feed indiscriminately on a range of terrestrial and aquatic invertebrates (including Odonata). Changes in morphology and foraging behaviour significantly influenced diet composition and created subtle shifts in the degree of selectivity displayed in prey choice. Interspecific differences in numeric and volumetric diet composition were attributed to variations in gape size and microhabitat selection. Within the diets of *L. nannotis* and *L. rheocola*, a decline in prey selectivity observed during the dry season reflected a reduction in foraging activity. Differences in the gape size and foraging behaviour of males and females of *L. nannotis* were responsible for sex-specific differences in diet composition. *L. nannotis* also displayed an ontogenetic shift in prey size and type. As snout vent length increased, *L. nannotis* consumed fewer, but larger prey and increasingly discriminated against dipterans, dipteran larvae and hemipterans. Importantly, *L. nannotis*, *L. rheocola* and *N. dayi* demonstrated the capacity to compensate for fluctuations in food availability by feeding on less lucrative prey." ["Most animals develop some kind of parental care in order to protect eggs or offspring from predation. Female newts (genus *Triturus*) protect eggs from predators by wrapping them individually in plant leaves. We studied oviposition characteristics of four newt species inhabiting the northern Iberian Peninsula (marbled newt, *Triturus marmoratus*; alpine newt, *T. alpestris*; palmate newt, *T. helveticus* and Bosca's newt, *T. boscai*). All of these species are able to wrap their eggs in aquatic plants in laboratory experiments, but - whereas *T. marmoratus*; *T. alpestris* and *T. helveticus* wrapped more than 90% of their eggs - *T. boscai* covered only half of the eggs completely with leaves. *T. boscai* is found in running waters more frequently than the other species, and lays larger eggs relative to female size, as is typical of running water urodeles. A parallel experiment exposing newt eggs to

predation by larvae of the dragonfly *Aeshna cyanea*, demonstrated the protective value of wrapping behaviour. About half of the unwrapped eggs were consumed, whereas protected eggs remained almost unattacked." 5063. Roush, S.A.; Amon, J.P. (2003): Repopulation of restored wetland habitat by odonata (dragonflies and damselflies). *Ecological Restoration* 21(3): 174-179. (in English). [Usa, Ohio; "Each of the restored wetlands supported a wide variety of Odonata (Tab. 1). We found 26 species total, with nine to 15 species at each site. Eight species *Archilestes grandis*, *Argia moesta*, *Celi-themis elisa*, *Ischnura hastata*, *Lestes disjunctus australis*, *L. unguiculatus*, *Perithemis tenera*, and *Sympetrum vitinum* were collected only once in our surveys, but notably were found at restored sites. While none of the species we found are rare, the Ohio Odonata Survey notes that several, such as *A. grandis*, *I. hastata*, and *L. congener*, are not widely collected. Some species were found in only one type of restored wetland habitat. For example, *Argomphus vittosipes*, *L. congener*, *L. disjunctus australis*, and *A. moesta* occurred in the seasonal marsh and nowhere else. Five species of dragonflies *Aeshna umbrosa*, *Libellula semifaciata*, *Somatochlora tenebrosa*, *S. rubicundulum*, and *S. vitinum* were found only in the restored fens. In addition, we found [...] *Amphiagrion sautum*, *A. grandis*, and *L. unguiculatus* only in the restored fens. We found *C. elisa*, *P. tenera*, and *S. semicinctorum* only in the restored groundwater marsh. Walker & Corbet (1975) noted that species such as *S. tenebrosa*, *A. saucium*, *L. unguiculatus*, and *S. semicinctorum* are restricted to spring-fed habitats and/or temporary pools. While our data support that finding, not all species we found at our fen sites were restricted to fens." (Authors)] Address: Amon, J.P., Dept Biol. 5066. Sinitshenkova, N.D. (2003): Main ecological events in aquatic insect history. *Acta zool. cracov.* 46 (Suppl.): 381-392. (in English). [The history of the adaptations to the aquatic life is traced from the Carboniferous to the Cretaceous. There are no Carboniferous insects with any obvious adaptations to aquatic life. The meganeurids could be proposed, but since their larvae are completely unknown, a terrestrial mode of life was suggested. In the Permian the aquatic insects became diverse and probably colonized lotic and lentic habitats. Wootton's suggestion that the insects inhabited first the running waters is questioned. Periodically flooded habitats are the most probable biotops of ancestral aquatic insects. First "aquatic odonate species" are known from the Upper Triassic of Australia.] Address: Sinitshenkova, N.D., Palaeontol. Inst., Russ. Acad. Sci., ul. 5070. Thompson, D.J.; Rouquette, J.R.; Purse, B.V. (2003): Ecology of the Southern Damselfly. *Conserving Natura 2000 Rivers Ecology Series No. 8*. English Nature, Peterborough. ISBN 1 85716 714 7: 26 pp. (in English). [In UK, *C. mercuriale* "is on the northern margin of its range. It has disappeared from, or is on the edge of extinction, in seven European countries along its northern boundaries, and is declining in three others, including Britain. In Britain there are three main centres of population the heathlands of Mynydd Preseli in Pembrokeshire and the New Forest, and the water meadow ditch systems of the Itchen and Test valleys. There are also small populations on the Dorset heaths, Dartmoor, East Devon pebble beds, Gower and two fens in Ox-

fordshire and Anglesey. The species is sensitive to a number of habitat factors. A requirement for a thermally sensitive microclimate is reflected in broad-scale habitat use (for example, use of shallow, sun-exposed, permanently flowing water bodies indicated by perennial, herbaceous, aquatic vegetation), and in habitat use for oviposition and emergence. The southern damselfly is semi-voltine in Britain, with a shorter larval growth period and flight period than in mainland European populations. Seasonal regulation is probably achieved by a facultative autumn diapause in the penultimate larval instar. Dispersal distances are relatively poor, which means that the already highly fragmented British populations are likely to become even more fragmented, with implications for its conservation. The main cause of the decline in the southern damselfly in Britain has been the use of unsympathetic grazing regimes in key habitats over long periods." (Authors). 5073. Anholt, B.R.; Negovetic, S.; Som, C.; Rauter, C. (2004): Predator complement determines the relative success of tadpoles of the *Rana esculenta* complex. Ecological Society of America Annual Meeting Abstracts 89: 19- [Verbatim: The hybridogenetic European waterfrog, *Rana esculenta*, is an obligate sexual parasite of its host, *R. lessonae*, across large regions of its distribution. *R. esculenta* is a superior competitor to *R. lessonae* in a wide range of conditions and is also a larger, more fecund frog than *R. lessonae*. In the absence of conditions that favour *R. lessonae* we expect that *R. esculenta* should competitively exclude *R. lessonae* and then go extinct for lack of mates. Amphibians have been found to segregate among habitats along an axis of pond permanence that determines the apex predator in the system. We therefore examined the change in frequency of the two taxa from the larval

stage to metamorphosis in water bodies that did or did not support fish. We found that in the absence of fish and the presence of large invertebrate and amphibian predators, the frequency of *R. lessonae* increased relative to *R. esculenta* from the larval stage to metamorphosis while in the presence of fish and absence of other predators, the opposite was true. This observation was supported in a laboratory experiment where we found that *R. esculenta* was more vulnerable to predation by dragonfly larvae. Differences in vulnerability were associated with differences in activity level of the two taxa in the presence of caged predators. These results suggest that the two taxa are adapted to different predator complexes and the hybridogenetic system is maintained by occasional dispersal between dissimilar water bodies.] Address: Anholt, B.R., Dept Biology, University of Victoria, PO Box 3020, Victoria, BC, V8W 3N5, Canada. 5077. Beldon, P.A.; Downer, V.J.; Luck, J.C.; Prendergast, H.D.V.; Sadler, D. (2004): The Dragonflies of Sussex: A Guide to their Distribution and Conservation. Essendon Press. ISBN 0-9525549-1-7: 81 pp. [County faunas are becoming increasingly popular and it is

refreshing to see the publication of this new work dealing with Sussex dragonflies. The idea of local lists dealing with the Sussex fauna and flora is not new. Undoubtedly the most comprehensive early work was The Victoria County History of the Counties of England: Sussex, Volume 1, which was published in 1905. This contained extensive annotated lists of plants and animals recorded from the county, each order being assigned to a different specialist. The section on Odonata, included within the Neuroptera, was written by the well-known Hastings naturalist the Rev. E.N. Bloomfield. In his introduction to the dragonfly section he states, "We have a fair record, but to complete the possible list *Orthetrum caerulescens*, Fabr. [Keelred Skimmer], should be looked for on boggy heaths, *Aeschna juncea*, Linn. [Common Hawker], around ponds, especially in fir woods, and *Erythromma najas*, Hansem. [Red-eyed Damselfly], over sluggish water, where no doubt they await discovery; while it is quite possible that the little *Agrion mercuriale*, Charp. [Southern Damselfly], may be hiding its charms amongst the rank herbage of some boggy stream." Although Southern Damselfly *Coenagrion mercuriale* appears to be genuinely absent from Sussex, the other three have indeed been recorded from the County. This latest book essentially presents the results of a survey carried out between 1989-2003 by members of the Sussex Dragonfly Recording Group, combined with data sent in by many visiting naturalists. Pre-1989 data is also plotted on each distribution map and is discussed briefly. A map of the county shows the total number of records received, in three categories by tetrads (2 x 2km squares). Following the Contents page are chapters entitled "Foreword", "Introduction", "The Sussex scene" and "Dragonfly recording", followed by the main species accounts. This latter section occupies 75% of the book and deals with the 12 damselfly and 17 dragonfly species that are currently regarded as permanent breeding residents in the County. Each species has been allocated a double page and is accompanied by a distribution map and several colour photographs. Although not intended to be an identification guide, the photos serve to point the recorder in the right direction, but for accurate determinations it is necessary to refer to detailed descriptions elsewhere. The maps show the modern administrative boundary between East and West Sussex, but not the City of Brighton or the boundary between Watsonian Vice-counties 13 and 14. Each map shows the eight differently coloured geological zones and labelled 10km grid lines, although to determine the 100km grid square code letters (SU, SZ, TQ, TV) it is necessary to refer to the map on pages 6 or 11. The maps also show rivers with major tributaries so that species associated with the different catchment areas can be identified at a glance. Records are plotted on a 1km grid square basis and are divided into three categories, distinguished by differently coloured spots: "pre-1989", "1989-2003 present only" and "1989-2003 probable/possible breeding". Chapter 5, "Species lost and won", discusses species not currently regarded as resident and breeding, including Scarce Emerald Damselfly *Lestes dryas*, which was apparently established at Powdermill Reservoir, near Brede, during the 1940s, and several species currently regarded as migrants. The final chapter, "Acknowledgements and credits", contains a comprehensive list of more than 200 contributors and compilers. A separate chapter giving a Sussex checklist, with synonymy, would have aided the collation of species with little or no breeding history in the County. Nevertheless

it is possible to compile a list by carefully extracting data from Chapters 4 and 5. There is plenty of room for 100km grid square code letters on each distribution map and it is hard to understand why these were omitted. The absence of a general index is also somewhat frustrating. However, these are but minor points of criticism and certainly should not deter naturalists from purchasing this excellent book." Peter Hodge, *Atropos* 26: 39-40.]

5080. Böhm, K. (2004): Zur Entwicklung und Phänologie von *Crocothemis erythraea* in Nordrhein-Westfalen: Nachweis einer zweiten Jahresgeneration? (Odonata: Libellulidae). *Libellula* 23(3/4): 153-160. (in German, with English summary). ["In summer 2003 two emergence cohorts were recorded at a pond in Düsseldorf (51°12'N, 6°44'E), Germany. The first cohort emerged in May and June, and the second from the end of July to mid-September. This is interpreted as a second annual generation originating from ovipositions of the first cohort. With 513 individuals the second generation was twice as large as the first and showed an emergence peak in the first half of August." 5084. Buczyński, P. (2004): Dragonflies (Odonata) from Poland in the collection of Museum and Institute of Zoology of Polish Academy of Sciences in Warsaw. Nowy Pam. Fizjogr., Warszawa, 3 (1-2): 15-26. (in Polish, with English summary). [Four of the five collections on Odonata deposited in the Museum and Institute of Zoology of Polish Academy of Sciences (MiIZ PAN) are discussed: the specimens by KRÜGER from Szczecin and the Baltic coast (1913-21) - the part of the voucher

specimen collection for the paper of the dragonflies of Pomorze (KRÜGER 1925); 2) the material by BAZYLUK from the vicinity of Siemień in Western Polesie (1929-50), the majority was published by BAZYLUK (1947, 2002) and BUCZYŃSKI (2003); 3) unpublished material from the Srodkowomazowiecka Lowland (1954-55); 4) unpublished material from 12 regions in different parts of the country, collected by researchers of MiIZ PAN (1945-50). All localities are mapped, and in total 46 odonate species are documented and discussed. Of special interest are *Sympecma paedisca*, *Aeshna affinis*, *Orthetrum albistylum*, and *Sympetrum fonscolombii*. The specimens of *S. paedisca* from the KRÜGER collections - wrongly published as *S. fusca* - are the oldest recorded ones of this species in north-western Poland. This is another example of wrong identification of this species (cf. BUCZYŃSKI 2003). There are also some old records of species like *Erythromma viridulum*, which in the past decade has been expanding its range in some European regions, or *Lestes barbarus*, often classified as "mediterranean species".] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. 5089. Che Salmah, M.R.; Abu Hassan, A.; Ameilia, Z.S. (2004): Odonate communities (Odonata: Insecta) in a tropical river basin, Malaysia. *Wetland Science* 2(1): 1-9. (in Chinese, with English summary). ["Odonata larvae were sampled from 16 tributaries of Kerian River in the Kerian River Basin (KRB) using a kick sampling technique from September 1998 to May 1999 encompassing both rainy and dry seasons. The distribution of odonate genera was significantly different ($F_{15,46} = 3.99$) among rivers in both seasons ($F_{15,16} = 4.70$) at $P = 0.05$. However, no seasonal influence was detected. Protoneuridae and Libellulidae were the most dominant families in this basin. Other families Gomphidae, Coenagrionidae, Macromiidae, Chlorocyphidae and Calopterygidae, were common but Aeshnidae and Eupheidae were rare. Several common species, *Prodasineura autumnalis*, *Brachythemis contaminata*, *Macromia gerstaeckeri*, *Paragomphus*, *Orthetrum brunneum* [sic], *Rhinocypha quadrimaculata* and *Copea marginipes* were identified. The calculated values of biological indices (H', D, E, R 1 and R2) showed that the dragonfly fauna in this river basin was slightly poor. Varied physico-chemical parameters of the river possibly as a result of human activities in surrounding areas were found to influence the distribution of the dragonfly larvae in the KRB. This study showed that the KRB provided favorable habitats for Protoneuridae and Libellulidae. Two most dominant species *Prodasineura autumnalis* and *Brachythemis contaminata* were obviously favoured by slightly acidic water of the Kerian river tributaries."] Address: Che Salmah, M.R., School of Biological Sciences, University Sains Malaysia, 11800 Minden, Pulau Pinang, Malaysia

5093. Cordero Rivera, A.; Andrés, J.A.; Córdoba-Aguilar, A.; Utzeri, C. (2004): Postmating sexual selection: allopatric evolution of sperm competition mechanisms and genital morphology in calopterygid damselflies (Insecta: Odonata). *Evolution* 58(2): 349-359. (in English). ["Postmating sexual selection theory predicts that in allopatry reproductive traits diverge rapidly and that the resulting differentiation in these traits may lead to restrictions to gene flow between populations and, eventually, reproductive isolation. In this paper we explore the potential for this premise in a group of damselflies of the family Calopterygidae, in which postmating sexual mechanisms are especially well understood. Particularly, we tested if in allopatric populations the sperm competition mechanisms and genitalic traits involved in these mechanisms have indeed diverged as sexual selection theory predicts. We did so in two different steps. First, we compared the sperm competition mechanisms of two allopatric populations of *Calopteryx haemorrhoidalis* (one Italian population studied here and one Spanish population previously studied). Our results indicate that in both populations males are able to displace spermathecal sperm, but the mechanism used for sperm removal between both populations is strikingly different. In the Spanish population males seem to empty the spermathecae by stimulating females, whereas in the Italian population males physically remove sperm from the spermathecae. Both populations also exhibit differences in genital morphometry that explain the use of different mechanisms: the male lateral processes are narrower than the spermathecal ducts in the Italian population, which is the reverse in the Spanish population. The estimated degree of phenotypic differentiation between these populations based on the genitalic traits involved in sperm removal was much greater than the differentiation based on a set of other seven morphological variables, suggesting that strong directional postmating sexual selection is indeed the main evolutionary force behind the reproductive differentiation between the studied populations. In a second step, we examined if a similar pattern in genital morphometry emerge in allopatric populations of this and other three species of the same family (*Calopteryx splendens*, *C. virgo* and *Hetaerina cruentata*). Our results suggest that there is geographic variation in the sperm competition mechanisms in all four studied species. Furthermore, genitalic morphology was significantly divergent between populations within species even when different populations were using the same copulatory mechanism. These results can be explained by probable local coadaptation processes that have given rise to an ability or inability to reach and displace spermathecal sperm in different populations. This set of results provides the first direct evidence of intraspecific

evolution of genitalic traits shaped by postmating sexual selection." 5098. Dumont, H.J. (2004): A note on dragonflies collected at light in a forest in the Ivory Coast (West Africa). Bulletin S.R.B.E./K.B. V.E. 140: 66-67. (in English). [Discussion of dragonfly specimens collected at a series of light traps, primarily designed to collect moths, in a forest in the south-east of the Ivory Coast by Dr. U. Dall'Asta (Tervuren Museum, Belgium) (23 Jan 1996-12

Feb 1996), at 13 stations across the Forêt Classée de Bossematié. 9 species have been caught, in most cases *Tholymis tillarga*. "Night-flying in dragonflies is often linked to long-distance migratory movement and is prompted at the maiden flight or occurs at a very teneral age. Some species, however, may end up in light traps after having been disturbed while roosting at night, and may not normally be night-active at all. This may apply to about half of the present species list!"] Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. Ledeganckstraat 35, B-9000 Gent, Belgium. E-mail: Henri.Dumont@rug.ac.be

5099. Englund, R.A. (2004): Report for the 2003 Pacific Biological Survey, Bishop Museum. Austral Islands, French Polynesia, Expedition to Rurutu and Tubuai. Prepared for: Délégation à la Recherche, (Ministère de la Promotion des Ressources Naturelles), B.P. 20981 Papeete, Tahiti, Polynésie française.

<http://www.bishopmuseum.org/research/pbs/pdf/australs2003.pdf>: V, 38 pp. (in English, with French summary). ["From 9-28 November 2003, staff from the Pacific Biological Survey (PBS) of the Bishop Museum in cooperation with other biologists conducted biological surveys in the Austral Islands of Tubuai and Rurutu as part of an [...] inventory and evaluation of biodiversity, a research program conducted in French Polynesia [...]. The objectives of this biodiversity assessment of the Austral Islands were: 1) to assess the native aquatic insect fauna and describe the overall biodiversity of this fauna, 2) to assess the biodiversity and status of Heteroptera and other important endemic phytophagous insects in native forest areas, 3) to assess the impacts or lack of impacts of introduced aquatic species on native stream biota, 4) to qualitatively assess the impacts of introduced species, feral ungulates, urbanization, on native insects, and 5) to provide museum specimens and an information baseline for future researchers. Significant findings of these surveys include a pristine native freshwater fauna lacking introductions of non-indigenous fish, amphibians, or aquatic reptiles on Rurutu, but two harmful invasive fish species were widespread on Tubuai. Tubuai is apparently the only Austral Island currently having introduced freshwater fish species. On Tubuai, alien fish were found in all aquatic habitats sampled with only one exception at the large cascade below the Mt. Panee summit; this was the highest elevation area on Tubuai with flowing water. This cascade flowed into a series of stair-step pools that were too steep and high gradient for introduced fish to access, and was a potential refuge area for native species that could be negatively impacted by introduced fish, such as endemic damselflies. Numerous undescribed and several described aquatic insect species were found on both Rurutu and Tubuai, including new species and range extensions of Heteroptera (true bugs), Diptera (aquatic flies), and Odonata (dragonflies and damselflies), and Coleoptera (beetles). One of the most important aquatic findings during this expedition was a new species of large endemic damselfly found on Rurutu only in undiverted, forested, and fast-flowing streams. It is possible that endemic damselflies have been eliminated on Tubuai by invasive fish species, though more intensive surveys are required to verify this. Although generally uncommon and not found in many French Polynesia islands, one species of native aquatic Coleoptera (beetles), *Rhantus* new sp. near *scheneri* was found at Tamatoa Stream in the lower elevation still-water *Hibiscus tiliaceus* areas. Aquatic in-

sects in the orders Ephemeroptera, Plecoptera, and Trichoptera (EPT) orders were not found on Tubuai or Rurutu. Areas that should receive the highest conservation priority on Rurutu include the makatea forest at Plateau Papanai with a mixed *Dodonea viscosa* shrubland forest that is one of the largest and most intact in French Polynesia, harboring unique species of biogeographically important endemic insects. A gully below the summit of Mt. Taatioe with the endangered *Cyrtandra elisabethae* plants and new species of green planthopper is of world-wide conservation and biogeographic importance and contains the largest patches of remnant native upland forest remaining on Rurutu, and with it the greatest native insect biodiversity on Rurutu. This area should be immediately fenced to keep grazing cattle out, and weeding could reduce the encroaching invasive plant species. The lack of action in protecting these forest patches from grazing cattle and other feral ungulates will certainly lead to the demise of native plants on Rurutu and the extinction of the unique insects associated with them. The native species found on both islands are important on a worldwide basis, and the conservation of this rich biodiversity is a critical component of the Polynesian culture found on these islands. It is of global significance to preserve the native biodiversity found on the Austral Islands to allow a greater understanding of the natural biological processes of dispersal and colonization of the fauna to these remote and isolated island areas." 5104. Gaines, K.H. (2004): Stable isotope analysis reveals complexity at different spatial scales in desert sinkhole food webs. *Ecological Society of America Annual Meeting Abstracts* 89: 171-172. (in English). [Verbatim: The Bitter Lake National Wildlife Refuge in southeastern New Mexico contains dozens of saline sinkholes in a desert scrub and grassland matrix. Most of these sinkholes support aquatic macroinvertebrate communities dominated by larval dragonflies and damselflies (Order Odonata), and some sinkholes also support populations of two rare fish species. In order to determine how the food webs in these sinkholes are structured, I collected fish, larval odonates and other aquatic insects, snails, amphipods, macroalgae, and macrophytes from pairs of sinkholes with and without fish in different locations in the sinkhole complex. These materials were then submitted for stable carbon and nitrogen isotope analysis. Results from these analyses suggest that superficially similar habitat patches separated by as little as twelve meters can support communities with significantly different diversities and trophic structures, and that the spatial scale at which food webs are examined may determine the degree of complexity perceived in a landscape.] Address: Gaines, Karen H., Univ New Mexico, Albuquerque, NM, 87131, USA. 5105. Ghassemzadeh, F (2004): Limnological studies of Bazangan Lake, northeast Iran. *Ecological Society of America Annual Meeting Abstracts* 89: 177. (in English). [Verbatim: The Bazangan Lake is the largest natural lake in northeast Iran. It is located between 60°29 east longitudinal and 36°17 north latitudinal. This lake is in a temperate area with low rainfall (200mm). The climate is dry and hot from June to September. The mean and the maximum depth of the lake are 6 and 11 meters respectively. Its surface area is about 690,000 square meters. Major environmental factors were measured at five stations. Five samples have been collected from each station. Water and air temperatures, salinity, conductivity, pH, viscosity and soluble reactive phosphorous were measured seasonally during a period of one year. The biota of the lake was monitored by recording the abundance and distribution of zooplankton and phytoplankton. Conductivity of the water is about 20,000 umhos/cm and pH is about 8. Thermal

stratification happened from end of June to the end of July. Thermocline was occurred at 4.25 to 6 meters depth. Major groups of algae identified in the lake including Chlorophyta, Cyanophyta and Diatoms. The zooplankton of the lake was few in species, but rather large population of them are present in some stations. The main identified species were: cladocera, Diaptomus, rotifera, Hexarthra, Branchionus, Synchaeta; Cladocera, Daphnia and chironomid, Chironomus. Collembola. Corixid, Trichocorixa are found along the shore. Much less common species was harpacticoid and a few cyclopoid. The littoral region contains a relatively sparse fauna although some species are present in high numbers such as hemiptera, odonata and coleoptera. The lake is hyposaline oligotrophic with low phytoplankton and zooplankton communities. It is concluded that salinity, low food as well as viscosity are the important factors for low diversity of organisms in this lake which providing less amount of food for fish in the lake. Therefore the diversity and abundance of fishes in the lake are also low.] Address: Ghassemzadeh, F., Azad Univ Mashhad, Mashhad, Iran

5107. Gunzburger, M.S. (2004): The role of tadpole predation in the habitat distribution and hybridization of two species of treefrogs. *Ecological Society of America Annual Meeting Abstracts 89 2004*: 193. (in English). [Verbatim: Closely related species that occur sympatrically often have mechanisms to partition niche space and maintain species identity. *Hyla cinerea* and *H. gratiosa* are sister taxa that are sympatric throughout the southeastern United States. These species have different breeding habitat preferences: *H. cinerea* prefers permanent ponds while *H. gratiosa* only breeds in fishless ponds. Occasionally viable, fertile hybrids between these species form that may introgress into both parental species. The objective of this research was to evaluate the importance of tadpole predation in the habitat distribution of these two closely related species and their hybrids. Predation experiments were performed using large mesocosms to evaluate survival and behavior of *H. cinerea*, *H. gratiosa*, and hybrid tadpoles in response to permanent pond (sunfish) and temporary pond (odonate naiad) predators. Small sized tadpoles of both species have similar survival and behavior with odonates, but with sunfish predators *H. gratiosa* tadpoles hide in refuges less and suffer greater predation than *H. cinerea* tadpoles. Hybrid tadpoles showed intermediate survival values between *H. cinerea* and *H. gratiosa* with odonates, but had extremely low survival with sunfish despite the fact that they adopt appropriate antipredator behavior. These results demonstrate that tadpole predation may be the mechanism leading to the habitat distribution of *H. cinerea* and *H. gratiosa*. Hybrid introgression may be a more significant threat to populations of *H. gratiosa* than *H. cinerea* because hybrid tadpoles are more likely to survive in temporary pond habitats with *H. gratiosa* tadpoles.] Address: Gunzburger, Margaret, Florida State Univ, Tallahassee, FL, 32306, USA

5108. Hadrys, H.; Melber, A. (2004): Biodiversität und Artenschutz: Paradebeispiel Libellen. *Stiftung Tierärztliche Hochschule Hannover. Forschung fürs Leben 2004*: 32-34. (in German, with English summary). ["Biodiversity and conservation biology: dragonflies, the classic example. More than 1 million species of insects have been identified, making these animals the most successful on Earth. Insects comprise the greatest portion of biodiversity in the animal kingdom. One of the most important groups of insects used for developing conservation strategies and as a bioindicator for quality and stability of environments is the order Odonata (dragonflies and damselflies). Due to the odonates complex reproduction behaviour and very specific habitat preferences, progressive anthropogenic changes to the environment have severe consequences on many odonates. For example, numerous species exist only in small isolated populations. The genetic diversity, i.e. adaptability, of a species and the survival of single populations is much more rapidly detectable at the genotypic level than by phenotypical methods. Based on genetic information, it is also possible to quickly identify isolation processes that threaten a population. Molecular genetic methods are becoming increasingly important for animals conservation in that they provide essential information on the condition of populations, species and habitats. This is demonstrated by the following study on the biodiversity of African dragonflies." (Authors)] Address: <http://www.tiho-hannover.de/service/presse/forsch/biodiversitaetumwelt.pdf>

5109. Hammond, J.I.; Sih, A. (2004): Investigating the response in spatial distributions when predators and prey are free to interact. *Ecological Society of America Annual Meeting Abstracts 89 2004*: 202. (in English). [Verbatim: Hundreds of studies have focused on the habitat and patch usage of predators and prey, with results establishing the overall pattern that predators tend to aggregate in areas with more prey while prey tend to avoid areas with higher predation risk. Almost all of these studies have eliminated the behavior of one player (e.g. the predator) by fixing it in space and therefore constraining its ability to respond to shifts in space use by the other player (e.g. the prey). Therefore, what spatial associations emerge if predators and prey are allowed to freely interact with each other? Surprisingly, we know little theoretically or empirically about these interactions. Simple theory constructed in a world where patches only differ in the level of a prey's resource, predicts predators should aggregate in the high resource areas while prey should tend to favor those patches as well. Thus the distributions result in a positive association. Using pairs of *Aeshna* dragonfly nymphs as predators and groups of *Hyla regilla* tadpoles consisting of either middle, late, or mixed stage individuals as prey, the spatial distributions of the predator and prey were examined in isolation and together. Interesting patterns emerge with late stage tadpoles shifting their spatial distributions from high densities in the high resource area without predators to a more even distribution with predators. Middle stage tadpoles and predators tend to have similar spatial distributions when isolated and together. Furthermore when the predators and prey were together, a significant negative spatial correlation was present between late stage tadpoles and predators regardless of the prey group type, which is contrary to initial theoretical predictions.] Address: Hammond, J.I., Univ Calif Davis, Davis, CA, 95616, USA

(in English). ["The neural systems that control escape behavior have been studied intensively in several animals, including mollusks, fish and crayfish. Surprisingly little is known, however, about the activation and the utilization of escape circuits during prey predator interactions. To complement the physiological and anatomical studies with a necessary behavioral equivalent, we investigated encounters between juvenile crayfish and large dragonfly nymphs in freely behaving animals using a combination of high-speed video-recordings and measurements of electric field potentials. During attacks, dragonfly nymphs rapidly extended their labium, equipped with short, sharp palps, to capture small crayfish. Crayfish responded to the tactile stimulus by activating neural escape circuits to generate tail-flips directed away from the predator. Tail-flips were the sole defense mechanism in response to an attack and every single strike was answered by tail-flip escape behavior. Crayfish used all three known types of escape tail-flips during the interactions with the dragonfly nymphs. Tail-flips generated by activity in the giant neurons were predominantly observed to trigger the initial escape responses to an attack, but non-giant mediated tail-flips were often generated to attempt escape after capture. Attacks to the front of the crayfish triggered tail-flips mediated either by the medial giant neuron or by non-giant circuitry, whereas attacks to the rear always elicited tail-flips mediated by the lateral giant neuron. Overall, tail flipping was found to be a successful behavior in preventing predation, and only a small percentage of crayfish were killed and consumed." 5131. Lorenz, A., Feld, C.K.; Hering, D. (2004): Typology of streams in Germany based on benthic invertebrates: Ecoregions, zonation, geology and substrate. *Limnologica* 34(4): 379-389. (in English). ["Based on 390 benthic invertebrate samples from near-natural streams in Germany we defined eight stream type groups by Non-metric multidimensional scaling (NMS). The taxa lists were restricted to Mollusca, Ephemeroptera, Odonata, Plecoptera, Coleoptera and Trichoptera species and evaluated on presence/absence level. At genus level, streams located in the lowlands differ from streams in lower mountainous areas and the Alps, while the two latter groups were undistinguishable. At species level, a clear separation of different stream size classes is visible in the lowlands; a second gradient is related to the bottom substrate. Streams in the Alps can be distinguished from streams in lower mountainous areas at species level. Within the lower mountainous regions a size gradient is detectable, a less obvious gradient indicates catchment geology. The resulting bottom-up stream typology is compared to other stream typological systems in Germany." 5132. Mao Sun; Shi Long Lan (2004): A computational study of the aerodynamic forces and power requirements of dragonfly (*Aeshna juncea*) hovering. *J. Exp. Biol.* 207: 1887-1901. (in English). ["Aerodynamic force generation and mechanical power requirements of a dragonfly (*Aeshna juncea*) in hovering flight are studied. The method of numerically solving the Navier Stokes equations in moving overset grids is used. When the midstroke angles of attack in the downstroke and the upstroke are set to 52° and 8°, respectively (these values are close to those observed), the mean vertical force equals the insect weight, and the mean thrust is approximately zero. There are two large vertical force peaks in one flapping cycle. One is in the first half of the cycle, which is mainly due to the hindwings in their downstroke; the other is in the second half of the cycle, which is mainly due to the forewings in their downstroke. Hovering with a large stroke plane angle (52°), the dragonfly uses drag as a major source for its weight-supporting force (approximately 65% of the total vertical force is contributed by the drag and 35% by the lift of the wings). The vertical force coefficient of a wing is twice as large as the quasi-steady value. The interaction between the fore- and hindwings is not very strong and is detrimental to the vertical force generation. Compared with the case of a single wing in the same motion, the interaction effect reduces the vertical forces on the fore- and hindwings by 14% and 16%, respectively, of that of the corresponding single wing. The large vertical force is due to the unsteady flow effects. The mechanism of the unsteady force is that in each downstroke of the hindwing or the forewing, a new vortex ring containing downward momentum is generated, giving an upward force. The body-mass-specific power is 37 W kg⁻¹, which is mainly contributed by the aerodynamic power." (Authors)] Address: Mao Sun, Institute of Fluid Mechanics, Beijing University of Aeronautics &

5135. Maybury, W.J.; Lehmann, F.-O. (2004): The fluid dynamics of flight control by kinematic phase lag variation between two robotic insect wings. *J. Exp. Biol.* 207: 4707-4726. (in English). ["Insects flying with two pairs of wings must contend with the forewing wake passing over the beating hindwing. Some four-winged insects, such as dragonflies, move each wing independently and therefore may alter the relative timing between the fore- and hindwing stroke cycles. The significance of modifying the phase relationship between fore- and hindwing stroke kinematics on total lift production is difficult to assess in the flying animal because the effect of wing-wake interference critically depends on the complex wake pattern produced by the two beating wings. Here we investigate the effect of changing the fore- and hindwing stroke-phase relationship during hovering flight conditions on the aerodynamic performance of each flapping wing by using a dynamically scaled electromechanical insect model. By varying the relative phase difference between fore- and hindwing stroke cycles we found that the performance of the forewing remains approximately constant, while hindwing lift production may vary by a factor of two. Hindwing lift modulation appears to be due to two different fluid dynamic phenomenons: leading edge vortex destruction and changes in strength and orientation of the local flow vector. Unexpectedly, the hindwing regains aerodynamic performance near to that of the wing free from forewing wake interference, when the motion of the hindwing leads the forewing by around a quarter of the stroke cycle. This kinematic relationship between hind- and forewing closely matches the phase-shift commonly used by locusts and some dragonflies in climbing and forward flight. The experiments support previous assumptions that active neuromuscular control of fore- and hindwing stroke phase might enable dragonflies and other functionally four-winged insects to manipulate ipsilateral flight force production without further changes in wing beat kinematics." 5137. McCauley, S. (2004): The role of dispersal and habitat selection in odonate species distributions. *Ecological Society of America Annual Meeting Abstracts* 89 2004: 331. (in English). [Verbatim: Species' distributions are affected by both local conditions and regional processes, including dispersal. A transition in the top predator community from fish to invertebrate predators is a critical gradient in aquatic communities. While the local factors affecting species distributions across this gradient are well studied, there has been less work on how dispersal and habitat selection affect the development of local communities along this gradient. This study relates dispersal and habitat selection (measured by colonization rates) to species' distributional breadths across a top predator gradient. To measure dispersal and colonization, 29 artificial ponds were established in 2002 and monitored through 2003. These artificial ponds (cattle watering tanks) were placed at varying distances of up to two kilometers from three lakes with alternative top predators (sunfish, minnow, and invertebrate predators) in a landscape context where species distributions in the surrounding natural ponds had been monitored for several years. Dispersal was quantified by adult censuses. In two years of sampling, 23 species of adult dragonfly were observed at tanks. Colonization was measured by collecting and identifying larvae from the tanks in three surveys each year. Fourteen species of dragonfly larvae colonized tanks. Distance from natural lakes did not affect species richness of either dispersers or colonists at tanks. There were, however, high levels of species turn-over between tanks near lakes and far from lakes and turn-over increased with distance. Results also found dispersal rates and distances were positively related to species' habitat breadth. Habitat generalists also colonized tanks at significantly greater rates than habitat specialists. These results suggest that differential dispersal and habitat selection between habitat specialists and generalists is an important mechanism in determining species distributions.] Address: McCauley, Shannon, Univ Michigan, Ann Arbor, MI, 48109, USA.

(Ott, J.: Hrg): *Biodiversität im Biosphärenreservat Pfälzerwald - Status und Perspektiven*. Mainz. ISBN 3-9804353-4-2: 108-123. (in German, with French and English summaries). [The present knowledge of the distribution and endangerment of several insect groups (among them: Odonata) in the biosphere reserve (BSR) Pfälzerwald, Rheinland-Pfalz, Germany is analysed, and their importance for all planning projects is pointed out. "A special entomological mapping of the BSR, covering all major and important groups, is lacking. There is no synopsis and evaluation

of existing data of museums, collections of universities and private persons, publications and the grey literature available. But such a general perspective is the basis and precondition of any serious assessment of the endangerment of the species and of any landscape planning, environmental impact assessment or monitoring programme (e.g. according to the EC habitats directive). Some causes of endangerment - especially focusing on insects - are listed and their consequences are pointed out. From the point of view of entomological nature conservation a more intensive data collection, their documentation in a central institution, the coordination of the activities with the French part of the BSR, more species protection programmes for highly endangered species and the integration of insects in environmental education is proposed and asked for." 5146. Piganeau, G.I.; Gardner, M.; Eyre-Walker, A. (2004): A broad survey of recombination in animal mitochondria. *Mol. Biol. Evol.* 21(12): 2319-2325. (in English). ["Recombination in mitochondrial DNA (mtDNA) remains a controversial topic. Here we present a survey of 279 animal mtDNA data sets, of which 12 were from asexual species. Using four separate tests, we show that there is widespread evidence of recombination; for one test as many as 14.2% of the data sets reject a model of clonal inheritance and in several data sets, including primates, the recombinants can be identified visually. We show that none of the tests give significant results for obligate clonal species (apomictic parthogens) and that the sexual species show significantly greater evidence of recombination than asexual species. For some data sets, such as *Macaca nemestrina*, additional data sets suggest that the recombinants are not artifacts. For others, it cannot be determined whether the recombinants are real or produced by laboratory error. Either way, the results have important implications for how mtDNA is sequenced and used." 5160. Suttle, K.B.; Power, M.E.; Levine, J.M.; McNeely, C. (2004): How fine sediment in riverbeds impairs growth and survival of juvenile salmonids. *Ecological Applications* 14(4): 969-974. (in English). ["Although excessive loading of fine sediments into rivers is well known to degrade salmonid spawning habitat, its effects on rearing juveniles have been unclear. We experimentally manipulated fine bed sediment in a northern California river and examined responses of juvenile salmonids and the food webs supporting them. Increasing concentrations of deposited fine sediment decreased growth and survival of juvenile steelhead trout. These declines were associated with a shift in invertebrates toward burrowing taxa unavailable as prey and with increased steelhead activity and injury at higher levels of fine sediment. The linear relationship between deposited fine sediment and juvenile steelhead growth suggests that there is no threshold below which exacerbation of fine-sediment delivery and storage in gravel bedded rivers will be harmless, but also that any reduction could produce immediate benefits for salmonid restoration." (Authors) Odonata are treated on the family level.] Address: Suttle, K.B., Dept Integrative Biol., University of California, Berkeley, California 94720-3140 USA. 5161. Switzer, P.V. (2004): Fighting behavior and prior residency advantage in the territorial dragonfly, *Perithemis tenera*. *Ethol. Ecol. Evol.* 16: 71-89. (in English). ["Many factors, including residency status, body size, age, and energetic reserves, have been implicated as possibly determining the winner in animal contests. In this study I investigated which of these factors were correlated with the outcomes of naturally-occurring territorial contests between male amberwing dragonflies (*P. tenera*). Amberwing contests consist of non-contact interactions and are characterized by a series of distinct stages that represent different levels of escalation. Prior residents did tend to win, but interestingly this residency advantage only occurred in interactions that were not escalated. For both non-escalated and escalated interactions, body size (wing length) did not influence the outcome. Age was correlated with outcome for escalated interactions, with the younger of the pair tending to win. Winning males had also spent less time in male-male interactions both the day of the interaction and during their entire life, suggesting that energy reserves may also affect the outcome of contests. In contrast to escalated interactions, age and time spent in male-male interactions was not related to the outcome of non-escalated interactions. The difference between the two opponents' sizes, ages, and time spent in previous male-male interactions did not correlate with duration or escalation level of contests. These results suggest that non-escalated interactions may occur when intruders are simply assessing the quality of the site. Contests that do not escalate, and thus the prior residency advantage, are probably a result of the intruder not challenging for ownership because the value of the territory is too low." 5164. Thomas, A.L.R.; Taylor, G.K.; Srygley, R.B.; Nudds, R.L.; Bomphrey, R.J. (2004): Dragonfly flight: free-flight and tethered flow visualizations reveal a diverse array of unsteady lift-generating mechanisms, controlled primarily via angle of attack. *J. Exp. Biol.* 207: 4299-4323. (in English). ["Here we show, by qualitative free- and tethered-flight flow visualization, that dragonflies fly by using unsteady aerodynamic mechanisms to generate high-lift, leading-edge vortices. In normal free flight, dragonflies use counterstroking kinematics, with a leading-edge vortex (LEV) on the fo-

rewing downstroke, attached flow on the forewing upstroke, and attached flow on the hindwing throughout. Accelerating dragonflies switch to in-phase wingbeats with highly separated downstroke flows, with a single LEV attached across both the fore- and hindwings. We use smoke visualizations to distinguish between the three simplest local analytical solutions of the Navier Stokes equations yielding flow separation resulting in a LEV. The LEV is an open U-shaped separation, continuous across the thorax, running parallel to the wing leading edge and inflecting at the tips to form wingtip vortices. Air spirals in to a free-slip critical point over the centreline as the LEV grows. Spanwise flow is not a dominant feature of the flow field spanwise flows sometimes run from wingtip to centreline, or vice versa depending on the degree of sideslip. LEV formation always coincides with rapid increases in angle of attack, and the smoke visualizations clearly show the formation of LEVs whenever a rapid increase in angle of attack occurs. There is no discrete starting vortex. Instead, a shear layer forms behind the trailing edge whenever the wing is at a non-zero angle of attack, and rolls up, under Kelvin Helmholtz instability, into a series of transverse vortices with circulation of opposite sign to the circulation around the wing and LEV. The flow fields produced by dragonflies differ qualitatively from those published for mechanical models of dragonflies, fruitflies and hawkmoths, which preclude natural wing interactions. However, controlled parametric experiments show that, provided the Strouhal number is appropriate and the natural interaction between left and right wings can occur, even a simple plunging plate can reproduce the detailed features of the flow seen in dragonflies. In our models, and in dragonflies, it appears that stability of the LEV is achieved by a general mechanism whereby flapping kinematics are configured so that a LEV would be expected to form naturally over the wing and remain attached for the duration of the stroke. However, the actual formation and shedding of the LEV is controlled by wing angle of attack, which dragonflies can vary through both extremes, from zero up to a range that leads to immediate flow separation at any time during a wing stroke." 5167. Vonesh, J.R. (2004): Sequential predator effects across three life-stages of the African treefrog, *Hyperolius spinigularis*. Ecological Society of America Annual Meeting Abstracts 89 2004: 525-526. (in English). [Verbatim: Due to their complex life cycles, amphibians may interact with different predators during different life-stages. These predators may occur in different habitats and thus may not interact directly. However, sequential predators in complex life histories may influence each other indirectly, through effects on prey size, density, and behavior. Here I examine the effects sequential predators on three stages (egg, larval, and post-metamorph) of the African treefrog *Hyperolius spinigularis*. This study was conducted at the Amani Nature Reserve, in the East Usambara Mountains of Tanzania. I monitored the density and survival of arboreal *H. spinigularis* clutches in the field to estimate how much egg-stage predation by another treefrog reduced the input of tadpoles into the pond. I then conducted experiments to determine; (1) how such reductions in initial larval density influence larval survival and size and age at metamorphosis in the presence and absence larval predators, dragonfly larvae, and (2) how plasticity in size/age at metamorphosis affects encounters with post-metamorphic predators, fishing spiders. Reductions in larval density by both egg- and larval-stage predators increased size at metamorphosis. Larger size had immediate benefits, as larger metamorphs had higher survival in encounters with fishing spiders. Thus, density-mediated effects of early predators gave rise to trait-mediated risk reduction in encounters with later life-stage predators.] Address: Vonesh, J.R., Dept Zool, Univ Florida, Gainesville, FL, 32611, USA

5168. Wang, Z.J. (2004): The role of drag in insect hovering. *J. Exp. Biol.* 207: 4147-4155. (in English). ["Studies of insect flight have focused on aerodynamic lift, both in quasi-steady and unsteady regimes. This is partly influenced by the choice of hovering motions along a horizontal stroke plane, where aerodynamic drag makes no contribution to the vertical force. In contrast, some of the best hoverers dragonflies and hoverflies employ inclined stroke planes, where the drag in the down- and upstrokes does not cancel each other. Here, computation of an idealized dragonfly wing motion shows that a dragonfly uses drag to support about three quarters of its weight. This can explain an anomalous factor of four in previous estimates of dragonfly lift coefficients, where drag was assumed to be small. To investigate force generation and energy cost of hovering flight using different combination of lift and drag, I study a family of wing motion parameterized by the inclined angle of the stroke plane. The lift-to-drag ratio is no longer a measure of efficiency, except in the case of horizontal stroke plane. In addition, because the flow is highly stalled, lift and drag are of comparable magnitude, and the aerodynamic efficiency is roughly the same up to an inclined angle about 60°, which curiously agrees with the angle observed in dragonfly flight. Finally, the lessons from this special family of wing motion suggests a strategy for improving efficiency of normal hovering, and a unifying view of different wing motions employed by insects." 5170. Wildermuth, H. (2004): *Nehalennia speciosa* in der Schweiz: ein Nachruf (Odonata: Coenagrionidae). *Libellula* 23(3/4): 99-113. (in German, with English summary). ["*N. speciosa* was recorded in Switzerland from 1867 to 1990, found at 17 localities that concentrated on the canton Zürich in the eastern Swiss Plateau. Until the first half of the seventies of the 20th century a number of small populations and some large ones were known. After 1976 they all became extinct or broke down to a large extent. Only at one locality that was monitored regularly a much reduced population survived during 14 years but never recovered. It is suggested that *N. speciosa* became extinct because of desiccation of its formerly already damaged habitats in the very long dry summer 1976 combined with changes in the vegetation due to slow eutrophication. Considering the fact that it is also extinct or highly endangered in the neighbouring countries of Switzerland and in view of the strong regressive tendencies of the sp. in Central Europe, its future in the Alpine region depends largely on the conservation of the last large populations known to exist in southern Bavaria." (Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

5171. Wildermuth, H. (2004): Wie haben die Libellen den trockenheißen Sommer 2003 überstanden? *mercuriale* 4: 29-31. (in German). [The impacts and effects of the hot summer 2003 on the very well known and monitored dragonfly population of the "Drumlinlandschaft" near Zürich, Switzerland is described and discussed in detail. Although, the abundance of many species decreased in 2003, none of the species disappeared. Obviously, in spite of many habitats fallen dry, microhabitats have been available which enabled some specimens to develop to imago. Conservation measures (e.g. blocking of ditches) realised in the past years have been successfully because water was retained in the locality.] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. (2004): A long-term rusty crayfish (*Orconectes rusticus*) invasion: dispersal patterns and community change in a north temperate lake. *Canadian Journal of Fisheries and Aquatic Sciences* 61(11): 2255-2266. (in English). ["Rusty crayfish (*Orconectes rusticus*) were first observed in Trout Lake, Wisconsin, in 1979 and took 19 years to completely disperse around the littoral zone, advancing at an average rate of 0.68 km/year¹. With the invasion of rusty crayfish, we found that fishes that share prey taxa with crayfish declined in numbers over time, but piscivorous fish species did not change in abundance. Snails declined from >10 000 to <5 snails·m² in one of the first invaded areas. Mean abundance of Odonata, Amphipoda, and Trichoptera decreased significantly lake-wide. Resident crayfish species nearly disappeared,

although total crayfish abundance, driven by high abundances of rusty crayfish, continued to rise. Submerged macrophyte species richness declined by as much as 80% at some locations. Together these responses demonstrate dramatic long-term changes in the littoral zone biota of Trout Lake. Continued invasions of similar lakes in the region suggest that these impacts are occurring on a region-wide basis with potentially irreversible effects on communities and ecosystems. Only through long-term natural experiments such as this study can researchers ascertain the full extent of invasions and their impacts on community and ecosystem process that respond at spatial and temporal scales not captured in mesocosm studies.] Address: Hill, Anna, M., Dept Biology, The Univ. of Louisiana at Monroe, Monroe, Louisiana 71209. 5177. Adite, A.; Winemiller, K.O.; Fiogbe, E.D. (2005): Ontogenetic, seasonal, and spatial variation in the diet of *Heterotis niloticus* (Osteoglossiformes: Osteoglossidae) in the So River and Lake Hlan, Benin, West Africa. *Environmental Biology of Fishes* 73: 367-378. (in English). ["The African bonytongue, *Heterotis niloticus* (Osteoglossidae), is an important fisheries and aquaculture species in West Africa. This species has frequently been characterized either as an omnivore, insectivore or detritivore, the latter, in part, because of its benthic feeding habitats and possession of a gizzard (thick-walled pyloric stomach). We examined diets of two populations of *H. niloticus* in the So River in southern Benin. A population from the river channel and seasonally flooded marginal plains was dominated by juvenile and subadult size classes. Adults size classes were common in a second population from Lake Hlan, a natural lake in the river floodplain located upstream from the channel study region. *Heterotis* of all sizes consumed a variety of food resources, ranging from aquatic invertebrates to small seeds. Aquatic invertebrates (including Odonata) composed a large proportion of the diets of juveniles, and adults consumed a mixture of aquatic invertebrates, seeds, and detritus. Seasonal dietary variation was observed in both populations, and diet breadth was not significantly different between populations. Aquatic invertebrates remained significant in diets of larger size classes; diets of fish between 100 and 200 mm began to include seeds and detritus, with a marked increase in the volumetric proportion of detritus in diets of fish between 300 and 400 mm in Lake Hlan and between 500 600 mm in the river. Relative gut length was inversely related to body size, which supports the notion that *Heterotis* is an omnivore and not a specialized detritivore. The thick-walled gizzard of *Heterotis*, which generally contained sand, probably aids digestion of seed coats. Because *Heterotis* consume mostly invertebrates and grass seeds in shallow waters of seasonal aquatic habitats and lakes in the river floodplain, foraging success and fishery production should be strongly dependent on the annual flood pulse." This dragonfly is regarded as rare by Wilson (2003). Samson So reported the following sightings of dragonflies: *Pseudagrion microcephalum* laying eggs at a rehabilitated freshwater pond of Mai Po Nature Reserve. One *Macrodiplax cora* was seen at Luk Keng marsh (near mangrove) on 29 September, and both sexes of this species were seen at Mai Po throughout October. *Gynacantha subinterrupta* was seen at Mai Po on 10 November and 5 December (both were male individuals).]

5183. Arrington, D.A.; Winemiller, K.O.; Layman, C.A. (2005): Community assembly at the patch scale in a species rich tropical river. *Oecologia* 144(1): 157-167. (in English). ["In tropical floodplain rivers, communities associated with structurally complex habitats are disassembled and reassembled as aquatic organisms repeatedly colonize new areas in response to gradual but continuous changes in water level. Thus, a neutral model reflecting random colonization and extinction dynamics may be sufficient to predict assemblage patterns at the scale of local habitat patches. If water level fluctuations and associated patch dynamics are sufficiently predictable, however, community assembly on habitat patches also may be influenced by species-specific responses to habitat features and/or species interactions. We experimentally manipulated structural complexity and proximity to source habitat (which influences colonization rate) of simulated rocky patches in the littoral zone of a tropical lowland river and demonstrate significant effects of both factors on species density of fishes and macroinvertebrates. Interspecific variation in vagility significantly affected assemblage response to habitat complexity. In a second experiment, created habitat patches were sampled over time intervals ranging from 1 day to 36 days to examine temporal dynamics of community assembly. A null-model test revealed that assemblage structure became increasingly non-random, concomitant with increasing species density, over time. Community dynamics in newly formed habitat patches appeared to be dominated by dispersal,

whereas in older patches, abundances of individual species increasingly were influenced by habitat characteristics. These data suggest that species-specific responses to environmental variation resulted, in part, because of species interactions. We conclude that community assembly in shallow habitats of this tropical lowland river is influenced by physical habitat characteristics, the spatial distribution of habitat patches, and species interactions as habitats are saturated with individuals." (Authors) Odonata are mentioned on several occasions.] Address: Arrington, D.A.; Perry Institute for Marine Science, 100 N US Hwy 1, Jupiter, FL 33477, USA. E-mail: aarrington@perryinstitute.org

5185. Bady, P.; Dolédec, S.; Fesl, C.; Gayraud, S.; Bacchi, M.; Schöll, F. (2005): Use of invertebrate traits for the biomonitoring of European large rivers: the effects of sampling effort on genus richness and functional diversity. *Freshwater Biology* 50: 159-173. (in English). ["1. Studies on biodiversity and ecosystem function require considering metrics for accurately describing the functional diversity of communities. The number of taxa (richness) is commonly used to characterise biological diversity. The disadvantage of richness as a measure of biological diversity is that all taxa are taken into account on an equal basis regardless of their abundance, their biological characteristics or their function in the ecosystem. 2. To circumvent this problem, we applied a recently described measure of biological diversity that incorporates dissimilarities among taxa. Dissimilarities were defined from biological traits (e.g. life history, morphology, physiology and behaviour) of stream invertebrate taxa and the resulting biological diversity index was considered as a surrogate for functional diversity. 3. As sampling effort is known to affect the number of taxa collected within a reach, we investigated how change in functional diversity is affected by sampling effort. We used stream invertebrate community data from three large European rivers to model accumulation curves and to assess the number of samples required to estimate (i.e. closeness to the maximal value) functional diversity and genera richness. We further evaluated the precision of estimates (i.e. similarity of temporal or spatial replicates) of the total functional diversity. 4. As expected, richness estimates were strongly dependent on sampling effort, and 10 replicate samples were found to underestimate actual richness. Moreover, richness estimates showed much variation with season and location. In contrast, functional diversity had greater accuracy with less sampling effort and the precision of the estimates was higher than richness both across sampling occasions and sampling reaches. These results are further arguments towards conducting research on the design of a biomonitoring tool based on biological traits." - 5190.** Bernard, R.; Wildermuth, H. (2005): Verhaltensbeobachtungen an *Nehalennia speciosa* in Bezug auf Raum, Zeit und Wetter (Odonata: Coenagrionidae). *Libellula* 24(3/4): 129-153. (in German, with English summary). ["The behaviour of *N. speciosa* was studied at five small bog lakes in NW Poland with regard to habitat use, diurnal activity and influence of the weather. In total we discerned 22 behavioural elements some of which were considered in the context of different environmental situations. The imagines stayed almost exclusively in a narrow belt of thin-leaved sedges at the edge of the open water or in corresponding vegetation of adjacent shallow water bodies. The diurnal pattern of the localization of imagines in the vertical profile of the vegetation is described, stressing their movement downwards from the late forenoon and upwards in the late afternoon. Reproductive activity started in the morning, peaked around two hours before solar noon, and decreased rapidly in the early afternoon. Generally, pre-copula and copula lasted longer in the morning than in the afternoon. Calm, warm and rather humid atmospheric conditions with subdued or sporadically interrupted insolation proved optimal for the species' activity, whereas wind, strong precipitation, and temperatures below ca 15°C as well as above ca 23-24°C with strong insolation were unsuitable. In light rain and under a cloudy sky - provided that conditions were calm and temperatures were around 20°C - activity was diminished but not completely suppressed. It is inferred that imagines of *N. speciosa* are morphologically and ecologically adapted to habitats with obtrusive obstacles to flight, a humid microclimate and small spatial compass." - 5192.** Block, M. de; Geenen, S.; Jordaens, K.; Bäckeljau, T.; Stoks, R. (2005): Spatiotemporal allozyme variation in the damselfly, *Lestes viridis* (Odonata: Zygoptera): gene flow among permanent and temporary ponds. *Genetica* 124(2): 137-144. (in English). ["Several insect species seem to persist not only in permanent but also in temporary ponds where they face particularly harsh conditions and frequent extinctions. Under such conditions, gene flow may prevent local adaptation to temporary ponds and may promote phenotypic plasticity, or maintain apparent population persistence. The few empirical studies on insects suggest the latter mechanism, but no studies so far quantified gene flow including both pond types. We investigated the effects of pond type and temporal variation on population genetic differentiation and gene flow in *Lestes viridis* in northern Belgium. We report a survey of two allozyme loci (*Gpi*, *Pgm*) with polyacrylamide gel electrophoresis in 14 populations from permanent and temporary ponds, and compared these results with similar data from the same permanent populations one year before. The data suggested that neither pond-drying regime, nor temporal variation have a substantial effect on population genetic structuring and did not provide evidence for stable population differentiation in *L. viridis* in nor-

thern Belgium. Gene flow estimates were high within permanent and temporary ponds, and between pond types. Our data are consistent with a source-sink metapopulation system where temporary ponds act as sinks in dry years, and are quickly recolonized after local population extinction. This may create a pattern of apparent population persistence of this species in permanent and temporary ponds without clear local adaptation." Cumulative species richness and composition were described by proportion coefficients and beta-diversity indices. The three man-made sites provided open space resources and more species were observed in each than in the floodplain forest. Twenty-nine of 42 species documented over a four-month peri-

od were observed in only one or two of the four wetlands studied. Large differences in species assemblages between the immediately adjacent ditch and marsh sites were the best evidence for high habitat affinity because distance and structural barriers to movement were absent. Such compositional asymmetry may reflect differential vegetative and reproductive suitability of the habitats. Results suggest that the open canopy wetlands supported high relative diversity of adult Odonata and that distinct odonate assemblages were found among different habitat types in this floodplain wetland complex." 5201. Carchini, G.; Domenico, M.D.; Chiarotti, F.; Tanzilli, C.; Pacione, T. (2005): Fluctuating asymmetry, body size, reproductive period and life time mating success of males of *Cercion lindeni* (Odonata: Coenagrionidae). *Eur. J. Entomol.* 102(4): 707-712. (in English). ["Mating success is linked to reproductive success in males, but parameters influencing it are poorly known. The relationships between lifetime mating success (LMS), fluctuating asymmetry (FA), body size (SIZE), reproductive period (RP) and emergence date (MD) of males of *Cercion lindeni* were investigated. Males were marked and photographed in their pre-reproductive period, and their matings monitored. RP was assumed to be the period between the MD and the last sighting of

each individual. Three different FA measures and the size of each individual were determined. The results showed that the individuals not present at the pond during the reproductive period had a higher FA (but not for meristic characters) than those present. For those individuals actually involved in reproductive activity, LMS was only positively correlated with RP, which was negatively related with MD, and this with SIZE." (Authors). 5202. Clausnitzer, V. (2005): Odonata Specialist Group. Species 43: 24. (in English). [Verbatim. The special issue of the International Journal of Odonatology Guardians of the watershed; Global status of dragonflies: critical species, threat and conservation, was used as a base for assessing a number of dragonflies for the IUCN Red List. Consequently nearly all dragonfly species listed previously on the IUCN Red List have been reassessed and numerous additions were made. All assessments were made, checked and submitted to the IUCN SSC Red List Programme by Dr. Frank Suhling and myself. In total, there was an increase from 155 to 350 dragonflies listed as Extinct, Critically Endangered, Endangered, Vulnerable, Near Threatened or Data Deficient. However, of previously listed species, 20 species were reassessed as Least Concern. About 6% of the global dragonflies are currently regarded as threatened. The listed species are regionally distributed as follows: 97 from Africa and the Orient, eight from islands in the Indian Ocean, 36 from North America, 10 from Hawaii, 65 from South and Middle America, 11 from Europe, 26 from Asia (excluding Japan and Sri Lanka), 32 from Japan, 20 from Sri Lanka, 25 from Australia, 19 from South Pacific islands, one from St. Helena, with the extinct species being originally from St. Helena Island. A member of the Odonata Specialist Group, Vincent Kalkman, participated in the IUCN Sampled Red List Index (SRLI) Species Selection Workshop, held at the Zoological Society of London, in March. One hundred dragonflies will be selected randomly from the global list for inclusion in the SRLI. In July there will be a meeting of the Odonata Specialist Group during the Symposium of the World Wide Dragonfly Association in Spain. Sacha Spector from the American Museum of Natural History will hopefully attend this meeting to discuss plans for a global dragonfly assessment, in co-operation with Piotr Naszkrecki of Conservation International.] Address: Clausnitzer, Viola, Graefestr. 17, D-06110 Halle/Saale, Germany. 5206. Crick, K. (2005): Variations in key features of the final instar larvae and exuviae of the Common Blue Damselfly *Enallagma cyathigerum* (Charpentier). *J. Br. Dragonfly Society* 21(1): 27-36. (in English). ["Some features used for species identification of final instar larvae and exuviae in published keys have proved to have levels of variability beyond that currently defined. This paper seeks to address those variations as they apply to *E. cyathigerum*, outlining in detail specific variations found through close examination of 253 individuals collected from a number of water bodies in the Blackwater Valley on the border of Hampshire and Berkshire. The features addressed include the species-specific characteristics of the caudal lamellae, the prementum and the short spine on the outer surface of the anterior palpal seta. The current published keys have proved to be very useful but their interpretation requires considerable dedication, at least when they are first put to the test. This report proposes a format for a mainly pictorial approach to an identification key for damselfly larvae." (Author)] Address: Crick, K., 29 Village Way, Yateley, Hampshire GU46 7SE, UK

5207. Crumrine, P.W. (2005): Size structure and substitutability in an odonate intraguild predation system. *Oecologia* 145(1): 132-139. (in English). ["Interactions between different size classes of predator species have the potential to influence survival of prey species in intraguild predation (IGP) systems, but few studies test for these effects. Using a substitutive design in a field setting, I measured the effects of two size classes of IG predators (large and small larvae of the dragonfly *Anax junius*) on the mortality of IG prey (larvae of the dragonfly *Pachydiplax longipennis*). I also examined whether combinations of large *A. junius* and *P. longipennis* and small *A. junius* and *P. longipennis* had sub-

stitutable effects on shared prey (larvae of the damselfly *Ischnura verticalis*). The presence of both size classes of *A. junius*, when alone and in combination with *P. longipennis*, significantly increased mortality of *I. verticalis*. In the presence of *P. longipennis*, large and small *A. junius* had similar effects on the mortality of *I. verticalis*, and effects of size-structured assemblages of *A. junius* were similar to the effects of each size class alone at the same density. The effects of the two size classes of *A. junius* on *P. longipennis* differed, and *P. longipennis* mortality was lower when exposed to size structured assemblages of *A. junius* than when exposed to only large *A. junius* at the same density. Results were similar to those in a laboratory study, although the effect of *P. longipennis* on *I. verticalis* was much lower in the field setting. These results demonstrate that interactions between different size classes of IG predators promote the survival of IG prey and highlight the importance of within-species size structure as a characteristic that may promote the coexistence of predators in IGP systems." 5213. De Block, M.; Stoks, R.; De Bruyn, L. (2005): Egg hatching patterns within and among populations of a damselfly occupying permanent and temporary ponds. *Archiv für Hydrobiologie* 163(2): 195-209. (in English). ["Although opposing selection forces cause drastic differences in community structure between temporary and permanent ponds, some species are able to persist in both pond types. Little is known about the underlying life history strategies that enable species to do so. This is especially true for embryonic development times. Here, we describe within and among population variation in natural egg hatching patterns of the damselfly *Lestes viridis* that occurs in both pond types. In general, egg hatching was synchronous both within and among populations. A two-year field monitoring study showed consistent regional differences in egg hatching and earlier egg hatching in temporary ponds. A common garden and two full-sib experiments suggested that differences in hatching dates among populations and families were not completely driven by differences in environmental conditions, but may have a genetic basis. Although the pattern of earlier egg hatching in temporary ponds, as observed in the field monitoring, is adaptive, it was not fully repeatable in the common garden experiment. This suggests that this pattern is caused by more benign environmental conditions at the temporary ponds relative to the permanent ponds, and not an adaptation to pond type.] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. 5214. De Knijf, G.; Tailly, M. (2005): Ei-afleg bij de Blauwe glazenmaker (*Aeshna cyanea*): enkele merkwaardige observaties. *Gomphus* 20(1): 21-26. (in Dutch, with English and French summaries). ["Oviposition from *A. cyanea*: some remarkable observations: Three remarkable observations of oviposition by *A. cyanea* are described. 1) on rocks forming a dam in full sunshine, at an at the time of observation dry pond, 2) in dead wood and bark of an elder (*Sambucus nigra*) at more than 4 m from the waterside and 3) in moss (*Amblystegium varium*) at 0,20 m above the water in mosses at 0,30 m above and 0,40 m from the waterside. Thus *A. cyanea* seems not to be linked strictly to water for its oviposition, but shows a predilection for moist, shadowed substrats like mosses, dead plants, branches, wood, mud and soil. The water level at the moment of hatching (shortly after the winter) is generally higher, so the prolarvae are at that time already in the water or have only a short distance to go; probably they are capable of jumping or creeping some meters to reach the water if necessary." 5216. Dumont, H.J.; Vanfleteren, J.R.; De Jonckheere, J.F.; Weekers, P.H.H. (2005): Phylogenetic relationships, divergence time estimation, and global biogeographic patterns of calopterygoid damselflies (Odonata, Zygoptera) inferred from ribosomal DNA sequences. *Systematic Biology* 54(3): 347-362. (in English). [The calopterygoid superfamily (Calopterygidae + Hetaeriniidae) is composed of more than twenty genera in two families: the Calopterygidae (at least 17) and the Hetaeriniidae (at least 4). Here, 62 calopterygoid (ingroup) taxa representing 18 genera and 15 outgroup taxa are subjected to phylogenetic analysis using the ribosomal 18S and 5.8S genes and internal transcribed spacers (ITS1, ITS2). The five other families of calopterygoid affinity (Polythoridae, Dictyriidae, Amphipterygidae, Euphaeidae, and Chlorocyphidae) are included in the outgroup. For phylogenetic inference, we applied maximum parsimony, maximum likelihood, and the Bayesian inference methods. A molecular phylogeny combined with a geographic analysis produced a well-supported phylogenetic hypothesis that partly confirms the traditional taxonomy and describes distributional patterns. A monophyletic origin of the calopterygoids emerges, revealing the Hetaeriniid clade as sister group to the Calopterygidae *sensu stricto*. Within Calopterygidae, seven clades of subfamily rank are recognized. Phylogenetic dating was performed with semiparametric rate smoothing by penalized likelihood, using seven reference fossils for calibration. Divergence time based on the ribosomal genes and spacers and fossil constraints indicate that Calopteryginae (10 genera, approximately 50% of all Calopterygidae taxa studied here), Vestalinae (1 genus), and Hetaeriniidae (1 genus out of 4 studied here) started radiating around 65 Mya (K/T boundary). The South American Iridictyon (without distinctive morphology except for wing venation) and Southeast Asian Noguchiphaea (with distinctive morphology) are older (about 86 My) and may be survivors of old clades with a Gondwanian range that went extinct at the K/T boundary. The same reasoning (and an even older age, ca. 150 My) applies to the amphipterygids Rimanelia and Pentaplebia (South America Africa). The extant Calopterygidae show particular species and genus richness between west China and Japan, with genera originating between the early Oligocene and Pleistocene. Much of that richness probably extended much wider in preglacial times. The Holarctic Calopteryx, of Miocene age, was deeply affected by the climatic cooling of the Pliocene and by the Pleistocene glaciations. Its North American and Japanese representatives are of Miocene and Pliocene age, respectively, but its impoverished Euro-Siberian taxa are late Pliocene-Pleistocene, showing reinvasion, speciation, and introgression events. The five other calopterygoid families combine with the Calopterygidae and Hetaeriniidae to form the monophyletic cohort Caloptera, with Polythoridae, Dictyriidae, and Amphipterygidae sister group to Calopterygoidea. The crown node age of the latter three families has an age of about 157 My, but the Dictyriidae and Polythoridae themselves are of Eocene age, and the same is true for the Euphaeidae and Chlorocyphidae. The cohort Caloptera itself, with about 197 My of age, goes back to the

early Jurassic. [Biogeography; Calopterygidae; dating; divergence times; damselflies; internal transcribed spacers; odonata; phylogeny; phylogeography; 18S and 5.8S ribosomal DNA.] (Authors) Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. Ledeganckstraat 35, B-9000 Gent, Belgium. E-mail: Henri.Dumont@rug.ac.be

5217. Dunn, R.; Budworth, D. (2005): Dragonflies in Derbyshire. Status and distribution 1977-2000. Derbyshire & Nottinghamshire Entomological Society: 52 pp. (in English). [This softback booklet contains a history of recording in Derbyshire, the status of each species, a small number of habitat and species photographs and a full set of 1 km distribution maps (22 odonate species). 5218. Dyatlova, E.S. (2005): The dragonflies of the southwestern Ukraine. M.Sc. thesis, Faculty of Biology, I.I. Mechnikov University of Odessa: 80 pp, 44 pp appendix. (in Russian). [This thesis consists of two parts, a faunistic one and one with detailed investigations into the ecology and biology of selected species. Between 2002 and 2004 dragonflies were recorded from 41 sites. These sites were mainly situated in the valleys and floodplains of the major rivers and streams entering the Black Sea at its northwestern coast, including the rivers Danube and Dniestr. Forty of the previously recorded 51 Ukrainian species were found with several new county records, Lestes dryas, Coenagrion ornatum, C. scitulum, Erythromma lindenii, Anax imperator, Gomphus vulgatissimus, Libellula fulva, L. depressa, Symptetrum flaveolum, and S. pedemontanum are of special interest. All records are detailed in the appendix. Based on these new findings and a comparison of the literature, suggestions are provided for conservation priorities of the Ukrainian odonate species in the form of a risk scale. The second part provides information of several unrelated observations such as the variability of wing patterns in the Calopteryx splendens complex (including the record of androchrome females), the variation in the male genitalia of Orthetrum coerulescens anceps and a chapter on meticulously described cases of wing anomalies in Platycnemis pennipes, Ischnura pumilio and Orthetrum brunneum. There is also a chapter on population biology. It describes the seasonal variation over three months in the sex ratio and colour morph ratios of Ischnura elegans and Coenagrion pulchellum at two sites. For the analysis of the colour morphs, more than 1200 and 200 individuals, respectively, of the two species were captured, scanned and their colour identified by commercial computer software.] Address: Dyatlova, Elena Sergeyevna, Institute of Zoology, Faculty of Biology, I.I. Mechnikov University of Odessa, Odessa, Ukraine

5221. Gäde, G.; Marco, H.G. (2005): The adipokinetic hormones of Odonata: A phylogenetic approach. *J. Insect Physiology* 51(3): 333-341. (in English). ["Adipokinetic neuropeptides from the corpora cardiaca of the major families of all three suborders of the Odonata were identified by one or more of the following methods: Isolation of the peptides from a methanolic extract of the corpora cardiaca by liquid chromatography, peak monitoring by fluorescence of the Trp residue and comparison of the retention time with those of known synthetic peptides of Odonata. Hyperlipaemic bioassays of the HPLC-generated fractions either in *Locusta migratoria* or, in a few cases, in *Anax imperator* or *Orthetrum julia*. Sequencing of the isolated, bioactive HPLC fraction by Edman degradation. Mass spectrometric measurement of the isolated, bioactive fraction. Sequence assignment revealed that the investigated Odonata species always contain only one adipokinetic peptide. This is always an octapeptide. The suborder Zygoptera contains the peptide code-named Psein-AKH, the Anisozygoptera and the families Aeshnidae, Cordulegastridae and Macromiidae of the Anisoptera contain Anaim-AKH, whereas Gomphidae, Corduliidae (with the exception of *Syncordulia gracilis*) and Libellulidae contain Libau-AKH; one species of Libellulidae has Erysi-AKH, a very conservative modification of Libau-AKH (one point mutation). When these structural data are interpreted in conjunction with existing phylogenies of Odonata, they support the following: Zygoptera are monophyletic and not paraphyletic. Anisozygoptera and Anisoptera are sister groups and contain the ancestral

Anaim-AKH which is independently and convergently mutated to Libau-AKH in Gomphidae and Libellulidae. The Corduliidae are of special interest. Only Corduliidae sensu stricto appear to contain Libau-AKH, other species placed into this family by most authorities contain the ancestral Anaim-AKH. Possibly, assignments of AKHs can untangle the paraphyly of this family." (Authors)] Address: Gäde, G.; Zoology Department, University of Cape Town, Private Bag, Rondebosch 7701, South Africa

5222. Garner, P. (2005): The Dragonflies of Herefordshire. Herefordshire Biological Records Centre: app. 70 pp. (in English). ["Herefordshire, as one of the most picturesque and unspoilt counties in lowland Britain is rich in wildlife. With magical rivers like the Wye and Lugg running through the heart of it and with an abundance of ponds and lakes it is a haven for dragonflies, and yet until 20 years ago it was largely unrecorded. This book is the product of 20 years of recording in which Peter Garner gives an intimate and personal account of Herefordshire's 27 species of which all but 3 have been proven or are likely to be breeding. "The Dragonflies of Herefordshire" will appeal to those who have a general love of the countryside, as well as dedicated dragonfly experts. Hopefully, even those who know more about dragonflies than Peter will still be interested by some of the detail of his observations, by the speculation of his hypotheses, and above all by the distribution of records from what was very likely, the least well recorded county in the country. Several records are of special note because Herefordshire is on the edge of their range: this applies to the Scarce Bluetailed Damselfly, Red-eyed Damselfly, Downy Emerald, Brown Hawker, Migrant Hawker, Golden-ringed, Black-tailed Skimmer, Ruddy and Black Darters." (Publisher)] Address: To order your copy, please send a cheque payable to "Herefordshire Council" to: The Dragonflies of Herefordshire Booklet Herefordshire Biological Records Centre, P. O. Box 144, Hereford. HR1 2YH. UK

5223. Gassmann, D. (2005): The Phylogeny of Southeast Asian and Indo-Pacific Calicnemiinae (Odonata, Platynemididae). *Bonner zoologische Beiträge* 53(1/2) (2004): 37-80. (in English). ["Phylogenetic relationships of Southeast Asian and Indo-Pacific damselflies of the subfamily Calicnemiinae (Odonata: Platynemididae) are examined by cladistic analyses using morphological characters. The strict consensus cladogram of the resulting equally most parsimonious trees supports the monophyly of the Papuan genus *Idiocnemis* Selys, the Philippine genus *Risioctnemis* Cowley and its subgenera, but leaves the basal relationships of the African genera and the Palawan genus *Asthenocnemis* Lieftinck partly unresolved. A preferred phylogenetic hypothesis is presented showing a well supported 'Indo-Pacific clade' consisting of Philippine, New Guinean and Solomon island taxa, and as sister group *Asthenocnemis*. *Risioctnemis* turns out to be a sister group of *Lieftinckia* / *Salomocnemis* (Solomon Islands), the sister taxon of those being the central New Guinean *Arrhenocnemis* Lieftinck. Together, these form a monophyletic group with the remaining Papuan taxa. *Idiocnemis leonora* Lieftinck is transferred to *Rhyacocnemis* Lieftinck comb. nov. The possible effects of taxon sampling are discussed." (Author).] Address: Gassmann, D., Institute of Evolutionary and Ecological Sciences, Leiden University, c/o National Museum of

Natural History, P.O. Box 9517, 2300 RA Leiden, The Netherlands. E-mail: gassmann@naturalis.nnm.nl

5224. Gassmann, D. (2005): Phylogenetic systematics and historical biogeography of Malesian Calicnemiine damselflies (Odonata, Platycnemididae). Thesis Leiden University: without pagination. (in English, with Dutch summary). ["The aim of the present study was to reveal phylogenetic relationships within the damselfly subfamily Calicnemiinae (Odonata, Platycnemididae) as a basis for a historical-biogeographic scenario for the Malesian species. Beside that, taxonomic revisions at subgeneric and species-group level contribute to our knowledge of the diversity of the group. Chapter 1 and Chapter 2 together contain a taxonomic revision of the damselfly genus *Idiocnemis* Selys, 1878, from New Guinea and surrounding islands. [...] In Chapter 3, the subgenus *Ignecnemis* Hämäläinen, 1991, of the Philippine genus *Risioicnemis* Cowley, 1934, is revised. [...] In Chapter 4 the phylogenetic relationships of South-east Asian and Indo-Pacific Calicnemiinae are examined by cladistic analyses using morphological characters. A parsimony analysis, based on 88 characters and including 84 taxa, was performed resulting in 732 equally most parsimonious trees. [...] Chapter 5 places the Calicnemiinae in a context with other groups of freshwater organisms in Malesia." (Author)] Address: Gassmann, D., Institute of Evolutionary and Ecological Sciences, Leiden University, c/o National Museum of Natural History, P.O. Box 9517, 2300 RA Leiden, The Netherlands. E-mail: gassmann@naturalis.nnm.nl

5225. Gohmert, J.; Martens, A. (2005): Der Sonnenbarsch *Lepomis gibbosus* als Prädator von Kleinlibellen bei der Eiablage (Teleostei: Centrarchidae; Odonata: Coenagrionidae). *Libellula* 24(1/2): 55-62. (in German, with English summary). ["In the summer of 2004 at a man-made lake near Karlsruhe, Germany, predation of *L. gibbosus* on *Erythromma viridulum* and *E. lindenii* was observed and recorded with a video camera. Four out of 15 observed attacks by *L. gibbosus* were successful. In eight cases, a fish appeared all of a sudden and jumped after a tandem of damselflies during oviposition. In six cases, a fish approached very slowly until it was very close to its prey and then suddenly snapped at the damselflies. In one case, the predator approached slowly, but the tandem recognised it and escaped before the fish was able to attack it." 5226. Grossmann, M. (2005): Tiere, Pflanzen und Pilze im Nationalpark „Hainich“ - Stand und Bilanz der bisherigen Erfassungen. *Landschaftspflege und Naturschutz in Thüringen* 42(3): 92-97. (in German). [Thuringia, Germany; the wood dominated National Park harbours a total of 34 odonate species (not specified in the article), including *Leucorrhinia pectoralis* and *Crocothemis erythraea*.] Address: Grossmann, M., Verwaltung Nationalpark Hainich, Bei der Marktkirche 9, D-99947 Bad Langensalza, Germany

5227. Günther, A. (2005): *Anax ephippiger* in Europa - immer Invasionen in eine Sackgasse? (Odonata: Aeshnidae). *Libellula* 24(3/4): 241-247 (in German, with English summary) ["From the end of September to early October 2004, massive migrations of immature *A. ephippiger* were observed at the Black Sea coast of Bulgaria. Their origin from a summer generation in Eu-

rope is considered as most likely. The first and most numerous aggregations were migrating ahead of a heavy rainfall front from the north-west. During daylight, the dragonflies migrated partly at altitudes of 50 m and more. The number of individuals, the direction and the intensity of the migration make a successful return into the core area of the species plausible." (Author) Address: Günther, A., TU Bergakademie Freiberg, IÖZ, AG Biologie/Ökologie, Leipziger Str. 29, D-09599 Freiberg, Germany. E-mail: andre.guenther@ioez.tu-freiberg.de

5228. Hadrys, H.; Schroth, W.; Schierwater, B.; Streit, B.; Fincke, O. (2005): Tree hole odonates as environmental monitors: Non-invasive isolation of polymorphic microsatellites from the neotropical damselfly *Megaloprepus caerulatus*. *Conservation Genetics* 6(3): 481-483. (in English). ["Because of their complex mating behaviour and life cycle (alternating aquatic and terrestrial stages) odonates provide important model systems for environmental monitoring, evolutionary ecology, and conservation genetics. Many odonate species are endangered and call for the use of non-invasive molecular studies. In *M. caerulatus* we have identified polymorphic microsatellite loci by means of the randomly amplified microsatellite technique (RAMS; Ender et al. 1996). Using the DNA from each a single leg of three unrelated individuals we screened 63 RAPD primers for small size banding patterns. A total of 95 RAPD profiles was hybridized with digoxigenin labelled di- and trinucleotide repeats (GAn, GTn, CAn and AATn) and 36 RAPD fragments harbouring microsatellite motifs were isolated. Cloning and sequencing of positive fragments revealed five polymorphic microsatellite loci. Since *M. caerulatus* is a viable bio-indicator for primary rainforests the microsatellite system can be used to study the effects of forest fragmentation on population viability." 5229. Hancox, J. (2005): Disappointing year for dragonflies. *Potteric Carr Nature Reserve. Recorder - an annual review of recording on the reserve* 8: 4. (in English). [Yorkshire, UK; 18 odonate species are briefly discussed. For a full paper see: <http://www.potteric-carr.org.uk/jan2005.pdf>] Address: Hancox, J., 57 Braithwell Road, Ravenfield, Rotherham S65 4LH, UK. E-mail to hancoxj@aol.com

5230. Hartman, K.; Kaller, M.; Howell, J.; Sweka, J. (2005): How much do valley fills influence headwater streams? *Hydrobiologia* 543(1-3): 91-102. (in English). ["Valley fill mining has the potential to alter headwater stream habitat in many areas in the eastern United States. In valley fill mining, overburden is removed to expose underlying coal seams. The overburden is then deposited in the adjacent valley. The deposited overburden from mining increases sedimentation, increases stream conductivity, and alters hydrologic regimes downstream of the fill. Changes in downstream communities are not well documented. However, it was suspected the increased sedimentation and conductivity would have deleterious effects upon the downstream macroinvertebrate communities. In southern West Virginia, four pairs of streams, each consisting of a fill and a reference stream, were selected as representative of watersheds experiencing valley fill mining. Stream pairs were selected for similar environmental conditions, with

one stream having a valley fill in its headwaters. Each stream was sampled by replicate Surber samples (n=9 per stream). Water chemistry and sediment measurements also were taken at each location. Valley fill streams experienced significantly higher specific conductance ($p < 0.01$), but did not have elevated levels of fine sediment. Fills exhibited elevated levels of Na, K, Mn, Mg, Ca, Ni and Fe relative to reference streams. Additionally, valley fill streams demonstrated significantly lower densities of Ephemeroptera, Coleoptera, Odonata, Non-insects, Scrapers, and Shredders ($p < 0.03$) than reference streams. Further, Ephemeroptera richness was negatively related to specific conductivity and many of the richness metrics were negatively related to metals, both of which were generally elevated in fill streams. It appears that at the minimum, valley fills increase specific conductance and metals in streams and this or some other unqualified factors structure the macroinvertebrate community downstream of the valley fill. However, given the level of disturbance in valley fills, it is surprising how little differences existed between fills and reference stream biota." (Authors)] Address: Hartman, Kyle, Division of Forestry, Wildlife & Fisheries Program, West Virginia University, 322 Percival Hall, Morgantown, WV, 26506-6125, USA. Email: hartman@wvu.edu

5231. Hofmann, B.; Martens, A. (2005): Eine Fang-Wiederfang-Studie zur Ortstreue und Kurzstreckenausbreitung von *Sympetrum sanguineum* (Odonata: Libellulidae). *Libellula* 24(1/2): 63-72. (in German, with English summary). ["In the summer of 2004, 117 males and three females were marked at two canals in the Upper Rhine floodplain south of Karlsruhe, Germany. 14 males (11.7%) were recaptured, one to 14 days after marking. Eleven individuals were recaptured at another canal section. The data suggest that *S. sanguineum* does not have a site fidelity." 5233. Ishizawa, N. (2005): The response to rotating objects by *Anotogaster sieboldii* (Selys) males, Pt 2 (Anisoptera: Cordulegastridae). *Odonatologica* 34(3): 211-218. (in English). ["It has been reported that the response to rotating objects by *A. sieboldii* males indicates recognition of the objects as females. The influences of colour, size and rotation velocity (RV) of discs on hovering ratio (HVR) were studied with experiments using a small electric rotating device. Among the rotating discs with white, yellow, orange, red, green, or blue alternating with black, the one with green elicited the highest HVR (98%), whereas the HVR to the yellow/black disc was lowest (32%). This suggests that yellow has a role as a warning coloration against predators rather than being involved in intraspecific recognition. - In the relationship of the HVR to RV of the green/black disc, the HVR reached a peak around 20-25 Hz. In relation of HVR to the size of the disc, the larger the diameter of the disc, the higher was the HVR, and when different sizes of discs were put side by side, *A. sieboldii* males had a tendency to respond to the lar-

ger disc of the pair.] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozavva City, Saitama Pref., Japan. E-mail: isizawa7@rivo.mediatti.net

5234. Jarvis, K.J.; Haas, F.; Whiting, M.F. (2005): Phylogeny of earwigs (Insecta: Dermaptera) based on molecular and morphological evidence: reconsidering the classification of Dermaptera. *Systematic Entomology* 30(3): 442-453. (in English). ["Dermaptera (earwigs) is a cosmopolitan order of insects, the phylogenetic relationships of which are poorly understood. The phylogeny of Dermaptera was inferred from large subunit ribosomal (28S), small subunit ribosomal (18S), histone-3 (H3) nuclear DNA sequences, and 43 morphological characters. Sequence data were collected for thirty-two earwig exemplar taxa representing eight families in two suborders: Hemimeridae (suborder Hemimerina); Pygidicranidae, Anisolabididae, Labiduridae, Apachyidae, Spongiphoridae, Chelisochidae and Forficulidae (suborder Forficulina). Eighteen taxa from ten additional orders were also included, representing Ephemeroptera, Odonata, Orthoptera, Phasmida, Embiidina, Mantodea, Isoptera, Blattaria, Grylloblattodea and Zoraptera. These data were analysed via direct optimization in poyunder a range of gap and substitution values to test the sensitivity of the data to variations in parameter values. These results indicate that the epizotic Hemimerus is not sister to the remaining Dermaptera, but rather nested as sister to Forficulidae + Chelisochidae. These analyses support the paraphyly of Pygidicranidae and Spongiphoridae and the monophyly of Chelisochidae, Forficulidae, Anisolabididae and Labiduridae." (Authors)] Address: Jarvis, K.J., Dept of Integrative Biology, Brigham Young University, Provo, Utah, USA

5235. Jeffries, M.; Eales, H.T.; Storey, G. (2005): Distribution and habitat of the Banded Demoiselle *Calopteryx splendens* (Harris) in Northumberland. *J. Br. Dragonfly Society* 21(1): 1-7. (in English). [Recent range expansions of *C. splendens* in Northumberland, UK are discussed with special emphasis on methodical problems (e.g. the documentation of negative records). Analysis of habitats with positive and negative records respectively show no significant differences; thus recent climate change must be responsible for the range expansions as observed with additional (odonate) species too.] Address: Jeffries, M., Division of Environmental Management, Ellison Building, Northumbria University, Newcastle upon Tyne NE1 8ST, UK

5236. Jenkins, D.K. (2005): Population studies of the Southern Damselfly *Coenagrion mercuriale* (Charpentier) in the New Forest. Part 9. The Crockford streams, 20 years on. *J. Br. Dragonfly Society* 21(1): 8-13. (in English). ["Following detailed monitoring of *C. mercuriale* in the Crockford area of the New Forest between 1985 and 1994, a follow up survey was carried out in 2004 to assess the effect of changes to the climate and habitat over the intervening years. Population numbers in all the sections of the stream system studied were at higher levels than previously recorded and were still increasing in mid June, when poor weather intervened." (Author)] Address: Jenkins, D.K., 7 Lakewood Road, Ashurst, Southampton SO40 7DH, UK

5237. Keat, S.; Thompson, D.J.; Kemp, S.J.; Watts, P.C. (2005): Ten microsatellite loci for the Small Red-eyed Damselfly *Erythromma viridulum* (Charpentier). *Molecular Ecology Notes* 5(4): 788-790. (in English).

["*E. viridulum* is the first recorded example of a migrant damselfly establishing colonies in the British Isles. To examine the population genetic structure of *E. viridulum*, a partial genomic library enriched for CA microsatellite loci was constructed. Of the 42 loci tested, 19 amplified spurious bands and 13 were monomorphic, leaving 10 polymorphic loci that resolved distinct alleles within the expected size range. The number of alleles ranged between two (LIST14-021, LIST14-40) and eight (LIST14-002). Observed and expected heterozygosities varied between 0.000-0.698 and 0.045-0.688, respectively." [NSG "Restloch Zechau", Thuringia, Germany, 02.07.2003 & 14.07.2004] Address: Kipping, J., Fockestr. 19, D-04275 Leipzig, Germany. E-mail: jens-kipping@t-online.de

5239. Kunz, B. (2005): *Boyeria irene* in Tunesien (Odonata: Aeshnidae). *Libellula* 24(1/2): 39-46. (in German, with English summary). ["New data from three field trips between 2000 and 2002 regarding the occurrence of the species in northern Tunisia are given, providing the first evidence that Tunisian *Boyeria* populations pertain actually to *B. irene*. Besides, a brief description of the habitats as well as some biological notes are given." (Author)] Address: Kunz, B., Hauptstr. 111, D-74595 Langenburg, Germany. E-mail: kunzFOTOGRAFIE@t-online.de

5240. Lambrechts, J. (2005): De libellenfauna van het gebied Houterenberg-Pinnekeswijer (Tessenderlo, West-Limburg). *Gomphus* 20(1): 3-16. (in Dutch, with English and French summaries). ["In 2000 and 2001 the nature reserve Houterenberg - Pinnekeswijer (Tessenderlo, Limburg, Belgium) was inventoried for dragonflies, as part of a study to elaborate a management plan. The collected data are treated in this article, as well as a number of later collected records by warden Bart Govaere. In total 24 dragonfly species were found, from which the following six are the most interesting from a faunistic point of view: *Coenagrion lunulatum*, *Leucorrhinia rubicunda*, *Lestes virens*, *Sympecma fusca*, *Cordulia aenea* and *Ischnura pumilio*. Especially the oligotrophe "ven" 'De Pinnekeswijer' is of great interest for dragonflies, housing populations of the first 5 mentioned species." (Authors)] Address: Lambrechts, J., Zuurbemde 9, B-3380 Glabbeek, Belgium. E-mail: natuur@aeolus-milieu.be or Jorglambrechts@hotmail.com

5241. Leelapaibul, W.; Bumrungsri, S.; Pattanawiboon, A. (2005): Diet of wrinkle-lipped free-tailed bat (*Tadarida plicata* Buchanan, 1800) in central Thailand: insectivorous bats potentially act as biological pest control agents. *Acta Chiropterologica*, 7(1): 111-119. (in English). ["Insectivorous bats are major predators of nocturnal insects and have the potential to act as biological pest control agents in farmlands. The objective of the present study was to establish the diet of the guano bat, *Tadarida plicata*. The study was carried out at the Khao Chong Pran Cave, which houses 2.6 million bats, and is surrounded by rice fields. A total of 1,925 faecal pellets were collected from 385 bats during their mor-

ning return from January to December 2002. Faecal analysis indicated that *T. plicata* fed on at least nine insect orders: Homoptera (28.4%), Lepidoptera (20.8), Hemiptera (16.4), Coleoptera (14.4), Diptera (7.0), Hymenoptera (6.6), Odonata (6.0), Orthoptera (0.5) and Psocoptera (0.1). Light traps indicated that Coleoptera (41.2%), Homoptera (25.3), Hemiptera (18.8) and Diptera (12.7) were the most abundant insects in the study area. Homopterans, most of which were white-backed planthopper (*Sogatella* sp., Delphacidae) had the highest percentage frequency of occurrence in the bats diet indicating that *T. plicata* potentially plays an important role in controlling this major crop pest. The presence of macropterous planthoppers and a large proportion of moths in its diet suggests that *T. plicata* feeds on windborne migrant insects at high altitude. Female bats fed significantly more on lepidopterans and coleopterans and less on damselflies than males. The diet diversity index of lactating females was higher than pregnant females. Diet did not differ significantly between the dry and rainy seasons for either sex." (Authors)] Address: Bumrungsri, S., Department of Biology, Faculty of Science, Prince of Songkla University, Hat Yai, Songkhla, Thailand. E-mail: sara.b@psu.ac.th

5242. Lohr, M. (2005): Das Naturschutzgebiet "Auf dem Berenbruch" bei Fürstenau. *Beiträge zur Naturkunde zwischen Egge und Weser* 17: 92-97. (in German). [Nordrhein-Westfalen, Germany; 22 odonate species are listed and briefly commented. Species conservation measures directed to the tree frog (*Hylas arborea*) favoured odonate species as *Lestes dryas* and *Sympetrum flaveolum*, dwelling ephemeral waters.] Address: Lohr, M., An der Kirche 22, D-37671 Hörter, Germany. E-mail: mlohr@fh-hoexter.de

5243. Lohr, M. (2005): Libellenbeobachtungen in Südpotugal (Odonata). *Libellula* 24(1/2): 87-107. (in German, with English summary). ["During a three-weeks' trip in May 2003, the southern Portuguese districts Algarve and Baixo Alentejo were visited. At 36 investigated localities 39 spp. were recorded in total. Reproduction was proved for 31 spp. by records of exuviae. The dragonfly communities of different types of water bodies are described, and noteworthy observations concerning the geographical range of some species are presented in detail. *Selysiotthemis nigra* is new for Portugal, exuviae were found near Faro. Furthermore, remarkable records of *Lestes dryas*, *Coenagrion sdtulum*, *Gomphus graslinii*, *Macromia splendens*, and *Oxygastera curtisii* from southwestern Portugal are discussed in the context of their distribution in the Iberian peninsula. The dragonfly communities of southern Portuguese rivers are characterized by a high species diversity. The distribution of some species found in these rivers is restricted to southwestern Europe, many species mainly inhabit this area. Hence, the responsibility of Portugal for the conservation of rivers that are still unaffected by barrages is very high." (Author)] Address: Lohr, M., FH Lippe und Hörter, Fachgebiet Tierökologie und Landschaftsökologie, An der Wilhelmshöhe 44, D-37671 Hörter, Germany. E-mail: mlohr@fh-luh.de

[This is a brief report from an excursion to the "Vennengebied van Ravels-Poppel", Belgium on 12-VI-2004. 21 odonate species including *Sympecma fusca* and *Leucorrhinia rubicunda* at Leiven, *Sympetrum flavolum* at Witgoor, and *Coenagrion pulchellum*, and *Brachytron pratense* at Zwart Water have been sighted.] Address: Loos, G., Kanaaldijk 1, B-2380 Revels, Belgium

5246. Luttbeg, B.; Hammond, J.; Sih, A. (2005): How predators and prey distribute themselves across space: comparing empirical data to alternative models of movement rules. ESA Annual Meeting, Montréal, Canada. August 2005: (in English). [Verbatim: While many studies have examined how prey distribute themselves in response to predators or how predators distribute themselves in response to prey, surprisingly few theoretical or empirical studies have examined how the two interact. How predators and prey distribute themselves is potentially shaped by the distributions of their 1) own species and 2) the other species, and 3) the distribution of resources and shelter across space. We present an examination of how these three factors affect the movement rules of prey (Pacific tree frog tadpoles, *Hyla regilla*) and predators (dragonfly nymphs, *Aeshna palmata*) in an experimental arena with two food patches that differ in the amount of prey's resource. Predator and prey distributions between the two patches were recorded at regular intervals over 3 hours and the minimum rates of movements between the patches were calculated. These data were compared to alternative models of how the probability of a prey or predator's switching patches depends on combinations of the proportion of prey, the proportion of predators, and the level of resources in the patch prior to individuals moving or not moving between patches. The relative evidence from the data for each of the alternative models were quantified using a model comparison approach utilizing Akaike Information Criteria. We find that prey movement between patches is primarily a positive function of the proportion of predators and prey in their current patch; i.e., that prey avoid both predators and competitors, but pay less attention to resources per se. For predators, their probability of movement decreased as the level of the prey's resource increases. That is, the predators appear to be basing their movement more on the distribution of the prey's resource than the distribution of prey and other predators. This surprising result matches a theoretical prediction that in a predator-prey race, predators should match the distribution of the prey's resource while prey should distribute themselves uniformly across patches. We compare these results to other metrics of how predators and prey are distributed, such as spatial overlap and coincidence.] Address: Luttbeg, B., University of California, Davis, Davis, CA

5247. Machado, A.B.M. (2005): *Schizocordulia* gen. nov. related to *Aeschnosoma* Selys with description of the female and additional data on the male of *Schizocordulia rustica* (Selys) comb. nov. (Odonata, Corduliidae). *Rev. Bras. Zool.* 22(3): 775-779. (in English, with Portuguese summary). ["The monotypical genus *Schizocordulia* is created for *Schizocordulia rustica* (Selys, 1871) comb. nov. known from a single male from Bahia, Brazil lacking the anal appendages. The female is described and the redescription of the male made by

GEISJKES (1970)] is completed by the description and illustration of the penis, the anal appendages and the pilose plate. The main characters separating the new genus from the closely related *Aeschnosoma* Selys, 1870 are the bifid male inferior appendage, the very long internal branch of the hamulus, the presence of a pilose plate on the male 7th abdominal segment, and the large and complex *vaivula vulvae* of the female. The study was based on 33 males and 2 females, which allowed an evaluation of the intraspecific variations in *Schizocordulia rustica*." (Author) The correct authorship of the species should be "Hagen in Selys, 1871" (Martin Schorr). For the full paper see: <http://www.scielo.br/pdf/rbzool/v22n3/26203.pdf> Address: Machado, A.B.M., Departamento de Zoologia, Inst. Cienc. Biol., Universidade Federal de Minas Gerais, Caixa Postal 486, 31270-901 Belo Horizonte, Minas Gerais, Brazil

5248. Malkmus, R. (2005): Libellen an den Bergbächen des Mount Kinabalu. *Natur und Museum* 1/2005: 6-15. (in German). [The author gives a concise description of the odonate fauna of Mount Kinabalu. Current knowledge totals the checklist of Odonata to 60 species. A brief history of dragonfly research in Mount Kinabalu is followed by a description of the faunas of different altitudes, and special emphasis is given to the riverine and the sun spot species. Many species are pictured by colour photographs. A closing chapter is directed to the relationship of the native people and dragonflies (e.g. usage as food).] Address: Malkmus, R., Schulstr. 4, D-97859 Wiesthal, Germany

5249. McCauley, S. (2005): Dispersal limitation and local performance: Interactions across life-history stages and consequences for species' distributions in anisopteran odonates.. 90th Annual Meeting in Montréal, Canada August 2005: (in English). [Verbatim: In many freshwater taxa, species' distributions are related to a habitat permanence gradient that is associated with a transition in the top predator community. Most studies of species' distributions across this gradient have focused on the role of trade-offs in local performance. However, for species which have limited abilities to withstand habitat drying, dispersal limitation may also be an important mechanism determining their ability to utilize habitats which dry regularly. I assessed the relative importance of local performance and dispersal limitation and how these processes may interact to determine species distributions in dragonfly species. I used a contrast of habitat specialist species restricted to permanent lakes with large bodied fish as top predators, and species with generalist distributions, occurring across the permanence and top predator gradient, to assess the role of local performance and dispersal limitation mechanisms in shaping species' distributions. I compared one aspect of local performance in habitat specialists and generalists - their vulnerability to alternative top predator types. I also compared larval traits expected to affect this and other aspects of local performance including larval activity levels and growth rates. I experimentally contrasted the effects of dispersal limitation in habitat specialists and generalists and related dispersal behavior to adult morphology. Dispersal limitation is a dominant mechanism structuring the breadth of species' distributions in these species. However, larval traits associated with species restricted to permanent lakes with large bodied fish predators were negatively related to adult traits that facilitate dispersal. These results suggest that traits affecting performance in diffe-

rent life-history stages may reinforce each other to shape species' distributions in this system.] Address: McCauley, Shannon, 1 University of Michigan, Ann Arbor, MI, USA

5250. McCreddie, J.W.; Ihle, D.T.; Adler, P.H. (2005): Biodiversity of larval damselflies and dragonflies (Insecta: Odonata) in the Lower Mobile/Tensaw Delta, Alabama. *Southeastern Naturalist* 4(2): 321-334. (in English). ["16 species of odonates, representing 9.2% of Alabama's odonate fauna, were collected from flowing waters 10 450 m wide in the poorly surveyed Mobile/Tensaw Delta of Baldwin County over a one-year period. The number of species was positively correlated with the number of specimens per site, with sites nearest Mobile Bay having fewer species, possibly reflecting higher salinities. Odonate assemblages in large flows of the Delta are unpredictable in terms of species co-occurrence, and fit a model of non-equilibrium community structure." 5252. Michaletz, P.; Doisy, K.; Rabeni, C. (2005): Influences of productivity, vegetation, and fish on macroinvertebrate abundance and size in Midwestern USA impoundments. *Hydrobiologia* 543(1): 147-158. (in English). ["The influences of productivity, vegetation coverage, and benthivorous fish abundance on macroinvertebrate abundance and mean size were examined in Midwestern USA impoundments. While impoundment productivity was not strongly related to total abundance and mean size of macroinvertebrates, it was related to specific taxa. As productivity increased, Ephemeroptera and Odonata abundance decreased and Diptera abundance increased. Despite the shift in taxonomic composition, mean individual size of the macroinvertebrate community varied little with changes in impoundment productivity. Relationships between macroinvertebrates and benthivorous fish were mixed. Macroinvertebrate abundance, especially Diptera, increased with increases in bluegill *Lepomis macrochirus* Rafinesque abundance and decreased with increases in channel catfish *Ictalurus punctatus* (Rafinesque) (which are stocked annually) abundance. Fish were not related to the mean size of macroinvertebrates. Macrophyte coverage was not related to macroinvertebrate abundance or mean size. Overall, macroinvertebrate abundance was mostly related to productivity and benthivorous fish in these impoundments. Mean size of macroinvertebrates did not differ with productivity, fish abundance, or macrophyte coverage." (Authors)] Address: Michaletz, P., Missouri Department of Conservation, 1110 South College Avenue, Columbia, MO, 65201, USA, Email: Paul.Michaletz@mdc.mo.gov

5253. Michels, U. (2005): Bemerkenswerte Nachweise im Makrozoobenthos der Weißen Elster. *Entomologische Mitteilungen Sachsen-Anhalt* 13(2): 79-81. (in

5254. Mitchell, F.L.; Lasswell, J.L. (2005): A Dazzle of Dragonflies. Peter N. Nevaumont Books (Texas A&M University Press). ISBN 1-58544-459-6: 224 pp. ["A Dazzle of Dragonflies" is a large, beautiful book that contains well-written information about dragonfly natural history, prehistory, and folklore. It also provides instructions on catching, collecting, rearing, photographing, and scanning odonates, as well as tips on creating a water garden to attract them. The abundant photos are in most cases exceptional, and the numerous other images, such as various wing patterns, eyes, and abdomens, are the result of scanning. These pictures are arranged or layouted as special kind of "Dragonfly Art", and as not otherwise to expect, they appear dead. But to see the wing venation is very fascinating. To scan wings is even better than to prepare black and white drawings of wing venation, cause you get the colours of the veins or pterostigma too. For me, the chapter on preserving Odonata is path breaking for the kind of documentation of specimens in collections. It is neither a field guide nor a scientific treatise: more than a hundred dragonflies are pictured in this coffee-table book, and best you browse it in your leisure time simply to enjoy our favourite beasts.

It is a little bit curious from the German point of view that Odonata are called "Hatzpferd", a name said to be still common for dragonflies among German people. The (nice) story of the Hatzpferd is told, but looking in Google for this expression, provides exactly zero hits. That's the situation: Checking Schäfer, Liselotte (1947): *Deutsche Synonymik der Libelle*. Dissertation an der Philosophischen Fakultät der Philipps-Universität zu Marburg. 303 pp., who compiled all the expressions in Germany referring to dragonflies, none hit the "Hatzpferd". There is only one quite similar from Blankenese near Hamburg: "Hetzepferd".

In spite of this: I don't want to miss this book. It is a very special one among the many books on dragonflies published in the past few years. (Martin Schorr)

5255. Moliár, A.; Ambrus, A. (2005): Odonata and aquatic beetle records from the hanság habitat reconstruction area. *Acta Biol. Debr. Oecol. Hung.* 13: 115-120. (in Hungarian, with English summary). ["The Nyirkai-Hany Habitat Reconstruction project was started in 2001 at the SE area of Hanság by the Fertő-Hanság National Park Directorate to extend and enhance the wetland habitat types of the area. The habitat reconstruction took place in three different beds successively involving 430 hectares. This paper presents the results of the Odonata monitoring started in the first year of flooding and beetle surveys of 2003-2004 years. The first years of the freshly flooded wetlands was characterized mainly by the large number of the widely distributed, generalist species, such as *Orthetrum cancellatum*, *Ischnura elegans* and later *Sympetrum vulgatum*, *Orthetrum albistylum* and *Noterus crassicornis*, *Noterus clavicornis*, *Hydrobius fuscipes* (Coleoptera). There were established small wetlands out of the directly flooded areas, by the increasing ground water table, filtered through the peat soils. These small water bodies support special, rich macroinvertebrate communities in dense vegetation and free of fish situation containing populations of such species as *Anaciaeschna isosceles*, *Brachytron pratense*, *Libellula quadrimaculata*, *Ischnura pumilio*, *Coenagrion pulchellum*, *Sympecma*

fusca (Odonata), *Hydrochus crenatus*, *Enochrus quadripunctatus* (Coleoptera)." (Authors)] Address: Ambros, A., Hortobágy National Park, Directorate, Thematic Information Centre of Nature Conservation, H-9495 Kópháza, Jurisich M. u. 16, Hungary

5259. Nekaris, K.A.I. (2005): Foraging behaviour of the slender loris (*Loris lydekkerianus lydekkerianus*): implications for theories of primate origins. *Journal of Human Evolution* 49(3): 289-300. (in English). [Members of the Order Primates are characterised by a wide overlap of visual fields or optic convergence. It has been proposed that exploitation of either insects or angiosperm products in the terminal branches of trees, and the corresponding complex, three-dimensional environment associated with these foraging strategies, account for visual convergence. Although slender lorises (*Loris* sp.) are the most visually convergent of all the primates, very little is known about their feeding ecology. This study, carried out over 10 ½ months in South India, examines the feeding behaviour of *L. lydekkerianus lydekkerianus* in relation to hypotheses regarding visual predation of insects. Of 1238 feeding observations, 96% were of animal prey. Lorises showed an equal and overwhelming preference for terminal and middle branch feeding, using the undergrowth and trunk rarely. The type of prey caught on terminal branches (Lepidoptera, Odonata, Homoptera) differed significantly from those caught on middle branches (Hymenoptera, Coleoptera). A two-handed catch accompanied by bipedal postures was used almost exclusively on terminal branches where mobile prey was caught, whereas the more common capture technique of one-handed grab was used more often on sturdy middle branches to obtain slow moving prey. Although prey was detected with senses other than vision, vision was the key sense used upon the final strike. This study strongly supports the notion that hunting for animal prey was a key ecological determinant in selecting for visual convergence early on in primate evolution. The extreme specialisations of slender lorises, however, suggest that early primates were not dedicated faunivores and lend further support to the emerging view that both insects and fruits were probably important components of the diet of basal primates, and that exploitation of fruits may account for other key primate traits." (Authors)] Address: Nekaris, K., Oxford Brookes University, School of Social Sciences and Law, Department of Anthropology, Nocturnal Primate Research Group, Oxford OX3 0BP, United Kingdom.

5263. Ogden, T.H.; Whiting, M.F.; Wheeler, W.C. (2005): Poor taxon sampling, poor character sampling, and non-repeatable analyses of a contrived dataset do not provide a more credible estimate of insect phylogeny: a reply to Kjer. Cladistics 21: 295-302. (in English). ["The wealth of data available for phylogenetic analysis of the insect orders, from both morphological and molecular sources, is steadily increasing. However, controversy exists among the methodologies one can use to reconstruct ordinal relationships. Recently, Kjer (2004) (Aligned 18S and insect phylogeny. Syst. Biol. 53, 506-514) presented an analysis of insect ordinal relationships based exclusively on a single source of information: 18S rDNA sequence data. Kjer claims that his analysis resulted in a more credible phylogeny for the insect orders and strongly criticized our previous phylogenetic results. However, Kjer only used a subset of the data that are currently available for insect ordinal phylogeny, misrepresented our analyses, and omitted other analyses we have published on insect ordinal phylogeny. In our estimation, Kjer did a poor job of representing the current state of affairs in insect ordinal phylogenetics. Furthermore, we examine a number of analytical issues that are relevant not only for insect phylogeny, but systematics as a science, such as: repeatability and objectivity, locating alignment boundaries, secondary structure, goodness of fit measure, epistemological coherence, practicality and homology." renced at many occasions.] Address: Ogden, T.H., Department of Integrative Biology, 401 WIDB, Brigham Young University, Provo, Utah 84602 USA. E-mail: heathogden@byu.edu

5264. Orizaola, G.; Brana, F. (2005): Plasticity in newt metamorphosis: the effect of predation at embryonic and larval stages. Freshwater Biology 50: 438-446. (in English). ["1. Some organisms under variable predator pressure show induced antipredator defences, whose development incurs costs and may be associated with changes to later performance. This may be of especial relevance to animals with complex life histories involving metamorphosis. 2. This study examines the effect of predation environment, experienced both during embryonic and larval stages, on palmate newt (*Triturus helveticus*) metamorphosis. Newt eggs were raised until hatching with or without exposure to chemical cues from brown trout (*Salmo trutta*), and larval development was monitored in the presence or absence of the cues. 3. Exposure to predator cues during the embryonic stage resulted in higher growth rates at the larval stage, reduced time to metamorphosis and size at metamorphosis. Metamorphs also had narrower heads and shorter forelimbs than those from predator-free treatments. In contrast, exposure to predator cues during the larval stage did not affect metamorph characteristics. 4. These results indicate that developing embryos are sensitive to predator chemical cues and that the responses can extend to later stages. Reversion of induced defences when predation risk ceased was not detected. We discuss the possible adaptive significance of these responses." (Authors) Odonata are treated in the discussion of the results of the study. - 5277.** Relyea, R.A.; Auld, J.R. (2005): Predator- and competitor-induced plasticity how changes in foraging morphology affect phenotypic trade offs. *Ecology* 86(7): 1723-1729. (in English). ["Studies of phenotypic plasticity frequently demonstrate functional trade-offs between alternative phenotypes by documenting environment-specific costs and benefits. However, the functional mechanisms underlying these trade-offs are often unknown. For example, predator-induced traits typically provide superior predator resistance but slower growth, while competitor-induced traits provide better growth but inferior predator resistance. While the mechanisms underlying predator resistance have been identified, the mechanisms underlying differential growth have remained elusive. To determine whether competitor and predator environments affect individual growth by induced changes in foraging morphology, we raised wood frog tadpoles (*Rana sylvatica*) under a factorial combination of competitors and predators (*Anax junius*) and assessed changes in mouthparts that might affect growth. In general, competitors induced relatively larger oral discs, wider beaks, and longer tooth rows, while predators induced relatively smaller oral discs, narrower beaks, and shorter tooth rows. These effects were interactive; the largest competitor-induced responses occurred under high predator density and the largest predator-induced responses occurred under low competition. Further, one of the tooth rows that commonly appeared under low predation risk was frequently absent under high predation risk. These discoveries suggest that predator and competitor environments can have profound effects on prey foraging structures and that these effects set up growth trade-offs between phenotypes that favor the evolution of phenotypically plastic responses." 5281. Rohr, J.R.; Crumrine, P.W. (2005): Effects of an herbicide and an insecticide on pond community structure and processes. *Ecological Applications* 15(4): 1135-1147. (in English). ["Virtually all species live within complex food webs, and many of these organisms are exposed to contaminants. However, we know little about how community processes, such as competition and predation, influence susceptibility to contaminants or how different types of contaminants shape communities. The objective of our study was to determine how realistic concentrations of the herbicide atrazine and the insecticide endosulfan influence the structure of a pond community when the presence of common community members was manipulated. We employed a factorial design in mesocosms to evaluate the effects of pesticide treatments (25 µg/L of atrazine, 10 µg/L of endosulfan, solvent control; two pulses separated by two weeks) and the presence or absence of wood frog tadpoles (*Rana sylvatica*), adult snails (*Planorbella trivolvis*), and caged dragonfly larvae (*Anax junius*) on a freshwater community. Tadpoles, snails, and chironomid larvae, *Polypedilum* sp. (Dipterans), all competed for periphyton. As a result, tadpoles reduced the survival, mass, and reproduction of snails; snails reduced the growth, development, inactivity, and dragonfly avoidance of tadpoles; snails and tadpoles reduced the abundance of chironomid larvae; and chironomid larvae reduced snail mass. The adverse effect of snails on tadpole growth and behavior was greater in the presence of the caged tadpole predator, *A. junius*. Neither pesticide affected dragonfly survival, but endosulfan directly reduced zooplankton (*Daphnia*), and atrazine indirectly reduced chironomid abundance. Atrazine also directly decreased periphyton, and endosulfan decimated chironomid larvae, resulting in indirect increases and decreases in competition for both snails and tadpoles, respectively. Consequently, relative to endosulfan, atrazine tended to decrease snail mass and reproduction and reduce tadpole mass, development, inactivity, refuge use, and dragonfly avoidance. However, the indirect effects of pesticides depended upon the presence of heterospecifics. The indirect benefit of endosulfan on snail mass was greater in the presence of caged dragonfly larvae, and endosulfan's indirect benefit on tadpole mass was greater in the absence of snails. The effect of pesticides on tadpole activity depended on both caged dragonflies and snails. Thus, environmentally realistic concentrations of pesticides directly and indirectly shaped species responses and community composition, but the initial composition of the community influenced these pesticide effects. These results empha-

size the importance of quantifying the effects of contaminants within complex natural communities." (Authors)] Address: Rohr, J.R., 101 Morgan Building, Dept of Biology, University of Kentucky, Lexington, Kentucky 40506-0225 USA

5283. Sánchez-Guillén, R.A.; Van Gossum, H.; Cordero Rivera, A. (2005): Hybridization and the inheritance of female colour polymorphism in two ischnurid damselflies (Odonata: Coenagrionidae). *Biological Journal of the Linnean Society* 85(4): 471-481. (in English). ["Female-limited polychromatism is frequent in many species of Odonata. *Ischnura elegans* has three colour morphs: one male-like coloured (androchrome) and two additional gynochrome brown morphs (*infuscans* and *rufescens-obsolata* morphs). A total of 19 progenies obtained from once-mated females were reared in the laboratory in three generations. Results indicate that the colour morphs are controlled by the same genetic system as previously described for *I. graellsii*, i.e. an autosomal locus with female-limited expression and with three alleles with a hierarchy of dominance ($p_a > p_i > p^0$). Five interspecific crossings between female *I. graellsii* and male *I. elegans*, five crossings between hybrid females and male *I. elegans* and one crossing between female *I. graellsii* and a hybrid male further confirmed that the genetic system is the same in both species. A survey of morph frequencies in north-west Spain revealed that *I. elegans* shows high variability in androchrome frequency (4-91%) between nearby populations, whereas in *I. graellsii* androchromes never are the majority morph (5-40%). The highest androchrome frequency in *I. graellsii* was found in populations closest to a locality where both species have hybridized, and that now has the highest androchrome frequency of *I. elegans*. We hypothesize that *I. elegans* genes have been incorporated into the genome of *I. graellsii* resulting in increased androchrome frequency in the latter species. Low androchrome frequency in *I. elegans* seems also related to the influence of *I. graellsii* genes. Therefore, we suggest that hybridization between both taxa is contributing to the temporal maintenance of contrasting androchrome frequencies in nearby populations." 5284. Sanderson, R. A.; Eyre, M. D.; Rushton, S. P. (2005): Distribution of selected macroinvertebrates in a mosaic of temporary and permanent freshwater ponds as explained by autologistic models. *Ecography* 28(3): 355-362. (in English). ["We investigated the aquatic macroinvertebrate fauna of 76 ponds and small pools in an urban fringe landscape, and related the presence of ten species to measures of water permanence, pond area and environmental conditions using logistic models. The incidence of all the species was strongly associated with variation in hydroperiod, but patterns were more variable with the other explanatory variables. To determine whether the presence of a species at neighbouring ponds increased its probability of occurrence at

a pond we constructed a series of autologistic models, that differed from the aspatial logistic model in that they included a spatial autocovariate in the predictor terms. The improvement of model fit on inclusion of this autocovariate, measured as the decline in deviance compared to the aspatial models, was determined across a range of lag distances. In seven of the ten species, the autologistic models explained the incidence of the species amongst the ponds better than the aspatial models. Spatial effects were typically over short distances (<200 m) before declining, but in two species appeared to reach an asymptote, and we propose that variation in dispersal ability is the most likely factor producing these spatial effects. We conclude that it is essential that some measure of spatial autocorrelation is considered when evaluating the distribution of aquatic macroinvertebrates at small or medium scales." 5287. Schenk, K.; Söndgerath, D. (2005): Influence of egg size differences within egg clutches on larval parameters in nine libellulid species (Odonata). *Ecological Entomology* 30(4): 456-463. (in English). ["In libellulids, egg size differs between species and populations. There are also size differences within egg clutches of individual females. Past experiments suggest that there are two different types of egg clutches in libellulids. Egg size decreases significantly during oviposition in species that perform non-contact guarding during oviposition. In contrast, in species ovipositing in tandem, egg size is randomly distributed. This study deals with the possible consequences of egg size variation within the different egg clutch types. The study examined whether there is a correlation between egg development time, offspring sex or larval size and egg size. The current experiments were conducted in Namibia and Germany. Five non-contact guarding and four tandem guarding libellulid species were used. In some species larger eggs needed more time to develop, in some species no correlation between egg size and egg development time could be found, whereas in other species larger eggs developed faster. The sex ratio was biased towards females in *Leucorrhinia dubia* and in *Sympetrum striolatum* and egg size was not associated with gender. In both egg clutch types larger eggs resulted in larger larvae. In this study, evidence was found that the effects of egg size diminished with progressing larval develop-

ment under good conditions. However, it is possible that the effects may have a greater influence under harsh circumstances." Authors)] Address: Schenk, Kamilla, Zoologisches Institut, Technische Universität Braunschweig, Fasanenstraße 3, D-38092 Braunschweig, Germany. E-mail: k.schenk@tu-bs.de

5288. Scher, O.; Thiéry, A. (2005): Odonata, Amphibia and Environmental Characteristics in Motorway Stormwater Retention Ponds (Southern France). *Hydrobiologia* 551(1): 237-251. (in English). ["Water and its protection against pollution is an urgent priority for all countries around the world. In that context, France, through its Water Law in 1992 obliged the motorway companies to build stormwater retention ponds along roads in order to protect the water resource from transport pollution and to control water flow during rainstorms. We propose to evaluate how much these ponds can be attractive for aquatic species and then evaluate their role in regional biodiversity. Six retention ponds, localized in the Mediterranean region, were investigated during one year (March 2002 March 2003) for their chemical and biological characteristics such as bottom type, trace metal composition, water quality and phyto-cenose composition. These variables were recorded and correlated with species richness of amphibian and dragonfly communities. Stormwater retention ponds showed a high concentration of copper and zinc in top sediment layer and herbicides in water column. Dragonfly richness was higher in ponds with a natural bottom than ones with an artificial bottom (PEHD membrane) while amphibian richness was more sensitive to the structure of the surrounding landscape. These habitats appeared to be very attractive for Odonata species and tend to favorize uncommon species present in the survey region such as *Ischnura pumilio* and *Erythromma viridulum*. Amphibian were found to be representative of anthropophilous guild." (Authors)] Address: Scher, O., Laboratoire de Biologie Animale, Université de Provence, E.R. 5299. Stoks, R.; De Block, M.; McPeck, M.A. (2005): Alternative growth and energy storage responses to mortality threats in damselflies. *Ecology Letters* 8(12): 1307-1316. (in English). ["The role of physiology in mediating the growth/predation risk trade-off has been largely ignored. We examined effects of predation risk on relationships between growth and storage molecules in *Enallagma aspersum* and *Ischnura verticalis* damselfly larvae that differ in this trade-off. In laboratory and field experiments, both species had similar growth and mortality rates and similar concentrations of storage molecules in the absence of mortality threats. However, in the presence of dragonfly predators *Ischnura* larvae had higher mortality rates and grew faster than *Enallagma* larvae. Consistent with the difference in growth rate, *Enallagma*'s total protein concentrations decreased under predation risk while those of *Ischnura* did not. Glucose and glycogen concentrations were not affected, while triglyceride concentrations were lower under predation risk in *Enallagma* but not in *Ischnura*. Species differences at the physiological level to the presence of mortality threats may be crucial to understanding patterns in metamorphic and post-metamorphic traits." 5300. Stoks, R.; Nyström, J.L.; May, M.L.; McPeck, M.A. (2005): Parallel evolution in ecological and reproductive traits to produce cryptic damselfly species across the holarctic. *Evolution* 59(9): 1976-1988. ["The damselfly genus *Enallagma* originated in the Nearctic, and two Nearctic lineages recently underwent radiations partly associated with multiple independent habitat shifts from lakes dominated by fish predators into lakes dominated by dragonfly predators. A previous molecular study of four Palearctic morphospecies and all representative Nearctic species identified the presence of

two cryptic species sets, with each set having Palearctic and Nearctic representatives. However, the cryptic species within each set are not sibling species. Here, we present quantitative data on ecologically important larval morphologies and behaviors involved in predator avoidance and on adult male morphological structures involved in mate recognition to quantify the phenotypic relationships among these cryptic species sets. For the adult stage, our data indicate strong parallel evolution of the structures involved in specific mate recognition the male cerci. For the larval stage, morphometric analyses show that the Palearctic species evolved a nearly identical morphology to the sibling-clade members in the Nearctic that live in waters where dragonflies are the top predators. This implicates the importance of dragonfly predation in the history of the Palearctic clade. Behavioral analyses suggest population differentiation in response to the actual predator environment in the Palearctic clade, consistent with the species differentiation seen in the Nearctic. Our results suggest parallel evolution of adult traits that influence specific mate choice and larval traits that influence ecological performance underlie the striking similarity of *Enallagma* species across continents. This concurrent parallel evolution in both stages of a complex life cycle, especially when both stages do not share the same selective environment, may be a very unusual mechanism generating cryptic species." 5301. Stoks, R.; De Block, M.; Van de Meutter, F.; Johansson, F. (2005): Predation cost of rapid growth: behavioural coupling and physiological decoupling. *Journal of Animal Ecology* 74: 708-715. (in English). ["1. Despite its prominent role in life-history theory, there is no direct empirical evidence for a behaviourally mediated predation cost of rapid growth. Moreover, we know little about how digestive physiology may also influence the shape of the growth/predation risk trade-off function. 2. We determined the role of behaviour and digestive physiology in experiments in which damselfly larvae were induced to grow slowly or rapidly by manipulating photoperiod (time stress), and exposure to a fish predator. 3. We showed that larvae under time stress grew more rapidly. Rapid-growing larvae had a higher foraging activity and a higher growth efficiency. 4. Under predation risk, larvae not only had a lower foraging activity but also a lower growth efficiency. 5. Rapid-growing larvae (i.e. those under time stress) balanced the growth/predation risk trade-off differently and took more risk in the presence of a predator, which resulted in a behaviourally mediated higher predation cost compared to slow-growing larvae. Their higher growth efficiency, however, made this cost smaller compared to a completely behaviourally mediated rapid-growth strategy. 6. Our results provide the first explicit experimental proof of a behaviourally mediated predation cost of rapid growth. Besides a behavioural coupling of growth and predation risk, resulting in the well-known trade-off, we also found a partial decoupling of these two processes by digestive physiology." 5306. Tol, J. van (2005): Revision of the Platystictidae of the Philippines (Odonata), excluding the *Drepanosticta halterata* group, with descriptions of twenty-one new species. *Zool. Med., Leiden* 79(2): 195-282. (in English). ["Thirty-one species of the family Platystictidae of the Philippines are revised, i.e. all species recognised, excluding the species of the *Drepanosticta halterata*-group. The following new taxa are described: 16 species in *Drepanosticta* Laidlaw: *D. acuta* spec. nov., *D. aurita* spec. nov., *D. centrosaunis* spec. nov., *D. dados* spec. nov., *D. flavomaculata* spec. nov., *D. furcata* spec. nov., *D. hermes* spec. nov., *D. krios* spec. nov., *D. luzonica* spec. nov., *D. malleus* spec. nov., *D. myzouris* spec. nov., *D. paruatia* spec. nov., *D. pistor* spec. nov., *D. quadricornu* spec. nov., *D. rhamphis* spec. nov., *D. trachelocele* spec. nov., two in *Protosticta* Selys, viz. *P. lepteca* spec. nov. and *P. plicata* spec. nov. and three in *Sulcosticta* gen. nov., viz. *S. striata* spec. nov., *S. pallida* spec. nov. and *S. viticula* spec. nov. The status of eleven previously described nominal taxa is established. One, *D. septima* Needham & Gyger, is doubtfully considered a synonym of *D. mylitta*.

Cowley. Based on a preliminary phylogenetic analysis, the species of Drepanosticta are divided into informal species groups. Most species of the Philippines have affinities to species of Sulawesi, the Moluccas and New Guinea. Several species confined to Palawan have sister-group relationships with species from Borneo. The affinities of various other species confined to the Sulu archipelago, are unsettled as yet. The species of Platystictidae here assigned to Protosticta Selys are presumably not closely related to the type species, *P. simplicinervis* Selys from Sulawesi. However, a better placement has to await a more detailed phylogenetic study of the family. For three species the new genus *Sulcosticta* gen. nov. is erected. These species are closely allied based on the structure of the appendages, but should have been assigned to different genera if based on the present generic definitions. Many species here described have small distributional ranges, a common phenomenon in Platystictidae. Since most forests in the Philippines are heavily under threat or have already disappeared in the last fifty years, several taxa described in this paper should be considered under threat of immediate extinction." (2005): Estudio del comportamiento de oviposición de *Protoneura capillaris* (Rambur, 1842) (Odonata: Protoneuridae). *Folia Entomol. Mex.* 44(2): 225-231. (in Spanish, with English summary). ["A study on the ovipositing behaviour of the Cuban endemic damselfly *P. capillaris* was carried out at the Dos Bocas stream, north of the city of Santiago de Cuba. The study was carried from 9 to 20 June of 2004 between 08:00 to 16:00 local time. A peak of ovipositing activity occurred between 12:30 to 13:30h. The oviposition behaviour lasts on average 54 min. During oviposition in tandem the males continued flapping their wings. Some factors affect the oviposition behavior, such as wind and intra and interspecific interference by other males and / or other tandems." 5310. Turgeon, J.; Stoks, R.; Thum, R.A.; Brown, J.M.; McPeck, M.A. (2005): Simultaneous quaternary radiations of three damselfly clades across the Holarctic. *American Naturalist* 165(4): E78-E107. (in English). ["If climate change during the Quaternary shaped the macroevolutionary dynamics of a taxon, we expect to see three features in its history: elevated speciation or extinction rates should date to this time, more northerly distributed clades should show greater discontinuities in these rates, and similar signatures of those effects should be evident in the phylogenetic and phylodemographic histories of multiple clades. In accordance with the role of glacial cycles, speciation rates increased in the Holarctic *Enallagma* damselflies during the Quaternary, with a 4.25× greater increase in a more northerly distributed clade as compared with a more southern clade. Finer-scale phylogenetic analyses of three radiating clades within the northern clade show similar, complex recent histories over the past 250,000 years to produce 17 Nearctic and four Palearctic extant species. All three are marked by nearly synchronous deep splits that date to approximately 250,000 years ago, resulting in speciation in two. This was soon followed by significant demographic expansions in at least two of the three clades. In two, these expansions seem to have preceded the radiations that have given rise to most of the current biodiversity. Each also produced species at the periphery of the clade's range. In spite of clear genetic support for reproductive isolation among almost all species, mtDNA signals of past asymmetric hybridization between species in different clades also suggest a role for the evolution of mate choice in generating reproductive isolation as species recolonized the landscape following deglaciation. These analyses suggest that recent climate fluctuations resulted in radiations driven by similar combinations of speciation processes acting in different lineages." 5311. Urgelles, R.; Dorn, N.; Trexler, J. (2005): The spatial distribution and relative abundance of larval dragonflies found in the freshwater marshes of the Florida Everglades. *ESA Annual Meeting, Montréal, Canada. August 2005:* 202. (in English). [Verbatim: Aquatic macroinvertebrates are essential tools for characterizing habitat quality since they are sensitive indicators of environmental stressors, such as altered hydrology and nutrient enrichment. Long-term monitoring of aquatic macroinvertebrates such as Anisoptera can be used to assess the progress of restoration initiatives, such as the one being conducted in the Florida Everglades. We present the first comprehensive spatial and temporal survey of dragonfly communities for Everglades freshwater marshes and use statistical methods to analyze the relationship between these assemblages and environmental variables. From 1997 to 2004, we collected and identified the naiads of 15 species of dragonfly from 20 sites (each composed of replicate ha plots) across broad spatial scales, encompassing wet and dry

season dynamics. In a preliminary analysis of two years of data, 2002 and 2003, we identified 13 dragonfly species and described their distributions and relative abundance based on their spatial extent (# of sites at which they were collected) and density (annual average # individuals/m²). Two species, *Celithemis eponina* and *Libellula needhami*, dominated the assemblage at most sites and showed considerable inter-annual dynamics. *C. eponina* annual average densities increased in 18 out of 20 sites from 2002 to 2003, while *L. needhami* decreased in density in 15 out of 20 sites. Since 2003 was a wetter year throughout the ecosystem than 2002, these shifts in dominance may indicate a greater ability by *C. eponina* to tolerate conditions associated with lengthening hydroperiod. At a site highly stressed with anthropogenic nutrient-enrichment, the normally dominant *C. eponina*, was completely absent, and *Pachydiplax longipennis*, a species that is at low densities or absent from all other sites, dominated the assemblage with extremely high densities. We are currently analyzing the remaining years and looking at longer-term responses of dragonfly assemblages to dry-down and re-wetting conditions. 5313. Van de Meutter, F.; Stoks, R.; De Meester, L. (2005): The effect of turbidity state and microhabitat on macroinvertebrate assemblages: a pilot study of six shallow lakes. *Hydrobiologia* 542: 379-390. (in English). ["Shallow lakes can occur in two alternative stable states, a clear-water state and a turbid state. This is associated with separate assemblages of fish, zooplankton and plants. Little is known about whether macroinvertebrate assemblages differ across both stable states. This study investigated this in a connected set of three turbid and three clear-water shallow lakes. To overcome confounding effects of differences in spatial structure of macrophytes in turbid and clear-water lakes, we sampled three microhabitats that occurred in both alternative stable states: open water, sago pondweed (*Potamogeton pectinatus*) and reed (*Phragmites australis*). Univariate analyses indicated no differences in the number of organisms, taxon richness or diversity between turbid and clear-water lakes. Multivariate analysis, however, showed significant differences in the macroinvertebrate community structure of both stable states. Nine taxa explained a significant amount of the va-

riation between both lake types, of which seven preferred the clear-water lakes. The number of organisms and the taxon richness were higher in reed than in the other microhabitats, but diversity and evenness did not differ among the microhabitats. Multivariate analyses could separate all three microhabitats. Eight taxa, mainly detritus feeders and collector gatherers, explained most of the variation in the data and preferred the reed microhabitat. The effects of stable state (6.8% explained variance) and microhabitat (13.1% explained variance) on the macroinvertebrate assemblages were largely independent from each other (1.5% shared variance). Although macroinvertebrates are not implemented in the initial theory of stable states, our results show clearly different assemblages across both stable states." 5314. Van de Meutter, F.; De Meester, L.; Stoks, R. (2005): Water turbidity affects predator prey interactions in a fish damselfly system. *Oecologia* 144(2): 327-336. (in English). ["Community structure may differ dramatically between clear-water and turbid lakes. These differences have been attributed to differences in the cascading effect of fish on prey populations, owing to the reduced efficiency of fish predation in the presence of macrophytes. However, recent theoretical ideas suggest that water turbidity may shape predator prey interactions, and it is predicted that prey will relax its antipredation behaviour in turbid water (H1). As a result, the nature of predator prey interactions is expected to shift from both direct and indirect in clear water to dominantly direct in turbid water (H2). We tested these ideas in a fish damselfly predator prey system. In a first behavioural experiment, we looked at antipredation behaviour of damselfly larvae isolated from habitats that differ in turbidity, in the presence of fish in clear and turbid water. As predicted in H1, the larvae were more active in turbid than in clear water. In a complementary enclosure experiment, we reared larvae in a clear-water pond and a turbid pond, respectively, and manipulated the origin of the larvae (clear-water, turbid pond), fish presence (absent, present), and vegetation density (sparse, abundant). In both ponds, fish had a direct negative effect on survival of the larvae, which was mitigated in the presence of vegetation. In the fish treatment, the change in average body mass tended to be higher in the turbid pond than in the clear-water pond, suggesting indirect effects of fish were mitigated in the turbid pond. This was supported by a negative effect of fish on the effective growth rate of larvae in the clear pond, but not in the turbid pond. These results are compatible with the idea that predator prey relationships are mainly governed by direct effects in turbid water, and by direct and indirect effects in clear water." 5316. Van Doorslaer, W.; Stoks, R. (2005): Growth rate plasticity to temperature in two damselfly species differing in latitude: contributions of behaviour and physiology. *Oikos* 111(3): 599-605. (in English). ["Plasticity in growth rate may be driven by behavioural and physiological mechanisms. Although these underlying mechanisms have direct implications for the importance of ecological and physiological costs associated with rapid growth, the contribution of behaviour and physiology to temperature-mediated plasticity in growth rate has largely been neglected. We studied the temperature-dependence of growth rate and its underlying behavioural and physiological mechanisms in two congeneric damselfly species that differ in latitudinal distribution. Larvae were reared from the egg stage at three temperatures (17°C, 22°C and 27°C). Within each species, growth rates showed a quadratic response curve with an optimum at 22°C. Behaviour, as measured by food intake, and physiology, as measured by growth efficiency and heartbeat as proxy for metabolic rate, jointly contributed to this temperature-induced plasticity in growth rate. At each temperature, growth rates were higher in the northern species. In line with the few other studies that compared northern and southern populations, both an increased food uptake and growth efficiency caused this pattern. Together with previous studies that focused on the population level, our results tentatively suggest that not only the latitudinal patterns in growth rate but also the mechanistic basis are similar at the species and at the population level." 5317. van Doorslaer, W.; Stoks, R. (2005): Thermal reaction norms in two Coenagrion damselfly species: contrasting embryonic and larval life-history traits. *Freshwater Biology* 50(12): 1982-1990. (in English). ["1. We studied the temperature-dependence of important life-history traits both at the embryonic (egg hatching success, embryonic development time and hatchling size) and the larval stage (larval growth rate, larval survival and larval size after 100 days) using full-sib families of two congeneric damselflies, *Coenagrion hastulatum* and *Coenagrion puella*, that differ in latitudinal distribution. Larvae were reared in the laboratory from the egg stage at four temperatures (12, 17, 22 and 27°C). 2. The observed patterns of thermal plasticity in embryonic traits showed that the northern species was more successful than the southern species at lower temperatures, in line with the pattern of temperature adaptation in thermal reaction norms. 3. At the larval stage, we found no consistent pattern of latitudinal compensation. The thermal family reaction norms indicate, however, the potential for latitudinal compensation to evolve. We observed an ontogenetic shift in thermal optima for larval growth rate, with a higher optimal temperature for growth rate during the first 2 weeks of the larval stage. 4. This is the first indication of the existence of latitudinal compensation at the interspecific level in an invertebrate; it is stage-specific, being present only in the embryonic stage. We argue that compensation in the embryonic stage may be much more likely than in the larvae and stress the importance of including more than one life-history stage when drawing conclusions about the adaptiveness of patterns in thermal reaction norms." 5318. Van Gossum, H.; Stoks, R.; De Bruyn, L. (2005): Lifetime fitness components in female colour morphs of a damselfly: density- or frequency-dependent selection?. *Biological Journal of the Linnean Society* 86: 515-523. ["In many damselfly species mature females exhibit colour polymorphism: one female morph resembles the conspecific male (androchrome) while the others do not (gynochromes). Hypotheses for the maintenance of such polymorphisms differ mainly as to whether they are based on density- and/or frequency-dependent selection and on the nature of the frequency dependence. We collected lifetime fitness data (individual lifespan, number of copulations and number of ovipositions) for female morphs of the damselfly *Ischnura elegans* from 15 insectaries differing in population parameters (density, sex ratio and ratio of andro- to gynochromes). Both density and frequency affected a specific set of the studied fitness components. While morph frequency influenced lifespan, sex ratio influenced the number of copulations, and density affected lifespan and the number of ovipositions. Clearly, discrepancies among studies may be generated if the studied fitness components differ. Our final fitness estimate, the number of ovipositions, was only influenced by density, thereby not supporting frequency-based hypotheses. Contrary to expectation under the current density-based hypothesis, androchromes compared to gynochromes had a lower number of ovipositions at high density. We discuss our findings in the light of mechanisms maintaining the female polymorphism." (Authors)] Address: Gossum, H. van, Evolutionary Biology Group, Universi-

ty of Antwerp (RUCA), Groenenborgerlaan 171, B-2020 Antwerp, Belgium. E-mail: hvgossum@ruca.ua.ac.be

5319. Van Gossum, H.; De Bruyn, L.; Stoks, R. (2005): Male harassment on female colour morphs in *Ischnura elegans* (Vander Linden): Testing two frequency-dependent hypotheses (Zygoptera: Coenagrionidae). *Odonatologica* 34(4): 407-414. (in English). ["In many Zygoptera species females occur in different colour morphs, with one morph coloured like the 6" (andromorph), while the others are not (gynomorph). Two hypotheses have been proposed to explain frequency-dependent harassment of female morphs. According to the first, males should prefer the more frequent of the 2 female morphs (learned-mate recognition hypothesis). According to the second, males should prefer andromorphs more if their frequency relative to male increases, but not so for gynomorphs which always should be attempted to mate with on encounter (mimicry hypothesis). Here, it is reported on a re-analysis of earlier published data on morph-specific harassment for *I. elegans*, which allows examination of the 2 proposed hypotheses. The data were collected in 8 insectaries with different ratios of males and female morphs. As reported earlier, male harassment is highest on the most common female morph supporting the learned-mate recognition hypothesis. The ratio of andromorphs to males had no morph-specific effects in amounts of male harassment, wherefore the data suggest rejection of the mimicry hypothesis." 5320. Van Gossum, H.; De Bruyn, L.; Stoks, R. (2005): Reversible switches between male and female mating behaviour by male damselflies. *Biology Letters* 1: 268-270. (in English). ["For many animal groups, both sexes have been reported to attempt to mate with members of their own sex. Such behaviour challenges theories of sexual selection, which predict optimization of reproductive success. We tested male mate choice between opposite- and same-sex members in the damselfly *Ischnura elegans*. Binary choice experiments were conducted following exposure periods in insectaries with only males or with both sexes present. We show that switches in choice between the opposite sex and the same sex can be induced and reversed again by changing the social context. We argue that the observed reversibility in male male- and female-directed mating behaviour is maladaptive and a consequence of strong selection on a male's ability to alter choice between different female colour morphs." 5323. Watts, P.C.; Kemp, S.J.; Saccheri, I.J.; Thompson, D.J. (2005): Conservation implications of genetic variation between spatially and temporally distinct colonies of the endangered damselfly *Coenagrion mercuriale*. *Ecological Entomology* 30(5): 541-547. (in English). ["1. Good conservation management is underpinned by a thorough understanding of species' historical and contemporary dispersal capabilities along with the possible adaptive or neutral processes behind any spatio-temporal genetic structuring. These issues are investigated with respect to *C. mercuriale* the only odonate species currently listed in the U.K.'s Biodiversity Action Plan in east Devon where its distribution has become fragmented. 2. The two east Devon *C. mercuriale* populations, only 3.5 km apart, have accumulated strong differences in frequencies of alleles at 14 microsatellite loci as a consequence of poor adult dispersal and drift. There is no contemporary migration between sites. 3. A genetic signature of population decline at both sites corresponds with known demographic reductions. *C. mercuriale* in east Devon are now significantly genetically less diverse than those from a population stronghold in the Itchen Valley. 4. Colonies would benefit from improved connectivity between areas and possibly by a transfer of individuals from other ecologically similar areas. 5. Because *C. mercuriale* has a semivoltine life cycle throughout the U.K., the possibility that alternate-year cohorts are reproductively isolated is explored. Genetic differentiation among cohorts is an order of magnitude less than between sites, suggesting that some larvae delay their development into adults for a year and recruit to a different cohort. 6. To our knowledge, this is the first study to document migration and gene flow between alternate-year cohorts in a species of odonate. From a conservation standpoint, the cohorts do not require separate management." 5330. Wildermuth, H. (2005): Beitrag zur Larvalbiologie von *Boyeria irene* (Odonata: Aeshnidae). *Libellula* 24(1/2): 1-30. (in German, with English and French summaries). ["Larvae of *B. irene* were studied with respect to morphology, morphometry, ethology and ecology shortly before the emergence period and during the flying season in the northern Provence, France. In all larval stadia the colour pattern varied considerably; besides bright beige individuals also almost black ones existed. The last five stadia could be determined by the relative length of the wing sheaths but not by the absolute body length or head width. Ultimate stadia were present in great number in June but only sparsely in July; clearly defined cohorts could not be recognized. The larval development is supposed to take usually two years, and three years exceptionally. Emergence occur-

red at night. It is inferred that the larvae are definitely adapted to current water with respect to their behaviour but morphologically only to a restricted scale. In the northern Provence they inhabit exclusively permanent rivers, with small spring-fed streams harbouring the largest population densities. They stayed mainly among pebbles and under large stones, and only rarely in other microhabitats as submerged root felts or plant debris. The sp. was most frequently found together with *Cordulegaster boltonii*, *Onychogomphus uncatatus*, and *O. f. fordipatus*. The larval biology and the habitat preference of the Provençal populations of *B. irene* are compared with those of Switzerland where they occur at lake shores, and with those of other spp. of the genus.] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. 5331. Wildermuth, H. (2005): Kleingewässer-Management zur Förderung der aquatischen Biodiversität in Naturschutzgebieten der Agrar- und Urbanlandschaft. Wirkungskontrolle am Beispiel Libellen im Schweizer Mittelland. *Naturschutz und Landschaftsplanung* 37(7): 193-201. (in German, with English summary). ["The study describes how the aquatic flora and fauna could be protected and promoted by suitable shaping and management, using the example of the 'Drumlinlandschaft Zürcher Oberlauf', which is the relic of an originally wide-stretched moorland in the Swiss Midland. After abandoning the extensive use of bedding and peat around 1950 the peat cuttings and ditches became widely overgrown reducing diversity and population sizes of aquatic organisms. In the course of 35 years of protection activities peat cuttings have been regenerated and maintained according to the rotation principle; ditches have been renewed, extended and retained in spatial and temporal sections, and measures were conducted for the regeneration of raised bogs. Efficiency controls showed that the species diversity of aquatic organisms (water plants, amphibia, water insects) could be conserved to a large extent. Additionally some species could be resettled in new partial areas. Monitoring controls concentrated on dragonflies which were mapped applying semi-quantitative methods. From the 49 species identified 23 regularly and eight species sporadically reproduce in the area. In the first year up to 28 species were found around to the newly created ponds and streams. At the longer existing ponds 26 species were identified in the sampling year 2004, including species requiring advanced succession stages. Two of them, *Lestes virens* and *Leucorrhinia pectoralis*, are considered as 'threatened with extinction' in Switzerland. On the basis of the exuvia the study explains how the partial population of the metapopulation of *L. pectoralis* developed and spread out during the last 20 years. In order to sustainably maintain the study suggests to establish a regional network of regenerated peat cuttings." (Author)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. 5332. Williams, L.R.; Bonner, T.H.; Hudson, J.D.; Williams, M.G.; Leavy, T.R.; Williams, C.S. (2005): Interactive effects of environmental variability and military training on stream biota of three headwater drainages in western Louisiana. *Transactions of the American Fisheries Society* 134: 192-206. (in English). ["We collected fishes and macroinvertebrates seasonally from eight headwater streams in three different drainage basins (the Red, Calcasieu, and Sabine rivers) crossing

Peason Ridge Training Area in west-central Louisiana. Peason Ridge is part of the Fort Polk military training facility. We used multivariate analyses to test the effects of physical variables (i.e., current velocity, depth, and substrate), time (seasonal variability), drainage basin, and military training activities on assemblage structure. Tributaries of the Red River had the highest gradient and were predominated by shallow, swift-flowing runs with sandy substrates. Southern tributaries of the Calcasieu and Sabine rivers were of lower stream gradient and contained deep, sluggish runs and pools with large amounts of woody debris and silt. Fish assemblages were structured primarily by military training and drainage basin. Faunal differences among drainage basins probably reflect differences in stream gradient. Fish assemblages in tributaries of the Sabine River were less diverse and showed evidence of historical degradation. Macroinvertebrate assemblages also were structured primarily by military training but had a strong seasonal component related to their short life cycles and high seasonal turnover. In contrast to fishes, macroinvertebrate assemblages were similar among drainages. Because military training was most intense in the Red River basin, its significance in these models probably represents differences in stream gradient among the basins because we found no negative effect on stream biota resulting from current training activities. Rather, historical logging and the resultant siltation coupled with isolation of populations by reservoirs." (Authors) Odonata are treated on the family level.] Address: Williams, L.R., School of Natural Resources, Ohio State University, 2021 Coffey Road, Columbus, Ohio 43210, USA

5333. Yoshimura, M.; Okochi, I. (2005): A decrease in endemic odonates in the Ogasawara Islands, Japan. *Bulletin of the Forestry and Forest Products Research Institute* 4(1) (No.394): 45-51. (in English, with Japanese summary). ["There are many endemic species in the Japanese Ogasawara Islands. However, many of these endemic species are likely to disappear as a result of reduction of habitat and the introduction of exotic species. Odonates are included within this category of species at risk. If the decrease in endemic odonates is due to a decrease in aquatic habitat, we have only to provide artificial ponds to conserve these species. In this study, we provided artificial ponds as a habitat for odonates in Chichi-jima and Ani-jima, Ogasawara Islands. We then examined the possibility of protection and enhancement of odonate populations. Endemic odonates were found in the natural ponds of Ani-jima and Ototojima. In Ani-jima, they could be collected both in the artificial and natural ponds. The artificial pond could provide habitat for endemic odonates. However, in Chichi-jima, few odonates could be collected both in the artificial and natural ponds. Here, invasive species, such as *Gambusia affinis* and *Anolis carolinensis*, are found, which considered to prey upon odonate larvae and adults. Extermination of invasive species may be necessary to conserve the endemic odonates in Chichi-jima." 5334. Zimmermann, W.; Petzhold, F.; Fritzlar, F. (2005): *Verbreitungsatlas der Libellen (Odonata) im*

Freistaat Thüringen. Naturschutzreport 22: 224 pp. (in German, with English summary). [The present atlas summarises field surveys, literature reviews and reviews of museum collections of odonates in the Free State of Thuringia/Germany. The history of dragonfly faunistics in Thuringia begun in 1807. Its further development can largely be traced from museum collections and recently from detailed field surveys and faunistic publications. Field surveys were carried out mainly between 1990 and 2004. 120 people contributed to the data collection. The existing literature on Thuringian odonates (101 publications and 178 unpublished surveys) is also reviewed as are museum collections (15). Together the three sources resulted in 37,581 records from 3,296 sites distributed over 444 grid cells (scale 1:25000). This represents a coverage of 76 % (Total: 588 squares). Sixty-two dragonfly species have been recorded in Thuringia to date. Among these, several species of the highest European protection status have stable populations, such as *Somatochlora alpestris*, *Coenagrion ornatum*, and *C. mercuriale*. All data, maintained in a geographical information system at the Thuringian State Department for Environment and Geology, are available to local authorities and nature protection offices. The value of water bodies to dragonflies are analysed per landscape unit: Maps specifying the water quality in each of the landscape units of Thuringia are compared to species numbers. For each species recorded in Thuringia the following information are presented: number of records, the proportional occupancy of grid cells, habitat, basic life-history, indications of population increases or declines (status of extinction risk). Additionally, a graph is provided showing the distribution points in the periods of before 1944, 1944-1984, 1985-2005, respectively, and phenology and altitudinal distribution. Each species and its habitats are depicted in a photograph. Further chapters address faunistic problems, corrections of earlier indications, species potentially expected in Thuringia, the importance of dragonflies in nature protection, specifically under the EU Habitats Directive as well as the description of dragonfly communities in running waters, in swamps/peat bogs, ponds, drainage ditches in agricultural areas, and water bodies in gravel pits. Finally, there are chapters on the increased occurrence of southern species, on migrating dragonflies, on fossil records from Thuringia and a list of local vernacular dragonfly names.] Address: Thüringer Landesanstalt für Umwelt und Geologie, Prüssingstr. 25, D-07745 Jena, Germany. www.tlug-jena.de

Zool. sci. 14(3): 505-509. (in English). ["The relationship between body size and the results of territorial conflicts was studied in males of the dragonfly, *O. japonicum japonicum*. Territorial residents were larger than intruders in body width, but not in hind wing length. Winners of territorial conflicts were larger than losers in body width, but not in hind wing length. This difference was attributed to the fact that residents were larger than intruders. The results of territorial conflicts were more strongly affected by the role of the opponents (resident or intruder) than by the difference in their body sizes. Territorial males arrived at the territorial sites earlier than non-territorial ones on a given day. The body size of males arriving at the study area earlier in a day was not larger than that of males arriving later." 5340. McCollum, S.A.; Leimberger, J.D. (1997): Predator-induced morphological changes in an amphibian: predation by dragonflies affects tadpole shape and color. *Oecologia* 109: 615-621. (in English). ["Predator-induced defenses are well studied in plants and invertebrate animals, but have only recently been recognized in vertebrates. Gray treefrog (*Hylachrysoxcelis*) tadpoles reared with predatory dragonfly (*Aeshna umbrosa*) larvae differ in shape and color from tadpoles reared in the absence of dragonflies. By exposing tadpoles to tail damage and the non-lethal presence of starved and fed dragonflies, we determined that these phenotypic differences are induced by non-contact cues present when dragonflies prey on *Hyla*. The induced changes in shape are in the direction that tends to increase swimming speed; thus, the induced morphology may help tadpoles evade predators. Altering morphology in response to predators is likely to influence interactions with other species in the community as well." 5342. Alcocer, J.; Escobar, E.; Lugo, A.; Peralta, L. (1998): Littoral benthos of the saline crater lakes of the basin of Oriental, Mexico. *International Journal of Salt Lake Research* 7(2): 87-108. (in English). ["Two saline crater lakes in the basin of Oriental, Puebla-Tlaxcala-Veracruz, were investigated for littoral benthic macroinvertebrates. Fifty taxa were identified with the oligochaetes, amphipods, chironomids and leeches the dominant organisms. These four taxa made up to 99 per cent in both number and biomass. *Limnodrilus hoffmeisteri*, *Hyalella azteca*, *Tanytus (Apelopia) sp.* and *Stictochironomus sp.* were the most abundant organisms. Unlike other saline lakes which have a littoral benthos dominated by chironomids, *Alchichica* and *Atexcac* were dominated by oligochaetes (70–73 per cent). The gastropod, *Physa sp.*, was found up to a salinity of 8 g L⁻¹; in other studies, it has been found in lower salinities. *L. hoffmeisteri* is also a typical inhabitant of freshwater lakes, particularly of deep waters. It was dominant in the shallow, saline waters of the two lakes studied. Salinity did not affect species richness. *Alchichica*, the most saline of the six crater lakes of Puebla (salinity, 7.4 g L⁻¹), had 30 per cent more species than the freshwater lakes, and double the species number of *Atexcac*. It seems the main factor controlling species richness and the density and biomass of organisms in *Alchichica* and *Atexcac* is the presence of aquatic vegetation. It does this by increasing habitat heterogeneity and providing food and protection against predators." (Authors) *Aeshna dugesii*] Address: Alcocer, J., Limnology Lab., Environmental Conservation and Improvement Project, UIICSE, UNAM Campus Iztacala, Av. de los Barrios s/n, Los Reyes Iztacala, Tlalnepantla, Edo. de Mexico, 54090, Mexico

(1998): The effect of a man-made lake on the diet of the African electric fish *Mormyrus rume Valenciennes, 1846* (Osteoglossiformes; Mormyridae). *Hydrobiologia* 380(1-3): 141-151. ["The diet of 223 specimens of *Mormyrus rume* (Mormyridae) from the Bia River on which a hydroelectric dam was built in 1959, was studied in relation to

locality, season and fish size. A feeding index was computed by combining the occurrence, numerical and weight percentages of the items identified in the stomach contents. This index showed that *M. rume* in the river ate principally invertebrates, especially chironomid larvae. In contrast, *M. rume* from the man-made lake contained mostly phytoplankton. This difference was statistically significant. In the lake, chironomid larvae and Bacillariophyceae constituted the main source of the diet of young fish. In larger specimens, *Chaoborus sp.* formed the main part of the diet. No significant temporal variation occurred in the dietary composition. The overall food composition was similar in each locality of the Bia River from one period to another." (Authors) The paper includes records of Odonata as diet of fishes.] Address: Kouamélan, P.E., Section of Ecology and Aquaculture, 1Katholieke Universiteit Leuven, B-3000 Leuven, Belgium

5345. McWilliam, H.A.; Death, R.G. (1998): Arboreal arthropod communities of remnant podocarp-hardwood rainforest in North Island, New Zealand. *New Zealand Journal of Zoology* 25: 157-169. (in English). ["Arboreal arthropod communities from three reserves of podocarp-hardwood rainforest in the North Island, New Zealand, were sampled continuously between June 1995 and May 1996 using omnidirectional window traps. Diptera made up 34% of the total number of arthropods captured, whereas Coleoptera contributed 12% and Araneae 11% to the total catch. The relative abundance and species richness of Diptera peaked in spring, Coleoptera in summer, and Araneae in autumn. Multivariate analysis of overall community structure suggests that season is the dominant determinant of community structure in the arboreal arthropod communities of these forest patches, whereas site, and to a lesser extent tree species, have minor effects. Given that 863 morphospecies were collected, the conservation value of small forest patches for forest-dwelling arthropods in New Zealand should not be underestimated." 5352. Hong, S.-J.; Woo, H.-C.; Lee, S.-U.; Huh, S. (1999): Infection status of dragonflies with *Plagiorchis muris* metacercariae in Korea. The Korean Journal of Parasitology 37(2): 65-70. (in English). ["*Plagiorchis muris* has been found in both house and field rats as well as in humans. The infection status of the second intermediate hosts of *P. muris* is prerequisite in understanding their biological features in an ecosystem. Six species of dragonflies were caught in a wide range of areas in Korea; and they were *Sympetrum darwinianum*, *S. eroticum*, *S. pedomontanum*, *S. infuscatum*, *Pantala flavescens*, *Calopteryx atrata*, and *Orthetrum albistylum speciosum*. The occurrence of *P. muris* metacercariae in dragonflies was nationwide with various infection rates. The metacercarial burden of *P. muris* in the surveyed areas was the highest in *S. eroticum* followed by *S. darwinianum*, *S. pedomontanum*, and *C. atrata*. The highest infection rate by *P. muris* metacercariae was found in *S. darwinianum* followed by *S. eroticum*. The metacercarial burden was particularly heavy in the dragonflies found in Hamyang-gun and Kosong-gun, Kyongsangnam-do. It is, therefore, likely that dragonflies play a significant role as the second intermediate host in the life cycle of *P. muris* in Korea." 5355. Stoks, R.; De Block, M.; Van Gossum, H.; Valck, F.; Lauwers, K.; Verhagen, R.; Matthysen, E.; De Bruyn, L. (1999): Lethal and sublethal costs of autotomy and predator presence in damselfly larvae. *Oecologia* 120(1): 87-91. (in English). ["We studied the costs of lamellae autotomy with respect to growth and survival of *Lestes sponsa* damselfly larvae in field experiments. We manipulated predation risk by *Aeshna cyanea* dragonfly larvae and lamellae status of *L. sponsa* larvae in field enclosures and compared differences in numbers, size and mass of survivors among treatments. In the absence of a free-ranging *A. cyanea* larva, about 29% of the *L. sponsa* larvae died. This was probably due to cannibalism. The presence of a free-ranging *A. cyanea* reduced larval survival by 68% compared to treatments in which it was absent or not permitted to forage on *L. sponsa* damselflies. Across all predator treatments, lamellae autotomy reduced survival by about 20%. The mean head width and mass of survivors was lower in the enclosures with a free-ranging *A. cyanea* compared to the other two predator treatments. This suggested that larvae grew less in the presence of a free-ranging predator, indicating that increased antipredator behaviours were more important in shaping growth responses than reduced population density. Mass, but not head width, of survivors was also reduced after autotomy. The fitness consequences of these effects for the adults may be pronounced. In general, these field data strongly suggest that lamellae autotomy affects population regulation of damselflies." (in Portuguese, with English summary). ["Ecological aspects of the collared lizard, *T. torquatus*, were studied monthly in a sandy coastal plain of south-eastern Brazil, from February 1996 to March 1997. We collected 108 specimens [...]. Based on the frequency of occurrence, major food items found in the stomach contents of *T. torquatus* were: ants (85.7%), beetles (32.4%), bees (31.4%), termites (22.8%), spiders (20.9%) and flowers (20.0%). Based on the relative number of prey ingested, main food items were: ants (41.2%), and termites (40.8%). Total number of prey found in the stomachs of the collared lizard was 2,903, which varied in individual stomachs from 1 to 268 (mean = 27.6; SD = 36.2). Most of the time *T. torquatus* is a sit-and-wait predator. Its opportunistic feeding behavior, including

invertebrates, small vertebrates (other lizard species), and vegetables (flowers and seeds), may contribute to the success of this lizard in colonizing a diversity of habitats." (Authors) Table 2 documents Odonata as very rare prey of female *T. torquatus*.] Address: Teixeira, R.L., Rua Bernardino Monteiro, 75, Centro, CEP 29650-000, Santa Teresa, ES, Brasil.

5358. Buckley, T.R.; Simon, C.; Flook, P.K.; Misof, B. (2000): Secondary structure and conserved motifs of the frequently sequenced domains IV and V of the insect mitochondrial large subunit rRNA gene. *Insect Molecular Biology* 9(6): 565-580. (in English). ["We have analysed over 400 partial insect (including *Aeshna cyanea*) mitochondrial large subunit (mit LSU) sequences in order to identify conserved motifs and secondary structures for domains IV and V of this gene. Most of the secondary structure elements described by R. R. Gutell et al. (unpublished) for the LSU were identified. However, we present structures for helices 84 and 91 that are not recognized in previous universal models. The portion of the 16S gene containing domains IV and V is frequently sequenced in insect molecular systematic studies so we have many more sequences than previous studies which focused on the complete mitochondrial LSU molecule. In addition, we have the advantage of investigating several sets of closely related taxa. Aligned sequences from thirteen insect orders and nine secondary structure diagrams are presented. These conserved sequence motifs and their associated secondary structure elements can now be used to facilitate the alignment of other insect mit LSU sequences." 5363. Moor, F.C. de; Barber-James, H.M.; Harrison, A.D.; Lugo-Ortiz, C.R. (2000): The macroinvertebrates of the Cunene River from the Ruacana Falls to the river mouth and assessment of the conservation status of the river. *African Journal of Aquatic Science* 25: 105-122. (in English). ["The proposed construction of a second hydroelectric power-generating dam on the Cunene (Kunene) River on the Namibia-Angola border, more than 100km downstream of the Ruacana hydroelectric power plant, will have a major influence on the aquatic biota of this river. In order to assess the potential impact of this impoundment a more detailed inventory of the biota in the river prior to this development was needed. Unfortunately the river presently does not represent an entirely undisturbed system as the operation of the Ruacana hydroelectric power station since 1970 has had a long-term effect on its biota. In the low-flow mid-summer season in particular, large areas of the river become irregularly inundated and exposed, sometimes on a daily basis, making them unsuitable for macroinvertebrate colonisation. There are six impound-

ments along the Cunene River upstream of the Ruacana Falls in Angola. These, however, do not have any major disruptive effects on daily flow variation in the Cunene River in Namibia although whole system biological consequences could be considerable but are unstudied. The Cunene River has a diverse freshwater fish fauna but, prior to the surveys reported here, the aquatic macroinvertebrates had been poorly studied. Surveys conducted by staff of the Department of Water Affairs (DWA) of Namibia and the Albany Museum, Grahamstown, in 1997 and 1998 have resulted in 216 aquatic macroinvertebrate species being recorded from Ruacana to the river mouth. The lower Cunene River, flowing through a very arid region, is biogeographically isolated and therefore highly vulnerable to change. The biota recorded reflects a fauna of widespread species and several elements of tropical origin. Several undescribed species may reflect some endemics but because of limited knowledge of the tropical rivers, this cannot be ascertained with certainty. From the aspect of conservation, the river contains a diversity of species with an abundance of filter-feeding species. Further surveys conducted during different seasons will undoubtedly record more taxa." (Authors) Tab. 7 includes 12 Odonata-taxa collected in 1997 and 1998.] Address: de Moor, F.C., Department of Freshwater Invertebrates, Albany Museum, Grahamstown 6139, South Africa 2111a Berg Road, Fish Hoek, Cape Town 7975, South Africa. (2000): Granite outcrop pools in south-western Australia: foci of diversification and refugia for aquatic invertebrates. *Journal of the Royal Society of Western Australia* 83: 149-161. (in English). ["Pools and streams on granite outcrops in south-western Australia are reliably filled, but highly seasonal, freshwater habitats that support a diverse array of aquatic invertebrates. A recent biological survey of the wheatbelt has more than doubled the number of invertebrates, to at least 230 species, known from these habitats. Granite outcrops contribute significantly to endemism in the aquatic fauna of the inland south-west and have particular conservation value for about 50 species, mostly rotifers, microcrustaceans, phreodrilid oligochaetes and chironomid midges, restricted to them. Outcrops may also be important for the wider aquatic invertebrate fauna as a freshwater habitat, if salinity in the Western Australian wheatbelt continues to increase." (Authors) 11 odonate species are listed in the appendix.] Address: Pinder, A.M., Department of Conservation and Land Management, CALMScience, PO Box 51, Wanneroo WA 6946, Australia. 5366. Ramsay, L.; Cannings, R.A. (2000): Dragonflies at Risk in British Columbia. In: L. M. Darling (Ed.) *Proceedings of a Conference on the Biology and Ma-*

agement of Species and Habitats at Risk, Kamloops, B.C., 15 - 19 Feb., 1999. Volume One. B.C. Ministry of Environment, Lands and Parks, Victoria, B.C. and University College of the Cariboo, Kamloops, B.C. 490pp.: 89-93. (in English). ["In 1993, British Columbia's dragonflies and damselflies (Order Odonata) were listed and ranked as to their conservation status in the province, based upon the knowledge at the time. Inventory efforts were then focused on the species considered at risk, in order to more accurately determine their status and to identify specific sites for conservation. For 3 years, surveys were conducted in 5 regions of the province: the northeast corner, the Lower Mainland, southern Vancouver Island, the Okanagan, and the Columbia Basin. During the course of these surveys, known ranges of many species were extended, knowledge of habitat requirements increased, and 3 new species were confirmed for the province. While many of the targeted species were found only sparsely or not at all, a number of them were discovered to be more abundant than previously thought, and their conservation ranks were changed accordingly." 5367. Reece, B.A. (2000): Early instar growth and survivorship in the common Baskettail Dragonfly *Epi-theca cynosura* (Anisoptera: Corduliidae). Thesis. Master of Science in Biological Sciences. Faculty of the Department of Biological Sciences. East Tennessee State University: 58 pp. (in English). ["Egg masses of *E. cynosura* were collected from Bays Mountain Park, Tennessee, USA, in June, 1999. Newly hatched individuals were placed into enclosures and sampled at scheduled time intervals throughout the summer. Enclosures were exposed to combinations of high and low densities and presence/absence of a second-year class *E. cynosura* predator. Survivorship, mean head widths, and mean dry masses were compared across treatments. Due to poor recovery of early-instar larvae, survivorship showed no significant differences in mortality among treatments. The predator present treatment caused significantly smaller head widths and dry masses only on days 42 and 55. The density treatment had a significant effect on larval growth from day 28 through day 86 (end of the experiment). Larvae from low density treatments had larger head widths and dry masses. The effects observed within the density treatments were likely to have resulted in a cohort split. Those individuals in the low density treatment followed a univoltine life history, and high density individuals followed a semivoltine life history. Density is probably a very important factor influencing the voltinism of *E. cynosura* at Bays Mountain Lake." 5378. Salmah, M.R.C.; Hassan, S.T.S.; Hassan, A.A. (2001): Local movement and feeding pattern of adult *Neurothemis tullia* (Drury) (Odonata: Libellulidae) in a rain fed rice field. *Tropical Ecology* 41(2): 233-241. (in English). ["The movements of *Neurothemis tullia* (Drury) (Odonata: Libellulidae) adults were studied in a rain fed rice field using the mark-release-recapture technique. Both male and female dragonflies were widely distributed within their home range of approximately 30 m radii. Adult movements were highly localized and the longest distance travelled was about 130 m. Diurnal feeding

pattern was studied by examining gut contents. Some individuals had taken preys as early as 0730 hr. Feeding activity however, peaked at 1030 hr and at 1730 hr. Daily food intake was highly variable between sexes and within hours of the day. Females fed more actively in the morning and their body weights were heavier than that of males at all hours of the day. Active feeding activity of both sexes reflected effective predation." (Authors)] Address: Che Salmah Md. Rawi, Malaysia. E-mail: csalmah@usm.my

5379. Soares, C.M.; Hayashi, C.; Esper Amaro de Faria, A.C. (2001): Influência da disponibilidade de presas, do contraste visual e do tamanho das larvas de *Pantala* sp. (Odonata, Insecta) sobre a predação de *Simocephalus serrulatus* (Cladocera, Crustacea). *Acta Scientiarum Maringá* 23(2): 357-362. (in Portuguese, with English summary). ["Influence of prey availability, visual contrast and size of dragonfly (*Pantala* sp.) larvae (Odonata, Insecta) on the predation of *Simocephalus serrulatus* (Cladocera, Crustacea). The influence of prey availability, visual contrast and size of dragonfly (*Pantala* sp) larvae on the predation of cladocerans (*Simocephalus serrulatus*) is provided. Twentyfour dragonfly naiads (12.57±0.05 mm and 100.01±9.16 mg) were employed to study the relation between predation rate and availability of cladocerans and visual contrast. 5, 10, 15 and 20 cladocerans/L were placed in 1L transparent and black plastic lined aquariums. Cladocerans (1.63±0.21 mm and 0.78 mg) were counted and replaced hourly for five consecutive hours. Twenty-four naiads of different sizes were placed in 50mL recipients to study effects of size of dragonfly larvae. Each larvae received 20 cladocerans; counting and reposition of individuals consumed every ten minutes during two consecutive hours were undertaken. Quadratic effect ($p<0.02$) in predation rate was reported, with an increase in prey availability: 21.67; 39.00; 42.44 and 49.67% were reported for densities of 5, 10, 15 and 20 cladocerans/L respectively. Predation rate ($p<0.02$) was higher in dark wall aquariums (42.67%) than in those with transparent walls (33.72%). Size of dragonfly larvae had a quadratic effect on the predation of cladocerans and highest value occurred with 13.23 mm naiads. While high prey availability increases predation rate, predation is higher in aquariums with dark walls and 13.23 mm-long larvae have the highest predation rate." (Authors)] Address: Soares, C.M., Departamento de Biologia, Programa de Pós-Graduação em Ecologia de Ambientes Aquáticos Continentais, Universidade Estadual de Maringá, Av. Colombo, 5790, 87020-900, Maringá, Paraná, Brasil. E-mail: cmsouares@uem.br

5381. Yourth, C.P. (2001): Ecological immunology in lestad damselflies: explaining variation in immune defense against parasitic water mites. Thesis. Master of Science. Dept Zoology, University of Toronto: 75 pp. (in English). ["This thesis tests predictions of the emerging theory of ecological immunology using variation in immune expression of *Lestes dryas* Kirby, *L. forcipatus* Rambur, *L. unguiculatus* Hagen, and *L. congener* Hagen to a generalist parasitic water mite, *Arrenurus planus* Marshall. Immune responses of the four lestad species were

compared as they relate to prevalence and intensity of mite infection; these measures of parasitism did not fully explain among-species variation. Within-species variation in immunity of *L. forcipatus* was related to time of season, but not to host body size or asymmetry, measures of host condition. When *L. forcipatus* were allowed to respond to Sephadex beads at a fixed temperature across season, no seasonal pattern in immunity was observed and a positive correlation between condition and immune response in males was detected. These results implicate seasonal variation in temperature as being a major factor in determining immune responsiveness of lestad damselflies." (Author). The thesis is available at: <http://www.collectionscanada.ca/obj/s4/f2/dsk3/ftp05/MQ63244.pdf>]

5389. Evans, R. (2002): Conservation assessment for selected dragonflies of the Allegheny National Forest. USDA Forest Service, Eastern Region December 2002: 35 pp. (in English). ["The objective of this document is to provide background information and review the conservation status for several odonate species in the Allegheny National Forest. These species were chosen based upon their rarity in the Allegheny National Forest and the State of Pennsylvania. The following species

are the focus of this report: *Helocordulia uhleri*, *Soma-tochlora elongata*, *Gomphus adelphus*, *G. descriptus*, *G. fraternus*, *G. quadricolor*, *G. viridifrons*, *Ophiogomphus mainensis*, and *Stylurus scudderi*. These species are found primarily in wetlands, rivers, and streams. Primary threats to these species include degradation of water quality by resource extraction, changes in riparian vegetation due to forest management practices, and sedimentation and pollution of streams from agricultural inputs into watersheds. Management considerations include protecting high quality streams in the Allegheny National Forest from future impacts. These species should continue to be monitored in Allegheny National Forest streams, and survey efforts should be expanded to document the ranges of these species." (Author) available from: http://www.fs.fed.us/r9/wildlife/tes/ca-overview/docs/insects_electeddragonflies.pdf Address: Evans, R., Western Pennsylvania Conservancy, 209 Fourth Avenue, Pittsburgh, PA 15222, USA

5398. Page, J. (2002): Dragonfly dramas: Desert whitetails and Flame skimmers cavort in the sinkholes of New Mexico's Bitter Lake Refuge. Smithsonian 32 (10): 20, 22. (in English). [Verbatim: "Gomphid!" someone shouted, and the little thing with the gleaming fuselage hovered, then sped away. I was standing on the whitish gypsum-rich hardpan that passes for soil in the desert about 15 miles north of Roswell, New Mexico. The air around me was filled with mostly unidentified flying objects. I now knew that this yellow-and-black creature was a Gomphid, a genus of dragonfly. But many of the dozens of other Odonata, the general scientific name for dragonflies and damselflies, which flew aerial gymnastics around me, remain nameless. This particular location—the Bitter Lake National Wildlife Refuge—hosts a great variety of these curious creatures. My expert guide, Robert R. Larsen, is a well-built man who carries a big white net as comfortably as many men carry a briefcase. By training a botanical illustrator and by preference a biological "investigator," Larsen was the scientist to whom the managers of the Bitter Lake National Wildlife Refuge turned when they identified an unusually large number of Odonata species helicoptering around the sinkholes of the refuge in 1998. With funds from the state Game and Fish Department, Larsen—a resident of Roswell who had been analyzing the plant life of the refuge—netted more than 50 species of dragonfly and some 30 species of damselfly. They included the largest dragonfly found in the United States (*Anax walsinghami*) and one of the nation's smallest damselflies (*Ischnura hastata*). An easy way to distinguish between a dragonfly and a damselfly is to observe the wings: the rear, or posterior, pair of dragonfly wings are broader than the front, or anterior, pair, while both sets of a damselfly's wings are essentially equal in size. Other distinguishing characteristics include the eyes of the damselfly, which are on opposite sides of its head, while dragonfly eyes are typically closer together, sometimes even connected. These bulging and usually colorful organs have up to 30,000 facets. Both creatures, however, enjoy expanded peripheral vision, a formidable feature for a predator, which both dragonflies and damselflies become early on in their lives. "I'm really glad the larvae aren't huge, or that I'm not really small," said Karen Gaines, a graduate student at the University of New Mexico who has been studying Odonata larvae at the refuge. Most dragonfly larvae, which are aquatic for one to two years, are utterly insatiable, eating everything they come across, including tadpoles, fish, and mosquito and other insect larvae. They even eat their own siblings. Eventually, the larva climbs out of the water; its outer "skin," or exoskeleton, splits open, it pulls its telescoped abdomen out of the casing and it gradually extends to full length. Within one to two hours, the wings clear, dry out and open up. After its wings harden, over the course of several hours to several days, the creature will become a remarkable aerialist. Some species can fly up to 35 miles per hour. Their wings work independently, so they can hover and change direction instantaneously. Some species are migratory and, with the wind's help, may travel hundreds of miles. Adult life is relatively brief, typically a matter of weeks, though some species can live for as long as a year. The time is spent voraciously feeding on mosquitoes, assorted moths and butterflies, and mating, a complex affair that turns a pair into an ac-

robotic and often airborne pretzel. Larsen reports seeing a large dragonfly carry off a minnow, a sight so remarkable that other scientists have questioned him on it. While I was standing right next to her, Karen Gaines swished her net in the air and caught a *Gomphus militaris* with the wing of a damselfly still hanging from its mouth. (Additional excellent detail about the biology of Odonata is covered in *Dragonflies of the World* by Jill Silsby, a new book published by Smithsonian Institution Press.). So why are there so many Odonata here? At first glance, their presence seems unlikely. After all, Bitter Lake lies at the northern edge of the Chihuahuan Desert, a refuge known mostly for its birdlife, especially its spectacular winter flocks of snow geese and sandhill cranes. It is a flat landscape lying west of a long low ridge called Comanche Hill. The Pecos River runs along the ridge, and the refuge itself contains many lakes left over when the river took a new course. The alkaline lakes for which the refuge is named are indeed bitter, making it the kind of place Louis L'Amour heroes steer clear of. Right where the Chihuahuan Desert meets the shortgrass prairie, Larsen told me, is an extremely diverse habitat for plant species. In addition to freshwater sloughs, ponds, marshes, springs, ditches and a half-mile-long stream known as the Lost River, the refuge contains more than 60 sinkholes. This is ideal habitat for dragonflies. Sinkholes are just as they sound—places where soluble bedrock dissolves, creating cavities or holes in the surface. Groundwater then often fills the hole. The process is typically slow, but local legend has it that one of the refuge's sinkholes formed overnight beneath a parked bulldozer. Some sinkholes here are but a few feet across, though one is large enough—about an acre—to be called (with a bit of exaggeration) Lake St. Francis, 70 feet deep with beautiful blue and Caribbean-green water. These sinkholes have become aquatic "islands" in this arid desert habitat. Sinkhole conditions differ a great deal. Some have steep, naked gypsum sides; others have reeds and grasses that grow right up to the water's edge. In some sinkholes, the water is so saline that it supports red and green algae blooms. Other sinkholes are saltier than seawater and invite species of dragonflies and damselflies usually found in estuaries, although the nearest seashore is a thousand miles away. The unique blend of conditions in each sinkhole creates entirely different ecosystems, even though one sinkhole may be only ten feet from another. As a result, each sinkhole, Gaines explained, seems to have its own special array of Odonata, and some species breed only in a single sinkhole. (Sinkholes also host the only known populations of certain other animal species, such as the last genetically pure species of the extraordinarily salt-tolerant Pecos pupfish and certain springsnails and amphipods.) "It's a natural outdoor laboratory," Gaines said. She keeps track of this confusing and colorful aerial menagerie with a little biological sleuthing. Gaines regularly places little ladders of wire mesh leading from the edge of sinkholes into the water. Because Odonata leave their larval casing on the ladder as they crawl out, she can identify which species breed in the Bitter Lake sinkholes and which migrate here after breeding elsewhere. Nearby Roswell may be a mecca for UFOs, but the dedicated scientists here at Bitter Lake have a pretty good handle on what's flying around. Already, I can spot the fluttering flight of the desert whitetail (*Libellula subornata*) and the bright red body of the flame skimmer (*L. saturata*). I was struck by how much these Odonata folk sounded like bird-watchers, singing out the name of a

dragonfly they see whizzing by for but an instant. Indeed, the common names of these creatures are just as exciting as bird names—or more so. After all, where's the poetry in spotting a crow or a snipe? But imagine spotting an Eastern amberwing, a seaside dragonlet or a Halloween pennant during a single outing at your neighborhood pond. And if your life list included the Comanche skimmer, the desert forktail and the black saddle bags, wouldn't your chest swell with pride?]

5406. Gainsbury, A.M.; Colli, G.R. (2003): Lizard assemblages from natural Cerrado enclaves in southwestern Amazonia: The role of stochastic extinctions and isolation. Biotropica 35(4) : 503-519. (in English, with Spanish summary). ["We used null model analyses to investigate the existence of structure in lizard assemblages from open vegetation enclaves in Rondonia, southwestern Amazonia, in relation to species richness, species co-occurrence, diet (including Odonata), and size overlap. These enclaves presumably have been isolated since the Holocene, providing a history of long-term isolation. We assumed that the presence of structure in lizard assemblages from the Rondonia enclaves is consistent with the notion that extinctions are a deterministic process, some species being more prone to extinction than others. We grouped enclaves into four

categories: latosoil cerrado, sandy cerrado, transitional forest, and rocky field. We collected 14 Cerrado lizard species, consisting of five families in all sampled areas. Analyses of species richness, co-occurrence, diet overlap, and size overlap patterns suggested lack of organization in the assemblages. The assemblages from the rocky fields of Guajará Mirim and the sandy cerrados in Vilhena were significantly structured in diet overlap, whereas the remaining assemblages lacked structure. This probably resulted from phylogenetic inertia and not from ecological interactions. Our results suggest that extinctions proceeded in a stochastic fashion and that historical factors had a dominant role in shaping lizard assemblages in detriment of present-day ecological factors. In addition, we identified endemic species in the enclaves as well as a tight association between unique ecogeographic features of the landscape and species occurrences. We propose that conservation measures in the region must adequately preserve these features to ensure the survival of the species." 5407. Gassmann, D. (2003): Phylogeny and distribution of the Philippine damselfly subgenus Risioecnemis (Igneoecnemis) Hämäläinen (Odonata: Platycnemididae). Fritz (ed.): 6th GfBS Annual Congress abstracts. Org. Divers. Evol. 3, Electr. Suppl. 17 (2003): 20. (in English). [Verbatim: Risioecnemis Cowley, 1934 is the largest genus of the zygopteran subfamily Calicneminae in the Indo-Pacific region. The group is endemic to the Philippines, except for the Sulu Archipelago and the Palawan island chain. Members of the group are confined to small, clear creeks in shady rainforest environment, occurring from lowland up to mid-montane forest. Two subgenera within the genus Risioecnemis are currently recognized: Risioecnemis Cowley, 1934 s. str., and Igneoecnemis Hämäläinen, 1991. A revision of the subgenus Risioecnemis was presented by Hämäläinen (1991). Mainly based on the large Roland A. Müller collection from the Philippines, which is now housed by the Natural History Museum in Leiden, a complete taxonomic revision of the subgenus Igneoecnemis has recently been completed by Gassmann & Hämäläinen (2002). In total, 20 species of sg. Igneoecnemis have been recognized, of which five were newly described. Several putative synapomorphies of Igneoecnemis species point to the monophyly of the group. However, the monophyly of the whole genus, i.e. Risioecnemis Cowley sensu lato, is less certain. Within the scope of a phylogenetic-biogeographical study on the Indo-Pacific Platycnemididae, the phylogeny of the Igneoecnemis species was reconstructed based on morphological characters. The distribution patterns of the species can be explained by Tertiary island arc connections as well as by the existence of larger islands during the Pleistocene. References: Gassmann, D. & Hämäläinen, M. (2002): A revision of the Philippine subgenus Risioecnemis (Igneoecnemis) Hämäläinen (Odonata: Platycnemididae). Tijdschr. Entomol. 145: 213-266. (in English). ["Adult aquatic insects emerging from streams may be a significant source of energy for terrestrial predators inhabiting riparian zones. In this study, we use natural abundance $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ values and an isotopic $\delta^{15}\text{N}$ tracer addition to quantify the flow of carbon and nitrogen from aquatic to terrestrial food webs via emerging aquatic insects. We continuously dripped labeled $\delta^{15}\text{N}\text{-NH}_4$ for 6 weeks into Sycamore Creek, a Sonoran desert stream in the Tonto National Forest (central Arizona) and traced the flow of tracer $\delta^{15}\text{N}$ from the stream into spiders living in the riparian zone. After correcting for natural abundance $\delta^{15}\text{N}$, we used isotopic mixing models to calculate the proportion of $\delta^{15}\text{N}$ from emerging aquatic insects incorporated into spider biomass. Natural abundance $\delta^{13}\text{C}$ values indicate that orbweb weaving spiders inhabiting riparian vegetation along the stream channel obtain almost 100% of their carbon from in-stream sources, whereas ground-dwelling hunting spiders obtain on average 68% of their carbon from in-stream sources. During the 6-week period of the $\delta^{15}\text{N}$ tracer addition, orb-web weaving spiders obtained on average 39% of their nitrogen from emerging aquatic insects, whereas spider species hunting on the ground obtained on average 25% of their nitrogen from emerging aquatic insects. To determine if stream subsidies might be influencing the spatial distribution of terrestrial predators, we measured the biomass, abundance and diversity of spiders along a gradient from the active stream channel to a distance of 50 m into the upland using pitfall traps and timed sweep net samples. Spider abundance, biomass and richness were highest within the active stream channel but decreased more than three-fold 25 m from the wetted stream margin. Changes in structural complexity of vegetation, ground cover or terrestrial prey abundance could not account for patterns in spider distributions, however nutrient and energy subsidies from the stream could explain elevated spider numbers and richness within the active stream channel and riparian zone of Sycamore Creek." sects. 20040050646 Tanner Research, Inc., Pasadena, CA, F49620-01-C-0030 Report No.(s): AD-A420888; AFRL-SR-AR-TR-04-0147; No Copyright; Avail: CASI; A04, Hardcopy <http://www.sti.nasa.gov/Pubs/star/star-0408.pdf>: 55 pp. (in English). ["In this project, we studied the physiology of a class of visual neurons that we have labeled small target, movement detectors (STMDs), which respond selectively to small moving visual targets. In-vivo intracellular recordings were made in several model species (the hoverfly *Eristalis tenax* and the dragonflies *Hemicordulia tau* and *Aeshna multicolor*), while subject to moving visual displays. We found some STMD neurons are capable of responding selectively to small moving targets against moving cluttered backgrounds. We characterized the receptive field properties of a class of small-field STMDs that we labeled elementary small target movement detectors' (ESTMDs), which may be an early stage in a hierarchy of STMD processing. Models were developed for aspects of the processing performed by STMD neurons, and tested in simulations. In 59 particular, a model for the ESTMD was developed and implemented in analog VLSI silicon." (Authors)] Address: to purchase from: <http://www.stormingmedia.us/88/8880/A888024.html>

5417. Sirot, L.K. (2003): The evolution of insect mating structures through sexual selection. *Florida Entomologist* 86(2): 124-133. (in English). ["Mating structures are of interest to a wide range of biologists because, in many taxa, mating structures are incredibly diverse and range widely in elaboration even between closely related species. As a result of this diversity, mating structures have been useful in species identification. Historically, the evolution of diverse mating structures has been attributed to post-zygotic selection for pre-zygotic isolation to avoid production of hybrid offspring. More recently, sexual selection has been proposed as an alternative explanation for the rapid diversification of mating structures. Mating structures could diversify between populations through sexual selection if sexual selection acted differently on mating structures in different populations. Eberhard (1985) wrote a comprehensive book explaining how sexual selection could result in the diversification of mating structures and providing examples to support the hypothesis, but none of the examples were experimental tests of the hypothesis. Since 1985, a few studies have experimentally tested this hypothesis. However, there have been no empirical studies that connect intraspecific selection with interspecific diversification. In this paper, I review the reproductive isolation and sexual selection hypotheses and two recent experimental tests of the sexual selection hypothesis. Then, I provide a description of a system that may allow one to establish a connection between sexual selection on mating structures within a species and diversification of mating structures between species." (Author) *Calopteryx haemorrhoidalis* was selected as example to test the hypothesis.] Address: Sirot, Laura, Department of Zoology, University of Florida, 223 Bartram Hall, Gainesville, FL 32611, USA

5421. Wykle, K. (2003): Beautiful Dancers: West Virginia's Dragonflies. *West Virginia Wildlife Magazine Summer 2003*: (in English). [Verbatim: "Beautiful Dancers: West Virginia's Dragonflies. By Jennifer Wykle: Sometimes you don't even realize they're around. A buzz by your head or a mysterious rustle of grass is the only evidence they may give of their presence. Until one day, you're on the river fishing and one of these interesting creatures lands right on your canoe. Then there's no mistake—it's a dragonfly! Dragonflies and damselflies belong to the order of insects called Odonata. Representatives from five families of dragonflies and three families of damselflies live in West Virginia. The adults have two pairs of wings and are surprisingly maneuverable when airborne. If you have ever tried to catch one you wonder how they always seem to vanish into thin air! Of the approximately 435 species in North America, 144 of these have been documented in West Virginia. As we survey different areas and cover more ground, additional species will be added to the state list. Dragonflies and damselflies are surprisingly easy to tell apart. When perched, dragonflies hold their wings out flat to the side while most damselflies fold their wings above their body. Generally, the large eyes of the dragonflies will touch each other while damselfly eyes are smaller and spread much further apart. Dragonflies are generally larger and much stronger fliers than damselflies and can be found considerable distances from water. Damselfly flight can be very erratic and they are almost always found over water or perched on overhanging vegetation. To make discussions easier, both groups are often lumped together and called dragonflies or odonates. Dragonflies have been around a long time - about 300 million years. Fossil records reveal that some dragonflies had wingspans of nearly three feet! The dragonflies that existed with the dinosaurs 180 million years ago are virtually the same in structure as dragonflies that fly today. Like most insects, dragonflies have three life stages: the egg, larva and adult. Eggs are deposited in or around water and the larvae are fully aquatic, equipped with gills. Larvae, depending on size and food availability, prey on other insect larvae, small fish and salamanders. Depending on the species and environmental conditions, time of transformation can vary greatly. Some species may live as larvae for only a month while others may spend eight years in the water. Adult dragonflies can live from one to nine months, depending on the species. Adults are

voracious predators taking insect prey while on the wing. Adults feed on a variety of flying insects such as mosquitoes, gnats and even other dragonflies. Like most groups of animals in the state, some dragonflies are extremely common while others are rare and hard to find even in their ideal habitats. They are rare in West Virginia either due to lack of appropriate habitat (the state lies on the edge of their range) or they are rare throughout their range. One such species, the Elusive Clubtail, fits the latter description. It had been considered a historically occurring species until it was spotted last June on one of the Ohio River islands. This species is extremely rare in some areas such as Pennsylvania and Massachusetts where it is considered lost from the state's fauna. Another surprise species was discovered this past summer. A tiny bright red damselfly was found at Green Bottom Wildlife Management Area in Cabell County hovering over duckweed. Appropriately called the Duckweed Firetail, the nearest known population occurs in central Kentucky. The Spadderdock Darner is another rare species making its home in West Virginia. This one is hard to miss with its bright blue eyes and blue markings up and down its abdomen. It likes fishless ponds and wetland areas and has only been found in two areas of the state. While a number of Odonates are hard to spot, there are many common species that can be observed on a nice sunny afternoon on the river or around your backyard pond. The Common Whitetail, with its black banded wings and white abdomen, patrols nearly all still or slow-moving bodies of water in the state. Along with this species you can find the Common Green Darner, a large dragonfly with a green thorax and blue-striped abdomen. Another common species and one of the most striking, the Ebony Jewelwing damselfly, has solid black wings with an iridescent green body. As it flutters along a variety of stream habitats, its appearance is unmistakable. Because odonates are an indicator of good water quality, they provide a measure of overall stream and wetland health. Unfortunately, habitat destruction and decreased water quality are ever growing threats here in West Virginia and around the globe. We need to preserve our aquatic areas because they are necessary for the survival of not only dragonflies, but for a wide variety of plants and animals. Dragonflies and damselflies are just one of the many unique groups of animals living here in the Mountain State. Go out and enjoy their brilliant colors and interesting flight patterns. They are a part of our state's rich biodiversity and are one of many groups that help to make our outdoor experience special. Jennifer Wykle is the DNR's state Zoologist stationed in Elkins." 5429. Carchini, G.; Solimini, A.; Ruggiero, A. (2004): Habitat characteristics and Odonata diversity in Central Italy ponds. 1st European Pond Workshop, Geneva 28-29 October 2004: 10- (in English). [Verbatim: In Mediterranean Italy natural lakes are not abundant because of the high permeability of the rocks (mainly limestone) and to the drainage of wetlands made in the last two centuries for agricultural purposes. Therefore ponds represent an important habitat type for the conservation of the odonate fauna. Ponds have often been preserved, and in some cases newly created, for watering of game or herds, particularly in mountain areas. However, this use may conflict with the conservation of a diversified odonate fauna. The aim of this study is to report on habitat requirements of Odonata of mountain ponds of Central Italy and to compare these results with those of a similar work on flatland ponds. 31 ponds, ranging from 1014 to 2004 m a.s.l., were qualitatively sampled for odonate larvae twice during 1998 summer, and a total of 14 species were collected, ranging from 0 to six species for pond. Several physical, chemical and biotic habitat variables were measured for each pond. A multiple regression analysis showed that the species number was affected positively by the amount of pond hydrophytae coverage and negatively by the amount of NH₄ concentration. The remaining variables did not enter the regression model, but some showed significant correlations with the selected ones. Particularly, hydrophytae coverage was negatively correlated with Chl-a concentration and positively with helophytae and frog presence; ammonium concentration was positively correlated with altitude, Chl-a, frog presence and the origin of the pond (higher NH₄ values in artificial ponds). A Canonical Correspondence Analysis gave a more detailed insight into the relations between Odonata (assessed as species presence/absence) and habitat variables. The lack of Odonata in several ponds was related to increasing values of NH₄, Chl-a and altitude. Among the remaining habitat variables two main groups were identified: the first included helophytae, newt and hydrophytae and corresponded to seven odonate species, the outermost with preference for astatic ponds: *Lestes dryas* and *Sympetrum flaveolum*. The second included depth, frog and fish, and corresponded to *Cercion lindeni*, *Ischnura elegans* and *Enallagma cyathigerum*, all *Coenagrionidae* of permanent water. Combining these results with others obtained by studying a set of ponds in a flatland game reserve, we noted: 1) the mountain ponds showed less odonates species, 2) the abundance of vegetation, inside and around the pond, increased the number of species while the eutrophication decreased it, 3) the presence of fish, newt or frog did not reduce the odonate diversity strongly, 4) the intensive use of ponds for game or herd watering could damage vegetation and shift the equilibrium of the pond toward a condition of high turbidity (= high Chl-a), causing a reduction of the odonate diversity.] Address:

5433. Crowhurst, R. (2004): 10. Optimal foraging in libellulid naiads. 2004 Entomological Society of Ontario Annual Meeting, Brock University: 12. (in English). [Verbatim: Optimal foraging theory predicts that an organism will attempt to maximize its energy intake by choosing prey that offer the highest caloric value per unit of handling time (time to catch and consume). I placed hungry dragonfly larvae (Odonata: Anisoptera: Libellulidae) individually in an environment with several types of naturally co-occurring prey. I observed which were the first three prey consumed, also noting the number of pursuits, strikes, as well as those prey that were within striking distance but were ignored by the naiads. Dragonfly larvae ate more isopods and amphipods relative to daphnia, clams and chironomids. Average dry mass of individual isopods and amphipods were the largest of the five prey items offered. Therefore, dragonfly nymphs appear to select larger prey items. However, isopods and amphipods also took the greatest length of time to catch and consume, and thus handling time does not appear to determine prey choice. However, prey choice did not follow a fixed pattern. Rather, prey choice varied between individual dragonflies and also within individuals from one replicate to the next. Keywords: Odonata, optimal foraging theory,

predation] Address: Crowhurst, Rachel, Brock University, 500 Glenridge Ave., St. Catharines, ON, Canada

5454. Horth, L. (2004): Predation and the persistence of melanic male mosquitofish (*Gambusia holbrooki*). *Journal of evolutionary biology* 17: 672-679. (in English). ["The empirical reasons for the persistent rarity of a genotype are typically complex and tedious to identify, particularly in nature. Yet rare morphs occur in a substantial fraction of phenotypic polymorphisms. A colour polymorphism has persisted for decades in the eastern mosquitofish, yet why this is so remains obscure. Here, I report the results of (1) intensive sampling at 45 natural sites to obtain the frequency distribution of the melanic (black) mosquitofish morph in Florida, (2) predation trials, conducted independently in mesocosms, with three different predatory species and (3) two mark-recapture studies, conducted in nature. This work (1) documents the rarity of melanic mosquitofish in nature, (2) demonstrates that melanic males experience a selective advantage over silver males in the presence of predators, (3) indicates no difference in the colour morphs survival at a natural site essentially devoid of these predators, although suggesting a higher rate of recapture for melanic males at a site rife with predators. Overall, selective predation appears to contribute to the persistence of the melanic morph, despite its rarity in

nature." (Author) An libellulid species (not determined) was used to conduct the experiments. Dragonfly larvae consumed highly significantly more silver than black males.] Address: Horth, Lisa, Section of Evolution and Ecology, University of California Davis, 1 Shields Ave., Davis, CA 95616, USA. 5460. Kefford, B.J.; Papas, P.J.; Metzeling, L.; Nuggeoda, D. (2004): Do laboratory salinity tolerances of freshwater animals correspond with their field salinity?. *Environmental Pollution* 129(3): 355-362. (in English). ["The degree to which laboratory derived measures of salinity tolerance reflect the field distributions of fresh-

water biota is uncertain. In this paper we compare laboratory-derived acute salinity tolerance (LC50 values) of freshwater macroinvertebrates (range 5.5–76 $\mu\text{S}/\text{cm}$) and fish (range 2.7–82 $\mu\text{S}/\text{cm}$) from southeastern Australia with the salinity from which they have been collected in the field. Only 4% of the macroinvertebrates were collected at salinity levels substantially higher than their 72-h LC50 obtained from directly transferring animals from low salinity water to the water they were tested (direct transfer LC50). This LC50 value was correlated with the maximum salinity at which a species had been collected. For common macroinvertebrates, the maximum field salinity was approximated by the direct transfer 72-h LC50. For adult freshwater fish, 21% of species were collected at salinities substantially greater than their acute direct transfer LC50 and there was a weak relationship between these two variables. Although there was a weak correlation between the direct transfer LC50 of early life stages of freshwater fish and the maximum field salinity, 58% of the field distribution were in higher than their LC50 values. In contrast, LC50 determined from experiments that acclimated adult fish to higher salinity (slow acclimation) provided a better indication of the field distribution: with only one fish species (7%) being in conflict with their maximum field salinity and a strong positive relationship between these variables. This study shows that laboratory measures of acute salinity tolerance can reflect the maximum salinity that macroinvertebrate and fish species inhabit and are consistent with some anecdotal observations from other studies." (Authors) Odonata accounted 12% of the total of 49 macroinvertebrate taxa available with laboratory LC50 and MFD. "Capsule": Acute laboratory salinity tolerances relate to maximum salinity where organisms occur in nature.] Address: Kefford, B.J., Department of Biotechnology and Environmental Biology, RMIT University, PO Box 71, Bundoora, 3083, Victoria, Australia. E-mail: ben.kefford@rmit.edu.au

5461. Kjer, K.M. (2004): Aligned 18S and insect phylogeny. *Syst. Biol.* 53(3): 506-514. (in English). ["The nuclear small subunit rRNA (18S) has played a dominant role in the estimation of relationships among insect orders from molecular data. In previous studies, 18S sequences have been aligned by unadjusted automated approaches (computer alignments that are not manually readjusted), most recently with direct optimization (simultaneous alignment and tree building using a program called "POY"). Parsimony has been the principal optimality criterion. Given the problems associated with the alignment of rRNA, and the recent availability of the doublet model for the analysis of covarying sites using Bayesian MCMC analysis, a different approach is called for in the analysis of these data. In this paper, nucleotide sequence data from the 18S small subunit rRNA gene of insects are aligned manually with reference to secondary structure, and analyzed under Bayesian phylogenetic methods with both GTR+I+G and doublet models in MrBayes. A credible phylogeny of Insecta is recovered that is independent of the morphological data and (unlike many other analyses of 18S in insects) not contradictory to traditional ideas of insect ordinal relationships based on morphology. Hexapoda, including Collembola, are monophyletic. Paraneoptera are the sister taxon to a monophyletic Holometabola but weakly supported. Ephemeroptera are supported as the sister taxon of Neoptera, and this result is interpreted with respect to the evolution of direct sperm transfer and the evolution of flight. Many other relationships are

well-supported but several taxa remain problematic, e.g., there is virtually no support for relationships among orthopteroïd orders. A website is made available that provides aligned 18S data in formats that include structural symbols and Nexus formats." (Author) The analysis also includes Odonata.] Address: Kjer, K.M., Department of Ecology Evolution and Natural Resources, 14 College Farm Road, Cook College, Rutgers University, New Brunswick, NJ 08901, USA. 5467. Lin, S.-C.; Chen, C.-S. (2004): Egg and larval developments of the Taiyal Darner *Aeshna petalura taiyal* Asahina (Odonata, Aeshnidae) at the Mt. Hohuan. *Endemic Species Research* 6(1): 29-38. (in Chinese, with English summary). ["*A. petalura taiyal* Asahina, 1938 is an endemic subspecies of dragonfly in Taiwan. It occurs widely in the mountain areas above 1,500m in elevation. Its larval habitat has been adversely affected by human activities, such as pond construction, water pollution, and fish releasing. This study was conducted between 1997-2000 to study egg and larval developments of the Taiyal darner in the Mt. Hohuan area. The results showed that the period of egg stage was about ten months. Eggs were laid at the end of summer, overwintered in a diapause condition, and hatched in the following spring. The larval voltinism showed univoltine or semivoltine at the two different sampling sites of the study area. The egg and larval stages were fairly long, and its habitat consisted of both aquatic and terrestrial environments, easily disturbed by human activities. For conservation of the Taiyal darner, it is recommended to protect whole lake and its adjacent environments." this discovery." (Authors)] Address: Machet, P., L'être Delangle, F-61140 La Chapelle d'Andaine, France

5472. Makihara, H.; Kitajima, H.; Goto, H.; Kato, T.; Makino, S. (2004): An evaluation of predation impact of the introduced lizard *Anolis carolinensis* on the endemic insect fauna of the Ogasawara Islands based on insect collection records and feeding experiments, with special reference to longicorn beetles (Insecta: Coleoptera: Cerambycidae). *Bulletin of the Forestry and Forest Products Research Institute* 3(2) (No.391): 165-183. (in Japanese, with English summary). ["In the Ogasawara Islands, [...] the population of the invasive lizard *Anolis carolinensis* has been growing since it was artificially introduced in the 1960s. As the lizard is diurnal and preys upon various small animals, there is rising concern that it endangers the survival of endemic insect species. In order to estimate the impact of *A. carolinensis* on the insect fauna, observations were made on the feeding behavior of the lizard under field or captive conditions. Of the insects provided as food, relatively small species (e.g. beetles smaller than 2 cm in body length) were eaten by the caged lizard, while larger species escaped predation. In Hahajima Is., where the lizard proliferated in the 1990s, we compared the numbers of longicorn beetles collected during our research trips before (in 1983, 1985 and 1986) and after (in 1995, 1996, and 1997) the proliferation. None of the 11 nocturnal species surveyed showed a marked decline in the number of collected specimens in 1995 to 1997. In contrast, we collected no specimens of three out of five diurnal species in the same period. These results suggest that the invasive lizard is responsible for a recent, marked decline of the population of at least some diurnal small insects by intensively feeding on them." (Authors) The study includes also feeding experiments with dragonflies.] Address: Makihara, H., Dept of Global Forest Research, Forestry & Forest Products Research Institute (FFPRI), 1 Matsunosato, Tsukuba, Ibaraki 305-8687, Japan. 5473. Mantel, S.K.; Dudgeon, D (2004): Effects of *Macrobrachium hainanense* predation on benthic community functioning in tropical Asian streams. *Freshwater Biology* 49(10): 1306-1319. (in English). ["1. *Macrobrachium hainanense* is a large predatory palaemonid shrimp, present at high densities in pools of low-order forested streams in Hong Kong. The present study investigated the impacts of *M. hainanense* on benthic community structure and functions in pools of two streams: Tai Po Kau Forest Stream and Tai Shing Stream. 2. Repeated whole-pool experiments involving shrimp density manipulations (removal, control and addition) were conducted in both streams between October 2000 and April 2002, and included a wet (May to September) and two dry (October to April) seasons. The three objectives of the study were to determine the effects of *M. hainanense* predation on benthic macroinvertebrate (including Odonata) abundance and species richness, rates of leaf litter breakdown because of effects on detritivores, and periphyton standing stocks by way of an effect on herbivores. 3. Wet season results showed consistent reductions in benthos densities and species richness following heavy rainfall, irrespective of shrimp manipulation. These results suggested that spate-induced disturbances might override biotic effects and play a dominant role in structuring benthic communities in stream pools in Hong Kong. 4. No significant, reproducible effects on any of the response variables

measured in either stream were found during the dry season. Litter breakdown was reduced in the absence of shrimps during one experiment only, suggesting it might be a type I error. These results signified no effect of shrimp removal on benthic communities, or on the functional processes of litter breakdown, or on periphyton accumulation. The large scale of the experimental units (8–40 m²), refuge availability, and the presence of benthic predatory fishes that cropped excess prey made available by removal of *M. hainanense*, may have contributed to the lack of any effect, despite the abundance of the predatory shrimps." (Authors)] Address: Dudgeon, D., Department of Ecology and Biodiversity, The University of Hong Kong, Pokfulam Road, Hong Kong SAR, China. E-mail: ddudgeon@hkucc.hku.hk

5474. Medianero, E.; Samaniego, M. (2004): The community of aquatic insects associated with contaminated waters in the Rio Curundú, Republic of Panama. *Folia Entomol. Mex.* 43(3): 279-294. (in Spanish, with English summary). ["From March 2000 to March 2001, samples of aquatic insects and of physicochemical variables were obtained from the riverbed of Rio Curundú (Panama). The objectives of the study were (1) to identify aquatic insects resident in waters of different levels of contamination; (2) to assess the diversity of insect communities from the source to the estuary of the river; and (3) to evaluate the effects of rainfall on annual patterns of insect abundance. Fifty-seven taxa were collected. Most of insects were associated with levels of biochemical need of oxygen (BNO) between 7.4 and 13.05 mg/l. However, some insect genera were associated with BNO levels of 62.5 and 188.5 mg/l. There was a relation between BNO and insect genera (chi-squared = 1674, $p < 0.007$). The diversity of insect communities decreased from the source to the estuary of the river. There was also a negative linear relation between rainfall and insect abundance ($F = 10.49$, $p < 0.0078$, $r = -0.70$)."] (Authors) Odonata are treated at the family / genus level.] Address: Samaniego, M., Instituto Smithsonian de Investigaciones Tropicales. The effects of chemical cues on the foraging of damselfly larvae *Enallagma antennatum* (Odonata: Zygoptera). 2004 Entomological Society of Ontario Annual Meeting Brock University: 20. (in English). [Verbatim: The trade-off between foraging rate and minimizing predation risk is ubiquitous in nature. To achieve an optimal balance in this trade-off, potential prey must have a method of predator detection that allows discrimination between risky and non-risky environments. Damselfly larvae typically respond to the presence of a predator by reducing foraging rates. In this study, we explore the way in which larvae of *Enallagma antennatum* use visual and chemical cues effects to assess predation risk. In trials comparing visual and chemical cues, damselfly larvae reduced foraging only in response to chemical cues. Further experiments revealed that damselfly larvae respond to chemical cues from predators that have recently fed on conspecific or familiar heterospecific prey items damselflies also reduced foraging in the presence of cues from injured conspecifics. Thus, damselfly larvae are able to distinguish between different chemical cues and appear to respond to these different chemical cues in a manner consistent with associated risk.] Address: Mortensen, L.M., Department of Biological Sciences, Brock University, 500 Glenridge Ave., St. Catharines, ON, Canada

(2004): Shifts in the food of Nile tilapia, *Oreochromis niloticus* (L.) in Lake Victoria, Kenya. *African Journal of Ecology* 42: 163-170. (in English, with French summary). ["Studies of the food of introduced Nile tilapia, *Oreochromis niloticus* (L.) with respect to size, habitat and season were conducted between November 1998 and October 2000 in Kenyan waters of Lake Victoria. Stomach contents of 1980 specimens collected by demersal trawl and seining were analysed. Nile tilapia originally known to be herbivorous, feeding mostly on algae has diversified its diet to include insects, fish, algae and plant materials. The major diet of fish <5 cm total length was zooplankton whereas bigger fish included a wider range of food items in their diet. There was spatial variation in diet with insects and algae dominating in the gulf and open water habitats respectively. There was no seasonal variation in the food items ingested and diel feeding regime indicated that *O. niloticus* is a diurnal feeder. The shift in diet could be due to ecological and environmental changes in Lake Victoria, which have been associated with changes in composition and diversity of fish and invertebrate fauna, emergence and dominance of different flora including water hyacinth *Eichhornia crassipes* (Mart.) Solms-Laub., and algae communities. The feeding habit of *O. niloticus* is discussed in the context of changes occurring in the lake." (Authors) Odonata comprise 1.1% of the gut content of 1980 Nile tilapia analysed during the period Nov. 1998 to Oct. 2000.] Address: Njiru, M., Kenya Marine and Fisheries Research Institute (KMFRI), PO Box 1881, Kisumu City, Kenya. - 5493.** Ramsay, L.; Cannings, R.A. (2004): Determining the status of British Columbia's dragonflies. T.D. Hooper, editor. Proceedings of the Species at Risk 2004 Pathways to Recovery Conference. March 2-6, 2004, Victoria, B.C. Species at Risk 2004 Pathways to Recovery Conference Organizing Committee, Victoria, B.C.: 1-12. (in English). ["To demonstrate how inventory provides information for assigning conservation status ranks, we looked at the changes in these ranks over a nine-year period. Preliminary conservation status ranks were assigned to British Columbia's dragonflies and damselflies (Class Insecta: Order Odonata) in 1993. Subsequently, we focused inventory efforts on the species considered to be at risk in order to more accurately determine their status. From 1996 to 2003, concentrated surveys were conducted throughout much of the province. During these surveys, known ranges of many species were extended, knowledge of habitat requirements increased, and five new species were confirmed for the province. Many of the targeted species were more abundant than previously thought, and their conservation ranks were changed accordingly. Others were found only rarely or not at all. Ranking poorly known species is challenging, particularly if samples are small or habitats are difficult to access. By increasing our knowledge of these species and their requirements, we can assign them more accurate ranks, thus ensuring that conservation efforts will target the species and habitats that truly require them." ["With their relatively simple nervous systems and purpose-designed behaviors and reflexes, insects are an excellent organism in which to investigate how visual information is acquired and processed to guide locomotion and navigation. Flies maintain a straight course and monitor their motion through the environment by sensing the patterns of optic flow induced in the eyes. Bees negotiate narrow gaps by balancing the speeds of the images in their two eyes, and they control flight speed by holding constant the average image velocity as seen with their two eyes. Bees achieve a smooth landing on a horizontal surface by holding the image velocity of the surface constant during approach, thus ensuring that flight speed is automatically close to zero at touchdown. Foraging bees estimate the distance that they have traveled to reach a food source by integrating the optic flow experienced en route; this integration gives them a visually driven "odometer." Insects have also evolved sophisticated visuomotor mechanisms for pursuing prey or mates and possibly for concealing their own motion while shadowing objects of interest." (Authors) Dragonflies are referred to several occasions, especially in the context of motion camouflage.] Address: Srinivasan, M.V., Center for Visual Science, Research School of Biol. (2004): On structural-functional organization of dragonfly mushroom bodies and some general considerations about purpose of these formations. *Journal of Evolutionary Biochemistry and Physiology* 40(6): 608-624. (in English). ["Anatomy as well as (for the first time) the fine structure have been studied of the mushroom bodies located in protocerebrum of the supraesophageal ganglion of dragonflies the most ancient flying insects on Earth. Used in the work are larvae of the last age (prior to winging), in which the mushroom body structure has already been completely formed and corresponds to that in imago. The total organization of the dragonfly mushroom bodies has been established to be more primitive than that of other insects studied so far. This involves both the number of interneurons (Kenyon cells) present in the mushroom bodies and the character of anaptic connections formed by these cells. There is confirmed the absence in dragonflies of the mushroom body calyces that in opinion of some authors are obligatory input gates into these structures. Peculiarities of the neuropil structure in the area of the absent calyces are studied in detail. For the first time in insects there are revealed the direct (without additional synaptic switching) pathways forming the afferent input from optic lobes into the mushroom body calyx area. Also detected are the direct pathways going from the mushroom bodies to the abdominal chain (efferent output). A possible functional significance of these findings as well as the general role of mushroom bodied in control of some forms of insect behavior are discussed." (2004): Assessing researcher impacts from a long-term sampling program of wetland com-munities in the Everglades National Park, Florida, U.S.A.. *Freshwater Biology* 49(0): 1381-1390. (in Eng-lish). ["1. Long-term monitoring requires repeated visits to a study site, greatly increasing the potential for cu-mulative visitation effects. For ecological studies in ge-neral, and for monitoring in particular, data must be evaluated for confounding artefacts from researcher presence. We compared aquatic communities at long-term sampling plots (nine sites, each with three plots, studied continuously from 6 to 22 years) in the Everglades National Park to previously unsampled reference plots adjacent to them to assess the effects of resear-cher visitation on the flora and fauna. 2. We identified two criteria that are sensitive to local habitat heteroge-neity for assessment of visitation impacts. First, the long-term plots must differ from adjacent reference plots by a magnitude that exceeded variation among plots separated by equal or greater distance (i.e. the difference is greater than expected by scaling of com-munity change proportional with distance); and second, multiple reference plots must consistently differ in direc-tion (e.g. greater abundance or less abundance) from adjacent long-term plots. We also tested for increased heterogeneity among samples from long-term plots compared with those not previously visited. 3. We found no evidence of researcher effects on fish or macroinver-tebrates, and only weak evidence for alteration of e-mergent plants and periphyton floating mats. Our failure to document visitor impacts may result from either low visitation rate or the dynamic nature of the wetlands studied." 5506. Abbott, J.; Svensson, E.I. (2005): Phenotypic and genetic variation in emergence and development time of a trimorphic damselfly. *J. Evol. Biol.* 18: 1464-1470. (in English). ["Although colour polymorphisms in adult organisms of many taxa are often adaptive in the context of sexual selection or predation, genetic correlations between colour and other phenotypic traits expressed early in ontogeny could also play an important role in polymorphic systems. We studied phenotypic and genetic variation in development time among female colour morphs in the polymorphic damselfly *Ischnura elegans* in the field and by raising larvae in a common laboratory environment. In the field, the three different female morphs emerged at different times. Among laboratory-raised families, we found evidence of a significant correlation between maternal morph and larval development time in both sexes. This suggests that the phenotypic correlation between

phenotypic correlation between morph and emergence time in the field has a parallel in a genetic correlation between maternal colour and offspring development time. Maternal colour morph frequencies could thus potentially change as correlated responses to selection on larval emergence dates. The similar genetic correlation in male offspring suggests that sex-limitation in this system is incomplete, which may lead to an ontogenetic sexual conflict between selection for early male emergence (protandry) and emergence times associated with maternal morph." 5508. Allen, E.W.; Prepas, E.E.; Gabos, S.; Strachan, W.M.; Zhang, W. (2005): Methyl mercury concentrations in macroinvertebrates and fish from burned and undisturbed lakes on the Boreal Plain. *Canadian Journal of Fisheries and Aquatic Sciences* 62(9): 1963-1977. (in English, with French summary). ["Methyl mercury (MeHg) concentrations in macroinvertebrates (including Odonata, e.g. *Cordulia shurtleffi*) and fish were compared among five lakes in burned catchments and five reference lakes on the western Canadian Boreal Plain to determine the influence of forest fire on MeHg bioaccumulation. Two years after fire, MeHg concentrations in five of six aquatic taxa were similar in burned and reference lakes. Among a larger set of 12 lakes, MeHg concentrations in biota were negatively correlated with lake water pH, trophic status, and hardness, reflecting a pre-existing gradient in water chemistry. Bio-magnification of MeHg (as determined by regression of MeHg concentration on baseline-adjusted $\delta^{15}N$) was negatively correlated with lake water chlorophyll a concentration. A subsequent logging experiment interrupted by fire provided an opportunity to compare pre- and post-fire MeHg concentrations in aquatic biota. Three months after fire, biota MeHg concentrations had decreased by 32%–50%, and lake water ammonium concentrations had increased 11-fold relative to the previous year. In this nutrient-rich setting, fire may lower MeHg concentrations in aquatic biota over the short-term by inducing an increase in lake productivity that dilutes MeHg at the base of the food web." 5509. Anholt, B.R.; Negovetic, S.; Rauter, C.; Som, C. (2005): Predator complement determines the relative success of tadpoles of the *Rana esculenta* complex. *Evolutionary Ecology Research* 7: 733-741. (in English). ["Question: Does the identity of the apex predator in a system predict the relative success of closely related amphibian larvae? Organisms: Larvae of the hybridogenetic European frog, *Rana kl. esculenta*, and its sexual host, *R. lessonae*. Site: Three ponds supporting predatory fish and four ponds without fish but containing large invertebrate (dragonflies) and amphibian predators in northern Switzerland. Background: *Rana*

esculenta is a better competitor than *R. lessonae* in a wide range of conditions and is also a larger, more fecund frog than *R. lessonae*. Under most conditions, models predict competitive exclusion of *R. lessonae* followed by extinction of *R. lessonae*. Methods: In the field, we measured the change in frequency of the two taxa from the larval stage to metamorphosis. In the laboratory, we measured the activity of the two taxa and measured their vulnerability to odonate predators. Conclusions: In the presence of fish, the frequency of *R. lessonae* declined relative to *R. esculenta* from the larval stage to metamorphosis. In the absence of fish and presence of other predators, the opposite was true. *Rana esculenta* was more active than *R. lessonae* and more vulnerable to predation. The two taxa are adapted to different predator complexes and the hybridogenetic system is maintained by occasional dispersal between dissimilar water bodies.] Address: Anholt, B.R., Dept Biology, University of Victoria, PO Box 3020, Victoria, BC, V8W 3N5, Canada. 5513. Bernard, R.; Wildermuth, H. (2005): *Nehalennia speciosa* (Charpentier, 1840) in Europe: a case of a vanishing relict (Zygoptera: Coenagrionidae). *Odonatologica* 34(4): 335-378. (in English). ["Based on all available data, the former and present distribution in Europe is presented and critically analysed. The sp. is extinct or has only survived at single or small clustered and isolated localities in many parts of the western borderlands of its former Eurasian area that extended from Belgium to Japan. It is continuously declining, especially W and S of the line running through the Baltic States, N and E Poland and S Belarus. The attached basic data from Asia reveal incomplete knowledge, but probably indicate a better situation in the eastern part of the range. The main aspects of the ecology and biology are outlined and discussed. Special attention is paid to the elements helpful in understanding the deep regress of the sp., i.e. to its habitat on a macro- and microscale as well as to its life-strategy. The high level of stenotopy and the highly specialized habitat-related behaviour, resulting in successful use of a narrow niche, are emphasized. These aspects make the sp. vulnerable in the face of high anthropogenic pressure in Europe. Limited dispersal abilities augment the danger of local extinction. The main threats are presented and some essential conser-

vation measures are proposed." (Authors)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

5514. Bernard, R.; Wildermuth, H. (2005): Verhaltensbeobachtungen an *Nehalennia speciosa* in Bezug auf Raum, Zeit und Wetter (Odonata: Coenagrionidae). *Libellula* 24(3/4): 129-153. (in German, with English summary). ["The behaviour of *N. speciosa* was studied at five small bog lakes in NW Poland with regard to habitat use, diurnal activity and influence of the weather. In total we discerned 22 behavioural elements some of which were considered in the context of different environmental situations. The imagines stayed almost exclusively in a narrow belt of thin-leaved sedges at the edge of the open water or in corresponding vegetation of adjacent shallow water bodies. The diurnal pattern of the localization of imagines in the vertical profile of the vegetation is described, stressing their movement downwards from the late forenoon and upwards in the late afternoon. Reproductive activity started in the morning, peaked around two hours before solar noon, and decreased rapidly in the early afternoon. Generally, precopula and copula lasted longer in the morning than in the afternoon. Calm, warm and rather humid atmospheric conditions with subdued or sporadically interrupted insolation proved optimal for the species' activity, whereas wind, strong precipitation, and temperatures below ca 15°C as well as above ca 23-24°C with strong insolation were unsuitable. In light rain and under a cloudy sky - provided that conditions were calm and temperatures were around 20°C - activity was diminished but not completely suppressed. It is inferred that imagines of *N. speciosa* are morphologically and ecologically adapted to habitats with obstrusive obstacles to flight, a humid microclimate and small spatial compass." (Authors)] Address: Bernard, R., Institut für Umweltbiologie, Abteilung Allgemeine Zoologie, Adam-Mickiewicz-Universität, Umultowska 89, PO-61-614 Poznan, Poland. E-mail: rbernard@amu.edu.pl

5515. Blakely, T.J.; Chadderton, W.L.; Harding, J.S. (2005): The effect of rotenone on orchard-pond invertebrate communities in the Motueka area, South Island, New Zealand. DOC Research & Development Series 220. Department of Conservation, Wellington: 26 pp. ["Rotenone is a naturally derived (organic) fish toxicant used widely in fisheries management. However, because of the non-specific nature of rotenone, nontarget animals may also be poisoned. The aim of this study was to determine whether past rotenone poisoning has had detectable effects on pond invertebrate communities and, if so, whether there is any evidence of community recovery. Water-chemistry parameters and invertebrate and plankton communities were investigated in a one-off survey of 18 orchard ponds around Motueka, South Island, New Zealand. Ponds were classified as either rotenone-free (pest fish present or pest fish absent) or rotenone addition, where rotenone had been used to eradicate pest fish species 6 months, 1 year and 3 years prior to our survey. We found few differences in water chemistry, physical conditions, or invertebrate taxonomic richness between groups of ponds. pH was circumneutral in all ponds, while conductivity ranged from 112-193 µS25/cm. Zooplankton diversity did not differ between groups: a total of 35 macroinvertebrate taxa were recorded from the 18 ponds, with 12-15 taxa found in each treatment group. However, there were subtle differences in macroinvertebrate and zooplank-

ton community composition. Our results indicated that invertebrate communities in the poisoned study-ponds were able to recover quickly; however, the impact of rotenone on benthic invertebrates is still uncertain, and the results of this study should be interpreted with caution as they were confounded by other variables, such as adjacent land-uses. Ponds in this study were dominated by pollution-tolerant taxa, and were already subjected to a cocktail of chemicals used on the adjacent orchards. Thus, the effect of rotenone may be undetectable in our ponds but more severe in pristine systems." (Authors) The study includes / discusses results from *Xanthocnemis zealandica* and *Austrolestes colenonis*. An additional three species are listed in appendix I and II.] Address: http://www.doc.govt.nz/Publications/004~Science-and-Research/D_OC-Research-and-Development-Series/PDF/drds220.pdf

5517. Bolnick, D.I.; Preisser, E.L. (2005): Resource competition modifies the strength of trait-mediated predator-prey interactions: a meta-analysis. *Ecology* 86: 2771-2779. (in English). ["Only a fraction of the individuals in a given prey population are likely to be killed and consumed by predators. In contrast, nearly all individuals experience the chronic effects of predation risk. When threatened by predators, prey adopt defensive tactics whose costs can lead to reduced growth, maturation rates, survivorship, fecundity, or population density. This nonconsumptive impact of predation risk on prey is known as a "trait-mediated interaction" (TMI) because it results from changes in prey traits such as behavior or physiology. Ecological theory suggests that the strength of TMI effects will reflect a balance between the conflicting demands of reproduction vs. predator avoidance. Competitor density and resource availability are expected to alter the balance between these conflicting forces. We conducted a meta-analysis of experimental studies that measured TMI effect size while varying competitor and/or resource density. The threat of predation had an overall negative effect on prey performance, but the strength of this effect varied with the level of competition. High competition exacerbated the negative effect of intimidation on prey density but moderated the negative effect of intimidation on prey life history and growth. We discuss these results in light of previously published theoretical expectations. Our results highlight the variable and context-dependent nature of interspecific interactions." 5523. Cannings, R.A.; Simaika, J.P. (2005): *Lestes disjunctus* and *L. forcipatus* (Odonata: Lestidae): An evaluation of status and distribution in British Columbia. *J. entomol. Soc. Brit. Columbia* 102: 57-63. (in English). ["Of the five species of the damselfly genus *Lestes* that live in British Columbia, *Lestes forcipatus* Rambur and *L. disjunctus* Selys are the most difficult to separate morphologically. Females can be readily distinguished by the size of the ovipositor, but males are difficult to separate. In British Columbia, *L. disjunctus* is more common, widespread and familiar. Before 1998, when it was first reported in BC, specimens of *L. forcipatus* were misidentified as *L. disjunctus* because the former is known mainly from eastern North America and most *Lestes* species are usually most readily identified using male characters. The identities of museum specimens of the two species were checked and corrected by us as necessary. Ecological and behavioural observations

and up-dated distribution maps of the species are presented. Throughout its range in BC, *L. forcipatus* is mostly sympatric with *L. disjunctus* but lives in a narrower range of habitats and localities mostly cool sedge marshes and fens. The two species show some temporal and behavioural separation." (Authors)] Address: Cannings, R., Royal British Columbia Museum, 675 Belleville Street, Victoria, British Columbia, Canada

5524. Carchini, G.; Solimini, A.G.; Ruggiero, A. (2005): Habitat characteristics and odonate diversity in mountain ponds of central Italy. *Aquatic Conservation: Marine and Freshwater Ecosystems* 15(6): 573-581. (in English). ["1. In central Italy mountain ponds represent an important habitat for the conservation of dragonflies; however, human disturbance of these fragile environments is threatening the stability of their biodiversity. 2. Thirty-one ponds, ranging in altitude from 1014 to 2004 m, were qualitatively sampled for odonate larvae twice during 1998. On each occasion a range of physical, chemical and biotic habitat variables were also measured. 3. The mountain ponds sampled had fewer species of Odonata than lowland ponds, and there was a large presence of pioneer species. 4. Multiple regression analysis showed that the number of odonate species was positively affected by the amount of macrophyte coverage of the pond surface and negatively affected by increasing ammonium concentration. 5. A Canonical Correspondence Analysis revealed that species number decreased with altitude, chlorophyll a and phosphorus concentrations. The presence/absence of each odonate species was weakly related to the habitat variables. 6. The intensive use of ponds for livestock watering results in damage to the peripheral vegetation, which tends to cause high turbidity and lower macrophyte coverage of the pond water. The inevitable outcome in these situations is a reduction of the odonate diversity." (Authors)] Address: Carchini, G., University of Tor Vergata, Department of Biology, via della Ricerca Scientifica, 00133, Roma, Italy. E-mail: carchini@uniroma2.it

5525. Chazal, A.C. (2005): Lepidoptera and Odonata surveys of Colonial National Historical Park, James City, Surry, and York counties, Virginia. Natural Heritage Technical Report 05-05. Virginia Dept of Conservation and Recreation, Division of Natural Heritage, Richmond, Virginia. Unpublished report submitted to Colonial National Historical Park. May 2005 : 49 pp. (in English). ["[...] Between May-July 2003 and April-October 2004, DCR-DNH conducted surveys over 18 days covering 17 different habitats, which were categorized into 6 habitat types: developed areas, fields, forested uplands, forested wetlands, marshes, and water (i.e. freshwater ponds). [...] 42 species of Odonata were observed. [...] The field habitats also had the highest species diversity and second highest totals (forested wetlands had higher totals) for Odonata. [...] 5 watch-listed species were observed: Aaron s Skipper (*Poanes aaroni*), *Anax longipes*, *Sympetrum ambiguum*, *Ischnura prognata*, and *Telebasis byersi*. All of these watch-listed species are considered common to very common and secure across their global ranges. The results of this survey represent 37 new county records for Lepidoptera and 26 for Odonata. Species accumulation curves indicate that further surveys for Lepidoptera and Odonata may increase the known fauna of COLO." (2005): Evolution and ecology of Calopterygidae (Zygoptera: Odonata): Status of knowledge and future research perspectives. *Neotropical Entomology* 34(6): 861-879. (in English, with Portuguese summary). ["We review the studies of evolution and ecology in the Calopterygidae. Adults are easily distinguished for their pigmented wings and territorial behaviour. Three genera have been well studied: *Hetaerina*, *Calopteryx* and *Mnais*. Larvae develop in riverine aquatic environments. Selection operates at this stage to produce large muscle mass for adults. The adult spends some days until sexually ready. During this time, it feeds extensively to produce muscle fat for egg production and flight. However, gregarine parasites may ingest the fat reserves. Males may use two mating tactics or strategies that may be genetically (*Mnais*) or environmentally (*Calopteryx* and *Hetaerina*) determined: territoriality and nonterritoriality. In *Mnais*, these strategies appear balanced in fitness terms. Males of *Calopteryx*, *Mnais* and *Phaon* show a precopulatory courtship that is not the case for *Hetaerina*. Male wing pigmentation seems to signal how good the male is to deal immunologically with parasites to females during the male courtship. During copulation, males displace the sperm the female has stored in the storage organs from previous matings. There is an enormous variation in male sperm displacement mechanisms and ability, and in genitalic morphology in both sexes. This variation possibly results from a coevolutionary game between the sexes to control stored sperm. After copulation, males guard females apparently to avoid that other males take the female in copulation. Our review suggests sources for research in this family." ["Variation in behavior, morphology and life history traits of larval anurans across predator gradients, and consequences of that variation, have been abundantly studied. Yet the functional link between morphology and burst-swimming speed is largely unknown. We conducted experiments with two divergent species of anurans, *Scaphiopus holbrookii* and *Rana sphenoccephala*, to examine how behavior and morphology influence predator (*Anax junius*) vulnerability, and whether tadpole shape is related to burst-swimming performance. *S. holbrookii*, a species that typically uses ephemeral pools, was more active, exhibited slower burst speeds, and was more susceptible to predation than *R. sphenoccephala*, a species associated with more permanent aquatic sites. Our analysis of morphology and burst speed defined a shared axis of shape variation associated with burst-swimming speed regardless of species. Tadpoles with a deeper tail fin and muscle and a smaller body produced faster speeds. The nature and breadth of the morphology /speed relationship suggests

it may represent a generalized ecomorphological paradigm for larval anurans." (Authors)] Address: Dayton, G.H., Section of Ecology and Evolutionary Biology, Dept of Wildlife and Fisheries Sciences, Texas A&M Univ., Tamus 2258, College Station, TX 77843-2258, USA. E-mail: gdayton@tamu.edu

5534. De Marco, P.; Vianna, D.M. (2005): Distribuição do esforço de coleta de Odonata no Brasil – subsídios para escolha de áreas prioritárias para levantamentos faunísticos. *Lundiana* 6 (suppl.): 13-26. (in Portuguese, with English summary). ["Distribution of Odonata sampling effort in Brasil – basis for choosing priority areas for faunistic inventories: There is an urgent need to prioritize conservation areas, so that the invested resources protect as much biodiversity as possible, especially in developing countries. A way to select such areas is to estimate the biodiversity distribution but this strategy is constrained by the lack of knowledge and/or by the inaccessibility of the available information on species distribution. Based on a database on Odonata distribution in Brazil, it is shown that the sampling-effort and the largest numbers of recorded odonate species and genera are concentrated in areas with large number of researchers. The 6203 records employed here are distributed in only 29% of the national territory. The species richness is concentrated mainly in the states of Rio de Janeiro, Minas Gerais and São Paulo, in the Amazon River varzea and in some isolated points, such as Cuiabá (Mato Grosso state). We suggest that the sampling and inventory efforts are increased for Odonata, especially in the Brazilian northeast and areas in the Brazilian and Guyana Shields, for which there is practically no information available." 5535. De Marco, P.; Latini, A.O.; Resende, D.C. (2005): Thermoregulatory constraints on behavior: Patterns in a neotropical dragonfly assemblage. *Neotropical Entomology* 34(2): 155-162. (in English, with Portuguese summary). ["Odonate species are classified in terms of their thermoregulatory behavior into flier and percher categories. Larger perchers could be more efficient thermoregulators in sunny sites and smaller perchers depend more on air temperature. In this paper, an analysis of the behavioral temporal budget of an odonate neotropical assemblage was performed to determine the role of body size on territorial defense and general behavioral strategies. This analysis revealed three groups based on time budget. The first and second groups contained the species that remained perched for most of the activity time, but species of the first group differ from the second group by the larger proportion of transition flights. The third group contained species which were usually observed patrolling or in reproductive activities. The larger species spent more time in patrol and territorial defense activities, while smaller species remained perched. Larger dragonflies, with better thermoregulatory abilities could spend more time in reproductive activities. The behavioral classification of fliers and perchers is considered extremely useful but could oversimplify the behavioral patterns among species that have a wide body size variation. It is proposed that a behavioral continuum associated with the body size variation in perchers could explain some patterns of species interactions in odonate communities." (Au-

5538. Deliz Quiñones, K.Y. (2005): Water quality assessment of a tropical freshwater marsh using aquatic insects. Thesis M.S., Biology, University of Puerto Rico, Mayagüez Campus: 127 pp. (in English, with Spanish summary). [Laguna Cartagena, located in the municipality of Lajas, is the only natural freshwater lagoon of Puerto Rico. The lagoon gives refuge to many animal and plant species, some of them endemic and endangered. Agriculture in contiguous lands has caused sedimentation and eutrophication, affecting not only the hydrology of the lagoon but also its capacity to sustain a high diversity of aquatic life. To restore the lagoon, its actual condition was assessed based on the physical-chemical [...] and biological characteristics (aquatic insects) of two sites on the southwestern section of the lagoon. A total of 67 insect species in 33 families were collected, including 17 odonate taxa. For the full paper see: <http://grad.uprm.edu/tesis/delizquinones.pdf>] Address: Deliz Quiñones, Katherine Y., no further details

5539. Della Bella, V.; Bazzanti, M.; Chiarotti, F. (2005): Macroinvertebrate diversity and conservation status of Mediterranean ponds in Italy: water permanence and mesohabitat influence. *Aquatic Conserv. Mar. Freshw. Ecosyst.* 15: 583-600. (in English). ["1. In Italy small water bodies, especially temporary ones, have been little studied. As a consequence, their conservation value as a biodiversity resource is often overlooked despite Mediterranean temporary waters being listed as a priority habitat in the Habitats Directive (92/43/EEC). 2. A monitoring programme was designed to determine which factors influence pond species richness,

and to analyse the variation in macroinvertebrate community structure within and among ponds. Three main contrasting mesohabitats (macrophyte beds, littoral sediments and central sediments) were defined within 21 ponds (8 permanent and 13 temporary) along the Tyrrhenian coast of Italy near Rome, from which invertebrate macrofauna was collected in March, May and June 2002. 3. The main environmental factors influencing the number of species in ponds were hydroperiod length, depth, surface area, dissolved oxygen concentration and macrophyte species richness. Temporary ponds contained a smaller number of taxa than permanent ponds, but both types of ponds supported similar numbers of rare and threatened species. The total number of species, and in particular Coleoptera, Odonata, and Hemiptera, was higher in macrophyte beds than in both littoral and central sediments. 4. Multivariate analysis (non-metric multidimensional scaling) showed that the overall variation in assemblage composition was greater between temporary and permanent ponds than among mesohabitats, suggesting that environmental variables, such as hydroperiod, have a stronger effect on macroinvertebrate communities than substratum type. 5. In terms of species of conservation interest, this study suggests that both pond types and all mesohabitats should be considered in order to obtain a correct evaluation of pond conservation value." (Authors) The list of Oonata includes 16 species.] Address: Valentina Della Bella, Department of Animal and Human Biology, University of Rome La Sapienza, Viale dell'Universita` 32, 00185 Rome, Italy. 5542. Dijkstra, K.D. (2005): A review of continental Afrotropical *Ceriagrion* (Odonata, Coenagrionidae). *J. Afrotrop. Zool.* 2: 3-14. ["The taxonomy of the *Ceriagrion* species of continental tropical Africa is discussed and a key provided. *C. annulatum* is not synonymous with *C. sanguinostigma*, but *Argiocnemis umbargae* is considered a junior synonym of *C. annulatum*, and *C. platystigma* with *C. sanguinostigma* of *C. varians*. The oriental genus *Argiocnemis* does not occur in Africa. The identities of *C. citrinum* and *C. ignitum* are clarified and the first records of *C. ignitum* and *C. mourae* since their descriptions are provided. The taxonomy of the complex of species including *C. hamoni*, *C. moorei*, *C. sakejii*, *C. suave* and possibly some Malagasy species remains unresolved, although at least *C. hamoni* and *C. moorei* are suspected to be conspecific with *C. suave*. The variability of *C. glabrum* is addressed in relation to the taxon *longispinum*." (Author)] Address: Dijkstra,

K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

5543. Dijkstra, K.-D. (2005): Taxonomy and identification of the continental African *Gynacantha* and *Heliaeschna* species (Odonata: Aeshnidae). *International Journal of Odonatology* 8(1): 1-32. (in English). ["The taxonomy of the *Gynacantha* and *Heliaeschna* species from continental Africa is problematic, and available keys are unsatisfactory. 'Traditional' characters such as venation and 'innovative' ones like abdominal denticulation are evaluated and their variability is measured and discussed. *G. quadrina* is a synonym of *G. africana* and not of *G. vesiculata*, *G. ochraceipes* is regarded a synonym of *G. vesiculata*, *G. victoriae* of *G. bullata*, *G. flavipes* and *G. sevastopuloi* of *G. nigeriensis*, *G. zuluensis* of *G. usambarica*, and *H. ukerewensis* of *H. trinervulata*. Analysis of the complex of large *Heliaeschna* species provides no basis for separating species and *H. lanceolata*, *H. libyana* and *H. mymondi* are treated as synonyms of the single variable species *H. fuliginosa*. The first records of *G. immaculifrons* and of specimens near *H. longfieldae* since their descriptions are provided. The probable male of *H. longfieldae* is diagnosed. Remarkable heterogeneity of characters in *G. manderica*, *G. villosa* and *H. longfieldae* is described. This may have taxonomic relevance, but study of more specimens is required. Afrotropical *Gynacantha* species can be assigned to three groups: the *africana*-, *bispina*- and *bullata*-groups. It is suggested that *Gynacantha* and *Heliaeschna* may not be monophyletic and that the *africana*-group may be more closely related to African *Heliaeschna* than to the other *Gynacantha* groups. Keys to the species of *Gynacantha* and *Heliaeschna* are provided for both sexes. Identification is still tentative for females of some species." (Author)] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

5544. Dinger, E.C.; Cohen, A.E.; Hendrickson D.A.; Marks, J.C. (2005): Aquatic invertebrates of Cuatro Ciénegas, Coahuila, México: Natives and exotics. *Southwestern Naturalist* 50: 237-281. (in English, with Spanish summary). [A recent survey of benthic macroinvertebrates of the Cuatro Cienegas basin found 118 species in the 21 sites collected. Four exotic macroinvertebrates that could threaten the native biota were found within or near the basin. The list includes 24 taxa, in most cases identified on the species level] Address: Dinger, E.C., Merriam-Powell Center for Ecological Research, Department of Biology, Northern Arizona University, Box 5640, Flagstaff, AZ 86011, USA. 5555. Fincke, O.M.; Jödicke, R.; Paulson, D.R.; Schultz, T.D. (2005): The evolution and frequency of female color morphs in Holarctic Odonata: why are male-like females typically the minority? *International Journal of Odonatology* 8(2): 183-212. (in English). ["We compiled data on the occurrence and frequency of distinct female variants among Holarctic Odonata and interpreted the data in light of harassment-based hypotheses. The major source of male confusion for male mimicry hypotheses is predicted to be signal similarity between andromorphs and male distractors; for the learned mate recognition hypothesis (LMR), it is predicted to be variation in female signals. Mapping morphism state onto molecular phylogenies of *Ischnura* and *Enallagma* failed to resolve the general ancestral female condition. However, it appeared that the andromorphic state may be ancestral in one case, and that blue structural colors were ancestral to orange and green pigmentations. Of the polymorphic species surveyed, 13% had more than two morphs, 4% had multiple heteromorphs but no andromorph, and 7% of 'monomorphic' congeners were functionally polymorphic because developmental variants mate. Such female signal variation lies beyond the scope of simple male mimicry, but nevertheless should exacerbate a male's problem in searching for mates. Andromorphs were the majority morph in at least some populations of 17% of the species for

which data were available. Andromorph frequencies of *Enallagma* species were generally higher than in *Ischnura* species, as expected if *Ischnura* andromorphs have higher signal apparency. Andromorph frequency varied significantly across habitats and species, as expected if per capita harassment and signal apparency vary among habitats. Quantification of signal apparency and per capita harassment across populations and among species is required to more rigorously test the extent to which variation in signal crypsis can explain observed variation in morph frequencies." 5558. Gaedecke, D.; Kasperski, J. (2005): Die natürlichen Grundwasseraustritte in der Naukluft und ihrer Umgebung (Namibia): Hydrogeologische Situation und ökologische Bewertung. Diplomarbeit. Institut für Umweltgeologie. Technische Universität Carolo-Wilhelmina zu Braunschweig: 12 + 92 pp. (in German, with English summary). ["The study of permanent spring discharges with special focus on the hydrogeological situation and ecological valuation, took place in the karstified Naukluft and Tsaris Mountains (central Namibia). In a total area of about 2500 km² 31 effluent seepages were sampled and investigated. The inspected springs varied from small water filled pools without vegetation to large spring brooks, stretching for several kilometres, and fringed by a forest. All analysed water samples fulfilled the Namibian standards for drinking water and held no risk to health. This classification only refers to the physico-chemical characteristics of the water samples, as a bacterial investigation did not yet take place. Referring to the Namibian guideline for the evaluation of drinking water (1991) six samples were of excellent water quality, the other 25 samples were of good quality. According to the WHO (2004) 23 samples fulfilled the requirements of drinking water. Applying the German drinking water decree (TVO, 2003) only nine water samples can be declared as drinkable. We suppose that all examined springs are fed by groundwater from aquifers which lay just below the surface. These aquifers seemed to have a low retention capacity and are mainly influenced by air temperature. In addition the aquifers consist of at least two groundwater levels which are probably not connected with each other. The inferior groundwater level might be fossil (boreholes up to 120 m). In order to test the suitability of Odonata as bioindicators for the quality of Namibian springs its distribution was correlated with test results and the local factors.

The potential diversity of the Odonata consists of nine Zygoptera and 21 Anisoptera species. During the field work 25 of these species were identified in the investigation area which can be deemed to be an isolated habitat. The physico-chemical properties of the spring waters did not seem to be a limiting factor for the distribution of the Odonata. Due to the almost unknown relations between environmental factors and the occurrence of species respectively communities no bioindicator could be defined. To strengthen the results of this study a hydrogeological, climatical and biological monitoring is needed." (Authors)] Address: c/o Suhling F., Inst. - 5566.** Gregory, M.B. (2005): Microhabitat preferences by aquatic invertebrate influence bioassessment metrics in piedmont streams of Georgia and Alabama. Proceedings of the 2005 Georgia Water Resources Conference, held April 25–27, 2005, at the University of Georgia. Kathryn J. Hatcher, editor, Institute of Ecology, The University of Georgia, Athens, Georgia.: 6 pp. (in English). ["The U.S. Geological Survey analyzed macro-invertebrate samples from woody debris and riffle habitats in 10 small Piedmont streams in Georgia and Alabama to determine if habitat preferences influence commonly used invertebrate community metrics. Eighty-seven commonly used metrics were compared, and 11 (13%) were found to be significantly different between habitats. Woody debris habitat had slightly higher taxa richness, whereas riffles had higher overall abundances and densities. Abundance metrics that differed significantly were Ephemeroptera, Plecoptera, and Trichoptera (EPT), Trichoptera, Corbicula, collector-gatherer, filtering-collector, and total abundance. Richness metrics that were significantly different were midge, Diptera, omnivore, and shredder. Corbicula richness (1 species) was the only richness metric that scored higher in riffle habitats. These results indicate that Piedmont biomonitoring studies that do not sample riffle habitat may underestimate sensitive EPT taxa because of a lack of habitat availability rather than changes in water-quality conditions. Furthermore, this study indicates the possible need for a correction factor to be applied to ecological condition metrics used by the State of Georgia that adjusts for the presence or absence of riffle habitat in Piedmont streams." (Author) The study includes a record of *Boyeria vinosa*.] Address: Gregory, M.B., U.S. Geological Survey, 3039 Amwiler Road, Suite 130, Peachtree Business Center, Atlanta, Georgia 30360-2824

- 5569.** Gusztak, R.W.; MacArthur, R.A.; Campbell, K. L. (2005): Bioenergetics and thermal physiology of American water shrews (*Sorex palustris*). *Jour. Comp. Physiol. B* 175: 87-95. (in English). ["Rates of O₂ consumption and CO₂ production, telemetered body temperature (T_b) and activity level were recorded from adult and subadult water shrews (*Sorex palustris*) over an air temperature (T_a) range of 3–32 °C. Digesta passage rate trials were conducted before metabolic testing to estimate the minimum fasting time required for water shrews to achieve a postabsorptive state. Of the 228 metabolic trials conducted on 15 water shrews, 146 (64%) were discarded because the criteria for inactivity were not met. Abdominal T_b of *S. palustris* was independent of T_a and averaged 38.64±0.07 °C. The thermoneutral zone extended from 21.2 C to at least 32 C. Our estimate of the basal metabolic rate for resting, postabsorptive water shrews (96.88±2.93 J g⁻¹ h⁻¹ or 4.84±0.14 ml O₂ g⁻¹ h⁻¹) was three times the mass-predicted value, while their minimum thermal conductance in air (0.282±0.013 ml O₂ g⁻¹ h⁻¹) concurred with allometric predictions. The mean digesta throughput time of water shrews fed mealworms (*Tenebrio molitor*) or ground meat was 50–55 min. The digestibility coefficients for metabolizable energy (ME) of water shrews fed stickleback minnows (*Culaea inconstans*) and dragonfly nymphs (*Anax* spp. and *Libellula* spp.) were 85.4±1.3% and 82.8±1.1%, respectively. The average metabolic rate (AMR) calculated from the gas exchange of six water shrews at 19–22 °C (208.0±17.0 J g⁻¹ h⁻¹) was nearly identical to the estimate of energy intake (202.9±12.9 J g⁻¹ h⁻¹) measured for these same animals during digestibility trials (20 °C). Based on 24-h activity trials and our derived ME coefficients, the minimum daily energy requirement of an adult (14.4 g) water shrew at T_a = 20 °C is 54.0 kJ, or the energetic equivalent of 14.7 stickleback minnows.] Address: Gusztak, R.W., Department of Zoology, University of Manitoba, Winnipeg, Manitoba, R3T 2N2, Canada. E-mail: campbelk@ms.umanitoba.ca
- 5570.** Han, B.-y. (2005): Differences in composition and dynamic of insect and mite community among three types of tea gardens. *Journal of Tea Science* 25: 249-254. (in Chinese, with English summary). ["From July 2002 to July 2003, a survey on the species richness and abundance of insects and mites in the tea plant, the aerial space above the tea plant and on the ground from organic, non-pollution and common tea gardens were conducted in Magushan Mountains in the Southern Anhui Province. In total, 29018 individuals of 79 species from 41 families were recorded from a common tea garden, 35117 individuals of 81 species from 41 families were recorded from a non-pollution tea garden, and 12727 individuals of 102 species from 57 families were recorded from an organic tea garden. The tea green leafhopper, *Empoasca vitis*, abundance and its percentage accounted for the total abundance in organic, non-pollution and common tea garden were 5176

and 40%, 14049 and 40% as well as 17590 and 60%, respectively. Wasps, ground beetles, tiger beetles, rove beetles and ladybugs are the major natural enemies in tea gardens, whose species richness and abundance in organic, non-pollution and common tea garden were 40 and 2620, 33 and 1898 as well as 29 and 1610, respectively. In all the three types of tea gardens, species richness was higher from March to April and from September to October, and was lower from late November to middle January. Insect and mite abundance was high from April to June and from September to October, and was lower from July to August due to the warm weather as well as from December to January due to the cold weather. The abundance in the common tea garden fluctuated more than in other two types of tea gardens. Though the Insect and mite abundance was highest in the non-pollution tea garden, the pests did not cause serious damage because of the appropriate forecast and control. In the organic tea garden, the abundance was the lowest, while the species richness was the highest, and the energy paths were complicated and the community may be stable. At the present stage, most of the organic tea gardens in China are established among the mountains where vegetation is flourishing and biodiversity is high, such ecosystems may enhance natural control." (Author) Table 1 also contains "Libellulidae".] Address: HAN Bao-yu, Key Laboratory of Tea Chemical Engineering of Ministry of Agriculture; Tea Research Institute, Chinese Academy of Agricultural Sciences, Hangzhou 310008, China

5574. Hayashi, F.; Dobata, S.; Futahashi, R. (2005): Disturbed population genetics: Suspected introgressive hybridization between two *Mnais* damselfly species (Odonata). *Zoological Science* 22: 869-881. (in English). ["*Mnais costalis* and *M. pruinosa* are damselflies (Odonata: Calopterygidae) with low dispersal abilities, both during their aquatic stream-living immature stage and their flying adult stage. A previous nuclear DNA (nDNA) sequencing and morphology study showed that these two species are very closely related, and cohabit widely in western Japan. The two species, however, segregate microhabitats along a stream: *M. costalis* lives in the lower reaches, and *M. pruinosa* in the upper reaches. In this study, our analyses were based on mitochondrial DNA (mtDNA), which usually mutates faster and is more variable among individuals than nDNA, and which is inherited maternally. We found that most COI haplotypes were shared between the two species, and that for most study sites interspecific riverine genetic structures were not clarified by mtDNA analysis. Incongruent population genetic structures based on nDNA and mtDNA suggested hybridization and introgression of mtDNA between the two species." [The paper compiles 32 odonate species stored in the collection of the Natur-Museum Luzern, Switzerland. 10 species were caught by light traps, one (*Libellula quadrimaculata*) was caught in a pitfall trap. The records by traps are discussed in some detail.] Address: Hoess, R., Normannenstr. 35, CH-3018 Bern, Switzerland. E-mail: ReneHoess@1st.ch

5579. Hofmann, T.A.; Mason, C.F. (2005): Habitat characteristics and the distribution of Odonata in a lowland river catchment in eastern England. Hydrobiologia 539(1): 137-147. (in English). ["The influence of habitat characteristics on the distribution of larval and adult Odonata communities in a lowland river in eastern England was studied. There was a longitudinal distribution of Odonata, with larval assemblages being influenced directly by marginal flow velocity, biochemical oxygen demand (BOD) and phosphate concentrations and indirectly by shade and cover of floating vegetation. Adult populations responded directly to shade, reed cover, amenity-managed land use and bank height, and indirectly to BOD and ammonia concentrations. Distribution patterns were strongly associated with both natural changes along the river system and management impacts. River management practices locally disrupted the natural displacement of species along the river, but whilst some forms of human interference on river systems were beneficial to species richness, the effects on stenotopic species were disadvantageous. To conserve Odonata management emphasis should be on the maintenance of suitable conditions for river specialists." 5580. Hopeman, M.M.; Abramson, Z.R. (2005): Sexual dimorphism in the Dark-winged damselfly *Calopteryx maculata*. University of Michigan Undergraduate Research Forum 2: 28-38. (in English). ["Pronounced sexual dimorphisms are suggestive of sexual selection. In *C. maculata*, a pronounced sexual dimorphism is seen in the degree of wing pigmentation; males have significantly darker wings than females. Territoriality in *C. maculata* makes it difficult to discern the function of sexual dimorphism. Previous studies have suggested that the degree of male wing pigmentation in a related species *C. haemoroidalis* may serve as a sexual signal to females or other males indicating their genetic quality. Various studies have shown that males of the species *C. haemoroidalis* with a higher degree of wing pigmentation are more likely to defend a territory, obtain more matings, have fewer gut parasites, and have larger fat reserves. In contrast, we found that there is no correlation between the degree of wing pigmentation and male mating or territorial success in *C. maculata*. We found that females were selective of territories but not of males. Our results suggest that the degree of wing pigmentation may play a role in species recognition by females." 5583. Jacquemin, G. (2005): A propos de l'identification à distance des Odonates adultes. *Martinia* 21(4): 47-50. (in French, with English summary). ["Many current odonatological surveys are led by naturalists coming from birdwatching, trying to use the same visual identification methods. Considering the dangers of identification with binoculars in odonatology, the author stresses the necessity to make absolutely reliable identifications, by "catching-releasing" the specimens, everytime it is possible. Identification with binoculars must be used very carefully, only when capture has not been possible, and only by very experienced odonatists. Identification keys with binoculars are therefore useless, and even dangerous for inexperienced people." (Author)] Address: Jacquemin, G., Biologie des Insectes, Université H. Poincaré, Nancy 1, BP 239, F-54506 Vandoeuvre-lès-Nancy, France

5585. Jeschke, J.M.; Tollrian, R. (2005): Effects of predator confusion on functional responses. *Oikos* 111: 547-555. (in English). ["When confronted with a swarm of their prey, many predators become confused and are less successful in their attacks. To shed light on the ecological, ethological and evolutionary consequences of predator confusion, we here investigate its effects on predator functional responses. We develop the first functional response model that considers confusion and compare it (1) qualitatively as well as (2) quantitatively to empirical data from two predator / prey systems, *Aeshna cyanea* / *Daphnia magna* (Crustacea) and *Chaoborus obscuripes* (Diptera) / *Daphnia obtusa*. (1) The qualitative comparisons show that, contrary to common belief, confusion does not necessarily lead to a dome-shaped functional response. The response can alternatively remain qualitatively unchanged and be affected only quantitatively. A non-dome-shaped respon-

se is thus no indication for the absence of predator confusion. The same is true for other swarming effects reducing foraging success, such as early warning of approaching predators. Our results hence question studies that have equated the absence of a dome-shaped response with the absence of a swarming effect. Our results also resolve the apparent paradox that swarming effects are quite common while dome-shaped functional responses are rather uncommon. (2) There is a good quantitative match between a parameterized version of our model and the empirically measured functional response in the *Chaoborus-Daphnia* system, suggesting that all crucial factors in this system are captured by the model." 5587. Johansson, F.; Crowley, P.; Brodin, T (2005): Sexual size dimorphism and sex ratios in dragonflies (Odonata). *Biological Journal of the Linnean Society* 86(4): 507-513. (in English). ["Sexual size dimorphism and biased sex ratios are common in animals. Rensch's rule states that sexual size dimorphism (SSD) would increase with body size in taxa where males are larger than females and decrease with body size in taxa where females are larger. We tested this trend in dragonflies (Odonata) by analysing body size of 21 species and found support for Rensch's rule. The increase in SSD with increasing size among species can be explained by sexual selection favouring large males. We also estimated the slope of the relationship between sex ratio and size ratio in populations of the 21 species. A negative slope would suggest that the larger sex suffers from high mortality in the larval stage, consistent with riskier foraging. The slope of this relationship was negative, but after correcting for phylogenetic non-independence with independent contrasts the relationship was no longer statistically significant, perhaps because of phylogenetic inertia or low sample size." 5588. Jordan, S.; Simon, C.; Foote, D.; Englund, R. A. (2005): Phylogeographic patterns of Hawaiian Megalagrion damselflies (Odonata: Coenagrionidae) correlate with Pleistocene island boundaries. *Molecular Ecology* 14: 3457-3470. (in English). ["The Pleistocene geological history of the Hawaiian Islands is becoming well understood. Numerous predictions about the influence of this history on the genetic diversity of Hawaiian organisms have been made, including the idea that changing sea levels would lead to the genetic differentiation of populations isolated on individual volcanoes during high sea stands. Here, we analyse DNA sequence data

from two closely related, endemic Hawaiian damselfly species in order to test these predictions, and generate novel insights into the effects of Pleistocene glaciation and climate change on island organisms. *Megalagrion xanthomelas* and *Megalagrion pacificum* are currently restricted to five islands, including three islands of the Maui Nui super-island complex (Molokai, Lanai, and Maui) that were connected during periods of Pleistocene glaciation, and Hawaii island, which has never been subdivided. Maui Nui and Hawaii are effectively a controlled, natural experiment on the genetic effects of Pleistocene sea level change. We confirm well-defined morphological species boundaries using data from the nuclear EF-1 α gene and show that the species are reciprocally monophyletic. We perform phylogeographic analyses of 663 base pairs (bp) of cytochrome oxidase subunit II (COII) gene sequence data from 157 individuals representing 25 populations. Our results point to the importance of Pleistocene land bridges and historical island habitat availability in maintaining inter-island gene flow. We also propose that repeated bottlenecks on Maui Nui caused by sea level change and restricted habitat availability are likely responsible for low genetic diversity there. An island analogue to northern genetic purity and southern diversity is proposed, whereby islands with little suitable habitat exhibit genetic purity while islands with more exhibit genetic diversity." 5592. Kefford, B.J.; Papas, P.J.; Nugegoda, D. (2005): Relative salinity tolerance of macroinvertebrates from the Barwon River, Victoria, Australia. *Marine and Freshwater Research* 54(6): 755-765. (in English). ["Salinity levels are rising in many freshwater environments, yet there are few direct measurements of salinity tolerance of organisms likely to be salt sensitive. The relative salinity tolerance to artificial seawater of macroinver-

tebrates from the Barwon River in Victoria, Australia, was assessed by measuring the 72-h lethal concentrations required to kill 50% of individuals (LC50). LC50 values ranged from an electrical conductivity of 5.5 to 76 $\mu\text{S cm}^{-1}$ (mean 31 $\mu\text{S cm}^{-1}$, $n = 57$) and followed a log-normal distribution. The most salt-sensitive groups tested were Baetidae (LC50 value range: 5.5–6.2 $\mu\text{S cm}^{-1}$), Chironomidae (10 $\mu\text{S cm}^{-1}$) and several soft-bodied non-arthropods (Oligochaeta, Gastropoda, Nematomorpha, Tricladida and Hirudinea; 9–14 $\mu\text{S cm}^{-1}$). Other groups, from least to most tolerant, were non-baetid Ephemeroptera (>12.6–15 $\mu\text{S cm}^{-1}$), Plecoptera (>12.6–>20 $\mu\text{S cm}^{-1}$), Trichoptera (9–>26 $\mu\text{S cm}^{-1}$), Corixidae (18–26 $\mu\text{S cm}^{-1}$), non-corixid Hemiptera (33–44 $\mu\text{S cm}^{-1}$), Coleoptera (19–54 $\mu\text{S cm}^{-1}$), Hydracarina (39 $\mu\text{S cm}^{-1}$) and Odonata (30–55 $\mu\text{S cm}^{-1}$), and macrocrustaceans (Decapoda, Isopoda and Amphipoda; 38–76 $\mu\text{S cm}^{-1}$)." [*Erythromma viridulum* was recorded at 5 new locations; second record of *E. najas*; in addition, records of *Brachytron pratense*, *Orthetrum cancellatum*, *Sympetrum fonscolombii*, and *Anax parthenope* are documented.] Address: Knill-Jones, S.A., 2 School Green Road, Freshwater, Isle of Wight, PO40 9AL, UK

5596. Koch, K.; Suhling, F. (2005): Do behavioural and life-history traits vary with mate-guarding intensity in libellulid odonates? *Canadian Journal of Zoology* 83 (12): 1631-1637. (in English). ["It has been demonstrated that in libellulid dragonflies the distribution of eggs during oviposition and the offspring size vary with the type of mate guarding during oviposition (non-contact guarding and contact guarding). In this study, we investigated the hypothesis that oviposition behaviour and life-history traits also differ between these two guarding types. Therefore, we studied oviposition behaviour and life-history traits in six species of a dragonfly assemblage of the Namib Desert. Among the oviposition behaviours, oviposition duration and number of pond changes differed significantly between the guarding types. Clutch size did not differ between the guarding types, whereas some offspring characters, namely egg width, temperature sum to hatch, and larval head width, differed between the guarding types. Eggs of tan-

dem species (those performing contact guarding) were larger, which might explain differences in all other offspring characters studied; bigger eggs need a lower temperature sum for egg development, result in bigger larvae, and have a faster growth rate, all traits that might be seen as an adaptation to temporary waters, which are major habitats of the tandem species. This observation is discussed in the light of different dispersal strategies between the species performing different guarding types." (Authors)] Address: Suhling F., Inst. Geoökologie, TU Braunschweig, Langer Kamp 19c, D-38102 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

5597. Kraft, P.G.; Wilson, R.S.; Franklin, C.E. (2005): Predator-mediated phenotypic plasticity in tadpoles of the striped marsh frog, *Limnodynastes peronii*. *Austral Ecology* 30(5): 558-563. (in English). ["We tested the phenotypic responses of larval striped marsh frogs (*Limnodynastes peronii*) to the odonate nymph predator, *Aeshna brevistyla*. When reared in the presence of dragonfly nymphs feeding upon conspecifics of *L. peronii* larvae the tadpoles showed a strong change in morphology. Morphological changes included an increase in total tail height, but also an unexpected marked change in head-body shape. In addition, we examined how tadpole development, as well as mass and length at metamorphosis, was affected by exposure to dragonfly nymphs. Larval development of *L. peronii* was strongly influenced by exposure to the predatory behaviour of dragonfly nymphs. Predator-induced tadpoles had significantly slower developmental rates than control larvae. Although metamorphs of non-exposed *L. peronii* were approximately 33% lighter than predator-exposed metamorphs and possessed lower jump distances, after adjusting for mass there was no difference in jump distance. The newly described morphological response may assist in more accurately relating morphological plasticity to fitness." 5598. Krisp, H.; Maier, G. (2005): Consumption of macroinvertebrates by invasive and native gammarids: a comparison. *J. Limnol.* 64(1): 55-59. (in English). ["The Ponto-Caspian gammarids *Dikerogammarus villosus* SOVINSKIJ and *Echinogammarus ischnus* STEBBING have invaded Central-European streams in the early 1990s. Declines in macroinvertebrates have been observed since the arrival of invasive species. To elucidate the predatory impact of gammarids on the macroinvertebrate community, we conducted laboratory experiments with macroinvertebrate prey taxa and native and invasive gammarids as predators. *Dikerogammarus villosus*, which is known to be a strong predator, consumed more and a broader range of prey than *E. ischnus* or the native gammarids, *Gammarus pulex* L. and *Gammarus roeseli* GERVAIS. *Echinogammarus ischnus* consumed a somewhat higher amount of prey organisms than *G. pulex* and a higher number and a broader range than *G. roeseli*. Adult *D. villosus* consumed up to 25 mg macroinvertebrate biomass (wet weight) per day which corresponds to approximately 1/3 of their own biomass. Chironomid larvae were preferred by all gammarids tested. Taking into account that gammarids density may surpass 1000 ind m^2 , our results suggest that the predatory behaviour of invasive gam-

marids, in particular of *D. villosus*, may have contributed to the decline of some macroinvertebrate taxa in some European streams." 5602. Leipelt, K.G.; Suhling, F. (2005): Larval biology, life cycle and habitat requirements of *Macromia splendens*, revisited (Odonata: Macromiidae). *International Journal of Odonatology* 8(1): 33-44. (in English). ["Information on larval biology of *Macromia splendens* was compiled and supplemented by hitherto unpublished data. Larvae inhabit mainly calm river stretches, sometimes artificial impoundments, and lentic margins of lotic sections. From the majority of records it is concluded that the larvae mainly dwell in sandy substrates in shallow water, which sometimes contains little leaf litter. Larvae occur in smaller numbers on substrates dominated by coarse detritus or on bedrock in deeper water. Larvae of *M. splendens* are able to burrow in sand, but such burrowing takes a long time, and sometimes parts of their body remain uncovered. Therefore, they are considered shallow burrowers. Based on head-width frequency distributions recorded at the Garden de Miallet, southern France, the species is believed to require two years per generation." (Authors)] Address: Leipelt, K.G., Institut für Geoökologie, Technische Universität Braunschweig, Langer Kamp 19c, D-38106 Braunschweig, Germany. E-Mail: k.leipelt@tu-bs.de

5611. Matsubara, K.; Tojo, S.; Suzuki, N. (2005): Age-related changes in flight muscle mass, lipid reserves and flight capacity during adult maturation in males of the territorial damselfly *Calopteryx atrata* (Odonata: Calopterygidae). *Zoological Science* 22: 587-592. (in English). ["In the territorial damselfly *Calopteryx atrata* Selys, length of the hindwing, the wing areas and the aspect ratio did not differ significantly among age classes during the pre-reproductive period, while the body mass of males increased about 2.5 times. This is due primarily to increase in mass of thorax and abdomen. The flight muscle mass accounted for the great part of the thorax mass, and began to increase from early in the pre-reproductive period and continued increasing until sexual maturation. The average flight muscle mass of sexually matured males was about 2.4 times of that of the youngest immature ones. On the other hand, the abdomen mass and total lipids increased remarkably in the latter half of the pre-reproductive period. The average total lipid content of mature males was about tenfold of that of the youngest immature ones. The maximum lift production per flesh body mass was positively correlated with the flight muscle mass and total lipid content. Such an increase in flight muscle mass and lipid reserves resulted in the increase of maximum lift force, and probably enhanced flight performance." 5614. McCauley, S. (2005): Differential dispersal propensities between individuals in male *Leucorrhinia intacta* (Odonata: Libellulidae). *International Journal of Odonatology* 8(2): 223-232. (in English). ["I compared males of *L. intacta* collected at two permanent and two previously dried ponds to assess whether males colonizing formerly dried sites differed in morphology or level of mite parasitism from males at permanent sites. Males colonizing sites that had local extinctions in the previous year due to pond drying were more similar to each other in body size and levels of parasitism than to males at sites which had not dried. Males at the two permanent sites differed significantly from each other in body size and these differences appear to reflect different local conditions. Comparison of males at two adjacent sites, one permanent and one which previously dried, found that the males colonizing the previously dried site were larger, in better condition, and had lower rates and numbers of mite parasites than males at the permanent site. Results from this study suggest two non-exclusive hypotheses about dispersal and colonization in this species. First, dispersal is condition dependent in this species with size and body condition positively correlated and mite parasitism negatively correlated with dispersal. Second, some permanent sites produce more males with the characteristics associated with dispersal than other potential source populations and therefore may contribute greater numbers of individuals to the dispersal pool." 5615. McCauley, S.J. (2005): Relationship between habitat distribution, growth rate, and plasticity in congeneric larval dragonflies. *Canadian Journal of Zoology* 83: 1128-1133. (in English). ["The relationship between habitat distribution, growth rate, and plasticity was examined in the larvae of three species of dragonfly in

the genus *Libellula* L., 1758. Growth rates were compared under three conditions: in the absence of predation risk, in the presence of sunfish (*Lepomis macrochirus* Rafinesque, 1819; Pisciformes: Centrarchidae), and in the presence of invertebrate predators. I assessed how the habitat distributions of the three species of dragonfly, specifically how commonly they occur with fish, were related to growth rates and to the level of growth plasticity under different levels of perceived predation risk. There was a negative relationship between growth rate and the frequency with which species coexist with sunfish. Growth-rate plasticity was limited and does not appear to be important in determining the ability of species to coexist with alternative top predator types. Only one species exhibited growth-rate plasticity, decreasing growth in response to the predator with which it most commonly coexists but not to the species which poses the greatest predation risk. A comparison of growth rates and activity levels in the presence and absence of these predators suggests that growth and activity level parallel each other in these species." (Author) Erratum: Relationship between habitat distribution, growth rate, and plasticity in congeneric larval dragonflies, S.J. McCauley: Ref.: Can. J. Zool. 83: 1128-1133 (2005). "In the above paper on pages 1130 and 1131, the last sentence of the captions to Figs. 2, 3, and 4 should have read Species are indicated as follows: *L. pulchella* (black), *L. luctuosa* (light gray), *L. incesta* (dark gray).]" Address: McCauley, Shannon, Department of Ecology and Evolutionary Biology, University of Michigan, 830 North University Avenue, Ann Arbor, MI 48109-1048, USA. 5637. Oertli, B.; Auderset Joye, D.; Castella, E.; Juge, R.; Lehmann, A.; Lachavanne, J.-B. (2005): PLO-CH: a standardized method for sampling and assessing the biodiversity in ponds. *Aquatic Conserv: Mar. Freshw. Ecosyst.* 15: 665-679. (in English). ["1. As ponds are now recognized as freshwater habitats clearly distinct from lakes and running waters, there is a need for standardized tools for assessing their ecological integrity and status, and particularly their biodiversity. 2. A standardized method was developed for sampling and assessing the species richness of ponds. Experiences accumulated in previous studies, together with data gathered from 80 Swiss ponds, provided the basis of the proposed method. 3. Five taxonomic groups were chosen as complementary representatives of pond inhabitants: aquatic plants, aquatic Gastropoda, aquatic Coleoptera, adult Odonata and Amphibia. 4. To sample aquatic flora, quadrats are located along transects perpendicular to the longest axis of the pond. The number of quadrats is calculated from a relationship with pond area. A nonparametric estimator (Jackknife-1) is used to estimate the true species richness from the observed richness. 5. Aquatic invertebrates (Gastropoda, Coleoptera) are collected with a hand net. Sampling is stratified within the dominant habitats. The number of samples is calculated from a relationship with pond area. As with the vegetation, the Jackknife-1 estimator is used to estimate the true species richness. 6. The species richness of adult Odonata is assessed using a standardized field survey method combining observations from early and late summer. The species richness is corrected with an abundance-based estimator (Chao1). The species richness of Amphibia is obtained from an exhaustive inventory. 7. For the assessment of biodiversity, species richness values derived from measurements are compared to values predicted for conditions that enable a high species richness. Generalized Additive Models are used to predict species richness from environmental predictors characterizing the pond. The ratio of measured richness to predicted richness allows the allocation of a quality status to each pond. Results are divided into five biological quality classes, as recommended in the EC Water Framework Directive (WFD).] Address: Oertli, B., Department of Nature Management, University of Applied Sciences of Western Switzerland, EIL HES de Lullier-Geneva, 150 route de Présinge, CH-1254 Jussy, Switzerland. 5638. Olberg, R.M.; Worthington, A.H.; Fox, J.L.; Bessette, C.E.; Loosemore, M.P. (2005): Prey size selection and distance estimation in foraging adult dragonflies. *Journal of Comparative Physiology A: Sensory, Neural, and Behavioral Physiology* 191(9): 791-797. (in English). ["To determine whether perching dragonflies visually assess the distance to potential prey items, we presented artificial prey, glass beads suspended from fine wires, to perching dragonflies in the field. We videotaped the responses of freely foraging dragonflies (*Libellula luctuosa* and *Sympetrum vicinum*) to beads ranging from 0.5 mm to 8 mm in diameter, recording whether or not the dragonflies took off after the beads, and if so, at what distance. Our results indicated that dragonflies were highly selective for bead size. Furthermore, the smaller *Sympetrum* preferred beads of smaller size and the larger *Libellula* preferred larger beads. Each species rejected beads as large or larger than their heads, even when the beads subtended the same visual angles as the smaller, attractive beads. Since bead size cannot be determined without referen-

ce to distance, we conclude that dragonflies are able to estimate the distance to potential prey items. The range over which they estimate distance is about 1 m for the larger *Libellula* and 70 cm for the smaller *Sympetrum*. The mechanism of distance estimation is unknown, but it probably includes both stereopsis and the motion parallax produced by head movements." (Authors)] Address: Olberg, R.M., Department of Biological Sciences, Union College, Schenectady, NY 12308, USA. Email: olberg@union.edu

["At a mountain rivulet in the Halkidiki peninsula, the semispecies *L. (viridis) viridis* and *L. (v.) parvidens* were shown to occur in syn-topic populations. This is the first secure record of *L. (v.) viridis* for Greece." (Authors)] Address: Olias, M., Humboldtstraße 29, D-09599 Freiberg, Germany. E-mail: markoolias@aol.com

5640. Opiel, S. (2005): Habitat associations of an Odonata community in a lower montane rainforest in Papua New Guinea. *International Journal of Odonatology* 8(2): 243-257. (in English). ["I sampled odonates in pristine lower montane rainforest in Papua New Guinea over several months, recording habitat characteristics for all encounters with adult odonates. Using ordination techniques such as cluster analysis and canonical correspondence analysis I then classified the odonate fauna into assemblages correlated with environmental factors. Within the 2.5 km² study area I found 61 species and a very high ratio of Zygoptera vs Anisoptera. Cluster analysis identified seven distinct assemblages associated with permanent rivers and creeks, temporary streams, puddles, or permanent standing water. Shading, water speed and water permanence were important factors distinguishing the assemblages. Anisoptera were absent from three habitats in the forest interior with temporary water sources. Species associated with temporary water sources and other microhabitats in the forest interior are presumed to be reliant on the high and aseasonal rainfall and the humid conditions of the rainforest. These species are likely to be very intolerant towards deforestation or other disturbance, and should be regarded as indicators for intact rainforest ecosystems. 40% of all species were considered as rare, and local endemism might be high, further stressing the importance of intact rainforest for the survival of many species of Odonata." (Author)] Address: Opiel, S., Department of Biology and Wildlife, 211 Irving 1, University of Alaska Fairbanks, Fairbanks, AK 99775, USA. E-mail: steffen.opiel@gmx.net

5641. Orr, A.G. (2005): Pocket Guide to Dragonflies of Peninsular Malaysia. Natural History Publications: VI + 127 pp. (in English). ["Dragonflies are among the most beautiful of insects. Peninsular Malaysia and Singapore are home to more than 230 species. [...] This book figures 98.7% of species known from Peninsular Malaysia and Singapore. For most, coloured drawings of the whole insect (omitting one pair of wings) are provided. Where necessary, coloured or monochrome drawings showing diagnostic features are also included. For some species, especially small Zygoptera, only detailed structures are figured, as the general resemblance between close species is strong. A wide range of larval types is also figured."] Address: Orr, A.G., Coope-

rative Research Centre for Tropical Rainforest Ecology and Management, Environmental Sciences, Griffith University, Nathan, Q 4111, Australia. E-mail: agorr@universal.net.au

5646. Pfau, H.-K. (2005): Structure, function and evolution of the 'glans' of the anisopteran vesica spermalis (Odonata). *International Journal of Odonatology* 8(2): 259-310. (in English). ["Comparative investigations of the distal part of the vesica spermalis ('glans') of the anisopteran male secondary copulatory apparatus reveal three different 'solutions' of combining the emptying-mechanism of the sperm-reservoir with a 'washing out' of sperm of the male predecessor. The responsible apparatus of the glans - actually driven by pressure-changes inside the erectile organ, which is a part of the whole vesica spermalis - is shortly apostrophized as 'two-way tap' (Gomphaeschnidae, Aeshnidae), pressure-suction pump (Austropetaliidae, Gomphidae, Petaluridae, Chlorogomphidae, Neopetaliidae, Cordulegastridae) and suction-pressure pump ('Corduliidae', Cordulephidae, Gomphomacromiidae, Synthemistidae, Libellulidae). The two types of sperm-pump are interpreted to effectuate an intensification of the sperm-jet and to serve as auxiliary devices in emptying the sperm-reservoir. On account of the opposite co-ordination of

extension and compression, the two types of sperm-pump are interpreted as alternative; no possibility could be detected to form evolutionary transitions without total loss of functions. This indicates two monophyletic groups: Petaluroidea and Libelluloidea. The phylogenetic relationships between these groups and the Gomphaeschnidae and Aeshnidae remained questionable. The different stages of evolution of the glans, which reflect phylogenetic splittings, are reconstructed. It is assumed that at the beginning a pre-gomphaeschnoid glans (or a gomphaeschnoid 'two-way tap' with tongue?) used two functional pores of ejaculation and scattered sperm on account of the erectile organ-coupled movements of the glans. Advanced glans-types of the Petaluroidea execute a three-phased delivery of sperm portions, the sperm transfer and displacement falling into the compression phase. Instead, in the Libelluloidea the sperm-transmission is two-phased and sperm-transfer and displacement are performed in the decompression phase." 5647. Picard, L.; Meurgey, F. (2005): Découverte d'une population de *Lestes macrostigma* (Eversmann, 1836) dans le département de Loire-Atlantique (Odonata, Zygoptera, Lestidae). *Martinia* 21(3): 122. (in French). [12/13-VI-2005, Guérande, France.] Address: Meurgey, F., Muséum d'Histoire naturelle de Nantes, 12, rue Voltaire, F-44000 Nantes, France. E-mail: Francois.Meurgey@mairie-nantes.fr

5648. Picard, L.; Meurgey, F. (2005): *Lestes macrostigma* (Eversmann, 1836) dans les marais saumâtres de Loire-Atlantique (Odonata, Zygoptera, Lestidae). *Martinia* 21(4): 139-150. (in French, with English summary). ["*L. macrostigma* is a rare Odonate in France (Dommanget, 1994). This species reproduces in salt-water marshes and more particularly in *Scirpus maritimus* formations. Although it is actually known in Vendée department, it was never found in Loire-Atlantique. Its presence is however suspected, and a deepened research in the department seemed necessary (Machet, 1990; Meurgey et al., 2000). This study was undertaken within the framework of a report of first year of Master research for Geography, heading "Terres et mers atlantique" (IGARUN, University of Nantes). The biogeographical aspect was preferred to the purely faunistic aspect. Thus, rather than to seek the species, the prospection was primarily centered on the research of the standard potential habitat, the formations with *Scirpus maritimus* (L)." 5649. Reinhardt, K. (2005): Sperm numbers, sperm storage duration and fertility limitation in the Odonata. *International Journal of Odonatology* 8(1): 45-58. (in English). ["The status of the Odonata as a model taxon for studying the evolution and diversity of reproductive behaviours is shown here to have declined relative to crickets and *Drosophila*. Very few available data on ejaculate size, the number of sperm stored by females and the duration of sperm storage reveal poor knowledge of these areas in the Odonata. Some observations tentatively suggest that species without direct sperm removal transfer larger numbers of sperm. Observations on the fertilization success of eggs laid by

sexually isolated females and the temporal variation in paternity were used to assess the longevity of the sperm population in the female. The generality of the claim that female odonates have full fecundity after a single mating can not be upheld. In addition, it is not clear whether any possible decrease in fertilization ability in isolated females is due to decreasing sperm quantity or quality. Costs and benefits of sperm longevity, sperm storage and multiple mating are discussed for both sexes. It is proposed that mating frequency and sperm storage duration may be linked in the Odonata. Testable predictions and ideas related to sperm biology are put forward in which odonates may be used to address general questions of evolutionary biology." 5651. Richter, O.; Söndgerath, D.; Suhling, F.; Braune E. (2005): Impact of climate change on population dynamics and temporal patterns of benthic assemblages of rivers. In: Zerger, A. & R.M. Argent (eds.) MODSIM 2005 International Congress on Modelling and Simulation. Modelling and Simulation Society of Australia and New Zealand. ISBN 0-9758400-1-0.: 531-537. (in English). ["Seasonal cycles of temperature, water regime and day length act as "Zeitgeber" (timer) triggering stage transitions in the life cycle of organisms provoking temporal patterns of communities at different levels of organization. Climate change is both affecting temperature forcings and water regime. Mathematical models are set up to investigate the mechanisms for the change of temporal patterns in aquatic invertebrates as brought about by climate change. Based on temperature data from rivers in Northern Germany a stochastic time series model was set up. This model combines a deterministic seasonal trend, a long term linear trend and an ARMA model for the stochastic component. The model is used to generate input temperature data for population dynamic models. Based on the scenarios for climate change of the IPCC, both an elevation of temperature and alterations of parameters of the stochastic process were taken into account. Biological populations are structured by age, size and stage. Two mathematical approaches were employed. For the simulation of long term time patterns in dragonfly populations, a projection matrix model is devised, i.e. the life cycle graph is mapped into a population matrix. The model yields emergence curves of larvae and adults. Figure 1 shows a simulation example of the projection matrix model. For the simulation of the time course of length density distributions of *Gammarus pulex*, a partial differential equation was employed. Transition probabilities and growth rates were devised as a function of temperature. The models are applied to the population dynamics of two common lotic invertebrates, *Gomphus vulgatissimus* and the amphipod *Gammarus pulex*. Most global change scenarios predict temperature rises especially in higher latitudes affecting the north-south temperature gradient. The model predicts that indications of global

change should imply both a shift of geographical extension of *G. vulgatissimus* and a shift to longer cycle lengths to higher latitudes. The emergence of temporal patterns and the synchronizing effect of temperature forcing are studied in a model system comprising a predator and a prey population which are under the control of different timers. If the development of the prey is controlled by day length and temperature and the development of the predator only by temperature a desynchronisation occurs." (Authors)] Address: Suhling F., Inst. 5653. Rudisill, T.; Bass, D. (2005): Macroinvertebrate community structure and physicochemical conditions of the Roman Nose spring system. Proc. Okla. Acad. Sci. 85: 33-42. (in English). ["Roman Nose State Park is located approximately 12 km north of Watonga, Oklahoma, in Blaine County in the Gypsum Hills of the Central High Plains ecoregion. Aquatic macroinvertebrate samples were collected and physical-chemical conditions were measured from the park's freshwater spring system during alternate months from January 2002 through November 2002. Water quality parameters measured included water temperature, dissolved oxygen, pH, alkalinity, turbidity, conductivity, nitrogen ammonia, nitrite, nitrogen, nitrate nitrogen, and phosphate. Water quality was always within acceptable parameters to support aquatic life during this period. However, possible contamination from agricultural activities and increasing human usage negatively impacted water quality. A total of 21,268 individuals from 64 taxa were collected and identified from three springs. Little Spring was the most populated both in the overall number of taxa (47) and the number of individuals (10,689). Middle Spring had significant differences in the number of individuals in the upper and lower sites. The month of November had both the highest number of individuals and taxa. Species diversity values were generally low: the values were always under 2.00 and usually increased at the lower sites. Significant differences in species diversity values were found over time in Little Spring and Middle Spring. Species similarity values were over 0.60 between springs for the combined collection times and over 0.45 between upper and lower sites of each spring for the collection times. Total species richness ranged from 37 to 47. Aquatic insects were the dominant group of invertebrates encountered throughout the study and included dipterans, ephemeropterans, odonates, coloeopterans, hemipterans, trichopterans, and collembolas. Continued work on this spring system is important to further inventory the invertebrates present and to determine if any patterns exist throughout the years, as well as to monitor the water quality trends of the springs." - 5654.** Russell, R.W. (2005): Interactions between migrating birds and offshore oil and gas platforms in the northern Gulf of Mexico. Final Report. U.S. Dept. of the Interior, Minerals Management Service, Gulf of Mexico OCS Region, New Orleans, LA. OCS Study MMS 2005-009: 348 pp- (in English). ["The Gulf of Mexico is a major ecological barrier confronted by hundreds of millions of migrating birds each spring and fall. Trans-Gulf migrations evolved in the absence of natural islands that could serve as stopover sites; thus, the installation of an artificial archipelago of nearly 4000 oil and gas production platforms in the northern Gulf over the past five decades has introduced a novel and potentially important component into the en route environment of trans-Gulf bird migrants. From 1998-2000, my research group at LSU studied the ecology of trans-Gulf migration and the influence of platforms on migrants using a team of field biologists stationed on an array of platforms across the northern Gulf. [...] The objectives of this study were to quantify spring and fall trans-Gulf migrations and to evaluate the influence of offshore platforms on trans-Gulf migrating birds. [...]"] (Authors) The paper also contains references to Odonata and collecting data on Odonata (see tab. 13.4) observed in the framework of the ornithological study. - 5663.** Srivastava, D.S.; Melnychuk, M.C.; Ngai, J.T. (2005): Landscape variation in the larval density of a bromeliad-dwelling zygopteran, *Mecistogaster modesta* (Odonata: Pseudostigmatidae). *International Journal of Odonatology* 8(1): 67-79. (in English). ["In the premon-tane rain forests of northwest Costa Rica, patches of secondary forest can contain high densities of large *Vriesea* spp. bromeliads. Such patches contain an average of $6,470 \pm 1,080$ (s.e.) larvae ha⁻¹ of the bromeli-

ad-dwelling pseudostigmatid, *M. modesta*, ca 36x higher than larval densities that we previously reported for adjacent primary forest. Using a new method to partition landscape variation in populations, we show that secondary forest has higher larval densities than primary forest because of higher bromeliad abundance (13% of effect), greater bromeliad size (33%), and greater larval abundance in bromeliads of similar size (54%). The last effect reflects additional effects of forest type after accounting for differences in the quantity of larval habitat. We use surveys of prey communities in bromeliads and adult densities in the two forest types to show that these additional effects of forest type are more likely due to adult behaviour, not larval resource limitation. This study demonstrates that certain areas of secondary forest can be disproportionately important for *M. modesta* populations, and has implications for estimating effects of forest loss and conversion on *M. modesta*." 5664. Subramanian, K.A. (2005): Dragonflies and Damselflies of Peninsular India - A Field Guide. Project Lifescape. Indian Academy of Sciences. Bangalore: 119 pp- (in English). ["The Indian subcontinent is one of the biologically richest regions of the world. Two global biodiversity hot spots, namely the eastern Himalayas and the Western Ghats, are in this region. Another biologically rich region, Sri Lanka, is just to the south of the subcontinent. The subcontinent is rich in odonates (damselflies and dragonflies); about 500 species are known. The dragonflies of the region are taxonomically well described thanks to the monumental work of Fraser. However, the natural history and distribution of most of the species is barely known. This lacuna is largely due to the lack of user-friendly field guides for amateur naturalists and students. As an initiative to generate interest in dragonflies among naturalists and students, Indian Academy of Sciences is publishing a field guide on the odonates of Peninsular India. The book is being published as part of Project Lifescape of the Academy. This project aims at producing user-friendly field guides and other resources to encourage field-based biology research among students. The book is divided into three parts. The first part gives a detailed account of the natural history of Odonata. The second part gives keys for the identification of odonate families for larval and adult stages. The third section gives species accounts for 26 damselflies and 34 dragonflies of Peninsular India. The book is lavishly illustrated with colour photographs or specimen scans of all the species described. In addition, the book also provides a checklist of odonates for the region (178 species) and a glossary of technical terms. The novelty of the book is provision of common English names of all species. The first edition of this book is entirely downloadable freely from this website." (Editor) The book is downloadable in three parts, each a PDF file: <http://www.ias.ac.in/initiat/scied/lifescape/odonates.html>].

5665. Suh, A.N.; Samways, M.J. (2005): Significance of temporal changes when designing a reservoir for conservation of dragonfly diversity. *Biodiversity and Conservation* 14(1): 165-178. (in English). ["While there has been much focus in biodiversity conservation that transcends place, few studies transcend time. Yet an appreciation of vegetational and hydrological successi-

on is essential for maintaining a habitat that has been created with the aim of conserving a particular group of organisms. This is a study of changes in a dragonfly assemblage over a period of 13 years at a biodiversity-rich, southern hemisphere reservoir. A total of 30 dragonfly species were recorded in this study, compared to 12 species before the reservoir was constructed in 1988, and 26 species in 1993, with 25 species resident in both 1993 and 2001. Two of these are local endemics. One other endemic was lost to succession in 1993 but reappeared in 2001. Three other species never reappeared after succession in 1993, yet six other species appeared after this date. Multivariate analyses identified structural and compositional vegetation, especially marginal forest, percentage vegetation cover, percentage shade, as the most important environmental variables determining dragonfly species composition. Other important environmental variables were grasses of tall, medium and short height categories, submerged vegetation, water flow and amount of open water. Not surprisingly, successional changes in vegetation physiognomy and in water conditions significantly increased Odonata species richness and diversity over the years. More importantly, the study shows that to maintain both high species richness, including endemics, it is essential to maintain a variety of biotopes using selective management of the marginal vegetation without allowing succession to proceed to a point where overgrowth of the bank and silting of the bottom begin to impoverish the fauna." 5666. Svensson, E.I.; Abbott, J. (2005): Evolutionary dynamics and population biology of a polymorphic insect. *J. Evol. Biol.* 18: 1503-1514. (in English). ["Conspicuous heritable polymorphisms are useful to address the question if morph frequencies are stable or whether they fluctuate between generations. Ecological geneticists have studied colour polymorphisms in the past, but there are few long-term studies of genetic dynamics across multiple generations. We studied morph-frequency dynamics and female fecundity in the trimorphic blue-tailed damselfly (*Ischnura elegans*). The morphs include a male-coloured (androchrome) type of female, which is thought to be maintained by frequency-dependent sexual conflict. Morph frequencies changed significantly between years across all populations. There was evidence for directional frequency change since androchrome females increased in 9 of 10 populations across a 4-year period. There was heterogeneity between populations in their evolutionary trajectories, partly caused by population age: androchrome frequencies were initially high in young populations but gradually decreased and approached the level of old populations. We discuss the possible causes of morph-frequency fluctuations, and the role of morph-specific fecundity, dispersal and other forces influencing evolutionary dynamics in this system." (Authors)] Address: Svensson, E., Section for Animal Ecology, Ecology Building, Lund University, SE-223 62 Lund, Sweden. E-mail: erik.svensson@zoekol.lu.se

5667. Svensson, E.I.; Abbott, J.; Härdling, R. (2005): Female polymorphism, frequency dependence, and rapid evolutionary dynamics in natural populations. *The American Naturalist* 165(5): 567-576. (in English). ["Rapid evolutionary change over a few generations has

been documented in natural populations. Such changes are observed as organisms invade new environments, and they are often triggered by changed interspecific interactions, such as differences in predation regimes. However, in spite of increased recognition of antagonistic male-female mating interactions, there is very limited evidence that such intraspecific interactions could cause rapid evolutionary dynamics in nature. This is because ecological and longitudinal data from natural populations have been lacking. Here we show that in a color-polymorphic damselfly species, male-female mating interactions lead to rapid evolutionary change in morph frequencies between generations. Field data and computer simulations indicate that these changes are driven by sexual conflict, in which morph fecundities are negatively affected by frequency- and density-dependent male mating harassment. These frequency-dependent processes prevent population divergence by maintaining a female polymorphism in most populations. Although these results contrast with the traditional view of how sexual conflict enhances the rate of population divergence, they are consistent with a recent theoretical model of how females may form discrete genetic clusters in response to male mating harassment." (Authors)] Address: Svensson, E., Section for Animal Ecology, Ecology Building, Lund University, SE-223 62 Lund, Sweden. E-mail: erik.svensson@zoekol.lu.se

5668. Tarr, T.L.; Baber, M.J.; Babbitt, K.J. (2005): Macroinvertebrate community structure across a wetland hydroperiod gradient in southern New Hampshire, USA. *Wetlands Ecology and Management* 13(3): 321-334. (in English). ["We conducted a field study to examine the influence of hydroperiod and concomitant changes in abiotic (wetland size, pH, conductivity, dissolved oxygen and water temperature) and biotic (predatory fish presence) characteristics on macroinvertebrate communities in isolated wetlands in southern New Hampshire. Invertebrates were sampled using dipnet sweeps in 42 wetlands with short (<4 months), intermediate (4–11 months) or long (permanent) hydroperiods in 1998 and 1999. We found that invertebrate genera richness, and to a lesser degree abundance, increased linearly along the hydrological gradient, and in response to temperature and dissolved oxygen. Relative abundance of genera also differed markedly with respect to hydroperiod. Most notably, invertebrate communities changed from Acilius-dominated communities to Notonecta-dominated communities. Invertebrate relative abundances in permanent wetlands also differed with respect to the occurrence of predatory fish. Some genera (e.g., Libellula, and Dytiscus) were more likely to occur in permanent wetlands without fish, whereas other genera (e.g., Buena, and Basiaesha) were more likely to occur in wetlands with predatory fish. Because aquatic invertebrate communities differed markedly with respect to wetland hydroperiod, and in relation to the occurrence of predatory fish, it is essential to retain a diversity of wetlands in the landscape to ensure the long-term persistence of aquatic invertebrate biodiversity." 5669. Teixeira, R.L.; Roldi, K.; Vrcibradic, D. (2005): Ecological comparisons between the sympatric lizards *Enyalius bilineatus* and *Enyalius brasiliensis* (Iguanidae, Leiosaurinae) from an Atlantic rain-forest area in southeastern Brazil. *Journal of Herpetology* 39(3): 504-509. (in English). ["Aspects of the ecology of the semi-

arboreal lizards *E. bilineatus* and *E. brasiliensis* were studied in a montane Atlantic forest region of Espírito Santo State, southeastern Brazil. Individuals of *E. bilineatus* were collected mainly in a coffee plantation, whereas *E. brasiliensis* was found only in the forest proper. *Enyalius brasiliensis* was significantly larger (up to 106 mm snout vent length, SVL) than *E. bilineatus* (up to 90 mm SVL). Both species were sexually dimorphic in body size, with females larger than males. The two species consumed a broad spectrum of prey but differed quantitatively in their diet composition. Ants and orthopterans dominated the diet of *E. bilineatus*, whereas *E. brasiliensis* preyed mainly on cockroaches and caterpillars. Clutch size of *E. bilineatus* varied from 2–6 (mean 5.44) and that of *E. brasiliensis* from 8–14 (mean 5.115). Ecological differences between the two species may result in differential susceptibilities to habitat perturbation, with *E. bilineatus* being more tolerant of disturbed areas and perhaps even benefitting from anthropic action, unlike the forest-dependent *E. brasiliensis*." (Authors) In table 2, one case of odonate prey in *E. bilineatus* is documented.] Address: Teixeira, R.L., Museu de Biologia Prof. Mello Leitao, Av. 5679. Vamosi, S.M. (2005): On the role of enemies in divergence and diversification of prey: a review and synthesis. *Can. J. Zool.* 83: 894-910. (in English, with French summary). ["Understanding the contribution of ecological interactions to the origin and maintenance of diversity is a fundamental challenge for ecologists and evolutionary biologists, and one that is currently receiving a great deal of attention. Natural enemies (e.g., predators, parasites, and herbivores) are ubiquitous in food webs and are predicted to have significant impacts on phenotypic diversity and on speciation, and extinction rates of their prey. Spurred by the development of a theoretical framework beginning in the late 1970s, there is now a growing body of literature that addresses the effects of enemy-prey interactions on the evolution of prey. A number of theoretical models predict that enemies can produce phenotypic divergence between closely related species, even in the absence of interspecific competition for resources. Effects on diversification of prey are more variable, and enemies may either en-

hance or depress speciation and extinction rates of their prey. Empirical evidences from a number of study systems, notably those involving predators and prey in aquatic environments and interactions between insects and flowering plants, confirm both predictions. There is now considerable evidence for the role of enemies, especially those that are size-selective or use visual cues when identifying suitable prey, on phenotypic divergence of sympatric and allopatric taxa. Enemies may spur diversification rates in certain groups under some circumstances, and hinder diversification rates in other cases. I suggest that further research should focus on the role of enemies in diversification of prey, with significant insights likely to be the product of applying traditional experimental approaches and emerging comparative phylogenetic methods." (Author) The paper compiles the results of Mark McPeck's studies related to the genus *Enallagma* in North America.] Address: Vamosi, S.M., Dept Biological Sciences, University of Calgary, 2500 University Drive NW, Calgary AB T2N 1N4, Canada. 5680. van Kleef, J.; James, A.C.; Stange, G. (2005): A spatiotemporal white noise analysis of photoreceptor responses to UV and green light in the dragonfly median ocellus. *J. Gen. Physiol.* 126(5): 481-497. (in English). ["Adult dragonflies augment their compound eyes with three simple eyes known as the dorsal ocelli. While the ocellar system is known to mediate stabilizing head reflexes during flight, the ability of the ocellar retina to dynamically resolve the environment is unknown. For the first time, we directly measured the angular sensitivities of the photoreceptors of the dragonfly median (middle) ocellus. We performed a second-order Wiener Kernel analysis of intracellular recordings of light-adapted photoreceptors. These were stimulated with one-dimensional horizontal or vertical patterns of concurrent UV and green light with different contrast levels and at different ambient temperatures. The photoreceptors were found to have anisotropic receptive fields with vertical and horizontal acceptance angles of 15° and 28°, respectively. The first-order (linear) temporal kernels contained significant undershoots whose amplitudes are invariant under changes in the contrast of the stimulus but significantly reduced at higher temperatures. The second-order kernels showed evidence of two distinct nonlinear components: a fast acting self-facilitation, which is dominant in the UV, followed by delayed self- and cross-inhibition of UV and green light responses. No facilitatory interactions between the UV and green light were found, indicating that facilitation of the green and UV responses occurs in isolated compartments. Inhibition between UV and green stimuli was present, indicating that inhibition occurs at a common point in the UV and green response pathways. We present a nonlinear cascade model (NLN) with initial stages consisting of separate UV and green pathways. Each pathway contains a fast facilitating nonlinearity coupled to a linear response. The linear response is described by an extended log-normal model, accounting for the phasic component. The final nonlinearity is composed of self-inhibition in the UV and green pathways and inhibition between these pathways. The model can largely predict the response of the photoreceptors to UV and green light." - 5684.** Wang, J.-K.; Sun, M. (2005): A computational study of the aerodynamics and forewing-hindwing interaction of a model dragonfly in forward flight. *The Journal of Experimental Biology* 208: 3785-3804. (in English). ["The aerodynamics and forewing-hindwing interaction of a model dragonfly in forward flight are studied, using the method of numerically solving the Navier-Stokes equations. Available morphological and stroke-kinematic parameters of dragonfly (*Aeshna juncea*) are used for the model dragonfly. Six advance ratios (J); ranging from 0 to 0.75) and, at each J , four forewing-hindwing phase angle differences (δ ; 180°, 90°, 60° and 0°) are considered. The mean vertical force and thrust are made to balance the weight and body-drag, respectively, by adjusting the angles of attack of the wings, so that the flight could better approximate the real flight. At hovering and low J ($J=0, 0.15$), the model dragonfly uses separated flows or leading-edge vortices (LEV) on both the fore- and hindwing downstrokes; at medium J ($J=0.30, 0.45$), it uses the LEV on the forewing downstroke and attached flow on the hindwing downstroke; at high J ($J=0.6, 0.75$), it uses attached flows on both fore- and hindwing downstrokes. (The upstrokes are very lightly loaded and, in general, the flows are attached.) At a given J , at $\delta=180^\circ$, there are two vertical force peaks in a cycle, one in the first half of the cycle, produced mainly by the hindwing downstroke, and the other in the second half of the cycle, produced mainly by the forewing downstroke; at $\delta=90^\circ, 60^\circ$ and 0° , the two force peaks merge into one peak. The vertical force is close to the resultant aerodynamic force [because the thrust (or bodydrag) is much smaller than vertical force (or the weight)]. 55-65% of the vertical force is contributed by the drag of the wings. The forewing-hindwing interaction is detrimental to the vertical force (and resultant force) generation. At hovering, the interaction reduces the mean vertical force (and resultant force) by 8-15%, compared with that without interaction; as J increases, the reduction generally decreases (e.g. at $J=0.6$ and $\delta=90^\circ$, it becomes 1.6%). A possible reason for the detrimental interaction is as follows: each of the wings produces a mean vertical force coefficient close to half that needed for weight support, and a downward flow is generated in producing the vertical force; thus, in general, a wing moves in the downwash-velocity field induced by the other wing, reducing its aerodynamic forces.] Address: Sun, M. 5689. Wilson, R.S.; Kraft, P.G.; Van Damme, R. (2005): Predator-specific changes in the morphology and swimming performance of larval *Rana lessonae*. *Functional Ecology* 19(2): 238-244. (in English). ["1. We investigated the morphological responses of larval *Rana lessonae* to the presence of two predators with substantially different prey-detection and capture techniques; larval dragonflies (*Aeshna cyanea*) and the Pumpkinseed Sunfish (*Lepomis gibbosus*). 2. We also examined the functional implications of any predator-induced morphological variation on their swimming ability by assessing performance during the initial stages of a startle response. 3. We found the morphological responses of larval *R. lessonae* were dependent on the specific predator present. Tadpoles raised in the presence of dragonfly larvae preying upon conspecific tadpoles developed total tail heights 5.4% deeper and tail muscles 4.7% shallower than tadpoles raised in a non-predator environment, while tadpoles raised with sunfish possessed tails 2% shallower and tail muscles 2.5% higher than non-predator-exposed tadpoles. 4. Predator-induced morphological variation also significantly influenced swimming performance. Tadpoles raised with sunfish possessed swimming speeds 9.5 and 14.6% higher than non- and dragonfly predator groups, respectively. 5. Thus, the expression of these alternative predator-morphs leads to a functional trade-off in performance between the different environments." 5690. Worthington, A.; Haggert, K.; Loosemore, M. (2005): Seasonality of prey size selection in adult *Sympetrum vicinum* (Odonata: Libellulidae). *International Journal of Odonatology* 8(1): 169-176. (in English). ["*S. vicinum* is a sit and wait predator, which takes off and pursues small flying insects during its long flying season (July to November). We investigated whether foraging individuals become less discriminating regarding prey size selection during the fall season because the changeable fall weather has an impact on the prey population. To investigate the seasonality of prey size se-

lection, we videotaped prey capture flights of females and teneral males chasing artificial prey of known sizes (1-8 mm beads) from September to October in 2002 and 2003 in upstate New York, USA. We calculated the probability of pursuit for each bead size and measured the distance of the bead at the time of takeoff (213 presentations in 2002 and 383 presentations in 2003). We found that 2 mm beads had the highest probability of eliciting takeoff in both years and throughout the study periods. Weather conditions, especially the early first hard frost in 2003, reduced prey abundance. *S. vicinum* opportunistically pursued a wide variety of prey sizes. The probability of pursuit of larger beads (3-5 mm) increased in late fall, but *S. vicinum* never pursued 8 mm beads. The mechanism of distance perception and therefore size detection is not known in Odonata and yet *S. vicinum* in this study is showing a preference for 2 mm beads no matter what the distance of the bead from the perch." (Authors)] Address: Worthington, Andrea, Department of Biology, Siena College, Loudonville, NY 12211, USA. E-mail: Worthington@siena.edu

5696. Abbott, J. (2006): Dragonflies and Damselflies (Odonata) of Texas, Volume I. Lulu. Press. ISBN: 1-4116-6525-2: 328 pp. (in English). [Damselflies and Dragonflies (Odonata) of Texas is an indispensable reference to the 223 species of odonates distributed throughout the Lone Star state. Included in this volume are detailed species distribution and seasonality information arranged so that users can quickly and easily search by scientific name, county name, or flight season. A variety of articles are also included on the natural history, collection and preservation, and diversity of Texas odonates. Whether using the book to find new species records in the deserts of west Texas or perusing articles in the comfort of your home, this volume is an essential guide for both life-long and budding odonatologists alike. The following contributions are written by John Abbott: "Collection Guidelines for the Odonata Survey of Texas", "The Dragonfly Society of the Americas Guidelines for Collecting", "Specific Collecting & Preservation Instructions", "Guidelines for Field Notes & Data Recording", "History of Odonata Study in the South-central U.S.", "Odonata Field Guides, Resources, Societies, & Suppliers", "Life History & Morphology of Odonata", "Seasonality of Odonata in Texas", "Statistical Summary of Odonata in Texas", "Abundance & Distribution of Texas Odonata", "Diversity of Texas Odonata by County", "Checklist of Dragonflies & Damselflies

of Texas", "Dragonflies & Damselflies of Texas Listed by County", "Distribution Maps of Texas Odonata", "Glossary of Terms Relating to Odonata", and "Index to Maps". The following papers are from different authors: "OdonataCentral.com: A model for the Web-based Delivery of Natural History Information and Citizen Science (J.C. Abbott & D. Broglie)", "Hornsby Bend - It's Not Just Birds (G.W. Lasley)", "Turquoise-tipped Darner (*Rhionaeschna psilus*): Backyard Surprise, D. Hardy)", "The Odonata of Kerr County and the Guadalupe River System of Texas (T. Gallucci)". This competently written book is a solid basement for all future odonatological study in Texas, USA. The missing information - basically a bibliography on the Texan Odonata - will come soon, I am quite sure. (Martin Schorr)] Address: Abbott, J.C., Patterson Labs 219, School of Bio. 5698. Amjad, H. (2006): Dragonflies of West Virginia. Lulu-Press. ISBN: 978-1-4116-8145-3: 163 pp. (in English). [The dragonflies of West Virginia called a "Festschrift dedicated to Carl Cook" is less a book than a collection of brief notes on dragonfly biology and other dragonfly affairs, and pictures of the species in any quality available. Compared with alternative treatises on the odonate state fauna in USA, this books lacks in nearly everything what makes a usefull contribution to odonatology: no maps, no checklists, no competent bibliography, many insufficient pictures and colour photos etc. I am very sorry, but the book on the West Virginian Odonata first has to be written. This attempt is not more than a very first draft to a solid regional fauna. (Martin Schorr) More usefull is the e-book from the same author: <http://www.wvdragonfly.us/wvdragonfly.pdf>] Address: <http://books.lulu.com/content/218176>

5699. Baird, I.R.C.; Ireland, C. (2006): Upright emergence in *Petalura gigantea* (Odonata: Petaluridae). *International Journal of Odonatology* 9(1): 45-50. (in English). ["During the 2003/2004 summer flying season, upright emergence of a male *Petalura gigantea* was observed and photographed in the Blue Mountains of New South Wales during an extensive survey for the species. This observation differed from the only previous illustration of a hanging back emergence style, and is compared with observations of emergence style for the other Petaluridae. While the earliest accounts illustrated or suggested a hanging back emergence style in *P. gigantea*, *Uropetala chiltoni* and *Tanypteryx hageni*, upright emergence has subsequently been documented in *T. pryeri*, *U. carovei* and *Tachopteryx thoreyi*. The observation of upright emergence in *P. gigantea* reported in this paper further suggests that upright emergence may be the norm for all petalurids. However, additional observations will be necessary to resolve the question of emergence style within the Petaluridae."]

5700. Beckemeyer, R.J. (2006): Hind wing fragments of Meganeuropsis (Protodonata: Meganeuridae) from the Lower Permian of Noble County, Oklahoma. *Bulletin of American Odonatology* 9(3/4): 85-89. (in English). ["Meganeurid Protodonata of the genera Meganeura (Carboniferous: Commentry, France) and Meganeuropsis (Permian: Wellington Formation, USA) are the largest insects known to have ever flown, with wing lengths equal to or greater than 300 mm. Specimens of such wings are relatively rare. A fragment of a 38 mm by 75 mm portion of the anal region of the hind wing of a Meganeuropsis griffenfly from the Wellington Formation of Noble County, Oklahoma, is figured and described." 5702. Brodin, T.; Mikolajewski, D.J.; Johansson, F. (2006): Behavioural and life history effects of predator diet cues during ontogeny in damselfly larvae. *Oecologia* 148(1): 162-169. (in English). ["A central issue in predator-prey interactions is how predator associated chemical cues affect the behaviour and life history of prey. In this study, we investigated how growth and behaviour during ontogeny of a damselfly larva (*Coenagrion hastulatum*) in high and low food environments was affected by the diet of a predator (*Aeshna juncea*). We reared larvae in three different predator treatments; no predator, predator feeding on conspecifics and predator feeding on heterospecifics. We found that, independent of food availability, larvae displayed the strongest anti-predator behaviours where predators consumed prey conspecifics. Interestingly, the effect of predator diet on prey activity was only present early in ontogeny, whereas late in ontogeny no difference in prey activity between treatments could be found. In contrast, the significant effect of predator diet on prey spatial distribution was unaffected by time. Larval size was affected by both food availability and predator diet. Larvae reared in the high food treatment grew larger than larvae in the low food treatment. Mean larval size was smallest in the treatment where predators consumed prey conspecifics, intermediate where predators consumed heterospecifics and largest in the treatment without predators. The difference in mean larval size between treatments is probably an effect of reduced larval feeding, due to behavioural responses to chemical cues associated with predator diet. Our study suggests that anti-predator responses can be specific for certain stages in ontogeny. This finding shows the importance of considering where in its ontogeny a study organism is before results are interpreted and generalisations are made. Furthermore, this finding accentuates the importance of long-term studies and may have implications for how results generated by short-term studies can be used." (Authors)] Address: Brodin, T.,

5703. Buczyński, P.; Buczyńska, E.; Kasjaniuk, A. (2006): Dragonflies (Odonata) and caddisflies (Trichoptera) of the nature reserve "Magazyn" (Western Polesie). *Parki nar. Rez. Przyr.* 24(2005): 117-130. (in Polish, with English summary). ["The nature reserve "Magazyn", with valuable aquatic and peat bog vegetation, protects the belt of marshes on the edge of the Sobibór Forests and the River Bug valley. Thirty three dragonfly species and sixteen caddisfly species were recorded within the reserve in the years 1999, 2002 and 2003. The most important habitat for the development of aquatic insects in the reserve was the permanent dystrophic water body dammed by the dike. The fauna of this habitat was similar to the fauna of peat bog lakes. The remaining habitats were of astatic character and they dried out in dry summers. The species richness of dragonfly fauna (46% of Polish fauna and 49% of the Lublin region) was associated with the following facts: many species were recognized as highly acid tolerant and the populations of the reserve were supplied with specimens from species-rich surface water that surrounds the area. The poverty of caddisfly fauna (6% of Polish fauna and 15% of the Lublin region one) results probably from specific water chemistry and poor variation in habitats. The nature reserve "Magazyn", important for the protection of flora and some groups of animals (leeches, aquatic beetles, fish, reptiles), has small significance for the protection of the examined insect groups. Nevertheless, it may play the role of an important component of the water network of middle-eastern Poland with well preserved types of marshy and aquatic habitats." 5704. Corbet, P.S.; Suhling, F.; Soendgerath, D. (2006): Voltinism of Odonata: a review. *International Journal of Odonatology* 9(1): 1-44. (in English). ["We classified 542 records of voltinism for 275 species and subspecies of Odonata according to three variables: geographical latitude, systematic position and habitat type. We sorted records according to voltinism – categories being three or more generations per year, two generations per year, one generation per year, one generation in two years and one generation in three or more years. We sought to correlate the voltinism of each record with latitude of the study site, thus demonstrating an overall negative correlation between voltinism and latitude. After allowing for phylogenetic similarity a negative correlation remains, although it decreases in strength after removal of taxonomic correlates, mainly between family and genus levels. A negative correlation exists at the species level within most families, with the exception of Lestidae. In genera for which we lacked data for latitudes 0-31°N/S no significant correlation between latitude and voltinism exists. In temporary waters most species complete at least one generation per year; most species in lentic perennial waters complete one generation or fewer; and the majority of species in lotic waters complete half a generation or less. We discuss the roles of exogenous and endogenous factors in influencing voltinism and identify those that may be affecting the correlation that the data reveal. We suggest projects that could improve un-

derstanding of voltinism in the context of seasonal regulation and the main types of odonate life cycle so far recognised." (Authors)] Address: Corbet, P.S., Crean Mill, St. Buryan, Cornwall TR19 6HA, UK. E-mail: mail@pcorbet.vispa.com

5705. Diaz de Pascual, A.; Guerrero, C. (2006): Diet of *Rana catesbeiana* (Shaw 1802: Ranidae: Amphibia) introduced into the Andes of Venezuela. 2006 Joint Meeting of Ichthyologists and Herpetologists July 12-17, 2006 : (in English). [Verbatim: Considering the predation of this invasive frog species on native amphibian population, we identified prey items in the diet of *Rana catesbeiana* in the Andes of Merida. During March to June of 2001, frogs were collected in a private Lagoon located at 3300 m of altitude by hand, nets and air-rifle. In total 337 stomach contents were examined. 474 prey items were found in their stomach content. This frog was deliberately introduced into the Andes of Merida, Venezuela in the decade of 1990 s without knowing up till now the purpose of its introduction. By the time of the preparation of this report, dense populations of the species occupy more than 20 freshwater habitats such as ponds, marshes, ditches and irrigation canals between an altitude of 1800 to 2600 m. Their population is spreading rapidly occupying all aquatic habitats available within a ratio of 4.3 Km from the dispersion center (Diaz de Pascual and Chacon-Ortiz, 2002). Individuals of this species were examined for the presence of *Batrachochytrium dendrobatidis* (Chytridomycosis) and 96% of the recently metamorphosed individuals were positive for the fungal disease (Hanselman R. et al, 2004). Frogs were dissected to get their stomachs and place the gut content on formalin 10%. They were divided in four age categories based on size as: Recently metamorphosed, juveniles, sub-adults and adults. We presented the data in terms of percentage of preys per each group category. The bullfrog diet varied among age groups: Stomachs of Recently metamorphosed individuals contained mainly Hymenoptera and Odonata, made up the proportion of 29.03% each, Diptera larvae (20.96%), Coleoptera unidentified (9.67%) and snails from Planorbidae family (8.06%). Juvenile diet consisted of Coleoptera (28.29%), Hymenoptera (22.36%), Odonata (9.21%), Homoptera (9.87%) and fish (5.26%). Sub-adult diet was composed of Coleoptera (34.26%), Hymenoptera (13.48%), Odonata (12.35%), Diptera (6.18%) and bullfrog juveniles (2.24%) and fish (6.18%). Adult bullfrogs contained juvenile and tadpoles of its own species (31.70%), fish from the species *Poecilia reticulata* (7.32%), Coleoptera (17.76%) and Odonata (14.63%). Diet differences] Address: Diaz de Pascual, Amelia, Universidad de Los Andes, Dept. Biología, Merida, Venezuela, 5101

5706. Dijkstra, K.-D.; Vick, G.S. (2006): Inflation by venation and the bankruptcy of traditional genera: the case of *Neodythemis* and *Micromacromia*, with keys to the continental African species and the description of two new *Neodythemis* species from the Albertine Rift (Odonata: Libellulidae). *International Journal of Odonatology* 9(1): 51-70. (in English). ["The Afrotropical 'neodythemistine' genera are an example of venation-biased classification in Odonata. This example is used to argue the bankruptcy of some traditional classifications in the order, particularly in the Libellulidae, and the need to apply alternative characters to define genera. Two groups of Afrotropical 'neodythemistines' are identified by male and female genitalia, supported by colour

patterns, and these correspond to the only two genera which we retain: *Micromacromia* and *Neodythemis*. A new classification is proposed on this basis: *Eothemis* and *Monardithemis* are synonyms of *Micromacromia*; *E. zygoptera* and *M. flava* are transferred to *Micromacromia*; *Neodythemis scalarum* is a synonym of *M. zygoptera*. *Allorrhizucha* and *Mesumbethemis* are synonyms of *Neodythemis*; *A. campioni*, *A. klingi*, *A. preussi*, *M. takamandensis* and *Micromacromia afra* are transferred to *Neodythemis*; *N. africana* and *N. gorillae* are synonyms of *N. afra*. A checklist of Afrotropical 'neodythemistine' species and a key to the continental species is provided. Two new *Neodythemis* species are described from the Albertine Rift; *N. munyaga* sp. nov. (holotype male: Uganda, Bwindi Impenetrable National Park, Buhoma, Munyaga Valley, alt. ca 1,600 m a.s.l., 17 v 2003) and *N. nyungwe* sp. nov. (holotype male: Rwanda, Nyungwe National Park, Karamba, alt. ca 1,500 m a.s.l., 28 x 1985)." (Authors)] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. 5711. Gyssels, F.; Robby, S. (2006): Behavioral responses to fish kairomones and autotomy in a damselfly. *Journal of Ethology* 24: 79-83. (in English). ["The threat-sensitivity hypothesis predicts that prey species assess and adjust their behavior in accordance with the magnitude of the threat posed by a predator. A largely overlooked characteristic of a prey that will affect its sensitivity to predators is its history of autotomy. We studied threat-sensitive behavior to fish kairomones in larvae of *Ischnura elegans* damselflies, which had undergone autotomy, from a fishpond and from a fishless pond. In agreement with their higher perceived risk, larvae from the fishpond showed fewer rigid abdomen bends, foraged less and walked more slowly than larvae from the fishless pond. In line with their higher vulnerability to predators, larvae without lamellae spent less time foraging than larvae with lamellae. There was a decrease in swimming activity in the presence of fish kairomones except for larvae with lamellae from the fishless pond. This may reflect differences in vulnerability of larvae without lamellae between pond types. Such context-dependent responses in activity to kairomones should be kept in mind when evaluating the ability of a prey to recognize kairomones." 5712. Hasegawa, E.; Kasuya, E. (2006): Phylogenetic analysis of the insect order Odonata using 28S and 16S rDNA sequences: a comparison between data sets with different evolutionary rates. *Entomological Science* 9(1): 55-66. (in English). ["Molecular phylogenetic analyses were conducted for the insect order Odonata with a focus on testing the effectiveness of a slowly evolving gene to resolve deep branching and also to examine: (i) the monophyly of damselflies (the suborder Zygoptera); and (ii) the phylogenetic position of the relict dragonfly *Epiphlebia superstes*. Two independent molecular sources were used to reconstruct phylogeny: the 16S rRNA gene on the mitochondrial genome and the 28S rRNA gene on the nuclear genome. A comparison of

the sequences showed that the obtained 28S rDNA sequences have evolved at a much slower rate than the 16S rDNA, and that the former is better than the latter for resolving deep branching in the Odonata. Both molecular sources indicated that the Zygoptera are paraphyletic, and when a reasonable weighting for among-site rate variation was enforced for the 16S rDNA data set, *E. superstes* was placed between the two remaining major suborders, namely, Zygoptera and Anisoptera (dragonflies). Character reconstruction analysis suggests that multiple hits at the rapidly evolving sites in the 16S rDNA degenerated the phylogenetic signals of the data set." 5713. Hof, C.; Brändle, M.; Brandl, R. (2006): Lentic odonates have larger and more northern ranges than lotic species. *Journal of Biogeography* 33(1): 63-70. (in English). ["Aim: We analysed latitudinal range, centres of distribution and northern range boundaries of Odonata occurring in Europe and North America with respect to larval habitat (standing water = lentic and running water = lotic). As lentic water bodies are thought to be less predictable in space and time than lotic habitats, species adapted to standing waters depend on effective dispersal ability for long-term survival. If species occurring in lentic habitats have a higher propensity for dispersal, then larger range sizes in lentic than in lotic species, as well as an increase in the proportion of lentic species with latitude, would be expected. Location: Europe, North America. Methods: Distributional and habitat data were collected from published sources for all odonates of Europe and North America. Species were assigned to lentic and lotic habitats according to the habitat of the larvae. From distribution maps we estimated the latitudinal range, centre of distribution and northern range boundary of each species. Differences in these distribution variables between lentic and lotic species were evaluated using ANOVA. We related the proportion of lentic species by latitudinal interval in Europe, and by political unit (state, province) in North America, to area, altitudinal range, longitude (only for North America) and latitude by means of generalized linear models. Results: Lentic damselflies and dragonflies had larger latitudinal spans, and more northern distribution centres and range boundaries, than lotic species. The proportion of lentic species increased with latitude. These findings were consistent between continents. Main conclusions: Our results support previous findings that distribution patterns of freshwater species depend on habitat preference. Evolution of dispersal propensity according to habitat characteristics is the most likely explanation. However, at present, alternative explanations, such as an increase in lentic habitats with latitude, cannot be ruled out." 5714. Hornung, C.; Pacas, C. (2006): Investigating damselfly populations at springs in Banff National Park, Canada, with special focus on *Argia vivida*, *Amphiargia abbreviatum*, and *Ischnura cervula* (Odonata: Coenagrionidae). *Aquatic Ecology* 40(1): 49-58. (in English). ["The objective of this study was to estimate *Argia vivida* populations, identify breeding habitat, and investigate movement of adults within Banff National Park, Al-

berta, Canada, during the summer of 2003. Mark-recapture techniques and standardized dip-net surveys were used to monitor *Argia vivida* at various life stages. A reproductive index identified which sites *Argia vivida* recognized as suitable breeding habitat, and exuvia surveys confirmed breeding sites. The basic structure of emergent and surrounding vegetation was measured to investigate the importance of available ovipositing or roosting sites and the condition of the matrix habitat. Data was recorded for *Amphiagrion abbreviatum* and *Ischnura cervula* (both Odonata: Coenagrionidae) to determine if these spring-associated damselflies were successfully breeding within Banff National Park. Comparisons were made between the highly protected Middle Springs and the heavily altered Cave & Basin Springs. Additional surveys at the Vermilion Lake cool spring and Middle Springs Bog investigated their use as breeding habitat for *Amphiagrion abbreviatum* and *Argia vivida*, respectively. Results suggest the ecological value of thermal springs extends beyond their origin to outflows and downstream pools. Conservation of *Argia vivida* must recognize the value of unobstructed thermal outflows, and consider the condition of the forested habitat surrounding springs with regard to its potential use as nocturnal roosts and dispersal corridors. *Amphiagrion abbreviatum* was confirmed breeding within Banff National Park, while no sign of breeding activity was recorded for *Ischnura cervula*." (Authors)] Address: Hornung, Christine, University of Alberta, 751 GSB, T6G 2H1, Edmonton, AB, Canada. E-mail: crhornung@hotmail.com

5715. Ilmonen, J.; Suhonen, J. (2006): Intraguild predation, cannibalism, and microhabitat use in *Calopteryx virgo* and *Somatochlora metallica* larvae: a laboratory experiment. *Aquatic Ecology* 40(1): 59-68. (in English). ["Intraguild predation (IGP) and cannibalism among co-occurring lotic odonate species was studied in Central Finland. A laboratory experiment was performed to assess the microhabitat use and cannibalism between intermediate and late instars of *C. virgo* larvae and predation by larger *S. metallica* larvae on the intermediate *C. virgo* instars. The experiment was run in small running-water aquaria where the larvae were able to divide their mutual habitat vertically by clinging onto artificial perches or crawling on the bottom. Life span of the small *C. virgo* larvae and attack rate on them were compared between the cannibalism and IGP treatments. The effect of predation on the activity, habitat use and spatial distribution of the small *C. virgo* larvae was examined. The IGP rate was 36%. The prey larvae spent the most of their time on the perches, whereas the *S. metallica* preferred the substrate. The large *C. virgo* larvae did not cannibalise smaller conspecifics. The presence of a predator (*S. metallica*) had no effect on the habitat use or activity of the prey (*C. virgo*) larvae. Habitat use differed more between those species than between conspecifics of different size classes of *C. virgo*. The spatial distribution between *S. metallica* and *C. virgo* showed a completely random pattern, whereas the two size classes of *C. virgo* aggregated in the vegetation. Absence of cannibalism and behavioural observations indicate that *C. virgo* may have a low tendency for intraspecific aggressions." (Authors)] Address: Email: jari.ilmonen@ymparisto.fi

5716. Joop, G.; Mitschke, A.; Rolff, J.; Siva-Jothy, M.T. (2006): Immune function and parasite resistance in male and polymorphic female *Coenagrion puella*.

BMC Evolutionary Biology 2006, 6:19. 10 pp. (in English). ["Background: Colour polymorphisms are widespread and one of the prime examples is the colour polymorphism in female coenagrionid damselflies: one female morph resembles the male colour (andromorph) while one, or more, female morphs are described as typically female (gynomorph). However, the selective pressures leading to the evolution and maintenance of this polymorphism are not clear. Here, based on the hypothesis that coloration and especially black patterning can be related to resistance against pathogens, we investigated the differences in immune function and parasite resistance between the different female morphs and males. Results: Our studies of immune function revealed no differences in immune function between the female morphs but between the sexes in adult damselflies. In an experimental infection females infected shortly after emergence showed a higher resistance against a fungal pathogen than males, however female morphs did not differ in resistance. In a field sample of adult damselflies we did not find differences in infection rates with watermites and gregarines. Conclusion: With respect to resistance and immune function 'andromorph' blue females of *Coenagrion puella* do not resemble the males. Therefore the colour polymorphism in coenagrionid damselflies is unlikely to be maintained by differences in immunity." (Authors)] Address: Joop, Gerrit, Zoologisches Institut, AG Ökologie, Technische Universität Braunschweig, Braunschweig, Germany. Email: g.joop@tu-bs.de;

5717. Joop, G.; Siva-Jothy, M.; Rolff, J. (2006): Female colour polymorphism: Gender and the eye of the beholder in damselflies. *Evolutionary Ecology* 20(3): 259-270. (in English). ["Damselflies provide a classic example of female colour polymorphism. Usually, one female morph resembles the blue male colour (andromorph) while one, or more, female morphs are seen as typically female (gynomorph). Damselfly species fall in two distinct groups with respect to recent developments in mimicry theory: in some species females are perfect, they match male colouration and black patterning, and in other species they are supposed to be imperfect mimics, only matching male colouration. However, the underlying assumption of one female morph looking male-like is mostly based on human vision. Therefore we investigated the black patterning and colour of the three female morphs in *Coenagrion puella*, an imperfect mimic, using image analysis. In *C. puella* the blue female morph is perceived as male-like. We found that the black patterning of such females cannot be distinguished from the other female morphs, and is clearly different from males. Furthermore, the blue colour of andromorph females differs from the blue colour of males. Intriguingly, however, the red content did not differ between blue males and females." 5718. Kefford, B.J.; Zaluzniak, L.; Nuggeoda, D. (2006): Growth of the damselfly *Ischnura heterosticta* is better in saline water than freshwater. *Environmental Pollution* 141: 409-419. (in English). ["Increasing salinity has the potential to affect freshwater organisms. Yet sub-lethal effects of salinity on macroinvertebrates are poorly understood. Growth and development of *I. heterosticta* was experimentally shown to be faster in 5–20 mS/cm than 0.1–1 mS/cm, while in 35 mS/cm all indivi-

duals died. In 30 mS/cm about half died and growth was similar to the 0.1 mS/cm treatment. The salinity-growth relationship cannot be explained indirectly, that is salinity affecting the survival of their prey. Tissue content and concentration of Ca, Mg, Na and K in emerged adults showed no evidence of deficiencies at low salinity. Heart beat rate was similar across treatments, except at 35 mS/cm, where it was slower. Respiration and feeding were similar at 0.1, 10 and 30 mS/cm. While there are similarities in *I. heterosticta* and other species' salinity response, there are differences and studies on more species are urgently needed." (Authors)] Address: Kefford, B.J., Department of Biotechnology and Environmental Biology, RMIT University, PO Box 71, Bundoora, 3083, Victoria, Australia. E-mail: ben.kefford@rmit.edu.au

5719. Kiyoshi, T.; Sota, T. (2006): Differentiation of the dragonfly genus *Davidius* (Odonata: Gomphidae) in Japan inferred from mitochondrial and nuclear gene genealogies. *Zoological Science* 23(1): 1-8. (in English). ["To infer the differentiation of Japanese *Davidius* dragonflies, we investigated the genealogies of the mitochondrial cytochrome oxidase subunit I gene (COI) and the nuclear ribosomal RNA gene region encompassing 18S, ITS1, 5.8S, and ITS2 sequences for three species endemic to Japan-*Davidius nanus*, *D. fujijama*, and *D. moiwanus* -as well as *D. lunatus* from the Korean Peninsula. According to the mitochondrial and nuclear gene genealogies, *D. nanus* and *D. moiwanus* are closely related and are sister to the continental species *D. lunatus*, whereas *D. fujijama* differentiated from an ancestor of the other three species. Although the mitochondrial DNA data did not resolve the relationships between *D. nanus* and three *D. moiwanus* subspecies, the nuclear DNA data indicate the monophyly of *D. moiwanus* and its subspecies. The nuclear gene genealogy suggests that isolated wetlands used by larval *D. moiwanus* derive from the ancestral riverine habitats of *D. nanus* and other *Davidius* species. The COI sequence divergence among local populations was much greater in *D. moiwanus* than in *D. nanus*, which may be the result of differences in the dispersal ranges associated with the habitat types of these species." 5720. Klaus, D.; Kaiser, C. (2006): Aktuelle Funde der Gemeinen Keiljungfer (*Gomphus vulgatissimus* [Linnaeus, 1758]) im Südraum Leipzig. *Mitt. sächs. Entomol.* 73: 19-20. (in German). [The latest known records of *G. vulgatissimus* from the environs of Leipzig, Sachsen, Germany dated from 1922. In 2005, along the river Pleiße near Rötha the species was rediscovered.] Address: Klaus, D., Heimstätten 10, D-04571 Rötha, Germany

5721. Koch, K. (2006): Effects of male harassment on females' oviposition behaviour in Libellulidae (Odonata). *International Journal of Odonatology* 9(1): 71-80. (in English). ["I investigated whether the level of male harassment affects females' oviposition behaviour, such that females oviposit unguarded under suboptimal conditions and/or vary oviposition duration, dip number, dip frequency or number of oviposition site changes. The study species were the libellulids *Crocothemis erythraea*, *Orthetrum chrysostigma*, *Pantala flavescens*, *Sympetrum fonscolombii*, *Trithemis annulata* and *T. kir-*

byi ardens. Only a few ovipositions under suboptimal conditions were observed and females hovered lower under high male harassment. However, in only a few species studied oviposition behaviour differed with the level of harassment. No evidence for a special female strategy to avoid the negative effects of males' harassment was found. Due to the great intraspecific variability females seemed to be able to react flexibly to current conditions, such as changing male density and the level of male harassment." 5723. Mazerolle, M.J.; Poulin, M.; Lavoie, C.; Rochefort, L.; Desrochers, A.; Drolet, B. (2006): Animal and vegetation patterns in natural and man-made bog pools: implications for restoration. *Freshwater Biology* 51(2): 333-350. (in English). ["1. Peatlands have suffered great losses following drainage for agriculture, forestry, urbanisation, or peat mining, near inhabited areas. We evaluated the faunal and vegetation patterns after restoration of a peatland formerly mined for peat. We assessed whether bog pools created during restoration are similar to natural bog pools in terms of water chemistry, vegetation structure and composition, as well as amphibian and arthropod occurrence patterns. 2. Both avian species richness and peatland vegetation cover at the site increased following restoration. Within bog pools, however, the vegetation composition differed between natural and man-made pools. The cover of low shrubs, Sphagnum moss, submerged, emergent and floating vegetation in man-made pools was lower than in natural pools, whereas pH was higher than in typical bog pools. Dominant plant species also differed between man-made and natural pools. 3. Amphibian tadpoles, juveniles and adults occurred more often in man-made pools than natural bog pools. Although some arthropods, including Coleoptera bog specialists, readily colonised the pools, their abundance was two to 26 times lower than in natural bog pools. Plant introduction in bog pools, at the stocking densities we applied, had no effect on the occurrence of most groups. 4. We conclude that our restoration efforts were partially successful. Peatland-wide vegetation patterns following restoration mimicked those of natural peatlands, but 4 years were not sufficient for man-made pools to fully emulate the characteristics of natural bog pools." (Authors) The detailed analysis of invertebrates also includes the Odonata.] Address: Mazerolle, M.J., USGS Patuxent Wildlife Research Center, 12100 Beech Forest Road, Laurel, MD 20708-4017, U.S.A. 5724. McCarhy, J.M.; Hein, C.L.; Olden, J.D.; vander Zanden, J.M. (2006): Coupling long-term studies with meta-analysis to investigate impacts of non-native crayfish on zoobenthic communities. *Freshwater Biology* 51(2): 224-235. (in English). ["1. Biological invasions are widely recognised as a significant component of human-caused environmental change and a primary

threat to native biodiversity. The negative impacts of species invasions are particularly evident for freshwater crayfish faunas. 2. This study provides novel insight into the ecological effects of native and non-native crayfish on zoobenthic communities (with emphasis on the non-native rusty crayfish, *Orconectes rusticus*) across broad scales by combining a meta-analysis of small-scale experimental studies with a long-term observational study conducted over a 24 year period in Sparkling Lake, Wisconsin, U.S.A. (46°00'N, 89°42'W). 3. The meta-analysis summarised quantitatively the results of cage experiments for seven species of crayfish spanning four continents. We found that total zoobenthos densities (primarily Gastropoda and Diptera) were significantly lower in treatments containing crayfish relative to controls; a result that was significant for non-native crayfish but not for crayfish in their native range, perhaps owing to a small sample size. In contrast to other species, rusty crayfish were also negatively associated with Ephemeroptera. 4. Results from the time series analysis comparing temporal trends in rusty crayfish and invertebrate abundances from Sparkling Lake were consistent with the findings from the meta-analysis. Rusty crayfish were negatively correlated with the abundance of total zoobenthos, Diptera, Ephemeroptera and Odonata, as well as families of Trichoptera. 5. By coupling the results from short and long-term research, our study offers greater insight into the nature of crayfish-invertebrate interactions in aquatic systems, revealing consistent effects of invasive crayfish on native fauna. The control and management of invasive species is facilitated by the knowledge that well executed small-scale studies may be extrapolated to understand larger-scale ecological interactions." 5726. Mitra, A. (2006): Current status of the Odonata of Bhutan: A checklist with four new records. Journal of renewable natural resources Bhutan 2(1): 136-143. (in English) ["Specimens of dragonflies were collected from Trashiyangtse and Pemagatshel districts of eastern Bhutan during the months of July and September 2003. One specimen of *Neurothemis fulvia* was collected on 5th September 2004 SamdrupJongkhar district. Altogether 61 specimens of Odonata belonging to 16 species and subspecies under 13 genera and four families were listed during the present study, which revealed four new records of odonates for Bhutan viz., *Orthetrum s. sabinana*, *Acisoma p. panorpoides*, *Brachythemis contaminata* and *Neurothemis fulvia*. An up-to-date checklist of 31 species and subspecies of odonates known till date from Bhutan had also been made. However, since the collection period was too short and didn't spread over the whole year, the above list of odonata from the concerned localities remained incomplete. The survey did not cover the southern, western and central districts of Bhutan and thus does not represent a complete check-

list of Odonates of Bhutan. An extensive Odonatological survey needs to be carried out to explore the rich diversity of these elegant insects and come up with a representative checklist of Odonates for Bhutan." (Author)] Address: Mitra, A., Department of Zoology, Sherubtse College, Kanglung, Bhutan.

5728. Oppel, S. (2006): Comparison of two Odonata communities from a natural and a modified rainforest in Papua New Guinea. International Journal of Odonatology 9(1): 89-102. (in English). ["The Odonata fauna of Papua New Guinea is species-rich, but human population growth and resulting modification of primary rainforests may lead to a loss of valuable habitat and species diversity. In this study, I compared the odonate assemblages of a natural tropical rainforest and a modified forest in order to assess the loss that could result from human forest alteration. I collected odonates and recorded habitat use at both study sites for several weeks. The assemblages were compared with similarity indices, and total species richness was estimated using a jackknife procedure. The natural forest community, with 61 species, had both a higher diversity and evenness than the village community, with 38 species. Altogether I found 78 species of 13 families, of which 21 were shared between the two areas. Among the families with more than one species, Megapodagrionidae and Libellulidae had the highest similarity between the two sites, whereas Coenagrionidae and Platynemididae had fairly dissimilar community composition. Three families occurred only in the natural forest. The most important habitats in the village were open sunny areas, artificial ditches, and small permanent creeks, compared to most running waters and the forest interior in the natural forest. Based on habitat preferences in the natural forest, species inhabiting temporary water sources under closed canopy rainforests are most vulnerable to forest modification. They comprised a third of the forest community, and I estimate that approximately 25% of natural rainforest species will disappear following human-induced forest alteration." (Author)] Address: Oppel, S., Dept Biology & Wildlife, 211 Irving 1, University of Alaska, Fairbanks, Fairbanks, AK 99775, USA. E-mail: steffen.oppel@gmail.com

5729. Oppel, S. (2006): Using distance sampling to quantify Odonata density in tropical rainforests. International Journal of Odonatology 9(1): 81-88. (in English). ["Quantitative data are essential for many aspects of ecological research. Several methods exist to quantify odonate abundance, but complications may arise when abundances in different habitats need to be compared. In this study, I explored a technique that can overcome the variable detectability of odonates in habitats with different visibility. Distance sampling is briefly introduced and the main assumptions are listed. I conducted line transect surveys using distance sampling protocol over several weeks in a rainforest locality in Papua New Guinea to assess the usefulness of distance sampling. The results suggested that estimates of encounter rate

and density of odonates are substantially higher when distance sampling is employed. Density in habitats with poor visibility, like the forest interior, is severely underestimated by traditional sampling methods, and this can lead to a misclassification of habitats. Distance sampling is a very useful technique for quantitative odonate sampling, but the sampling effort required for precise estimates is very high. For the rainforest locality in this study at least 15 months of intensive sampling would be required. Further limitations of distance sampling are discussed." 5731. Principe, R.E.; del Corigliano, M.C. (2006): Benthic, drifting and marginal macroinvertebrate assemblages in a lowland River: temporal and spatial variations and size structure. *Hydrobiologia* 553(1): 303-317. (in English). ["Aquatic macroinvertebrates living in anastomosing lowland rivers use different habitats and respond differently to the hydrological regime. In this paper, the structure and composition of benthic, drifting and marginal macroinvertebrate assemblages are analyzed in the lowland river Ctlamochita (Córdoba, Argentina). The assemblages were studied in an annual cycle; a comparison among the composition of benthos, drift and marginal fauna was carried out; and size structure of the assemblages was characterized. Samples were obtained from two sites: a rural and an urban site. In total 73 taxa of aquatic macroinvertebrates were collected. Benthos was characterized by Chironomidae and Oligochaeta; marginal fauna was mainly constituted by Coleoptera, Heteroptera, Decapoda, the Trichoptera *Nectopsyche* sp., Ephemeroptera and Odonata. Drifting assemblage was composed by macroinvertebrates from local and remote upstream benthos, and from the marginal zone. Marginal fauna diversity was higher than benthos and drift. Total biomass of the assemblages pooled together was relatively equitably among size classes. Larger size classes consisted of organisms from the marginal zone whereas the smallest ones were composed by benthic and drifting organisms. In the study area there is habitat partitioning in the lateral dimension of the river. Marginal fauna was more diverse due to the asymmetry of transport and deposit processes, which generate a heterogeneous habitat in the bankside. The relation between fine substrate and high current velocity determines an unstable habitat in the central channel, which makes colonization by benthic macroinvertebrates difficult." (Authors)] Ad-

5733. Raab, R.; Chovanec, A.; Pennerstorfer, J. (2006): *Libellen Österreichs*. Springer. Wien. ISBN 3-211-28926-7: X, 345 pp. (in German). [This book on Austrian Odonata, produced in collaboration with several co-authors, is characterised by a high-quality presentation, and furnished with many colour photographs, graphs and maps. Eleven chapters comprise highly readable contributions: A special recommendation should be given to the introduction into the biology of Odonata written by Johann Waringer which contains some original ideas and sketches about the eggs and the embryology of Odonata, or the respiration of the larvae. Interesting are the description of the local fauna of several regions in Austria, and the chapter on the function of dragonflies as bio-indicators. Brief accounts are given to the threat and conservation of Odonata in Austria, the data sources, and a general introduction into the climatic and geographical conditions in Austria. The 77 odonate species recorded in Austria to date are treated in a monographic style. On two or three pages a compact treatment of the Austrian Odonata is presented: The distribution in Austria is briefly described, and all available records are mapped with time-scale details. Additional information is given to the altitudinal distribution, emergence period, and phenology. The part on the habitat and biology of the species is based - in most cases - on the the book of Sternberg & Buchwald on the dragonflies of Baden-Württemberg, Germany. Only few species are treated with original data resulting from studies in Austria (e.g. *Coenagrion hylas* and [in Chapter 7.3] *Cordulegaster heros* and *Thecagaster bidentata*). Threat and conservation measures are also outlined for each species. In summary, this book is a highly welcome contribution to the knowledge of the central European Odonata. (Martin Schorr) Available at: Springer-Verlag, Tiergartenstrasse 17, D-69 121 Heidelberg, Germany. <http://www.springer.com/dal/home/life+sci?SGWID=1-10027-22-76448852-0>

5734. Reinhardt, K. (2006): Open questions in the evolution of openwing perching in the Zygoptera (Odonata): a comment on Dennis Paulson. *International Journal of Odonatology* 9(1): 103-110. (in English). ["In a recent paper D.R. Paulson (2004; IJO 7: 505-515) presented five hypotheses concerning the way wings are held in the Zygoptera during perching. A critical ex-

amination suggests that most of them have substantial flaws that prevent their testing. Based on Bechly's phylogeny (1998; <<http://www.bechly.de/system.htm>>) I suggest that the wing perching mode in the Odonata has changed five or six times, depending on whether the ancestral situation in the Odonata was closedwing or openwing perching, respectively. Combining parts of Paulson's hypotheses into a more plastic cost-benefit framework is suggested as an alternative approach, such as the investigation of possible trade-offs between thermoregulatory and foraging benefits and costly predation risk." 5738. Sformo, T.; Doak, P. (2006): Thermal ecology of interior Alaska dragonflies (Odonata: Anisoptera). *Functional Ecology* 20(1): 114-123. (in English). ["1. We examined the thermal ecology of Interior Alaska dragonflies (Odonata: Anisoptera). The relationships between mass and passive cooling rate, wing loading, minimum flight temperature (MFT) and thermoregulating ability were examined. These properties were also compared between the behavioural classes: perchers and fliers. All factors with the addition of seasonal and daily flight activity were related to generalized thermal strategies. 2. Passive cooling rate decreased while wing loading and MFT increased with mass. 3. While all species were able to elevate thoracic temperature, larger species were better able to maintain a constant temperature. 4. Both the smallest and largest species of dragonflies were capable of activity at ambient temperatures of approximately 14 °C by employing different thermal strategies: low MFT and physiological heat production, respectively. 5. For small species active in cool conditions low MFT may be favoured

cool conditions low MFT may be favoured even if accompanied by poor thermoregulating ability. By contrast, thermoregulation and specialization for high-temperature performance may be favoured in both small and large species during the warmer summer flight season. 6. The smallest and largest dragonflies in Interior Alaska have the shortest and longest daily activity periods, respectively. However this pattern does not hold for the intermediate-sized dragonflies. Thermal strategy displays no clear relationship to daily activity pattern." 5739. Slos, S.; Stoks, R. (2006): Behavioural correlations may cause partial support for the risk allocation hypothesis in damselfly larvae. *Ethology* 112(2): 143-151. (in English). ["Prey animals are often confronted with situations that differ in predation risk. According to the risk allocation hypothesis, prey animals should adaptively allocate antipredator behaviour in accordance with the magnitude and frequency of those risk situations. According to the first prediction prey animals should increase foraging in the safe situations and decrease foraging in the dangerous situations as these situations become relatively more dangerous. The second prediction is that with increased time spent in the dangerous situations, progressively more foraging effort is shown in both the dangerous and safe situations, especially in the safer ones. Prey animals may, however, show maladaptive behaviour due to behavioural correlations across risk situations. Here we test for the first time both predictions generated by the risk allocation hypothesis while considering behavioural correlations. We reared larvae of the damselfly *Ischnura elegans*, from the egg stage, under five rearing risk conditions: (i) in isolation, (ii) in the presence of conspecific larvae, (iii) in the presence of one fish, (iv) in the presence of two fish, and (v) in the presence of two fish for 50% of the time. For each rearing risk condition, we scored their behaviour in the absence and in the presence of fish. In accordance with the first prediction, in the absence of a predator, larvae reared under increasing risk conditions increased their level of foraging. In accordance with the second prediction, in the absence of a predator, larvae that were more frequently exposed to fish during rearing, increased foraging. However, opposite to the predictions from the risk allocation hypothesis, foraging increased both with increasing rearing risk, and with increased predator exposure frequency. The observed positive behavioural correlation of foraging activity across test situations with and without fish, may generate the combination of adaptive patterns in the absence of fish and the maladaptive patterns in the presence of fish. Former studies of the risk allocation hypothesis also found, at best, mixed support, and we hypothesize that behavioural correlations across risk situations, if present, will likely cause partial deviations from model predictions.] Address: Slos, Stefanie; Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. 5740. Sokolova, Y.Y.; Kryukova, N.A.; Glupov, V.V.; Fuxa, J.R. (2006): *Systemostrema alba* Larsson 1988 (Microsporidia, Thelohaniidae) in the dragonfly *Aeshna viridis* (Odonata, Aeshnidae) from south Siberia: Morphology and molecular characterization. *Journal of Eu-*

karyotic Microbiology 53(1): 49-57. (in English). ["An octospore microsporidium was found in the nymphs of *Aeshna viridis*, collected in intermittent streams near Novosibirsk, Siberia, Russia in 2003. Spores were uniloculate and measured $6.1 \pm 0.07 \times 3.0 \pm 0.04$ μm on fresh smears. The polar filament was anisofilar having 10-11 anterior coils (thicker filament diam.) and 10-11 posterior (thinner filament diam.) coils. Sporophorous vesicles were persistent and measured $12.3 \pm 0.23 \times 11.9 \pm 0.20$ μm . The infection was restricted to the adipose tissue and caused the formation of whitish "cysts" containing mature octospores. Based on ultrastructural similarity we consider this Siberian isolate to be *Systenostrema alba*, a species described from *Aeshna grandis* collected in Sweden (Larsson 1988). Maximum likelihood, neighbor joining, and maximum parsimony analyses of the small subunit rDNA all placed *Systenostrema alba* (Accession no. AY953292) as the sister taxon to a clade consisting of *Thelohania solenopsae*, *Tubulinosema ratisbonensis*, and *T. acridophagus*." 5741. Suhling, F.; Sahlen, G.; Martens, A.; Marais, E.; Schütte, C. (2006): Dragonfly assemblages in arid tropical environments: a case study from western Namibia. *Biodiversity and Conservation* 15: 311-332. (in English). ["Dragonflies have been proposed as indicators for the ecosystem health of freshwater wetlands. For their useful functioning as indicators it is, however, necessary to identify species compositions in specific habitats and species-habitat associations, particularly in the tropics, where such knowledge is still weak. We examined the dragonfly species composition of 133 localities in the arid environment of western Namibia. An analysis of nestedness indicated that distinct, and predictable patterns of species associations can be expected. Discriminant analyses revealed that most of the nine habitat types separated by structural and hydrological parameters are well discriminated by their dragonfly assemblages. Spring brooks in particular host a specific assemblage, which is threatened due to the habitat restriction of several species, as well as by recent habitat loss and degradation. Using a hierarchical method of several criteria we demonstrated the selection of a set of potential indicator species from the species set, most of these being useful indicators for spring brook assemblages. The conservation status of certain habitats and species is discussed. We propose that dragonflies will have a high indicator potential for threatened freshwater wetlands in such areas and may also serve as an indication of the sustainable use of water resources including evaluating measures to rehabilitate environments." 5744. Tynkkynen, K.; Kotiaho, J.S.; Luojumäki, M.; Suhonen, J. (2006): Interspecific territoriality in *Calopteryx damselflies*: the role of secondary sexual characters. *Animal Behaviour* 71(2): 299-306. ["Interspecific territoriality is usually interpreted to result from interspecific interference competition, although it may also originate from mistaken species recognition. In the latter case, it may be based on similarity of secondary sexual characters. In the damselfly *Calopteryx splendens*, males have pigmented wing spots as a sexual character, and males with the largest spots resemble males of another species, *Calopteryx virgo*. Probably because of this resemblance, *C. virgo* males are more aggressive towards large- than small-spotted *C. splendens* males. We examined whether wing spot size of *C. splendens* males affects territorial interactions between the species. In a removal experiment, the number of territorial *C. splendens* increased after *C. virgo* males were removed. However, interspecific territoriality was incomplete since before the removal the territories of the species partially overlapped. Wing spot size of *C. splendens* seemed to affect interspecific territoriality: before the removal territorial and nonterritorial *C. splendens* males had similar spot sizes and the distance to the nearest *C. virgo* territory increased with wing spot size of *C. splendens*. In addition, after the removal of *C. virgo*, the relation between wing spot size and the distance to the nearest old *C. virgo* territory disappeared. Our results suggest that mistaken species recognition may account for the interspecific territorial behaviour in the two species. Furthermore, interspecific territoriality may cause negative selection on wing spot size and thus may explain character displacement in wing spot size of *C. splendens* males." 5745. Watts, P.C.; Saccerril, I.J.; Kemp, S.J.; Thompson, D.J. (2006): Population structure and the impact of regional and local habitat isolation upon levels of genetic diversity of the endangered damselfly *Coenagrion mercuriale* (Odonata: Zygoptera). *Freshwater Biology* 51(2): 193-205. (in English). ["1. *C. mercuriale* is one of Europe's most threatened damselflies. There is concern for the long-term persistence of many of its U.K. colonies because adult lifetime movement is limited, making

isolated populations susceptible to extinction. 2. Using 14 microsatellite loci we characterised levels of genetic diversity, evidence for a recent decline and the spatial genetic structure for *C. mercuriale* population in Wales, U.K. 3. Spatial isolation is not an absolute predictor of low genetic diversity at either local or regional scales. 4. One population inhabiting a remote, edge of range site is genetically impoverished with levels of variability (at microsatellite loci) among the lowest reported for any insect species. 5. Agricultural land and high ground are physical barriers to dispersal by adults. 6. Consistent with work from elsewhere, movement by mature *C. mercuriale* in Pembrokeshire is sufficient to prevent significant genetic differentiation throughout a habitat matrix of some 3-4 km if the suitable habitat sites are <2 km apart and lack barriers to movement. Even within a good habitat matrix, however, genetic isolation by distance develops within 10 km." (Authors)] Address: Watts, P.C., School of Biological Sciences, The Biosciences Building, Crown Street, University of Liverpool, Liverpool, L69 7ZB, UK. E-mail: p.c.watts@liv.ac.uk

5746. Wohlfahrt, B.; Mikolajewski, D.J.; Joop, G.; Suhling, F. (2006): Are behavioural traits in prey sensitive to the risk imposed by predatory fish?. *Freshwater Biology* 51: 76-84. (in English). ["1. Behavioural differences among prey species may result from evolutionary adaptations that facilitate coexistence with different predators and influence vulnerability to predators. It has been hypothesised that prey species modify their behaviour in relation to the risk posed by particular predators. 2. We examined the relationship between anti-predator behaviour and predation risk in five species of larval odonates in combination with three predatory fish species (perch, gudgeon and rudd) that differ in foraging behaviour. The odonates, *Platycnemis pennipes*, *Coenagrion puella*, *Lestes sponsa*, *Sympetrum striolatum* and *Libellula depressa*, differ with regard to their life cycle and habitat, including water depth, occurrence in temporary ponds and co-existence with fish. 3. The odonate species differed in their response to fish: (i) Two species showed a flexible response. Larval *C. puella* reduced activity in the presence of fish, regardless of species, whereas *L. depressa* altered their activity only in the presence of gudgeon. (ii) Independent of fish species, all odonates except *L. depressa* exhibited spatial avoidance of fish. This was interpreted as a more general anti-predator response. (iii) In some cases the odonates showed no response to predators and their behaviour was thus independent of predation risk. 4. Our results confirm that all odonates responded to the presence of at least some predatory fish, and that some odonate species discriminated between fish species. However, we found no significant correlation between behavioural modifications and predation risk, indicating that anti-predator responses and predation risk depend on the particular predator and the species being preyed on." 5747. Zuellig, R.E.; Kondratieff, B.C.; Schmidt, J.P.; Durfee, R.S.; Ruitter, D.E.; Prather, I.E. (2006): An annotated list of aquatic insects of Fort Sill, Oklahoma, excluding Diptera with notes on several new state records. *Journal of the Kansas Entomological Society* 79(81): 34-54. (in English). ["Qualitative collections of

aquatic insects were made at Fort Sill, Lawton, Oklahoma, between 2002 and 2004. Ephemeroptera, Plecoptera, Trichoptera, Odonata, Coleoptera, aquatic Heteroptera, Neuroptera, and Megaloptera were targeted. Additional records are included from a survey that took place in 1999. More than 11,000 specimens from more than 290 collections were examined. Based on the current understanding of aquatic insect systematics, 276 taxa distributed over 8 orders, 46 families, and 141 genera were identified. Twenty-three of the 276 taxa [...] are reported from Oklahoma for the first time. The three most diverse orders included Coleoptera (86 species), Odonata (67 species) and Trichoptera (59 species), and the remaining taxa were distributed among Heteroptera, (30 species), Ephemeroptera (21 species), Plecoptera (6 species), Megaloptera (4 species), and Neuroptera (3 species). Based on previous published records, many of the species collected during this study were expected to be found at Fort Sill; however, 276 taxa of aquatic insects identified from such a small geographic area is noteworthy, especially when considering local climatic conditions and the relatively small size of Fort Sill (38,300 ha). Despite agricultural practices in Oklahoma, the dust bowl days, and the development of water-based recreation at Fort Sill, a high percentage of the total known aquatic insect fauna of Oklahoma can be found in a small geographic area." 5748. Arnqvist, G. (1997): The evolution of animal genitalia: distinguishing between hypotheses by single species studies. *Biological Journal of the Linnean Society* 60: 365-379. (in English). ["Rapid evolution of genitalia is one of the most general patterns of morphological diversification in animals. Despite its generality, the causes of this evolutionary trend remain obscure. Several alternative hypotheses have been suggested to account for the evolution of genitalia (notably the lock-and-key, pleiotropism, and sexual selection hypotheses). Here, I argue that thorough intraspecific studies are the key to gaining insight into the patterns and processes of genitalic evolution. Critical assumptions and predictions that may be used to distinguish between the different hypotheses are identified and discussed. However, current knowledge of selection on genitalia, or even of the degree of phenotypic and genotypic variability of genital morphology, is highly limited, allowing only a very tentative assessment of the various hypotheses. In-depth single species studies of current patterns and processes of selection on genitalia are badly needed, and a single species research program is briefly outlined." (Author) The paper includes many references to Odonata.] Address: Arnqvist, G., Dept. of Animal Ecology, University of Umea°, S-901 87 Umea, Sweden

5749. Kruuk, L.E.B.; Gilchrist, J.S. (1997): Mechanisms maintaining species differentiation: predator-mediated selection in a *Bombina* hybrid zone. *Proceedings of the Royal Society B: Biological Sciences* 264(1378): 105-110. (in English). ["Mechanisms which prevent gene flow will maintain differentiation between species, and therefore contribute to biological diversity. We describe an experimental study of such mechanisms in a hybrid zone between the fire-bellied toad *Bombina bombina* and the yellow-bellied toad *B. variegata*. In this system, preference for different breeding habitats reduces the frequency of hybridization. A comparison of habitat ecology shows that the semi-permanent ponds in which *B. bombina* usually breeds have higher densities of aquatic predators than the temporary puddles typically used by *B. variegata*. We

test for behavioural adaptations in tadpoles to these different levels of predation. *B. bombina* tadpoles are significantly less active than *B. variegata*, both before and after the introduction of a predator to an experimental arena; this reduces their vulnerability as many predators detect prey through movement. Behavioural differences translate into differential survival: *B. variegata* suffer higher predation rates in laboratory experiments with three main predator types (*Triturus* sp., *Dytiscus* larvae, *Aeshna* nymphs). This differential adaptation to predation will help maintain preference for alternative breeding habitats, and thus serve as a mechanism maintaining the distinctions between the two species." 5750. Williamson, D.L.; Adams, J.R.; Whitcomb, R.F.; Tully, J.G.; Carle, P.; Konai, M.; Bove, J.M.; Henegar, R.B. (1997): *Spiroplasma platyhelix* sp. nov., a new mollicute with unusual morphology and genome size from the dragonfly *Pachydiplax longipennis*. *International journal of systematic bacteriology* 47(3): 763-766. (in English). ["*Spiroplasma* strain PALS-1T from the gut of the dragonfly *Pachydiplax longipennis* was shown to be distinct from other species, groups, and subgroups of the genus *Spiroplasma* as determined by reciprocal serological metabolism inhibition and deformation tests. However, this strain cross-reacted extensively with representatives of other groups when it was used as an antigen. Electron microscopy of cells of strain PALS-1T revealed cells surrounded by a single cytoplasmic membrane. Light microscopy revealed helical cells that exhibited twisting motility rather than rotatory or flexing motility. Variations in the tightness of coiling were transmitted from one end of the helix to the other. The strain was resistant to penicillin, which confirmed that no cell wall was present. The organism grew well in M1D and SP-4 liquid media under either aerobic or anaerobic conditions. Growth also occurred in 1% serum fraction medium and in conventional horse serum medium. The optimum temperature for growth was 30°C, at which the doubling time was 6.4 h. Multiplication occurred at temperatures from 10 to 32°C. Strain PALS-1T catabolized glucose and hydrolyzed arginine but not

urea. The guanine-plus-cytosine content of the DNA was 29.61 mol%. The genome size was 780 kbp, the smallest genome size in the genus *Spiroplasma*. Strain PALS-1 (5 ATCC 51748) is designated the type strain of a new species, *Spiroplasma platyhelix*." 5751. Winemiller, K.O.; Adite, A. (1997): Convergent evolution of weakly electric fishes from floodplain habitats in Africa and South America. *Environmental Biology of Fishes* 49: 175-186. (in English). ["An assemblage of seven gymnotiform fishes in Venezuela was compared with an assemblage of six mormyriiform fishes in Zambia to test the assumption of convergent evolution in the two groups of very distantly related, weakly electric, nocturnal fishes. Both assemblages occur in strongly seasonal floodplain habitats, but the upper Zambezi floodplain in Zambia covers a much larger area. The two assemblages had broad diet [including Odonata] overlap but relatively narrow overlap of morphological attributes associated with feeding. The gymnotiform assemblage had greater morphological variation, but mormyriiforms had more dietary variation. There was ample evidence of evolutionary convergence based on both morphology and diet, and this was despite the fact that species pairwise morphological similarity and dietary similarity were uncorrelated in this dataset. For the most part, the two groups have diversified in a convergent fashion within the confines of their broader niche as nocturnal invertebrate feeders. Both assemblages contain midwater planktivores, microphagous vegetation dwellers, macrophagous benthic foragers, and long-snouted benthic probers. The gymnotiform assemblage has one piscivore, a niche not represented in the upper Zambezi mormyriiform assemblage, but present in the form of *Mormyrops deliciosus* in the lower Zambezi and many other regions of Africa." 5754. Englund, R.A.; Filbert, R.B. (1999): Flow restoration and persistence of introduced species in Waikele stream, O'ahu. *Micronesica* 31(2): 143-154. (in English). ["Unintentional stream flow restoration in Waikele Stream, O'ahu, Hawai'i resulted from the demise of sugar cane cultivation on O'ahu and subsequent cessation of direct surface water diversions in 1989. Previous artificial stream studies in Hawai'i have suggested that increases in the base flow of a diverted stream would displace or reduce introduced fish populations. Surveys of Waikele Stream, conducted in 1993 and 1997-1998 from the Waikele Springs area downstream to the beginning of the tidal reach found that despite an increase in stream flow, introduced fish remained abundant and native species appeared to have declined. In fact, two new introduced aquatic taxa, a dragonfly and a shrimp, had appeared. These results indicate that although restoring hydrological conditions is an important first step in overall restoration of degraded aquatic ecosystems, flow restoration alone is not a panacea, especially in O'ahu streams with naturally low discharge rates. For stream and wetland restoration to fully succeed, introduced fish and other alien aquatic species must be eradicated by methods other than simply increasing stream base flows." (Authors) Tab. 2 lists 7 Odonata species, with the exception of *Pantala flavescens* exclusively introduced species.] Address: Englund, R.A., Hawaii Biological Survey, Bishop Museum, 1525 Bernice Street, Honolulu, HI, 96817, USA. 5755. De Marco Júnior, P.; Furieri, K.S. (2000): Ecology of *Leptagrion perlongum* Calvert, 1909: a bromeliad-dweller Odonate species. *Boletim do Museu de Biologia Prof. Melle Leitão (Nova Série)* 11/12: 135-148. (in English, with Portuguese summary). ["*Leptagrion* is an Odonate genus completely associated with bromeliads in South-America. Two species are known as threatened in the Atlantic Forest, but they are still poorly studied. Here we attempt to present an overview of the general population ecology and some aspects of the natural history of one of them, *Leptagrion perlongum*, a common species in Santa Lúcia Biological Station (EBSL), Santa Teresa, ES. We gave special attention to the preferences of this species on some bromeliad species present, the general characteristics of the bromeliads where *L. perlongum* was successfully developed, and the pattern of population fluctuation during a year of study. We determined the preferences among bromeliads using an exuviae sampling, and the adult population abundance using a scan sampling in a site with high concentration of bromeliads. *L. perlongum* preferred *Vriesea jongheii*, *Neoregelia magdalenae* and *Nidularium procerum*, and avoided *V. ensiformis*. These preferences were generally explained, not only by differences in volume of water held, but also by effects of habitat preferences and plant aggregation. In 19.1% of the bromeliads exuviae were found in December 1998. The monthly emergence rate in January 1999 was 0,095 adult/bromeliad, with 7.9% of the bromeliads with new exuviae. Adult abundance rose in the rainy season

and the extension of the dry season was considered the primary regulation factor acting on this population." (Authors) Address: De Marco, P., Lab. Ecologia Quantitativa, DBG, Universidade Federal de Viçosa, 36571-000, Viçosa, MG, Brazil. E-mail: pdemarco@mail.ufv.br

5756. Eklöv, P. (2000): Chemical cues from multiple predator-prey interactions induce changes in behavior and growth of anuran larvae. *Oecologia* 123(2): 192-199. (in English). ["Chemical signals are used as information by prey to assess predation risk in their environment. To evaluate the effects of multiple predators on prey growth, mediated by a change in prey activity, I exposed small and large bullfrog (*Rana catesbeiana*) larvae (tadpoles) to chemical cues from different combinations of bluegill sunfish (*Lepomis macrochirus*) and larval dragonfly (*Anax junius*) predators. Water was regularly transferred from predation trials (outdoor experiment) to aquaria (indoor experiment) in which activity and growth of tadpoles was measured. The highest predation mortality of small bullfrog larvae in the outdoor experiment was due to *Anax*, and it was slightly lower in the presence of both predators, probably resulting from interactions between predators. There was almost no mortality of prey with bluegill. The activity and growth of small bullfrog larvae was highest in the absence of predators and lowest in the presence of *Anax*. In the presence of bluegill only, or with both predators, the activity and growth of small bullfrog tadpoles was intermediate. Predators did not affect large tadpole activity and growth. Regressing mortality of small bullfrog tadpoles against activity and growth of bullfrog tadpoles revealed a significant effect for small bullfrog larvae but a non-significant effect for large bullfrog larvae. This shows that the response of bullfrog tadpoles to predators is related to their own body size. The experiment demonstrates that chemical cues are released both as predator odor and as alarm substances and both have the potential to strongly alter the activity and growth of prey. Different mechanisms by which chemical cues may be transmitted to species interactions in the food web are discussed." (Author)] Address: Eklöv, P., Animal Ecology, Department of Ecology and Environmental Science, Umeå University, S-901 87 Umeå, Sweden. E-mail: Peter.Eklov@eg.umu.se

5759. McIntyre, P.B.; McCollum, S.A. (2000): Responses of bullfrog tadpoles to hypoxia and predators. *Oecologia* 125(2): 301-308. (in English). ["Low dissolved oxygen concentrations present numerous challenges for non-air-breathing aquatic organisms. Amphibian larvae and their predators can respond to oxygen levels by altering their behavior and physiology, but the ecological consequences of these responses are generally unknown. We conducted two laboratory experiments to study the effects of dissolved oxygen on respiratory behavior and susceptibility to predation of larval bullfrogs (*Rana catesbeiana*). In the first, we exposed small, lungless tadpoles to a predatory salamander larva (*Ambystoma tigrinum*) under high and low oxygen conditions. More tadpoles were consumed in high oxygen tanks than in low ones, presumably because salamanders remained near the surface in the low oxygen tanks while most tadpoles rested on the bottom. Tadpole activity depended on both oxygen and predator presence: swimming decreased after addition of salamanders under high oxygen, but increased under low oxygen. In the second experiment, we examined the effect of predator chemical cues on the air-breathing rate of large tadpoles with well-developed lungs under low oxygen conditions. In the presence of chemical cues produced by dragonfly larvae consuming bullfrog tadpoles, air-breathing and swimming were significantly reduced relative to controls. These experiments demonstrate the potential impact of dissolved oxygen on predator-prey interactions, and suggest that outcomes depend on the respiratory ecology of both predator and prey." (Authors)] Address: McCollum, S.A., Department of Biology, Cornell College, Mount Vernon, IA 52314, USA

5760. Pornsin-Sirirak, T.N.; Lee, S.W.; Nassef, H.; Grasmeyer, J.; Tai, Y.C.; Ho, C.M.; Keennon, M. (2000): Mems wing technology for a battery-powered ornithopter. The 13th IEEE Annual International Conference on MEMS, Miyazaki, Japan, January 23-27, 2000: 709-804. (in English). ["The objective of this project is to develop a battery-powered ornithopter (flapping-wing) Micro Aerial Vehicle (MAV) with MEMS wings. In this paper, we present a novel MEMS-based wing technology that we developed using titanium-alloy metal as wingframe and parylene C as wing membrane. MEMS technology enables systematic research in terms of repeatability, size control, and weight minimization. We constructed a high quality low-speed wind tunnel with velocity uniformity of 0.5% and speeds from 1 m/s to 10 m/s. We have tested and have studied the unsteady-state aerodynamics of various types of MEMS wings (including an anisopteran wing). Finally, we built lightweight ornithopters with electricpowered transmission system and have demonstrated successful free flights with flight duration ranges from 5 to 18 seconds." (Authors)] Address: Pornsin-Sirirak, T.N., Caltech Micromachining Laboratory, 136-93, Pasadena, CA 91125, USA

5761. Seino, M.; Kakazu, Y. (2000): Dynamic pattern formation for wings of Pterygota in an eclosion - Pattern analysis for wings with the imago. *Progress of Theoretical Physics Suppl* (1996-2002), No. 138: 600-601. (in English). ["The vein and cell patterns for the fore and hind wing of Lepidoptera, Hemiptera, Orthoptera and Odonata are analyzed and discussed. For vein patterns of them, the fractal properties are shown and the inequality between four orders is obtained. The nature of wings observed by mass distributions for fractal dimen-

sions of the vein pattern is presented." (Authors)] Address: Seino, M. & Kakazu, Y., Faculty of Science, University of the Ryukyus, Okinawa 903-0213, Japan

2001

5762. Hashimoto, H. (2001): Biomimetics research on flying insects for developing high performance, small-sized actuator. Proceedings of the school of engineering of Tokai university 41(2): 25-34. (in Japanese, with English summary). ["This paper describes the development of highperformance, small sized actuators based on the vibration mechanism of flying insects' wings. At first, the three-dimensional observation of flight muscles in some kinds of winged insects such as bees, dragonflies, and cicadae are presented. In the 3-D observation of flight muscles, sequential sections through thoraces are sliced at the thickness of 30 μ m by the rotating knife and taken photos by camera with three-dimensional internal structure microscope automatically and repeatedly. The 3-D images are reconstructed by a computer based on the digital data after recording. From the 3-D observation, it is confirmed that the winged insects can be classified into three groups at least by the differences of morphology of flight muscles. Then, relation between morphology of flight muscles and function of wings are examined experimentally. In the indirect-flight-muscle type of insects, the deflections of thoracic exoskeleton are measured under the static load. The obtained load-deflection diagrams show linear relation between them. In the direct-flight-muscle type of insects, the ultra high speed video camera is used to record the wing motion under the free flight conditions by making use of their nature of high sensitivity to light. The frequencies of wing vibration are determined from the analyses of recorded data on videotapes. It is found that the vibration frequencies depend on the wing mass in the case of losing weight and independent on it in the case of gaining weight. Finally, the application of these knowledges based on the biological experiments to the development of driving circuit and mechanism for small-sized actuator is presented." (Author) Specimens of *Orthetrum albostylum speciosum*, *Sympetrum darwini*, *S. frequens* and *Pantala flavescens* were used in this study.] Address: not transliterated into English language.

5763. Morita, T.; Yamano, K.; Yamamoto, Y.; Ichinose, T. (2001): Dragonfly fauna of the rainwater storage ponds in a rural landscape in Hokudan-cho, Awaji Island, Hyogo Prefecture. Landscape Planning and Horticulture 2: 51-54. (in Japanese, with English summary). ["There are many rainwater storage ponds in the Awaji Island. Especially, Hokudan-cho has more than 3000 ponds. We surveyed dragonfly fauna of 24 rainwater storage ponds from June 2000 to September 2000 in a rural area of north part of Hokudan-cho. All species were recorded for 40 minutes once a month in all ponds. In the result, 37 species were recorded and some species clearly preferred to coastal area or hilly area. However, it is suggested that some microhabitat structures influenced the distribution of dragonfly species." (Authors)] Address: Ichinose, T., Lab. of Landscape Planning, Awaji Landscape Planning and Horticulture Academy (ALPHA), Institute of Natural and Environmental Science, University of Hyogo, Nojimatokiwa 954-2, Ho-

kudan-cho, Tsuna-gun, Hyogo, Japan. E-mail: tomohiroichinose@yahoo.co.jp

5764. Wells, R.D.S.; Clayton, J.S. (2001): Ecological impacts of water net (*Hydrodictyon reticulatum*) in Lake Aniwhenua, New Zealand. New Zealand Journal of Ecology 25(2): 55-63. (in English). ["The ecological impacts of *Hydrodictyon reticulatum* blooms (1989-94) were studied at Lake Aniwhenua (a constructed lake) in North Island, New Zealand by collating fish, invertebrate and macrophyte data collected towards the end of a four year bloom period and following its decline. *Hydrodictyon reticulatum* had some localised impacts on the biota of the lake. Some macrophyte beds were smothered to the extent that they collapsed and disappeared, and dense compacted accumulations of *H. reticulatum* caused localised anoxic conditions while it decayed. However, fish and some invertebrates in the lake benefited from the *H. reticulatum* blooms. High numbers of *Ceriodaphnia* sp. (maximum, 5.5 x 10⁴ m⁻²) were recorded amongst *H. reticulatum*, and gastropods were exceptionally abundant, the most common being *Potamopyrgus antipodarum* (maximum, 1.8 x 10⁵ m⁻²). *Hydrodictyon reticulatum* was consumed by three species of common gastropods in experimental trials, with *Austropeplea tomentosa* consuming up to 1.3 g dry weight *H. reticulatum* g⁻¹, live weight of snail day⁻¹. Gastropods comprised the major portion of the diet of *Oncorhynchus mykiss* in Lake Aniwhenua during and after the *H. reticulatum* bloom. A marked peak in sports fishing (with exceptional sizes and numbers of fish caught) coincided with the period of *H. reticulatum* blooms and the abundant invertebrate food source associated with the blooms." (Authors) Odonata resp. *Procordulia grayi* are included in the analysis.] Address: Wells, R., National Institute of Water and Atmospheric Research, P.O. Box 11 115, Hamilton, New Zealand. 5765. Celik, K. (2002): Community structure of macrobenthos of a Southeast Texas sand-pit lake related to water temperature, pH and dissolved oxygen concentration. Turk. J. Zool. 26: 333-339. (in English, with Turkish summary). [Texas, USA; Barry's lake is a warm monomictic lake and no anoxic conditions were observed at any depth during the entire study period (June 1995 to February 1996, which covered climatic extremes). "A total of 50 taxa and 5614 individuals of macrobenthos were collected. The dominant organisms were *Chaoborus punctipennis* (Say), *Limnodrilus hoffmeisteri* (Claparede), and *Dero obtusa* (Udekem). The only established populations at 6.5 m were *Chaoborus punctipennis*, *Limnodrilus hoffmeisteri*, and *Chironomus* sp. Species diversity ranged from 0.9 to 3.9 and generally decreased with depth. The number of individuals increased with depth, while the species and species diversity decreased with depth." (Author) The table includes four odonate taxa.] Address: Celik, K., Department of Biology, Balikesir University, 10100 Balikesir, Turkey

5766. Holmen, M. (2002): Bidrag om fund og status for de i Danmark rødlistede arter af guldsmede og vandnymfer. <http://hem.passagen.se/trollslaenda/nof/pdf/odroe.pdf>: 66 pp. (in Danish, with English summa-

ry). ["A contribution on records and status for the Danish Red List dragonflies and damselflies (Odonata). This publication presents Danish records and status reviews since 1764 for the 21 species of Odonata in the Danish 1997 Red List. Records earlier than 2000 and some additional from 2000-2001 have been included. It has been compiled from studies of some major collections, literature and archived notes and by several private contributions of records. However, some additional records no doubt also exist, as not all relevant collections have been studied and not all information on Danish Odonata records have been available for this publication. Since 1991, at least 4 species have been recorded for the first time from Denmark, but their status and localities are not presented, as they are not in the 1997 Red List and at least partly would appear less relevant for the list. A brief review on previous surveys of Danish Odonata is provided." (Author) Available at: <http://hem.passagen.se/trollslaenda/nof/pdf/odroe.pdf>] Address: Holmen, M., Gadeledsvej 48, Gadevang, DK.-3400 Hillerod, Denmark. E-mail: ma@fa.dk

5767. Huber, A.; Kovacs, T.; Ambrus, A. (2002): Data on the Odonata fauna of North-East Hungary. *Fol. hist.-nat. Mus. matraensis* 26: 179-188. (in Hungarian, with English summary). [The Aggtelek National Park Directorate is bordered by the river Hernád, river Sajó and the state border between Hungary and Slovakia. Dragonfly collections realized between 1997 and 2001 resulted in 47 odonate species. *Coenagrion ornatum*, *Brachytron pratense*, *Stylurus flavipes*, *Ophiogomphus cecilia*, *Leucorrhinia pectoralis*, and *Sympetrum danae* are of particular interest.] Address: Huber, A., Aggteleki Nemzeti Park, Igazgatoság, Tengersizem oldal 1, HU-3758 Josvapo, Hungary

5768. Ichinose, T.; Morita, T. (2002): Factors influencing the distribution of dragonflies (Odonata) in the agricultural landscape in Hokudan-cho, Hyogo prefecture. *Journal of the Japanese Institute of Landscape Architects* 65: 501-506. (in English). ["There is a huge number of small irrigation ponds in the agricultural landscape of the north of Awaji Island, Hyogo Prefecture. Recently, managements of many ponds have been abandoned. However, these ponds are used as habitat by many organisms. They have an important role to maintain biodiversity in this area. Odonata were surveyed in 24 irrigation ponds in Hokudan-cho, the north of Awaji Island. Thirty-seven species were caught and/or observed from June to September 2000. The number of dragonfly species had no relation with water body area of irrigation ponds. Twenty-four ponds were classified to five types by TWINSPAN (Two-way Indicator Species Analysis). The classification of TWINSPAN was analyzed by Classification and Regression Trees using explanatory variables about environmental factors of irrigation ponds. The results showed that altitude, neighboring woodlots, water body area and water quality influenced the component of dragonfly species. Especially, it was important for species preferring edge and/or inside of woodlot that over 45 percents of pond surroundings were adjacent to woodlots. It was also suggested that surrounding land uses influenced the distribution of dragonfly species." (Authors)] Address: Ichinose, T., Lab. of Landscape Planning, Awaji Landscape Planning and Horticulture Academy (ALPHA), Institute of Natural and Environmental Science, University of Hyogo, Nojimatokiwa 954-2, Hokudan-cho, Tsuna-

gun, Hyogo, Japan. E-mail: tomohiroichinose@yahoo.co.jp

5771. Ma, Z.-m.; Yang, Z.-z.; Mao, B.-y. (2002): A new record species of *Aristocypha Laidlaw* (1950) (Odonata: Libellaginidae) [sic] from China. *Entomotaxonomia* 24(3): 170. (in Chinese., with English title). [A. hylaryae (Fraser), 2 females, locality not transliterated, alt. 1650 m, 26-VII-1998.] Address: Ma, Z.-m., Dali Medical Coll., Dali, Yunnan-67000, China

5772. Svidersky, V.L.; Plotnikova, S.I. (2002): Insects and vertebrates: Analogous structures in higher integrative centers of the brain. *Journal of Evolutionary Biochemistry and Physiology* 38(5): 627-639. (in English). ["This work deals with studies on anatomical relationships, neuronal composition, and some synaptic connections that exist in the central complex (CC) in the suprasophageal ganglion in larva of dragonfly g. *Aeshna*. It has been shown that CC contains protocerebral bridge of an elongated and slightly curved cylindrical shape, fan-shaped and ellipsoid bodies of a bean-like shape and two small roundish noduli. There were revealed (stained) neurons providing both internal connections of CC and its connections with other CNS regions. Connections with tritocerebrum, the higher center of the autonomic nervous system, and subesophageal ganglion, an intermediate relay between supraesophageal ganglion and truncal brain, have been established. The existence of connections of CC with nuclei of abdominal nervous chain is suggested. Connection of ocelli with the CC has been traced. Unipolar neurons of the same type have been revealed, each of them giving collaterals to protocerebral bridge and ending as bushy terminals that form the main part of glomerule in the fan-

shaped and ellipsoid bodies. Glomeruli are arranged in rows, in which cross connections have been found. It has been established that the structure of neuropils of the fan-shaped and ellipsoid bodies represent a shielding structure described in the cerebral cortex, midbrain cortex, and cerebellar cortex of vertebrates. Thus, in insects, like in vertebrates, the shielding structures developed not only in optic centers, but also in structures performing higher integrative functions. A possible functional role of the central complex is discussed." 5779. Carchini, G.; die Domenico, M.; Pacione, T., Solimini, A.G.; Tanzilli, C. (2003): Species distribution and habitat features in lentic Odonata. *Ital. J. Zool.* 70: 39-46. (in English). ["The relationships between species assemblages and pond characteristics were investigated in a well preserved Mediterranean coastal woodland. Data on adult abundance were collected fortnightly. Pond area and depth, shade, riparian vegetation, presence of four classes of aquatic plants, presence of fish and both the distances from pond to pond and from pond to sea were considered as pond features. Results showed the presence of 23 Odonata species on 23 ponds. A Mantel test showed that the matrices of pond to pond topographic distances and that of pond to pond faunistic similarity were independent, which supports the hypothesis that the adult Odonata actively choose their breeding site. A stepwise multiple regression showed that only pond size, minimum water level and riparian vegetation had significant effects (all positive) on the total number of Odonata species in each pond. On the other hand, a canonical correspondence analysis showed that the composition of Odonata species assemblages was sensitive to almost all variables. From the point of view of Odonata conservation, both the moderate effect of *Gambusia holbrooki* and the positive effect of the riparian vegetation on the number of Odonata species appear particularly interesting for restoring or creating Odonata habitats." 5784. Kravitz, E.A.; Hubery, R. (2003): Aggression in invertebrates. *Current Opinion in Neurobiology* 13: 736-743. (in English). ["Invertebrates are outstanding model systems for the study of aggression. Recent advances and promising new research approaches are bringing investigators closer to the goal of integrating behavioral findings with those from other disciplines of the neurosciences. The presence of highly structured, easily evoked behavioral systems offer unique opportunities to quantify the aggressive state of individuals, to explore the mechanisms underlying the formation and maintenance of dominance relationships, to investigate the dynamic properties of hierarchy formation, and to explore the significance of neural, neurochemical and genetic mechanisms in these behavioral phenomena. [...] Dominance enhances feeding opportunities in dragonflies [Baird J.M., May, M.L.: Fights at the dinner table: agonistic behavior in *Pachydiplax longipennis* (Odonata: Libellulidae) at feeding sites. *J. Insect Behav.* 16:189-216] but few physiological studies that relate specifically to aggression have been carried out using these models." (Authors)] Address: Kravitz, E.A., Department of Neurobiology, Harvard Medical School, 220 Longwood Avenue, Boston, MA 02115, USA. E-mail: edwardkravitz@hms.harvard.edu

5785. Laranjeiro, A.J. (2003): Estabilidade da entomofauna num mosaico de plantação de eucalipto e áreas naturais de conservação. Tese de Doutorado, Escola Superior de Agricultura Luiz de Queiroz (ESALQ), Universidade de São Paulo: XX, 142 pp. (in Portuguese, with English summary). ["Stability of the entomofauna in a region composed by eucalypt plantations and conservation areas. Due to the large spreading of commercial forests in Brazil, in the last decades, one can detect a enormous pressure from the environmentalists and the governmental agencies for evaluation studies and environmental monitoring of forestry enterprises. On the other hand, the forestry enterprises are concerned with the stability of such forests in order to ensure the goals of this agribusiness. The recent spreading of forest

planted areas give chance to a number of pests, either native or introduced ones, to start a process of colonization and adaptation. And one knows that the environmental equilibrium is fundamental for the integrated forest pest management. Therefore this research was carried out to determine the interactions among the main environments of the ecosystem where the plantations are located, as well as the influence of the silvicultural management on the insect communities of the eucalypt plantation and the neighboring natural reservoirs. The entomofauna was monitored by using light and Malaise traps in a watershed of a region with high silvicultural activity, located in the north of the State of Espírito Santo, Brazil, from 1994 to 2002." (Author) Odonata are treated on the family level. For the full paper see: <http://www.teses.usp.br/teses/disponiveis/11/11146/tde-14072003-083640/> Address: Laranjeiro, Alberto Jorge. 5786. Miserendino, M.L. Pizzolon, .A. (2003): Distribution of macroinvertebrate assemblages in the Azul-Quemquemtreu river basin, Patagonia, Argentina. *New Zealand Journal of Marine and Freshwater Research* 37: 525-539. (in English). ["Longitudinal and seasonal changes in physical and chemical variables, and macroinvertebrate community structure-function were examined in the Azul-Quemquemtreu river system in the subantarctic forest of Patagonia, Argentina. Patagonian mountain streams have a marked seasonal discharge pattern and may have high suspended sediment loads because of forestry and other land-use practices. The main physical differences among sites were in substrate size (boulder-pebble/ sand), mean width (3–37 m), discharge (<math><1-80\text{ m}^3\text{ s}^{-1}</math>), total alkalinity (275–1210 meq litre⁻¹) and conductivity (31–137 $\mu\text{S cm}^{-1}$). Species richness and Ephemeroptera, Plecoptera, and Trichoptera richness decreased from upstream sites to the mouth of the river system and were affected by land use. Macroinvertebrate assemblages were influenced by physical (substrate size, width, discharge, current velocity) and chemical (alkalinity and conductivity) variables, and mean density of macroinvertebrates was significantly higher at the Quemquemtreu sites than the Azul sites. Canonical Correspondence Analysis indicated that seasonal trends in macroinvertebrate community composition were related to changes in environmental characteristics of the river, especially water temperature and discharge. The composition of benthic communities in rivers of the Patagonian Andes largely reflect characteristics related to stream size, but factors at the reach scale best explain variation in abundance data. Collector-gatherers were the dominant functional feeding group at all sites. Faunas have similarities with those of New Zealand in taxonomic-functional composition, with a predominance of Chironomidae (Diptera), Leptophlebiidae (Ephemeroptera), and Gripopterygidae (Plecoptera)." (Authors) The only odonate species – *Rhinoeschna variegata* – is reported from one of the six localities sampled for macroinvertebrates.] Address: Miserendino, Laura, Laboratorio de Ecología Acuática, Universidad Nacional de la Patagonia, Sarmiento 849, 9200 Esquel, Chubut, Argentina. 5787. Mochizuki, H.; Komaki, H.; Morita, M.; Kusamichi I. (2003): Observation of dragonfly flying in air and flow. *Transactions of Visualization Society of Japan* 23(12): 115-121. (in Japanese, with English summary). ["The flapping of a dragonfly, *Pantala flavescens*, hori-

zontally flying in a field was observed with a high speed video camera. As a result, it was clarified that a frequency of the flapping with maximum amplitude in the observation was the same order as one of the flapping in a wind tunnel. Also, it was observed that vortices regularly occurred every one cycle by flapping with large amplitude in the wind tunnel and diverged downstream with combining each other. The flow upstream of the dragonfly flapping was induced in three forms of curved flow lines into the region around the body. Furthermore, wakes were generated in horizontal, downward and upward directions according to these forms." (Authors)] Address: Mochizuki, H., Faculty of Agriculture, Kagoshima University

5788. Samson, N. (2003): Étude du degré de dispersion et des facteurs favorables à la reproduction de la Cordulie à corps fin, *Oxygastra curtisii* (Dale, 1834), dans les Mauges (49). Centre Permanent d'Initiatives pour l'Environnement Loire et Mauges, Maison de Pays « La Loge, F-49600 Beaupreau: 73 pp. (in French). ["L'espèce *Oxygastra curtisii* (Dale, 1834) est présente en France sur l'ensemble du territoire mais sa fréquence est moindre dans le nord. Le CPIE Loire et Mauges s'intéresse à cette espèce d'intérêt patrimonial car sa présence dans les Mauges est marquée. De cette observation est née la volonté de mener une étude plus poussée sur la Cordulie à corps fin. La problématique de cette étude est double. Il s'agit de cerner les conditions favorables à la reproduction de l'espèce ainsi que son degré de dispersion dans le paysage bocager des Mauges. Pour répondre à cette problématique, les recherches ont porté sur les lieux d'émergence et de vie des larves, le comportement des imagos ainsi que leurs déplacements dans le maillage bocager. La méthodologie mise en place a eu pour but d'aborder le plus d'étapes possibles du cycle biologique: l'émergence, par une recherche des exuvies sur des plaquettes de suivi choisies pour leurs caractéristiques favorables à la présence d'*Oxygastra curtisii*, d'après la bibliographie étudiée, les imagos matures, par la technique de capture/marquage qui permet de récolter des informations à l'échelle de la population, des sexes et de l'individu. Le suivi a lieu dans le paysage bocager, dans le but d'étudier leur comportement et le degré de dispersion, et en contexte aquatique pour observer les comportements liés plus précisément à la reproduction. 115 exuvies ont été récoltées, 102 imagos ont été marqués (80 mâles et 22 femelles), 10% de ces imagos ont été contrôlés et des comportements sexuels ont été constatés (comportements territoriaux, accouplements et pontes). La recherche des exuvies a permis de prouver la reproduction de l'espèce sur l'Evre, de déterminer la période d'émergence et les caractéristiques des sites d'émergence. Le suivi des imagos a permis de préciser le cycle biologique de l'espèce Le but final de cette étude est de prendre en compte la présence d'*Oxygastra curtisii* lors de travaux sur le bocage et les ripisylves." (L'auteur)] Address: Centre Permanent d'Initiatives pour l'Environnement Loire et Mauges, Maison de Pays « La Loge, F-49600 Beaupreau, France

5789. Sukhacheva, G.A.; Kryukova, N.A.; Glupov, V.V. (2003): On the roles of morphological and biochemical criteria in species identification: An example of dragonfly larvae of the genus *Aeshna*. *Biology Bulletin* 30(1): 63-68. (in English). ["Dragonflies belong to the group of organisms with numerous well-differentiated

species-specific characters at the adult stage, on the one hand, and a significantly smaller number or even the absence of such characters at the early ontogenetic stages. An example of the genus *Aeschna* is used to show difficulties in revealing morphological and biochemical characters allowing identification of larval dragonflies belonging to closely related species of the family. Distinct morphometric characters can be found only in late-instar larvae. The presence of species-specific proteins in the homogenates of thoracic muscles provides the possibility of using biochemical tests for species identification of larvae. Infestation by parasites has no effects on the biochemical parameters studied. Species identification of the early-instar dragonfly larvae is still problematic." 5790. Sutcliffe, K.E. (2003): The conservation status of aquatic insects in south-western Australia. PhD Thesis, Murdoch University: ["Freshwater ecosystems in south-western Australia have been extensively altered over the last two centuries as a result of human activities. The effect this has had on aquatic fauna, particularly invertebrates, is largely unknown because of inadequate knowledge of the pre-existing fauna. Future changes in the composition of aquatic fauna will also go undetected unless current distributions of existing species are well documented. This thesis addresses the problem by investigating the current distributions and conservation status of aquatic insects in south-western Australia from three orders: Odonata, Plecoptera and Trichoptera. Extensive distributional data was collected by identifying larval specimens from a large number of samples collected throughout the south-west as part of an Australia-wide macroinvertebrate bioassessment project. In addition, a database created from a species-level biological study of the wheatbelt region of Western Australia was utilised, and previously published records of occurrence for species within the south-west were compiled. These results were then used to assess the conservation status of each species using the IUCN red list criteria. Environmental parameters measured at time of sampling were also examined using logistic regression to determine which factors are important in influencing the distributions of aquatic insects in south-western Australia. The conservation value of sites based on Odonata, Plecoptera and Trichoptera compositions was also determined and the degree of protection provided for sites of high conservation value investigated. The high rainfall forested region of the south-west was found to be important for a large number of species, including the majority of those found to be rare and/or restricted. Overall, 37% of species were found to be threatened, with the Trichoptera containing both the greatest number and highest proportion of threatened species. Logistic regression results generally agreed with the distributions obtained for each species, with rainfall and other parameters indicative of streams in the headwaters of forested catchments being positively associated with species found to be restricted to the high rainfall region. Two parameters known to be affected by human disturbance in the south-west, conductivity and nutrient concentrations, were found to be important in determining the occurrence of many species and this could have important consequences for aquatic insect conservation. Widespread species occurring within the low rainfall region of the south-west did not show as

many significant relationships to measured environmental parameters, possibly due to their greater ecological tolerances and adaptations which allow them to persist in a low rainfall environment. The implications of results are discussed, and recommendations for the conservation and management of aquatic insects in south-western Australia are given." 5792. Tanida, Y. (2003): Locomotion by Tandem and Parallel Wings (A Note on the Flight of Dragonflies and Beetles). *JSME International Journal Series B* 46(2): 244-249. (in English). ["A two-dimensional analysis was carried out on the locomotion by tandem and parallel wings in relation to the free flight of dragonflies and beetles, remarking the mutual interference between fore and hind wings. The results obtained are summarized as follows: In the case of tandem wings, (1) High thrust and propulsive efficiency can be achieved when the forewing oscillates with a definite phase lag behind the hindwing, as in the case of real dragonflies, (2) Somewhat smaller amplitude of hindwing leads to optimum condition for work sharing of two wings, (3) The hard forewing does not serve for the thrust and propulsive efficiency, whereas the hard hindwing does for the augmentation of them; In the case of parallel wings, (4) The hard wing placed near the soft wing acts nearly as an infinite plate, as for the ground effect, increasing both thrust and propulsive efficiency." 5793. Argerich, A.; Puig, M.A.; Pupilli, E. (2004): Effect of floods of different magnitude on the macroinvertebrate communities of Matarranya stream (Ebro river basin, NE Spain). *Limnetica* 23(3-4): 103-114. (in English, with Spanish summary). ["In October 2000, the Matarranya River suffered an extraordinary flood with a measured flow rate of approximately 450 m³/s in the town of Vall-de-roures and a return period of about 500 years, according to the Ebro Hydrographic Confederation. The objective of this study was to determine the influence of the consequent perturbation on the structure and composition of the macroinvertebrate community and its subsequent recovery. To this end, two sites in the headwaters of the river, about which information from previous studies was available, were chosen as sampling sites. The Parrissal station, 8 km from the source with a practically natural flow regime, and at Vall-de-roures, 18 km from the source and from which part of the flow has been deviated, to be returned in summer from the waters collected in the reservoir on the Pena River. Sampling was carried out one, five and fifteen months after the flood and the data was compared with that obtained before the perturbation, (December, 1998 and February, 1999). On the other hand, we analyzed the effects of smaller floods occurring in October 1984

(Parrissal) and June 1986 (Vall-de-roures). The results point to different patterns of recovery in the two sampling points after the 2000 flood, the community density recovering more rapidly in the site less affected by anthropic intervention (Parrissal), while the biological quality of the stretch studied in Vall-de-roures involved increased taxonomic richness and greater structuring of the community. The flood events of lesser magnitude did not seem to affect the community structure in Parrissal, while in Vall-de-roures the abundance of the predominant groups varied." 5794. Broomhall, S.D. (2004): Egg temperature modifies predator avoidance and the effects of the insecticide endosulfan on tadpoles of an Australian frog. *Journal of applied ecology* 41: 105-113. (in English). ["1. Attention is shifting from simplistic explanations of global amphibian declines that posit a single cause (such as climate change, pesticide contamination or disease) to more complex scenarios that involve interactive effects. Temperature is a pervasive influence on frog development, particularly during the egg and larval stages. However, the effect of temperatures experienced early in ontogeny on later larval behaviour or response to agrochemicals is little known. 2. Eggs of the Australian frog *Limnodynastes peronii* were reared at two temperatures that simulate naturally occurring cool and warm temperature regimes ($14\pm 3^{\circ}\text{C}$ and $20\pm 3^{\circ}\text{C}$). Tadpoles were then exposed to sublethal concentrations of the organochlorine insecticide endosulfan, at a common temperature. Endosulfan often contaminates aquatic environments, yet its effects on Australian frogs are unknown. Tadpoles reduced feeding after 48 h of exposure to endosulfan concentrations that occur in the field (both $0.03\mu\text{g l}^{-1}$ and $1.3\mu\text{g l}^{-1}$). Feeding remained depressed at $1.3\mu\text{g l}^{-1}$ endosulfan up to 9 days after tadpoles were transferred to endosulfan-free water. 3. Egg-rearing temperature and endosulfan interacted to affect tadpole length. Further, tadpoles exposed to endosulfan were significantly shorter than control tadpoles. They were also more vulnerable to capture by an invertebrate (odonate) predator than controls of the same size when tested 9 days after transfer to clean water. While warm egg-rearing temperatures significantly decreased vulnerability to capture, tadpoles were proportionally more adversely affected by endosulfan. Thus, egg-rearing temperature altered predator avoidance and changed the way in which endosulfan affected growth. Moreover, endosulfan significantly decreased feeding, growth and predator avoidance. 4. Synthesis and applications: Not only can short-term exposure to endosulfan at levels within regulatory guidelines and frequently reported in natural waterbodies influence tadpole viability, but the sensitivity of the tadpoles to this effect depends upon the thermal regimes that they encounter over their first few days of life. These data therefore suggest that existing water quality prescriptions may not provide adequate protection, while also illustrating how aspects of climate and thermal regimes might interact with pesticides to have cumulative effects on amphibian fitness." 5795. Cale, D.J.; Halse, S.A.; Walker, C.D. (2004): Wetland monitoring in the Wheatbelt of south-west Western Australia: site descriptions, waterbird, aquatic invertebrate and groundwater data. *Conservation Science W. Aust.* 5(1): 20-135. (in English). ["The Wheatbelt of south-west Western Australia contains a range of wetland types with varying salinity, including many naturally saline lakes and playas. The increase in salinity of most wetlands during the last 50 years as a result of land-clearing is a major threat to wetland biodiversity. As part of the State Salinity Strategy, a wetland monitoring program began in 1997 at 25 wetlands from locations throughout the wheatbelt. The aim of the monitoring program was to document trends in biodiversity at the 25 wetlands and relate these trends to physical conditions in the wetlands and patterns of surrounding landuse. This report summarizes existing information on the wetlands and provides, as baseline conditions, results of initial waterbird, aquatic invertebrate and groundwater monitoring. It documents the monitoring methods used and highlights the need for a long-term program. There was a strong negative relationship between aquatic invertebrate species richness and salinity. A negative relationship also existed for waterbird richness, although other factors determined numbers of species in many wetlands with salinity being a constraint on maximum potential waterbird richness rather than a determinant of the actual number of species. Further salinization is likely to change detrimentally both invertebrate and waterbird communities. Such changes are apparent in historical waterbird data from some wetlands. The ultimate cause of increased salinity in wetlands is rising groundwater, although sometimes wetlands are more directly affected by the increased surface run-off that results from high watertables in the catchment than by groundwater beneath the wetland." (Authors) The following odonate species are tabled: *Ilschnura aurora aurora*, *Ilschnura heterosticta heterosticta*, *Austroagrion coeruleum*, *Xanthagrion erythroneurum*, *Austrolestes annulosus*, *A. aridus*, *A. analis*, *A. io*, *A. psysche*, *Hemianax papuensis*, *Aeshna brevistyla*, *Hemicordulia tau*, *Procordulia affinis*, *Orthetrum caledonicum*, *Diplacodes bipunctata*, and *Agrioptera insignis allogenae*.] Address: Cale, D.J., Science Division, Department of Conservation and Land Management, PO Box 51 Wanneroo Western Australia 6956. (2004): An annotated list of the name bearing type specimens of species-group names in Odonata in the Insect Collection of the Institute of Zoology, Chinese Academy of Sciences. *Pan-Pacific Entomologist* 80: 81-90. (in English). ["Species-group names of the order Odonata, including Aeshnidae, Calopterygidae, Coenagrionidae, Cordulegastridae, Euphaeidae, Gomphidae, Libellulidae, Megapodagrionidae, Platycnemididae and Synlestidae, deposited in the insect collection of the Institute of Zoology, Chinese Academy of Sciences, are listed alphabetically by species names published originally, along with an abbreviated citation to the original description, museum specimen number, sex, locality data, collector, collecting date, specimen condition and remarks where available. The type collection includes 71 name-bearing types of Odonata consisting of 39 holotypes, 10 allotypes, 12 paratypes, 1 neotype and 9 syntypes, and includes 50 species described by S. J. Navas, H. F. Chao and M. A. Lieftinck." (Author)] Address: Xiao-Lin Chen, Insect Collection, Institute of Zoology, The Chinese Academy of Sciences, Beijing, 100080, P.R.China. E-mail: xlchen@ioz.ac.cn

5798. Deer, L.A.; Gertz, L.; Kelley, C.; Osterrieder, K.; Rice, T.M. (2004): Dragonfly larvae (Insecta:Odonata) have high tolerance to acute metal exposure. Poster presentation at the 25th annual meetings of the Society of Environmental Toxicology and Chemistry, Portland, OR: (in English). [Verbatim. Odonates (Insecta: Odonata; dragonflies and damselflies) occupy important trophic levels in freshwater systems. They have a biphasic lifecycle, with aquatic predatory larvae and aerial terrestrial predatory adults. Additionally, odonates can reach high levels of abundance in some habitats and are important food items of both aquatic and terrestrial predators. Therefore, odonates could be exposed to aquatic toxicants from a variety of sources and could then transfer bioaccumulated toxicants to their predators. Despite their presence and importance in aquatic ecosystems, there is very little field or laboratory data regarding the impact that environmental chemicals have on odonates. We have developed methods for the laboratory maintenance and testing of odonate larvae collected from the Mobile, Alabama region. In acute toxicity tests primarily with *Erythemis simplicicollis* (Libellulidae), larvae approximately 10 mm in length were exposed in individual containers to amounts of copper and cadmium above 100 mg/L. Using immobility as the endpoint, larvae were able to tolerate high levels of both metals, with EC50 values above 25 mg/L. This species of odonate appears to be extremely resistant to metals compared in general to other common aquatic test species (e.g. *Daphnia*, *Xenopus*). High resistance to metal pollution could make odonate larvae a potential indicator of poor water quality in contaminated habitats. Their ability to withstand and accumulate high levels of metals might also put their predators at risk from ingestion of contaminated larvae or adults. We are continuing our laboratory tests with other species and other chemicals, and we are also investigating the use of these organisms as field indicators of water quality from watersheds such as the Mobile Delta.]

5799. Frydrychová, R.; Grossmann, P.; Truba, P.; Vítková, M.; Marec, F. (2004): Phylogeny of TTAGG telomeric repeats in insects. *Genome* 47: 163-178. (in English). ["We examined the presence of TTAGG telomeric repeats in 22 species from 20 insect orders with no or inconclusive information on the telomere composition by single-primer polymerase chain reaction with (TTAGG)₆ primers, Southern hybridization of genomic DNAs, and fluorescence in situ hybridization of chromosomes with (TTAGG)_n probes. The (TTAGG)_n sequence was present in 15 species and absent in 7 species. In a compilation of new and published data, we combined the distribution of (TTAGG)_n telomere motif with the insect phylogenetic tree. The pattern of phylogenetic distribution of the TTAGG repeats clearly supported a hypothesis that the sequence was an ancestral motif of insect telomeres but was lost repeatedly during insect evolution. The motif was conserved in the "primitive" apterous insect orders, the Archaeognatha and Zygentoma, in the "lower" Neoptera (Plecoptera, Phasmoda, Orthoptera, Blattaria, Mantodea, and Isoptera) with the exception of Dermaptera, and in Paraneoptera (Psocoptera, Thysanoptera, Auchenorrhyncha, and Sternorrhyncha) with the exception of Heteroptera. Surprisingly, the (TTAGG)_n motif was not found in the "primitive" pterygotes, the Palaeoptera (Ephemeroptera and Odonata). The Endopterygota were heterogeneous for the occurrence of TTAGG repeats. The motif was conserved in Hymenoptera, Lepidoptera, and Trichoptera but was lost in one clade formed by Diptera, Siphonaptera, and Mecoptera. It was also lost in Raphidioptera, whereas it was present in Megaloptera. In contrast with previous authors, we did not find the motif in Neuroptera. Finally, both TTAGG-positive and TTAGG-negative species were reported in Coleoptera. The repeated losses of TTAGG in different branches of the insect phylogenetic tree and, in particular, in the most successful lineage of insect evolution, the Endopterygota, suggest a backup mechanism in the genome of insects that enabled them frequent evolutionary changes in telomere composition." 5802. Keeley, C.; Gertz, L.; Osterrieder, K.; Rice, T.M. (2004): Use of dragonfly larvae (Insecta:Odonata) in toxicological tests. Poster presentation at the 25th annual meetings of the Society of Environmental Toxicology and Chemistry, Portland, OR: (in English). [Verbatim: Odonates (Insecta: Odonata; dragonflies and damselflies) are important members of freshwater ecosystems as both predators and prey. They have an aquatic predatory larval stage and an aerial terrestrial predatory adult stage. Additionally, odonates can be very abundant in certain habitats and are preyed upon by a variety of aquatic and terrestrial predators. Despite their presence and importance in aquatic ecosystems, there is very little field or laboratory data regarding the impact that environmental chemicals have on odonates. Odonate larvae could be useful test organisms in toxicological research because many species are easily collected in large numbers and are of a reasonable size. However, before laboratory experiments such as acute and chronic tests can be conducted, methods for the maintenance of odonates need to be established. We have developed methods for housing and feeding odonate larvae. Using primarily *Erythemis simplicicollis* (Libellulidae), we hold larvae in individual ventilated plastic cups in order keep track of individuals and to keep food items in close proximity. Cups are contained in a filtering, recirculation system with reconstituted hard water under a 12L:12D photoperiod regime at 22°C. Larvae are fed small fish or tadpoles as food every few days. We have found that larvae can survive in these conditions and continue to grow and molt for several weeks. They require only infrequent feeding and produce little waste. We prefer that larvae spend at least one week and have one meal under these conditions before being used in toxicity tests. Our system is easy to construct and maintain and should be useful for anyone interested in maintenance of odonates or animals with similar habits.]

5804. Lehmann, F.-O. (2004): The mechanisms of lift enhancement in insect flight. *Naturwissenschaften* 91: 101-122. (in English). ["Recent studies have revealed a diverse array of fluid dynamic phenomena that enhance lift production during flapping insect flight. Physical and analytical models of oscillating wings have demonstrated that a prominent vortex attached to the wings leading edge augments lift production throughout the translational parts of the stroke cycle, whereas aerodynamic circulation due to wing rotation, and possibly momentum transfer due to a recovery of wake energy, may increase lift at the end of each half stroke. Compared to the predictions derived from conventional steady-state aerodynamic theory, these unsteady aerodynamic mechanisms may account for the majority of total lift produced by a flying insect. In addition to contributing to the lift required to keep the insect aloft, manipulation of the translational and rotational aerodynamic mechanisms may provide a potent means by which a flying animal can modulate direction and magnitude of flight forces for manoeuvring flight control and steering behaviour. The attainment of flight, including the ability to control aerodynamic forces by the neuromuscular system, is a classic paradigm of the remarkable adaptability that flying insects have for utilising the principles of unsteady fluid dynamics. Applying these principles to biology broadens our understanding of how the diverse patterns of wing motion displayed by the different insect species have been developed throughout their long evolutionary history." (Author) Many references to Odonata are made.] Address: Lehmann, F.-O., Department of Neurobiology, University of Ulm, Albert-Einstein-Allee 11, 89081 Ulm, Germany. 5805. Peterson, K.J.; Lyons, J.B.; Nowak, K.S.; Takacs, C.M.; Wargo, M.J.; McPeck, M.A. (2004): Estimating metazoan divergence times with a molecular clock. *Proceedings of the National Academy of Sciences U S A*. 101(17): 6536-6541. (in English). ["Accurately dating when the first bilaterally symmetrical animals arose is crucial to our understanding of early animal evolution. The earliest unequivocally bilaterian fossils are approximately 555 million years old. In contrast, molecular clock analyses calibrated by using the fossil record of vertebrates estimate that vertebrates split from dipterans (*Drosophila*) approximately 900 million years ago (Ma). Nonetheless, comparative genomic analyses suggest that a significant rate difference exists between vertebrates and dipterans, because the percentage difference between the genomes of mosquito and fly is greater than between fish and mouse, even though the vertebrate divergence is almost twice that of the dipteran. Here we show that the dipteran rate of molecular

evolution is similar to other invertebrate taxa (echinoderms and bivalve molluscs) but not to vertebrates, which significantly decreased their rate of molecular evolution with respect to invertebrates. Using a data set consisting of the concatenation of seven different amino acid sequences from 23 ingroup taxa (giving a total of 11 different invertebrate calibration points scattered throughout the bilaterian tree and across the Phanerozoic), we estimate that the last common ancestor of bilaterians arose somewhere between 573 and 656 Ma, depending on the value assigned to the parameter scaling molecular substitution rate heterogeneity. These results are in accord with the known fossil record and support the view that the Cambrian explosion reflects, in part, the diversification of bilaterian phyla." (Authors) The analysis includes *Enallagma aspersum* and *Lestes congener*. 5808. Brodin, T. (2005): Predator effects on behaviour and life-history of prey. Doctoral thesis, Department of Ecology and Environmental Science, S-901 87 Umeå, Sweden. ISBN: 91-7305-964-1: 34 pp. (in English). ["In

this thesis I investigate predator-induced effects on behavioural and life-history characteristics of prey. At any moment a given predator is capable of attacking a small number of prey. However, the mere presence of a predator may impact a much larger number of individuals, as prey implement various behavioural and developmental mechanisms to reduce the risk of predation. It has become increasingly clear that predator induced responses have the potential to affect patterns of species abundance and distribution as well as individual fitness of prey. I study these responses by incorporating field surveys, semi-field experiments and laboratory experiments. All experiments were done in an aquatic environment using fish or large odonate larvae as predators and damselfly-or diving beetle larvae as prey. My work highlights the importance of monitoring prey behaviour when studying life-history characteristics. I show that fish presence is an important factor for determining species abundance and distribution of odonates, and that prey behaviour may be a good predictor for fish vulnerability. Larval damselflies react behaviourally to predator presence by reducing activity and/or restricting habitat use. I confirm that such anti-predator responses have positive effects on prey survival in the presence of a predator but negative effects on growth and development of prey. In addition, my results suggest that the increase in per capita food resources for surviving prey following a predation episode (i.e. thinning) can have a stronger positive effect on prey growth and development than the negative effect of anti-predator responses. I also show that the strength of an anti-predator response is dependent on resource availability of the prey, with prey responding less strongly when resources are scarce. My results also indicate that the strength of the anti-predator response of damselfly larvae depends on predator diet and larval age. Predators feeding on prey conspecifics induce a stronger behavioural response in young larva than predators that feed on prey heterospecifics do. This diet-effect was not found in larvae late in ontogeny, due to an increased activity of larva where predators consumed damselflies. Such increased larval activity can be explained as a reaction to a time-constraint. Finally, I found that activity of damselfly larvae is genetically determined and that this has led to a behavioural syndrome that might limit larval plasticity to a certain activity-range. This phenomenon may have implications for how well larvae are able to react to both biotic and abiotic changes in the environment." 5809. Buttstedt, L.; Zimmermann, W. (2005): Über Entwicklungsnachweise der Feuerlibelle, *Crocothemis erythraea* (Brülle, 1832), in Thüringen und Sachsen-Anhalt (Odonata). *Entomologische Nachrichten und Berichte* 49(3-4): 171-179. (in German, with English summary). ["An overview of the 24 localities of *C. erythraea* known in Sachsen-Anhalt and Thuringia, Germany in 2005 is provided. In 2003 and 2004, the authors studied six of the inhabited water bodies in detail. Development of the species at one site in Thuringia and at two sites in Sachsen-Anhalt is confirmed. The two sites with the largest number of exuviae are briefly characterized. Observations on biology and behaviour made at the rain water collection basin at Artern are communicated and discussed. The temporal pattern of emergence is documented from 69 exuviae collected in 2004. Variati-

ons in size and pigmentation of the same exuviae are described. Our records of confirmed reproduction are at approximately 51°20'N which agrees reasonably with records from Hesse, Lower Saxony, Sachsen-Anhalt, and Brandenburg." (Authors)] Address: Zimmermann, W., Thomas-Müntzer-Str. 5, D-99423 Weimar, Germany

5810. Carnier (2005): Gemeine Winterlibelle *Sympetma fusca* und Gebänderte Heidelibelle *Sympetrum pedemontanum* im Kreis Wesermarsch. Beitr. Naturk. Nieders. 58: 41-42. (in German). 5811. Catling, P.M. (2005): A Potential for the Use of Dragonfly (Odonata) Diversity as a Bioindicator of the Efficiency of Sewage Lagoons. *Canadian Field-Naturalist* 119(2): 233-236. (in English). ["In order to determine whether a relationship existed between water quality and odonate fauna in sewage ponds, data were gathered at each of six ponds of similar construction and equal size and depth in an adjacent series of improving water quality at a lagoon system near Embrun in eastern Ontario. Numbers of nymphs of different species of Odonata were recorded in spring and fall, and similar data was collected on adults in June and July. The data on species presence and abundance for each of three pairs of cells in the sequence was then compared with the corresponding chemical data which included biological oxygen demand, total phosphorus, total nitrogen and suspended solids. Water quality improved through the system and species diversity in the final ponds was twice that of the ponds receiving wastewater. Numbers of individuals also increased through the system. Occurrence of *Anax junius*, *Enallagma civile* and *Ischnura verticalis* alone was associated with poorer water quality. Higher diversity including *Lestes disjunctus*, *Leucorrhinia* spp. and *Erythemis simplicicollis*, indicates higher water quality. A potential exists for Odonata species diversity, numbers of individuals and occurrence of particular species to be used as a bioindicator of water quality and a means of evaluating efficiency of a lagoon system. Advantages include data that reflects a time period rather than a point in time and also low costs." (Author)] Address: Catling, P.M., Biology, University of Ottawa, 30 Marie Curie, Ottawa, Ontario K1N 6N5 Canada; catlingp@em.agr.ca

5812. Céréghino, R.; Cayrou, J. (2005): Life-cycle phenology of some aquatic insects: implications for pond conservation. *Aquatic Conserv: Mar. Freshw. Ecosyst.* 15: 559-571. (in English). ["1. Life-cycles and growth patterns were determined for 21 dominant aquatic insect species in small permanent ponds in an arid, karstic region (SW France, site fr7300909 of the Natura 2000 conservation network). The species studied are widely distributed throughout Europe, but some life-cycle patterns are reported here for the first time. 2. The life-history patterns of the 21 species can be divided into five main types: (i) a semivoltine cycle spreading over 2 years; (ii) slow univoltine cycles; (iii) fast univoltine cycles; (iv) multivoltine life-cycles with a long winter generation and two or three summer generations per year; and (v) bivoltine life-cycles with two fast generations per year. Growth was either exponential over the whole developmental period for a given cohort, or divided into two or three successive periods during each of which

the growth rate was fairly constant. 3. Biodiversity estimates strongly depend on the temporal and spatial scale over which observations are made. Ponds thus provide useful models to show how life-history patterns enable many temporally segregated populations to utilize small ecosystems. Conservation frameworks should therefore carefully consider the time-frame needed to survey ponds, as many species with fast cycles could be overlooked. The spatial scale needed to manage threatened habitats and thus preserve pond networks must be broadened, rather than attempting to target individual water bodies for particular management actions." (Authors) The following Odonata are treated: *Coenagrion scitulum*, *Chalcolestes viridis*, *Libellula depressa*, *Anax imperator*.] Address: Céréghino, R., Laboratoire d'Ecologie des Hydrosystèmes, UMR 5177, Université Paul Sabatier, 118 route de Narbonne, 31062 Toulouse cedex 4, France. 5813. Cheng, P.; Hu, J.; Zhang, G.; Xu, B.; Wu, X. (2005): The measurement of the flight gesture and the wing deformation of dragonfly in free flight. *Proceedings of SPIE -- Volume 5852 Third International Conference on Experimental Mechanics and Third Conference of the Asian Committee on Experimental Mechanics*, Chenggen Quan, Fook Siong Chau, Anand Asundi, Brian Stephen Wong, Chwee Teck Lim, Editors: 879-885. (in English(?)). ["Using the phase shifting and the grating projection method, the kinematical parameters of dragonfly in free flight were measured. In our experiment, during projecting parallel sine fringes on the dragonfly's wings with a projector, the high speed CCD TV camera (1000 frames per second) recorded the dragonfly and the fringes projected on the dragonfly's wing, then the shape of the dragonfly's wings in every frame could be gutted using SCPM (Spatial-Carrier Phase Measurement) method. According to this data, we designed a program which can show the change of the gesture of the dragonfly's wing, the 3-D figure, the contour line and the curve of any transversal of the dragonfly's wing at any given time. From the figures of the 3-D deformation, we also can see that the deformation is not completely negative, it must could be control by the dragonfly via the veins on the wing." 5814. Clistenes de Alcântara Santos, A. (2005): Feeding ecology of the Molé Trachelyopterus galeatus Linnaeus, 1766 (Siluriformes, Auchenipteridae) in the lower course of the São José and Santo Antônio Rivers (Chapada Diamantina, Bahia). *Sitientibus Série Ciências Biológicas* 5(2): 93-98. (in Portuguese, with English summary). ["The São José and Santo Antônio Rivers are representative affluents of the Paraguaçu River, although they have demonstrated different physiographic conditions and differ in their degrees of anthropogenic disturbance. In this work, the feeding ecology of *T. galeatus* was described, as well as the possible effects of the alterations previously caused by former diamond mining on the São José bed and margins. Feeding was analyzed through the Frequency of Occurrence and by the Volumetric method combined in an Alimentary Index. The niche width was then calculated. The results indicate a lesser contribution of allochthonous items in the São José River. This may be due to the effects of deforestation along its margins, which would influence species that are dependent upon

those resources. Among the parameters analyzed, the lesser proportion of allochthonous items in the diet of fish from the São José River was marked and can be considered an indirect result of previous mining activity in the area." (Authors) The diet also includes Odonata.] Address: Clisteres de Alcântara Santos, A., Laboratório de Ictiologia, Departamento de Ciências Biológicas, Universidade Estadual de Feira de Santana, Km 03, BR 116, 44031-460, Feira de Santana, Bahia, Brasil. 5817. Culhane, F. (2005): The impact of forest disturbance on Odonata communities and the potential use of Odonata as indicators of environmental disturbance, Buton Island, Indonesia. Department of Zoology, Trinity College Dublin, Moderation Thesis 2005: 105 pp. (in English). ["Odonata have been shown to be sensitive and reliable indicators of environmental disturbance (e.g. Stewart & Samways, 1998). A forest stream is influenced by the nature of the catchment and reflects aspects of forest quality and disturbance. Macroinvertebrate assemblages including Odonata larvae, in streams and rivers, have been used extensively as bioindicators of forest disturbance. The aim of this project was to look at the impact of forest disturbance on communities of Odonata and the implications that might have for use of Odonata in bioindication. Seven sites on Buton Island, Indonesia were sampled over a period of five weeks in autumn 2004. GIS data were used to classify sites into disturbed or undisturbed forest. Odonata larvae were collected by kick sampling in two kinds of habitat at each site. Assessment of environmental variables of forests was carried out at the study sites. Larvae were identified to family level and then divided into morphospecies. The length of each larva was mea-

sured. Differences in species composition, diversity measures, functional groups and size frequency distribution were used to show differences between disturbed and undisturbed sites. Thirty-four morphospecies in nine families of Odonata were found. Species richness and diversity differed among sites and were lower at disturbed sites. It was found that the distribution of Zygopteran larvae differed between habitats, and between disturbed and undisturbed sites based on caudal appendage morphology, implying a potential use for caudal appendage type in biomonitoring. The width of size frequency distribution was lower at disturbed sites. Most sites contained morphospecies which were unique to it, thus, a range of habitats from pristine to moderately disturbed would conserve the greatest number of Odonata species." 5818. DuBois, B. (2005): Damselflies of the North Woods. Kollath-Stensaas Publishers. ISBN 0-9673793-7-7: 132 pp. (in English). [This fieldguide is the damselfly companion to Kurt Mead's Dragonflies of the North Woods (see OAS 3740). Like this book, it is appropriate for a far larger area than the "north woods". It will be appropriate to large areas of Ontario in Canada, Minnesota, Wisconsin, Michigan, and Iowa. The book starts with a long, well-illustrated section on morphology, behaviour, and life history of damselflies. The 39 species recorded (plus a further 7 which may appear in the region) are individually discussed and illustrated on a two-page spread with very good photos. Diagnostic characters or structures are specifically indicated by arrows. Information is also provided on the life cycles. A graph of the flight and a range map are also given for each species. The focus of the field guide is more on colour patterns than structures. (Martin Schorr)] Address: Kollath-Stensaas Publishers. 394 Lake Avenue South, Suite 406, Duluth, MN 55802, USA

5821. Hayashi, F.; Tsuchiya, K. (2005): Functional association between female sperm storage organs and male sperm removal organs in calopterygid damselflies. *Entomological Science* 8(3): 245-252. (in English). ["Fe-

male damselflies in the family Calopterygidae have two sperm storage organs: a spherical bursa copulatrix and a tubular spermatheca. Male flies have a peculiar aedeagus with a recurved head with which to remove bursal sperm, and lateral spiny processes to remove spermathecal sperm. The lateral processes differ among species and populations in terms of their width relative to the spermathecal duct: the narrower processes are physically able to access spermathecal sperm, while the wider ones are not. In the present study, sperm storage patterns and aedeagal structures were compared between two calopterygid species with different spermathecal structures –*Calopteryx cornelia* and *Mnais pruinosa*– with respect to not only sperm quantity (number) but also sperm quality (viability), by using a recently developed method based on live/dead dual fluorescence. *Calopteryx cornelia* is a typical spermathecal sperm remover. In this species, viability was similar between bursal and spermathecal sperm. In contrast, in *M. pruinosa*, the spermatheca was much smaller than the bursa and often contained no sperm. Even when the spermatheca of this species did contain sperm, a high percentage of it was dead. Although the spermatheca of *M. pruinosa* has such atrophic tendencies, males have nevertheless developed long and spiny lateral processes similar to those of *C. cornelia*, suggesting the processes have functions other than spermathecal sperm removal. They possibly function as stoppers or guides for manipulating the aedeagal head to remove the sperm mass from the bursa." 5823. Hufnagel, L.; Gaal, M. (2005): Seasonal dynamic pattern analysis in service of climate change research: A methodical case-study. Monitoring and simulation based on an aquatic insect community. *Applied ecology and environmental research* 3(1): 79-132. (in English). ["Our aim was to approach an important and well-investigable phenomenon – connected to a relatively simple but real field situation – in such a way, that the results of field observations could be directly comparable with the predictions of a simulation model-system which uses a simple mathematical apparatus and to simultaneously gain such a hypothesis-system, which creates the theoretical opportunity for a later experimental series of studies. As a phenomenon of the study, we chose the seasonal coenological changes of aquatic and semiaquatic Heteroptera community. Ba-

sed on the observed data, we developed such an ecological model-system, which is suitable for generating realistic patterns highly resembling to the observed temporal patterns, and by the help of which predictions can be given to alternative situations of climatic circumstances not experienced before (e.g. climate changes), and furthermore; which can simulate experimental circumstances. The stable coenological state-plane, which was constructed based on the principle of indirect ordination is suitable for unified handling of data series of monitoring and simulation, and also fits for their comparison. On the state-plane, such deviations of empirical and model-generated data can be observed and analysed, which could otherwise remain hidden." (Authors) The analysis also includes Odonata.] Address: Hufnagel, L., Department of Mathematics and Informatics, Corvinus University of Budapest, H-1118 Budapest, Villanyi ut 29.43, Hungary. [Hessen, Germany; the 17 odonate species of the bog are briefly characterised by morphology and ecology. The development of the odonate fauna (population trends), based on investigations in 1982-1985, 2002, and 2004, is discussed. Of special interest are records of *Coenagrion hastulatum*, *Aeshna juncea*, *A. subarctica elisabethae*, *Somatochlora arctica*, *S. flavomaculata*, *Sympetrum danae*, and *Leucorrhinia dubia*. *L. pectoralis* seems to have been extinct since the 1980th.] Address: Jenrich, J., Fliegerstr. 11, D-36129 Gersfeld, Germany

5826. Joop, G. (2005): Maintenance of female colour polymorphism in the coenagrionid damselfly *Coenagrion puella*. Dissertation, Fachbereich für Biowissenschaften und Psychologie der technischen Universität Carolo-Wilhelmina zu Braunschweig: 116 pp. (in English, with German summary). ["How colour polymorphisms are maintained is still an unresolved question. Selection should favour the morph best adapted (Moran 1992). Furthermore, the maintenance of a polymorphic system is supposed to be costly, therefore it seems only profitable under quickly or steadily changing envi-

ronmental conditions (Moran 1992). Colour polymorphism is a common trait in damselflies, especially in female coenagrionids (Odonata: Zygoptera). This has been discussed in literature for more than 100 years and several hypotheses to explain these polymorphisms have been developed (Fig. 1). As a model organism I chose the azur damselfly, *Coenagrion puella*. In this species males are blue while females show three colour morphs, green, blue and intermediate. The question is how these female colour morphs are maintained. The focus of the presented work to answer this question is on differences in and colouration on thorax and abdomen of male and polymorphic female *C. puella*, furthermore on differences in immune parameters and reproductive strategies. For black content no differences between the female morphs were found. Males however have a smaller black content than females. In colour composition it was found that blue females are of a different blue than males, and all three female morphs differ in colour composition. The haemolymph's haemocyte numbers and Phenoloxidase activity (PO) and their regulation under the risk of predation and parasitism in the larval stage were investigated as immune parameters. Here differences between the sexes were found. This led to the question, whether there are similar differences between the female morphs. Therefore haemocyte numbers and PO in adult male and polymorphic females were investigated. Furthermore differences in mortality in the presence of a newly introduced entomopathogenic fungi and parasite numbers in the field were examined. For all this parameters no differences between the female morphs were found but differences between the sexes. For reproductive strategies it is discussed, which impact the between the morphs differing egg shapes could have on the choice of oviposition substrate. From these results the question, how this polymorphism evolved and if it evolved parallel in all coenagrionid species, arose. To answer this a new molecular phylogenetic tree of the coenagrionids was build. So far it seems that the female colour polymorphism evolved several times within this group. In summary, I conclude that none of the in figure 1 presented factors maintains this polymorphism alone, but rather a combination of all of them. If I included, that the polymorphism might have evolved several times within the coenagrionids under differing selection pressures, the question of the maintaining factors becomes even more complex." (Author)] Address: Joop, Gerrit, Zoologisches Institut, AG Ökologie, Technische Universität Braunschweig, Braunschweig, Germany. Email: g.joop@tu-bs.de

5827. Jourde, P. (2005): Les libellules de Charente-Maritime. Bilan de sept années de prospection et d'étude des Odonates 1999-2005. Annales de la Société des Sciences Naturelles de la Charente-Maritime, supplément, décembre 2005: 144 pp. [This regional fauna directed to the Département Charente-Maritime at the central western (Atlantic) border of France, impresses by a clear layout presenting each of the 62 species on one page. There, you find information on the distribution (with detailed maps), habitats, ecology, conservation status, phenology, and also the vernacular names in French, English, and German, and an explanation of the Latin names. As usual, and necessary for a regional fauna, the general reader is introduced by a brief biology of the Odonata, the geography of the region, and a detailed treatment of all relevant odonatological publications referring to the department. Also appended are a bibliography, checklists, an index, and many impressive

colour photos of habitats and species. The fine resolution of the maps is quite fascinating and some apparently very common European species as *Lestes sponsa*, *Aeshna cyanea*, or *Sympetrum vulgatum* appear not so common after all! This is a very sophisticated presentation of a regional fauna, and it is highly recommended to everyone interested in the Odonata of France or the distribution of the species in Europe. (Martin Schorr)] Address: Société des Sciences naturelles de Charente-Maritime, Muséum d'Histoire naturelle, 28 rue Albert 1er, F-17000 La Rochelle Prix : 20 € (+ 3 € shipping).

5830. Kövecses, J.; Sherwood, G.D.; Rasmussen, J. B. (2005): Impacts of altered benthic invertebrate communities on the feeding ecology of yellow perch (*Perca flavescens*) in metal-contaminated lakes. Can. J. Fish. Aquat. Sci. 62: 153-162. (in English, with French summary). ["Metal contamination can disrupt trophic links in food webs by altering the taxonomic composition and size structure of benthic macroinvertebrate communities. Benthic macroinvertebrates and yellow perch (*Perca flavescens*) were collected from six lakes along a gradient of cadmium (Cd) and copper (Cu) contamination in Quebec, Canada. The two most contaminated lakes had significantly lower densities of several benthic macroinvertebrate taxa and significantly lower Shannon's index than less contaminated lakes. The stomach contents of perch from the most contaminated lakes were less diverse, with a greater reliance on chironomids and (or) zooplankton than perch from other study lakes. The size of prey in perch from the most contaminated lakes did not increase with age and the mean prey size was smaller than in other, less contaminated lakes. Perch from lakes with medium to low levels of contamination weighed significantly more than perch from lakes with high levels of contamination. This reduction in growth is attributed to the increased costs of foraging on a simplified prey base in metal-contaminated systems." (Authors)] Address: Kövecses, Jennifer, Department of Biology, McGill University, 1205 Dr. Penfield, Montreal, QC H3A 1B1, Canada. E-mail: Jennifer.kovecses@elf.mcgill.ca

5831. Krauss, V.; Pecyna, M.; Kurz, K.; Sass, H. (2005): Phylogenetic mapping of Intron positions: A case study of translation initiation factor eIF2y. Molecular Biology and Evolution 22: 74-84. (in English). ["Eukaryotic translation initiation factor 2 (eIF2) is a G protein that delivers the methionyl initiator tRNA to the small ribosomal subunit and releases it upon GTP hydrolysis after the recognition of the initiation codon. eIF2 is composed of three subunits, a, b, and c. Subunit c shows the strongest conservation, and it confers both

tRNA and GTP/GDP binding. Using intron positioning and protein sequence alignment, here we show that eIF2y is a suitable phylogenetic marker for eukaryotes. We determined or completed the sequences of 13 arthropod eIF2y genes. Analyzing the phylogenetic distribution of 52 different intron positions in 55 distantly related eIF2y genes, we identified ancient ones and shared derived introns in our data set. Obviously, intron positioning in eIF2y is evolutionarily conserved. However, there were episodes of complete and partial intron losses followed by intron gains. We identified 17 clusters of intron positions based on their distribution. The evolution of these clusters appears to be connected with preferred exon length and can be used to estimate the relative timing of intron gain because nearby precursor introns had to be erased from the gene before the new introns could be inserted. Moreover, we identified a putative case of intron sliding that constitutes a synapomorphic character state supporting monophyly of Coleoptera, Lepidoptera, and Diptera excluding Hymenoptera. We also performed tree reconstructions using the eIF2y protein sequences and intron positioning as phylogenetic information. Our results support the monophyly of Viridiplantae, Ascomycota, Homobasidiomyceta, and Apicomplexa." (Authors) The study includes *Enallagma cyathigerum*.] Address: Krauss, V., Dept of Genetics, Uni. 5832. Kuki, N.; Okubo, K. (2005): Relationship between dragonfly communities and environmental conditions at paddy field areas in the Kamiina district, Nagano Prefecture, Central Japan. *Journal of The Japanese Institute of Landscape Architecture* 68(5): 579-584. ["The purpose of this study was to study the relationship between dragonflies in paddy areas and their environmental condition. We selected five study areas which differed in their environment (two non-consolidated paddy areas in hilly and mountainous areas, one consolidated paddy area in hilly and mountainous area, one non-consolidated paddy area in urbanized area, one consolidated paddy area in urbanized area.) in the Kamiina district, Nagano Prefecture. The number and behaviour of dragonflies were recorded by the route census method. The survey of land utilization was carried out on these areas. The number of all of the species was twenty-three. The number of species and individuals were higher in 3 hilly and mountainous areas than in 2 urban areas. Five study areas were classified into 3 hilly and mountainous area region and 2 urban areas by TWINSpan. Dragonfly communities were classified to seven types. Each type corresponded different environment conditions of waterside, forest and others. It was confirmed that the environmental selection and behaviour of mature dragonflies corresponded to the each species character. The environmental selection of mature dragonflies were different between hilly and mountainous area and urban area. It was clear that dragonfly communities were affected by consolidation and urbanization." (Authors)] not stated in English

5833. Kuki, N.; Kumiko, O. (2005): Relationship between dragonfly communities and the environmental conditions at paddy field area in Kamiina district, Nagano Prefecture, Central Japan. *Journal of the Institute of Japanese Landscape Architecture, Annual Scientific Research Meeting Abstracts Vol. 2005*: 122. (in English). ["The purpose of this study was to know relationship between dragonflies in paddy area and envi-

ronmental condition. We selected five various condition study areas (two non-consolidated paddy areas in hilly and mountainous areas, one consolidated paddy area in hilly and mountainous area, one non-consolidated paddy area in urbanized area, one consolidated paddy area in urbanized area.) in the Kamiina district, Nagano Prefecture. The number and behavior of dragonflies were recorded by route census method. The survey of land utilization was carried out on these areas. The number of all of the species was twenty-three. The number of species and individuals were higher in 3 hilly and mountainous areas than in 2 urban areas. Five study areas were classified into 3 hilly and mountainous area region and 2 urban areas by TWINSpan. Dragonfly communities were classified to seven types. Each type corresponded different environment conditions of waterside, forest and others. It was confirmed that the environmental selection and behavior of mature dragonflies corresponded to the each species character. The environmental selection of mature dragonflies were different between hilly and mountainous area and urban area. It was clear that dragonfly communities were affected by consolidation and urbanization." (Authors)] Address: Kuki, N., Graduate School of Agricultural Sciences, Shinshu University, Japan

5834. Kurosawa, N.; Handa, M.; Imai, K.; Sasaki, Y.; Itoh, H.; Urato, H. (2005): A study on the environmental factors of nursery ponds for naiads of the rare damselfly *Coenagrion terue* in consideration of its feeding habit. *Journal of The Japanese Institute of Landscape Architecture* 68 (5): 575-578. (in Japanese, with English summary). ["C. terue living in Sawada Springs in Hitachi Seaside Park, Japan is a rare population as its habitat is near the shore while most other populations of this species are distributed in high lands. Office of Hitachi Seaside Park has been trying to conserve this population by placing ponds and repairing existing ponds in this area. We thought that providing optimal food supply for the larvae was one of the important means to maintain this population and the strength of sunlight was also an important environmental factor for nursery ponds for the naiads. In this study, to clarify which were actual species of prey on larvae and the relationship between food supply and the degree of sunlight, we examined gut contents of larvae, meiobenthos as prey in ponds, the strength of sunlight and the density of larvae. The main prey of larvae were benthic Arthropoda. Body widths of prey were limited to 100-500µm and the maximum body widths of prey were proportional to the head widths of larvae. Not only the density of larvae, but also the number of species and the density of prey tended to be lower in dark ponds than those in bright ponds." (Authors)] Address: not stated in English

5835. Lai, W.; Yan, J.; Motamed, M.; Green, S. (2005): Force Measurements on a Scaled Mechanical Model of Dragonfly in Forward Flight. 12th Int'l Conf. Advanced Robotics (ICAR), Seattle, Washington, USA, July 18-20, 2005: 6 pp. (in English). ["A dynamically scaled flapping-wing model has been developed to investigate the aerodynamic phenomena and flight performance of insect-scale flapping wings. The mechanism consists of two wings, each having 3 rotational degrees of freedom, mounted on a linear stage to permit translation in a fluid-filled tank. Each wing is equipped with a sensor for instantaneous measurement of the time-varying forces and torques. The setup permits one wing to be designated as the forewing and the o-

ther as the hindwing so that interactions between them can be analysed to understand flight for four-winged insects. The apparatus is versatile enough to explore a range of wing morphologies as well as operational wing trajectory parameters." 5836. Lefebvre, F.; Poulin, R. (2005): Progenesis in digenean trematodes: a taxonomic and synthetic overview of species reproducing in their second intermediate hosts. *Parasitology* 130: 587-605. (in English). ["Precocious egg production, i.e. progenesis, has been documented for a number of species in scattered reports throughout the trematode literature. The last 2 extensive studies on the subject date from Buttner in the early 1950s (in French) and from Tang in the early 1980s (in Chinese). Overall, 43 species were then known for their ability to produce eggs at the metacercarial stage while still in the second intermediate host. Here, we update the list, and document the existence of progenesis in a total of 79 digenean trematode species, for which we provide information on the taxonomy of the hosts (including Odonata), the facultative or obligate character of progenesis, relevant references, as well as some other pertinent biological information. We then review the subject by asking 7 questions of fundamental evolutionary importance. These include: What favours progenetic development? What are the associated costs and benefits? How are progenetic eggs released from the host? While exposing the various opinions of previous authors, we attempt to give a synthetic overview and stress on the importance of the metacercarial cyst wall (whether it is present, and if so its thickness) in the evolution and the adoption of a progenetic life-cycle." 5838. Machida, K.; Shimanuki, J. (2005): Structure analysis of the wing of a dragonfly. *Proceedings of SPIE 5852, Third International Conference on Experimental Mechanics and Third Conference of the Asian Committee on Experimental Mechanics*, Chenggen Quan, Fook Siong Chau, Anand Asundi, Brian Stephen Wong, Chwee Teck Lim, Editors: 671-676. (in English). ["It is considered that wing corrugation increases not only the warping rigidity but also the flexibility. The wing of a dragonfly has some characteristic structures, such as "Nodus", "Stigma". Nodus is located in the center of the leading edge, and stigma like a mark is located near the end of the wing. It is considered that these structures not only increase the flexibility of the wing, but also prevent fatigue fracture of wings. Therefore, to investigate the mechanism of dragonfly's wing, the configura-

tion of wing used for analyses was measured using an optical coordinate profile measuring machine and a laser microscope. Moreover, several 3-D models of the dragonfly's wing were made, and calculated by the 3-D finite element method." 5843. Rychła, A. (2005): Dragonflies -Odonata- of standing waterbodies from the Landscape Park "Łuk Mużakowa" (district Luuskie) covering species diversity and their protection. *Chrońmy Przyrodę Ojczyzną* 61(6): 67-79. (in Polish, with English summary). ["This paper summarizes the investigation of dragonflies in the Landscape Protection Area (LPA) "Luk Muzakowa" in Poland. 39 species were found in 28 anthropogenic waterbodies. These waterbodies varied significantly in their physio-chemical water properties and were at different succession stages. 25 of the species developed in the investigated waterbodies. The reproductive behaviour of 3 species (*Aeshna isosceles*, *Libellula depressa* and *Orthetrum coerulescens*) was observed, but the occurrence of neither larvae nor exuviae could be found. The images of 7 species (*Calopteryx splendens*, *C. virgo*, *Sympecma fusca*, *Gomphus flavipes*, *Syrmpetrum flaveolum*, *S. pedemontanum* and *S. striolatum*) were observed. The highest species diversity (30 species) was noted in the southern part of the "Luk Muzakowa" (group E, with the youngest waterbodies). In the northern part of the LPA (group A, with the oldest waterbodies), 19 species were found. The high habitat diversity in the studied area supports the occurrence of dragonflies with various ecological requirements. Of the species documented, 3 (*G. flavipes*, *Leucorrhinia albifrons* and *L. pectoralis*) are protected by the Polish legislation and the European FFH-directive. The *L. albifrons*, *A. juncea* and *O. coendescens* are included in the Red List of dragonflies in Poland." (Author)] Address: Rychła, Anna, ul. Osiedlowa 12, Płoty, PO-66-016 Czerwieńsk, Poland. (in English). ["The dietary composition of *T. melanopogon* from two different habitats was analyzed following faecal pellet analysis method. Representatives of 11 insect orders and spiders (Araneidae) contributed to the diet. Forest bats fed on 1-9 insect orders and araneids indicating opportunistic feeding behaviour, while the semi-urban bats fed on 3-8 insect orders and araneids indicating selective feeding behaviour. Although both the forest bats and semi-urban bats fed on the same spectrum of insect prey they showed differential use of them. Forest bats fed predominately on Coleoptera, Homoptera, Lepidoptera, Hemiptera, Orthoptera, Odonata and Araneidae, while the semi-urban bats preferred Lepidoptera, Coleoptera, Diptera, Orthoptera, Odonata, Hemiptera, Araneidae and Homoptera. Variation in terms of consumption of a particular kind of insect prey between the sexes was evident only among the semi urban bats only with respect to the most significant prey items - coleop-

terans, lepidopterans and dipterans." (Authors)] Address: Srinivasulu, B., Wildlife Biology Section, Zoological Dept, Osmania University, Hyderabad, Andhar Pradesh 500007, India. E-mail: bharisrini@yahoo.co.in

5845. Stone, M.L.; Whiles, M.R.; Webber, J.A.; Williard, K.W.J.; Reeve, J.D. (2005): Macroinvertebrate communities in agriculturally impacted southern Illinois streams: Patterns with riparian vegetation, water quality, and in-stream habitat quality. *Journal of environmental quality* 34(3): 907-917. (in English). ["Relationships between riparian land cover, in-stream habitat, water chemistry, and macroinvertebrates were examined in headwater streams draining an agricultural region of Illinois. Macroinvertebrates and organic matter were collected monthly for one year from three intensively monitored streams with a gradient of riparian forest cover (6,22, and 31% of riparian area). Bioassessments and physical habitat analyses were also performed in these three streams and 12 other nearby headwater streams. The intensively monitored site with the least riparian forest cover had significantly greater percent silt substrates than the sites with medium and high forest cover, and significantly higher very fine organics in substrates than the medium and high forested sites. Macroinvertebrates were abundant in all streams, but communities reflected degraded conditions; noninsect groups, mostly oligochaetes and copepods, dominated density and oligochaetes and molluscs, mostly *Sphaerium* and *Physella*, dominated biomass. Of insects, dipterans, mostly Chironomidae, dominated density and dipterans and coleopterans were important contributors to biomass. Collector-gatherers dominated functional structure in all three intensively monitored sites, indicating that functional structure metrics may not be appropriate for assessing these systems. The intensively monitored site with lowest riparian forest cover had significantly greater macroinvertebrate density and biomass, but lowest insect density and biomass. Density and biomass of active collector-filterers (mostly *Sphaerium*) decreased with increasing riparian forest. Hilsenhoff scores from all 15 sites were significantly correlated with in-stream habitat scores, percent riparian forest, and orthophosphate concentrations, and multiple regression indicated that in-stream habitat was the primary factor influencing biotic integrity. Our results show that these drainage ditches harbor abundant macroinvertebrates that are typical of degraded conditions, but that they can reflect gradients of conditions in and around these streams." 5847. Vonesh, J.R. (2005): Sequential predator effects across three life stages of the African tree frog,

Hyperolius spinigularis. *Oecologia* 143(2): 280-290. (in English). ["While theoretical studies of the timing of key switch points in complex life cycles such as hatching and metamorphosis have stressed the importance of considering multiple stages, most empirical work has focused on a single life stage. However, the relationship between the fitness components of different life stages may be complex. Ontogenetic switch points such as hatching and metamorphosis do not represent new beginnings—carryover effects across stages can arise when environmental effects on the density and/or traits of early ontogenetic stages subsequently alter mortality or growth in later stages. In this study, I examine the effects of egg- and larval-stage predators on larval performance, size at metamorphosis, and post-metamorphic predation in the African tree frog *Hyperolius spinigularis*. I monitored the density and survival of arboreal *H. spinigularis* clutches in the field to estimate how much egg-stage predation reduced the input of tadpoles into the pond. I then conducted experiments to determine: (1) how reductions in initial larval density due to egg predators affect larval survival and mass and age at metamorphosis in the presence and absence of aquatic larval predators, dragonfly larvae, and (2) how differences in mass or age at metamorphosis arising from predation in the embryonic and larval environments affect encounters with post-metamorphic predators, fishing spiders. Reduction in larval densities due to egg predation tended to increase per capita larval survival, decrease larval duration and increase mass at metamorphosis. Larval predators decreased larval survival and had density-dependent effects on larval duration and mass at metamorphosis. The combined effects of embryonic and larval-stage predators increased mass at metamorphosis of survivors by 91%. Larger mass at metamorphosis may have immediate fitness benefits, as larger metamorphs had higher survival in encounters with fishing spiders. Thus, the effects of predators early in ontogeny can alter predation risk even two life stages later." (Author)] Address: Vonesh, J.R., Tyson Research Center, Washington University at St. Louis, P.O. 5849. Watts, P.C.; Daguet, C.; Thompson, D.J., Kemp, S.J. (2005): Exuviae as a reliable source of DNA for population-genetic analysis of odonates. *Odonatologica* 34: 183-187. (in English). ["Genetic analyses are widely used for a variety of ecological research, especially to aid species' conservation programs. Where genetic material is required from rare endangered species it is essential that the samples be collected non-destructively, the ultimate goal should be to develop reliable DNA extraction protocols that may be used with non-invasively collected samples. In this paper, we describe and compare three methods of DNA extraction (DNeasy tissue kit, proteinase-K/TNES and Chelex-100) that use odonate (*Coenagrion mercuriale*) exuviae

as a non-invasive source of genetic material. DNA extracted from exuviae produced consistent genotypes at five polymorphic microsatellite loci for all of the samples processed using the DNeasy tissue kit and proteinase-K/TNES methods and 4 out of the 6 exuviae treated with Chelex-100. Exuviae offer an effective source of genetic material from endangered odonates and also highly mobile species that are too difficult to catch in significant numbers. As such, we expect DNA extracted from exuviae to be widely applied to odonatological genetic research." 5852. Knight, T.M.; McCoy, M.W.; Chase, J.M.; McCoy, K.A.; Holt, R.D. (2005): Trophic cascades across ecosystems. *Nature* 437: 880-883. (in English). ["Predation can be intense, creating strong direct and indirect effects throughout food webs. In addition, ecologists increasingly recognize that fluxes of organisms across ecosystem boundaries can have major consequences for community dynamics. Species with complex life histories often shift habitats during their life cycles and provide potent conduits coupling ecosystems. Thus, local interactions that affect predator abundance in one ecosystem (for example a larval habitat) may have reverberating effects in another (for example an adult habitat). Here we show that fish indirectly facilitate terrestrial plant reproduction through cascading trophic interactions across ecosystem boundaries. Fish reduce larval dragonfly abundances in ponds, leading to fewer adult dragonflies nearby. Adult dragonflies consume insect pollinators and alter their foraging behaviour. As a result, plants near ponds with fish receive more pollinator visits and are less pollen limited than plants near fish-free ponds. Our results confirm that strong species interactions can reverberate across ecosystems, and emphasize the importance of landscape-level processes in driving local species interactions." ISBN: 1-55557-233-2: 22. (in English). [Verbatim: From September to November 2005, a study was conducted to find, identify, and map Odonate nymphs in the Poultney River of Vermont and New York. Samples were taken at various sites, from the headwaters to approximately twenty-five miles downstream, in an effort to identify the different species of Odonata that occupy the main waterway and its tributaries. Habitats included small rocky brooks, medium sized rocky rivers, and slow moving shallow reaches with silt and clay. Over three hundred individual nymphs were collected, representing more than twenty genera. Portions of the Poultney River form the border between NY State and Vermont. *Enallagma divagans*, which had previously been undocumented in the state of Vermont or nearby counties of NY, was found in this border stretch. Diversity and distribution of species will be discussed.] Address: The University of the State of New York, The State Education Department, ALBANY, NY 12230, USA; <http://www.nysm.nysed.gov/nhc/nhcabstracts2006.pdf>

5856. Azrina, M.Z.; Yap, C.K.; Ismail, A.R.; Ismail, A.; Tan, S.G. (2006): Anthropogenic impacts on the distribution and biodiversity of benthic macroinvertebrates and water quality of the Langat River, Peninsular Malaysia. *Ecotoxicology and Environmental Safety* 64(3): 337-347. (in English). ["A study of the impacts of anthropogenic activities on the distribution and biodiversity of benthic macroinvertebrates and water quality of the

Langat River (Peninsular Malaysia) was conducted. Four pristine stations from the upstream and 4 stations at the downstream receiving anthropogenic impacts were selected along the river. For 4 consecutive months (March–June 1999), based on the Malaysian DOE (Malaysia Environmental Quality Report 2000, Department of Environment, Ministry of Science, Technology and Environment Malaysia. Maskha Sdn. Bhd. Kuala Lumpur, 86pp; Malaysia Environmental Quality Report 2001, Department of Environment, Ministry of Science, Technology and the Environment Malaysia) water quality index classes, the upstream stations recorded significantly ($P < 0.05$) higher Biological Monitoring Working Party scores and better water quality indices than those of the downstream. The total number of macrobenthic taxa and their overall richness indices and diversity indices were significantly ($P < 0.05$) higher at the upstream stations (54 taxa) than at the downstream stations (5 taxa). The upstream of the Langat River was dominated by Ephemeroptera and chironomid dipterans while other orders found in small quantities included Trichoptera, Diptera, Plecoptera, Odonata, next term Ephemeroptera, Coleoptera, and Gastropoda. On the other hand, the downstream of the river was mainly inhabited by the resistant Oligochaeta worms *Limnodrilus* spp. and *Branchiodrilus* sp. and Hirudinea in small numbers. The relationships between the physicochemical and the macrobenthic data were investigated by Pearson correlation analysis and multiple stepwise regression analysis. These statistical analyses showed that the richness and diversity indices were generally influenced by the total suspended solids and the conductivity of the river water. This study also highlighted the impacts of anthropogenic land-based activities such as urban runoff on the distribution and species diversity of macrobenthic invertebrates in the downstream of the Langat River. The data obtained in this study supported the use of the bioindicator concept for Malaysian rivers. Some sensitive (Trichopteran caddisflies and Ephemeroptera) and resistant species (Oligochaeta such as *Limnodrilus* spp.) are identified as potential bioindicators of clean and polluted river ecosystems, respectively, for Malaysian rivers.] Address: Yap, C.K., Department of Biology, Faculty of Science, Universiti Putra Malaysia, 43400 UPM Serdang, Selangor, Malaysia. 5857. Bao, I.; Hu, J.-.; Yu, Y.-I.; Cheng, P.; Xu, B.-q.; Tong, B.-g. (2006): Viscoelastic constitutive model related to deformation of insect wing under loading in flapping motion. *Applied Mathematics and Mechanics* 27(6): 741-748. (in English). ["Flexible insect wings deform passively under the periodic loading during flapping flight. The wing flexibility is considered as one of the specific mechanisms on improving insect flight performance. The constitutive relation of the insect wing material plays a key role on the wing deformation, but has not been clearly understood yet. A viscoelastic constitutive relation model was established based on the stress relaxation experiment of a dragonfly wing (in vitro). This model was examined by the finite element analysis of the dynamic deformation response for a model insect wing under the action of the periodical inertial force in flapping. It is revealed that the viscoelastic constitutive relation is rational to characterize the biomaterial property of insect wings in contrast to the elastic one. The amplitude and form of the passive viscoelastic deformation of the wing is evidently depen-

dent on the viscous parameters in the constitutive relation." (Authors)] Address: Email: tongbg@gucas.ac.cn

5859. Beauger, A.; Lair, N.; Reyes-Marchant, P.; Peiry, J.-L. (2006): The distribution of macroinvertebrate assemblages in a reach of the River Allier (France), in relation to riverbed characteristics. *Hydrobiologia* 571: 63-76. (in English). ["Macroinvertebrate assemblages of large alluvial streams are poorly documented. This study identified the physical characteristics affecting the macroinvertebrates community distribution in a large alluvial river devoid of major anthropogenic impacts. It was oriented towards the influence of the characteristics of the physical habitat (velocity, depth, grain-size classes of mineral substrates, macrophytes) on macroinvertebrates (richness, density, body size, feeding habits), with particular attention to the pollution-sensitive taxa. The study was carried out in June during a period of hydrological stability. The effects of water velocity, depth and substrates on taxa were evaluated with multivariate analyses. Mineral substrates were most abundant while macrophytes accounted for only 3% of sampled habitat. Invertebrates that were present were those characteristics of the transition zone between upper and middle life reaches. Among the 63 taxa sampled, 14 were abundant. In relation to the characteristics of the physical environment, the macroinvertebrate assemblages were discriminated by substrate, velocity, and depth. Habitat exploitation, however, appeared complex. The highest community richness, EPT richness, and density were found in various substrates where the velocity ranged between 30 and 120 cm s⁻¹, depths ranged from 16 to 50 cm. The most pollution-sensitive taxa preferred riffle habitats with velocities >70 cm s⁻¹ and substrate >64 mm. This suggests that rapid bioassessment programmes should be carried out in the mineral substrates of the geomorphological unit riffles where richness is high and density sufficient to represent the macroinvertebrate community, including pollution-sensitive taxa." 5861. Beirincx, K.; Van Gossum, H.; Lajeunesse, M.; Forbes, M. (2006): Sex biases in dispersal and philopatry: insights from a meta-analysis based on capture-mark-recapture studies of damselflies. *Oikos* 113(3):

539-547. (in English). ["Sex-biased dispersal is well known for birds and mammals, typically by females and males, respectively. Little is known about general patterns of sex-biased dispersal in other animal taxa. We reviewed return rates for a model group of invertebrates (damselflies) and explored putative costs and benefits of dispersal by males and females. We used published capture-mark-recapture data and examined whether a sex bias existed in likelihood of recapture at least once, at both emergence and/or breeding sites. We assessed whether this metric of likelihood of recapture was indicative of dispersal or philopatry, and whether any emerging pattern(s) were consistent across damselfly families. Using a meta-analysis, we found a higher likelihood of recapture at least once for males than for females at both natal sites and breeding sites, which seemed attributable to higher female-biased dispersal, although female-biased mortality cannot be discounted particularly for some species. Sex biases in dispersal among damselflies may be understood based on sex differences in maturation rate and foraging behaviour, both of which should affect the costs and benefits of dispersing. This hypothesis may be useful for explaining patterns of dispersal in other animal taxa." (2006): The mapping of visual space by identified large second-order neurons in the dragonfly median ocellus. *Journal of Comparative Physiology A: Neuroethology, Sensory, Neural, and Behavioral Physiology*: 1-19. (in English). ["In adult dragonflies, the compound eyes are augmented by three simple eyes known as the dorsal ocelli. The outputs of ocellar photoreceptors converge on relatively few second-order neurons with large axonal diameters (L-neurons). We determine L-neuron morphology by iontophoretic dye injection combined with three-dimensional reconstructions. Using intracellular recording and white noise analysis, we also determine the physiological receptive fields of the L-neurons, in order to identify the extent to which they preserve spatial information. We find a total of 11 median ocellar L-neurons, consisting of five symmetrical pairs and one unpaired neuron. L-neurons are distinguishable by the extent and location of their terminations within the ocellar plexus and brain. In the horizontal dimension, L-neurons project to different regions of the ocellar plexus, in close correlation with their receptive fields. In the vertical dimension, dendritic arborizations overlap widely, paralleled by receptive fields that are narrow and do not differ between different neurons. These results provide the first evidence for the preservation of spatial information by the second-order neurons of any dorsal ocellus. The system essentially forms a one-dimensional image of the equator over a wide azimuthal area, possibly forming an internal representation of the horizon. Potential behavioural roles for the system are discussed." 5867. Bönsel, A. (2006): Schnelle und individuenreiche Besiedlung eines revitalisierten Waldmoores durch *Leucorrhinia pectoralis* (Odonata: Libellulidae). *Libellula* 25(3/4): 151-157. (in German, with English summary). ["In 2003 a drained forest mire in Mecklenburg-Pomerania, Germany, was revitalized by damming up the water to a maximum depth of 1.3 m. Three years later a large indigenous population of *L. pectoralis* was recorded at the new water body. In spite of the cryptic situation of the revitalized habitat many individuals must have found it promptly. Forests around the habitats do not constitute dispersal barriers for the sp., which is endangered in central Europe, and large occurrences nearby are not a prerequisite for colonizing new habitats. As in this region the revitalisation of mires is associated with few conflicts of interest and only little financial support is needed, this measure is recommended for the protection and promotion of *L. pectoralis*." 5871. Bressler, D.W.; Stribling, J.B.; Paul, M.J.; Hicks, M.B. (2006): Stressor tolerance values for benthic macroinvertebrates in Mississippi. *Hydrobiologia* 573: 155-

172. (in English). ["Conceptually, tolerance values represent the relative capacity of aquatic organisms to survive and reproduce in the presence of known levels of stressors. Operationally, they represent the relative abundance and colocation of organisms and stressors. These numeric values are then used for calculating tolerance metrics. Defensibility of biological assessments using tolerance metrics is compromised if the origins of the tolerance values or technical foundations of metrics are unknown. To minimize circularity and maximize objectivity, we define stressed conditions using physical and chemical factors. Also, since single, isolated stressors in stream systems are rare, we used an approach that combines multiple physical and chemical characteristics into a single general stressor gradient. In this paper, we describe development of tolerance values for benthic macroinvertebrate taxa collected from 455 wadeable stream sites throughout Mississippi, USA, except the Alluvial Plain. Principal components analysis (PCA) was used to develop a gradient that incorporated direct (instream physical and chemical) and indirect (land use) stressors, which was then scaled from 0 to 10. Weighted averaging of the relative abundance of each taxon was used to assign tolerance values based on the point of greatest relative abundance along the stressor gradient. Tolerance values were derived for 324 (including Odonata on the genus level) of the 567 taxa collected from the study sites, and primarily represented sensitivity to agricultural influences including degradation of physical habitat and nutrient enrichment, the dominant stressors within the state. We suggest that this approach could be used in other areas of the country to develop new tolerance values, refine existing ones, and may be a useful approach for other taxonomic groups." 5872. Bried, J.T.; Ervin, G.N. (2006): Abundance patterns of dragonflies along a wetland buffer gradient. *Wetlands* 26: 878-883. (in English). ["Local abundance of animals with aquatic and terrestrial life stages may be useful to determine criteria for protective buffers around wetlands. Maiden flights and daily commutes of adult Odonata occur between wetland breeding area and adjacent upland habitat used for foraging, maturation, and nocturnal roosting. We measured abundance of dragonflies adjacent to a wetland in Mississippi, USA to determine if abundance varied with distance from water. Sexually mature males and combined females/prereproductive adult males (females-immatures) were recorded 10–160 m from the littoral edge of a 185 ha shallow reservoir. The number of dragonflies was dominated by *Celithemis eponina* throughout the study period. Mean abundance did not change with distance from water out to 160 m, both for all species combined and for each of three dominant species. In the assemblage, mature males outnumbered females-immatures in the 10–40 m distance, whereas the reverse occurred in the 130–160 m distance. At the species-level, there was a mixed response in the mature male: female-immature ratio, with little resemblance to the assemblage pattern. Results of this study suggest that wide buffer zones around wetlands may be essential to protect Odonata assemblages, especially females and sexually immature adults. Furthermore, odonate flight behavior may serve as a useful bio-criterion to determine the width of ecologically significant wetland buffers." 5877. Butler, R.G.; de Maynadier, P. (2006): Significance of littoral and shoreline habitat integrity to lacustrine damselfly conservation. Abstracts of the Northeast Natural History Conference IX. April 20 – April 21, 2006. N.Y. State Mus. Circ. 70. ISBN: 1-55557-233-2: 23. (in English). [Verbatim: Shoreline development can have significant impacts on native lacustrine biota including a variety of aquatic macroinvertebrate groups. In an effort to better understand the habitat associations and sensitivities of lacustrine damselflies (Odonata: Zygoptera), we sampled adults in littoral macrophyte habitat during two flight periods at 35 randomly selected pond and lake sites in southern Maine during 2000 and 2001. Habitat data were collected during the same period to help characterize water body, shoreline disturbance, and aquatic vegetation at each study site. Non-metric multidimensional scaling was used for ordination of damselfly assemblages, and resulting coordinates from the most stable three-axis solution were related to site variables using forward stepwise multiple regression. Our results suggest that the diversity and composition of damselfly assemblages were related to the abundance and richness of littoral zone macrophytes, extent of riparian habitat conversion, benthic substrate granularity, and habitat productivity; all variables subject to anthropogenic degradation on excessively developed waterbodies. Additionally, we developed a Habitat Tolerance Index useful for distinguishing between relative habitat specialists and generalists from among a diverse community of 19 lacustrine species. Finally, species-specific damselfly associations with multiple genera of floating and emergent macrophytes were assessed using both nonparametric correlation and multiplicative regression yielding significant relationships for 17 species, including two damselflies of regional conservation concern, *Enallagma laterale* and *E. pictum*. We conclude that the protection of littoral habitat integrity, with special emphasis on emergent and floating macrophytes, is critical to the conservation of a diverse lacustrine damselfly fauna.] Address: University of the State of New York, The State Education Dept, ALBANY, NY 12230, USA; <http://www.nysm.nysed.gov/nhc/nhcabstracts2006.pdf>

5879. Castillo, L.E.; Martínez, E.; Ruedert, C.; Savage, C.; Gilek, M.; Pinnock, M.; Solis, E. (2006): Water quality and macroinvertebrate community response following pesticide applications in a banana plantation, Limon, Costa Rica. *Science of The Total Environment* 367(1): 418-432. (in English). ["Pesticides used in banana production may enter watercourses and pose ecological risks for aquatic ecosystems. The occurrence and effects of pesticides in a stream draining a banana plantation was evaluated using chemical characterization, toxicity testing and macrobenthic community composition. All nematicides studied were detected in the surface waters of the banana plantation during application periods, with peak concentrations following applications. Toxicity tests were limited to the carbofuran application and no toxicity was observed with the acute tests used. However, since pesticide concentrations were generally below the lowest LC50 value for crustaceans but above calculated aquatic quality criteria, there remains a risk of chronic toxicity. Accurate ecological assessments of pesticide use in banana plantations are currently limited by the lack of local short-term chronic toxicity tests and tests using sensitive native species. Relatively constant levels of four pesticides (imazalil, thiabendazole, chlorpyrifos and propiconazole), which had toxic effects according to the 96h hydra and 21d daphnia chronic test, were recorded in the effluent of the packing plant throughout the study, indicating that the solid waste trap used in this facility was not effective in eliminating toxic chemicals. Certain taxa, such as *Heterelmis* sp. (Elmidae), *Heteragrion* sp. (Megapodagrionidae, Odonata), *Caenis* sp. (Caenidae, Ephemeroptera), and *Smicridea* sp. (Hidropsychidae, Trichoptera), were more abundant at reference sites than in the banana farm waters, and may be good candidates for toxicity testing. Multivariate analyses of the macroinvertebrate communities clearly showed that the banana plantation sites were significantly different from the reference sites. Moreover, following the pesticide applications, all the banana plantation sites showed significant changes in community composition, with the same genera being affected at all sites and for all pesticides (terbufos, cadusafos and carbofuran). Consequently, the results presented here show that multivariate analysis of community composition was more sensitive in distinguishing pesticide effects than the toxicity tests and richness and composition measures used. We conclude that monitoring macroinvertebrate communities can be a powerful tool in the assessment of ecological effects of banana production." (2006): The population of Odonata (dragonflies) in small tropical rivers with reference to asynchronous growth patterns. *Aquatic Insects* 28(3): 195-209. (in English). ["The odonate larval communities in three small rivers in Penang Island were studied. Mo-

re species of dragonflies were found in the Botanical Garden and Titi Teras rivers (13 and 11 respectively) of relatively similar environmental parameters. Fewer (nine) dragonfly species were collected from the Youth Park River which has a lower dissolved oxygen (DO) and a higher biological oxygen demand (BOD), conductivity and turbidity. A mixture of sand, gravel and pebble substrate of Botanical Garden River with dense growth of submerged *Hydrilla*, grasses and *Cladias* (Araceae) provided suitable habitats for the dragonflies. The sandy substrate and relatively fast flowing water of Titi Teras River was highly preferred by gomphids. In the Youth Park River, the small community of dragonfly larvae was dominated by tolerant *Pseudagrion rubriceps*, *P. microcephalum*, *Orthetrum chrysis* and *Crocothemis servilia*. Based on the larval instar distribution of *Ictinogomphus decoratus* and *O. chrysis*, very asynchronous populations of these dragonflies occurred in each river. Young larvae were continuously introduced into the populations resulting in undulating growth rate curves. The growth rates of these two species were higher in the Titi Teras River when compared to those in other rivers. Density-dependent mortality, asynchronous cannibalism and fish predation could play important roles in regulating the larval dragonfly population in these rivers." 5885. Córdoba-Aguilar, A. (2006): Sperm ejection as a possible cryptic female choice mechanism in Odonata (Insecta). *Physiological Entomology* 31(2): 146-153. (in

English). ["The few odonate studies of sperm use suggest that females spend apparently more sperm than appears necessary during oviposition (sometimes females may have their sperm stores reduced to 50% after a single oviposition episode). Furthermore, some studies document that females eject sperm during and after copulation. This raises the question of whether sperm reduction may be interpreted as a cryptic female choice mechanism. Using two zygopterans, *Ischnura denticollis* Burmeister and *Enallagma praevarum* Hagen, and one anisopteran, *Pantala flavescens* Fabricius, it is shown that females mate more than once, show a marked reduction in stored sperm, and that this is by ejection of sperm before to oviposition. The extent of sperm reduction is inversely related to the number of eggs laid. When mated to the same male, females show similar reductions in sperm stores and egg load and only rarely does the vaginal duct contain sperm. This suggests that marked sperm reduction is common in this insect order and is not explained by an excess of sperm obstructing the egg passage. It is suggested that female's sperm shortage is better explained as a cryptic female choice mechanism aimed at favouring the sperm of some males. This study provides exciting research avenues for future studies of female choice in an animal taxa whose sexual biology is otherwise regarded as controlled by males." 5886. Costa, J.M.; De Souza, L.O.; Muzon, J. (2006): Descriptions of three new species of Odonata from Brazil. *Zootaxa* 1314: 53-68. (in English). ["Three new species are described here: *Oxyagrion zielmae* sp. nov. (Coenagrionidae) from one male collected at Costa Rica, Mato Grosso do Sul state; *Lestes fernandoi* sp. nov. (Lestidae) from a pair from Imperatriz, Maranhão state and *Perithemis capixaba* sp. nov. (Libellulidae) from one male from Mutum Preto, Espírito Santo state, all deposited at Museu Nacional, Rio de Janeiro, Brazil. *Oxyagrion zielmae* is similar to *O. pavidum* Selys, 1876 but differs by having cerci and paraprocts the same size, pterostigma long and narrow and terminal segment of genital ligula with the two lobes larger than in *O. pavidum*. *Lestes fernandoi* is compared with *L. auritus* Hagen in Selys, 1862; *L. bipupillatus* Calvert, 1909; *L. dichrostigma* Calvert, 1909; *Lestes falcifer* Sjöstedt, 1918; *L. forficula* Rambur, 1842; *L. minutus* Selys, 1862 and *L. paulistus* Calvert, 1909. The new species is most similar to *Lestes falcifer* and *L. paulistus*, but differ by the peculiar color of pterothorax, caudal appendages and genital ligula. *Perithemis capixaba* is similar to *P. mooma* Kirby, 1889 but differs by having the first segment of vesica spermalis slowly rounded, in *P. mooma* this structure is trapezoidal. Illustrated keys to new species are included." (Authors)] Address: Costa, J.M., Departamento de Entomologia, Museu Nacional, Universidade Federal do Rio de Janeiro, Quinta da Boa Vista, São Cristóvão, BR-20942-040 Rio de Janeiro, Brazil. 5887. Coupry, Y.; Nepoux, V. (2006): *Tauriphila australis* (Hagen, 1867), nouvelle espèce pour la Guyane. *Martinia* 22(3): 108. (in French). [French Guyana, 11-VIII-2002] Address: Coupry, Y., allée des Glycines, F-70170 Port sur Saône Allée des Marcassins, F-60360 Lamorlaye, France

5888. Couteyen, S. (2006): Effets de l'introduction de la truite arc-en-ciel (*Oncorhynchus mykiss* Walbaum, 1792) sur les populations larvaires de deux espèces de Zygoptères de l'Île de la Réunion. *Martinia* 22(2): 55-63. (in French, with English summary). ["The effect of predation by rainbow trout on the larval populations of *Coenagrion reuiniensis* (Fraser, 1957) and *Enallagma glaucum* (Burmeister, 1839) has been studied. Faced with the predator, the two species react differently: a local extinction of *C. reuiniensis* has been observed as the larval density has shifted from over 4 larvae per square metre to 0, while no significant impact of the predator on the *E. glaucum* has been recorded. The fact that 7 larvae of *C. reuiniensis* were discovered in the analysis of 30 trout stomachs' contents whereas no larva of *E. glaucum* was found, confirms the greater susceptibility of *C. reuiniensis* to the predation. These two types of response can be explained by the different larval ways of life. The larvae of *C. reuiniensis*, an endemic species, are epibenthic and usually colonise vegetationless habitats. On the contrary, the larvae of *E. glaucum*, which can also be found in Africa, hide in underwater grass-banks. This makes them difficult to reach for a predator moving in free water." (Author)] Address: Couteyen, S., 188 chemin Nid Joli, F-97430 Le Tampon, La Réunion, France. E-mail: couteyensf@vanadoo.fr

5889. Danks, H.V. (2006): Key themes in the study of seasonal adaptations in insects II. Life-cycle patterns. *Applied Entomology and Zoology* 41(1): 1-13. (in English). ["Recent work on selected topics of particular interest for understanding insect life-cycles is reviewed, including habitat patterns, kinds of variation, the spreading of risk and prolonged diapause, trade-offs and developmental plasticity, circannual rhythms, the concept of life cycles as developmental choices, and development or delay as the default response. Seasonal adaptations have a wider range of components than has often been appreciated. Variation in life-cycle traits, including the duration of development and the timing of emergence, can be wide, narrow, or discontinuous. Trade-offs encompass multiple simultaneous traits and are not always structured as might be expected. Diapause, cold hardiness, reproductive pattern, and other traits have evolved many times independently. Such complex interactions can be understood only by examining the detailed features of a species' habitat, because how developmental decisions are made and whether continuous development or delays are programmed reflect the predictability of habitats and the environmental signals they supply. Ecological context is important, not just mechanisms of adaptation. Therefore, although most previous studies have paid more attention to insect response than to habitat, interpreting the seasonal relevance of life-cycle patterns requires measurement and analysis for individual species of habitat characteristics and their variation, on a range of temporal and spatial scales, in much more detail than has been customary." (Author) Reference is given to *Aeshna viridis*.] Address: Danks, H.V., Group of Insect Physiology and Molecular Biology, Research Institute for Bioresources, Okayama University; Kurashiki, 710-0046, Japan

5890. De Knijf, G.; Anselin, A.; Goffart, P.; Tailly, M. (2006): *De Libellen van België. Verspreiding. Evolutie. Habitats.* Libellenwerkgroep Gomphus. ISBN 90-403-0249-9: 369 pp. (in Dutch, with English and German summaries). [Long years of intensive work finally resul-

ted in this impressive compilation of the knowledge on the Belgian Odonata. On approximately 150 pages, the distribution of the 69 Belgian species is documented in detail and mapped in different time scales. In a monographic style and condensed on two pages, the range of each species, the present distribution, and range extensions or range contractions are discussed extensively. Information on habitat and the phenology are added. Plenty of additional information like a history of Belgian odonatology, habitats and their characteristic Odonata, Red Lists, monitoring schemes, and an outlook on future developments of the regional odonata fauna, and many many impressive pictures and graphs which helps to interpret the data are included into this book. Vernacular names, a bibliography and very extensive summaries in English (Adrian Parr) and German (Martin Schorr) are added. This review is a brief one, but it refers to a very big book on a regional odonate fauna, and a significant contribution to the knowledge of the European Odonata. The book is recommended to everyone interested in European Odonata. Congratulations!! (Martin Schorr) Address: www.gomphus.be

5891. Deubel, T.; Wanke, S.; Weber, C.; Wedekind, F. (2006): Modelling and manufacturing of a dragonfly wing as basis for bionic research. design 2006 - 9th International Design Conference, Dubrovnik / Kroatien, 15.-18.05.2006. "Design Society", DS 36: Proceedings of the Design 2006 (D. Marjanovic, ed.), S. Faculty of Mechanical Engineering and Naval Architecture, University of Zagreb 2006: 215-220. (in English). ["In nature we find many examples for highly optimised principles and solutions. The wing of the dragonfly is such a structure. The wing is very light and at the same time very stiff and has impressive aerodynamic properties. In order to understand how nature could achieve such opposed properties it was necessary to build an enlarged model to carry out further research into the aerodynamics of the single wing on the one hand and into the effects of the interferences between the four wings on the other hand in a wind tunnel. The enlarged model of the dragonfly wing was derived from cross cut sections of an actual dragonfly wing using the CAD/CAM/NC solution CATIA V5 and a NC-milling machine. In the future the findings may be useful to develop light aircraft which have a high fuel efficiency and great manoeuvrability." NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

5893. Dijkstra, K.-D.; Lewington, R. (2006): Field guide to the dragonflies of Britain and Europe. British Wildlife Publishing. ISBN-0-953-1399-4-8 (paperback): 320 pp. (in English). [This guide to the European and north African dragonflies, drawing on the knowledge of experts from throughout Europe, brings together much of the latest thinking on identifying the region's 160 species of dragonflies. Illustrated by Richard Lewington with his superb artwork, as well as more than 100 photographs, this guide is intended to enable dragonfly-watchers to identify any species they might encounter. The book has been designed to allow rapid comparison of similar species, and in most cases the artwork and text for each species are placed together. There is a general introduction, including a full glossary of terms and simple keys and tables to families and genera. A full checklist is also included at the end of the guide. In addition to the identification material there is a country-by-country section, written by regional experts. The text on each country provides a summary of the main geographical features relating to dragonfly habitats, followed by a more detailed 'tour' of some of the best places to see dragonflies. Such section is necessarily full of omissions and personal tastes, and if one would use the information, it would often not be sufficiently precise to find the relevant localities. Appendix 1 contains a discussion platform on taxonomic problems. This is a highly welcomed contribution to the debate, but it may prove less useful for a general reader of the book. On the other hand some problems are "solved" "en passant" such as *Aeshna serrata* - *A. ossiliensis* and *Coenagrion mercuriale* - *C. castellani* without discussion among the European odonatologists or any publication on this subject known to me. Appendix 2 relates to "vernacular names" - the English ones. What about the vernacular names in, say, Polish? No odonatologist in Europe is using other names than the Latin ones, otherwise it definitely would be impossible to talk about the same species. For someone outside Britain it is also difficult to understand why 'Britain' is treated separately from Europe (A Field guide to the Dragonflies of Britain and Europe), while on the other hand a large part of Europe, Russia till the Ural mountains is missing. Likewise, the north African countries and Turkey (in most parts) belong to the continents of Africa or Asia. Dear publisher: welcome in Europe! However including the species of Turkey - what of course is welcome, as for the African ones! - would have made it necessary also to include *Pseudagrion syriacum* (Selys, 1887) and *Ischnura intermedia* Dumont 1974. When I used this book and tried to identify a dragonfly from the Canary island from some brilliant photographs, I ended up with female of *Diplacodes lefebvrei* - which does not occur on the Canaries. An expert in the Canary odonate fauna by contrast, identified the specimen as a female of *Trithemis arteriosa* (which regrettably is not pictured laterally in the book). So it was not always possible to make a correct identification. Trying to read the labels of the illustrations, and even some of the text made me hope that the publisher will prepare a larger-sized edition to be used on the desk top. Yes, I think this book isn't perfect. But it is great! Nowhere you will find as much information on identification European, north African, and Turkish Odonata as in this book, including many species most of us never have seen pictured anywhere. The detailed descriptions of the species and the brilliant

colour pictures will enable you to determine most of the species without any problems. This book is indispensable for everyone interested in the European odonate fauna. Thanks KD and co-workers, Thanks Richard Lewington, Thanks dear publisher! (Martin Schorr)] Address: British wildlife Publishing, The Old Dairy, Milton on Stour, Gillingham, Dorset, SP8 5PX, UK

5894. Dijkstra, K.-D.; Suhling, F.; Müller, O. (2006): Review of the genus *Zygonoides*, with description of the larvae and notes on 'zygonychine' Libellulidae (Odonata). *Tijdschrift voor Entomologie* 149: 275-292. (in English). ["*Zygonoides* Fraser, 1957 – formerly considered a subgenus of *Olpogastra* Karsch, 1895 – is reinstated as a genus. It comprises *Z. fuelleborni* (Grünberg, 1902), *Z. fraseri* (Pinhey, 1956), *Z. lachesis* (Ris, 1912) and *Z. occidentis* (Ris, 1912). The latter was formerly considered a subspecies or form of *Z. fuelleborni*, but is found to be a good species near *Z. fraseri*. The larvae of *Z. fuelleborni*, *Z. fraseri* and *Z. occidentis* are described. Adult and larval characters are compared with those of the other 'zygonychine' genera *Celebothemis*, *Olpogastra*, *Onychothemis*, *Zygonychidium* and *Zygonyx*. Identification, distribution and ecology of the species are outlined." (Authors)] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

5895. Dijkstra, K.-D. (2006): The *Atoconeura* problem revisited: taxonomy, phylogeny and bio-geography of a dragonfly genus in the highlands of Africa (Odonata, Libellulidae). *Tijdschrift voor Entomologie* 149: 121-144. (in English). ["The genus *Atoconeura* previously comprised two species; one with five subspecies. Principal Component Analysis of 33 characters of 148 specimens and cladistic analysis of 28 characters revealed six discrete taxa, partly with narrowly overlapping ranges. Subspecies *aethiopica*, *kenya* and *pseudeudoxia* of *biordinata* are raised to specific rank; the synonymy of *chirinda* with *biordinata* is confirmed; *A. luxata* sp. n. is described from West Africa. A key to the species is provided and the poorly known behaviour, ecology and biogeography are discussed. The author has not witnessed oviposition; one report suggests that it may be perched, solitary and epiphytic, which is unusual within the family. The species are largely restricted to streams above 1000 m, except *A. luxata* sp. n. that is only known below that altitude, but always at the foot of highlands. Four species demonstrate a distribution pattern recalling a 'ring species' in highlands, circling Lake Victoria and the dry north of Tanzania. The phylogeny suggests an expansion of the genus from the western lowlands to the eastern highlands, or vice versa, followed by an expansion through the Albertine Rift and Eastern Arc Mts to the Kenyan and ultimately Ethiopian highlands. Especially in the case of a western origin there appears to have been a tendency of the species to occur at increasing altitudes in the course of their evolution." (Author)] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

5896. Dijkstra, K.-D.B. (2006): Taxonomy and biogeography of *Porpax*, a dragonfly genus centred in the Congo Basin (Odonata, Libellulidae). *Tijdschrift voor Entomologie* 149: 71-88. (in English). ["The tropical African genus *Porpax* is revised, five species are recognised, including the new species *P. sentipes* from Congo-Kinshasa. All species are fully diagnosed for both sexes

and new records are included. A key to the species and illustrations of important characters are provided. The peculiarities of the genus are discussed, but little is known of its ecology. *P. garambensis* and *P. sentipes* sp. n. are confined to the Congo Basin, while *P. asperipes* is also present in the adjacent Lower Guinean forest. *P. risi* is spread out across highlands in south-central Africa. *P. bipunctus* is known from four disjunct rainforest regions from Liberia to eastern Congo and has different markings in each region. This distribution coincides with Africa's main rainforest refugia and is the best example of such disjunction seen in Afrotropical Odonata so far. The species' isolation appears to be linked to an ephemeral habitat, confining it to areas with perennial and predictable rainfall." (Author)] Address: Dijkstra, K.D., Gortestraat 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

5897. Dijkstra K.-D.; Clausnitzer, V.; Vick, G.S. (2006): Revision of the three-striped species of *Phyllogomphus* (Odonata, Gomphidae). *Tijdschrift voor Entomologie* 149: 1-14. (in English). ["The taxonomy of the *Phyllogomphus* species occurring from Cameroon eastwards, characterised by three-striped sides of the thorax, has been confused by misinterpretation of the identity of the most widespread species, *P. selysi*, and substantial variation in the species. Of sixteen named taxa, only four are considered valid species after clarifying the identity of *P. selysi*, matching females to the correct males, and accounting for variation, particularly of size, colour and the morphology of the vulvar scale: *P. annulus* is not a synonym of the true *P. selysi* but of Fraser's interpretation of the latter species; *P. dundomajoricus* and *P. dundominusculus* are junior synonyms of *P. annulus*; *P. montanus*, *P. hartwigi*, *P. perisi* and *P. margaritae* of *P. coloratus*; *P. orientalis*, *P. edentatus*, *P. latifasciae*, *P. symoensi*, *P. brunneus* and *P. corbettae* of *P. selysi*. Keys to the species and distribution maps are provided, and the taxonomy of the genus is discussed." (Authors)] Address: Dijkstra, K.D., Gortestr. 11, NL-2311 MS Leiden, The Netherlands. E-mail: Dijkstra@naturalis.nnm.nl

5904. Feng, H.-Q.; Wu, K.-M.; Ni, Y.-X.; Cheng, D.-F.; Guo, Y.-Y. (2006): Nocturnal migration of dragonflies over the Bohai Sea in northern China. *Ecological Entomology* 31(5): 511-520. (in English). ["A sudden increase and subsequent sharp decrease of catches of dragonflies in a searchlight trap, with *Pantala flavescens* predominating, observed at Beihuang Island in the centre of the Bohai Gulf, in 2003 and 2004, indicated a seasonal migration of these insects over the sea during the night in China. The movements were associated with the onset of fog. 2. Simultaneous radar observations indicated that the nocturnally migrating dragonflies generally flew at altitudes of up to 1000 m above sea level, with high density concentrations at about 200-300 or 500 m; these concentrations were coincident with the temperature inversion. 3. During early summer, the dragonflies oriented in a downwind direction, so that the displacement direction varied between different altitudes. In contrast, during late summer, the dragonflies
