ciated with predator activity (predator odour, conspecific or heterospecific alarm substances) induces defence responses in the aquatic oligochaete *Stylaria lacustris*, which is vulnerable to common littoral predators. The field results indicated that predators injure the oligochaetes and a great proportion, up to 45% of individuals in the population, were found to be damaged. The results of the laboratory experiments revealed that chemical odours from damselfly larvae feeding on *S. lacustris* did not induce the defence response in the oligochaetes. On the contrary, oligochaetes detected and responded to alarm substances from damaged conspecifics alone and substances from damaged cladoceran *Daphnia magna*. We discussed conditions favouring the responses to damage released prey alarm cues instead of predator odours in *Stylaria lacustris*. Our data suggest that the selection of responses to alarm cues from damaged prey vs. predator odours may be dependent on three factors: (1) non-species-specific predation, (2) divergence of food niche of the different stages of the predator and (3) complex food web with multiple predators." 7566. Leunda, P.M.; Oscoz, J.; Miranda, R.; Arino, A.H. (2009): Longitudinal and seasonal variation of the benthic macroinvertebrate community and biotic indices in an undisturbed Pyrenean river. *Ecological Indicators* 9: 52-63. (in English) ["The present work aims to analyze the spatio-temporal variability in benthic macroinvertebrate assemblages and biotic indices in an undisturbed and unpolluted Pyrenean river. Samples were collected seasonally over 2 year-cycles (2001–2002) at fifteen sampling sites along the Erro River (Ebro River Basin, Spain) during a exhaustive biomonitoring program following the IBMWP–IASPT scoring system protocol routinely applied in Iberia. Despite absolute values of the biotic indices showed high spatio-temporal variation, the IBMWP–IASPT scoring system proved useful because water quality classes were consistent throughout seasons and years as well as along-river. The original macroinvertebrate families' presence/absence data matrix was reduced in a number of ways to conduct different statistical procedures in order to detect and separate the underlying near-natural spatial and temporal gradients of the assemblage composition in the Erro River. Along-river, spatial variation of the macroinvertebrate community composition was well assessed by similarity analysis, which clearly detected physical features on the river (drought-affected reach, gorge, towns and flow gauging weirs). Categorical principal component analysis (CATPCA) synthesized and jointly ordered macroinvertebrate samples in a spatio-temporal gradient in the factorial map defined by the first two principal components providing a parsimonious way to assess the assemblages' variation. These two variation gradients throughout the macroinvertebrate families' occurrence data were subsequently confirmed separately by several correspondence analyses and revealed additional information, as the representative families for each sampling site group and season could be identified. Furthermore, these spatio-temporal gradients were discussed and put in relation with changes in the aquatic habitat (water temperature, conductivity, total dissolved solids, water velocity, channel width, canopy cover, etc.). The near-natural functioning of the Erro River promoted us to emphasize that conservation efforts should aim to maintain the free-flowing as a permanent source

of variability." (Authors) Odonata are treated on the family level.] Address: Leunda, P.M.; Dept Zool. & Ecol., Univ. of Navarra, PO Box 177, E-31080, Pamplona/Iruña, Navarra, Spain. E-mail: pedro.leunda@gavrn.com

7567. Lorion, C.M.; Kennedy, B.P. (2009): Relationships between deforestation, riparian forest buffers and benthic macroinvertebrates in neotropical headwater streams. *Freshwater Biology* 54(1): 165-180. (in English) ["1. Few studies have evaluated the effectiveness of riparian buffers in the tropics, despite their potential to reduce the impacts of deforestation on stream communities. We examined macroinvertebrate assemblages and stream habitat characteristics in small lowland streams in southeastern Costa Rica to assess the impacts of deforestation on benthic communities and the influence of riparian forest buffers on these effects. Three different stream reach types were compared in the study: (i) forested reference reaches, (ii) stream reaches adjacent to pasture with a riparian forest buffer at least 15 m in width on both banks and (iii) stream reaches adjacent to pasture without a riparian forest buffer. 2. Comparisons between forest and pasture reaches suggest that deforestation, even at a very local scale, can alter the taxonomic composition of benthic macroinvertebrate assemblages, reduce macroinvertebrate diversity and eliminate the most sensitive taxa. The presence of a riparian forest buffer appeared to significantly reduce the effects of deforestation on benthic communities, as macroinvertebrate diversity and assemblage structure in forest buffer reaches were generally very similar to those in forested reference reaches. One forest buffer reach was clearly an exception to this pattern, despite the presence of a wide riparian buffer. 3. The taxonomic structure of macroinvertebrate assemblages differed between pool and riffle habitats, but contrasts among the three reach types in our study were consistent across the two habitats. Differences among reach types also persisted across three sampling periods during our 15-month study. 4. Among the environmental variables we measured, only stream water temperature varied significantly among reach types, but trends in periphyton abundance and stream sedimentation may have contributed to observed differences in macroinvertebrate assemblage structure. 5. Forest cover was high in all of our study catchments, and more research is needed to determine whether riparian forest buffers will sustain similar functions in more extensively deforested landscapes. Nevertheless, our results provide support for Costa Rican regulations protecting riparian forests and suggest that proper riparian management could significantly reduce the impacts of deforestation on benthic communities in tropical streams." (Authors) Ephemeroptera and Diptera were much less important in terms of total insect biomass, while Odonata and Coleoptera were more prominent, particularly in riffle habitats in the forest reaches.] Address: Lorion, C., Oregon Department of Fish and Wildlife, Corvallis Research Lab, 28655 Hwy 34, Corvallis, OR 97333, USA. 7568. Luttbeg, B.; Hammond, J.I.; Sih, A. (2009): Dragonfly larvae and tadpole frog space use games in varied light conditions. *Behavioral Ecology* 20(1): 13-21. (in English) ["Predators and prey often engage in a game where predators attempt to be in areas with higher prey densities and prey attempt to be in areas with lower predator densities. A few models have predicted the resulting distributions of predators and prey, but litt-

le empirical data exist to test these predictions and to examine how abiotic and biotic factors shape the distributions. Thus, we observed how *Anax* dragonfly nymphs and Pacific tree frog tadpoles (*Pseudacris regilla*) either together or separately distributed themselves in an arena with a high- and a low-prey resource patch. Trials were conducted in high- and low-light conditions to manipulate predation risk and to view the effects of this abiotic factor. Counter to the model predictions, we found that predators were not more abundant in high-resource (HR) patches, and they thus did not force prey toward being uniformly distributed. Using a model selection approach to assess what factors affected predator and prey patch-switching movement, we found that prey more often left patches that had more predators present, but predators surprisingly more often left patches with more prey present. Light levels did not affect predation risk; however, in the dark with the associated reduction in visual information predators preferred HR patches. This caused a lower coincidence of prey and predators in patches. Predators also switched patches less often when they occupied the same patch as the other predator. This suggests that predator distributions, and indirectly prey distributions, are affected by the risk of intraguild predation." (2009): Monitoring of aquatic macroinvertebrates as bioindicator for assessing the health of wetlands: A case study in the Central Himalayas, India. *Ecological Indicators* 9: 118-128. (in English) ["The present contribution encompasses the first case study on the aquatic macroinvertebrates as bioindicators for assessing the health of Asan wetland (area 3.2 km²), located in the foothills of Central Himalayas, India. Monthly sampling from all the sampling sites in five replicates was made for a period of 12 months (July 2002–June 2003) at 9:00–11:00 h. A total of 32 species of macroinvertebrates were found with the Ephemeroptera and Gastropoda being the most abundant component of invertebrates communities. The Shannon–Wiener diversity index calculated for macroinvertebrates ranged from 3.50 to 4.61. Seasonal fluctuations in the density of macroinvertebrates revealed maximum density (451–503 ind m²) during winter and minimum (126–143 indm²) during monsoon season. The density of macroinvertebrates was influenced by the anthropogenic disturbances and water level fluctuations causing disturbance in the littoral zone of the wetland. The statistical relationships between turbidity, transparency, dissolved oxygen and water temperature and macroinvertebrates of Asan wetland were also computed for assessing the impact of anthropogenic disturbances on macroinvertebrates." (Authors) The monthly density of larvae/m² for the following species is documented: *Enall-*

Archives of Environmental Contamination and Toxicology 56(1): 77-84. (in English) ["Odonate larvae are important organisms in aquatic ecosystems but have been rarely studied in laboratory toxicity tests. Only a few previous studies have been conducted on odonates and their responses to heavy metals. We exposed two species of libellulid larvae (Pachydiplax longipennis, Erythemis simplicicollis) to equimolar concentrations of cadmium, lead, or copper in 7-day survival tests. Larvae were tolerant of high concentrations of cadmium and lead, as no significant decrease in survival was observed at exposures as high as 0.893 and 2.232 mM, respectively. In contrast, larvae were more sensitive to copper exposure, demonstrating significantly decreased survival to exposures as low as 2.360 µM. In whole animal samples, larvae accumulated very high concentrations (>1000 µg/g dry weight) of all three metals in an exposure-related manner. Much of this accumulation could probably be attributed to adsorption or accumulation of metal within the exoskeleton, because odonate larvae are known to sequester metals into this material. Our results were generally consistent with previous observations indicating that odonates are tolerant to metal exposures, even in comparison with other aquatic invertebrates. However, there are few studies that have used odonates in toxicity tests and compared these organisms to other aquatic life. Based on their abundance and their simple requirements in the laboratory, we believe that odonate larvae can be useful toxicological model organisms." (2009): Evaluating the relative importance of patch quality and connectivity in a damselfly metapopulation from a one-season survey. Oikos 118(1): 67-76. (in English) ["The area-and-isolation paradigm, which has been the primary focus of metapopulation research, may not hold in some animal metapopulations if within-patch preference is more important than patch area or connectivity. Recently, regression analyses have been used to evaluate the effect of patch connectivity and various patch qualities including area. However, their relative importance is not easy to determine, because patch qualities and connectivity are often spatially autocorrelated. In this paper, we try to evaluate the relative importance of within-patch quality, patch connectivity and spatial autocorrelation using variation partitioning methods from community ecology. We constructed three regression models: within-patch quality, PCNM (principal coordinates of neighbor matrices) and patch connectivity based on a one-season survey of a damselfly Copera annulata metapopulation. The contribution of within-patch quality was larger than that of connectivity. There was no prominent effect of patch area. We conclude that the area-and-isolation paradigm is not applicable to this C. annulata metapopulation. The spatial autocorrelation extracted by PCNM had the largest contribution; it contained almost all of the variation of connectivity and overlapped with variation explained by within-patch quality. Connectivity corresponded most closely to medium-scale spatial structure captured by PCNM (ca 640 m). The mean effective dispersal scale was estimated to be 53 m. Within-patch quality, debris accumulation and vegetation cover in the pond corresponded with the medium and small (ca 201m) spatial scales from PCNM, though we could not clearly explain the cause of this correspondence. We believe that our method will contribute to quick and effective evaluation of spatial and non-spatial aspects of metapopulation." Perkins comprehensively surveyed the insect fauna of the Hawaiian Islands one century ago, initially as the collector for the Fauna Hawaiiensis survey project and subsequently as an entomologist with the Hawaiian Sugar Planters' Association. The Hawai'i he observed was in a period of rapid transformation. Thus, he has the unique distinction of being the first and last person to record the habits of many native Hawaiian species. The islands on which he collected were already heavily impacted by exotic herbivores-including goats, cattle, sheep, and pigs-yet he was able to sample remnant pockets of native vegetation that are now lost in a jungle of exotic introductions. His broad understanding of insect natural history allowed him to document ably the habits of insect groups that we are only beginning to understand 100 yr later. Moreover, his collections and extensive taxonomic contributions afford us a firm foundation for future taxonomic and evolutionary studies of the uniquely rich and highly endemic Hawaiian insect biota." 7578. Bennett, B.L. (1998): Land use influences on benthic invertebrate assemblages in southern Appalachian agricultural streams. MSc Thesis, Dept Biology, Faculty of the Virginia Polytechnic Institute and State University Blacksburg: VIII, 98 pp. (in English) ["I investigated the role of land use in structuring benthic invertebrate assemblages in agricultural streams in the French Broad River drainage in western North Carolina. I sampled six agricultural streams (3 with cleared headwaters and 3 with forested headwaters) at three points along a gradient (headwaters, a midpoint, and a downstream site). At each site, I measured a variety of physico-chemical parameters, including temperature, chlorophyll a, discharge, nutrients, and suspended solids.

Invertebrates were sampled at all sites in October 1996 and April 1997. Riparian vegetation was assessed for each site at multiple spatial scales using GIS data from the 1950s, 1970s, and 1990s. Forested agricultural (FA) streams had more riparian vegetation than cleared agricultural (CA) streams in both the 1950s and the 1970s. Cleared agricultural streams had less organic matter, more primary production, higher nitrates, and warmer temperatures than FA streams. Total and EPT taxa richness was greater in FA streams. Pollution-sensitive Plecoptera were relatively more abundant in FA streams, while tolerant Diptera were more abundant in CA streams. High diversity and Plecoptera abundance was related to high habitat quality, more riparian vegetation, low nitrates, and low summer temperatures. Higher invertebrate diversity was related to the land use 25-50 years as well as the current land use (forested, moderate agriculture, or heavy cattle impact). These results indicate a long-term legacy of agricultural influences on stream invertebrate assemblages." *Boyeria grafiana*, *B. vinosa*, *Gomphus lividia*, *Lanthus parvulus*, and *Ophiogomphus mainensis* are listed.] Address: Bennett, Barbara Loraine, Dept Biology, Virginia Polytechnic Institute and State University Blacksburg, VA 24061-0406, USA

(2001): Invertebrate communities in Temporary streams of the island of Majorca: a comparison of catchments with different land use. *Limnetica* 20(2): 255-266. (in English, with Spanish summary) ["This study compares the invertebrate communities in two catchments in the Mediterranean island of Majorca, Spain. The Soller catchment is highly urbanised, with areas of intensive agriculture. The catchment of stream Sant Jordi is covered in a large part by a mature forest of Mediterranean Quercus. Upper and middle reaches of the latter were chosen as reference sites of well-preserved environmental conditions. Diptera was the richest taxon in both catchments, followed by Coleoptera and Trichoptera in the Sant Jordi catchment, and by Mollusca in Soller. Overall, invertebrate species richness was similar in the two catchments. Species composition and representation differed and Crustacea were proportionally more abundant in the Sant Jordi catchment sites than in Solier. In the latter catchment, Diptera (mainly Chironomidae) and Oligochaeta were more abundant than in the Sant Jordi catchment. Main factors influencing community structure in both catchments were identified, i.e. allochthonous organic inputs

from riparian vegetation and land use effects on this, local wastewater discharge, length of the dry period, saltwater intrusion and watertable lowering due to increasing groundwater extraction at downstream sites." (Authors) Odonata are also treated on the family level.] Address: Moya, G., Departament de Biologia Ambiental, Universitat de les Illes Balears, 0707 1 Palma de Mallorca, Spain

7585. Boix, D.; Sala, J.; Moreno-Amich, R. (2001): The faunal composition of Espolla pond (NE Iberian Peninsula): the neglected biodiversity of temporary waters. *Wetlands* 21(4): 577-592. (in English) ["The faunal composition, richness, and their determinant factors were analyzed in a Mediterranean temporary pond located in NE Spain. The aquatic community was sampled weekly over 7 periods of flooding during 4 years (1996–1999). Composition of the pond community was found to be influenced by duration of the hydroperiod and, secondarily, by seasonality. Insects and crustaceans were the most well-represented types of fauna. The small numbers of species captured over all hydroperiods spend the dry periods in situ or have an important dispersal capacity. Comparison of the faunal composition of several temporary ponds of temperate latitudes confirms the great diversity of faunal groups found in temporary aquatic environments, and this richness is comparable to that found in permanent water bodies. The richness of these temporary ponds is related to flooded surface and to hydroperiod duration. The peculiarity of the fauna of temporary waters, together the deteriorating condition of those habitats, make it necessary for more active policies of preservation to be pursued." (Authors) In tab. 2 larval records of *Chalcolestes viridis* and *Anax imperator* are listed.] Address: Boix, D., Institute of Aquatic Ecology and Dept. of Environmental Sciences, University of Girona, Campus de Montilivi, Faculty of Sciences, 17071—Girona, Catalunya, Spain

Toronto Entomologist's Association, Toronto, Ontario: 4-5. (in English) ["Notes are provided on seven species which are additions to the reported fauna of Lanark County, Ontario. Included are *Enallagma vernale*, *Gomphaeschna furcillata*, *Gomphus quadricolor*, *Ophiogomphus rupinsulensis*, *Williamsonia fletcheri*, *Nannothemis bella*, and *Pantala flavescens* bringing the county list to 87 species." (Authors)] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, ON, K0A 2P0, Canada; E-Mail: brownell@achilles.net

7594. Catling, P.M. (2002): A new identification problem in field surveys: *Tamea lacerata* and *Epitheca princeps*. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 3. Toronto Entomologist's Association, Toronto, Ontario: 58-61. (in English) [Field identification characters are outlined to discriminate *Tamea lacerata* and *Epitheca princeps*.] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, ON, K0A 2P0, Canada; E-Mail: brownell@achilles.net

7595. Catling, P.M.; Brownell, V.R. (2002): Observations of Odonata in Ontario made in 1996, 1997 and 1998. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 3. Toronto Entomologist's Association, Toronto, Ontario: 63-190. (in English) ["The observations in the following table totaling 1937, were recorded prior to the concept of a major Odonata survey in Ontario. Many were collected during a study of the ecology of gravel pit ponds. Others were collected during floristic surveys. In general the emphasis was on Zygoptera in connection with ecological studies. Very few records of larvae are included. The lack of data on numbers and sexes, and the way in which the data was collected places some limitations on its use in the analysis of trends. It is useful in contributing to an understanding of geographic occurrence, flight periods and in connection with regional studies. Many of the observations are supported by voucher specimens in the collection of the observers and/or in the Ontario Survey collection at CNC (Agriculture and Agri-Food Canada, Ottawa). As with the summary data produced in volumes 1-3 of Ontario Odonata, these observations are part of a limited access database maintained by the Toronto Entomologists Association and the Natural Heritage Information Center (NHIC) in Peterborough. Among the noteworthy species listed in the following summary is *Hetaerina titia* originally discovered in Ontario by P. Pratt and Jo Barton in 1985 (see Great Lakes Entomologist 31 (3-4): 205-208. 1998). The male of *H. titia* is longer, more slender and darker than the male of *H. americana* and has conspicuous dark colouration at the wing tips especially the hindwing." (Authors)] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, ON, K0A 2P0, Canada; E-Mail: brownell@achilles.net

7596. Catling, P.M.; Brownell, V.R. (2002): Notes on the Odonata of Murphys Point Provincial Park, Lanark County, Ontario.. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 3. Toronto Entomolo-

gist's Association, Toronto, Ontario: 20-23. (in English) ["Forty-six species of Odonata are reported for Murphys Point Provincial Park in Lanark County, on the Frontenac Axis of the Canadian Shield, approx. 50 km NNE of Kingston, Ontario. Less common Ontario species present included *Enallagma geminatum*, *E. vesperum*, *Lestes forcipatus*, *L. vigilax*, and *Celithemis eponina*. *Pachydiplax longipennis*, and *Celithemis eponina* reach their northern limit in the general region of the park, and provide an example of the pattern of disjunction from the Carolinian zone of extreme southwestern Ontario into the Frontenac Axis." (Authors)] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, ON, K0A 2P0, Canada; E-Mail: brownell@achilles.net

7597. Catling, P.M. (2002): An evaluation of some characters separating male *Lestes disjunctus* and *Lestes forcipatus* in Ontario. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 3. Toronto Entomologist's Association, Toronto, Ontario: 51-58. (in English) ["Using scatter diagrams and analysis of variance, five characters were evaluated in ninety-three males of *L. forcipatus* and *L. disjunctus* throughout Ontario. The analysis included the morphological characters: (1) relative length of abdominal segments 2 and 3; (2) shape of the penis vesicle; (3) relative size of distal tooth of superior appendage; (4) length of the anterior lamina; and (5) proximity of basal swelling to basal tooth of the superior appendage. Also included were the colour pattern characters: (1) extent of dark colour on side of thorax above metapleural suture; and (2) colour of ventral surface of abdominal segment 10. The length of the anterior lamina discriminated groups well but is a difficult field character. Size of distal tooth on superior appendage along with coloration are recommended to distinguish the two species since both are highly correlated with length of anterior lamina and are also easy to use." (Author)] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, ON, K0A 2P0, Canada; E-Mail: brownell@achilles.net

7598. Catling, P.M.; Brownell, V.R. (2002): A preliminary assessment of changes in status of Ontario dragonflies since Walker's published survey in 1941. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 3. Toronto Entomologist's Association, Toronto, Ontario: 36-48. (in English) ["To elucidate changes in status of Ontario Odonata, the number of records for each of 164 species in Walker's published survey was compared with the number of records for the same species in the year 1999 and year 2000 seasonal summaries. Based on criteria established for reasonable evidence, 29 species have declined and 14 have increased. The result of a greater number of declining species suggests that the threat to dragonfly biodiversity has increased. Species for which there was particularly good evidence of decline, based on meeting 2 of the 3 numeric sub-criteria, included *Somatochlora minor*, *Epiaeschna heros*, *Aeshna verticalis*, and *Somatochlora kennedyi*. Species for which there was particularly good evidence for increase (based on meeting 2 of the 3 numeric sub-criteria) included *Tamea lacerata*, *Argia apicalis*, *Erythemis simplicicollis*, *Celithemis elisa* and *Enallagma civile*. Significantly more than expected of the declining species are currently considered to be at risk and thus rarity criteria that provide a basis for assigning risk are supported. Although based largely on rarity, S-ranks are often indicative of decline. Significantly more than expected of the declining species were associated

with good water quality while significantly more of the increasing species are associated with poor water quality. Thus deteriorating water quality over the past 50 years is implicated as a factor in status change. Species for which there was significant evidence of increase were more often than expected associated with ponds and lakes, than with rivers and streams. A significantly larger than expected proportion of the increasing species had a southern Carolinian or Carolinian Subunit distribution pattern, and a significantly smaller than expected proportion of the decreasing species had such a pattern. This provides further evidence for an increase in "southern" species associated with climate warming. An increase in the numbers of most migratory and/or wandering species is correlated with the recent northward extension of this group, also likely attributable to climatic warming." (Authors)] Address: Catling, P.M., 2326 Scrivens Drive, R.R. 3, Metcalfe, ON, K0A 2P0, Canada; E-Mail: brownell@achilles.net

7599. Catling, P.M. (2002): Checklist of Ontario Odonata. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 3. Toronto Entomologist's Association, Toronto, Ontario: 33-35. (in English) ["Following is an update to the checklist of Ontario Odonata (including 166 species, one with 2 subspecies) (Catling and Brownell 2000: Damselflies and Dragonflies of Ontario: Resource Guide and Annotated List. ProResources, 2326 Scrivens Drive, Metcalfe, Ontario, Canada. 200 pp.). That list included additions made after 1975 to the list that could be generated from publications of Dr. E.M. Walker (Walker 1953, 1958, Walker and Corbet 1975). These additions included: *Dromogomphus spoliatus*, *Gomphaeschna furcillata*, *Enallagma anna*, *E. basidens*, *E. triviatum westfalli*, *Hetaerina titia*, *Macromia taeniolata*, *Ophiogomphus mainensis*, *Progomphus obscurus*, *Stylurus amnicola*, and *Stylurus laurae*. The changes made in this edition of the checklist include the dropping of *Sympetrum janeae* which appears too indistinct to warrant recognition (e.g. Donnelly 2001, pp. 9-10), the dropping of *Sympetrum occidentale* following the suggestion of Dr. N. Donnelly upon whose authority and collections it was originally included (see also Donnelly 2001, p. 10), the listing of *Lestes australis* as a species (Donnelly 2001) and the addition of *Ischnura kellicotti*, discovered in 2001." 7606. Kauppinen, J. (2002): Relative importance of different coloration, smell and shape in the predation of wasps: field experiments on hunting dragonflies (Odonata: *Aeshna grandis*). Master of Science thesis, Dept Biological and Environmental Science Ecology and Environmental Management, University of Jyväskylä: 18 pp. (in English) ["Aposematism is a phenomenon, where poisonous or acrid prey signal their unprofitability to potential predators with conspicuous colouration or some other feature. The mechanisms of aposematism have – excluding a small number of exceptions – been studied from the vertebrate predators' (especially birds) point of view. In contrast, the possible impact of invertebrate predators to the evolution of aposematism has gained only little interest. Dragonflies are a numerous group of invertebrate predators that feed mainly on flying insects and exercise prey selection by vision. Although it has been reported that colours do work as cues in the mating systems of dragonflies no studies have been carried out tackling the question whether dragonflies use their colour vision when exercising prey selection. In the present field experiments I investigated whether hunting *Aeshna grandis* avoid attacking on wasps (Hymenoptera: *Vespula norvegica*), that are a highly unprofitable group of prey for most predators. Further, I was interested in finding out which features of the wasp – colouration, smell and shape – affect the attack rates of hunting dragonflies. To tackle these questions I carried out four field experiments. In the wasp avoidance experiment I offered four different types of living prey (black flies, black-and-yellow flies, black wasps and black-and-yellow wasps) to the hunting dragonflies. I stunned the prey items with carbon dioxide and manipulated all of them either with black or yellow paint. According to the results, the dragonflies avoided the wasps over the flies. Within the flies the black-and-yellow coloured individuals were significantly avoided over the black ones suggesting that aposematic colouration on harmless fly provided a selective advantage against invertebrate predators. Interestingly, there was no significant difference in the reactions towards the black and the black-and-yellow wasps indicating that some other feature in wasps might work as well as an aposematic signal. In the next three experiments I studied the relative importance of the possible aposematic signals: coloration, shape and smell in wasps. First, I tested whether hunting dragonflies react differ-

ently on solid black, black-and-yellow striped and solid yellow artificial prey items. In accordance with the wasp experiment dragonflies clearly avoided the black-and-yellow artificial prey items over the solid black or solid yellow ones. In the second experiment I used two artificial prey types (prey item soaked in mashed wasps and prey item soaked in mashed flies) to test if the smell of the prey alone causes different reactions against the prey. The results suggest that smell of the prey did not have any influence on the dragonfly hunting reactions. In the third experiment I offered artificial wasp shaped and a fly shaped prey item to free flying dragonflies. According to the results there was a slight but not significant difference suggesting that dragonflies were more reluctant in attacking the wasp shaped items than the fly shaped ones. My results suggest that most likely the typical black-and-yellow striping combined with shape makes wasps highly intimidating to dragonflies. Since black-and-yellow striping alone significantly decreased attack rate, even profitable prey species (Batesian mimics) are able to exploit the dragonflies' avoidance to certain colours and colour patterns. It is a task for future work to investigate whether these avoidances are learned or whether they have a genetical basis." (Author)] Address: Kauppinen, J., Vehntie 23, FIN-04400 Järvenpää, Finland

7607. Laking, B.J.; Holt, M.; Falls, J.B. (2002): An annotated checklist of the Odonata of Manitoulin District, Ontario. In: Catling, P.M., C.D. Jones & P. Pratt (Eds): Ontario Odonata, vol. 3. Toronto Entomologist's Association, Toronto, Ontario: 23-31. (in English) [An annotated checklist of the Odonata of Manitoulin District, Ontario is provided with records for 67 species (22 Zygoptera, and 45 Anisoptera). Forty new species have been discovered since 1991. The dragonfly fauna indicates a tension zone with some southern species at or near to their northern limits including *Calopteryx maculata*, *Ischnura posita*, *Nasiaeschna pentacantha* and *Libellula pulchella*, and some northern species at or near their southern limits such as *Aeshna sitchensis* and *Ophiogomphus colubrinus*. The high level of biological significance of the Misery Bay area is further supported by a relatively high odonate diversity including 6 species in various threat categories." 7613. Wang, L.-p. (2003): Breeding habitat selection and breeding biology of Blue-tailed Bee-eaters (*Merops philippinus*) on Kinmen Island. Department of Forestry, National Taiwan University, Taipei. Adviser: Yuan Hsiao-Wei: 52 pp. (in Chinese, with English summary) ["I studied habitat selection and breeding biology of blue-tailed bee-eaters (*Merops philippinus*) on Kinmen Island from 2000 to 2002. Blue-tailed bee-eaters were found to only build nest holes on Kinmen layer and sandy soils, which both had lower clay content. On the 822 Blue-tailed bee-eater individuals observed, 84% of them built nest holes on natural cliffs and 16% used artificial habitats, and 92% built nest holes into one-side open colony and only 8% built radical colony. Scan observations revealed the major diet of Blue-tailed bee-eaters were insects that were mostly Odonata (49%), Homoptera (17%), Diptera (13%) and Lepidoptera (12%). I compared the water quality of nearest water bodies of six nest colonies, no significant difference in dissolved oxygen, BOD, pH value and some nutrients nutrients (PO₄-3, NO₃-, N, Cl-, SO₄-2, NH₄+, HCO₃-, CO₃-, Ca, Mg, Na, K). was found between retained and abandoned

nest colonies. Nevertheless, the nearest water bodies of abandoned nest colonies had lower electro-conductivity, which positively correlated with abundance and species richness of dragonflies, the main diet of Blue-tailed bee-eaters. I found that Blue-tailed bee-eaters preferred to build nest holes on cliffs with lower vegetation. We suggested lower vegetation structure might increase their ability to detect nest predators and thus decrease the chance of nest predation. Blue-tailed bee-eaters were mainly colonial breeding and monogamy in Kinmen during the study period. In the breeding season of 2001, 83% of the chicks hatched within a period of nine days, suggesting Blue-tailed bee-eaters might be synchrony breeding. We also found 16 nests had more than two adults jointly feeding chicks, which suggests Blue-tailed bee-eaters might adapt cooperative breeding." (Author)] Address: not transliterated

7615. Zhu, C.-j.; Muraoka, J.; Mizuno, H. (2003): Visual simulation of dragonflies based on aerodynamics. *The Journal of the Society for Art and Science* 2(4): 146-155. (in Japanese, with English summary) ["A dragonfly is a familiar insect by which the sense of season can be shown. The expression of a dragonfly by CG can be expected as an element improving the sense of season in landscape simulation, virtual reality, etc. This paper proposes the flight model of a dragonfly based on aerodynamics. In this model, a dragonfly can be made to fly in real time considering the force caused by the flapping of the wings, performing flight characteristics including steep rise, sudden stop, hover and rapid turn. Furthermore, the flight route of a dragonfly can be easily established depending on the control-points placed in the space." (Authors)] Address: Mizuno, H., hmizuno@tohtech.ac.jp

7618. Goncalves, J.F.; Santos, A.M.; Esteves, F.A. (2004): The influence of the chemical composition of *Typha domingensis* and *Nymphaea ampla* detritus on invertebrate colonization during decomposition in a Brazilian coastal lagoon. *Hydrobiologia* 527: 125-137. (in English) [The aims of this study were to investigate the structure and composition of the invertebrate community during the detritus decomposition (colonization features) of the two most abundant aquatic macrophytes *T. domingensis* and *N. ampla* in Jurubatiba Lagoon and verify if the chemical composition of the substratum has any influence on invertebrate colonization and which are the functional groups possibly affected by these compounds. The substratum *T. domingensis* had higher percentages of cell wall fraction ($F = 108.33$; $p < 0.0001$) and organic matter ($F = 225.77$; $p < 0.0001$), while nitrogen ($F = 408.61$; $p < 0.0001$) and phosphorus ($F = 224.59$; $p < 0.0001$) contents were higher in *N. ampla*. These differences in the chemical composition of the substrata influenced the decomposition rate, and the detritus of *N. ampla* (4.37% DW day⁻¹) decomposed approximately 26 times faster than the *T. domingensis* (0.17% DW day⁻¹) detritus. The main groups of invertebrates that colonized both substrate were Chironomidae, with more than 50% of the total, followed by Oligochaeta, Nematoda, Copepoda and Cladocera. The results showed that the slow breakdown rate of *T. domingensis* detritus provided a higher probability for colonization and that the main driving force structuring the invertebrates' community was degradative ecological succession (DES).] (Authors) *T. domingensis* was colonized by odonate larvae after 9 days (Libellulidae, Aeshnidae) with a strong increase of abundance/biomass after app. 60-90 days. *N. ampla* was colonized earlier by larvae of Libellulidae and Gomphidae (in high abundances after 9 resp. 16 days).] Address: Gonçalves Jr., J.F., Dept of General Biology, Benthic Ecology Laboratory, Federal University of Minas Gerais, ICB, 486, CEP: 30161-970 Belo Horizonte, MG, Brazil. 7620. Kuki, N.; Okubo, K. (2004): The relationship between dragonfly communities and environmental conditions in paddy field area on Kamiina district, Nagano prefecture. Abstracts of the Annual Meeting of the Ecological Society of Japan 51: 365. (in English) ["The purpose of this study was to know relationship between dragonflies in paddy area and environmental condition. We selected five various condition study areas (two non-consolidated paddy areas in hilly and mountainous areas, one consolidated paddy area in hilly and mountainous area, one non-consolidated paddy area in urbanized area, one consolidated paddy area in urbanized area.) in the Kamiina district, Nagano Prefecture. The number and behaviour of dragonflies were recorded by route census method. The survey of land utilization was carried out on these areas. The number of all of the species was twenty-three. The number of species and individuals were higher in 3 hilly and mountainous areas than in 2 urban areas. Five study areas were classified into 3 hilly and mountainous area region and 2 urban areas by TWINSpan. Dragonfly communities were classified to seven types. Each type corresponded different environment conditions of waterside, forest and others. It was confirmed that the environmental selection and behaviour of mature dragonflies corresponded to the each species character. The environmental selection of mature dragonflies were different between hilly and mountainous area and urban area. It was clear that dragonfly communities were affected by consolidation and urbanization."] (Authors) Address: Okubo, K., Department of Forest Science, Faculty of Agriculture, Shinshu University, Japan.

7624. Harman, W.N.; Hingula, L.P.; Macnamara, C.E. (2005): Does long-term macrophyte management in lakes affect biotic richness and diversity?. *J. Aquat. Plant Manage.* 43: 57-64. (in English) ["We hypothesize that the richness and diversity of the biota in Lake Moraine (42°50'47"N, 75°31'39"W) in New York have been negatively impacted by 60 years of macrophyte and algae management to control Eurasian watermilfoil (*Myriophyllum spicatum* L.) and associated noxious plants. To test this hypothesis we compare water quality characteristics, richness and selected indicators of plant diversity, zooplankton, benthic macroinvertebrates and fish in Lake Moraine with those in nearby Hatch Lake (42°50'06"N, 75°40'67"W). The latter is of similar size and would be expected to have similar biota, but has not been subjected to management. Measurements of temperature, pH, oxygen, conductivity, Secchi transparency, calcium, total phosphorus and nitrites + nitrates are comparable. Taxa richness and the diversity indices applied to the aquatic macrophytes are similar in both lakes. The greatest disparity is the lack of Eurasian watermilfoil and Canadian waterweed (*Elodea canadensis* Michx.) in the main basin of Lake Moraine. The elimination of the former was the intent of a 2001 application of fluridone (1-methyl-3-phenyl-5-(3-(trifluoromethyl) phenyl)-4(1H)-pyridinone[C₁₉H₁₄F₃NO]) and the loss of the latter was a related consequence. Zooplankton richness is similar in both lakes. The diversity of benthic macroinvertebrates is similar; however, richness at the genus level is quite different. There is a paucity of species collected in Lake Moraine that are intolerant to winter lowering of water levels. Fish species richness in both lakes is similar, but there are differences in specific taxa and percent abundance directly related to stocking and the balance between forage fish populations and piscivorous fish populations in the two lakes. That phenomenon also appears responsible for some of the variation in the zooplankton communities in both lakes. Overall, taxonomic richness and diversity in Lake Moraine and Hatch Lake are remarkably similar. Annual winter drawdown of water levels is implicated as having greater effect on the biota than long-term herbicide utilization. The hypothesis is rejected." (Authors) Odonata accounted to app. 20% of genus-diversity, but to less than 1% of biomass.] Address: Harman, W.N., SUNY College at Oneonta, Biological Field Station (BFS), 5838 ST HWY 80, Cooperstown, NY 13326.

7625. Hua, Y.; Li, H. (2005): Food web and fluid in pitchers of *Nepenthes mirabilis* in Zhuhai, China. *Acta Bot. Gallica* 152(2): 165-175. (in English, with French summary) [*N. mirabilis* "attracts ants and flying insects with floral and extrafloral nectaries, color of pitcher and flower, and possibly flower odor. Its slippery rim and collar trap preys, but some wasps can hold legs on the outside of the rim. Its preys include arthropods in four classes (with nine orders in insect class), plus very few snails and lizards. Fresh fluid sinks, kills, and digests preys (including lizards) quickly, but allows frogs to live in; while old fluid allows mosquitoes to hatch in it. Fluid reaches its maximum amount at pitcher opening. Then, the pH decreases gradually from 6 to 1.9, as the color

changes slowly from colorless to yellow, and finally both pH and color reverse as pitchers dying. Proteinase nepenthesins could be resulted in these special conditions through long evolutionary adaptation." (Authors) The prey includes Coenagrionidae; regrettably it is not outlined if this records are by accident or occur regularly.] Address: Li, H., Biology Department, Frostburg State University, MD 21532, USA. 7626. Johnson, K.E.; Eidiētis, L. (2005): Tadpole body zones differ with regard to strike frequencies and kill rates by dragonfly naiads. *Copeia* 2005(4): 909-913. (in English) ["We assessed *Anax junius* dragonfly naiad strike frequencies and kill probabilities against *Rana sylvatica* (Wood Frog) tadpoles. Strikes fell into five categories according to their placement on the tadpole body: anterior head/body, posterior head/body, head/body-tail intersection, anterior tail, and posterior tail. The kill probability was calculated for each category as the number of kills divided by the number of contacts made in that category. These probabilities varied; a higher probability was found for both the anterior and posterior head/body, and values declined for successively posterior categories. Neither the kill probability nor the size of the body zone influenced the number of strikes to that zone. Surprisingly, the dragonfly naiads struck most frequently at the relatively narrow region of the head/body-tail intersection, suggesting that dragonfly naiads may aim at a specific target." 7627. Ketelaar, R.; Groenendijk, D.; Joop, P. (2005): Soortbeschermingsplan Hoogveenglanslibel - Species Protection Plan *Somatochlora arctica* 2006-2010. Directie Kennis, Ministerie van Landbouw, Natuur en Voedselkwaliteit, Rapport DK nr. 2005/033: 56 pp. (in Dutch, with English summary) ["*Somatochlora arctica* is a characteristic species of bogs and wet heaths. In the Netherlands, it declined during the last century, and at the moment, only four populations are left. These are situated in the eastern and southern parts of the country (figure 2). The Moorland Emerald can be characterised by its ability to survive in extreme environments. The female deposits her eggs in small, very shallow pools with an overgrowth of *Sphagnum* moss, and therefore hardly any visible water. The larvae are well able to survive prolonged drought and freezing. However, competition with larvae of other dragonfly species is a limiting factor. Adults display a leisurely flight in open woods, tree tops and at woodland edges, where they feed on small insects, and also copulate. As the adults only visit the aquatic breeding sites briefly, it is difficult to establish the species' presence. Aims: During the time allotted to this Species Protection Plan, the aims are: • to know more about the ecology of the Moorland Emerald and the measures required for its conservation, and to convey this knowledge to those concerned with nature conservation in the field; • to integrate this new knowledge into hydrological parts of peat restoration projects and into scientific visions on the functioning of peat ecosystems. Bottlenecks: The future of the Moorland Emerald in the Netherlands is precarious. Important causes are: • desiccation of peatland habitat due to agricultural and forestry practices, excessive usage of ground water, and reduction of

slightly buffered water supply from seepage. • eutrophication of its habitats by nitrogen from agriculture and traffic. Shifts in plant communities may occur, in particular, *Betula pubescens* and *Molinia caerulea* dominance on peat bogs and wet heaths. • habitat loss and fragmentation, reducing population size and isolating populations. • lack of knowledge concerning the ecology of the Moorland Emerald and the hydrology of wet heaths and peat bogs. This lack of knowledge exists also at the level of practical management, illustrating the difficulty of assessing the probability and possibility of raised bog restoration in the Netherlands. • climate change may also affect this species negatively, but measures taken to minimise any of its effects are beyond the scope of this Species Protection Plan. Measures: To ensure that there are sustainable populations of the Moorland Emerald in the Netherlands, the following measures need to be taken: • counter desiccation on both small and large scales by preventing surface drainage and designating buffer zones. For at least two locations, agreements have to be made with nature conservation bodies in neighbouring countries. • reduce eutrophication by taking local measures; these measures should also be supported by national policy. • enlarge and improve present and potential habitats during the term of this Species Protection Plan. • set up research on the ecology of the Moorland Emerald, with particular attention to its breeding sites. At the same time, set up monitoring of all known populations in order to evaluate the effect of local measures. All appropriate measures for the Moorland Emerald in the Netherlands are summed up in an Action Plan. The main purpose of this Species Protection Plan is to increase the current knowledge and subsequently, to apply the new knowledge at the level of practical management, so that effective measures can be taken. The implementation of these measures is the responsibility of the Ministry of Agriculture, Nature and Food Quality, the provinces of Gelderland, Noord-Brabant, Limburg and Overijssel, together with the different owners of nature reserves where the Moorland Emerald occurs. Furthermore, local water boards should also play a crucial role when hydrology plays an important part in a peat restoration project. As these measures take the whole ecosystem into account, they fit into the framework of the so-called "Survival Plan for Forest and Nature". In the case of at least two populations, the co-operation of German or Belgium local authorities needs to be sought." (Authors)] Address: Ketelaar, P., p/a De Vlinderstichting, Postbus 506, NL-6700 AM Wageningen, The Netherlands. E-mail: ketelaar@vlinderstichting.nl

7628. Kobayashi, H.; Toda, H. (2005): Life history of a water mite (*Piona carnea*) in Lake Shirakomaiké. 11-15. (in Japanese, with English summary) ["Life history of *P. carnea* was studied in a mountain humic lake (Lake Shirakomaiké) in Nagano prefecture, Japan from May in 1999 to February in 2000. *P. carnea* appeared in plankton assemblage from late May to late October. Females having eggs were observed between late May and late July. They attached their eggs on aquatic plants in the west coast of the lake from late June to late July. In the coastal area, the first larval stage (larvae) appeared from early July to early August, and parasitized the 2nd and 3rd-year larvae of Odonata. The second larval stage (nymphs) was observed in a plankton assemblage from early July to mid September. In mid September the second pupae were observed on aquatic plants in the west coast. New recruitments of adults

appeared in late September. *P. carnea* disappeared from plankton assemblage until the end of October, and accumulated in the lake bottom from November to probably April. A dense population was found on 18 November (267 individuals nr2) and on 7 February (281 individuals nr2) in the bottom at the lake center. *P. carnea* completes its life history each year in Lake Shirakomaiké." 7632. Pennuto, C.M.; Lane, O.P.; Evers, D.C.; Taylor, R.T.; Loukmas, J. (2005): Mercury in the Northern Crayfish, *Orconectes virilis* (Hagen), in New England, USA. *Ecotoxicology* 14: 149-162. (in English) ["Biologists and policy makers continue to seek environmental correlates of mercury bioavailability in aquatic ecosystems. In this study, we assessed the effects of drainage basin, habitat type, size class, and sex on mercury con-

centrations in *O. virilis*. Drainage basin, habitat type, and size class had significant effects on mercury concentration in crayfish tail muscle even though animals from roughly half the sites examined had mean mercury values at or below expected background levels. The low observed mercury values in crayfish tail muscle indicate a low consumptive risk. Contrary to expectations, crayfish from brooks had higher mercury concentrations than animals from other habitat types, possibly as a result of point source contamination or varying diet compositions among habitats. We suggest that crayfish represent a good indicator of mercury bioavailability in aquatic ecosystems and provide a synthesis for lower food webs. Our understanding of mercury dynamics in lower food webs has been hindered by an under appreciation of the complexity in foraging habits of macroinvertebrates. Further studies focusing on benthos with well-understood life histories and foraging behaviour are essential to improve our understanding of mercury transfer and bioavailability through aquatic systems." (Authors) Patterns in total mercury concentration of benthic macroinvertebrates in lake and river habitats are compared between orders, and including Odonata.] Address: Pennuto, C.M., Dept of Biology & Center for Great Lakes Research, Buffalo State College, Buffalo, NY, USA, 14222. 7633. Smith, M.J.; Drew, M.M.; Peebles, M.; Summers, K. (2005): Predator cues during the egg stage affect larval development in the Gray Treefrog, *Hyla versicolor* (Anura: Hylidae). *Copeia* 2005(1): 169-173. (in English) ["The presence of predators can induce changes in the morphology and behaviour of the potential prey. In this study, we examined the effects of different predator induced changes in water chemistry experienced during the egg stage on larval development in the Gray Treefrog. The potential predators of amphibian eggs and tadpoles used in this study included larval odonates (Aeshnidae), crawfish, and leeches. Tadpoles from eggs exposed to leech-induced changes in water chemistry were consistently smaller throughout their larval development than the tadpoles in the control and other potential predator treatments. Size at metamorphosis did not differ significantly among treatments, but the tadpoles in the leech treatment were significantly older at metamorphosis than tadpoles in the other treatments. These results highlight some of the potential fitness consequences for larval *H. versicolor* that received predator cues during the egg stage." (Authors) Nested analysis of variance showed a significant effect of predator treatment on age at metamorphosis. Tadpoles exposed to the leech treatments were significantly older at metamorphosis than the tadpoles in the control ($P < 0.05$), crawfish ($P < 0.05$), and odonate ($P < 0.08$) treatments. All other treatments did not differ significantly from each other in age at metamorphosis.] Address: not stated

7634. Stoks, R.; Nystrom, J.L.; May, M.L.; McPeck, M.A. (2005): Parallel evolution in ecological and reproductive traits to produce cryptic damselfly species across the Holarctic. *Evolution* 59(9): 1976-1988. (in English) ["The damselfly genus *Enallagma* originated in the Nearctic, and two Nearctic lineages recently underwent radiations partly associated with multiple independent habitat shifts from lakes dominated by fish predators into lakes dominated by dragonfly predators. A previous molecular study of four Palearctic morphospecies and all representative Nearctic species identified

the presence of two cryptic species sets, with each set having Palearctic and Nearctic representatives. However, the cryptic species within each set are not sibling species. Here, we present quantitative data on ecologically important larval morphologies and behaviours involved in predator avoidance and on adult male morphological structures involved in mate recognition to quantify the phenotypic relationships among these cryptic species sets. For the adult stage, our data indicate strong parallel evolution of the structures involved in specific mate recognition - the male cerci. For the larval stage, morphometric analyses show that the Palearctic species evolved a nearly identical morphology to the sibling-clade members in the Nearctic that live in waters where dragonflies are the top predators. This implicates the importance of dragonfly predation in the history of the Palearctic clade. Behavioural analyses suggest population differentiation in response to the actual predator environment in the Palearctic clade, consistent with the species differentiation seen in the Nearctic. Our results suggest parallel evolution of adult traits that influence specific mate choice and larval traits that influence ecological performance underlie the striking similarity of *Enallagma* species across continents. This concurrent parallel evolution in both stages of a complex life cycle, especially when both stages do not share the same selective environment, may be a very unusual mechanism generating cryptic species." (Authors)] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U. Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

7635. Stolen, E.D. (2005): Great Egrets gleaning dragonflies. *Florida Field Naturalist* 33(1): 15-16. (in English) ["Although mainly piscivorous, the Great Egret (*Ardea alba*) takes a variety of food items including dragonflies (McCrimmon et al. 2001, Hancock and Kushlan 1984, Palmer 1962). Clark (1980) described gleaning of dragonflies from low salt marsh vegetation by Tricolored Herons (*Egretta tricolor*) near a nesting colony. Gleaning of insects is noted as a foraging behaviour of Great Egrets in Kushlan (1978), but I could find no published description of gleaning behaviour for the Great Egret. On the morning of 24 March 2003, I was measuring foraging rates of wading birds feeding in impounded salt marsh habitat along the Black Point Wildlife Drive on Merritt Island National Wildlife Refuge near Titusville, Florida. Between 10:30 and 12:00 I observed four Great Egrets gleaning dragonflies which were perched on the ends of stems of sand cord grass (*Spartina bakeri*) and salt grass (*Distichlis spicata*). From my observation point 35 m away, the length of each dragonfly's body appeared to be less than one-quarter of the length of a Great Egret bill, which is typically in the range of 11 cm (Palmer 1962). Two of the Great Egrets that gleaned dragonflies were foraging in a loose mixed species foraging aggregation (individuals separated by 15-50 m) including four Great Egrets, and one Tricolored Heron. The other two Great Egrets observed eating dragonflies were foraging solitarily (greater than 100 m to the nearest other wading bird). During the time the birds were observed gleaning dragonflies, the birds were moving slowly through the vegetation with the neck extended in an upright posture and body angled away from the ground. The dragonflies were captured with rapid strikes of the head and neck and were swallowed immediately. One of the birds captured six fish and one dragonfly during the three minutes I observed its foraging behaviour; two others captured only dragon-

flies during the three minutes (one and three dragonflies captured). The last individual observed gleaning dragonflies was not observed long enough to quantify its foraging behavior. Thus, dragonfly gleaning behaviour appeared to be a foraging strategy rather than incidental or opportunistic captures during foraging for other prey. The weather was typical of early spring in Florida, with clear skies and air temperature around 22°C with a light wind around 11 km/h. On numerous occasions while conducting monthly aerial surveys of wading bird foraging habitat use during the past six years, I have noticed small groups of Great Egrets foraging in non-flooded *Spartina bakeri* salt marsh during the winter dry season. These groups typically consist of 2-10 individuals separated by 10-100 body lengths. Individuals appear to be standing upright and are stationary or moving slowly within the tall (1-2 m) grass. Accounts of Great Egrets taking various small mammals (Palmer 1962) led me to assume that the birds were foraging for terrestrial vertebrates, but clearly they may have been foraging for insects." 7638. Van de Meutter, F. (2005): Local and regional processes in macroinvertebrate communities in shallow lakes. Proefschrift voorgedragen tot het behalen van de graad van Doctor in de Wetenschappen. Katholieke Universiteit Leuven. Faculteit Wetenschappen. Departement Biologie. Laboratorium voor Aquatische Ecologie:

205 pp. (in English, with Dutch summary) ["This thesis consists of three major parts. A first part deals with the interaction of the local factors turbidity and predation with lake macroinvertebrates and macroinvertebrate community structure in lakes. In the second part we investigate to what extent the presence of littoral invertebrate predators may interfere with horizontal migration behaviour of *Daphnia*. Finally, in the third part we focus on the effects of the regional process dispersal and the interaction between dispersal and the drainages of the lakes, on structuring lake macroinvertebrate (meta)communities." (Author) Odonata are studied in many cases, especially in Chapter 2 (Water turbidity affects predator-prey interactions in a fish-damselfly system), Chapter 3 (Behavioural linkage of pelagic prey and littoral predators: microhabitat selection by *Daphnia* induced by damselfly larvae), and Chapter 4 (Spatial avoidance of littoral and pelagic invertebrate predators by *Daphnia*). *Summaries: Chapter I: The effect of turbidity state and microhabitat on macroinvertebrate assemblages: a pilot study of six shallow lakes.* Shallow lakes can occur in two alternative stable states, a clear-water state and a turbid state. This is associated with separate assemblages of fish, zooplankton and plants. Little is known about whether macroinvertebrate assemblages differ across both stable states. This study investigated this in a connected set of three turbid and three clear-water shallow lakes. To overcome confounding effects of differences in spatial structure of macrophytes in turbid and clear-water lakes, we sampled three microhabitats that occurred in both alternative stable states: open water, sago pondweed (*Potamogeton pectinatus*) and reed (*Phragmites australis*). Univariate analyses indicated no differences in the number of organisms, taxon richness or diversity between turbid and clear-water lakes. Multivariate analysis, however, indicated a trend towards differences in the macroinvertebrate community structure of both stable states. Two taxa explained a significant amount of the variation between both lake types, both of which preferred the clear-water lakes. The number of organisms and the taxon richness were higher in reed than in the other microhabitats, but diversity and evenness did not differ among the microhabitats. Multivariate analyses separated all three microhabitats. Four taxa, mainly detritus feeders and collector-gatherers, explained most of the variation in the data and preferred the reed microhabitat. The effects of turbidity state (11.8 % explained variance) and microhabitat (24 % explained variance) on the macroinvertebrate assemblages were largely independent from each other (2 % shared variance). Although macroinvertebrates are not implemented in the initial theory of stable states, our results indicate different assemblages across both stable states. *Chapter II: Water turbidity affects predator-prey interactions in a fish-damselfly system.* Community structure may differ dramatically between clear-water and turbid lakes. These differences have been attributed to differences in the cascading effect of fish on prey populations, due to the reduced efficiency of fish predation in the presence of macrophytes. However, recent theoretical ideas suggest that water turbidity may shape predator-prey interactions, and it is predicted that prey will relax its antipredation behaviour in turbid water (H1). As a result, the nature of predator-prey interactions is expected to shift from both direct and indirect in clear water to dominantly direct in turbid water (H2). We tested these ideas in a fish-damselfly predator-prey system. In a first behavioural experiment, we looked at antipredation behaviour of damselfly lar-

vae isolated from habitats that differ in turbidity, in the presence of fish in clear and turbid water. As predicted in H1, the larvae were more active in turbid than in clear water. In a complementary enclosure experiment, we reared larvae in a clear-water pond and a turbid pond, respectively, and manipulated the origin of the larvae (clear-water, turbid pond), fish presence (absent, present), and vegetation density (sparse, abundant). In both ponds, fish had a direct negative effect on survival of the larvae, which was mitigated in the presence of vegetation. In the fish treatment, the change in average body mass tended to be higher in the turbid than the clear pond, suggesting indirect effects of fish were mitigated in the turbid pond. This was supported by a negative effect of fish on effective growth rate of larvae in the clear pond, but not in the turbid pond. These results are compatible with the idea that predator-prey relationships are mainly governed by direct effects in turbid water, and by direct and indirect effects in clear water.

Chapter III: Behavioural linkage of pelagic prey and littoral predators: microhabitat selection by Daphnia induced by damselfly larvae. Only recently ecologists started treating the previously separately considered benthic, littoral and pelagic zones of lake ecosystems as closely connected compartments. Here we study a link between organisms belonging to a different compartment - namely the pelagic and the littoral - through behaviour in a series of laboratory experiments. Waterfleas of the genus *Daphnia* are inhabitants of the pelagic zone and suffer a high predation pressure from syntopic vertebrate predators (mainly fish). Presumably to escape this predation, they sometimes migrate in the day to the littoral to seek refuge within macrophytes and return to the pelagic at night. Zygopterans from the genus *Ischnura* do commonly co-occur in ponds with *Daphnia* and are known as opportunistic predators of *Daphnia*. In two initial experiments in microcosms in the lab we showed that *Ischnura* larvae are littoral predators strongly associated with macrophytes. Although we found that predation rates of individual *Ischnura* larvae on *Daphnia* are approximately 1.5 fold lower in macrophytes compared to open water, total predation from *Ischnura* on *Daphnia* per unit area is tenfold higher within macrophytes than in open water, making the open water a safer place for *Daphnia* with regard to *Ischnura* predation. In a third microcosm experiment we monitored horizontal distribution of *Daphnia* in the absence, presence and odour only of *Ischnura* larvae. After 2 hours, on average 10 % less *Daphnia* remained within the vegetation when *Ischnura* larvae or only their odour were present compared to when *Ischnura* or *Ischnura* odour were absent. We interpret this as a behavioural anti-predation response of *Daphnia* to the presence of *Ischnura* larvae that seems primarily chemically mediated. The observed horizontal migration of the pelagic prey driven by the littoral predator may couple both lake compartments and may interact with the predator-prey relationships within the pelagic.

Chapter IV: Spatial avoidance of littoral and pelagic invertebrate predators by Daphnia. Studies on spatial avoidance behaviour of predators by prey often ignored the fact that prey typically face multiple predators which themselves interact and show a spatial pattern in abundance and predation rates. In a series of laboratory experiments we investigated predation risk and horizontal migration of the cladoceran *Daphnia magna* between open water and vegetation in response to two important invertebrate predators with a contrasting spatial distribution: pelagic *Chaoborus* and vegetation-as-

sociated *Ischnura*. As expected, predation risk by *Chaoborus* was higher in open water due to higher numbers and higher predation rates of *Chaoborus*, while for *Ischnura*, predation risk was highest in the vegetation due to higher densities but despite lower predation rates of *Ischnura*. In accordance with this, *Daphnia* moved into the vegetation in the single presence of the pelagic *Chaoborus*. In the single presence of *Ischnura*, however, *Daphnia* showed no response. We hypothesize this may be the result of a constitutive behaviour of *Daphnia* to avoid pelagic fish, which impedes a response to the open water. In the combined predator treatment, *Daphnia* migrated to the open water zone. The increased risk of predation in the vegetation, due to a facilitating effect of *Chaoborus* on *Ischnura* predation rates is believed to have caused this migration of the *Daphnia*. This response of *Daphnia* declined through time and *Daphnia* moved toward the vegetation. A decline in the activity of the *Ischnura* larvae through time may have switched the risk balance in favour of the vegetation environment.

Chapter V: Lake-to-lake dispersal of lentic macroinvertebrates through lake outlets. Little is known on dispersal of lentic macroinvertebrates. We quantified dispersal of lentic macroinvertebrates through lake connections in a highly connected lake system, and investigated the role of connection properties and timing (day, night) on dispersal rate. Furthermore, by comparing dispersing macroinvertebrate assemblages with the macroinvertebrate assemblages of source lakes, we tested whether dispersal was neutral or a taxon-specific process. Many taxa dispersed through the lake connections, probably mainly by passive transport. Taxon richness of the dispersing macroinvertebrate assemblage was proportional to taxon richness in the source lakes. The number of individuals that dispersed, however, was not related to source lake densities, possibly because of the highly patchy distribution of lentic macroinvertebrates within lakes and the relatively short sampling time. Baetidae, Chironomidae and Physidae exhibited higher dispersal rates, corrected for source pond densities, than a selection of seven other macroinvertebrate families, indicating that the extent of dispersal may be taxon-specific. None of the physical properties of the connections affected dispersal. The number of dispersing macroinvertebrates was higher during the night than during daytime. Of seven frequently dispersing families, Chaoboridae and Chironomidae showed higher dispersal during the night, probably resulting from diel vertical migration behaviour. Dispersal rates of actively and passively over-land dispersers through lake connections did not differ. Since over-land dispersal probably is more frequent in active dispersers compared to passive dispersers, dispersal through lake-outlets in connected lake systems may generate different spatial patterns compared to over-land dispersal with regard to the composition of communities and the genetic structure of populations.

Chapter VI: Rapid response of macroinvertebrates to drainage management of shallow lakes. Shallow lakes throughout the world are subject to drainages, either as part of fish farming practices to harvest the fish, or as part of lake restoration projects. Lake drainages of fish lakes are known to improve macrophyte and zooplankton diversity, but the effect on the macroinvertebrate community is poorly known. In this study, we investigated temporal trends in the macroinvertebrate community following lake drainage in six shallow connected lakes. We evaluated drainage effects for all macroinvertebrates at the family level and for Coleoptera, Hemi-

ptera and Odonata at the genus or species level. After the drainages, diversity increased for all macroinvertebrates at the family level, Hemiptera and Odonata. Taxon richness increased for Coleoptera, Hemiptera and Odonata. Recolonization of the lakes by the former inhabitants occurred within the first year after the drainages and was supplemented with a set of species that previously were rare or did not occur in the lakes. Changes in the environmental conditions of the lakes were small and transient, except for the decline in fish. The fact that species that occurred in the lakes before the drainages rapidly recolonized the lakes is attributed to the high connectivity in our study system. The occurrence of supplementary species probably was linked to the decline in fish predation, suggesting fish was a dominant factor in shaping the communities. In summary, lake drainage has a positive effect on the diversity and richness of macroinvertebrates in shallow connected lakes. This positive effect seems largely due to a combination of a decline in fish predation following lake drainage and the high rate of recolonization amongst others via connections to nondrained lakes. Lake drainage therefore probably is the most cost-effective lake restoration tool in shallow connected lakes. Other restoration tools may be more favourable in isolated lakes where recolonization may be constrained.

Chapter VII: Metacomunity structure of lentic macroinvertebrates: contrasting active and passive dispersers. Macroinvertebrates inhabiting ponds and lakes can be categorized as active or passive dispersers. Because dispersal over land is assumed to be very limited in passive dispersers, connections between lakes may provide important additional dispersal corridors between lakes. Active dispersers can easily fly from lake to lake over land, and the additional contribution of dispersal via lake connections to dispersal may be negligible. As a result, metacomunities of active and passive macroinvertebrate dispersers may be differentially affected by lake connectivity and hence show different spatial structures. We investigated this hypothesis in a system of 34 connected lakes. In agreement with our expectations, we found that communities of passively dispersing macroinvertebrates were regionally structured according to a spatial model that incorporated the connections among the lakes, while active dispersers were not. Active dispersers, and surprisingly also passive dispersers, were also strongly structured conform the spatial model of Euclidian distances among the lakes, possibly suggesting that over-land dispersal as well was an important dispersal mechanism. These results confirm the importance of connectivity among habitats for metacomunity structure and dynamics, but also indicate that the net effect of connectivity on metacomunity structure depends on the prevailing mode of dispersal of the organisms.

Chapter VIII: Habitat selection drives macroinvertebrate community turnover along the hydroperiod gradient. Community turnover along the hydroperiod gradient is generally assumed to result from local selective mechanisms, abiotic limitation and species sorting, while the possibility of habitat selection behaviour is largely ignored. In this study, the colonizing assembly of macroinvertebrates in small, fishless habitats deviated strongly from that observed in a surrounding large set of fish lakes. By studying distance-similarity relationships, we could show that fish lakes did not act as sources for the colonization of the fishless habitats. We argue that neither abiotic limitation, nor species sorting due to invertebrate predators in the fishless habitats or due to fish in the fish lakes were able to

explain the observed patterns. Our results indicate that strong habitat selection may substantially contribute to community turnover along environmental gradients observed in nature, thereby offsetting a direct role for abiotic limitation and species sorting.] Address: Van de Meutter, F., Laboratorium voor Aquatische Ecologie, K.U. 7640. Venturelli, P.; Tonn, W.M. (2005): Invertebrate communities of littoral macroinvertebrates in small boreal lakes. *J. N. Am. Benthol. Soc.* 24(4): 904-918. (in English) [Canada, Alberta; "Recent comparative studies suggest that macroinvertebrates in small Boreal Plains lakes respond to large fluctuations in fish densities caused by winterkill and subsequent recovery even when such fluctuations involve the normally piscivorous northern pike (*Esox lucius*). We introduced pike into a boreal lake made fishless by a past winterkill to isolate experimentally the effects of pike on littoral macroinvertebrates. We compared postmanipulation macroinvertebrate data from the experimental lake (EXP) to premanipulation data from the same lake, to parallel data from 2 unmanipulated reference lakes (R1 and R2) containing pike, and to data from mesocosms within EXP. Pike in all 3 lakes preyed heavily upon macroinvertebrates; diets consisted predominantly of the amphipod *Gammarus lacustris* in R1 and R2 and erpobdellid leeches in EXP. Principal components analysis (PCA) of macroinvertebrate communities distinguished between systems with and without fish and detected a shift in the macroinvertebrate community of EXP and predator-exposed control mesocosms away from large conspicuous taxa (e.g., odonates, coleopterans, and leeches) toward less-conspicuous taxa such as dipterans and trichopterans following manipulation. Responses of individual taxa were generally in agreement with PCA; erpobdellid leeches and odonates showed consistent negative responses to pike. Our study provides experimental evidence at the whole-lake scale that northern pike can affect littoral macroinvertebrates in small boreal lakes, and demon-

strates the sensitivity that littoral food webs in these systems can have to changes in the density of fish." (Authors)] Address: Venturelli, P., Dept Biological Sciences, University of Alberta, Edmonton, Alberta, Canada T6G 2E9

(in English) ["The foraging behaviour of *G. gekko* was observed at the visitor complex of the Khao Khiao Open Zoo at the Khao Khiao-Khao Chomphu Wildlife Sanctuary in Chon Buri Province, Thailand. Foraging parameters of *G. gekko* (foraging period, time spent moving, foraging attempts, foraging success, prey size consumed, and foraging distance) did not vary significantly between males, females, and juveniles. Individuals foraged between 18:01 and 09:00 hrs. Peak emergence time was between 18:01 and 20:00 hrs. Peak retreat time was between 04:01 and 07:00 hrs. Major food items included insects of the orders *Lepidoptera*, *Orthoptera*, and *Coleoptera*. Prey sizes of males, females, and juveniles were not significantly different, indicating no prey size selection. This may have been due to low insect availability in the habitat. *G. gekko* tended to be a sit-and-wait forager spending most of the time waiting for active prey. However, it sometimes foraged more actively when insect abundance was relatively high. Foraging behavior of males tended to be more variable than females and juveniles. In addition, variation in foraging parameters among individuals was noted. Foraging strategies of *G. gekko* observed in this study are interpreted in the context of optimal foraging theory." (Authors) *Odonata* are preyed, but seem to play a minor role as food source compared with other insect orders.] Address: Thirakhupt, K., Dept Biology, Faculty of Science, Chulalongkorn University, Pathumwan, Bangkok, 10330 Thailand. 7649. Graca, M. (2006): Allochthonous organic matter as a food resource for aquatic invertebrates in forested streams. The importance of forests for dragonflies in different continents. In: Rivera, AC (ED). 2006. *Forests and Dragonflies*. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. Pensoft Series Faunistica 61: 37-47. (in English) ["This paper summarises the role of organic matter in the ecology of forested low order streams. Forests are among (lie most productive systems on Earth. More than 90% of forest primary production will end in detrital pathways, in soil and water. The amount of energy in the form of plain litter entering forested low order streams is several times higher than the energy synthesized by aquatic producers: therefore leaves produced in the riparian zones are a main energy source and decomposition is an important ecological process in those systems. Decomposition is mainly a biological process initiated by aquatic fungi and shredding invertebrates. Those organisms promote the transformation of leaves into fine particles used by bacteria, collectors and filter-feeding invertebrates. There-

fore, much of the energy allocated into secondary production in streams has an allochthonous origin. Nutrients liberated as a result of decomposition are used further downstream, in lakes or estuaries by primary producers. The rate at which leaf litter is decomposed is controlled by intrinsic leaf properties (nutrient content, plant chemical and physical defences) as well as environmental factors (e.g. nutrients in water). Disturbances of riparian zones and eutrophication can affect decomposition and, for this reason, changes in decomposition rates could be used as a functional parameter to assess stream health. Given that the standing stock of leaf litter has a positive effect on leaf consumers, allowing high biomass and diversity, it is likely to also affect top invertebrate predators including odonates: however, the literature on this subject is still scarce." 7650. Harzsch, S. (2006): Neurophylogeny: Architecture of the nervous system and a fresh view on arthropod phylogeny. *Integrative and Comparative Biology Advance Access* published February 28, 2006. doi: 10.1093/icb/iccj011: 1-33. (in English) ["The phylogenetic relationships within the Arthropoda have been controversial for more than a century. Today, comparative studies on the structure and development of the nervous system contribute important arguments to this discussion, so that the term "neurophylogeny" was coined for this discipline. The large number of recent studies on the nervous system in various nonmodel arthropods indicates that we are far advanced in the process of analyzing the cellular architecture of the arthropod nervous system in a depth that will ultimately provide characters at a level of resolution equal or even superior to that of characters traditionally used in morphological phylogenetic studies. This article sets out to summarize the current state of the discussion on arthropod phylogeny (including Odonata) and briefly evaluates the morphological characters that have been used as arguments in favour of the traditional Tracheata hypothesis. Then, a thorough overview is given of characters derived from structure and development of the arthropod brain and the ventral nerve cord from the cellular level to the level of larger neuropil systems. These characters support the new Tetraconata hypothesis suggested by Dohle and provide evidence for a clade that unites malacostracan and remipede crustaceans with the Hexapoda." (Author)] Address: Harzsch, S., Universität Ulm, Abt. Neurobiologie & Sektion Biosystematische Dokumentation, Albert-Einstein-Str. 11, D-89081 Ulm, Germany. E-mail: steffen.harzsch@uni-ulm.de

7651. Hoess, R. (2006): Catalogue of type material in the Odonata collection of the Natural History Museum Basel. *Entomologica Basiliensia et Collectionis Frey* 28: 1-31. (in English) ["A list of all types, apart from topotypes, present in the Odonata collection of the Natural History Museum, Basel is provided, whether they are indicated in the literature or not. The respective original descriptions are also listed. The type status, method of conservation, state of preservation, and the content of labels is given for each of the 111 specimens, belonging to 57 taxa, as well as additional information e.g. on other types of the respective taxon. The collection holds types of about 1% of the extant species of Odonata, thus being one of the more important Odonata collections worldwide; 37 taxa are represented by their primary types, and seven genera by type material of the

respective type species. Most specimens have been collected on expeditions made by non-specialist odonatologists." (Author)] Address: Hoess, R., Normannenstr. 35, 3018 Bern, Switzerland. E-mail: ReneHoess@1st.ch

7652. Honcu, M. (2006): Dragonflies (Odonata) of Kokorínsko Protected Landscape Area. Bohemia centralis 27: 231-239. (in Czech, with English summary) [In the past 15 years, a total of 33 Odonata species was registered in the Kokorínsko Protected Landscape Area (Central and Northern Bohemia, Czech Republic), representing 46,5 % of all dragonflies living in the Czech Republic. "Common species prevail, owing to the low altitude the sub-mountain and mountain species were not found. Very surprising is the occurrence of Ophiogomphus cecilia, Leucorrhinia pectoralis and two mediterranean species Crocothemis erythraea and Aeshna isosceles. Noteworthy is the occurrence of Lestes dryas, Brachytron pratense, Gomphus vulgatissimus, Somatochlora flavomaculata, Sympetrum danae, and S. flaveolum. The population of G. vulgatissimus found in the Pšovka brook is one of the most abundant in Northern Bohemia." (Author)] Address: Honcu, M., Vlastivídné muzeum a galerie Ěeská Lípa, Nám. Osvození 297, CZ - 470 01 Česká Lípa, Czech Republic. E-mail: honcu@muzeum.clnet.cz

7658. Mauffray, B. (2006): Additional records of Georgia (United States) Odonata from the B.E. Montgomery archives. Notulae Odonatologicae 6(8): 86-87. (in English) ["In 2006, the B.E. Montgomery archives, housed at the International Odonata Research Institute, Gainesville, Florida, USA, was sorted. A number of county records omitted from Mauffray & Beaton (2005, Bull. Am. Odonatol. 9[2]: 21-66) are listed here with a few notes on "doubtful" and "expected" species." (Author)] Address: Mauffray, B., 4525 N.W. 53rd Lane., Gainesville, FL 32653, USA. E-mail: iori@afn.org

7659. McPeck, M.A.; Gavrillets, S (2006): The evolution of female mating preferences: Differentiation from species with promiscuous males can promote speciation. Evolution 60(10): 1967-1980. (in English) ["Females of many species are frequently courted by promiscuous males of their own and other closely related species. Such mating interactions may impose strong selection on female mating preferences to favor trait values in conspecific males that allow females to discriminate them from their heterospecific rivals. We explore the consequences of such selection in models of the evolution of female mating preferences when females must interact with heterospecific males from which they are completely postreproductively isolated. Specifically, we allow the values of both the most preferred male trait and the tolerance of females for males that deviate from this most preferred trait to evolve. Also, we consider situations in which females base their mating decisions on multiple male traits and must interact with males of multiple species. Females will rapidly differentiate in preference when they sometimes mistake heterospecific males for suitable mates, and the differentiation of female preference will select for conspecific male traits to differentiate as well. In most circumstances, this differentiation continues indefinitely, but slows substantially once females are differentiated enough to make mistakes rare. Populations of females with broader preference functions (i.e., broader tolerance for males with trait values that deviate from females' most preferred values) will evolve further to differentiate if the shape of the function cannot evolve. Also, the magnitude of separation that evolves is larger and achieved faster when conspecific males have lower relative abundance. The direction of differentiation is also very sensitive to initial conditions if females base their mate choices on multiple male traits. We discuss how these selection pressures on female mate choice may lead to speciation by generating differentiation among populations of a progenitor species that experiences different assemblages of heterospecifics. Opportunities for differentiation increase as the number of traits involved in mate choice increase and as the number of species involved increases. We suggest that this mode of speciation may have been particularly prevalent in response to the cycles of climatic change throughout the Quaternary that forced the assembly

and disassembly of entire communities on a continent-wide basis." (Authors) References to damselflies (Enallagma) are made.] Address: McPeck, M., Dept Biol. Sci., Dartmouth College, Hanover, New Hampshire 03755, USA. E-mail: mark.mcpeek@dartmouth.edu

7660. Meurgey, F. (2006): A possible economic impact of libellulid larvae on production of freshwater shrimps in Guadeloupe, French West Indies (Anisoptera: Libellulidae). *Notulae Odonatologicae* 6(7): 79-80. (in English) ["It seems, the odonate presence in shrimp farming ponds has a negative effect on shrimp production. As recorded at Pointe Noire, an approx. 20% decrease of post-larvae production was noticed for several years, mainly due to *Pantala flavescens* predation on shrimps. There are two rearing basins at this site, the largest of these has a surface of ca 100 m². During two days, 2302 exuviae were collected there and numerous final instar larvae were observed." 7661. Michael, J.L.; Batzer, D.P.; Fischer, J.B.; Gibbs, H.L. (2006): Fate of the herbicide sulfometuron methyl (Oust) and effects on invertebrates in drainages of an intensively managed plantation. *Can. J. Forest. Res.* 36: 2497-2504. (in English, with French summary) ["The off-site movement and impacts on water quality and aquatic ecosystems of sulfometuron methyl applied as the herbicide Oust to catchments in short-rotation plantations in the coastal plain of South Carolina were studied. Sulfometuron methyl was applied at the rate of 0.053 kg active ingredients ha⁻¹ to 5.4- and 5.9-ha catchments (C5 and C6, respectively). Off-site movement of sulfometuron methyl in drainage ditches was observed between application on 14 March 2001 and 14 June 2001 for the first five flow-producing rain events on C5 and the first four events on C6. The maximum observed concentrations (24 µg L⁻¹ on C5 and 23 µg L⁻¹ on C6) occurred during the first storm. Subsequent maximum concentrations for flow-producing storms were 10.0, 5.0, 0.5, and 0.1 µg L⁻¹ on C5 and 15.1, 6.7 and 0.5 µg L⁻¹ on C6. Pulsed inputs of sulfometuron methyl to stormflow were ephemeral and the maximum concentration for each storm event lasted 15 min or less. The faunal communities observed in these drainage ditches were dominated by a diversity of invertebrates typical of wetland habitats, such as midges, mosquitoes, water beetles, physid snails, and water fleas. Negative effects of sulfometuron methyl treatment on these communities in treated watersheds were not observed." (Authors) Tab. 2 lists a few Odonata on the genus level.] Address: Michael, J.L., Forestry Sciences Laboratory, Southern Research Station, USDA Forest Service, 520 DeVall Drive. Auburn. AL 36849. 7665. Nijboer, R.; Verdonschot, P.; Piechocki, A.; Tomczyk, G.; Klukowska, M. (2006): Characterisation of pristine Polish river systems and their use as reference conditions for Dutch river systems. *Alterra-rapport* 1367, ISSN 1566-7197: 221 pp. (in English) ["A central feature of the European Water Framework Directive are the reference conditions. The ecological quality status is determined by calculating the distance between the present situation and the reference conditions. To describe reference conditions the natural variation of biota in pristine water bodies should be measured. Because pristine water bodies are not present in the Netherlands anymore, water bodies (springs, streams, rivers and oxbow lakes) in central Poland were investigated. Macrophytes and macroinvertebrates were sampled and environmental variables were measured. The water bodies appeared to have a high biodiversity and a good ecological quality. They contain a high number of rare macroinvertebrate species. There are only few species that can not occur in the Netherlands, but their abundances were low. The Polish water bodies are suitable to describe reference conditions for similar Dutch water types. The data resulting from this project can be used

to update the descriptions of reference conditions in the 'Handboek Natuurdoeltypen' or to develop the descriptions for the Water Framework Directive types." (Authors) Odonata are part of the water body indicator system. The list of taxa also includes *Aeshna viridis*, *Stylurus flavipes*, and *Ophiogomphus cecilia*] Address: Alterra, P.O. Box 47; 6700 AA Wageningen; The Netherlands. E-mail: info.alterra@wur.nl

7666. Orlova, M.I.; Telesh, I.V.; Berezina, N.A.; Antsulevich, A.E.; Maximov, A.A.; Litvinchuk, L.F. (2006): Effects of nonindigenous species on diversity and community functioning in the eastern Gulf of Finland (Baltic Sea). *Helgol. Mar. Res.* 60: 98-105. (in English) ["An increase of xenodiversity in plankton and benthos in the eastern Gulf of Finland was observed from 1998 to 2004. Nonindigenous species account for 4.8% of all species found and up to 96% of total biomass. Invasive benthic omnivores, the alien amphipods *Gmelinoides fasciatus* and *Pontogammarus robustoides* and the predaceous fish *Perccottus glenii* with their versatile diets strongly affect the community structure. Invasive sessile seston-feeders that directly (through grazing and water clearance) and indirectly (through recycling of nutrients) interact with other ecosystem components, are mainly represented by the zebra mussel *Dreissena polymorpha*, which affect the structure of benthic and planktonic communities as well as benthicpelagic coupling. The invasive predatory cladocerans *Cercopagis pengoi* and *Evadne anonyx* and larvae of *D. polymorpha* are only temporary components in the zooplankton, which is limiting their overall effect. Alien benthic bioturbators, the polychaetes *Marenzelleria neglecta* and the oligochaete *Tubificoides pseudogaster* account for a high proportion of total abundance and biomass but their effects on native species need further research." (Authors) The content of stomachs of *Perccottus glenii* included Odonata.] Address: Orlova, Marina, Laboratory of Freshwater and Experimental Hydrobiology, Zoological Institute of the Russian Academy for Sciences, Universitetskaya Emb., 1., 199034 St. Petersburg, Russia. 7667. Orr, A.G. (2006): Odonata in Bornean tropical rain forest formations: Diversity, endemism and applications for conservation management. In: Cordero Rivera A (Ed.) *Forest and Dragonflies. Fourth WDA International Symposium of Odonatology*, Pontevedra (Spain), July 2005. Sofia-Moscow: Pensoft: 51-78. (in English) ["The island of Borneo was originally almost completely covered by closed canopy tropical rainforest. Owing to an aseasonal, hot, perhumid climate and high rainfall, forests were well supplied with streams and standing water. Consequently the rich, largely endemic odonate fauna must have evolved in association with these forests, and non-forest species, common today in disturbed land, must formerly have been rare opportunists in forest gaps or localised lacustrine species, it is estimated that at least 70 % of the fauna is presently confined to forest habitats and probably depends on forest for its survival. This study relates odonate distribution to a mosaic of complex tropical rain forest formations in Brunei. The tiny sultanate of Brunei still enjoys about 80% forest cover, representative of all the seven major formations found on the island and a great many of the 30+ sub-formations, and results from a nation-wide survey of odonates from most habitats are considered to be broadly applicable to the entire island of Borneo and many other parts of equatorial

south-east Asia. Greatest odonate diversity, both a and b, and greatest endemism, is found in the primary lowland mixed dipterocarp forests, especially those growing in highly dissected landscapes such as occur at the KBFSC. at the edges of the central uplands. High diversity and endemism is also found in swamp forest, especially freshwater swamp, with certain endangered peat swamp formations also important. The highly vulnerable kerangas forest harbours fewer species, none uniquely, and the mangrove fauna is still more depauperate, with only a single wide-ranging specialist restricted to this habitat. Secondary dipterocarp forest is certainly less rich in odonates than primary forest, but lack of sites for parallel comparisons makes it difficult at present to state how serious this effect is. These results emphasise the importance of conserving a wide range of primary forest formations to achieve satisfactory odonate conservation, a strategy congruent with the conservation of charismatic land-based vertebrates and forest peoples." (Author)] Address: Orr, B., 26 Currimundi Rd, Caloundra, Q4551, Australia

7668. Park, H.-h.; Lee, J.-h. (2006): Arthropod trophic relationships in a temperate rice ecosystem: A stable isotope analysis with ^{13}C and ^{15}N . *Environ. Entomol.* 35(3): 684-693. (in English) [Korea; "Arthropod trophic relationships in temperate rice fields during the growing season were explored in 2000 and 2001 by measuring signatures of naturally occurring carbon and nitrogen stable isotopes. ^{13}C and ^{15}N values for rice plants, soil, and arthropods varied slightly between both years, and the values were rather distinctive according to functional groups. Isotopic changes in rice plants affected values for herbivorous insects. Seasonal changes in ^{13}C and ^{15}N values for predators indicated that prey composition of their diets changed seasonally. Early in the season, there were two distinct clusters: (1) rice plants-herbivorous insects-parasitoids cluster and (2) filter-feeders/detrivores and predators cluster. The correlations in each case suggest interactions. During mid-season, the rice plants-herbivorous insects-parasitoids interaction was maintained, and herbivorous insects such as planthoppers were linked to predators. Also, detrivores such as Entomobryidae spp. seemed to be linked. During the late season, close interactions occurred at all trophic levels. Our study provided isotopic evidence that filter feeders/detrivores such as Chironomidae and Entomobryidae play a valuable role in maintaining the predator complex in the rice ecosystems during the rice-growing season. Also, fundamental data of stable carbon and nitrogen isotopes acquired in this study would be of value for use in advanced community studies for rice fields." (Authors) Table 1 includes Aeshnidae and Lestidae, and the means of carbon and nitrogen stable isotope ratios of sampled specimens.] Address: Park, H.-h., Entomology Program, School of Agricultural Biotechnology, College of Agriculture and Life Sciences, Seoul National University, San 56-1, Shillim-dong, Gwanak-gu, Seoul 151-921, Republic of Korea

7669. Prunier, F. (2006): Sex ratio y Biometría en tres poblaciones de libélulas de Sierra Morena: *Anax imperator*, *Boyeria irene*, *Cordulegaster boltoni immaculifrons* (Insecta: Odonata). *Boletín de la Sociedad Andaluza de Entomología* 13(2005): 67-71. (in Spanish, with English summary) [Total length and sex ratio were measured in three Andalusian (Spain) populations.] Address: E-mail: florent.prunier@netcourrier.com

7670. Reinhardt, K. (2006): A note on emergence and oviposition of *Paragomphus nyasicus* Kimmins at Lake Malawi, Malawi (Anisoptera: Gomphidae). *Notulae Odonatologicae* 6(8): 88-90. (in English) ["In the night of 22 to 23 Sept. 2001, emergence of the species was observed at Chembe village, Lake Malawi. About one individual per 1 metre beach emerged on a strip of 50 m length, all exuviae were very close to the waterline. Most individuals emerged after midnight, 6 to 9 h after sunset which is later than previously reported for tropical gomphids. This emergence delay may either be typical for *P. nyasicus* or be caused by human activity at the beach which lasted until well after dusk. The sex ratio was equal. Females oviposited by abdomen dipping onto the sand that has just been touched by the tiny lake waves. The dipping frequency appeared to be correlated to the frequency by which these little wavelets would roll onto the sand. Males patrolled or perched on the sand very close to the waterline but did not appear to show territorial activity." (Author)] Address: Reinhardt, K., Dept Animal & Plant Sciences, Univ. Sheffield, Sheffield S10 2TN, UK. E-mail: K.Reinhardt@sheffield.ac.uk

7671. (in English) [*Crocothemis servilia*: 18-VI-2004, vicinity of Meghri in southern Armenia, close to the border of Iran (38°53.443'N, 46°15.926'E; 516 m asl). *Lindenia tetraphylla*, 1 ♀, 23-VI-1958, Mingeçaur (40°46'12"N, 47°2' 56"E). *Selysiotthemis nigra*, 1 ♂, 1 ♀, both from Mingeçaur, dated 29-VI-1958 and 23-VI-1958, respectively.] Address: Tailly, M., Hoonakkerdreef 35, B-8791 Waregem, Belgium. E-mail: marc.tailly@pandora.be

7672. Tol, J. van (2006): The status of seven nomina nova introduced by H. Steinmann (1997). *Notulae Odonatologicae* 6(8): 94-95. (in English) ["[...] As will be explained below, it has appeared that all new names are unnecessary replacement names. It is considered worthwhile to publish the arguments, since such catalogues may have long-lasting impact on the use of scientific names. The names are in alphabetical order of species-group names. A general remark can also be made. Steinmann argues for all names to be replaced that they are junior secondary homonyms; they are actually junior primary homonyms.

**cancer* Steinmann, 1997b: 172, *Onychogomphus*. — Replacement name for *Gomphus* (*Onychogomphus*) *ruptus* Selys, 1858 (nee Selys, 1857). STEINMANN (1997b) includes two nominal taxa in his catalogue, viz. *Nihonogomphus ruptus* Selys, 1857, and *Onychogomphus ruptus* Selys, 1858. For the latter he proposes *O. cancer* as a replacement. However, both nominal taxa refer to the same taxonomic species. The references of Steinmann to Selys (1857, *Monogr. Gomph.*: 393), and to Selys (1858, *Mem. Soc. r. Set, Liege* 11: 653) pertain to the same publication (E. de SELYS, 1858, *Monographic des Gomphines*, Muquardt, Bruxelles).

**johnsoni* Steinmann, 1997b: 12, *Aeshna* — Replacement name for *Aeshna gigas* Bartenev, 1909 (nee Rambur, 1842). *Aeshna gigas* Bartenev is considered a junior synonym of *Aeshna crenata* Hagen, 1856 (B.F BELYSHEV, 1973: 405, *The dragon/lies of Siberia*, Vol. 1, part 2, Nauka, Novosibirsk), so a replacement name was unnecessary.

**kiautai* Steinmann, 1997a: 201, *Argia*. — Replacement name for *Argia apicalis* Matsumura, 1913 (nee Say, 1839). The status of *Argia apicalis* Matsumura was ascertained by ASAHINA (1951: 15, *Kontyu* 19: 15-22), when he introduced the name *Rhipidolestes okinawana* sp. n. [recte: *okinawanus*] for this species.

**schmidti* Steinmann, 1997a: 259, *Enallagma*. — Replacement name for *Enallagma risi* Pinhey, 1962 (nee Schmidt, 1961). The homonymy of *Enallagma risi* Pinhey was already recognised by PINHEY (1966: 9, *Arnoldia* 2(33): 1-24), who introduced *Enallagma angolicum* nom. nov. for this species. Presently assigned to *Pinheyagrion*.

**secundus* Steinmann, 1997b: 112, *Gomphurus*. — Replacement name for *Gomphus septima* Westfall, 1956 (nee Needham, 1930). Both nominal taxa *Septimus* Needham, 1930 and *septima* Westfall, 1956 were indeed described in *Gomphus* (contra e.g. BRIDGES, 1991: VII. 190, *Catalogue of the family-group, genus-group and species-group names of the Odonata of the World*, Privately published, Urbana). These names should, however, not be considered homonyms. *Septimus* is an adjective, but *septima* appears to be a noun in apposition. 'This species is named for Dr Septima Smith ...' (WESTFALL, 1956: 253, *Quart. J. Fla. Acad. Sci.* 19: 251-258). Both names cannot be considered 'variant spellings' of the same name. Since a difference of one letter is sufficient to prevent homonymy (*Int. Comm. Zool. Nomenclature*, 1999, *International Code of Zoological Nomenclature*, London: Article 57.6), *Gomphurus secundus* Steinmann is an unnecessary replacement name.

**vilma* Steinmann, 1997b: 52-53, *Gynacantha*. — Replacement name for *Aeschna viridis* Rambur, 1842 (nee Eversmann, 1836). This name has not been used as a valid name for a taxonomic taxon since RAMBUR (1842, *Histoire naturelle des Insectes. Neuropteres*. Roret, Paris). The status is thus uncertain, and should be considered a nomen oblitum. Based on the same type, the name *Gynacantha vilma* has to be considered a nomen oblitum as well." (Author)] Address: Tol, J. van, National Museum of Natural History, P.O. Box 9517, NL-2300 RA Leiden, The Netherlands

7673. Tolasch, T. (2006): *Wiederfund von Gomphus flavipes* (Charpentier, 1825) in Hamburg nach über 70 Jahren. *Bombus* 70/71: 292. 7676. Ward, P.; Labandeira, C.; Laurin, M.; Berner, R.A. (2006): Confirmation of Romer's Gap as a low oxygen interval constraining the timing of initial arthropod and vertebrate terrestrialization. *Proceedings of the National Academy of Sciences of the USA* 103(45): 16818-16822. (in English) ["The first terrestrialization of species that evolved from previously aquatic taxa was a seminal event in evolutionary history. For vertebrates, one of the most important terrestrialized groups, this event was interrupted by a time interval known as Romer's Gap, for which, until recently, few fossils were known. Here, we argue that geochronologic range data of terrestrial arthropods show a pattern similar to that of vertebrates. Thus, Romer's Gap is real, occupied an interval from 360 million years before present (MYBP) to 345 MYBP, and occurred when environmental conditions were unfavorable for air-breathing, terrestrial animals. These model results suggest that atmospheric oxygen levels were the major driver of successful terrestrialization, and a low-oxygen interval accounts for Romer's Gap. Results also show that terrestrialization among members of arthropod and vertebrate clades occurred in two distinct phases. The first phase was a 65-million-year (My) interval from 425 to 360 MYBP, representing an earlier, prolonged event of complete arthropod terrestrialization of smaller-sized forms (425-385 MYBP) and a subsequent, modest, and briefer event of incipient terrestrialization of larger-sized, aquatic vertebrates (385-360 MYBP). The second phase began at 345 MYBP, characterized by numerous new terrestrial species emerging in both major clades. The first and second terrestrialization phases bracket Romer's Gap, which represents a depauperate spectrum of major arthropod and vertebrate taxa before a major Late Paleozoic colonization of terrestrial habitats." (Authors) Fig. 1 includes Odonata.] Address: Berner, R.A., Department of Geology and Geophysics, Yale University, New Haven, CT 06520-8109, USA. E-mail: robert.berner@yale.edu.

(in French) [Golf du Saint-Laurent, Quebec, Canada; 39 odonate species were recorded at 13 localities. The records of the following species are treated with more detail: *Nehalennia irene*, *Anax junius*, *Cordulegaster maculata*, *Somatochlora franklini*, *S. kennedyi*, *S. septentrionalis*, *S. walshii*, *Pantala flavescens*, and *P. hymenaea*.] Address: E-mail: balbu1@globetrotter.net

7684. Cecala, K.K.; Price, S.J.; Dorcas, M.E. (2007): Diet of larval Red Salamanders (*Pseudotriton ruber*) examined using a nonlethal technique. *Journal of Herpetology* 41(4): 741-745. (in English) [North Carolina, USA; "Because larval stream salamanders are more abundant within streams than adults, feed and forage throughout the year, and may spend multiple years in streams before transformation, larvae may play a more important role than adults in trophic interactions within streams. We conducted a study using larval *P. ruber* to determine (1) the prey composition of larval salamanders, (2) whether feeding rates are affected by stream water temperature, (3) whether larval size affects the diversity of prey items, and (4) whether nonlethal stomach flushing is an effective technique for examining the diet of larval salamanders. We found that larvae consumed a wide diversity of prey items including individuals of the families Chironomidae (36.52% of prey items) and Sphaeriidae (15.17%) as well as terrestrial prey (7.87%) and other salamanders (2.25%). We also found that feeding rates were negatively correlated with stream water temperature, and larger larvae consumed a wider diversity of prey items than smaller individuals. Our results also suggest that nonlethal stomach flushing did not affect survivorship. These findings suggest that larval Red Salamanders are generalist predators that can play important trophic roles in stream ecosystems." (Authors) Odonata contributed 0.56% to the prey items; 1.47% of the salamanders had preyed on Odonata.] Address: Cecala, Kristen, Department of Biology, Davidson College, Davidson, North Carolina 28035-7118, USA

7685. Clopton, R.E.; Cook, T.J.; Cook, J.L. (2007): Revision of *Geneiorhynchus* Schneider, 1875 (Apicomplexa: Eugregarinida: Actinocephalidae: Acanthosporinae) with recognition of four new species of *Geneiorhynchus* and description of *Geneiorhynchus manifestus* n. sp. 7688. Dechruksa, W.; Krailas, D.; Ukong, S.; Inkapatanakul, W.; Koonchornboon, T. (2007): Trematode infections of the freshwater snail family Thiaridae in the Khek river, Thailand. *Southeast Asian J. trop. med. public health* 38(6): 1016-1028. (in English) ["The freshwater snail family Thiaridae was studied at five different locations: water sources for the Khek River, Thailand. Snail samples were collected by hand using counts per unit of time sampling method between December 2004 and October 2005. The physico-chemical quality of the water changed with the seasons and affected the sampling areas during both the dry season and the flood season. A total of 9,568 snail samples comprised of 14 species were found. These were 284 *Tarebia granifera*, 24 *Melanoides tuberculata*, 86 *Thiara scabra*, 3,295 *Paracrostoma pseudosulcospira pseudosulcospira*, 736 *P. paludiformis paludiformis*, 3,266 *P. paludiformis ubiosa*, 117 *P. morrisoni*, 304 *Brotia* (*Brotia*) *binodosa binodosa*, 1,250 *B. (Brotia) microsculpta*, 146 *B. (Senckenbergia) wykoffi*, 1 *B. (Brotia) pagodula*, 5 *B. (Brotia) binodosa spiralis*, 5 *B. (Brotia) insolita* and 49 *B. (Brotia) manningi*. The cercariae were investigated

using shedding and crushing methods where they were categorized into two types and five species. The first type, Parapleurolophocercous cercariae, were comprised of Haplorchis pumilio Looss, 1899 and Centrocestus formosanus Nishigori, 1924. The second type, Xiphidiocercariae were comprised of Acanthatrium hitaense Koga, 1953, Loxogenoides bicolor Kaw, 1945 and Haematoloechus similis Looss, 1899. The cercarial infection rates in the above 5 species were 0.1% (5 : 9,568), 0.2% (15:9,568), 0.3% (24:9,568), 0.4% (37 : 9,568) and 0.1% (5: 9,568), respectively. 5 species of snails were susceptible to trematode infections. They were T. granifera, M. tuberculata, T. scabra, P. paludiformis paludiformis and B. (Senckenbergia) wykoffi; infections were found in 26.1% (74:284), 33.3 % (8:24) , 1.2% (1:86), 0.3% (2:736) and 0.7% (1:146), respectively." Bishop Museum Technical Report 37: 334 pp. (in English) [This report documents the journals written by Bishop Museum curator Edwin Horace Bryan, Jr. (1898–1985) as he participated on one of the Whitney South Seas Expedition trips to the South Pacific. These notes span most of the year 1924 (February through November). He traveled from Honolulu to Samoa including the northern Cooks and Fiji. Many brief but general notes on dragonflies are made, and in a few cases the folk names of Odonata are noted (Savaii Island: Odonata - semu. Dragonflies - mataga).] Address: Evenhuis, N.L., Pacific Biological Survey, Bishop Museum, 1525 Bernice Street, Honolulu, Hawai'i 96817, USA. E-mail: neale@bishopmuseum.org

7691. Ferletic, U. (2007): Small red damselfly Ceragrion tenellum (Insecta: Odonata) in Slovenia. Graduation Thesis (University studies), Biotechnical faculty, Department of biology, University of Ljubljana: XI, 88 pp. (in Slovenian, with English summary) [C. tenellum is rare and endangered in Slovenia. "It is found only in Iskra and the Vipava valley. From May to October 2004 I checked 17 localities for presence of the species, number of individuals and habitat characteristics. On four localities present plant species were determined and on two localities population size was estimated. C. tenellum was found on 10 localities, only 4 of which support numerous and stable populations, while on others few specimens were occasionally observed. Two populations sizes were estimated with 209±109 and 51±20 specimens respectively in July and 179±78 and 43±17 specimens in August. Four plant species were found on all four localities. To preserve C. tenellum in Slovenia the four localities with the strongest populations should be kept in the present state, whereas for the other localities long term monitoring would be needed." 7693. Griffis-Kyle, K.L.; Ritchie, M.E. (2007): Amphibian survival, growth and development in response to mineral nitrogen exposure and predator cues in the field: an experimental approach. Oecologia 152: 633-642. (in English) ["Mineral nitrogen (N) has been suggested as a potential factor causing declines in amphibian populations, especially in agricultural landscapes; however, there is a question as to whether it remains in the water column long enough to be toxic. We explored the hypothesis that mineral N can cause both lethal and sublethal toxic effects in amphibian embryos and larvae in a manipulative field experiment. We sampled 12 ponds, fertilizing half with ammonium nitrate fertilizer early in the spring, and measured hatching, survival, development, growth, and the incidence of deformities in native populations of wood frog (*Rana sylvatica*) and eastern tiger salamander (*Ambystoma tigrinum tigrinum*) embryos and larvae held in situ enclosures. We found that higher ammonium concentrations negatively affect *R. sylvatica* more strongly than *A. tigrinum*. *R. sylvatica* tended to have lower survival as embryos and young tadpoles, slowed embryonic development, and an increased proportion of hatchlings with deformities at experimentally elevated ammonium. *A. tigrinum* did not experience significantly reduced survival, but their larval development was slowed in response to elevated ammonium and the abundance of large invertebrate predators. Variable species susceptibility, such as that shown by *R. sylvatica* and *A. tigrinum*, could have large indirect effects on aquatic community structure through modification of competitive or predator-prey relationships. Ammonium and nitrate + nitrite concentrations were not correlated with other measures that might have affected amphibians, such as pH, pond area, depth, or vegetation. Our results highlight the potential importance of elevated ammonium on the growth, development and survival of amphibians, especially those that breed in surface waters receiving anthropogenic N inputs." (Authors) Odonata are treated on the order level.] Address: Griffis-Kyle, K.L., Department of Fishery and Wildlife Sciences, New Mexico State University, MSC 4901, P.O. 7695. Hicham, K.; Lotfi, A. (2007): The dynamics of macroinvertebrate assemblages in response to environmental change in four basins of the Etueffont landfill Leachate (Belfort, France). *Water Air Soil Pollution* 185: 63-77. (in English) ["We investigated the relationships between the composition and structure of macroinvertebrate communities and some environmental variables over a year in four basins of the Etueffont landfill leachate (Belfort, France) using co-inertia analysis. Culicidae larvae were the dominant macroinvertebrate group in the studied basins, contributing to 87% of the total zoobenthos density, followed by Corixidae (8.8%), Chironomids (2.5%) and other larvae (each <1%). The lowest density of chironomid larvae was recorded in the first basin which is used as a discharge system for the leachate produced by the landfill. In basin 4, however, the Baetidae, Orthocladiinae (*Orthocladius* spp., *Chaetocladius* spp. and *Isocladius* spp.) and Tanyptodinae (*Psectrotanyptus* spp.) developed favoured by low levels in ammonia, COD, BOD, EC, metals and high oxygen concentrations. The co-inertia analysis illustrated both temporal and spatial variabilities in the basins and revealed a strong relationship between environmental conditions and benthic macroinvertebrates assemblages. This ordination technique showed that the chironomid community structure might be used successfully to differentiate between sites with different levels and types of pollution." (Authors) Gomphidae and Zygoptera are rarely represented.] Address: Lotfi, A., Laboratoire de Biologie Environnementale, INRA 3184, Université de Franche-Comté, 1, Place Leclerc, 25030 Besançon Cedex, France. 7697. Huang, H.; Sun, M. (2007): Dragonfly forewing-hindwing interaction at various flight speeds and wing phasing. *AIAA Jour.* 45(2): 508-511. (in English) ["Dragonflies are accomplished fliers. Scientists have always been fascinated by their flight. Experimental and computational studies on a single airfoil in dragonfly hovering mode were conducted by Freymuth [1] and Wang [2], respectively. They showed that large vertical force was produced during each downstroke. In each downstroke, a vortex pair was created; the large vertical force was explained by the downward two-dimensional jet induced by the vortex pair [2]. Recently, due to the advances in computational and experimental techniques and facilities, researchers are beginning to study dragonfly aerodynamics and forewing-hindwing interactions using three-dimensional model wings [3-5]. Sun and Lan [3] studied the aerodynamics and the forewing-hindwing interaction of a dragonfly in hover flight, using the method of computational fluid dynamics (CFD). Maybury and, Lehmann [4] and Yamamoto and Isogai [5] conducted experimental studies on the forewing-hindwing interaction at hovering conditions. Wang and Sun [6] extended the computational study of Sun and Lan [3] to the case of forward flight. In most of these studies, only hovering flight was considered. Only Wang and Sun [6] investigated the effects of forward flight speed, but the investigation was limited to a few phase

differences ($\gamma(d) = 0, 60, 90, \text{ and } 180 \text{ deg}$; $\gamma(m)$ denotes the difference in phase angle between the forewing and the hindwing stroke cycles, positive when the hindwing leads the forewing and negative when the forewing leads the hindwing). Because the distance of a wing from the wake of another wing depends on the flight speed and the relative motion of the fore- and hindwings, it is expected that the forewing-hindwing interaction is strongly influenced by the flight speed and the relative phase difference. Therefore, it is desirable to study the forewing-hindwing interaction by systematically varying the flight speed and the phase angle. Moreover, in the above studies [3-6], attention was mainly paid on whether or not the aerodynamic forces were changed by the forewing-hindwing interaction, while how the interaction occurred was not well understood. It is of interest to make further investigation on the flow field of the wing wake to reveal how the forewing-hindwing interaction occurs. In the present study, we address the above questions by numerical simulation of the flows of model dragonfly wings. The phasing and the flight speed are systematically varied. Advance ratio (the nondimensional flight speed) ranges from 0 to 0.6. At each advance ratio, eight phase differences, $-180, -135, -90, -45, 0, 45, 90, \text{ and } 135 \text{ deg}$, are considered." 7700. Kawase, N.; Natuhara, Y. (2007): Suitable habitats and the habitat network of a threatened aeshnid dragonfly, *Aeschnophlebia longistigma* Selys (Odonata: Aeshnidae) in suburban areas of Sakai City, Osaka Prefecture, Japan. *Jpn. J. Environ. Entomol. Zool.* 18(3): 123-131. (in Japanese, with English summary) ["Suitable habitats (ponds or marshes that are well covered by tall aquatic plants) of the threatened *A. longistigma* were identified by observing aerial photographs of suburban area of Sakai City. Field surveys were then

carried out to find adult dragonflies in those identified habitats. Although 19 suitable habitats were found in the area investigated, adult dragonflies were found only in 10 of the 19 habitats. Additionally, only 3 of 10 habitats were regarded as suitable breeding habitats or sources by determining the existence of larval exuviae or teneral adults. In the 3 habitats, a tall-growing aquatic plant *Phragmites australis* was seen to dominate. As a result of analyzing the distances of the 10 habitats, adults dragonflies found in the 7-sink habitats were traveling $2,260 \pm 841$ m from the nearest 3-source habitats." 7701. Kratzer, E.B.; Batzer, D.P. (2007): Spatial and temporal variation in aquatic macroinvertebrates in the Okefenokee swamp, Georgia, USA. *Wetlands* 27(1): 127-140. (in English) ["Aquatic macroinvertebrates of the Okefenokee Swamp have been largely overlooked despite their ecological importance and value as water quality indicators. In a two-year study we analyzed taxon richness and abundances of individual macroinvertebrate taxa in the Okefenokee Swamp to assess temporal variation among seasons and spatial variation among five plant community habitats (marsh prairies, cypress forest, scrub-shrub thickets, deepwater lakes, and boat trails) and across six areas of the Okefenokee. Chironomid and ceratopogonid midges and water mites numerically dominated the macroinvertebrate community, and chironomids, dytiscid beetles, and libellulid dragonflies had the greatest generic richness. Multivariate analysis of macroinvertebrate community structure did not show clear patterns among seasons, habitats, or areas. Furthermore, few individual taxa had either spatial or temporal variation in abundance. Wetland macroinvertebrate communities were relatively homogenous across the Okefenokee Swamp possibly because conditions important to these organisms did not vary dramatically among habitats or seasons. Alternatively, most resident taxa might be ecological generalists able to exploit a broad range of conditions." 7702. Mahan, R.D.; Johnson, J.R. (2007): Diet of the Gray Treefrog (*Hyla versicolor*) in relation to foraging site location. *Journal of Herpetology* 41(1): 16-23. (in English) [Missouri, USA; using a stomach-flushing technique, stomach contents of *H. versicolor* also resulted in one prey item identified as a mandible of a "Coenagrionidae". "Despite growing concern over habitat destruction, little is known regarding the activities of pond-breeding amphibians in the terrestrial environment. Yet, because most pond-breeding amphibian species spend the majority of their time in terrestrial habitats, it is important to understand what role terrestrial habitat plays in their life history. We examined the stomach contents of the Gray Treefrog (*Hyla versicolor*) in central Missouri using a stomach-flushing technique. Treefrogs were stomach-flushed; stomach contents were dried and weighed; and prey items were counted and identified for frogs caught in both artificial arboreal refugia and at breeding ponds. The majority of prey consisted of ants (41.2%) and beetles (29.6%). Both males and females caught in artificial refugia contained greater stomach content mass than those caught at breeding

ponds. There was a positive correlation between mass of stomach contents and distance from breeding ponds, with the average number of beetles per stomach increasing with distance from ponds. There was also greater stomach content mass in frogs found in artificial refugia on white oaks than red oaks or sugar maples, but there was no relationship between tree diameter and stomach content mass. These results demonstrate the importance of protecting terrestrial habitat to maintain foraging areas for treefrogs." 7704. Ramsey, J.B.; White, D.S.; Jin, H.-S. (2007): Spatial distribution of benthic macroinvertebrates in a sidearm embayment of Kentucky Lake. *Journal of the Kentucky Academy of Science* 68(1): 50-58. (in English) ["The macrobenthos of Ledbetter Embayment, Kentucky Lake, were sampled monthly (January 2005 through July 2006) to determine community structure with focus on the physical and chemical factors influencing spatial distribution and density. We collected 38 species, including 27 insects, four molluscs, two crustaceans, and three annelids. Species composition was similar to that observed in other midwestern reservoirs except that some taxa, typically rare in other systems, were very abundant. Mean density was 1158 m² and density increased with water depth. Macroinvertebrate distribution was patchy. Profundal collector-gatherers were associated with depositional zones created by flow patterns within the embayment driven by the main stem current. Most littoral species showed associations with allochthonous input or substrate heterogeneity provided by incoming streams. The physical structure of Kentucky Lake embayments and commensurate patterns of organic matter deposition, depth, and substrate composition appear to be the primary factors structuring the macrobenthos." (Authors) Four odonate taxa are listed on the genus level.] Address: Ramsey, J., Hancock Biological Station and Center for Reservoir Research, 561 Emma Drive, Murray, Kentucky 42071

7705. Richards, L.A.; Windsor, D.M. (2007): Seasonal variation of arthropod abundance in gaps and the understorey of a lowland moist forest in Panama. *Journal of Tropical Ecology* 23: 169-176. (in English) ["Treefalls gaps contribute to the habitat heterogeneity of tropical forest floors. Previous studies have shown that these gaps play an important role in plant and bird communities, however less is known about their role in arthropod communities. Using eight Malaise traps we investigated the difference in arthropod abundance of 19 taxonomic groups between gaps and understorey for 21wk during the rainy season and 8wk in the dry season on Barro Colorado Island, Panama. More (33.8%) arthropods were collected in gaps during the rainy season and 32.2% more in the understorey during the dry season. To assess the possible factors contributing to these differences we measured light, plant densities and young leaf densities, as indicators of abiotic factors and food resources for insect herbivores. Arthropod abundance was negatively correlated with light in the dry season.

Thus, abiotic stress may explain the pattern of abundance in the dry season. While there was no correlation with light in the rainy season, predator abundance was positively correlated with herbivore abundance. The plant and young leaf density data suggest that there is significantly higher food availability for herbivores in gaps. Thus, less stressful abiotic conditions and more food resources may contribute to more herbivores followed by more predators in gaps during the rainy season." (Authors) Odonata capture rate in gaps was higher than in understory both in rainy and dry season.] Address: Richards, Lora, Dept of Biology, Univ. of Utah, 257 S. 1400 E., Salt Lake City UT 84112, USA. 7708. Schotthoefer, A.M.; Labak, M.; Beasley, V.R.; (2007): *Ribeiroia ondatrae* cercariae are consumed by aquatic invertebrate predators. *J. Parasitol.* 93(5): 1240-1243. (in English) ["Trematodes amplify asexually in their snail intermediate hosts, resulting in the potential release of hundreds to thousands of free-living cercariae per day for the life of the snail. The high number of cercariae released into the environment undoubtedly increases the probability of transmission. Although many individual cercariae successfully infect another host in their life cycle, most fail. Factors that prevent successful transmission of cercariae are poorly understood. Microcrustaceans and fish have been observed to eat cercariae of some species, although the possibility that predation represents a significant source of mortality for cercariae has been largely unexplored. We tested the cercariophagic activity of several freshwater invertebrates on *Ribeiroia ondatrae*, a trematode that causes limb deformities in amphibians. Individuals of potential predators were placed into wells of multiwell

plates with 10–15 cercariae, and numbers of cercariae remaining over time were recorded and compared with numbers in control wells that contained no predators. Of the species tested, *Hydra* sp., damselfly (Odonata, Coenagrionidae) larvae, dragonfly (Odonata, Libellulidae), larvae, and copepods (Cyclopoida) consumed cercariae. In some cases, 80–90% of the cercariae offered to damselfly and dragonfly larvae were consumed within 10 min. In most cases, predators continued to consume cercariae at the same average rates when offered cercariae together with individuals of an alternate prey item. *Hydra* sp. ate fewer cercariae in these trials. Our findings suggest the need for field and laboratory studies to further explore the effects of predators on transmission of *R. ondatrae* to amphibian larvae. In addition, the results suggest that conservation of the biodiversity and numbers of aquatic predators may limit adverse impacts of trematode infections in vertebrate hosts." 7711. Tsuyuki, K.; Sudo, S.; Igarashi, S. (2007): Flow characteristics around a dragonfly wing obtained using liquid particles and numerical simulation. *Journal of the*

Japanese Society for Experimental Mechanics 7(3): 240-246. (in Japanese, with English summary) ["This paper describes the application of liquid particles to the measurement of the airflow around the forewing of the dragonfly, *Sympetrum frequens*. The particles with the diameter of approximately 10 µm were obtained by heating a mixture of glycols and distilled water. They were scattered as tracer particles in a wind tunnel. A PIV system was used to analyze the airflow around the dragonfly forewing with $Re = 1.1 \times 10^3$. On the other hand, a three-dimensional dragonfly forewing model was constructed for a numerical simulation. This simulation was used to obtain the velocity distributions around the model as well as the aerodynamic characteristics such as lift and drag coefficients. The experimental velocity results were in a good agreement with those of the simulation. Therefore, it was confirmed that the use of liquid particles comprising glycols was suitable for the analysis of low Reynolds number flows by the PIV system." 7712. Ueuma, Y.; Sagawa, T. (2007): A preliminary report of Odonata and such liek [sic] faunas of Hangando moor in Mt. Hakusan. Annual Report of The of Hakusan Nature Conservation Center 34: 31-33. (in Japanese, with English translation of the title) [Highland bogs are not known until now from the Hakusan Mountains. However, it is said that such a bog was located upper reach of the Myodani river at Hakuho, Hakusan city, Ishikawa prefecture (Matsumura et. al, 1980), and the precise location was not clear. This time we conducted a preliminary investigation of the bog on July 19, 2007. The bog was located at a height of ca. 1400 m a. s. l., and as the area was called Hangando for a long time, we named the bog Hangando moor. The vegetation of the area is Japanese beech, Japanese oak trees, cedars and bamboo grass and low bushes. The moor was divided by a small stream on the east and the west, in the former with three bog pools and the latter, one bog, wider and deeper than the east bogs, and small pools. The moor was covered with bog moss, and surrounded by grassy field of dew grass and lilies. We could not find such a proof of a high moor there as Matsumura et. al. indicated. Table 1 shows our findings from the two areas. At the west area rather a lot of *Leucorrhinia dubia*, the first specimen from Ishikawa prefecture; formerly only photos of the species were recorded, were sighted (Photo 3). Others are *Cordulia aenea amurensis*, the first specimen from the Hakusan Mountains in Ishikawa prefecture, *Coenagrion lanceolatum*, seemingly exuvia of *Aeshna juncea* and *Sympetrum frequens*. In the water salamanders and water beetles were found and 5 species of birds were seen. At the east, *L. dubia* (>10) and *Ceriagrion melanurum* were sighted. It is noticeable that such a lot of *L. dubia* were found from the Hakusan Mountains, and also the location of *L. dubia* and *C. a. amurensis* there seems to be the western limit in Japan. (Naoya Ishizawa)] Address: Ueuma, Yasuo, Hakusan Nature Conservation Center, Japan

7721. Boros, E.; Forro, L.; Gere, G.; Kiss, O.; Vörös, L.; Amdrikovics, S. (2008): The role of aquatic birds in

the regulation of trophic relationships of continental soda pans in Hungary. *Acta Zoologica Academiae Scientiarum Hungaricae* 54 (Suppl. 1): 189-206. (in English) ["The aim of this study was to estimate the population sizes, food resources, food selection and trophic regulation of aquatic birds in these soda pans. We classified the estimated density of birds into 3 simple nutrient cycling guilds: net-importer, exporter-importer and the net-exporter. The most important aquatic bird guild was the net-importer guild (51–70%), and the second was the exporter-importer guild (41–27%), while the relative densities of the net-exporter guild was the lowest (8–3%) in the investigated 2 pans. The captive foraging experiment demonstrated that the filter-feeder wildfowl (*Anas* species) could successfully remove the microcrustacean plankton and invertebrate nekton from the water. The biomass of planktonic crustaceans was significantly more by an order of magnitude than the biomass of the other invertebrates (benthos [including Odonata], nekton). The relatively simple trophic relationships demonstrate the bottom up function of some keystone herbivore aquatic bird species, while the top down control is determined by several wildfowl and wader species. The external nutrient load of the aquatic birds causes hypertrophic level of inorganic nutrient resources for the algae, while the planktonic primary production varied only between oligotrophy and mesotrophy because of the extreme physical conditions of these waters. The observed net heterotrophy and several trophic relationships seem to be regulated by aquatic birds." (Authors)] Address: Boros, E., Naturglob Ltd., H-1196 Budapest, Kossuth L. u. 76, Hungary. 7723. Brown, J.W.; Bahr, S.M. (2008): The insect (Insecta) fauna of Plummers Island, Maryland: Brief collecting history and status of the inventory. *Bulletin of the Biological Society of Washington* 15: 54-64. (in English) ["Plummers Island, a small site situated along the northern shore of the Potomac River in Montgomery County, Maryland, has been the research home of the Washington Biologists' Field Club for more than 100 years. Field

work conducted by club members from 1901 to about 1925 resulted in the accumulation of thousands of insect specimens of all orders from the Island, most of which are deposited in the collections of the National Museum of Natural History, Smithsonian Institution. Little collecting was conducted from ca. 1930–1950. In the 1960s sampling by Karl Krombein focused on bees and wasps and that by Terry Erwin on carabid beetles. Since 1998 the Lepidoptera fauna, leaf beetles (Chrysomelidae), and darkling beetles (Tenebrionidae) all have been the subject of investigations. In 2005 and 2006 Malaise traps were deployed to sample other orders (e.g., Trichoptera, Diptera, Hymenoptera). While the four major insect orders (i.e., Coleoptera, Diptera, Lepidoptera, and Hymenoptera) are represented by large numbers of historical specimens, only Lepidoptera have been surveyed thoroughly in recent times; notable exceptions include specific families: carabid beetles, leaf beetles, darkling beetles, sawflies, and bees and wasps. Based on an examination of the insect collection of the National Museum of Natural History and a review of relevant literature, we document 3012 insect species in 253 families, encompassing 18 insect orders: Collembola, Odonata, Dermaptera, Blattodea, Phasmatodea, Orthoptera, Psocoptera, Thysanoptera, Hemiptera, Neuroptera, Megaloptera, Coleoptera, Mecoptera, Trichoptera, Lepidoptera, Diptera, Siphonaptera, and Hymenoptera.] Address: Brown, J.W., Systematic Entomology Laboratory, P.S.I., Agricultural Research Service, U.S. Department of Agriculture, National Museum of Natural History, Smithsonian Institution, P.O. 7724. Caillouët, K.A.; Carlson, J.C.; Wesson, D.; Jordan, F. (2008): Colonization of abandoned swimming pools by larval mosquitoes and their predators following Hurricane Katrina. *J. Vector Ecol.* 33(1): 166-172. (in English) ["Thousands of flooded swimming pools were abandoned in New Orleans following Hurricane Katrina and provided a natural experiment to examine colonization of a novel aquatic habitat by mosquito larvae and their aquatic predators. We conducted a randomized survey of flooded swimming pools in two neighborhoods in January 2006 and found that 64% contained mosquito larvae, 92% contained predatory invertebrates, and 47% contained fishes. We collected 12,379 immature mosquitoes representing five species, primarily *Culiseta inornata*, and secondarily, the arboviral vector *Culex quinquefasciatus*. Dragonfly nymphs in the families Aeshnidae and Libellulidae were the most common predatory invertebrates collected among a total of 32 non-mosquito invertebrate species. Eleven species of fishes were collected, with *Gambusia affinis* accounting for 76% of the catch. Diversity of fishes in swimming pools was positively correlated with proximity to a levee breach and the fish assemblage found in swimming pools was similar to that found along shorelines of Lake Pontchartrain and drainage canals that flooded the study area. Mosquito larvae were rare or absent from pools containing fishes; however, path analysis indicated that the presence of top predators or abundant competitors may somewhat mitigate the effect of *Gambusia affinis* on mosquito presence." 7725. Chen, J.-S.; Chen, J.Y.; Chou, Y.F. (2008): On the natural frequencies and mode shapes of dragonfly

wings. *Journal of Sound and Vibration* 313: 643-654. (in English) ["A base-excitation modal testing technique is adopted to measure the natural frequencies and mode shapes of dragonfly wings severed from thoraxes. The severed wings are glued onto the base of a shaker, which is capable of inducing translational motion in the lateral direction of the wing plane. Photonic probes are used to measure the displacement history of the shaker base and the painted spots of the wing simultaneously. A spectrum analyzer is employed to calculate the frequency response functions, from which the natural frequencies and the associated mode shapes of the wing structure can be extracted. Our experimental results show that the fundamental natural frequency of dragonfly wings is in the order of 170 Hz when it is clamped at the wing base. The average flapping frequency 27 Hz of dragonflies is about 16% of the fundamental natural frequency. At this frequency ratio, the inertial force of the wing is negligible compared to the elastic force. In other words, the wing deformation during flapping flight is solely due to the balance between the external aerodynamic force and the elastic force of the wing structure. The wing structures are generally lightly damped, with damping ratio in the order less than 5%." (Authors) Study species are *Orthetrum pruinosum* and *O.sabina*.] Address: Chen, J.-S., Department of Mechanical Engineering, National Taiwan University, Taipei 10617, Taiwan. 7726. Craig, C.N.; (2008): Nestedness in Playa odonates as a function of area and surrounding land use. *Wetlands* 28(4): 995-1003. (in English) ["As degradation of wetlands continues to occur as a result of human activities, it is important to identify aquatic and amphibious species' extinction risks and the relative hospitalities of sites to support intact biotic communities; one such technique involves comparing the nestedness of assemblages as an assay of predictability and stability. We measured the degree of nestedness of odonate communities in the playa wetland complex of the Texas panhandle (data from 23 species in 73 playas in the summers of 2003–05) under current conditions as well as four simulations of future socioeconomic and climate change. Compared to randomized (null model) assemblages, significant nestedness was found for the system as a whole as well as for each year separately and for playas within each of the two dominant regional forms of land cover (cropland and grassland). Cropland and grassland playas were further split into three size categories, based on natural size breaks. Although departures from nestedness (idiosyncrasy) were unrelated to playa size or surrounding land use, larger playas surrounded by cropland displayed lower nestedness than did smaller ones whereas grassland playas showed the opposite pattern. This relationship between playa area and surrounding land-use type showed that there is lower stability in odonate community composition in even large playas if those playas are surrounded by agriculture. Departures from nestedness mainly consisted of unexpected species presences rather than absences, with idiosyncratic species being larger in total body length and including two range extensions. Under simulations of playa losses, community patterns were similar to contemporary data, suggesting that the ephemeral and dynamic nature of playas may already expose the odonate community to selective pressures possible under future land conversion." - 7729.** Davis, C.A.; Bidwell, J.R. (2008): Response of aquatic invertebrates to vegetation management and agriculture. *Wetlands* 28(3): 793-805. (in English) ["Wetland managers rely on a variety of vegetation management techniques to set back plant succession, enhance seed production, create hemi-marsh conditions, and reduce the coverage of invasive plants in wetlands. We evaluated the effects of vegetation management techniques (prescribed burning, cattle grazing, mowing, and disking) on aquatic invertebrate communities in seasonal wetlands in the Rainwater Basin Region of Nebraska, USA. Because many of these wetlands are embedded in an agricultural landscape, we also evaluated the effects of agriculture on aquatic invertebrates. We conducted the study in 24 wetlands during spring 2004 and 2005. In general, aquatic invertebrate richness and diversity were similar among wetlands subjected to different management regimes. However, richness and diversity were highest in grazed wetlands and lowest in disked wetlands. Regardless of the management regime, total benthic and nektonic invertebrate biomasses were higher in managed wetlands than unmanaged wetlands. In 2004, naidid oligochaete biomass was highest in farmed wetlands. Cattle grazing, mowing, and prescribed burning seemed to have the greatest influence on individual taxa; 12, eight, and seven of the taxa (out of 32) had higher biomasses in grazed, mowed, and burned wetlands, respectively. Within mowed wetlands, the biomasses of some taxa (*Gyraulus*, *Lymnaea*, and *Physa*) were lower in managed areas than unmanaged areas, emphasizing the need to leave some areas unmanipulated to provide cover. Because of high spatial and temporal variability in wetlands and aquatic invertebrate communities, the response of aquatic invertebrates to vegetation management techniques was not consistent and no management regime offered a particular advantage in enhancing aquatic invertebrate communities. However, managers should be aware that some type of physical manipulation of aquatic vegetation in wetlands is still warranted on a regular basis to reduce nuisance vegetation, enhance seed production, and create optimal habitat conditions for migratory waterfowl and other wetland-dependent birds. [...] Each of the Odonata taxa differed among treatments. *Enallagma* biomass was highest in grazed wetlands, while *Lestes* biomass was highest in farmed wetlands. *Libellula* biomass was higher in grazed and reference wetlands than in mowed and farmed wetlands." (Authors)] Address: Davis, C.A., Natural Resource Ecology and Management Department, 008C Agricultural Hall, Oklahoma State University, Stillwater, Oklahoma, USA 74078. - 7730.** Davis, R.S.; Peterson, R.K.D. (2008): Effects of single and multiple applications of mosquito insecticides on nontarget arthropods. *Journal of the American Mosquito Control Association* 24(2): 270-280. (in English) ["Mosquito management plans have been implemented in the United States and globally to manage mosquito vectors of West Nile virus and many other diseases. However, there is public concern about ecological risks from using insecticides to manage mosquitoes. Two studies were conducted during the late summers of 2004 through 2006 at Benton Lake National Wildlife Refuge near Great Falls, MT. The first experiment was conducted in 2004 and 2005 to assess acute impacts of mosquito adulticides (permethrin and d-phenothrin) and larvicides (*Bacillus thuringiensis israelensis* and methoprene) on nontarget aquatic and terrestrial arthropods after a single application. The second experiment was conducted in 2005 and 2006 to assess longer-term impacts of permethrin on nontarget terrestrial arthropods after multiple repeated applications. For aquatic samples, in the first study, no overall treatment effects were observed despite a potentially deleterious effect on amphipods on sample date 1 in 2004. During the same study, 1 of 54 responses had a significant overall treatment effect for sticky-card samples. Many of the responses for stickycard samples suggested significant time effects and time 3 treatment effects. Three response variables were associated with fewer individuals present in the insecticide-treated plots in a multivariate analysis. For the multiple-spray study conducted in 2005 and 2006, 6 of the response variables collected via sticky cards exhibited significant overall treatment effects, but none was associated with fewer individuals in the insecticide-treated plots. None of the responses collected using sweep-net sampling suggested overall treatment effects. Time and time 3 treatment effects were prevalent in 2005, but no discernable pattern was evident. In general, nearly all of the responses evaluated for either study indicated few, if any, deleterious effects from insecticide application. [...] Interactions between treatment and time were significant for Odonata. Samples had relatively lower counts of odonates for the larvicide-treated plots on the first sampling date followed by a slight increase on date 2. Each of the adulticide-treated plots and the control plots started with relatively more odonates on date 1, followed by a decrease on date 2. Power to detect multivariate overall treatment effects was generally low for stickycard samples during 2004 (0.05–0.717), with some exceptions within certain dates, including Araneae, Coleoptera, and the large size class in the eastern plots, as well as Bombyliidae, Ceratopogonidae, Chironomidae, Hymenoptera, Odonata, and predators in the western plots (.0.85)." - 7733.** Duan, X.-d.; Wang, Z.-y. (2008): Experimental study on the effect of habitat isolation on river ecology. In: *Advances in Water Resources and Hydraulic Engineering – Proceedings of 16th IAHR-PAD Congress and 3rd Symposium of IAHR-ISHS (Vol.VI: Hydropower Hydraulics)*. Eds.: Changkuan Zhang & Hongwu Tang. ISBN: 978-7-302-18662-5: 86-91. (in English) ["The field investigations and an experiment were conducted in the Juma river in the suburbs of Beijing (China) to study the effect of habitat fragmentation on river ecology, using benthic macro-invertebrates as indicator species. Three experimental plots were isolated from a relatively undisturbed stream habitat with sheet iron. The benthic assemblages and water parameters were measured by sampling periodically. The results indicate that the abundance, taxa richness and bio-diversity of invertebrates significantly decrease in the experimental plots owing to the habitat isolation. The smaller the experimental habitat plot, the more significantly these biotic indices decrease. The contents of the dissolved oxygen in the studied plots present the inconsistent variations. The comparison of the benthic communities shows that the relative abundances of Ephemeroptera and Diptera reduces significantly in the isolated plots, and that of the Odonata and Lamellibranchia increase significantly. It is also found that the benthic communities need some time to stabilize after isolation, and then present apparent variation over time. There is a relatively high degree of taxa turnover between isolated plots and the non-isolated reach, which can be attributed to the flight and dispersal of many aquatic insects in their adult stage. However, the benthic communities in isolated plots are not nested subsets in the natural non-isolated stream. This paper also gives some suggestions of the river restoration and the preservation of river ecological integrity based on the study and the present status of the rivers in China." - 7734.** Fidelis, L.; Nessiman, J.L.; Hamada, N. (2008): Spatial distribution of aquatic insects communities in small streams in Central Amazonia. *Acta Amazonica* 38(1): 127-134. (in Portuguese, with English summary) ["Small streams, at the Biological Dynamics of Fragmented Forest Project – INPA ca. 80 Km north from the city of Manaus (Amazonas, Brazil), were studied concerning the composition of the aquatic insects communities in different substrates. In each one of the 20 stretches, four samples of the principal biotopes were collected: leaf litter in riffle areas, leaf litter deposited on the bottom of the stream, sand and roots/vegetation on marginal banks. The aim of this study were to evaluate the aquatic insect fauna and relate it with specific substrates inside the igarapé. Leaf litter in riffle presented high richness number (106) while sand showed the lowest value (55). Higher similarity values occurred between leaf litter deposited on the bottom and marginal roots/vegetation. Lower values occurred between leaf litter in riffle and sand substrates. Some collected taxa were considered indicators of one type of substrate, but there were some taxa that showed no preference. The indicator taxa occurred in riffle litter were found in deposited leaf litter in Southeast streams of Brazil. This indicates the current velocity may be responsible for the community established. The size of the stream is related to the order and flow regime. In this study bigger streams (presenting higher values of flow and order) showed more distinct communities in each substrate than the smaller ones." (Authors) The samples include "Progomphus".] Address: Fidelis, Luana, INPA / DCEN, Caixa Postal 478, CEP: 69070-970, Manaus – AM. E-mail: luafidelis@uol.com.br

7748. Kim, S. B.; Jeon, H.S.; Oh, H.S.; Jung, Y.H.; Kim, W.T. (2008): Phylogenetic relationships of the Anisoptera (Insecta, Odonata) of Jeju Island, Korea, based on partial mitochondrial 16S ribosomal RNA sequences. *Korean J. Genetics* 30: 53-61. (in English) ["The phylogenetic relationship of the suborder Anisoptera distributed on Jeju Island, Korea, was analyzed by comparing partial mitochondrial 16S ribosomal RNA (rRNA) gene sequences. The length of the partial mitochondrial 16S rRNA genes for the 27 species of the Anisoptera studied ranged from 405 to 421 base pairs (bp). No intra-genus length-variations were identified in the genera *Anax* and *Orthetrum*, while the genes of *Somatochlora* and *Sympetrum* displayed lengths of 411 to 412 and 406 to 411 bp, respectively. The GC content of the partial mitochondrial 16S rRNA gene ranged from 26.76% to 30.83%. A parsimony analysis of the unambiguously aligned mitochondrial 16S rRNA gene sequences from 28 species, including outgroup species, produced eight equally most parsimonious trees. The strict consensus tree had three large independent groups: group I (family Aeshnidae), group II (family Libellulidae), and group III (family Corduliidae). Interestingly, the eight species of the genus *Sympetrum* were clearly distinguishable from the other species. The strict consensus tree, based on the mitochondrial 16S rRNA gene sequences, contained monophyletic groups. These results concurred with previous studies published by several researchers that were based on morphological characteristics." 7751. Kulesza, A.E.; Holomuzki, J.R.; Klarer, D.M. (2008): Benthic community structure in stands of *Typha angustifolia* and herbicide-treated and untreated *Phragmites australis*. *Wetlands* 28(1): 40-56. (in English) ["We compared benthic community structure among stands of *T. angustifolia* (narrow-leaf cattail) and herbicide-treated (Glypro) and untreated *P. australis* (common reed) over two summers in a Lake Erie coastal wetland (i.e., drowned river mouth). Both macrophytes are invasives, but only *Phragmites* is currently controlled by herbicides because of its reputed "undesirable" effects on wetland community structure and function. Macroinvertebrate diversity was similar among stand types and relatively high (Shannon-Weaver indices 2.6-4.2), probably because of high system primary productivity and a mix of lentic and riverine species. Proportions of macroinvertebrate functional feeding groups were also similar, but Jaccard's similarity indices were relatively low (29%-57%), suggesting macroinvertebrate compositional differences among stand types. Coleopterans particularly affected species presence/absence patterns, but their presence was associated with low water level rather than hydrophyte type per se. Moreover, total macroinvertebrate densities were greater in both *Phragmites* treatments than in *Typha*; a pattern generated mostly by gastropods ($\geq 95\%$ *Gyraulus deflectus* and *Physella gyrina*) and chironomids. Microalgal food supply likely plays a part in explaining these density differences, given diatom-dominated epiphyton was denser on submerged shoots of *Phragmites* than on *Typha*. Common diatom assemblages were similar among stand types, but species richness was significantly greater on untreated-*Phragmites* than on herbicide-treated, early senescent *Phragmites* and untreated-*Typha*. However, advanced senescence from herbicide application (~3 months) did not apparently affect macroscale habitat suitability and structure above and below the waterline, given counts of ovipositing odonates (mostly *Ischnura* and *Enallagma*) and captures of juvenile fishes ($>90\%$ *Lepomis* spp.) were similar among stand types. Overall, our results suggest that benthic community structure is comparable between similarly-aged stands (~4 yrs old) of invading reed and cattail and is not directly or indirectly affected by Glypro application." (Authors) Of the 813 Odonata individuals observed, a total of 86 were observed to oviposit; 93% of these were zygopterans, and 7% were anisopterans. The main genera of zygopterans observed were *Ischnura* and *Enallagma*, whereas the main genus of anisopterans observed was *Anax*. Counts of ovipositing odonates did not significantly differ among stand types or among sample dates.] Address: Holomuzki, J., Dept of Evolution, Ecology, and Organismal Biology, The Ohio State University, 1680 University Drive, Mansfield, Ohio, USA 44906. 7752. Machida, K.; Oikawa, T.; Shimanuki, J. (2008): Structure analyses of the wings of *Anotogaster sieboldii* and *Hybris subjacens*. *Journal of the Japanese Society for Experimental Mechanics* 8(2): 142-146. (in Japanese, with English summary) ["In general, it is known that structures of living things are optimized. The wings of a dragonfly are very thin and light. Although it is having the structure of bearing the load produced in the

case of an advanced flight such as "Flapping flight", "Glide", and "Hovering". The wings of a dragonfly are made by veins and membranes. In addition, the wings of a dragonfly have some characteristic structures, such as "Nodus". Thus, the wings of a dragonfly have many complicated structures. The costal vein configuration of the wings of a dragonfly is different from them of other insects. So, we paid attention to the costal vein configuration of the wings of a dragonfly. Therefore, in this study, we researched about the effect of the costal vein. As a result, it was showed that the configuration of costal vein made the deformation of bending and torsion small. In addition, it was showed that the configuration of costal vein closely related to nodus. In this study, several 3-D models of the dragonfly's wing were created and analyzed by the 3-D finite element method (FEM)." (Authors)] Address: not transliterated.

(2008): Mean mass-specific metabolic rates are strikingly similar across life's major domains: Evidence for life's metabolic optimum. *Proceedings of the National Academy of Sciences* 105(44): 16994-16999. (in English) ["A fundamental but unanswered biological question asks how much energy, on average, Earth's different life forms spend per unit mass per unit time to remain alive. Here, using the largest database to date, for 3,006 species that includes most of the range of biological diversity on the planet—from bacteria to elephants, and algae to sapling trees—we show that metabolism displays a striking degree of homeostasis across all of life. We demonstrate that, despite the enormous biochemical, physiological, and ecological differences between the surveyed species that vary over 1020-fold in body mass, mean metabolic rates of major taxonomic groups displayed at physiological rest converge on a narrow range from 0.3 to 9 W kg⁻¹. This 30-fold variation among life's disparate forms represents a remarkably small range compared with the 4,000- to 65,000-fold difference between the mean metabolic rates of the smallest and largest organisms that would be observed if life as a whole conformed to universal quarterpower or third-power allometric scaling laws. The observed broad convergence on a narrow range of basal metabolic rates suggests that organismal designs that fit in this physiological window have been favoured by natural selection across all of life's major kingdoms, and that this range might therefore be considered as optimal for living matter as a whole." 7757. Pelabon, C.; Hansen, T.F. (2008): On the adaptive accuracy of directional asymmetry in insect wing size. *Evolution* 62(11): 2855-2867. (in English) ["Subtle left-right biases are often observed in organisms with an overall bilateral symmetry. The evolutionary significance of these directional asymmetries remains uncertain, however, and scenarios of both developmental constraints and adaptation have been suggested. Reviewing the literature on asymmetry in insect wings (including a paper on *Calopteryx maculata*), we analyze patterns of directional asymmetry in wing size to evaluate the possible adaptive significance of this character. We found that directional asymmetry in wing size is widespread among insects, with left- and right-biased asymmetries commonly observed. The direction of the asymmetry does not appear to be evolutionarily conserved above the species level. Overall, we argue that the very small magnitude of directional asymmetry, 0.7% of the wing size on average, associated with an extremely imprecise expression, precludes directional asymmetry from playing any major adaptive role." 7761. Pryke, J.S.; Samways, M.J. (2008): Conservation of invertebrate biodiversity on a mountain in a global biodiversity hotspot, Cape Floral Region. *Biodivers. Conserv.* 17: 3027-3043. (in English) ["Mountains present particular challenges for biodiversity conservation. Table Mountain is a significant mountain in a global biodiversity hotspot, the Cape Floristic Region. It has outstanding angiosperm diversity and endemism. Yet, aerial and foliage invertebrates in the area have been poorly studied, despite their importance as pollinators and predators. These plant and invertebrate assemblages are under great pressure from human disturbance. Aerial and foliage invertebrates were sampled with a range of techniques. Sites were chosen to make comparisons between vegetation structure and type, elevation and aspect. In total, 216 species from 63 families and 14 orders were recorded. Vegetation structure (fynbos or forest) and elevation were the most important environmental variables for both aerial and foliage invertebrates. Peak time for aerial invertebrate abundance was spring and summer in the fynbos and spring in the forests, while the foliage invertebrates showed very little seasonal variation. There was no correlation between the diversity of aerial and foliage invertebrates. When these results were compared with others on epigaeic invertebrates, it became clear that epigaeic and aerial invertebrates are not correlated, while epigaeic and foliage invertebrates were only partially correlated, but not sufficiently so to consider one as a reliable estimator of the other. The management pointer from this study is that sites at all elevations are vital for the conservation of biodiversity on Table Mountain. Both the aerial and epigaeic/foliage invertebrate assemblages will need to be monitored separately to maintain the mountain's conservation status." 7765. Sadeghi, S. (2008): Aspects of infraspecific phylogeography of *Calopteryx splendens*. PhD thesis.

Dept Biology, Univ. Ghent. ISBN 978-90-8756-015-7: IV, 166 pp. (in English, with Iranian summary) [*Calopteryx splendens* Harris (1780) (Odonata: Calopterygidae) is a widespread damselfly, found in most of Europe, large parts of Siberia and much of west and central Asia. There is great variation among males in wing coloration. Traditionally subspecific taxa have been distinguished by the size and position of the pigmented wing spot, and by (mating) behavior. About a dozen of subspecies have been recognized. *Calopteryx splendens splendens*; *C. s. xanthostoma*; *C. s. caprai*; *C. s. balcanica* in Europe and various other names, such as *C. s. intermedia*, *C. s. orientalis*, *C. s. taurica*, *C. s. tschaldirica*, *C. s. waterstoni*, *C. s. amasina*, and so on, refer to putative subspecies, all of which are more or less geographically confined, but often with overlapping ranges and strong variation in wing spot size. For more than a century wing and wing spot characters have been used as criteria for *Calopteryx* species and subspecies identification. Most results suggest that wing pigmentation is a reliable signal of male quality and plays a role in mate recognition by females. Size and density of wing pigmentation is also correlated with immunological condition and animal resistance against disease. In spite of these indications, the question arises whether variation in wing spot is really a taxonomically valid discriminator. We used two morphological (traditional and geometric morphometries) and one molecular (AFLP) method to quantify and analyze morphological and molecular data. Comparing the results of these methods helped us to show some unclear and ambiguous relations between these populations and lighted some aspects of phylogeography of the (sub)species. In morphological study, the question was how well populations (subspecies) are recognizable based on wing and wing spot sizes and wing shape (irrespective of wing spot). In both morphological methods, left fore wing of the male specimens were evaluated because generally only males bear wing spot. For traditional morphometry, 10 different wing characters were measured using a semi-automatic image analysis program. Geometric morphometric study was implemented based on collected superimposed data from 19 digitized landmarks following the procrustes method. We used AFLP as molecular method because of its low start-up time and cost effective generation of data from a large number of distributed loci in the whole genome. In this part, the first aim was to investigate patterns of *C. splendens* population structure and the spatial distribution of genetic diversity, and the second aim was to determine whether there is a consistent spatial distribution pattern of *C. splendens* based on genetic and morphological diversity of wings, in other words whether the genetic differences are compatible with morphological differences of wings. Our results in traditional and geometric morphometries (regardless of wing spot) confirmed differentiation of *C. s. waterstoni* from other populations. Likewise, a relationship between two populations from north-east border of Turkey (*C. s. tschaldirica*) and Ireland, both with a small wing spot, was supported. Populations of *C. s. orientalis* from north of Iran and south of Turkmenistan (16 and Tm254 respectively) also showed close relations, which differentiate them from other groups in both morphometric techniques. The relationship between *C. s. xanthostoma* and *C. s. amasina* (from Turkey) was more remarkable than European populations in both morphometric methods. However, the results of these two morphometric methods were not consistent in many cases, while geometric morphometric analysis showed

wing shape differences between entire populations; traditional morphometry did not revealed such differences based on linear measurements of wing characters between most of populations. In general, geometric morphometric of Eurasian populations showed that two almost separate European and Asian groups of *C. splendens* are recognizable except some relations of *C. s. waterstoni* (from Turkey) to Eastern European populations, and *C. s. xanthostoma* (from Spain) to Asian populations. These conclusions were partly confirmed by AFLP results, but were not consistent with results of traditional morphometry which is mainly affected by linear size and area of wing and wing spot. Hence, use of wing spot patterns must be studied critically before those are used up as systematic characters at any taxonomic level. The AFLP results of our samples showed low levels of gene flow between populations except one case in the central Asia between Russian and Kazakhstani populations which is partly due to lack of effective obstacles and presence of Irtysh river. Many populations showed double or more geographical origin, a circumstance that can reflect rapid diversification and introgression. The reasons of this situation and likely relations between three main subspecies, *C. s. waterstoni*, *C. s. intermedia* and *C. s. xanthostoma* have been discussed. The deepest split in the phylogeography of *C. splendens* populations was found within the unglaciated areas in the east border of Turkey and Azerbaijan. We discuss the isolation of *C. s. waterstoni*. We interpret the unexpected relation between Azerbaijani and French populations as an intrusion of *intermedia*-genes in both. The conclusion drawn from comparison of the data in all three analyses is that the results of shape analysis between populations was more akin to molecular data and more reliable than linear measurements of wing characteristics, although some populations showed the same result in both methods. These observations suggest that wing spot similarity necessarily cannot capture the full genetic grouping of populations and therefore, is not an infallible character in *Calopteryx splendens* subspecies." 7767. Slos, S.; Stoks, R. (2008): Predation risk induces stress proteins and reduces antioxidant defense. *Funct. Ecol.* 22(4): 637-642. (in English) ["1. Despite its wide ecological relevance, we know little about the physiological mechanisms underlying the growth vs. mortality by predation trade-off. Here, we test for two costly, potential physiological correlates of the fight-or-flight response that may contribute to the growth reduction under predation risk: induction of stress proteins (Hsp60 and Hsp70) and of antioxidant enzymes (superoxide dismutase, SOD and catalase, CAT), in larvae of the damselfly *Enallagma cyathigerum*. 2. Under predation risk, there was a growth reduction and an increase in oxygen consumption, indicative of the fight-or-flight response. Predation risk did not affect Hsp60 levels but induced an increase in energetically costly Hsp70 levels. 3. Under predation risk, levels of SOD remained

constant and those of CAT decreased. Together with the increase in respiration, this should inevitably result in oxidative stress. 4. Our results suggest that induction of stress proteins may contribute to the partly physiologically mediated growth reduction under predation risk and that oxidative stress is a novel cost of predation risk that may have important long-term negative fitness consequences for the prey. The latter adds to the recent insight that costs of stressors and life-history trade-offs may not always directly operate through increased energy consumption and differential allocation, but, may also work through the increased production of reactive oxygen species." 7768. Srivastava, D.S.; Trzcinski, M.K.; Richardson, B.A.; Gilbert, B. (2008): Why are predators more sensitive to habitat size than their prey? Insights from bromeliad insect food webs. *American Naturalist* 172(6): 761-771. (in English) ["Ecologists have hypothesized that the exponent of species-area power functions (z value) should increase with trophic level. The main explanation for this pattern has been that specialist predators require prior colonization of a patch by their prey, resulting in a compounding of the effects of area up trophic levels. We propose two novel explanations, neither of which assumes trophic coupling between species. First, sampling effects can result in different z values if the abundances of species differ (in mean or evenness) between trophic levels. Second, when body size increases between trophic levels, effects of body size on z values may appear as differences between trophic levels. We test these alternative explanations using invertebrate food webs in 280 bromeliads from three countries. The z value of predators was higher than that of prey. Much of the difference in z values could be explained by sampling effects but not by body size effects. When damselflies occurred in the species pool, predator z values were even higher than predicted, as damselflies avoid small, drought-prone bromeliads. In one habitat, dwarf forests, detrital biomass became decoupled from bromeliad size, which also caused large trophic differences in z values. We argue that there are often simpler explanations than trophic coupling to explain differences in z values between trophic levels." 7769. Stamper, C.E.; Downie, J.R.; Stevens, D.J.; Monaghan, P. (2008): The effects of perceived predation risk on pre- and post-metamorphic phenotypes in the common frog. *Journal of Zoology* 277(3): 205-213. (in English) ["Where organisms undergo radical changes in habitat during ontogeny, dramatic phenotypic reshaping may be required. However, physiological and functional interrelationships may constrain the extent to which an individual's phenotype can be equally well adapted to their habitat throughout the life cycle. The phenotypic response of tadpoles to the presence of a predator has been reported for several species of anuran but the potential post-metamorphic consequences have rarely been considered. We reared common frog *Rana temporaria* tadpoles in the presence or absence of a larval odonate predator, *Aeshna juncea*, and examined the consequences of the result-

ing phenotypic adjustment in the aquatic larval stage of the life cycle for the terrestrial juvenile phenotype. In early development tadpoles developed deeper tail fins and muscles in response to the predator and, in experimental trials, swam further than those reared in the absence of a predator. While the difference in swimming ability remained significant throughout the larval period, by the onset of metamorphosis we could no longer detect any differences in the morphological parameters measured. The corresponding post-metamorphic phenotypes also did not initially differ in terms of morphology. At 12 weeks post-metamorphosis, however, frogs that developed from predator-exposed tadpoles swam more slowly and less far than those that developed from tadpoles reared in the absence of predators, the opposite trend to that observed in the larval stage of the life cycle, and had narrower femurs. These results suggest that there may be long-term costs for subsequent life-history stages of tailoring the larval phenotype to prevailing environmental conditions." itat less than 20 years ago. The nearest population exists in a distance of 20 km.] Address: Sy, T., RANA - Büro für Ökologie und Naturschutz, Frank Meyer, Mühlweg 39, D-06114 Halle(Saale), Germany. E-mail: thoralf.sy@rana-halle.de

7773. Tafangenyasha, C.; Dube, L.T. (2008): An investigation of the impacts of agricultural runoff on the water quality and aquatic organisms in a Lowveld sand river system in southeast Zimbabwe. *Water Resour. Manage.* 22: 119-130. (in English) ["In this research we examined the hypothesis that agricultural pollution is a key determinant of variability in nutrients concentrations and benthic fauna in a semi-arid tropical lowveld region of southeast Zimbabwe. Water quality was monitored in the river water column and river bottom sediments at a time when dissolved oxygen concentration was thought to be very low during the winter period in the rivers passing through low input agricultural sections and intensive commercial agricultural sections. The surveys used established chemical methods and biological methods. Benthic fauna assemblages were used to complement chemical cases of nutrient loading at localities chosen for sampling. Unpolluted control sites were not significantly different (t test, $p < 0.05$) from polluted sites in levels in mean values of dissolved oxygen, conductivity, total dissolved solids and mean density (no.m²) of benthic invertebrates in May. Significant differences (t test, $p < 0.05$) were not found in mean values of calcium, magnesium, potassium, total nitrogen, nitrate nitrogen, ammonia nitrogen and total phosphorus in river bottom sediments in May and August. These data certainly do not support the notion that the Runde River is severely polluted by the upstream agricultural activities and the hypothesis that agricultural runoff is a key determinant of water quality is rejected. As the data suggests the Runde River may be receiving moderate nutrient pollution. The positive effects of moderate eutrophication on fish catch and the trade-off in pollution implied here needs to be addressed by appropriate agricultural and environmental policies that relate to water pollution and land use." (Authors) Four Odonata taxa are listed at the genus level.] Address: Tafangenyasha, C., Department of Environmental Science and Health, National University of Science and Technology, P. 7777. Vilaseca, C.J.; Baptiste, L.G.; López-Ávila, A. (2008): Incidence of the margins on the natural biological control of *Spodoptera frugiperda* (J. E. Smith) (Lepidoptera: Noctuidae) in rice crops. *Revista Corpoica – Ciencia y Tecnología Agropecuaria* 9(2): 45-54. (in Spanish, with English summary) ["Multiple researches have shown the environmental, economic and productive benefits that can be generated when including natural vegetation in the margins of the crops. This happens thanks to the presence of natural habitats, which are the ones that promote biotic factors such as natural enemies and abiotic ones as temperature, humidity or rain that can affect negatively the pests. The objective of this research was to evaluate and compare the effect of other natural systems present at the same landscape such as crop of oil palm and gallery forests over the natural biological control of *Spodoptera frugiperda* in growing areas of rice. For this purpose, an area of study was selected at the Colombian plain foothills (Villanueva, Casanare), a place that is characterized for having big extensions of rice, surrounded by oil palms plantations and gallery forests. The abundance of *S. frugiperda* in the stages of larva and imago was evaluated, as well as the parasitism of eggs and larvae and the diversity of natural enemies and other arthropods. It was found that plantations of oil palm, as the gallery forests promote the natural biological control of *S. frugiperda* by increasing the diversity of the natural enemies and reduction of the pest population in the borders of the crop. The importance of parasitoids as *Apanteles marginiventris* and predators of the order Odonata in the control of *S. frugiperda* was identified. It is highlighted the importance to associate perennial crops as oil palm with transitory crops as rice in the planning of agroecosystems on the region and promote the conservation of gallery forest, as long as they can become key factors in the natural biological control of pests. Nevertheless, aspects as the low quality of the habitat and frequently use of chemical pesticides affected the results." (Authors)] Address: Vilaseca, C.J., Ecólogo. Pontificia Universidad Javeriana, Bogotá. Colombia. E-mail: javiervila4@hotmail.com

7780. Wildermuth, H. (2008): Die Falkenlibellen. Libellen Europas Bd. 5 in "Die Neue Brehm-Bücherei 653". ISBN: 3-89432-896-7: 496 pp. (in German) [The late Philip Corbet writes in his foreword to this outstanding book on odonate biology exemplified using the European Corduliidae: "The prospect of a book devoted to the family Corduliidae, or Emeralds, will instantly appeal to any odonatologist. Members of this family are strikingly elegant, and they possess a romantic, almost magical, quality, being furtive in their habits and frequenting wild, beautiful and remote habitats. The elusive habit of corduliids means that relatively little information has been placed on record about their biology." The information presented in this monograph comprises a comprehensive synopsis of observations published by other workers, integrated and greatly enlarged by own researches of H. Wildermuth, in the field and laboratory. "The content of this book upholds the best tradition of the science of natural history: meticulous field observations are extended by behavioural experiments and microscopic dissections conducted in the laboratory. The book's scope embraces all aspects of the family that any reader might wish to learn about: systematics; nomenclature; evolution; the life cycle, including the morphology and natural history of all developmental stages; adult life, including maturation, foraging, and reproductive behaviour; neurophysiology, with special emphasis on the visual system of Corduliidae; and habitat selection and threat and conservation of the dragonfly family." Monographs of the eleven European species comprise information on the discovery and name of each species, taxonomic information, descriptions of imago and larva, emergence, flight period, habitat, habits, accompanying species, threats and conservation measures, needs of research, and distribution differed according to the European countries. The book also includes an extensive bibliography, and an excellent(!) register. Corbet: "A definitive monograph of a family of Odonata is always to be welcomed and admired. It represents an immense commitment of time, effort and expertise. In the hands of a first-class, all-round biologist such as Hansruedi Wildermuth it constitutes an immensely valuable contribution to a field of science: it saves the aspiring investigator from devoting time to a laborious literature search, which should be an obligation but nowadays is sadly often dispensed with; and it points up possible avenues for fruitful research. In gratitude and

admiration, I commend this fine book to all odonatologists. I am confident that odonatology as a science will benefit if investigators are encouraged to adopt Hansruedi Wildermuth's rigorous methodology, especially in the field, so that, by the exercise of appropriate rigour, observations can be standardised and made comparable between habitats. I commend this book to its fortunate readership. It sets a new, high standard for monographs in odonate biology (Philip S. Corbet in his foreword). There is only to add that the book is completely written in German language. As Dr. B. Kiauta wrote in his review of the book, the author is well known for the excellence of his research and lucidity of his writings. The latter will facilitate everyone not common with the German language to read this book overcoming difficulties with the language. I am sure: This book is worth to refresh your German. 7782. Yoshimura, M. (2008): Longitudinal patterns of benthic invertebrates along a stream in the temperate forest in Japan: in relation to humans and tributaries. *Insect Conservation and Diversity* 1: 95-107. (in English) [" 1. The relationship between benthic invertebrate assemblage composition and surrounding land use has been examined in various ways, but most studies are undertaken at a coarse scale, or they compare obviously different landscapes. In Japan, these obvious differences in landscape are rare, and humans reside even in remote montane areas. 2. In order to clarify the influence of human residence on benthic invertebrate assemblages, seasonal and site differences among benthic samples collected from a 15-km stretch of Kuroson Stream and their relation with riparian land use were examined. 3. The number of individuals and genera differed significantly both spatially and temporally. Multivariate assemblage structure also differed significantly across space and time along the stream. 4. Increase of residential areas affected the in-stream benthic invertebrate assemblage. Site differences along the stream and the effect of human residence were not masked by the potentially homogenizing influence of tributary streams. 5. The composition of surrounding vegetation was the most important factor influencing benthic community structure. The presence or absence of human residential areas and seasonal change were also important variables. 6. Benthic invertebrates may be carried and migrate to main streams from tributaries; however, this phenomenon was not observed. As-

semblages of benthic invertebrates that inhabit a particular site do not change and are considered to vary seasonally across a certain range." (Author). The following taxa are listed: *Epiophlebia* spp., *Lanthus* spp., and *Calopteryx* spp.] Address: Yoshimura, M., Forest Biodiversity Group, Kansai Research Center, Forestry and Forest Products Research Institute, Nagaikyutaro 68, Momoyama, Fushimi, Kyoto 612-0855, Japan. 7784. Zessin, W. (2008): Einige Aspekte zur Biologie paläozoischer Libellen (Odonoptera). *Entomologica generalis* 31(3): 261-278. ["Some aspects concerning the biology of Palaeozoic dragonflies (Odonoptera): In the more than 320 million years old evolution the monophyletic group Odonoptera (dragonflies) developed a number of unique morphological adaptations. One of them is the very complex mating behaviour ('tandem position' and 'wheel position') which is the strongest argument for a monophyletic status of the recent dragonflies. A first theory concerning the development of this strange behaviour as well as the evolution of such unique structures was published by Zessin [1995]; it was modified subsequently by Bechly, Brauckmann, Zessin & Gröning [2001] and Zessin et al [2001]. Based upon two fossil specimens of *Namurotypus sippeli* Brauckmann & Zessin 1989 and *Erasipteroides valentini* (Brauckmann 1985) of Namurian B age from Hagen-Vorhalle, Germany, with preserved wings as well as even the male and female genitalia, the evolution of the 'mating wheel' and of the mode of oviposition of recent dragonflies with its peculiar copulation apparatus is discussed; both specimens are therefore of outstanding scientific value for the reconstruction of the development of these body structures. The enlargement of the wing-span of certain Late Palaeozoic Odonoptera [as for example the specimens mentioned above from the Namurian B of Hagen-Vorhalle; *Erasipterella piesbergensis* Brauckmann 1983, and *Piesbergtypus hielscheri* Zessin 2006 of Westphalian D age of the Piesberg near Osnabrück, Germany, and other Permocarboneous species from Central Europe and North America] is discussed in connection with the supposed increasing oxygen concentration in the air during the Late Carboniferous and Early Permian; largest known insect at all is

the Early Permian *Meganeuropsis permiana* Carpenter 1939 with a wing-span of 72 cm. The flying ability of the giant Odonoptera is discussed, too, by focussing on *Stephanotypus schneideri* Zessin 1983. Gliding flight is assumed to be predominant, interrupted by phases of wing flapping. Improvements of the flight ability by nodus- and pterostigma-like structures within the wings were already developed during the Late Carboniferous. Certain characters of the head (size of mandibles and eyes) and spiniferous legs (with three terminal claws) recommend a predatory mode of life similar to the ones of recent Odonoptera. The well-preserved large orthopteroid-like ovipositor of *Erasipteroides valentini* (Brauckmann 1985) suggests an endophytic or an endosubstratic oviposition in soils at the bottom of ponds. The giant dragonflies (Meganisoptera) were not able to adapt their mode of life to the rapidly decreasing oxygen concentration in the air at the end of the Permian period and became completely extinct. Other, smaller Permocarboneous Odonoptera with petiolate wing-base - for example such Protozygoptera as *Bechlya ericrobinsoni* Jarzembowski & Nel 2002, *Oboraneura kukalovae* Zessin 2008, the species of the Kennedyidae Tillyard 1925 and *Saxonagrion minutus* Nel et al 2000 (firstly grouped by NEL et al 2000 with the Zygoptera Selys 1854, then, NEL et al 2008, with the Panodonata) - survived the Permian/ Triassic crisis and gave origin to the rich diversity of the Mesozoic and to the recent species. The so-called 'secondary copulation' must have already evolved during Permocarboneous or Lower Triassic, because each of the recent suborders of the Odonata [Anisoptera, Anisozygoptera, and Zygoptera] share it; therefore their common stem species (presumably of Permian or Triassic age) must already have had 'secondary copulation' (with the female taking off the sperm from a special structure at the 2nd and 3rd abdominal segment while forming a 'mating wheel' with the male). The larval instars of the giant Odonoptera are poorly known; a single wing of a nymph is described from the Stephanian of Wettin (Sachsen-Anhalt, Germany) as *Schlechtendaliola nympha* Handlirsch 1919." 7789. Abbott, J.K.; Gosden, T.P. (2009): Correlated morphological and colour differences among females of the damselfly *Ischnura elegans*. *Ecological Entomology* 34(3): 378-386. (in English) ["1. The female-limited colour polymorphic damselfly *Ischnura elegans* has proven to be an interesting study organism both as an example of female sexual polymorphism, and in the context of the evolution of colour polymorphism, as a model of speciation processes. 2. Previous research suggests the existence of correlations between colour morph and other phenotypic traits, and the different female morphs in *I. elegans* may be pursuing alternative phenotypically integrated strategies. However, previous research on morphological differences in southern Swedish individuals of this species was only carried out on laboratory-raised offspring from a single population, leaving open the question of how widespread such differences are. 3. The present study therefore analysed multi-generation-

al data from 12 populations, investigating morphological differences between the female morphs in the field, differences in the pattern of phenotypic integration between morphs, and quantified selection on morphological traits. 4. It was found that consistent morphological differences indeed existed between the morphs across populations, confirming that the previously observed differences were not simply a laboratory artefact. It was also found, somewhat surprisingly, that despite the existence of sexual dimorphism in body size and shape, patterns of phenotypic integration differed most between the morphs and not between the sexes. Finally, linear selection gradients showed that female morphology affected fecundity differently between the morphs. 5. We discuss the relevance of these results to the male mimicry hypothesis and to the existence of potential ecological differences between the morphs." (Authors)] Address: Abbott, Jessica, Department of Animal Ecology, Ecology Building, Lund University, SE-223 63 Lund, Sweden. E-mail: abbottj@queensu.ca

7790. Anderson, R.C. (2009): Do dragonflies migrate across the western Indian Ocean? *Journal of Tropical Ecology* 25(4): 347-358. (in English) ["In the tropical Indian Ocean, the Maldives Islands lack surface freshwater, so are unsuitable for dragonfly reproduction. Nevertheless, millions of dragonflies (Insecta, Odonata; mostly globe skimmer, *Pantala flavescens*) appear suddenly every year starting in October. Arrival dates in the Maldives and India demonstrate that the dragonflies travel from southern India, a distance of some 500–1000 km. Dates of arrival and occurrence coincide with the southward passage of the Inter-tropical Convergence Zone (ITCZ). Circumstantial evidence suggests that the dragonflies fly with north-easterly tail winds, within and behind the ITCZ, at altitudes over 1000 m. It is proposed that this massive movement of dragonflies is part of an annual migration across the western Indian Ocean from India to East Africa. Arrival dates in the Seychelles support this hypothesis. Dragonflies also appear (in smaller numbers) in the Maldives in May, with the onset of the southwest monsoon, suggesting a possible return migration from Africa. These proposed migrations of dragonflies, regularly crossing 3500 km or more of open ocean, were previously unknown. It is known that these dragonflies exploit ephemeral rain pools for reproduction; the monsoons and ITCZ bring not only alternating, seasonal rains to India and Africa, but also appropriate winds for dragonflies to follow those rains. Several bird species migrate from India across the western Indian Ocean to wintering grounds in Africa. They do so at the same time as the dragonflies, presumably taking advantage of the same seasonal tail winds. Many of these birds also eat dragonflies; the possible significance of this was not previously appreciated." (Author)] Address: Anderson, C., Manta Marine Pvt Ltd, P.O. 7792. Baldaccini, G.N.; Leone, L.M.; Taddei, C. (2009): The running waters macroinvertebrates community: sampling techniques. *J. Environ. Monit.* 11: 756-760. (in English) ["The community of running water macroinvertebrates has proved to be one of key subjects for fluvial ecology and bioindication studies, thanks both to the different trophic roles within the range of taxa and to the ease with which they may be collected and identified. However, the complex nature of this community creates problems concerning the complete identification of the full range of taxa, even when restricting the taxonomic classification to families and genera. Even so, the need to use the community for the implementation of indexes of Ecological Status of freshwaters and for the detection of reference conditions, necessarily means a deeper knowledge of this structure. Hence, a standard methodology of the capture effort is required to identify not only the ecological quality but also a reference community for each selected fluvial typology and for each section examined. Starting from the processing of data collected during intercalibration exercises of the IBE method, the authors analyse the results underlining the share given by the size of the sample collected (catchment effort), and by the distribution models of different taxa within the community, in order to give a contribution to the evaluation of the reliability level of standard samples. The results confirm the models already described in previous publications and lead us to accept the presence of marginal degrees of uncertainty in standard samples." 7798. Borisov, S.N. (2009): Distribution patterns of dragonflies (Odonata) in Central Asia. *Entomological Review* 89(1): 26-33. (in English) ["The dragonfly fauna of Central Asia reveals distinct vertical differentiation. Three groups of species can be distinguished: mountain (24 species), plain (18), and plain-mountain (34) ones. The ranges observed can be classified into 7 principal types: plain, mountain, continuous boreo-montane, disjunctive Central Asian boreo-montane, disjunctive Tien Shan boreo-montane, Central Asian, and Pamir-Alay plain-mountain. The leading factors determining the distribution of dragonflies are the temperature and the presence of streams suitable for preimaginal development; the former factor determines the potential ranges, and the latter, the actual ones. The present-day composition, structure, and vertical distribution of the dragonfly fauna formed during the historical time, after the development of artificial irrigation canals which provided new habitats for dragonflies. Original Russian Text © S.N. Borisov, 2009, published in *Zoologicheskii Zhurnal*, 2009, Vol. 88, No. 1, pp. 11–17." 7799. Bots, J.; van Dongen, S.; Adriaens, T.; Dumont, H.J.; Stoks, R.; van Gossum, H. (2009): Female morphs of a colour polymorphic damselfly differ in developmental instability and fecundity. *Animal Biology* 59: 41-54. (in English) ["Sex-limited colour polymorphism occurs in several animal taxa and is usually explained in the context of sexual selection. Specifically, for polymorphism restricted to the female sex, multiple phenotypes may have evolved in response to male harassment. Such male harassment is generally considered to entail differential costs to female morphs, which may ultimately result in fitness differences. However, contrary to this prediction, most previous studies do not support that female morph (andromorphs and heteromorphs) differ in measures of quality and (or) fitness components. In this study, we evaluate quality and fitness differences between mated female morphs of the damselfly *Enallagma cyathigerum*. We suggest that many earlier studies may have failed to observe morph differences in quality or fitness because selection by male harassment was weak. Here, we selected a study population for which our expectation was that levels of per female capita male harassment were high. Nevertheless, also in this population mated female morphs did not differ in body size or condition (body mass/body length). However, mated female morphs did differ in levels of developmental instability: heteromorphs consistently showed a higher level of fluctuating asymmetry than andromorphs. Also, mated female morphs differed in fecundity: andromorphs had a lower clutch size than heteromorphs. In addition, larger females contained more eggs, but the slope of this relationship was steeper in heteromorphs. In conclusion, mated female morphs of the damselfly *E. cyathigerum* at our study site clearly differed in one quality estimate (developmental instability) and in our measure of fitness (fecundity)." 7800. Bots, J.; Breuker, C.J.; van Kerkhove, A.; van Dongen, S.; De Bruyn, L.; van Gossum, H. (2009): Variation in flight morphology in a female polymorphic dam-

selfly: intraspecific, intrasexual, and seasonal differences. *Can. J. Zool.* 87(1): 86-94. (in English, with French summary) ["In aerial animals, flight morphology needs to be designed to allow daily behavioural activities. Within species differences in behaviour can therefore be expected to relate to differences in flight morphology, not only between males and females but also between same-sex members when they use different behavioural strategies. In female polymorphic damselflies, one female morph is considered a male mimic that resembles the male's body colour and behaviour (andromorph), whereas the other is dissimilar (gynomorph). Here, we questioned whether males, andromorphs, and gynomorphs of the damselfly *Enallagma cyathigerum* differ in flight morphology, with andromorphs being more similar to males than gynomorphs. In addition, we evaluated whether differences in flight morphology are consistent or whether some morphs are more plastic in response to seasonal environmental fluctuations. Most morphometrics showed similar seasonal plasticity for males and both female morphs, which could only partly be explained from allometry. Consistent with high manoeuvrability in flight, males had broader wings and lower wing loading than females. Variation between female morphs was less pronounced, with no consistent differences in length, aspect ratio, total surface, and wing loading. However, we detected morph-specific differences in shape and width, with andromorphs having broader wings than gynomorphs similarly to males." 7802. Bredenhand, E.; Samways, M.J. (2009): Impact of a dam on benthic macroinvertebrates in a small river in a biodiversity hotspot: Cape Floristic Region, South Africa. *Journal of Insect Conservation* 13(2): 297-307. (in English) [Suitable reservoirs and monitoring methods are needed to manage scarce water supplies in dry countries. We assessed here the impact on aquatic macroinvertebrates of the only dam on the Eerste River, which runs through the heart of a biodiversity hotspot, the Cape Floristic Region, South Africa. The dam and associated activities, were the only forms of disturbance in this otherwise pristine area. We sampled over 20,000 macroinvertebrate individuals and illus-

trated some categorical effects of the impoundment and its effects on macroinvertebrate assemblages. Macroinvertebrate species diversity below the dam was only half of that in the pristine catchment area above the dam. Furthermore, Ephemeroptera, Plecoptera and Trichoptera diversity and abundance dropped to almost zero as a result of the impoundment. In contrast, the abundance of the Diptera family Chironomidae increased substantially below the dam. These changes in macroinvertebrate diversity mirrored those recorded in biologically less diverse areas, but are of major concern in this biodiversity hotspot with its rich endemic fauna. We conclude that such an impoundment, while important for human welfare, results in a high price being paid in terms of loss of local biodiversity." (Authors) All specimens - including Odonata - were identified to family level according to South African Scoring System version 5 protocol.] Address: Samways, M.J., Dept Ent. & Nematol., Univ. 7804. Bried, J.T. (2009): Location and seasonal differences in adult dragonfly size and mass in northern Mississippi, USA (Odonata: Libellulidae). *Int. J. Odonatology* 12(1): 123-130. (in English) ["Size and mass are often uniformly related within individuals and populations, but the relationship may vary in time or space. I asked whether isolated adult dragonfly populations within the same environmental context (climate, physiography, ecoregion) differ in both size and mature mass, and whether earlier emerging dragonflies are both larger and heavier on average. Differences were apparent among locally separated populations (ca 130-160 km apart), with the most northerly populations containing larger and heavier adults on average. Site-level environmental variation probably exerted a larger influence than broad-based ecogeographic rules (e.g., Bergmann's rule) at this fine scale. On average, earlier emerging dragonflies tended to outsize and/or outweigh later emerging dragonflies, a commonly observed pattern in adult odonates and other insect taxa. Size and mass did not produce the same results in every case, suggesting the size-mass relationship within dragonfly species can vary among spatially or seasonally isolated adult populations." (2009): Odonata enter the biodiversity crisis debate: The first global assessment of an insect group. *Biological Conservation* 142(8): 1864-1869. (in English) ["The status and trends of global biodiversity are often measured with a bias towards datasets limited to terrestrial vertebrates. The first global assessment of an insect order (Odonata) provides new context to the ongoing discussion of current biodiversity loss. A randomly selected sample of 1500 (26.4%) of the 5680 described dragonflies and damselflies was assessed using IUCN's Red List criteria. Distribution maps for each species were created and species were assigned to habitat types. These data were analysed in respect to threat level for regions and habitat types. We have found that one in 10 species of Odonata is threatened with extinction. This threat level is among the lowest of groups that have been assessed to date, suggesting that previous estimates of extinction risk for insects might be misleading. However, Odonata only comprise a small invertebrate order, with above-average dispersal ability and relatively wide distribution ranges. For conservation science and policy to be truly representative of global biodiversity a representative cross-section of invertebrates needs to be included." 7808. Contreras-Garduno, J.; Canales-Lazcano, J.; Jiménez-Cortés, J.G.; Juárez-Valdez, N.; Lanz-Mendoza, H.; Córdoba-Aguilar, A. (2009): Spatial and temporal population differences in male density and condition in the American rubyspot, *Hetaerina americana* (Insecta: Calopterygidae). *Ecological Research* 24(1): 21-29. (in English) ["Increased resource availability should favour higher animal density. It may also affect sex ratio, the male condition, and mating competition over access to females, although the direction of these variables is not straightforward to predict. Using a non-experimental approach, we carried out preliminary research using the territorial *H. americana* by comparing two spatially separated populations and the same population in two different seasons (each comparison with varying population densities). We first compared the sex ratio by counting males (using two categories, territorial and non-territorial) and females; relative foraging time (as an indicator of how much feeding resources each site provides); wing spot size (a sexual ornament), body size and immune melanization response (these two variables were used to assess male condition); and fighting time and contest number (to assess competition). For the seasonal comparison we used a third population in which we only compared male spot size and two indicators of condition and immune response, phen-

oloxidase (PO) and nitric oxide (NO) activity. The high-density population had higher values of non-territorial males (but similar sex ratio), relative foraging time, contest time and number, wing spot (but similar body size) and melanization response than the low-density population. According to season, at high density, males had higher values of wing spots, PO, and NO. Our results suggest that in a population where animals have more dietary resources, males reach a better condition despite the competition being more intense." 7809. Córdoba-Aguilar, A.; Serrano-Meneses, M.A.; Cordero-Rivera, A. (2009): Copulation duration in non-territorial Odonate species lasts longer than in territorial species. *Annals of the Entomological Society of America* 102(4): 694-701. (in English) ["We tested whether long copulation duration is more likely to have evolved in nonterritorial odonate species than in territorial species, given that nonterritorial males do not incur the costs of territory defense. A phylogenetic comparative method that controls for the phylogenetic nonindependence of species was used to compare copulation duration among 46 species of the two main odonate suborders (Anisoptera and Zygoptera). Copulation duration of nonterritorial anisopteran species was longer than for territorial dragonflies; however, this relationship was not found for Zygoptera. Long copulations in Anisoptera may be related to a male's ability to manipulate a female's stored sperm. It is suggested that constraints that prevent a territorial male from lengthening copulation do not seem to operate in Zygoptera. Other selective processes (i.e., cryptic female choice and/or sexual conflict) may also be important determinants of copulation duration in the Zygoptera. To our knowledge, this is the first exploration of the relation copulation duration and mating systems in insects." 7811. Couteyen, S., (2009): Biogéographie et spéciation des Odonates de l'île de la Réunion. *Ann. soc. entomol. Fr.* (n.s.) 45(1): 83-91. (in French, with English summary) ["The odonatological fauna of la Réunion is fundamentally of Mauritian origin for the geological history of the Mascarenes and the different routes taken by cyclones in the south-west of the Indian Ocean. The study of the Odonata distribution according to various

aquatic ecosystems of the island shows that: 1. Indigenous species with wide repartition are mainly found in open ecosystems of low and moderate altitude (from 0 to 800 meters). These ecosystems include as many as 13 species and have the highest Odonata density. 2. The Odonata fauna of la Réunion can be distinguished from those of the other islands of the Madagascan Region by the presence of two species originated from the continent which are confined above an altitude of 1000 meters. 3. For most of them, endemic species live in forested ecosystems. Those ecosystems do not hold more than five species of the odonatological fauna of the island. Finally, it seems that the speciation of Odonata in la Réunion doesn't take place in the diversified ecosystems with widely distributed species, but in a set of marginal ecosystems with low Odonata diversity." 7814. Dibble, C.J.; Kauffman, J. E.; Zuzik, E.M.; Smith, G.R.; Rettig, J.E. (2009): Effects of potential predator and competitor cues and sibship on wood frog (*Rana sylvatica*) embryos. *Amphibia-Reptilia* 30(2): 294-298. (in English) ["Chemical cues emitted from predators or competitors are often important for animals living in aquatic ecosystems as they allow potential prey to assess predation risk and make appropriate risk-sensitive responses. In our experiment, we examined if *R. sylvatica* embryos exposed to potential predator and competitor cues would alter their time to hatching, size at hatching, or survivorship. Eggs from four different sibships were subjected to a variety of cues including dragonfly larvae (potential tadpole predator), mosquito fish (*Gambusia affinis*; a non-native potential egg and tadpole predator), and overwintered tadpoles of *Rana* sp. (potential competitors). We found no significant effects of any of the cues. However, we did find sig-

nificant variation in mean time to hatching and mean hatchling size among sibships. Our results suggest that wood frog embryos may have limited ability to respond to some cues at the embryonic stage, at least for the concentrations and conditions used in this experiment. Our results do indicate genetic or parental effects can affect embryonic wood frog development rate and hatchling size." 7817. Dumont, H.J. (2009): Aquatic insects of the Nile basin, with emphasis on the Odonata. *Monographiae Biologicae* 89: 631-646. (in English) ["Much work has been done on the Diptera of the Nile, because many species are vectors of disease of man and cattle. Some biogeographic work has been done on the Heteroptera, but the group that is known best is that of the Odonata. With c. 250 species out of an estimated 900 for Africa, the Nile is not particularly rich. Unlike the Congo basin, it lacks a high degree of endemism. Relatively most endemic species are found on the faunistically depauperate Ethiopian plateau, followed by the East African lake zone. Quite a few wide-ranging Afrotropical species have used the Nile valley as a pathway to reach the Mediterranean shores, while in Lower Egypt some Palaearctic species of Irano-Turanian extraction occur. There has been exchange, across Sinai with the Levant, and perhaps across the Bab-el-Mandeb passage with Arabia. Some of these exchanges have been recent, others are older, and (sub) speciation has occurred since. Old endemics of Arabia and The Levant (at genus level) may not have had anything to do with the Nile. Their ancestors may have used the Red Sea valley as a pathway for dispersal before the opening of Bab-el-Mandeb. Not only the Afrotropical fauna of the Levant is a pluvial relict of Pleistocene age; also in West Sudan, relicts of an African forest fauna are found in a mountainous Sahel environment (Jebel Marra). Oriental elements in the Nile fauna are extre-

mely rare." (Author)] Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. Ledeganckstraat 35, B-9000 Gent, Belgium. E-mail: Henri.Dumont@ugent.be

7818. Ellenrieder, N.v. (2009): Odonata of the Argentine Yungas cloud forest: distribution patterns and conservation status. *Odonatologica* 38(1): 39-53. (in English) ["Odonata of streams, small rivers and ponds were sampled in the Yungas cloud forest of NW Argentina, and presence / absence information of species from samples and from examination of collections was recorded in a spatial-relational data base. Alpha, beta, and gamma diversity and total species richness expected for the area were estimated. Similarity in composition of odonate communities from lotic and lentic environments were analyzed according to latitudinal and altitudinal gradients, using multivariate cluster analysis. Assemblages from NW Argentina were compared to those from equivalent sites in SE Peru. Odonata species diversity was found to follow both a latitudinal (decreasing from N to S) as an altitudinal gradient (decreasing from low to high elevations). Based on IUCN (2001) criteria, the conservation status of the odonate species endemic to the Yungas cloud forest was assessed at a global scale; 6 species were assessed as of Least Concern and 2 as Near Threatened." 7821. Fincke, O.M.; Santiago, D.; Hickner, S.; Biebek, R. (2009): Susceptibility of larval dragonflies to zebra mussel colonization and its effect on larval movement and survivorship. *Hydrobiologia* 624: 71-79. (in English) ["Colonization by the zebra mussel, *Dreissena polymorpha*, was quantified for five dragonfly species that differed in size and larval habits in a Michigan lake. Both larger size and a non-burrowing habit independently increased susceptibility to colonization. In 2005, over 50% of the final instars of the sprawlers *Didymops*

transversa and Hagenius brevistylus were colonized, as well as younger instars. Rarely colonized were Progomphus obscurus and Dromogomphus spinosus, whose larvae burrow under sand, and the sprawler Epithea princeps, whose final instars were lightly covered with sand. Hagenius larvae that had been preyed upon carried more mussels than those dying of other causes. More generally, mussel attachment decreased the probability that sprawlers left the water to emerge, the distance that some species traveled before emerging, and the ability of an overturned sprawler to right itself. On average, final instars of Didymops and Hagenius remaining in the water carried three times as many mussels as individuals known to emerge. Compared to uncolonized individuals, Epithea and Progomphus with mussels emerged closer to the water line. Among colonized Didymops, the distance traveled on land before emerging decreased with increasing mussel load. Of the colonized Didymops that could right themselves, righting time increased with mussel load. Because the two common species of sprawlers were disproportionately colonized, and mussel attachment decreased their chances of emerging, our results suggest that *D. polymorpha* has the potential to affect the community structure of this guild of aquatic and terrestrial predators." 7823. Fontanarrosa, M.; Collantes, M.B.; Bachmann, A.O. (2009): Seasonal patterns of the insect community structure in urban rain pools of temperate Argentina. *Journal of Insect Science* 9:10: 18 pp. (in English) ["Temporary aquatic environments are widespread in the world, and although there are considerable regional differences in their type and method of formation they have many physical, chemical and biological properties in common. With the aim to increase knowledge of urban temporary pool fauna, the objectives of this work were to assess the seasonal patterns of species composition, richness, and diversity of the aquatic insect community inhabiting rain pools in urban temperate Argentina, and to identify the environmental variables associated to these patterns. Four temporary pools of an urban green space in Buenos Aires City were studied throughout a 1-year period. Eleven flood cycles with very varied hydroperiods and dry periods, mainly associated with rainfall, were identified. Insect species richness in these temporary urban pools, 86 taxa were documented, was found to be within the range reported for wild temporary water bodies of other regions of the world. The present results provide evidence for the existence of a clear link between habitat and community variability. Hydroperiod and seasonality were the main environmental factors involved in structuring the insect communities of the studied water bodies. Urban pools in green spaces have the potential to act to its dwellers like corridors through the urban matrix. Taking into ac-

count these characteristics and their accessibility, urban temporary pools can be considered as promising habitats for the study of ecological processes involving the insect community." 7828. Gosden, T.P.; Svensson, E.I. (2009): Density-dependent male mating harassment, female resistance,

and male mimicry. *Am. Nat.* 173: 709-721. (in English) ["Genetic variation in female resistance and tolerance to male mating harassment can affect the outcome of sexually antagonistic mating interactions. We investigated female mating rates and male mating harassment in natural populations of *Ischnura elegans*. This damselfly species has a heritable sex-limited polymorphism in females, where one of the morphs is a male mimic (androchrome females). The three female morphs differ in mating rates, and these differences are stable across populations and years. However, the degree of premating resistance toward male mating attempts varied across generations and populations. Male mating harassment of the female morphs changed in a density-dependent fashion, suggesting that male mate preferences are plastic and vary with the different morph densities. We quantified morph differences in male mating harassment and female fecundity, using path analysis and structural equation modeling. We found variation between the morphs in the fitness consequences of mating, with the fecundity of one of the nonmimetic morphs declining with increasing male mating harassment. However, androchrome females had lower overall fecundity, presumably reflecting a cost of male mimicry. Density-dependent male mating harassment on the morphs and fecundity costs of male mimicry are thus likely to contribute to the maintenance of this female polymorphism." (2009): Behaviour of damselfly larvae (*Enallagma cyathigerum*) (Insecta, Odonata) after long-term exposure to PFOS. *Environmental Pollution* 157(4): 1332-1336. (in English) ["Perfluorooctane sulfonic acid (PFOS) is a persistent and ubiquitous environmental contaminant that has been detected in organisms worldwide. Here, we evaluate whether long-term (1 and 4 months) exposure to PFOS contamination affects the behavioural performance of freshwater larvae of the damselfly *E. cyathigerum*. Our results show reduced behavioural performance with increasing PFOS concentration. In 1 month exposed larvae, no observed effect concentrations (NOECs) were 100 µg/L for general activity. In 4 months exposed larvae, NOECs were 10 µg/L, for each behavioural trait, except swimming acceleration of male larvae where the NOEC was 100 µg/L. When faced with PFOS concentrations above the NOEC, *E. cyathigerum* larvae were less active, less capable to escape a simulated predator attack and less efficient in foraging. Together, our results show that damselfly larvae suffer reduced survival-related behavioural performance." 7832. Hamasaki, K.; Yamanaka, T.; Tanaka, K.; Nakatani, Y.; Iwasaki, N.; Sprague, D.S. (2009): Relative importance of within-habitat environment, land use and spatial autocorrelations for determining odonate assemblages in rural reservoir ponds in Japan. *Ecological Research* 24(3): 597-605. (in English) ["To clarify the major factors affecting odonate assemblages in rural reservoir ponds among within-habitat environments, land use around ponds and spatial autocorrelation, we surveyed odonate adults in 70 study ponds in Ibaraki Prefecture, Japan, during three sampling periods in 2005. Redundancy analyses (RDA) for these three factor groups were executed to determine their strength in explaining the odonate species composition. Their relative contributions were also evaluated by the method of variation partitioning. A total of 41 odonate species were recorded in the study ponds, and 24 of them, excluding rare species, were used for our analysis. Summed effects including all three factor groups explained approximately 39% of the variation in odonate species composition. We found that spatial autocorrelation was the most important, though the within-habitat environment and land use had comparable effects. We conclude that spatial autocorrelation should be considered in this type of analysis, though we could not clearly explain what caused such a spatial structure. Pond area and debris that had accumulated at the bottom of ponds were selected as the within-habitat environment, and the forests and paddy fields around ponds were selected for land use after the procedure of forward stepwise selection. These results suggest that the recent decrease of forests around the ponds has had a negative effect on the odonate assemblages." 7833. Hammers, M.; Sánchez-Guillén, R.A.; Gossum, H. van (2009): Differences in mating propensity between immature female color morphs in the damselfly *Ischnura elegans* (Insecta: Odonata). *Journal of Insect Behaviour* 22: 324-337. (in English) ["Female-limited color polymorphisms occur in a variety of animal taxa where excessive male sexual harassment may explain the coexistence of multiple female color morphs. In the color polymorphic damselfly *Ischnura elegans*, mature and immature female color morphs coexist at the mating site where males are in search for suitable mating partners. Here, we study male preference and female mating propensity for the two immature female morphs.

As would be expected, compared to mature morphs, both immature female morphs mate much less. Within immature females, one morph consistently mates more frequently compared to the other morph, a pattern that is similar for the ontogenetically corresponding mature female morphs. Preference experiments with the two differently colored immature female morphs, however, did not indicate male mate preference for either morph. Low mating frequencies of immature females at natural sites in combination with relatively high attractiveness of immature models in terms of male preference indicate that female behavior influences female mating success." (2009): Insect wing shape evolution: independent effects of migratory and mate guarding flight on dragonfly wings. *Biological journal of the Linnean society* 97(2): 362-372. (in English) ["Although, in some insect taxa, wing shape is remarkably invariant, the wings of Anisopteran dragonflies show considerable variation among genera. Because wing shape largely determines the high energetic costs of flight, it may be expected that interspecific differences are partly due to selection. In the present study, we examined the roles of long-distance migration and high-maneuvrability mate guarding in shaping dragonfly wings, using a phylogeny-based comparative method, and geometric morphometrics to quantify wing shape. The results obtained show that migration affects the shape of both front and hind wings, and suggest that mate guarding behaviour may also have an effect, especially on the front wing. These effects on front wing shape are at least partly independent. Our findings are interesting when compared with the geographically widespread and ecologically diverse dipterans *Acalyptatae* (including the genus *Drosophila*). The wings in that group are similar in function and structure, but show strikingly low levels of interspecific variation." 7842. Jorcin, A.; Nogueira, M.G.; Belmont, R. (2009): Spatial and temporal distribution of the zoobenthos community during the filling up period of Porto Primavera Reservoir (Paraná River, Brazil). Braz. J. Biol. 69(1): 19-29. (in English, with Portuguese summary) ["This study is part of the limnological monitoring undertaken by the Energy Company of the State of São Paulo (CESP) during the filling up process of the Porto Primavera Reservoir (Hydroelectric Power Plant Engenheiro Sérgio Motta). This reservoir, located in the high Paraná River between the States of São Paulo and Mato Grosso do Sul, is the fourth largest in the country. The first filling up phase started in December 1998 and the second phase in March 2001. Samples for benthic community and sediment characteristics analysis were quarterly collected between August of 1999 and November 2001 and also in August of 2002 (11 sampling campaigns). Samplings were carried out at 13 stations distributed in the reservoir, and at one point located downstream of the dam. 128 invertebrate taxa were identified [(including "Gomphidae" and "Aphylla") ...] Noticeable variations in the fauna density were observed, considering both different periods and locations. The maximum density of organisms (mean value of 7812 ind.m²) was recorded in the center of the reservoir, and the minimum (mean value 9 ind.m²) in the more lacustrine area near the dam. The greatest species richness per sample (24 taxa) was observed in the reservoir upstream (fluvial zone). The maximum diversity (Shannon-Wiener Index) per station/period, 3.82 and 3.86 bits.ind⁻¹, were calculated in the transitional river/reservoir zone during the beginning (August 1999) and in the reservoir central zones in the end (August 2002) of the filling up period, respectively. There was no clear relation between the distribution of the different faunistic groups and the sediment granulometric characteristics. However, the decrease or even total absence of organisms was observed at stations with high organic matter concentration (>40%) in a low degradation state (coarse detritus). This fact may be related to the lack of sediment deposits, which would cause difficulties to the fixation of the benthic fauna. Additionally, in those conditions more reduced chemical conditions are expected in function of the intense decomposition process of the flooded vegetation." (Authors)] Address: Jorcin, A., Depto de Zoologia, Instituto de Biociências, Universidade Estadual Paulista – UNESP, Distrito de Rubião Júnior, CEP 18600-000, Botucatu, SP, Brazil. 7846. Kim, S.-B.; Oh, H.-S.; Kim, W.-T.; Tadauchi, O. (2009): Phenetic analysis of the Anisoptera (Insecta: Odonata) in Jeju Island, Korea, based on morphological characters. J. Fac. Agr., Kyushu Univ. 54(1): 123-132. (in English) ["This study was conducted from April 2002 to September 2007 to investigate the relationships of 27 species of Anisoptera which were collected in wetlands of Jeju Island, using a phenetic analysis of external morphological characters. The generated phenogram revealed the presence of two superfamilies within Anisoptera, Aeshnoidea and Libelluloidea. Moreover, the three groups, Aeshnidae, Libellulidae and Corduliidae, were clearly branched. As a result, the phenogram was similar to that of the ordinary systematic classification. The Aeshnidae was divided into Anax and Gynacantha, and Polycanthagyna and Aeschnophlebia. Three species of Anax (e.g., guttatus, parthenope and nigrofasciatus) presented to have very similar external morphological characteristics. Particularly, A. guttatus has confused its name, e.g., someone treated it as a synonym with A. parthenope due to the presence of very similar morphological characters. However, major differences were observed in the upper edge of the frons and the anterior femur in these species. Therefore, we obtained

a conclusion that is more valid to classify *A. guttatus* as an independent species rather than as a synonym. The Libellulidae consisted of three subgroups. When the relationship of the genus *Sympetrum* were considered, the key characteristics were determined to be the patterns of the first lateral suture, the second lateral suture and the humeral suture. The Corduliidae was divided into Macromiinae and Cordulinae. Particularly, *Somatochlora graeseri* and *S. clavata* were confirmed to be unregistered species in Jeju Island." (Authors) *Anax parthenope*; *A. nigrofasciatus*; *A. guttatus*; *Gynacantha japonica*; *Polycanthagyna melanictera*; *Aeschnophlebia anisoptera*; *Somatochlora graeseri*; *Somatochlora clavata*; *Epophthalmia elegans*; *Macromia amphigena*; *Lyriothemis pachygastra*; *Orthetrum albistylum*; *O. melania*; *Crocothemis servilia*; *Deilelia phaon*; *Sympetrum striolatum*; *S. darwinianum*; *S. eroticum*; *S. uniforme*; *S. kunkeli*; *S. infuscatum*; *S. risi*; *S. speciosum*; *Pseudothemis zonata*; *Rhyothemis fuliginosa*; *Pantala flavescens*; *Tramea virginia*] Address: Oh, Hong-Shik, Dept of Science Education, Cheju National University, Jeju 690-756, Korea. 7847. Koch, K.; Quast, M.; Sahlén, G. (2009): Morphological differences in the ovary of Libellulidae (Odonata). *International Journal of Odonatology* 12(1): 147-156. (in English) ["All female Odonata have been assumed to produce oocytes continuously during their mature life span. However, a recent study of ovariole orientation and development led to the suggestion that Libellulidae are divided into two groups of species, one with continuous, the other with stepwise oocyte production. To find more evidence of this division, we compared the size variation and growth within the vitellarium of the ovary, studying oocytes, and follicle cells. We found that morphological characters discriminate between the two ovary types in eight of the 10 investigated species. In both types we found an increase in all measurements from the anterior to the posterior end of the vitellarium. The increase in oocyte width and follicle cell length was significantly higher in species with a continuous oocyte production. We also noted that follicle cells may have more than one nucleus and that their number can vary during vitellogenesis. Our study confirmed the hypotheses that two different ovary types exist in Libellulidae. The two species not fitting into this grouping could be an artefact of small sample size due to intraspecific phenotypic plasticity, or else there might be more than two ovary groups, or even a continuum. We could not offer an explanation as to how the process of stepwise oocyte production differs from continuous based production on morphological characters." 7848. Küry, D. (2009): *Krebsschere* (Stratiotes aloides) in Naturschutzweihern der Schweiz. *Bauhinia* 21: 49-56. (in German, with English summary) ["*S. aloides* is an aquatic macrophyte which colonizes shallow water zones of meso- to eutrophic lakes, lowland rivers and ditches. It is distributed in northern and eastern parts of Central Europe as well as in southern Scandinavia. In the past it has been introduced in other regions of Europe like France and Switzerland. Since several years *S. aloides* has been planted out in newly created ponds where it had rapidly overgrown most of the water surface. By introducing this neophyte conservationists intend to foster the pond fauna. However, the

consequences for the pond ecosystem are disadvantageous. Allelopathic effects inhibit the growth of other hydrophytes and planktic algae. In consequence, faunistic diversity decreases and over-growing increases. The management of ponds should aim at creating habitats similar to the stagnant waters which existed more than 150 years ago, when the floodplains were still natural landscapes." (Author) Special emphasis is given to *Aeshna viridis*, and the disadvantageous effects of *S. aloides* in Swiss waterbodies for dragonflies and additional macrozoobenthic species.] Address: Küry, D., Life Science AG, Greifengasse 7, 4058 Basel, Switzerland. 7849. Lehmann, F.-O. (2009): Wing-wake interaction reduces power consumption in insect tandem wings. *Experiments in Fluids* 46(5): 765-775. (in English) ["Insects are capable of a remarkable diversity of flight techniques. Dragonflies, in particular, are notable for their powerful aerial manoeuvres and endurance during prey catching or territory flights. While most insects such as flies, bees and wasps either reduced their hind wings or mechanically coupled fore and hind wings, dragonflies have maintained two independent-controlled pairs of wings throughout their evolution. An extraordinary feature of dragonfly wing kinematics is wing phasing, the shift in flapping phase between the fore and hind wing periods. Wing phasing has previously been associated with an increase in thrust production, readiness for manoeuvrability and hunting performance. Recent studies have shown that wing phasing in tandem wings produces a twofold modulation in hind wing lift, but slightly reduces the maximum combined lift of fore and hind wings, compared to two wings flapping in isolation. Despite this disadvantage, however, wing phasing is effective in improving aerodynamic efficiency during flight by the removal of kinetic energy from the wake. Computational analyses demonstrate that this increase in flight efficiency may save up to 22% aerodynamic power expenditure compared to insects flapping only two wings. In terms of engineering, energetic benefits in four-wing flapping are of substantial interest in the field of biomimetic aircraft design, because the performance of man-made air vehicles is often limited by high-power expenditure rather than by lift production. This manuscript provides a summary on power expenditures and aerodynamic efficiency in flapping tandem wings by investigating wing phasing in a dynamically scaled robotic model of a hovering dragonfly." 7852. Levine, T.D.; Lang, B.K.; Berg, D.J. (2009): Parasitism of mussel gills by dragonfly nymphs. The American Midland Naturalist 162(1): 1-6. (in English) ["Predators of unionoid mussels are generally identified as fishes or aquatic mammals. During a mark and recapture study of the critically endangered mussel *Popeinaias popeii*, we discovered a nymph of the dragonfly *Gomphus militaris* eating the gills of a gravid mussel; larvae and gill material were found in the nymph's gut. Many (15.2%) of the other mussels captured during a quantitative survey exhibited damage consistent with that inflicted by this dragonfly. Few non-gravid mussels were damaged and gravid mussels exhibited substantially more damage in gills used for brooding larvae than in gills not typically used for brooding. This previously unreported parasitic relationship may reflect a unique cost associated with reproduction and should be considered in the development of conservation strategies for *P. popeii*. Our observations underscore the need for basic ecological data when monitoring endangered species." (Authors)]

7853. Li, Z.-x.; Shen, W.; Tong, G.-s.; Tian, J.-m.; Yu-Quoc, L. (2009): On the vein-stiffening membrane structure of a dragonfly hind wing. Journal of Zhejiang University Science A 10(1): 72-81. (in English) ["Aiming at exploring the excellent structural performance of the vein-stiffening membrane structure of dragonfly hind wings, we analyzed two planar computational models and three 3D computational models with cambered corrugation based on the finite element method. It is shown that the vein size in different zones is proportional to the magnitude of the vein internal force when the wing structure is subjected to uniform out-of-plane transverse loading. The membrane contributes little to the flexural stiffness of the planar wing models, while exerting an immense impact upon the stiffness of the 3D wing models with cambered corrugation. If a lumped mass of 10% of the wing is fixed on the leading edge close to the wing tip, the wing fundamental frequency decreases by 10.7%~13.2%; if a lumped mass is connected to the wing via multiple springs, the wing fundamental frequency decreases by 16.0%~18.0%. Such decrease in fundamental frequency explains the special function of the wing pterostigma in alleviating the wing quivering effect. These particular features of dragonfly wings can be mimicked in the design of new-style reticulately stiffening thin-walled roof systems and flapping

wings in novel intelligent aerial vehicles." (Authors)] Address: Li, Z.-x., 1Institute of Structural Engineering, Zhejiang University, Hangzhou 310058, China. E-mail: lizx19993@zju.edu.cn

7854. Locklin, J.L.; Vodopich, D.S. (2009): Bidirectional gender biases of gregarine parasitism in two co-existing dragonflies (Anisoptera: Libellulidae). Odonatologica 38(2): 133-140. (in English) ["Parasitism affects all taxa and influences individual and population success. Parasitism of adult dragonflies is widespread and frequently includes gregarine (Apicomplexa) life stages in the gut of the host. This research investigates variation in gregarine parasite prevalence and load in male versus female adults of *Erythemis simplicicollis* and *Brachymesia gravida* associated with 2 central Texas reservoirs in close proximity. Parasite prevalence was biased toward male *E. simplicicollis* and toward female *B. gravida*. Results suggest that gender bias in parasite prevalence is influenced by gender behaviour and environment more so than by immuno-response differences between genders." 7856. Manger, R.; Dingemanse, N.J. (2009): Adult survival of *Sympecma paedisca* (Brauer) during hibernation (Zygoptera: Lestidae). Odonatologica 38(1): 55-59. (in English) ["The survival of hibernating adults was assessed in its winter habitat in the Netherlands to gain insight in the potential importance of this life-history phase for the population dynamics of this endangered species Compared to other Odonata, monthly survival rates (Dec. 2004 - March 2005) were high (mean \pm SE = 0.75 \pm 0.08), but overall winter survival was low (0.42). Potential causes of mortality during hibernation

are discussed. The results imply that effective protection of this species in the Netherlands may benefit from protection of both its breeding and wintering habitat.] Address: Manger, R., Stoepveldsingel 55, 9403 SM Assen, The Netherlands. E-mail: rmanger@planet.nl

7857. Marinov, M. (2009): Spatial modelling of dragonfly habitats in New Zealand (Odonata: Insecta). Dissertation. Master of Applied Sciences, Lincoln Univ., Christchurch, New Zealand: VI, 50 pp., 15 app. (in English) ["While New Zealand is poor in Odonata species the seventeen species thus far established have great natural importance (Moore 1989). Ten of them are endemic to the islands representing the country. Those include four genera known to occur only in this part of the world (Rowe 1987). This poses a great responsibility on New Zealand to protect this natural treasure. Damselflies and dragonflies are considered well protected within the national parks, but the loss of habitats could severely impact them in the future. This suggests that a habitat assessment should be prepared for the whole country that will serve as base-line data set for monitoring the development of the natural environment for the Odonata species in New Zealand. Fourteen species have been selected for this analysis. Their biological features and ecological requirements were considered in preparing a working habitat assessment methodology. Habitat models were developed using ArcGIS 9.2 software. Multistep spatial analysis was carried out to reclassify the layers containing the important information on the land topology representing crucial elements in the Odonata species habitats. The final outputs are individual species maps where the New Zealand territory is marked with four different colour classes corresponding to the ranks of importance that each area is considered to have for individual species. The models are named probabilistic in that they reveal the areas where the ecological demands of the species are approached at a maximum level. However, they should not be used as distribution maps. Probabilistic models are contrasted against deterministic models used in other Odonata habitat models. The strengths and weaknesses are discussed and some important conclusions and recommendations are described and suggested." 7858. McMeeking, RM; Ma, LF; Arzt, E. (2009): Mechanism maps for frictional attachment between fibrillar surfaces. *Journal of applied mechanics - Transactions of the ASME* 76(3)(Art. No. 031007): 8 pp. (in English) ["The mechanics of frictional attachment between surfaces with pillars, inspired by the head fixation system of dragonflies, is analyzed. The system consists of two surfaces of interdigitating pillars held together through friction, as by the densely packed bristles of two brushes when pressed together. The adhesive strength of the system is promoted by high elastic modulus, high friction coefficient, large aspect ratio, and dense packing of the fibers. However, the design is limited by the compressive buckling, the compressive indentation or cracking of the contacting pillars, yielding in shear or similar mechanisms that limit the achievable friction stress, and tensile failure of the pillars upon pull-out. Maps, which summarize the strength of the adhesive system and the failure limits and illustrate the trade-off among the design parameters, are presented. Case studies for steel, nylon, and ceramic pillars show that

useful strength can be achieved in such attachments; when buckling during assembly and contact failure can be avoided, adhesive performance as high as 30% of the tensile strength of the pillar material may be possible." 7859. McPeck, M.A.; Shen, L.; Farid, H. (2009): The correlated evolution of three-dimensional reproductive structures between male and female damselflies. *Evolution* 63(1): 73-83. (in English) ["For many taxa, species are defined by the morphologies of reproductive structures. In many odonates, these structures are the cerci of males (used to hold females during mating) and the thoracic plates of females where the male cerci contact the females' bodies. A previous study showed that the shapes of cerci of *Enallagma* males (Zygoptera: Coenagrionidae) are best explained by an evolutionary model of punctuated change at the time of speciation, with a homogeneous rate of change across the entire phylogeny of the genus. In the present study, we examine the evolution of shape change in the corresponding female plates. We found that, like male cerci, the shapes of *Enallagma* female thoracic plates could best be explained by an evolutionary model of punctuated change at the time of speciation, with a homogeneous rate of change across the clade. Moreover, the evolutionary contrasts quantifying the rates of change in male cerci and female thoracic plates were positively related across the history of the clade, demonstrating that these male and female structures evolve in a correlated fashion. This pattern of evolution suggests that these structures are primary signals of species identity during mating." (Authors)] Address: McPeck, M., Dept Biol. Sci., Dartmouth College, Hanover, New Hampshire 03755, USA. E-mail: mark.mcpeek@dartmouth.edu

7861. Møller, A.P.; Mousseau, T.A. (2009): Reduced abundance of insects and spiders linked to radiation at Chernobyl 20 years after the accident. *Biology letters* 5(3): 356-359. (in English) ["Effects of low-level radiation on abundance of animals are poorly known. We conducted standardized point counts and line transects of bumble-bees, butterflies, grasshoppers, dragonflies and spider webs at forest sites around Chernobyl differing in background radiation by over four orders of magnitude. Abundance of invertebrates decreased with increasing radiation, even after controlling for factors such as soil type, habitat and height of vegetation. These effects were stronger when comparing plots differing in radiation within rather than among sites, implying that the ecological effects of radiation from Chernobyl on animals are greater than previously assumed. [...] The total number of dragonflies was 105 during

point counts, with abundance decreasing significantly with radiation, time of day and habitat." (Authors)] Address: Møller, A.P., Department of Biological Sciences, University of South Carolina, Columbia, SC 29208, USA. E-mail: anders.moller@u-psud.fr

7862. Nagel, L.; Robb, T.; Forbes, M.R. (2009): Parasite-mediated selection amidst marked inter-annual variation in mite parasitism and damselfly life history traits. *Ecoscience* 16(2): 265-270. (in English) ["Parasite-mediated selection in host populations is thought to vary in magnitude temporally. We monitored variation in life history traits that are known or suspected to influence fitness in a population of damselflies parasitized by larval water mites. Mite prevalence and intensity varied considerably over 5 y and was often higher in females. Prevalence and intensity were highest in the years when the damselfly emergence periods were early and of short duration, which also corresponded to damselflies emerging at larger sizes. Mites appeared to exert negative effects on apparent survival in some years only, and only for females, suggesting that parasite-mediated selection on damselflies is variable and dependent on other factors such as emergence times, weather, and sex and body size of hosts." 7865. Ninomiya, T.; Yoshizawa, K. (2009): A revised interpretation of the wing base structure in Odonata. *Systematic Entomology* 34(2): 334-345. (in English) ["Homology of the wing base structure in the Odonata is highly controversial, and many different interpretations of homology have been proposed. In extreme cases, two independent origins of insect wings have been suggested, based on comparative morphology between the odonate and other pterygote wing bases. Difficulties in establishing homology of the wing base structures between Odonata and other Pterygota result mainly from their extreme differences in morphology and function. In the present paper, we establish homology of the wing base structures between Neoptera, Ephemeroptera and Odonata using highly conservative and unambiguously identifiable characters (the basal wing hinge and subcostal veins) as principal landmarks. Homology of the

odonate wing base structure with those of Ephemeroptera and Neoptera can be identified reliably. Based on this interpretation, the ancestral condition of the insect wing base structure is discussed." 7866. Novelo-Gutiérrez, R.; Gómez-Anaya, J.A. (2009): A comparative study of Odonata (Insecta) assemblages along an altitudinal gradient in the Sierra de Coalcomán Mountains, Michoacán, Mexico. *Biodivers. Conserv.* 18: 679-698. (in English) ["Odonate diversity in the Coalcomán Mountain Range (CMR), Michoacán State, Mexico, was surveyed, and samplings were made during 2 years in eight streams along an altitudinal gradient. Presence-absence data were analyzed using non-parametric and parametric methods. Beta and gamma diversities were estimated using Whittaker's and Lande's formulae, respectively. A total of 2,526 adults and 489 larvae were captured, yielding 116 species (c diversity), 44 genera and 9 families. 5 new species were discovered. The genus *Argia* was the most important contributor to Zygoptera diversity and total richness (c diversity), yielding 40.4 and 14.7%, respectively. The non-parametric estimator Chao2 provided the closest theoretical estimate of species richness, and Clench's model fit the data well (R² ranged from 99.44 to 99.99) to explain a high proportion of the variance (98.8). We conclude that beta diversity is important at the landscape scale, supporting the hypothesis that Mexico is a beta diverse country. Our results triple the number of known species of Odonata for Michoacán. Given the considerable richness of odonates at local and landscape scales, our results support the proposal of the Coalcomán Mountain Range as a priority area for conservation and related research." 7868. Obolewski, K.; Głinska-Lewczuk, K.; Kobus, S. (2009): An attempt at evaluation the influence of water quality on the qualitative and quantitative structure of epiphytic fauna dwelling on *Stratiotes aloides* L., a case study on an oxbow lake of the Lyna river. *J. Elementol.* 14(1): 119-134. (in English, with Polish summary) ["The paper contains the results of a study on the dependence of the qualitative and quantitative structure of the phytophilous macrofauna dwelling on *S. aloides* (water soldier) on the quality of waters in a lentic oxbow lake of the Lyna River. The observations were carried out during the vegetative season (April – June) 2006 at high and moderate water levels. During the study, a total of 18 taxa of invertebrates dwelling on the above plant species were identified, with the exact number of taxa varying in time: 11 taxa were noticed in April and May, and in June their number went up to 13. The examination of hydrochemical parameters of the oxbow lake waters revealed that the density of macrofauna was lower at higher values of proper conductivity and macronutrients, ammonia nitrogen and COD, increasing at high levels of sulphates. High concentrations of ammonia nitrogen and non-organic components coincided with decreased biomass of epiphytic animals on water soldier. Additionally, it has been observed that elevated concentrations of potassium ions have a negative influence on the biomass of most epiphytic animals (except *Erbodella* sp.)." (Authors) The biomass of Odonata is considered in tables and graphs.] Address: Obolewski, K., Chair of Land Reclamation and Management, University of Warmia and Mazury, pl. Łódzki 2, Olsztyn-Kortowo 10-719, Poland. E-mail: obolewsk@apsl.edu.pl

7869. Parkes, K.A.; Amos, W.; Moore, N.W.; Hoffman, J.I.; Moore, J. (2009): Population structure and speciation in the dragonfly *Sympetrum striolatum* / *nigrescens* (Odonata: Libellulidae): An analysis using AFLP markers. *Eur. J. Entomol.* 106(2): 179-184. (in English) ["There has been a long-standing debate as to whether *Sympetrum striolatum* (Charpentier, 1840) and the darker northern form, *S. nigrescens* (Lucas, 1912) should be recognised as separate species of dragonfly. Here we address this question using genetic analysis based on AFLP markers and samples collected from sites across the species' United Kingdom range. The program STRUCTURE finds no support for specific status. Instead, it reveals strong patterns of divergence between populations sampled from Scottish islands and those on the mainland, suggesting that salt water is a major barrier to gene flow. Thus, the dark form is quite likely to reflect a beneficial polymorphism that allows individuals to take advantage of short periods of warmer weather. Our AFLP markers appear to be very rapidly evolving, showing little or no overlap between congeneric species, and hence are ideally suited to answering questions relating to the levels of gene flow among populations within species." 7875. Reece, B.A.; McIntyre, N.E. (2009): Community assemblage patterns of odonates inhabiting a wetland complex influenced by anthropogenic disturbance. *Insect Conservation and Diversity* 2(2): 73-80. (in English) ["1. Many wetland complexes around the world are highly influenced by human activity (chiefly land conversion for agriculture). Measuring the impact of such activity hinges not only upon using appropriate wetland indicator taxa but also upon metrics that are sensitive enough to capture subtle effects. 2. Over a 5-year period, we quantified the distribution and community structure of odonates occupying a wetland complex in Texas. When using traditional community metrics, there were no significant differences in diversity or evenness in the odonate assemblages in wetlands surrounded by the two dominant regional forms of land use (tilled cropland and grassland). Similarity analyses likewise failed to detect any significant differences in odonate community composition with land use. 3. Discriminant function analysis, however, revealed that species co-occurrences could be distinguished on the basis of surrounding land use, which indicates that odonate assemblages in these wetlands are structured in a manner that typical community metrics fail to adequately describe. 4. Differences between the approaches are discussed, particularly with regard to the use of presence-absence data." 7878. Remsburg, A.J.; Turner, M.G. (2009): Aquatic and terrestrial drivers of dragonfly (Odonata) assemblages within and among north-temperate lakes. *J. N. Am. Benthol. Soc.*, 2009, 28(1):44-56: 44-56. (in English) ["The physical structure of vegetation influences di-

versity, interactions, movement, and thermoregulation of animals. Vegetation structure might be a good indicator of habitat requirements of generalist predators, such as Odonata, and thereby affect species diversity. Odonates use aquatic and terrestrial habitats during larval and adult life stages, respectively, but the relative importance of vegetation in these habitats is poorly understood. We compared how aquatic and riparian habitat variables affected odonate larvae from 41 sites (each 30 m in shoreline length) on 17 lakes in northern Wisconsin. We used principal components analyses to reduce multiple habitat variables to 2 lakelevel axes (lake size and development, lake wetlands and predators), 2 site-level littoral axes (littoral macrophytes, littoral muckiness), and 2 site-level riparian axes (riparian structural complexity, riparian tall wetland plants). Most (61.6%) of the variance in larval species richness occurred at the site level. Density of the most abundant family, Gomphidae, was positively related to riparian tall wetland plants, whereas species richness was positively correlated with abundance of littoral macrophytes (on the basis of multiple linear regression with an information theoretic approach). Surveys in 18 paired littoral microsites in 9 lakes indicated that larvae from the clasper and sprawler behavioral guilds were most abundant in microsites with submerged macrophytes. However, predation risk, assessed by tethering larvae in patches of submerged macrophytes, did not differ between habitats with and without macrophytes. We tested whether shoreline plants affected recruitment from the adult stage by comparing adult odonate behaviors in response to 2 riparian vegetation treatments. Adult damselfly abundance was higher where we placed potted wetland plants than at manicured lawns without tall vegetation. Our results indicate that odonate larvae might be influenced by vegetation structure in both aquatic and riparian habitats and demonstrate how animals with complex life histories link aquatic and terrestrial communities." 7881. Sarzetti, L.C.; Labandeira, C.C.; Muzón, J.; Wilf, P.; Cúneo, N.R.; Johnson, K.R.; Genise, J.F. (2009): Odonatan endophytic oviposition from the Eocene of Patagonia: The ichnogenus *Paleoovoidus* and implications for behavioral stasis. *Journal of Paleonto-*

logy 83(3): 431-447. (in English) ["We document evidence of endophytic oviposition on fossil compression / impression leaves from the early Eocene Laguna del Hunco and middle Eocene Río Pichileufú floras of Patagonia, Argentina. Based on distinctive morphologies and damage patterns of elongate, ovoid, lens-, or teardrop-shaped scars in the leaves, we assign this insect damage to the ichnogenus *Paleoovoidus*, consisting of an existing ichnospecies, *P. rectus*, and two new ichnospecies, *P. arcuatum* and *P. bifurcatus*. In *P. rectus*, the scars are characteristically arranged in linear rows along the midvein; in *P. bifurcatus*, scars are distributed in double rows along the midvein and parallel to secondary veins; and in *P. arcuatum*, scars are deployed in rectilinear and arcuate rows. In some cases, the narrow, angulate end of individual scars bear a darkened region encompassing a circular hole or similar feature indicating ovipositor tissue penetration. A comparison to the structure and surface pattern of modern ovipositional damage on dicotyledonous leaves suggests considerable similarity to certain zygopteran Odonata. Specifically, members of the Lestidae probably produced *P. rectus* and *P. bifurcatus*, whereas species of Coenagrionidae were responsible for *P. arcuatum*. Both Patagonian localities represent an elevated diversity of potential fern, gymnosperm, and especially angiosperm hosts, the targets of all observed oviposition. However, we did not detect targeting of particular plant families. Our results indicate behavioral stasis for the three ovipositional patterns for at least 50 million years. Nevertheless, synonymy of these oviposition patterns with mid-Mesozoic ichnospecies indicates older origins for these distinctive modes of oviposition." (Authors)] Address: Muzón, J., Inst. Limnol. 7882. Schouten, M.A.; Verweij, A.; Barendregt, A.; Kleukers, R.M.J.C.; Kalkman, V.J.; de Ruiter, P.C. (2009): Determinants of species richness patterns in the Netherlands across multiple taxonomic groups. *Biodiversity and Conservation* 18: 203-217. (in English) ["We examined the species richness patterns of five different species groups (mosses, reptiles and amphibians, grasshoppers and crickets, dragonflies, and hoverflies) in the Netherlands (41,500 km²) using sampling units of 5 × 5 km. We compared the spatial patterns of species richness of the five groups using Spearman's rank correlation and used a stepwise multiple regression generalized linear modelling (GLM) approach to assess their relation with a set of 36 environmental variables, selected because they can be related to the several hypotheses on biodiversity patterns. Species richness patterns of the five groups were to a certain extent congruent. Our data suggest that environmental heterogeneity (in particular habitat heterogeneity) is one of the major determinants of variation in species richness within these five groups. We found that for taxonomic groups comprising a low number of species, our regression model explained more of the variability in species richness than for taxonomic groups with a large number of species." 7883. Schultz, T.D. (2009): Diversity and habitats of a prairie assemblage of Odonata at Lostwood National

Wildlife Refuge, North Dakota. *Journal of the Kansas Entomological Society* 82: 91-102. (in English) ["An inventory of the Odonata at the Lostwood National Wildlife Refuge (LNWR) was conducted during the summer of 2003. Adult censuses and larval sampling at 32 wetland sites produced 10 dragonfly and 14 damselfly species that were resident in the refuge. In 2006, two additional species were added. The odonate fauna of LNWR consisted primarily of widespread, common species that are adapted to fishless lentic communities and tolerant of alkaline and impermanent water regimes. *Enallagma annexum*, *E. boreale*, *Lestes disjunctus*, *L. congener*, *Sympetrum costiferum*, and *S. internum* were the most abundant odonates at the refuge. The odonate communities of semipermanent, oligosaline ponds were the most diverse and included species of *Aeshna*, *Anax*, *Libellula*, *Leucorrhinia*, *Sympetrum*, *Lestes*, *Coenagrion*, *Enallagma*, *Ischnura*, and *Nehalennia*. Large polysaline lakes were inhabited only by *Ischnura damula* and four species of *Enallagma*. Seasonal ponds that remained flooded until mid-July produced large numbers of *S. internum*, *L. disjunctus*, and *L. unguiculatus*. Spring-fed bogs and fens supported several species that were rare at the refuge including *Sympetrum danae*, *S. semicinctum*, and *Amphiagrion abbreviatum*. Long-term monitoring of odonate diversity and abundance may be useful in tracking the effects of climate change in the prairie pothole region but must take into account yearly fluctuations due to variation in winter and summer precipitation." 7885. Simaika, J.P.; Samways, M.J. (2009): Reserve selection using Red Listed taxa in three global biodiversity hotspots: Dragonflies in South Africa. *Biological Conservation* 142(3): 638-651. (in English) ["The Red List can be used as a gauging tool by conservationists to assess which species require focused conservation attention. Mapping the relative distributions of species, and identification of centers of richness, endemism and threat are a first step towards site-oriented conservation action. We use here a specially developed biodiversity index, based on three weighted sub-components assigned to each species: geographical distribution, Red List status, and sensitivity to habitat change. We test this approach using what is called here the Dragonfly Biotic Index (DBI) to prioritize sites for conservation action, with special emphasis on species occurrence in three global hotspots in southern Africa. Using a selected set of the 23 top prioritized sites, we compare the DBI's performance to that of a rarity-complementarity algorithm. As with several other taxa, local endemism levels are highest in the Cape Floristic Region (CFR), while richness is highest in the north east, particularly in the stream systems of the Maputland-Pondoland-Albany (MPA) hotspot. Red Listed Odonata species are also concentrated in the CFR, while richness is highest in the MPA hotspot. Site prioritization using the DBI reveals that CFR sites protect Red Listed taxa rather well,

despite the fact that catchments are only partially protected. The DBI demonstrates high levels of redundancy in representing Red Listed species, in other words, the same species are represented in several catchments. The value in the DBI thus lies in maximizing redundancy (i.e. representation) of globally Red Listed species. The rarity-complementarity algorithm represents all species, but without greater emphasis on the rare and threatened (i.e. Red Listed) species. We conclude that the DBI is of great value in selecting biodiversity hotspots, while the algorithm is useful for selecting complementarity hotspots. We identify protection gaps and thus recommend continued searches in centers of endemism and existing reserves, as well as gap areas. These searches will hone Red List assessments and identify priority sites, as well as monitor already-identified sites for changes in quality of habitat." 7886. Simaika, J.P.; Samways, M.J. (2009): An easy-to-use index of ecological integrity for prioritizing freshwater sites and for assessing habitat quality. *Biodiversity and Conservation* 18(5): 1171-1185. (in English) ["Prioritizing and assessing the condition of sites for conservation action requires robust and ergonomic methodological tools. We focus here on prioritizing freshwater sites using two promising biodiversity indices, the Dragonfly Biotic Index (DBI) and Average Taxonomic Distinctness (AvTD). The AvTD had no significant association with either species richness or endemism. In contrast, the DBI was highly significantly associated with species richness and endemism, although the strengths of the associations were weak. These associations are related to how the sub-indices in the DBI are weighted, and how species are distributed geographically. Additionally, the DBI was found to be very useful for site selection based on its ability to measure ecological integrity, combined with level of threat, at multiple spatial scales. The AvTD was found to be useful principally for regional use. As the DBI is a low-cost, easy-to-use method, it has the additional use as a method for assessing habitat quality and recovery in restoration programs. The DBI operates at the species level, and is therefore highly sensitive to habitat condition and has great potential for environmental assessment and monitoring freshwater biodiversity and quality. Practical, worked examples of river restoration are given here. In view of the ease and versatility by which the DBI can be employed, we recommend its testing and possible integration into freshwater management and conservation schemes elsewhere in the world." 7887. Slos, S.; Meester, L.D.; Stoks, R. (2009): Behavioural activity levels and expression of stress proteins under predation risk in two damselfly species. *Ecological Entomology* 34(3): 297-303. (in English) ["1. It has become apparent that predators may strongly decrease prey fitness without direct contact with the prey, as they induce the development of defence systems that limit the availability of energy for growth and reproduction. Recent studies suggest that stress proteins may help prey organisms deal with this stress. The pattern is not general, however, and little is known about species differences in physiological traits in coping with

predator stress, and covariation of physiological with other antipredator traits. 2. To explore these issues, we quantified levels of constitutive and fish-induced stress proteins (Hsp60 and Hsp70) and anti-predator behaviours in larvae of two damselfly species that differ in lifestyle. Both stress proteins were fixed at higher levels in *Erythronma najas*, which has a slow lifestyle, than in *Lestes sponsa*, which has a fast lifestyle. Similarly, anti-predator behaviours were fixed at safer levels in *E. najas* than in *L. sponsa*. 3. These results suggest that stress proteins may be part of anti-predator syndromes of damselfly larvae, and there may be trait co-specialisation between stress proteins and behavioural anti-predator traits. Studies formally testing these hypotheses in more species may prove rewarding in advancing our understanding of the functional integration of physiological anti-predator traits in relation to the prey's lifestyle." 7888. Slos, S.; De Block, M.; Stoks, R. (2009): Autotomy reduces immune function and antioxidant defence. *Biology letters* 5(1): 90-92. (in English) ["Costs of autotomy, an antipredator defence, are typically explained by impaired mobility; yet physiologically mediated costs may also play a role. Given the resemblance to wounding, a decreased immune function and an associated reduction in antioxidant defence is expected after autotomy. In line with this, after lamellae autotomy, larvae of *Lestes viridis* showed lower levels of innate immunity (i.e. phenoloxidase, PO) and antioxidant defence (superoxide dismutase, SOD). Levels of catalase (CAT) remained, however, unaffected. In line with its cytotoxicity, PO covaried positively with CAT, yet negatively with SOD. We identified a novel cost of autotomy in terms of a reduced innate immunity, which may provide an alternative explanation for the often observed costs of autotomy and which may generate indirect interactions between predators and parasites.] Address: Stoks, R., Laboratorium voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. 7890. Stevens, L.E.; Bailowitz, R.A. (2009): Odonata Biogeography in the Grand Canyon Ecoregion, Southwestern USA. *Annals of the Entomological Society of America* 102(2): 261-274. (in English) ["The Odonata fauna of the Grand Canyon ecoregion (GCE) on the southern Colorado Plateau includes 89 species (35 genera, seven families), including 49 Anisoptera species (25 genera, four families) and 40 Zygoptera species (10 genera, three families), and with 58 Odonata species in Grand Canyon (GC; 24 genera, seven families). Three biogeographic hypotheses account for this relatively high regional species richness: faunal affinity (origin), elevation effects on range, and landform impacts across spatial scale. The GCE Odonata assemblage is the result of mixing of taxa from adjacent Neotropical and Nearctic regions. Allochthonous taxa include 34.8% tropical (Mexican, Caribbean, Neotropical, or Pantropical) and 21.3% boreal (Nearctic or Holarctic)

species. Autochthonous species (43.8%) are range-centered in North American, neither clearly Nearctic nor Neotropical, with a strong Pacific Coast influence. Area-adjusted species richness is negatively linearly related to elevation. Tropical species have lower elevation ranges than do boreal species, whereas the elevation ranges of both allochthonous groups overlap those of autochthonous species. Odonata generally overcome landform-based range constraints at coarse spatial scales, but barrier/filter and corridor effects predominate over refuge and null biogeographic effects in GC. Anisoptera and Zygoptera biogeographic patterns are similar, except that 9-fold more Zygoptera species exist in refugia in GC compared with Anisoptera. Although no GCE Odonata previously have been considered rare or at risk, 15 (16.9%) species are restricted to three or fewer localities, four (4.5%) of species have been detected at only a single locality, and four high-elevation Nearctic species may be at risk of extirpation through climate change impacts on their habitats." 7892. Strobbe, F.; McPeck, M.A.; de Block, M.; De Meester, L.; Stoks, R. (2009): Survival selection on escape performance and its underlying phenotypic traits: a case of many-to-one mapping. *Journal of evolutionary biology* 22(6): 1172-1182. (in English) ["Selection often operates not directly on phenotypic traits but on performance which is important as several traits may contribute to a single performance measure (many-to-one mapping). Although largely ignored in the context of selection, this asks for studies that link all relevant phenotypes with performance and fitness. In an enclosure experiment, we studied links between phenotypic traits, swimming performance and survival in two *Enallagma* damselflies. Predatory dragonflies imposed survival selection for increased swimming propensity and speed only in *E. annexum*; probably *E. aspersum* was buffered by the former species' presence. Accordingly, more circular caudal lamellae, structures involved in generating thrust while swimming, were selected for only in *E. an-*

nexum. Other phenotypic traits that contributed to swimming speed were apparently not under selection, probably because of many-to-one mapping (functional redundancy). Our results indicate that not only the phenotypic distributions of syntopic prey organisms but also many-to-one mapping should be considered when documenting phenotype–performance–fitness relationships." 7893. Svensson, E.I.; Abbott, J.K.; Gosden, T.P.; Coreau, A. (2009): Female polymorphisms, sexual conflict and limits to speciation processes in animals. *Evolutionary Ecology* 23(1): 93-108. (in English) ["Heritable and visually detectable polymorphisms, such as trophic polymorphisms, ecotypes, or colour morphs, have become classical model systems among ecological geneticists and evolutionary biologists. The relatively simple genetic basis of many polymorphisms (one or a few loci) makes such species well-suited to study evolutionary processes in natural settings. More recently, polymorphic systems have become popular when studying the early stages of the speciation process and mechanisms facilitating or constraining the evolution of reproductive isolation. Although colour polymorphisms have been studied extensively in the past, we argue that they have been underutilized as model systems of constraints on speciation processes. Colouration traits may function as signalling characters in sexual selection contexts, and the maintenance of colour polymorphisms is often due to frequency-dependent selection. One important issue is why there are so few described cases of female polymorphisms. Here we present a synthetic overview of female sexual polymorphisms, drawing from our previous work on female colour polymorphisms in lizards and damselflies. We argue that female sexual polymorphisms have probably been overlooked in the past, since workers have mainly focused on male-male competition over mates and have not realized the ecological sources of genetic variation in female fitness. Recent experimental evolution studies on fruit flies (*Drosophila melanogaster*) have demonstrated significant heritable variation among female genotypes in the fitness costs of resistance or tolerance to male mating harassment. In addition, female-female competition over resources could also generate genetic variation in female fitness and promote the maintenance of female sexual polymorphisms." 7895. Tajima, Y.; Watanabe, M. (2009): Changes in the number of spermatozoa in the female sperm storage organs of *Ischnura asiatica* (Brauer) during copulation (Zygoptera: Coenagrionidae). *Odonatologica* 38(2): 141-149. (in English) ["Spermatozoan dynamics in the female sperm storage organs of *I. asiatica* were examined with interrupted copulation experiments in the field. The copulation process was divided into 3 stages (I, II and III) according to the movements of the male abdomen. Females interrupted just after the termination of stage I of copulation contained a much lower number of spermatozoa, both in the bursa copulatrix and in the spermatheca, than solitary females captured before being attached by males. At the tip of the male's secondary genitalia, there was a pair of horns which might be used to remove sperm from the bursa copulatrix and the spermatheca during copulation. The latter was joined to the base of the former by a spermathecal duct. Since each horn of the male genitalia was significantly shorter than the spermathecal duct, the spermatheca might be inaccessible to males. The actual position of the horns in the female sperm storage organs during stage I of copulation was observed by freezing copulating pairs using quick-freeze aerosol sprays. The horns were in the bursa copulatrix, but no horns had entered the spermatheca. Additional mechanisms of sperm removal from the spermatheca are proposed." 7901. van Huyssteen, P.; Samways, M.J. (2009): Overwintering dragonflies in an African savanna (Anisoptera: Gomphidae, Libellulidae). *Odonatologica* 38(2): 167-172. (in English) ["To better understand overwintering capability of dragonflies in the African savanna, observed individuals were placed into predetermined age categories at sites along the Mogalakwena river, Limpopo province, South Africa, during mid-winter. Age categories were determined by degree of wing wear each individual had sustained. The Dragonfly Biotic Index (DBI) was used to categorize species into rare, widespread generalists versus rare, narrow-range specialists. All the recorded species were common, widespread generalists, occupying microhabitats created by the winter dry season decrease in water level and flow rate, and able to survive seasonal habitat changes. Seven of the 8 species were libellulids, and 1 gomphid.

Their ability to thermoregulate by selecting appropriate perch sites, in addition to their high habitat tolerance, plays an important role allowing them to survive as adults throughout winter. It is confirmed that the libellulids observed here were highly habitat tolerant, common and widespread species whose success comes about at least partly from their ability to overwinter and be ready to take advantage of the first rains." (Authors) The species involved in this study are: *Ictinogomphus ferox*, *Orthetrum chrysostigma*, *Crocothemis erythraea*, *C. sanguinolenta*, *Trithemis annulata*, *T. arteriosa*, *T. furva*, and *T. kirbyi*.] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. Stellenbosch, Private Bag X1, ZA-7602, Matieland, South Africa. E-mail: samways@sun.ac.za

7902. Velasquez, N.; Bautista, K.; Guevara, M.; Ramirez, D.; Realpe, E.; Perez-Gutierrez, L.A. (2009): Larval development and growth ratio in *Ischnura cruzi* De Marmels, with description of last larval instar (Zygoptera: Coenagrionidae). *Odonatologica* 38(1): 29-38. (in English) ["Under stable laboratory conditions larval stages were measured and morphologically compared in order to establish growth ratio and total number of instars through their postembryonic development. Head width, total length, metafemur length, forewing pad length, and length and width of prementum were measured to determine variation between instars, and growth ratio was calculated. By Dyar's Law, 12 larval instars were estimated. Fundamental morphological differences were found in order to distinguish the stages and at the same time to have a record of the morphological development through the stages. Finally, the last larval instar is described and illustrated." 7903. Villanueva, R.J.T. (2009): Dragonflies of Babuyan and Batanes group of islands, Philippines (Insecta: Odonata). *IDF-Report* 17: 1-16. (in English) ["Odonata were recorded and voucher specimens collected between April 23 and May 14 2008. In the islands of Sabtang and Itbayat >90% of the known freshwater system was explored while for Batan and Calayan approximately 60 and 40 percent respectively. In total 33 species belonging to 21 genera and 7 families were found. In addition to this three unidentified species were seen. All these species are new to the islands and one species is new to the Philippines. Furthermore, four of the recorded species (*Amphicnemis* in Calayan, *Drepanosticta* 1 & 2 in Calayan and Batan, *Teinobasis* in Calayan and Batan) are probably new to science. For a further four species the material shows differences with the specimens from the mainland. Some of these might also represent species new to science. Nearly 55 percent of the recorded species are Anisoptera. On the island of Calayan I found 29 species, most of which are forest specialists. Among these species are three probably new species, *Amphicnemis*, *Drepanosticta* and *Teinobasis*. Some of the species, *Diplacina*, *Neurobasis* and *Teinobasis* requires further comparison with known species. Only one species (*Rhyothemis regia*) noted on the island was not captured. On Sabtang, I found 12 species including a new record for the Philippines (*Tramea virginia*). On Batan, 9 species were found including two possibly new species of Zygoptera. Only one species noted in the island was not collected. The island of

Itbayat has nine species including possible one new species. Two species were noted only by sighting and could not be confirmed for proper identification." (Author)] Address: Villanueva, R.J.T., D3C Gahol Apartment, Lopez Jaena St., Davao City, 8000 Philippines. E-mail: reaganjoseph@lycos.com

7904. Vukusic, P.; Stavenga, D.G. (2009): Physical methods for investigating structural colours in biological systems. *J. R. Soc. Interface* 6, Suppl 2: S133-S148. (in English) ["Many biological systems are known to use structural colour effects to generate aspects of their appearance and visibility. The study of these phenomena has informed an eclectic group of fields ranging, for example, from evolutionary processes in behavioural biology to micro-optical devices in technologically engineered systems. However, biological photonic systems are invariably structurally and often compositionally more elaborate than most synthetically fabricated photonic systems. For this reason, an appropriate gamut of physical methods and investigative techniques must be applied correctly so that the systems' photonic behaviour may be appropriately understood. Here, we survey a broad range of the most commonly implemented, successfully used and recently innovated physical methods. We discuss the costs and benefits of various spectrometric methods and instruments, namely scatterometers, microspectrophotometers, fibre-optic-connected photodiode array spectrometers and integrating spheres. We then discuss the role of the materials' refractive index and several of the more commonly used theoretical approaches. Finally, we describe the recent developments in the research field of photonic crystals and the implications for the further study of structural coloration in animals." (Author) *Neurobasis chinensis* exhibits bright and highly saturated iridescent green hind wings as a result of the melanin-backed multilayer in its wing membrane.] Address: Vukusic, P., School of Physics, University of Exeter, Exeter EX4 4QL, UK. 7905. Wilson, S.R.; Ricciardi, A. (2009): Epiphytic macroinvertebrate communities on Eurasian watermilfoil (*Myriophyllum spicatum*) and native milfoils *Myriophyllum sibiricum* and *Myriophyllum alterniflorum* in eastern North America. *Canadian Journal of Fisheries and Aquatic Sciences* 66(1): 18-30. (in English, with French summary) ["Aquatic macrophytes play an important role in the survival and proliferation of invertebrates in freshwater ecosystems. Epiphytic invertebrate communities may be altered through the replacement of native macrophytes by exotic macrophytes, even when the macrophytes are close relatives and have similar morphology. We sampled an invasive exotic macrophyte, *M. spicatum*, and native milfoils *M. sibiricum* and *M. alterniflorum* in four bodies of water in southern Quebec and upstate New York during the summer of 2005. Within each waterbody, we compared the abundance, diversity, and community composition of epiphytic macroinvertebrates (including Odonata on different taxonomical levels) on exotic and native *Myriophyllum*. In general, both *M. sibiricum* and *M. alterniflorum* had higher invertebrate diversity and higher invertebrate biomass and supported more gastropods than the exotic *M. spicatum*. In late summer, invertebrate density tended to be higher on *M. sibiricum* than on *M. spicatum*, but lower on *M. alterniflorum* than on *M. spicatum*. Our results demonstrate that *M. spicatum* supports macroinvertebrate communities that may dif-

fer from those on structurally similar native macrophytes, although these differences vary across sites and sampling dates. Thus, the replacement of native milfoils by *M. spicatum* may have indirect effects on aquatic food webs." (Authors)] Address: Ricciardi, A., Redpath Museum. 7906. Wissinger, S.A.; Greig, H.; McIntosh, A. (2009): Absence of species replacements between permanent and temporary lentic communities in New Zealand. *J. N. Am. Benthol. Soc.* 28(1): 12-23. (in English) ["The species composition of lentic communities often shifts along hydroperiod gradients, in part because temporary-habitat specialists replace closely related permanent-habitat specialists. These replacements reflect tradeoffs between traits that facilitate coexistence with permanent-habitat predators and those that prevent desiccation. The evidence for species replacements and the underlying tradeoffs is considerable in North America, but few studies have explored this pattern in other regions. We compared benthic communities in permanent and temporary habitats on the South Island of New Zealand. Ordination across 58 sites showed that community composition was distinctly different between the 2 types of habitats. Assemblages in permanent habitats had .23 the number of species as those in temporary habitats. We found little evidence for temporary-habitat specialists; i.e., species in temporary communities were a nested subset of those in permanent communities. Quantitative sampling at 12 intensively studied sites revealed that chironomids, water bugs, beetles, and crustaceans accounted for 90% of the biomass in temporary, but only 14% of the biomass in permanent habitats, which were dominated by molluscs, annelids, caddisflies, and odonates. Damselflies, dragonflies, caddisflies, and several other large-bodied taxa common in permanent habitats were absent from most temporary habitats. We propose 2 explanations for the absence of species replacements in these groups in the New Zealand habitats that we studied. First, drying is unpredictable within and between years, perhaps precluding the evolution of temporary-habitat specialization. Second, fish predation on benthic invertebrates, a driver for phylogenetic diversification in North America, appears to be comparatively weak in New Zealand. Comparative studies across a range of climates and faunas will be needed to identify the ecological and phylogenetic contexts that favour evolution of generalists vs specialists along permanence gradients." 7909. De Knijf, G.; Anselin, A.; Demolder, H. (1997): The odonatofauna of the Damvallei (east-Flanders, Belgium); past glory or still worthwhile? *Biol. Jaarh. Dodonaea* 64, 1996 (1997): 75-91. (in English) ["The Damvallei, rich in aquatic habitats, hosted an impressive number (39) of interesting dragonfly (Odonata) species before the construction of a highway junction in 1967. A dragonfly survey was undertaken in the area between 1992-1995 to compare present-day with former species richness. A number of species linked to mesotrophic ponds and marshes, oligotrophic waterbodies and oxygen-rich slow running rivers and brooks have disappeared from the area. Although several species have been lost since 1970, the presence of healthy populations of several interesting species, in particular *Coenagrion pulchellum* and *Erythromma najas* and of a high species richness (26), indicates that the area is still valuable for dragonflies. However it urgently needs a proper dragonfly-friendly management." (Author)] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. 7910. Jacobsen, D.; Schultz, K.; Encalada, A. (1997): Structure and diversity of stream invertebrate assemblages: the influence of temperature with altitude and latitude. *Freshwater Biology* 38: 247-261. (in English) ["1. Structure and diversity of the macroinvertebrate fauna were studied in relation to altitude and latitude among three groups of streams from Ecuador (lowland: 100-600 m, Central Valley: 2600-3100 m, Paramo: 3500-4000 m), and one group from the temperate lowland region of Denmark. The streams in the four regions were comparable with regard to physical characteristics such as size, current and substratum. 2. In terms of faunal composition the Ecuadorian highland streams bore more resemblance to the Danish lowland streams than the Ecuadorian lowland streams. The greater similarity between the Ecuadorian highland and the Danish streams, however, was due to the large number of insect families in the Ecuadorian lowlands, many of which were not found in the other regions. Of ten physico-chemical parameters measured, maximum stream temperature explained by far the most variability in faunal composition. 3. The number of insect orders

and families increased linearly with maximum stream temperature and therefore decreased with altitude and latitude. A compilation of literature data on insect richness and maximum water temperature from streams around the world confirmed this pattern, yielding a common linear relation for both temperate and tropical streams. This pattern may arise due to a direct temperature effect on speciation but is probably also related to geological history and the influence of climatic changes on stream ecosystems. We estimate that small, tropical, lowland streams have, on average, a two- to fourfold higher species richness than temperate lowland streams. [...] The number of insect orders decreased with altitude. In the lowland streams nine orders were found. Odonata comprised 8%, Hemiptera 7%, Megaloptera 0.8% and Lepidoptera 0.5% of the lowland fauna, but, except for a few Odonata in the Central Valley, these four orders were absent in the Central Valley and the Paramo streams." 7916. Schutte, G.; Reich, M.; Plachter, H. (1997): Mobility of the rheobiont damselfly *Calopteryx splendens* (Harris) in fragmented habitats (Zygoptera: Calopterygidae). *Odonatologica* 26(3): 317-327. ["*C. splendens* is common along slow-flowing streams and rivers in central Europe. This species is well-suited for studies on the population structure and mobility of semi-aquatic rheobiont organisms. In this study the authors investigated a local population over a 2 km stretch of river in central Germany, by habitat analysis and mark-recapture-experiments. Emergent aquatic vegetation only influences density if the coverage is lower than 10%. Adult damselflies mainly use vegetation along the banks. Unused, moderately eutrophicated stands of herbaceous vegetation without trees and shrubs are preferred. In-

solation in the morning is the primary factor for the selection of the males' territories and thus determines the pattern of density. The investigated population turns out to be much bigger than expected. 2649 individuals have been marked individually (1543 male, 1106 female). 47% of the males and 29% of the females have been recaptured at least once. Most individuals migrated less than 300 m, which is roughly the home range size, but 23 individuals covered more than 1000 m. Three bridges spanned the investigated stretch of river. None of them caused a complete fragmentation of the habitat, but in the case of a wide but low bridge, more than 70% of the approaching damselflies turned back. However, 13% of all recaptured individuals successfully crossed at least one bridge." 7923. Hecker, K.R. (1999): Testing for sex biases and morph biases in parasitism of zygopterans (Odonata) by gregarines (Eugregarinidae). M.Sc. thesis, Carleton Univ. Ottawa, Ontario: 72 pp. (in English) ["I studied gregarine parasites of *Enallagma boreale* to elucidate causes and consequences of sex biases in parasitism of adult hosts. I found some evidence that adult females had higher prevalence and intensity of infection than males. Both sexes showed a positive correlation between number of gregarines and longevity under conditions of food stress. This may be because food ingested with the infective cysts is more beneficial than the parasites are harmful. I also studied *Nehalennia irene* damselflies and their gregarine parasites, predicting that female morphs would differ in measures of parasitism, therefore balancing the advantages accrued to one morph at high population densities. I found that female morphs did not differ in measures of parasitism. There was no significant difference in prevalence between the sexes across five separate ponds. although females had more gregarines than males. I found no correlation between the number of gregarines and longevity of hosts.] Address: <http://www.collectionscanada.gc.ca/obj/s4/f2/dsk2/ftp01/MQ48490.pdf>

The authors consider only rare or endangered taxa (= redlisted species from Lithuania, Finland, Germany or Norway, and from Karelia). The species list bases on literature data from the 1880s (!).] Address: not stated

7925. Pleguezuelos, J.M.; Poveda, J.C.; Monterrubio, R.; Ontiveros, D. (1999): Feeding habits of the common chameleon, *Chamaeleo chamaeleon* (L.,

1758) in the southeastern Iberian Peninsula. *Israel Journal of Zoology* 45(2): 267-276. (in English) ["We present the feeding habits of *C. chamaeleon* at Taramay, a small coastal valley in the southeastern Iberian Peninsula. Fecal pellets collected from sexed and measured specimens trapped in the field were used for diet analysis. 34 fecal samples provided a total of 777 identified prey items. All prey were arthropods and the numerically dominant groups were Diptera, Hymenoptera, Orthoptera, and Heteroptera. We failed to find sexual differences in diet preference, but there was a seasonal shift in the prey consumed. Orthoptera, the largest prey type, was consumed less in spring than summer or autumn. Examination of grasshopper phenology in coastal habitats of the southeastern Iberian Peninsula, and of the change in chameleon habitat utilization and mobility during the mating period, verified that the common chameleon appears to consume grasshoppers in approximate proportion to their abundance. Prey consumed were smaller than in previous studies. We believe the earlier findings may have been biased due to the diet consisting of captive specimens. Most of the prey consumed in the present study were flying insects, perhaps reflecting the arboreal habits of this climbing species; and most prey were also mobile, as has been predicted for sit-and-wait foragers such as the common chameleon." (Authors) Lestidae are very rarely represented in the diet of the chameleon.] Address: Pleguezuelos, J.M., Dept of Animal Biology and Ecology, University of Granada, 18071 Granada, Spain

7928. Last, L.L.; Whitman, R.L. (2000): Aquatic macroinvertebrates of the Grand Calumet river. *Proceedings of the Indiana Academy of Science* 108 / 109

(1999/2000): 45-81. (in English) ["The Grand Calumet River is potential habitat for a rich community of aquatic macroinvertebrates. Historical surveys of these organisms have been limited to post-industrialization of the Calumet Region; but because river habitats and conditions prior to industrialization have been described, past macroinvertebrate community composition can be inferred. In the past 20 years, several surveys have been conducted in the Grand Calumet that have focused on a limited area, but when these studies are amassed the information available covers much of the river. In this paper, the aquatic macroinvertebrate communities in the river are described, and options for restoration are discussed. Many of the macroinvertebrates present are indicators of high levels of pollution, but a few pollution-sensitive species have been found. There is evidence, however, that the sediment quality has improved since the 1960's, likely due to pollution controls that have been put into place. Restoration opportunities should consider the macroinvertebrate community and the potential to improve sediment habitat without damaging the community structure." (Authors) Odonata are treated at the genus level.] Address: Last, L.L., U.S. Geological Survey, Biological Resources Division, Lake Michigan Ecological Research Station, 1100 North Mineral Springs Road, Porter, Indiana 46304 USA

7929. Strayer, D.L.; Smith, L.C. (2000): Macroinvertebrates of a rocky shore in the freshwater tidal Hudson River. *Estuaries* 23(3): 359-366. (in English) ["We studied the macroinvertebrate fauna of a rocky shore in the freshwater tidal Hudson River during 1992-1994, the early years of the zebra mussel (*Dreissena polymorpha*) invasion. The macroinvertebrate community was numerically dominated by chironomids, nematodes, oligochaetes, gastropods, zebra mussels, and planarian flatworms. The community was a mixture of species typical of stony warm water rivers and lake shore, freshwater generalists and semiterrestrial species. Overall macroinvertebrate densities were moderate to low (2,800-14,600 m²). Density was a strong function of season and elevation with consistently low densities in the early spring and in the intertidal zone. This pattern suggests that physical harshness (alternating submergence and desiccation; ice and low temperatures) limits the distribution of invertebrates at this site. [...] A weak correlation between the densities of zebra mussels and those of other macroinvertebrates nonetheless suggests that the zebra mussel invasion may have affected community structure." (Authors) Mean density of Odonata: 2 specimens / m².] Address: Strayer, D.L., Inst. Ecosystem Studies, Box AB, Millbrook, New York 12545, USA

Nigeria, after impoundment: the faunal characteristics. *African Journal of Science and Technology (AJST) Science and Engineering Series* 2(1): 72-81. (in English) ["A study of a 3 Km stretch of a perennial rainforest stream in southern Nigeria describes the macrobenthic faunal characteristics of pools (dam site stations) and runs. A total of 84 invertebrate taxa made up of 2,535 individuals were recorded. The overall faunal abundance was not significantly different at the study stretch. The abundance of the major taxonomic groups was however significantly different (P < 0.05) at the study stations. Hemiptera and Diptera were the most abundant invertebrate groups recorded. The high number of benthic invertebrates observed is a reflection of the physical and chemical stability of the study stream." (Authors) The study includes records of "Petaluridae" at several stations.] Address: Edokpayi, C.A., Department of Zoology, Marine Biology and Fisheries, University of Lagos, Akoka, Lagos, Nigeria

7932. Harp, G.L.; Trial, L. (2001): Distribution and Status of *Ophiogomphus westfalli* (Odonata Gomphidae) in Missouri and Arkansas. *Journal of the Arkansas Academy of Science* 55: 43-50. (in English) ["*O. westfalli* is endemic to the Interior Highlands (Ozark Plateaus and Ouachita Mountains), in Missouri, Arkansas and southeastern Kansas. First described in 1985, its life history is still little known. Prior to 1997, this species was known from only six sites in Missouri and 10 in Arkansas. From late May through late July in both 1999 and 2000 we surveyed 49 sites, three of them twice each, on Missouri Ozark streams in order to further clarify the distribution and relative abundance of this dragonfly. Adults, nymphs and/or exuviae were found at 23 sites. Literature and museum searches bring to 72 locations in Missouri and 10 in Arkansas where this species has been found. Small to moderate-sized populations, restricted to the Interior Highlands, are known from at least 82 locations. Therefore, it is recommended that its global and Missouri rankings be changed from G2 and S2 to G3 and S3, respectively. Distribution and abundance of this species needs further study in Arkansas." 7942. MacRury, N.K.; Graeb, B.D.S.; Johnson, B.M.; Clements, W.H. (2002): Comparison of dietary mercury exposure in two sympatric top predator fishes, largemouth bass and northern pike: a bioenergetics modeling approach. *Journal of Aquatic Ecosystem Stress and Recovery* 9: 137-147. (in English) ["Physical and ecological factors, including lake temperature, fish physiology, and diet, influence methylmercury (MeHg) exposure in fish. We employed bioenergetics modeling to compare dietary MeHg exposure in sympatric top predators, largemouth bass (*Micropterus salmoides*) and northern pike (*Esox lucius*). We compared simulations using field data to hypothetical simulations with (1) \pm 25% change in mean daily lake temperature for juvenile and adult bass and pike; (2) \pm 25% change in long-term growth rate of pike; (3) adult bass diet shift from generalist predator to strict piscivore. Bass and pike MeHg exposures were similar in baseline simulations and reflected patterns in field tissue concentrations. This occurred despite the fact that bass consumed highly contaminated benthic invertebrates (including Odonata), while pike exclusively consumed less contaminated fish prey. Higher temperatures increased adult bass and pike MeHg exposures by 35% and 27%, respectively. Shifting adult bass diets to 100% fish resulted in a 54% decrease in exposure, while increasing pike growth rates resulted in a 24% decrease. Bioenergetics modeling proved useful in understanding the influence of temperature, prey-base, and predator growth on differences in Hg exposure across fish species." 7949. Boano, G.; Rolando, A. (2003): Aggressive interactions and demographic parameters in *Libellula*

fulva (Odonata, Libellulidae). Italian Journal of Zoology 70(2): 159-166. (in English) ["Male aggressive interactions and demographic parameters (sex ratio, survival, abundance and life span) of *L. fulva* were studied for four years at a marsh in northwestern Italy by monitoring marked individuals. Perching males attacked every dragonfly passing near the perch. However, the mean homospecific attack distance was significantly longer than the heterospecific one and this suggests that males were able to discriminate among species, at least partially. In some instances, aggressive males succeeded in catching and copulating with females. Release-recapture analyses indicate that the sex ratio was very biased towards males, even though male and female capture probabilities were equal. Females had a slightly greater mortality rate than males, but this difference in adult survival is not sufficient to explain why adult females were rather rare at our study site. Life span estimates are in keeping with field observations, indicating that most males stayed alive for less than 10 days. All these results suggest a connection between interactions and demographic parameters. Male aggressive behaviour can in fact be viewed as an adaptation to a sexual environment here the time for reproduction is very short and the probability of meeting a partner is very low. Aggressions may in fact enhance males' probabilities to catch (and copulate with) females which are flying through the site. Weather conditions influenced males' behaviour, attack distance being significantly and positively related with light intensity. Vice-versa, weather conditions did not influence survival, maybe because of mild temperatures and scanty rain. The aggressive behaviour of *L. fulva* males might be classed as territoriality. However, the classical "defence of resource approach" seems to be scarcely appropriate here, since no resource located inside the hypothetical territory was defended, at least at the perch site." 7951. Catling, P.M. (2003): Dragonflies (Odonata) of the Northwest Territories, Status ranking and preliminary atlas. University of Ottawa: 49 pp. (in English) ["Thirty-five species of Odonata are given status ranks in the Northwest Territories based on number of occurrences and distributional area within the territory. Nine species are ranked as S2, may be at risk, including *Aeshna subarctica*, *Lestes congener*, *Nehalennia irene*, *Ophiogomphus colubrinus*, *Somatochlora albicincta*, *S. forcipata*, *S. franklini*, *S. sahlbergii* and *S. septentrionalis*. Many of these are widespread and on the edge of their range in the Northwest Territories. The most restricted species overall in North America is the Palearctic - East Beringian *S. sahlbergii*. *O. colubrinus* appears rare and local in the western part of its range. Nineteen species are ranked as S3, sensitive and 7 are ranked as S4, secure. The ranking is based on a database of 1040 records each defined as unique combination of

date, location and collector. Rejected taxa and possible additions are outlined. Regions requiring further survey are noted. Information on collecting and inventory is provided. Distribution maps for the species in the Northwest Territories are included." (Author)] Address: <http://www.enr.gov.nt.ca/live/documents/documentManagerUpload/AtlasDragonflies.pdf>

7958. Mkize, N. (2003): A contribution to cabbage pest management by subsistence and small-scale farmers in the Eastern Cape, South Africa. Submitted in fulfilment of the requirements for the Degree of Master of Science in Entomology, Rhodes University: X, 108 pp. (in English) ["The interaction between farmers, agricultural scientists and extension workers is sometimes overlooked in agricultural entomology. In an attempt to respond to this reality this study examines some foundation of this interaction in relation to the pest management practices of subsistence and small-scale farmers and also highlights the problems that might arise in the implementation of IPM. Problems involving pests occurrence; language barriers; beliefs, knowledge and perception about insects, and visual literacy are examined. The thesis has a two-fold focus, firstly the study of pests on cabbages of subsistence farmers in Grahamstown and secondly a broader focus on other aspects such as cultural entomology, perception of insects and visual literacy specifically in relation to Xhosa speaking people in the Eastern Cape." (Author) Names of Odonata (general, Zygoptera, Anisoptera) in isiXhosa language are listed in tables 2 and 3.] Address: <http://eprints.ru.ac.za/752/1/Mkize-MSc.pdf>

7959. Nekaris, K.A.I. ; Rasmussen, D.T. (2003): Diet and feeding behaviour of Mysore Slender Lorises. *International Journal of Primatology* 24(1): 33-46. (in English) ["We studied the feeding ecology of the Mysore slender loris (*Loris lydekkerianus lydekkerianus*) for 10.5 month in a dry scrub forest at Ayyalur Interface Forestry Division, Tamil Nadu, South India. We recorded and analyzed 1240 feeding incidents, which indicate that the lorises were almost exclusively faunivorous, with 96% of all feeding events representing animal prey. Of prey items that could be identified (n = 605), 62.9% were ants and termites. Lorises fed on 9 orders and 17 families of insects, including Odonata, plus spiders, molluscs, and small vertebrates. Lorises infrequently fed on gums and a legume pod. They usually grabbed prey with one hand, while other appendages firmly held the substrate. Many of the identifiable prey

items belong to insect taxa likely to contain toxic chemicals. Consumption of insects inferred to be toxic was accompanied by an elaborate behavioural repertoire of sneezing, slobbering and urine-washing. A high proportion of insects eaten by slender lorises (71%) occurred in patches or aggregations. The utilization of aggregated social insects may have implications for understanding the unusually high degree of gregarious behaviour exhibited by the lorises." (2003): The impact of wetland vegetation drying time on abundance of mosquitoes and other invertebrates. *Journal of the American Mosquito Control Association* 19(4): 361-366. (in English) ["Vegetation management for constructed treatment wetlands often involves knocking down emergent vegetation with heavy equipment and inundating the dead vegetation after a period of drying. Such practices create favourable conditions for larval mosquitoes. We studied the relationship between length of the drying period for an emergent macrophyte, *Typha* sp., and the abundance of aquatic invertebrates in replicated 0.18-m³ wading pools. The mosquito, *Culex tarsalis*, was significantly more abundant in pools containing vegetation aged for 2 wk before inundation compared to pools containing vegetation aged 5 wk, freshly cut vegetation, or without vegetation. Potential larval mosquito food resources (particles between 2 and 61 µm in equivalent spherical diameter) in the 2-wk aging treatment did not differ significantly from the other treatments during the 5-wk experiment. The abundance of other larval culicids, nonculicine Diptera, and potential mosquito predators (i.e., Dytiscidae and Aeshnidae) did not differ significantly among the vegetation aging treatments."] Address: Sanford, Michelle, Department of Entomology, University of California, Riverside, Riverside, CA 92521, USA

7965. Thipaksorn, A. (2003): Diversity, distribution and Wolbachia infection of rice field odonate insects in Thailand. M.Sc. diss., Fac. Graduate Stud., Mahidol Univ., Bangkok. ISBN974-04-3551-3: xiii+115 pp. ["Odonate insects are important predators of rice pests that play a valuable role in the rice ecosystem. Twenty-nine odonate species, 15 zygoptera and 14 anisoptera, were collected from rice fields in 36 provinces around Thailand from 1998 to 2000. Within all rice odonate species, three zygopteran species, *Agriocnemis pygmaea*, *Agriocnemis f. femina* and *Ischnura senegalensis*, had the highest numbers of individuals. Within the anisoptera, the species with the highest number of individuals was *Diplacodes trivialis*. The distributions of 15 coenagrionid and 11 libellulid odonate species were extended with many new provincial records. The distribution and phylogenetic relationships of the reproduction-modifying bacteria called Wolbachia in odonate insects were also studied. Using a PCR-based method and wsp gene primers, four odonate species, *Agriocnemis f. femina*, *Pseudagrion pruinatum* (Zygoptera), *Brachythemis contaminata* and *Neurothemis t. tullia* (Anisoptera) were found to be infected with Wolbachia and the percentage of Wolbachia infection among species of the Order Odonata was 13.79 %. All procedures used for phylogenetic reconstruction (maximum parsimony, maximum likelihood and neighbor-joining methods) place all odonate Wolbachia strains in the Con and Pip subgroups within the B group of Wolbachia strains. The wsp gene sequences of *Agriocnemis f. femina* and *Brachythemis contaminata* were in the Pip subgroup, but Wolbachia sequences from *Neurothemis t. tullia* and *Pseudagrion pruinatum* were grouped together into the Con subgroup of B group Wolbachia strains. The low Wolbachia infection frequencies and identical wsp gene sequences in odonate species that are not closely related suggest that Wolbachia might have recently invaded rice field odonate populations through some means of horizontal transmission. Identical wsp gene sequences were found from all three positive populations of *A. f. femina* collected from different regions of Thailand. This finding supports the hypothesis that Wolbachia-infected damselflies spread into uninfected populations. Further study should be done to investigate the rates at which Wolbachia-infected damselflies could spread into uninfected populations." (Author) "The subjects treated in this well-styled and beautifully produced dissertation were earlier summarized in 3 journal papers, viz. the diversity and distribution in *Malangpo* 18(2001): 171-174, and *Notulae odonatologicae* 6(2003): 20-24; and the Wolbachia infection in *Curr. Microbiol.* 47(2003): 314-318. As to the Thai ricefield Odonata, all species are here described and keyed, their distribution is listed per province (along with the quantitative data), and a map is provided. The distribution and phylogenetic relationships of the reproduction-modifying Wolbachia in *Agriocnemis f. femina*, *Pseud-*

agrion pruinatum, *Brachythemis contaminata* & *Neurothemis t. tullia* form the main and most important part of this work. All procedures used for phylogenetic reconstruction (maximum parsimony, maximum likelihood, and neighbour-joining methods) place the odonate Wolbachia strains (wsp gene sequences) in the Pip (*A. femina*, *B. contaminata*) and Con (*P. pruinatum*, *N. tullia*) subgroups within the B group of Wolbachia strains. The low infection frequencies and the identical wsp gene sequences in not closely related spp. suggest that Wolbachia might have recently invaded rice field odonate populations through some means of horizontal transmission." Address: Thipaksorn, A., Biol. Sect., Mahidol Wittayanusom Sch., Salaya, Phutthamonthon, Nakhon Pathom-73170, Thailand

7966. Whiteman, H.H.; Sheen, J.P.; Johnson, E.B.; Vandeuken, A.; Cargille, R.; Sacco, T.W. (2003): Heterospecific prey and trophic polyphenism in larval Tiger salamanders. *Copeia*, 2003(1): 56-67. (in English) ["Polyphenisms (environmentally cued polymorphisms) are ubiquitous, yet the specific proximate mechanisms producing alternative morphs are generally not well known. We tested hypotheses for the role of large heterospecific prey in the cannibalistic polyphenism within larval tiger salamanders, *Ambystoma tigrinum nebulosum*, to determine whether heterospecific prey directly or indirectly influence the production of cannibal morphs. Field surveys suggested, and laboratory experiments confirmed, that macroinvertebrate prey induce cannibals via an increase in body size variation within larval salamander populations. Dietary data and laboratory foraging experiments revealed that cannibals preferred conspecifics even when their capture success was greater on macroinvertebrates. Typical morphs, in contrast, consumed only macroinvertebrate and other prey and never successfully cannibalized conspecifics. Our results support the indirect hypothesis that cannibals are induced via increased body size variation within a population of larvae, as a result of differential consumption of large heterospecific prey, and do not rely on consumption of heterospecific prey once they are cannibals. The cannibalistic polyphenism is one example of phenotypic plasticity in which the functional significance and the proximate mechanisms producing the two morphs are becoming clearer, allowing further study of the molecular and physiological basis of the alternative phenotypes." (Authors) Odonata included into this study were larvae of *Coenagrion resolutum* and *Enallagma cyathigerum*.] Address: Whiteman, H.H., Dept Bio. Sci., Murray State University, Murray, Kentucky 42071, USA

2004

7967. Achmed, S.; Kashif, M.; Nisar, S. (2004): Efficacy of Monomethypo 5G and Chlorpyrifos 40EC against insect pests and their effect on natural enemies in rice eco-system. *Pak. Entomol.* 26(1): 87-94. (in English) ["An experiment for the efficacy of monomethypo 5G @ 7 kg arce-1 against rice leaf folder (*Cnaphalocrocis medinalis*, G.M), rice stem borers (*Tryporyza* spp.) and chlorpyrifos 40 EC @ 1000 ml acre-1 and effect on natural enemies (dragonflies, damselflies and green lacewings) was laid out in Randomized Complete Block Design (RCBD). Three treatments, i.e., monomethypo 5G, chlorpyrifos 40EC and a control were replicated thrice. Results showed that % leaf folder infestation level, pop-

ulation density of naiads and adults of Odonata and adults of green lace wings on Basmati super was not significantly different from that of Basmati-385 ($P=0.20$) for one tail and $P<0.41$ for two tail t-test. The effect of insecticides was more evident in chlorpyrifos 40EC than in monomehyppo 5G treated plots at 24, 46,72 hr, one week after the application compared to the check plots. It was also found that ~50% reduction in population of natural enemies of naiads and adults of Odonata flies and green lace wings was observed." (Authors)] Address: Nisar, S., College of Agriculture, University of Agriculture, DG Khan, Pakistan

7968. Bracken, B.; Lewis, C. (2004): First records and emergence of Variegated Meadowhawk (*Sympetrum corruptum*) in Prescott-Russell County. Ontario Odonata 4: 1-3. (in English) ["On 17-VIII-1997, at a sewage lagoon east of Ottawa, Canada near the town of Embrun (45.2584·N, 75.3313· W), we collected one teneral female *S. corruptum*, and observed a second teneral. This is the second record of the species for the Ottawa valley and the first record for eastern Ontario away from the Great Lakes. The new eastern Ontario record is an extension of 202 km northeast from the nearest known Ontario collection from Sandbanks Provincial Park (Prince Edward County) on Lake Ontario. The observation of these tenerals, incapable of flight, is also of interest in indicating emergence at the site." (Authors)] Address: Lewis, Christina Lewis, 22-246 Harcourt Ave. Ottawa, ON K2B 5C3, Canada. E-mail: ha-genius@primus.ca

7969. Bree, D. (2004): Additional records of Arrowhead Spiketail (*Cordulegaster obliqua*) in Ontario. Ontario Odonata 4: 6-8. (in English) ["*C. obliqua* is reported from two locations in eastcentral Ontario, Canada which are first county records for Peterborough and Frontenac. The nine previous records from Ontario are outlined. Information on the small stream habitats at the two new locations and on ovipositing behaviour is provided. Possible reasons for the rarity of this species in Ontario are discussed." (Author)] Address: Bree, D., Box 123, Bloomfield, Ontario K0K 1G0, Canada

7970. Cating, P.M. (2004): The Austral Spreadwing, *Lestes australis*, in Ontario. Ontario Odonata 4: 18-22. (in English) ["Documentation for the occurrence of *L. australis* in Ontario, Canada is discussed. No fully reliable Ontario records are known. The literature reports are problematic because they are based on females which cannot be identified with certainty. Other reports lack supporting evidence or the voucher lacks some characteristic features. More study of this species in Ontario is needed. Identification is discussed." (Author)] Address: Cating, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

7971. Cating, P.M. (2004): Rapid recovery of Odonata populations at a completely dried up pond. Ontario Odonata 4: 15-17. (in English) ["In 2001, a shallow gravel pit pond completely dried up to a dusty sun-baked expanse and remained completely dry for three months. Water returned in 2002 and 14 species of adult Odonata, and over 100 individuals as well as 3 species of nymphs were observed. The uncommon *Enallagma aspersum* was present and *Lestes forcipatus* and *L. unguiculatus* were ovipositing at the pond. Periodically dry ponds are an important habitat for Odonata. To a degree their periodic drying out can be viewed as a ne-

cessary and natural process." (Author)] Address: Cating, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

7972. Cating, P.M. (2004): Ontario Odonata records through the years. Ontario Odonata 4: 23-27. (in English) ["Records from the Ontario Odonata Database and those published in Ontario Odonata as part of the annual Ontario Odonata summary are mapped. For mapping purposes, the records were divided into the "Walker Period" with 6,000 records up to and including 1975, the 1976-1998 pre-annual summary period with 10,000 records, and then each year of the annual summary (1999-2001) including a total of almost 16,000 records. A map also features all the 32,000 Ontario records combined. These maps illustrate the tremendous amount of survey work (both historical and contemporary) that has occurred in Ontario, as well as identifying those areas that could most benefit from more detailed surveys in the future. They also demonstrate the effectiveness of a well-coordinated effort to compile and maintain records in a central repository." (Author)] Address: Cating, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

7973. Cating, P.M. (2004): *Anax junius* overwintering in eastern Ontario. Ontario Odonata 4: 9-10. (in English) ["Populations of *A. junius* in southern Canada are both resident and migrant. The resident population is said to overwinter as half grown larvae and emerge in late June. A resident population has not been reported north of Toronto and was not expected in eastern Ontario based on a 1965 study at approximately the same latitude at Montreal which found no evidence of overwintering. In April 2002 overwintering larvae of *Anax junius* were found at three locations in the Ottawa and St. Lawrence valley regions of Ontario, far beyond the Carolinian region which was the previously known limit of resident populations." (Author)] Address: Cating, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

7974. Cating, P.M. (2004): A preliminary study of dragonflies at eastern Ontario sewage lagoons in relation to water quality. Ontario Odonata 4: 28-32. (in English) ["To better understand the Odonata species composition at sewage ponds and its relationship to water quality, numbers of individuals of each species were recorded from 15 sewage ponds and the same data was collected for nymphs from 10 sewage ponds. The ponds studied were distributed throughout eastern Ontario. The numbers and presence of species was related to clarity which was shown to be related to water quality and chemical parameters. Seventeen species of adults and thirteen species of larvae were recorded. The predominant species were *Ischnura verticalis* and *Enallagma civile* and these were also characteristic of the poorest water quality. Species of *Lestes* and *E. ebrium* occurred only in the pools with relatively clean water. More species occurred in clean ponds." (Author)] Address: Cating, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

7975. Cating, P.M. (2004): Another record of Zebra Mussel attached to an exuvium of *Epitheca princeps*, and inferences of effect. Ontario Odonata 4: 5. (in English) ["An exuvium of *E. princeps* with an attached Zebra Mussel was found 30 cm above the water level along the wall of a marina at Presqu'île Bay (44.0188 N,

77.7276 W, Northumberland Co.), Canada." Address: Catling, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. E-mail: catinggp@agr.gc.ca

7976. Che Salmah, M.R.; Wahizatul Afzan, A. (2004): Distribution of Odonata (Insecta) in various ecosystems in northern Peninsular Malaysia. *Wetland Science* 2(3): 184-191. (in English) ["Odonata larvae and adults were collected from fourteen sites of various habitats including rivers, rice fields, mountain streams, freshwater and peat swamps, oil palm, sugarcane and rubber plantations and lake. Out of 51 species recorded, Libellulidae made up the most dominant of 10 families followed by Gomphidae and Coenagrionidae. Other families were less common. Riverine and stream ecosystems were the most diverse, both with six families and 19 and 13 species respectively. In the rice fields, Libellulidae and Coenagrionidae were represented by 17 and seven species respectively. The poorest fauna of Odonata was recorded from a lake system. A few of libellulids were found to be pollution tolerant and widespread in distribution. Many odonate species were restricted to preferred habitats or water parameter gradients that could be used as bioindicators of respective habitats or parameters." (Authors)] Address: Mrs. Wahizatul Afzan Bt. Azmi, Fac. Science & Technol., Kustem, Mengabang Telipot, 21030 Kuala Terengganu, Terengganu, Malaysia. E-mail: wahizatul@kustem.edu.my

7977. Clausnitzer, V. (2004): Ecology and biogeography of the dendrolimnetic *Coryphagrion grandis* (Odonata). In: Breckle, S.-W., Schweizer, B. & Fangmeier, A. (eds) "Results of worldwide ecological studies". Heimbach, Stuttgart: 243-256. (in English) ["A study on the ecology of *C. grandis* was undertaken in coastal forests of East Africa. The results are compared with other dragonfly species, known to breed in phytotelmata as well. These ecological and additional morphological and genetic results of this study show, that the monotypic *C. grandis*, which was placed for conveniences within the Megapodagriidae, belongs to the otherwise South and Central American Pseudostigmatidae. Although the separation from the neotropical Pseudostigmatidae occurred at least 100 million years ago, the morphology and biology *C. grandis* is still very similar to the former. These findings support biogeographical considerations about historical forest distribution in Africa, stability of East African coastal forests and the species loss due to extinctions in West and Central Africa. Since the future of *C. grandis* depends on the survival of the last coastal and lower Eastern Arc forests in East Africa, a short conservation chapter is added in the end." (Author)] Address: Clausnitzer, Viola, Friedländer Weg 53, 37085 Göttingen, Germany. E-mail: violacl@t-online.de

7978. Cook, J. (2004): Notable records of Emeralds (*Somatochlora* spp.) from Leeds-Grenville, eastern Ontario. *Odonata* 4: 4. (in English) [*S. forcipata* and *S. walshii*, both previously known from Mer Bleue bog, are reported for the second time in eastern Ontario. *S. williamsoni* also occurred at the location near a slow moving stream 2 km SW of Bishops Mills in a general region of extensive marshes and swamps. The distinction between females of *S. williamsoni* and *S. tenebrosa* is discussed.] Address: Cook, Joyce, R.R. 3 North Augusta Ont. K0G 1R0, Canada. E-mail: joyce-cook@carleton.ca

7979. Costa, S.M. (2004): Distribution and species richness of Odonate at Brookhaven National Laboratory. Prepared in partial fulfillment of the requirements of the Office of Science, DOE Science Undergraduate Laboratory Internships (SULI) Program under the direction of Dr. Timothy M. Green in the Environmental and Waste Management Services Division at Brookhaven National Laboratory: 17 pp. (in English) ["Odonate research was conducted at Brookhaven National Laboratory during the summer of 2004. The purpose for the research was to continue the Odonata research that began in the summer of 2003, which consisted of identifying and cataloging the specimens found at the Laboratory. Identification was to species level when ever possible. In addition the 2004 goal was to survey the bodies of water at the Lab primarily for adult odonates, to observe species richness, and catalog and preserve the specimens collected in support of the New York Odonate Atlas. To date a total of forty-six species have been identified at Brookhaven National Laboratory between the two summers of research. Twenty-five adults and twelve larvae were identified during the summer of 2003 and fifteen different adults species were found and identified during the summer of 2004. Future research may continue at the ponds in order to expand cataloging of Odonates; to possibly look at a link between species richness and pH of ponds; and to continue the larger on going biotic inventory of the Lab." 7983. Lekka, E.; Kagalou, I.; Lazaridou-Dimitriadou, M.; Albanis, T.; Dakos, V.; Lambropoulou, D.; Sakkas, V. (2004): Assessment of the Water and Habitat Quality of a Mediterranean River (Kalamas, Epirus, Hellas), in accordance with the EU Water Framework Directive. *Acta hydrochim. hydrobiol.* 32(3): 175-188. (in English, with German summary) ["In the present study, the water quality of Kalamas river (NW Greece) was evaluated using physicochemical and hydromorphological parameters and benthic macroinvertebrates. Statistical analyses (Cluster and FUZZY analyses) were performed and two biotic scores (BMWP' and HS) were used in order to classify the sites according to water quality. Kalamas river appeared to have excellent to moderate water quality at all sampling sites except one (close to the delta area) which was "fairly or significantly polluted". During the low flow season water quality appeared poorer than during the high flow season. The Greece ecological parameters (hydromorphological, chemical, and biological) used for this integrated approach are the ones proposed by the New Water Directive 2000/60 EC for an efficient surveying monitoring of running waters." (Authors) Taxa - including Odonata - are treated on the order level.] Address: Lazaridou-Dimitriadou, Maria, Department of Zoology, School of Biology, Faculty of Sciences, Aristotle University of Thessaloniki, 54006, Thessaloniki, Greece. E-mail: mlazarid@bio.auth.gr

7984. Płaska, W. (2004): The influence of predators on the forming of species diversity of zooplankton of some water ecosystems of the Łężna-Włodawa lake-land. *Teka Kom. Ochr. Kszt. Srod. Przyr.*, 2004,1: 180-183. (in Polish, with English summary) ["The studies were conducted within two lakes and two subsided ponds situated in the Leczna-Włodawa Lake District. In the studied water bodies, 73 zooplanktonic taxa were found to occur; the highest number of taxa - 44 - occurred in Lake Usciwierz, the lowest one - 24 - in the depression reservoir Szczecin. The highest values of frequency (35-40%) were found in Lake Usciwierz and the depression reservoir Nadrybie, the lowest one - from 10% to 19% - occurred in Lake Piastfczno and the depression reservoir Szczecin. The obtained results showed that within water bodies with escalating pressure of predators the species diversity of zooplankton was also high." (Authors) Odonata contributed highly to the biomass of predators.] Address: Płaska, W., Katedra Hydrobiologii i Ichtiologii Akademii Rolniczej, ul. Akademicka 13, 20-950 Lublin, Poland

7985. Pratt, P.D.; Paiero, S.M. (2004): *Archilestes grandis* (Rambur) (Odonata: Lestidae), new to Canada. *Ontario Odonata* 4: 11-12. (in English) ["One adult male *A. grandis* was collected while perched on foliage in the Ojibway Prairie Provincial Nature Reserve (42° 15' 43", 82° 04' 12") on August 26, 2002." 7986. Armstrong, K.N.; Storey, A.W.; Davies, P.M. (2005): Effects of catchment clearing and sedimentation on macroinvertebrate communities of cobble habitat in freshwater streams of southwestern Australia. *Journal of the Royal Society of Western Australia* 88: 1-11. (in English) ["The removal of riparian vegetation from along first order streams of the northern jarrah forest reduced ecological health, as assessed by an examination of cobble communities. Macroinvertebrate diversity was significantly lower in cleared compared to uncleared reaches. There was also an associated decrease in the biomass and a change in the composition of epilithon communities, from those dominated by the angiosperm *Potamogeton ?crispus* to thin slimes dominated by diatoms. Extensive growths of filamentous algae were not observed on cobbles in cleared reaches. Species of Odonata (*Argiolestes minimus*), Ephemeroptera, Trichoptera and Chironomidae were the most notable absences from cobbles in cleared reaches. Grazer abundance also was reduced. Few species in cobble habitats appeared to benefit from catchment clearing although there was a significant increase in the abundance of the undescribed chironomid *Orthocladiinae* V61, which may be a useful indicator species. We also tested the effect of short term elevations in suspended sediment through experimental addition of sediment in an attempt to separate the effects of sediment from others related to catchment clearing. There was no significant difference in macroinvertebrate diversity between control and sediment-added cobbles, and both had higher diversity than cobbles in cleared reaches. We concluded that the changes in the epilithic cover in cleared reaches caused indirectly the changes in the macroinvertebrate community, either through a change in the composition of food sources or loss of refugia. Sedimentation in cobble environments might have greater impact in the longer term than noted in this study, and also might have impact on other stream mesohabitats." (Authors)] Address: Armstrong, K.N., School Animal Biology (M092), Univ. Western Australia, Crawley, WA 6009, Australia

7987. Boelter, R.A. (2005): Predation of native anurans by bullfrogs (*Rana catesbeiana*: Ranidae) in the South of Brazil. *Dissertação de Mestrado, Mestrado em Biodiversidade Animal, Universidade Federal de Santa Maria, RS, Brasil*: 36 pp. (in Portuguese and English) ["Bullfrogs have been introduced in many continents causing impact on native species. We have studied the influence of bullfrogs on the native anuran fauna through the diet analysis of 291 specimens, collected between May 2002 and June 2003, in an area in the South of Brazil. In order to check the feeding importance of the food items, the Pinkas index was used, classifying them by their relative importance (IRI). To analyze ontogenetic changes in the diet, we compared the variation among weight classes. The most important item found in the bullfrog diet was the anuran (IRI = 2157.71) from the Leptodactylidae, Hyliidae, Microhylidae and Ranidae families, totalizing nine preyed species. Anurans were found in all weight classes. These results show a potentially strong predation pressure on the native anuran fauna. A control program for this invasive species in natural environments in the South of Brazil is suggested to be undertaken urgently." (Authors) Odonata are represented as app. 10% of food items in bullfrog stomachs.] Address: Boelter, R.A., Curso de Mestrado em Biodiversidade Animal, Universidade Federal

7993. Englund, R.A. (2005): Threats to native aquatic insect biodiversity in Hawai'i and the Pacific and challenges in their conservation. Dissertation, University of Hawai'i: IX, 202 pp. (in English) [Although the decline in numbers and diversity and threat to native insects in the Hawaiian Islands is widely recognized by field scientists there has been little progress in either documenting the real decline of native species, or in demonstrating specific causes of the overall decline of these species. Additionally, few conservation actions to either restore populations or mitigate actual threats to native arthropods have been mentioned in the literature. The following chapters examine several assessments of relevant aquatic systems and the native aquatic insects dwelling within, where there has either been a perceived or real decline of these native Hawaiian aquatic arthropods because of threats from invasive or introduced species. The large adaptive radiation of the endemic native damselflies (Coenagrionidae: Megalagrion) in Hawai'i has received considerable attention and study since at least the 1880s. Endemic Megalagrion are in many ways reflective of a great loss because they are largely now found in remote upper headwater areas of streams, yet they also represent the hope of preserving highly diverse freshwater ecosystems found throughout the Hawaiian archipelago. The first two chapters of this dissertation examine the impacts of two differing taxa of introduced fish on Hawaiian Megalagrion, Pocciliidae (livebearers or mosquitofish family) and Salmonidae (trout). The effects of each fish species on native aquatic insects depended mainly on the invasive status of each group; for example. Chapter 1 (Englund 1999) examines the impacts of introduced poeciliids on native damselflies. Damselflies were completely eliminated on the island of O'ahu wherever species in the highly invasive mosquitofish family were found, and only remnant populations were found in high elevations lacking introduced fish. Chapter 2 (Englund and Polhemus 2001) examines the impacts of the non-invasive rainbow trout (*Oncorhynchus clarki*) on Megalagrion damselflies. Damselflies and all other native aquatic insects were not found to be harmed by trout in the uppermost elevations of Kaua'i streams where trout reproduce naturally, and even had more robust populations than in some nearby non-trout containing streams. The lack of impacts on native damselflies by a large, generalist predator such as rainbow trout pointed out a seeming paradox. Whereas the small but ubiquitous mosquitofish appears to have completely devastated native aquatic fauna wherever it has been introduced outside of its natural range, trout, because of their restricted range and smaller population sizes have had minimal, if any impacts on native invertebrates in Hawai'i. Because introduced fish species have caused either the extinction or severe range contractions of Megalagrion damselflies in Hawai'i, long-term monitoring of the remnant

populations has become necessary to preserve these remaining populations. Chapter 3 (Englund 2001) provides a case study in both the monitoring and preservation of a remnant O'ahu damselfly population now found in only 95 m of Ashless stream at the Tripler Army Medical Center. Chapter 3 also provides several harrowing examples of how this species was nearly eliminated in the past 10 years through accidents and mismanagement. Not only are the endemic *Megalagrion* now missing from all lowland areas of O'ahu (with the exception of the Tripler population), lowland aquatic insect diversity throughout O'ahu is at a remnant status, and biodiversity surveys for native aquatic insects in the Pearl Harbor watersheds in Chapter 4 (Englund 2002) indicated a near absence of native aquatic insects in these freshwater habitats. Lower Pearl Harbor watersheds were documented to have lost many native aquatic insect taxa such as all native Heteroptera, damselflies, Coleoptera, and many Diptera species, while introduced insect species were abundant. A variety of conservation measures have been suggested to either restore or maintain the current levels of freshwater biodiversity in Hawai'i. In Chapter 5 (Englund and Filbert 1999), the case of significantly increasing and restoring stream flow in a formerly diverted stream was examined to determine whether this factor alone would lead to a restoration of native aquatic species. It was found that merely increasing stream flow by itself was not enough to rid the stream of any alien aquatic species, in fact, several new nonindigenous aquatic species became established after stream flows were increased. The results of Chapter 5 confirm that an integrated, balanced and possibly drastic approach will be required to maintain and preserve Hawai'i's native aquatic insect fauna. A wide-variety of conservation measures in the Hawaiian archipelago will be needed to maintain current biodiversity levels, and also hopefully restore native freshwater biodiversity in selected areas. To put the Hawai'i problem into perspective, a brief review of the impacts of invasive species on native insects in other tropical areas is provided in Chapter 6. This review chapter also provides a synthesis of the problem facing Hawaiian freshwater insects and other terrestrial arthropods in Hawai'i and elsewhere due to invasive species, and how the Hawaiian case study of invasive species impacts has many parallels to other vulnerable biotas. Finally, drawing on a mixed record of past mistakes and successes in Hawai'i and elsewhere, some potential practical conservation measures intended to preserve and restore endemic island aquatic insects are provided in Chapter 6." 7998. Stevens, L.E.; Bailowitz, R.A. (2005): Distribution of *Brechmorhoga* clubskimmers (Odonata: Libellulidae) in the Grand Canyon region. *Western North American Naturalist* 65(2): 170-174. (in English) ["We examined the distribution of *B. mendax* and *B. pertinax* in northern Arizona and southern Nevada. *Brechmorhoga*

mendax occurs widely throughout the Southwest and in Arizona up to the Mogollon Rim, and up the Colorado River from the west to at least River Mile 132 (downstream from Lees Ferry, Arizona) at elevations of 110–1460 m. In Grand Canyon it occurs along small to large tributaries and on the mainstream at elevations below 650 m. The only previously reported locality for *B. pertinax* in the United States is in southeastern Arizona, where it was presumed to be accidental. We report *B. pertinax* along 5 small, perennial tributaries emanating from Redwall Formation aquifer springs on the south side of central Grand Canyon. Those springs habitats may be threatened by regional groundwater depletion. *B. pertinax* appears to be somewhat more stenotolerant in its habitat requirements than *B. mendax*, a finding in keeping with these differences in range. The presence of isolated populations of *B. pertinax* in Grand Canyon is an example of a Neotropical influence on the fauna and indicates biogeographic corridor and refuge functions of this large, deep canyon." (Authors)] Address: Stevens, L.E., Museum of Northern Arizona, 3101 N. Ft. Valley Rd, Flagstaff, AZ 86001, USA. E-mail: farvana@aol.com

7999. Toth, S. (2005): Monitoring dragonflies on the section of the Dráva between Ortilos and Vízvár (Insecta: Odonata). *Natura Somogyiensis* 7: 35-48. (in English) ["The power plant planned on the Croatian section of the Drava can result in unfavourable changes in the fauna of wetlands by the river and may - among others - affect the dragonflies developing there, too. This necessitates the long-term monitoring of the local dragonfly fauna. Already the experiences of the first few years of monitoring referred to the fact that the shallower wetlands of the area are particularly vulnerable. In the course of the examination, it turned out that the dragonfly fauna of the area is rich- 14 of the 48 species detected so far are protected by law. Outstanding among these are the 5 taxa listed in the Bern Convention (*Aeshna viridis*, *Gomphus flavipes*, *Ophiogomphus cecilia*, *Leucorrhinia caudalis*, *L. pectoralis*). The composition of the local fauna - similarly to the national situation - is dominated by Pontic-Mediterranean, Siberian and West-Siberian faunal elements. However, the proportions alter to some extent from group to group. The author gives a detailed analysis of the composition of the fauna of the individual sampling sites and offers a separate depiction of the quantitative composition of the fauna according to the suborder." 8005. Cordoba-Aguilar, A.; Contreras-Garduno, J. (2006): Differences in immune ability in forest habitats of varying quality: dragonflies as study models. In: Rivera, AC (ED). 2006. Forests and Dragonflies. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. *Pensoft Series Faunistica* 61: 268-278. (in English) ["In this chapter we review the potential use of dragonflies for testing current ideas of differences in immune ability related to habitat quality. It is known that immune ability in insects can be affected by a number of biotic and abiotic factors. We briefly review these factors in dragonflies. Given the fact that the same species of dragonfly may live in forests of varying quality (e.g. food abundance), this can lead to immune ability differences among dragonfly populations. We examine the literature regarding this, in particular studies of varying parasite burden and immune ability to advance the hypothesis that forest quality can be assessed using immune ability. One particular trait that may be used for this is male wing pigmentation. Current knowledge suggests that this trait is sexually selected (the more pigmentation, the more successful the male is in leaving more offspring), sensitive to environmental stress (such as food supply) and an indicator of immune ability. These conditions make pigmentation ideal to see the response of dragonflies to forest quality and environmental stress." 8009. Djernaes, M.; Damgaard, J. (2006): Exon-Intron structure, paralogy and sequenced regions of elongation factor-1 alpha in Hexapoda. *Arthropod Systematics & Phylogeny* 64(1): 45-52. (in English) ["Elongation factor-1 alpha (EF-1a) is already widely used and shows even more promise for phylogenetic studies of Hexapoda. However, paralogous copies and the presence of nitrons pose problems. We survey exon-intron structure, presence of paralogous copies and the number and extent of sequenced regions in all hexapod orders. We assess the phylogenetic utility of the exon-intron structure of EF-1a, which is unexpectedly dynamic with widespread losses and several independent instances of intron gain. Paralogous copies of EF-1a are present in Hemiptera, Thysanoptera, Neuropterida, Coleoptera, Hymenoptera and Diptera. With the presented information about exon-intron structure and paralogous copies, researchers will be able to realise the full phylogenetic potential of EF-1a, including exon-intron structure as this can provide additional characters and help to define clades and paralogous copies. We recommend a suitable focus region of 500 bp for future studies of EF-1a in Hexapoda." (Authors) The study includes Odonata.] Address: Damgaard, J., Biological Institute and Zoological Museum, University of Copenhagen, Denmark. E-mail: JDamgaard@bi.ku.dk

8010. Eason, P.K.; Switzer, P.V. (2006): International Journal of Comparative Psychology 19: 268-281. (in English) ["Spatial learning is evident in dragonflies on a variety of spatial scales. Mature dragonflies must be able to locate a variety of features in the habitat that are critical to survival and reproduction, including sites for breeding, foraging, roosting, and thermoregulating. In many species, these sites do not coincide in space. Because individuals may repeatedly use particular sites for different activities, they must learn both the locations of these sites and routes among them. Further evidence of spatial memory in dragonflies is provided by their site specificity on a finer scale. Breeding males, for example, often are faithful not only to a particular area, but to a specific territory site within that area. Males appear to become faithful to a territory site through localization, a process during which they explore the site and develop a spatial map of the location of the territory and its resources. Males also respond to their interactions with other individuals, adjusting both their choice of territories and their space use within their territories to reflect those interactions. In eastern amberwing dragonflies (*Perithemis tenera*), males are not faithful to territories on which they have lost a fight with another male; in contrast, males are more likely to be faithful to territories on which they successfully mated than to territories on which they obtained no matings. Similarly, while on territories, male amberwings adjust their position in response to negative and positive interactions. They

move away from the side of the territory from which neighbors most frequently intruded, and they move toward locations from which they pursued a female. Territorial amberwings thus modify their space use at both the territory and within-territory spatial scale in response to their social environment. Their responses are consistent with the hypothesis that they learn from their positive and negative experiences and adjust their future space use accordingly. Further study of spatial learning in dragonflies would greatly enhance studies of dragonflies' behaviour and ecology, and help us understand learning in general." 8011. Gapud, V.P. (2006): Damselflies (Odonata: Zygoptera) of Greater Luzon, Philippines with description of two new species. *Philippine entomologist* 19(2): 1-42. (in English) ["39 species of damselflies are recorded for Greater Luzon. Of these, 21 are endemic to Luzon and 11 are endemic to the Philippines. Two new species, *Drepanosticta makilingia* and *Amphicnemis isabelae*, are described and illustrated. Thirty of the 39 species are similarly illustrated. The Philippine Odonata are represented by 309 species (Hämäläinen & Müller 1997) with an overall endemism of 65.7%. Of these, the Zygoptera include 186 species with very high endemism (85.5%). Majority of endemic damselflies such as *Risicnemis*, *Drepanosticta*, *Argiolestes*, *Rhinagrion*, *Amphicnemis*, and *Teinobasis* are forest dwellers. Many species remain undescribed and are waiting to be discovered. In 2001, *Argiolestes baltazarrae* Gapud and Recueno-Adorada, was described from a lowland forest beside an inundative river in Digsinan, San Mariano, Isabela, within the Northern Sierra Madre Natural Park. It is not known how many new species will turn out in this biodiversity corridor." (Author)] Address: Gapud, V.P., Univ. Philippines, Coll. Agr., Pest. Biol. and Biodivers. 8012. Hadrys, H.; Clausnitzer, V.; Groeneveld, L.F. (2006): The present role and future promise of conservation genetics for forest Odonates. In: Rivera, AC (ED). 2006. Forests and Dragonflies. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. *Pensoft Series Faunistica* 61: 279-299. (in English) ["Although the history of conservation genetics as a discipline dates back more than two centuries, odonates have only recently entered the scene. This is highly unfortunate since – especially in tropical forests – odonates may serve as prime examples for the application and potential of conservation genetic research. Faced with the same conservation problems as the forests themselves, they epitomize the difficulties of maintaining biodiversity in tropical forests. To date, no data exist on population structures, dynamics, viabilities or histories of afro-tropical forest odonates. Below, a case study is introduced that demonstrates the application of population genetic research to three African damselfly species of the genus *Pseudagrion*. The three species selected represent a habitat gradient ranging from open habitats in Namibia to isolated mountain forests in Kenya and Tanzania. The results of mitochondrial (ND1) sequence analyses revealed strong inter- and intraspecific differences in the population structures of all three species, reflecting their habitat adaptations and demographic distribution. Mean genetic diversity and genetic isolation patterns increased with habitat specificities and restricted distributional range of the species. The two species

with a wider distributional range, *Pseudagrion massaicum*, and *P. kersteni* displayed similar low genetic diversities in Namibia but showed considerable differences in population sub-structures between Namibian and East African populations. The third species, *P. bicocculans*, an endemic of high-elevated mountain forests in Kenya and Tanzania, shows a multifold higher genetic diversity and complete genetic isolation between populations. The comparison with divergence values of true species suggests, that speciation in this species is well advanced. Given that the strong divergence patterns are neither correlated with geographic distance nor with the differences in morphological traits, the results provide a good example on how genetic data can provide information about conservation units and cryptic speciation processes. Future challenges in conservation genetic research for tropical forest species should focus on establishing as many genetic species profiles of current conditions as possible. Those data sets are valuable snapshots of the current conditions and may serve as calibration points for future conservation work." (in English) ["The hatching rate of the eggs of *N. pygmaea*, an endangered dragonfly species in Korea, was experimented in different temperature conditions (10, 15, 20, 25, and 30 °C) in laboratory. *N. pygmaea* eggs were collected from female adults inhabited a small wetland in Mungyong-si, Gyeongsangbuk-do, Korea, in July 2006. The hatching rate was evaluated from the number of hatched nymphs for the period of 100 days. As a result, the hatching rates were 83, 89, and 76% at 20, 25, and 30 deg C, respectively; however, eggs were not hatched at

10 °C and 15 °C during the experiment period. The derived thermal threshold for egg hatching was 14.3 °C, which is relatively higher than the values of other temperate dragonflies." (Authors)] Address: Bae, Y.J., Seoul Women's University, Seoul, Republic of Korea. E-mail: yjbae@swu.ac.kr

8018. Kishimoto, N.; Natori, M.C.; Higuchi, K.; Ukegawa, K. (2006): New deployable membrane structure models inspired by morphological changes in nature. American Institute of Aeronautics and Astronautics, 47th AIAA/ASME/ASCE/AHS/ASC Structures, Structural Dynamics, and Materials Conference, Newport, Rhode Island, 2006/05/01 - 2006/05/04 : 10 pp. (in English) ["Some characteristics of morphological changes in nature are discussed and morphological changes in space structure systems are investigated. Essentially space structure systems change their forms and functions, since they must be initially stowed due to spatial constraints of transportation systems, and deployed in their designed orbits. Recently various concepts of membrane structures are proposed for future large space systems, since they can be compactly stowed, and can easily realize space structures with large area. In their developments, it is a major important issue to ensure the reliability of their deployment processes. From the viewpoint of deployment processes, various morphological changes of some plants, insects (including *Anax parthenope* and *Davidius nanus*), and animals are investigated. The efficient characteristics in their morphological changes such as high redundancy, sequential deployment, utilization of gravity forces, and so on are introduced. A new concept of deployable membrane structure models derived especially from the observation of insects' metamorphosis including eclosion of butterflies, dragonflies, cicadas, and so on is proposed. Numerical results of its deployment behaviour are also shown." - 8025.** Morgan da Costa, F.L.; Oliveira, A.; Callisto, M. (2006): Inventory of benthic macroinvertebrates diversity in the Peti Environmental Station Reservoir of Minas Gerais, Brazil. *Neotropical Biology and Conservation* 1(1): 17-23. (in Portuguese, with English summary) ["The aim of this study was to inventory the diversity of benthic macroinvertebrates of the reservoir of the Peti Environmental Station in Minas Gerais State through the evaluation of these communities in space and temporal scales during the rainy and dry periods from June - 2002 up to June - 2004. The Peti reservoir has almost 50 years and is used for hydropower generation. The benthic macroinvertebrates are an important tool for the evaluation of water quality and environment monitoring through inventories of diversity and data on community structure. A total of 16 taxa was found and the most abundant groups were Chaoboridae (47,51%), the Chironomidae genera *Coelotanytus* (15,1%) and *Chironomus* (2,77%), *Bivalvia* (19,11%) and *Oligochaeta* (9,54%). There were no significant variations ($R = 0,1927$; $p > 0,05$) for the biotic data among the sampling stations during the studied periods. The evaluation of the distribution and structure of the benthic community showed that the quality of the reservoir's water is preserved, because there was no predominance of bad quality indicator organisms. This situation is due to the constant oxygenation of the hypolimnion which is probably related with the reservoir operation." - 8030.** Parr, A.J. (2006): The changing trends of Britain's Odonata. *Atropos* 28: 27-31. (in English) ["Given the increasing numbers of dragonfly enthusiasts in recent years, it is not surprising that new species to Britain have been discovered, and that ranges have become better documented. Considering the small size of the British dragonfly fauna—approximately 47 resident or regular migrant species recorded prior to 1995—the seven new species recorded since then is, however, impressive, and suggestive of more than just increased observer awareness. The colonisation of Small Red-eyed Damselfly, in particular, is an event of significance—even past historic colonists such as Migrant Hawker seem to have taken some while to become widely established. Range changes now being observed for some of our more traditional residents are also substantial, and cannot simply be artefacts of improved coverage. Distribution maps for some species are out of date almost as soon as they are published, and Britain's dragonfly fauna seems to be in a state of flux. Given the nature of the trends being observed in Britain and the near Continent, and the fact that many other taxa, including birds and Lepidoptera, are behaving similarly, it would seem that change is being driven by some broad-scale controlling variable, such as climate. Indeed, in retrospect, modern changes seem to have begun somewhere in the 1980s, at roughly the same time as the British and Northern Hemisphere mean annual temperatures started to rise sharply above their 1961-1990 average (Hadley Centre 2006; University of East Anglia 2006). Many of the events of the last decade or so thus seem likely to be linked to climate change and global warming, whatever the precise underlying reasons behind this phenomenon. It will be of considerable interest to continue monitoring changes to the British dragonfly fauna in the years to come." In: Rivera, AC (ED). 2006. *Forests and Dragonflies*. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. Pensoft Series Faunistica 61: 209-224. (in English) ["Dragonflies are well-known to be sensitive to light conditions, with the various species having a range of light conditions that they prefer. When these conditions are changed, such as by human removal of the tree canopy, the odonate assemblage changes accordingly, with forest species being replaced by species preferring sunlit habitats. Most of the South African species, including the national and local endemics, are mostly species that inhabit sunlit habitats, especially those fringed with indigenous grasses and bushes. During the 20th century, many of the South African riparian corridors became invaded and radically transformed by alien trees, especially *Acacia* spp. As these trees are a threat to hydrological processes, a massive national 'Working for Water Programme' was started to clear riparian zones of these alien trees. These trees were also posing a major threat to local biodiversity, especially endemic odonates. Some odonate species were even on the verge of extinction as a result of shading of their habitats by the alien trees as well as from various synergistic impacts such as over-abstraction of water and damage to the banks by domestic livestock. The recovery of some of these odonate species as a direct result of alien tree removal has been absolutely remarkable, and is a strong message in support of genuinely effective and positive conservation action involving removal of alien trees." (2006): Biological measures and water quality indices in a micro-watershed polluted with urban and tannery sewage in south Brazil. *Acta Biologica Leopoldensia* 28(1): 17-24. (in Portuguese, with English summary) ["The article is based on a comparative study between biological measures based on the benthic macroinvertebrate communities and the Water Quality Index (WQI) determined by physical-chemical parameters. The data were collected in the downstream region of the Sinos river basin, in the State of Rio Grande do Sul, at six sites located in the longitudinal gradient of the Peão creek and in the Sinos river. The macroinvertebrate sampling followed the methodology proposed by the Environmental Protection Agency (EPA) of the United States of America and the water analyses were conducted according to standard methods established by the American Public Health Association (APHA). The macroinvertebrate communities were

evaluated by the Shannon-Wiener diversity index, the Hilsenhoffs Family-level Biotic Index and the Biological Monitoring Working Party (BMWP) Score System. These biotic indices presented a strong correlation with the WQI. Whereas the Shannon-Wiener diversity index and the BMWP biotic score system indicated a positive correlation with the WQI values ($r = 0.680$ and $r = 0.567$ respectively), the Hilsenhoff Biotic Index presented a negative correlation ($r = -0.667$). Thus, the benthic macroinvertebrates are important indicators of the water quality and can provide relevant information for the water quality management program in the Sinós river basin." (Authors) Odonata are treated on the family level.] Address: Strieder, M.N., Programa de Pós-Graduação em Biologia – Universidade do Vale do Rio dos Sinós - UNISINOS, Caixa Postal 275, 93001-970, São Leopoldo, RS, Brasil. 8039. Sulem; S.Y.; Brummett, R.E. (2006): Relative importance of various predators in *Clarias gariepinus* fry mortality in Cameroon. *NAGA, WorldFish Center Quarterly* 29(3/4): 74-77. (in English) [The authors study interspecific competition between fishes and dragonflies. "To estimate the relative importance of the most common predators of *C. gariepinus* fry, increasing levels of protection were afforded to exclude amphibians, aquatic arthropods and birds. At a stocking density of 10 larvae/m² in nursing ponds, fencing off amphibians resulted in a 28 per cent decrease in mortality. Holding fry in hapas to protect them from both amphibians and aquatic arthropods decreased mortality by an insignificant 5.7 per cent. Installation of bird-netting over the hapas reduced mortality by 21.7 per cent. The remaining 4.9 per cent of total mortality, which could not be explained, was attributed to opportunistic cannibalism, disease and/or handling stress. Increasing stocking density to 40/m² and, thus, reducing the food available per fry increased mortality by 28.3 per cent." (Authors) Aquatic arthropods were most notably dragonfly larvae that entered the pond after filling through direct oviposition from the airborne female. But: "The selection of such hapas as a defense against aquatic insects was based on the observation that these predators are common in open ponds at the PARC, but have never been found in hapas. Presumably, any insect eggs laid directly into a hapa are vulnerable to predation by the larval catfish." The breeding hapa is a box-like enclosure (2 m x 1.5 m x 1.0 m) stitched out of square-meshed mosquito netting cloth and tied on to bamboo poles fixed in ponds or tanks so that about 0.3 m is above the water level while its bottom is 0.3 m above the pond bottom. For more details see e.g.: <http://aquacomm.fcla.edu/1728/1/Better-Practice5opt.pdf>] Address: Sulem, S.Y., IITA-Cameroon (Attn: R.E. Brummett), c/o L.W. Lambourn & Co. 8040. Tam, T.-w.; Lee, V.L.F. (2006): 17th International Symposium of Odonatology at Hong Kong Wetland Park. *Hong Kong Biodiversity* 12: 16. (in English) ["The symposium provided a valuable platform for odonate experts to share their experience and research findings. Keynote speakers talked about the uses and values of dragonflies for monitoring freshwater ecosystem health, dragonfly biodiversity in South East Asia and dragonfly conservation in Africa. Other participants presented papers on dragonfly biology, morphology, ecology, conservation, taxonomy, reproduction and habitat enhancement. The symposium included a field trip to Sha Lo

Tung for participants to appreciate the 'winged jewels' and the Hong Kong countryside. There was also a five-day tour to Nankanshan mountain ranges, in mainland China, after the symposium. Nearly half of the participants joined the tour. They found it to be a great opportunity to examine this unexplored insect group, making a few new records (e.g. *Aciagrion tillyardi* and *Philosina* sp.) for the area. [...]" (Authors)] Address: not stated

8041. Taylor, P. (2006): Movement behaviours of a forest odonate in two heterogeneous landscapes. In: Rivera, AC (ED). 2006. *Forests and Dragonflies*. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. *Pensoft Series Faunistica* 61: 225-238. (in English) ["The results from an empirical survey of *C. maculata* along streams in both a largely forested landscape and a more open, agricultural landscape are compared so simple measures of landscape structure, and the output from a behavioural simulation model based on a set of simple rules that govern how *C. maculata* accesses resources in the two landscapes. In the more open landscape, only proximity of the forest to the stream explains the empirical pattern of distribution, but in the more forested landscape, only simulated use of streams does. Further, populations are aggregated at broader spatial scales in the more open landscape. Collectively, the results suggest that *C. maculata* move more extensively when compared to the more closed, forested landscape, which has implications for landscape scale population structure." 8044. Wagstaff, W. (2006): An unusual Migrant Hawker *Aeshna mixta*. *Atropos* 28: 84. (in English) [UK; "... around St Agnes, Isles of Scilly, on 16 VIII 2005 I noticed a hawker dragonfly zipping about over Bracken *Pteridium aquilinum* near the sandbar across to the Isle of Gugh. It was not easy to get views until it perched about 60ft from us, at which point I was able to set my telescope up. I soon realised that although it was probably a *A. mixta*, a species I had seen many times on Scilly, it showed far more orange on the abdomen compared to any I had seen before. [...] Having subsequently looked up *A. mixta* in the available literature I could find no reference to any hawker showing the orange that was so obvious in the field." Adrian Parr comments on the "abnormal" colour as follows: "As can be seen from the shape of the markings on abdominal segments S2/S3, this individual is actually a female *A. mixta*, despite the blue abdominal spots (the yellow markings in *A. mixta* are known to become bluish in some individuals, an effect in part probably related to ageing but likely to involve other factors). Females of many species of hawker show a more brownish ground colour to that of the

males with which most people are more familiar, and in *A. mixta* this is quite orangey. This individual nicely illustrates some of the subtle variation that it is difficult to convey in field guides, where there is space for only one or two illustrations."] Address: Wagstaff, W., 42 Sally Port, St Mary's, Isles of Scilly, TR210JE, UK

8045. Walia, G.K.; Sandhu, R.; Goyal, S. (2006): Cytogenetical analysis of *Nepogomphus modestus* from Palampur area of Himachal Pradesh, India (Gomphidae : Anisoptera). *Chromosome Science* 9: 99-100. (in English) [Primary spermatocyte chromosome analysis of *N. modestus* "showed haploid number $n(\text{male}) = 12$ consisting of 11 bivalents and a univalent. In the complement, m chromosomes were lacking. The univalent, the largest element in the complement, is X chromosome. The result indicates that diploid chromosome number of *Nepogomphus modestus* is $2n(\text{male}) = 23 = 22A+X$. *N. modestus* is the first species described cytologically among three species known to genus *Nepogomphus*." Thesis presented in partial fulfilment of the requirements for the degree of Master of Science, Department of Conservation Ecology and Entomology, Faculty of Agricultural Sciences, University of Stellenbosch: 123 pp. (in English) [Young crocodilians primarily predate on insects (Coleoptera, Orthoptera and Odonata) and arachnids. These decrease in importance as the crocodilian increases in size. Larvae of *Orthetrum* sp., *Trithemis* sp., and *Phyllomacromia* sp. were identified as stomach items in young crocodiles.] Address: <http://etd.sun.ac.za/bitstream/10019/1300/1/Wallace,%20KM.pdf>

8047. Watanabe, M. (2006): Mate location and competition for mates in relation to sunflecks of forest floors. In: Rivera, AC (ED). 2006. Forests and Dragonflies. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. *Pensoft Series Faunistica* 61: 259-268. (in English) ["Although most forest odonate species have a maiden flight away from water and sexually immature adults stay in the forests foraging for food, mature males of some species (e.g. *Platycnemis echigoana*, *Letes sponsa* and hyaline-winged males of *Mnais pruinosa costalis*) tend to remain in forests. To locate females in the forests, males mainly perch in sunflecks (a sunlit site in the forest floor) and adopt a sit-and-wait tactic. Some of them try to occupy perching sites. Territorial behaviour of males of *P. echigoana* is described at sunflecks in climax deciduous forests, Males showed patrolling flight along the periphery of the sunfleck. and hovering flight above it. suggesting that such flight was a display associated with the occupation of the sunfleck. Flight behaviour of the damselfly, *L. sponsa*, in The forest floor also showed male-male interference and the existence of a lek-like mating system is discussed. Some solitary males interfered in copulation in the forest floor, while others were also observed on the shoreline of the pond throughout the day. but they did not harass pairs ovipositing in tandem. Although hyaline-winged males of *M. pruinosa costalis* adopt, sneak tactics, a male that failed in occupying a perching site to intercept females entering the territory is called an 'opportunist', which moves around forest floor with sunflecks to search females. The longest copula dura-

tion was observed in the opportunists, suggesting that the entire sperm displacement must be occurred. These observations point to functional relationships with habitat selection and thermoregulation. Perching behaviour under direct, sunlight at sunflecks was shown to result in considerable variation in thermoregulatory properties. The relationships of thermoregulation to mate location strategy are different among species. A male that has been able to perch in direct sunlight will gain an advantage over an individual that lies not. and this advantage may manifest, itself in fights with other males. Forest structures with sunflecks are discussed from the viewpoint of habitat selection acting on female choice. These relationships are also relevant to other behaviours, particularly oviposition behaviour by water. Adults that showed mating behaviour in the forests oviposit in tandem by water. The importance of sunflecks in the forest floor is discussed in relation to the life history strategies of the damselfly species inhabiting forests." 8049. Wilson, K.D.P. (2006): New *Planaeschna* record from Hong Kong (Odonata: Aeshnidae). *Porcupine* 34: 5-6. (in English) [Verbatim: During late October 2005 I undertook a crepuscular survey of dragonflies at Wu Kau Tang. In the 10-20 minute feeding frenzy which takes place just before dusk, I captured a total of seven aeshnid specimens using a net. Six of the seven specimens were identified as *Gynacantha japonica* Barteneff and the remaining specimen belongs to the genus *Planaeschna* McLachlan. It may represent an undescribed species. No previous species of *Planaeschna* has been recorded from Hong Kong. The genus *Planaeschna* is mainly confined to Indo-China with outliers occurring in South China, Thailand, Burma, India (Assam) and Japan. Seven species of *Planaeschna* have been described from China, which are *P. celia* Wilson & Reels, 2001 (Hainan), *P. gressitti* Karube, 2002 (Guangdong), *P. maolanensis* Zhou & Bao, 2002 (Guizhou), *P. risi* Asahina, 1964 (Japan & Taiwan), *P. shanxiensis* Zhu & Zhang (Shanxi), *P. suichangensis* Zhou & Wei, 1980 (Guangdong, Guangxi & Zhejiang), *P. taiwana* Asahina, 1951 (Taiwan). In addition, a further five species of *Planaeschna* have been described from Vietnam. A total of 17 species have been described to date with nine of these named in the last 10 years. The Hong Kong female *Planaeschna* does not belong to *suichangensis*, which is the most widespread and abundant *Planaeschna* species recorded from Guangdong. Currently the female *gressitti* is unknown but the abdomen does not have yellow spots, adjacent to the transverse carina, which are linked to basal, ventral yellow spots to form a yellow median from S3-8. This ringed pattern is possessed by male *gressitti* (Karube, 2002) and in all other *Planaeschna* species the feature is exhibited by both males and females. The Hong Kong female does not have this feature so is most unlikely to belong to *gressitti*. Two new species of *Planaeschna* from central and north Guangdong await description but the Hong Kong female does not belong to either of these new species. It is closest to *risi* but further specimens are

nevertheless required, especially a male, before a clear placement of the Hong Kong *Planaeschna* can be made. *Planaeschna risi* was recorded from Guangxi by Wilson (2005) but evaluation of further material from Guangxi and Guangdong indicates this material does not in fact belong to *risi*, which is endemic to Taiwan and the Ryukyu islands. The Hong Kong female *Planaeschna* was collected over abandoned marshy agricultural land at San Uk Ha, Wu Kau Tang on the evening of 30 October 2005. *Planaeschna* larvae dwell in flowing streams usually in montane, forested areas. Most species are known from altitudes exceeding 500 m. Only one species, described from North Vietnam, *Planaeschna cucphuongensis* Karube, is known from lowland forest (Karube, 1999). The new *Planaeschna* species is likely to breed in montane forested tributary streams in the country park surrounding Wu Kau Tang but its larvae may utilize the tributaries or main stream flowing through the Wu Kau Tang basin i.e. the area covered by the Wu Kau Tang Outline Zoning Plan.] Address: Wilson, K.D.P., Dragonfly Ecological Services, 18, Chatsworth Road, Brighton, BN1 5DB, UK. (2007): Seleção intra-sexual na libélula *Homeoura nepos* (Zygoptera: Coenagrionidae): conflito sexual e sistema de acasalamento. *Dissertação apresentada ao Departamento de Ecologia da Universidade de Brasília, como requisito parcial à obtenção do grau de Mestre em Ecologia, Instituto de Ciências Biológicas Departamento de Ecologia*: 60 pp. (in Portuguese, with English summary) ["Sexual dimorphism, agonistic interactions and the type of association between males and their sexual partners are characteristics subjected to selective pressures that determine the type of mating system of a species. In Odonata. Two types of mating systems occur: resource defense

polygyny and polygyny through scramble competition. In the latter type, there is no consensus concerning the role of sexual dimorphism, the influence of individual size in agonistic interactions and the type of selective pressures that influence the occurrence of tandem (post copulation guarding). In this study I used *Homeoura nepos* as the model species to analyze: 1) type of sexual dimorphism; 2) effect of environmental temperature, body size and local density of males, male distance to the shore, and residency upon agonistic interactions; 3) influence of male and female density at the oviposition site, and the effects of environmental temperature and wind upon tandem duration and upon oviposition events that occur during tandem; and 4) the effect of male body size on tandem duration. In the species analyzed, females had longer wings than males, male density at the sites where interactions occurred influenced agonistic encounters and resident males won more fights, supporting the hypothesis of asymmetric contest. Tandem duration was longer when other females were abundant in the immediate area and there was also a positive tendency between tandem duration and temperature, which suggests that environmental temperature can contribute to male permanence in tandem. Oviposition events were more abundant in sites with higher male density. The wind had no effect on the behaviours evaluated. It is assumed that *H. nepos* presents scramble competition polygyny. Nevertheless, some predictions of this hypothesis concerning post copulatory association were not met, indicating the necessity of more studies on the behaviour of tropical damselflies." (2007): Composition et distribution des assemblages d'invertébrés dans la zone hyporhéique d'une plaine alluviale de la Moyenne-Durance. *Ecologia mediterranea* 33: 5-13. (in French, with English summary) ["Alluvial flood plains are among the most heterogeneous and dynamic ecosystems in the world. This heterogeneity is linked to the mosaic of terrestrial and aquatic habitats in surface waters, as well as to the functional relationships between surface and subsurface waters via the hyporheic zone (i.e. the ecotone between benthic and groundwater compartments). In natural systems, discharge and flow variability influence the connectivity among habitats and ecological conditions within habitats that contribute to the richness of flood plains. However, the natural dynamics of many rivers and streams have been impacted by regulation and low residual discharge that change the composition

and structure of invertebrate assemblages. In the Durance River, a regulated river in the south-east of France, the benthic fauna of the main channel has been widely studied, but the hyporheic zone has never been considered. In this study, we present some first data on the composition and the distribution of invertebrate assemblages from the hyporheic zone of an alluvial flood plain located in the middle stretch of the Durance. This study provides some biological information on a poorly known compartment of this sub-Mediterranean system." 8064. De Block, M.; Stoks, R. (2007): Flight-related body morphology shapes mating success in a damselfly. *Animal behaviour* 74: 1093-1098. (in English) ["A small-male mating advantage has been only rarely encountered in territorial species and may be an artefact of selection on covarying traits linked to flight-related body morphology. Here, we explicitly tested its occurrence in the territorial damselfly, *Lestes viridis*, while taking into account two key traits shaping flight performance: relative thorax mass and wing asymmetry. Morphological correlates of mating success were determined by comparing sets of mated and unmated males in a natural population at two different collection dates. We showed consistent morphometric differences between mated and unmated males across both sampling dates, suggesting consistent sexual selection on these traits. Mated males were smaller, had a higher relative

thorax mass (proxy for flight-muscle ratio), and showed lower levels of fluctuating asymmetry in the hindwings compared with unmated males. Moreover, these patterns remained when taking their potential covariation into account, suggesting they were directly selected for. As such, we provided the first multivariate proof for a small-male mating advantage in a territorial species taking into account two other key traits related to flight-related body morphology. Given the assumed mechanistic base (low energy consumption and high flight manoeuvrability), we hypothesize that a small-male mating advantage may not be that rare in flying territorial species." 8065. De Knief, G. (2007): Report of the European Odonata camp in Romania. Libellenvereniging Vlaanderen - nieuwsbrief 1(3): 12-13. ["The dragonfly fauna of Romania is one of the least known in Europe. To better understand its fauna, a European fieldwork meeting was organised in July 2007 with almost 30 odonatologists from 9 different European countries. In total 42 species were observed and an area of approximately 120 by 150 km was investigated. Along the streams in the mountains we found *Cordulegaster heros* and *C. bidentata* widely distributed. The fieldwork shows that it is likely that *C. boltonii* is absent in this region and is replaced by *C. heros*. Research on mountain lakes and peatbogs (1500-2000m asl) resulted in the discovery of *Somatochlora arctica* and several populations of *S. alpestris*. Both species were hitherto unknown or very doubtfully cited for Romania. Other remarkable faunistic findings were one of the first records of *Erythromma lindenii* and the first evidenced record of *Lestes viridis* for Romania." (Author)] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. E-mail: geert.deknijf@inbo.be

8066. De Knijf, G. (2007): Excursion of the 12th of August to the nature reserve Hageven in Neerpelt. Libellenvereniging Vlaanderen —nieuwsbrief 1(3): 8-9. (in Dutch, with English summary) ["A total of 23 species were observed during the fieldtrip. The most interesting were the high numbers of *Lestes virens* (>120) and the rediscovery of *Somatochlora flavomaculata* at several fens. The main reason for this fieldtrip was to assess the status of the once rather common *Sympetrum depressiusculum* in the reserve. We only could find 3 and 4 individuals at two different localities in the reserve. This low number is very alarming since the species disappeared at most sites the last 5 years in Flanders." 8067. De Marmels, J. (2007): *Tepuibasis* gen. nov. from the Pantepui region of Venezuela, with descriptions of four new species and with biogeographic, phylogenetic and taxonomic considerations on the *Teinobasinae* (Zygoptera: Coenagrionidae). *Odonatologica* 36(2): 117-146. (in English) [The new genus *Tepuibasis* includes 7 species, all endemic to Pantepui; - 4 are new to science, viz.: *T. garciana* sp. n. from the Serranía de Maigualida, *T. nigra* sp. n. from Cerro Yutajé and Cerro Yaví, *T. rubicunda* sp. n. from Cerro Guanay, and *T. thea* sp. n., also from Cerro Guanay. *T. chimantai* (De Marmels, 1988), comb. n., *T. fulvum* (Needham, 1933),

comb. n. and *T. neblinae* (De Marmels, 1989) comb. n. are transferred to *Tepuibasis* from *Aeolagrion* Williamson, 1917. The new genus falls within *Teinobasinae* Tillyard, 1917 (= *Amphicneminae* Fraser, 1957 syn. n. = *Nehalenniinae* De Marmels, 1984 syn. n), and herein within *Teinobasini*, because of the presence of an articulated ventrobasal spur on the male cercus. Other noticeable features of *Tepuibasis* are a bifid apical penis segment, and a spiny, auricle-like process directed proximad, at the base of each of the lobes forming bifid tip. *Tepuibasis* evolved out of ancestral *teinobasine* stock with considerable morphogenetic potential reflected by the large number of recent genera present in cratonic S. America, which is equaled only by insular SE Asia. Taxogeny of *Tepuibasis* was triggered by the uplift of the Guyana shield, and the vicariant species are the result of secondary isolation through fracturing and partial erosion of these highlands." (Author)] Address: De Marmels, J., Inst. Zool. Agrícola, Fac. Agronomía, Univers. Central de Venezuela, Apdo. 4579, Maracay 2101, Edo. Aragua, Venezuela. E-mail: demarmjc@hotmail.com

8068. Duffey, A. (2007): Genetic structuring among naturally isolated dune lake populations; a microcosm of evolutionary processes on oceanic islands. Thesis submitted for the degree of Doctor of Philosophy, Queensland University of Technology, Faculty of Science, School of Natural Resource Sciences: XIII, 121 pp. (in English) ["Oceanic islands have been used as model systems for studies of evolution and speciation as the range of island sizes coupled with their known geological chronosequence make them ideal systems for the study of spatial and temporal variations in species diversity and distributions. These processes also occur on continental islands and mainland habitats but features of oceanic islands, notably their clearly delimited boundaries, natural isolation and simple geological composition make them more amenable to study. The perched dune lakes of Fraser Island, Australia share many of the properties of oceanic islands. The naturally isolated formation of the perched lakes, clearly delimited boundaries of the freshwater habitat and phase difference compared to the surrounding, terrestrial environment have significant implications for the biota these lakes support. Inhabitants of the perched dune lakes consist of the aquatic and semi-aquatic descendants of colonisers that were able to traverse a land barrier and survive in the oligotrophic acidic waters over subsequent generations. Barriers to ongoing gene flow among lake populations, are however likely to be different for species with different life history characteristics. I therefore sought to assess the effects of three different life history characteristics on post-colonisation inter-population gene flow. A representative species was selected to represent one of each of the following life history characteristics: • Aquatic species confined to lake for entire life cycle - freshwater shrimp *Caridina* indistincta, • Semi-aquatic species capable of terrestrial dispersal - freshwater turtle *Emydura krefftii*, • Semi-aquatic species capable of aerial dispersal - odonate *Orthetrum boumiera*. 137-250 individuals were sampled per species across six lakes separated by 1-6km. Regions of the mitochondrial genome were targeted and molecular screening methods developed and employed to assess the relative levels of post-colonisation gene flow among lake populations. Parsimony analysis of the 25 unique haplotypes identified in the species with no apparent inter-lake dispersal mechanism, the freshwater

shrimp *Caridina indistincta*, demonstrated that there was no sharing of derived haplotypes among lake populations. Star shaped genealogies were identified in four lake populations indicative of a population expansion and mismatch distribution analysis confirmed a recent population expansion estimated to have occurred no more than 200,000 years ago. This demonstrates that each of the perched dune lakes was colonised by *C. indistincta* soon after their inception but that no ongoing gene flow among lake populations has occurred. The population genetic structure of the species assessed which is capable of terrestrial dispersal suggests that although this species of freshwater turtle, *Emydura krefftii*, is capable of overland dispersal, gene flow among lake populations is limited. Even at the small spatial scale examined in this study, *E. krefftii* populations displayed a pattern of isolation by distance ($r=0.854$, $p<0.03$). Nested clade analysis also suggested a pattern of restricted gene flow with some long distance dispersal in recent times with long distance dispersal and a possible range expansion occurring historically. The species examined in this study that displayed the most extensive gene flow among lake populations was the dragonfly *Orthetrum boumiera* (population pairwise $i>st$ all <0.1). No relationship was found between genetic and geographic distance ($r=-0.0852$, $p>0.05$) and nested clade analysis could not identify a geographical association among haplotypes indicative of panmixia. While larval life stages of this species are fully aquatic, the winged adult stages of this species appear to be connecting seemingly isolated lake populations, at least at the spatial scale examined here. The results of this study have demonstrated that these perched dune lakes provide 'island like' models for recent biogeographic processes. The pattern of colonisation and subsequent diversification identified in these populations takes the form of in-situ 'genetic radiations' with those populations that are isolated forming monophyletic clades endemic to a single lake. The genetic diversity and endemism identified in this study has occurred over much smaller temporal ($<500,000$ years) and spatial (<6.5 km) scales than in studies of oceanic island fauna. However, the mode of formation of the perched dune lakes and the implications that their natural isolation and abiotic genesis have for the evolution of colonisers of these unique habitats has resulted in them being analogous to true oceanic islands." (Author) Address: Duffy, Angela, further details not stated

8069. Duran, M.; Kara, Y.; Akyildiz, G.K.; Özdemir, A. (2007): Antimony and heavy metals accumulation in some macroinvertebrates in the Yesilirmak River (N Turkey) near the Sb-mining area. *Bull. Environ. Contam. Toxicol.* 78: 395-399. (in English) [Mobility and the biological role of Antimony (Sb), its behaviour and transfer into food chain, are not well known. Total Sb concentrations in natural waters have been reported to be in the range of 0.01–1.1 mg/L (US EPA 1996). Acutely toxic concentrations of Sb are in the range of 22–36 mg/L fish (Lin and Hwang 1998), and 9–20 mg/L for daphnids (Anderson 2000), although the toxicity database is small. All these concentrations are above the typical range of concentrations in mine effluents. Therefore, Sb is unlikely to contribute appreciably to effluent acute toxicity. A decline in biodiversity of macroinvertebrate communities has generally related to metal pollution but Sb is not often studied in contrast to Zn, Cu and Cd. "This work presents total Sb, Cd, Pb, Zn and Cu accumulation in water, sediments, some macro-

invertebrate from active antimony mining area. We were interested in comparing heavy metal levels between mine impacted and non impacted sites. Also, this study addresses the impact of Sb-mining on biological components of macroinvertebrate of this part of Yesilirmak River." (Authors) *Leucorrhinia dubia* was identified in the effluent of the mine - certainly wrongly so as *L. dubia* does not inhabit running waters but mires and bogs. Accumulation of heavy metals is presented. The density of the odonate taxa is higher in the effluent of the mine compared with the unimpacted stretch of the water. Antimony and lead concentrations are higher in specimens from the effluent.] Address: Duran, M., Fac. of Science and Arts, Dept of Biology, University of Pamukkale, Denizli 20070, Turkey. 8071. Ferris, G.; Rudolph, V.H.W. (2007): Responses of larval dragonflies to conspecific and heterospecific predator cues. *Ecological Entomology* 32: 283-288. (in English) ["1. In cannibalistic populations, smaller individuals are subject to predation by larger conspecifics, and small individuals commonly alter their behaviour in response to cannibals. Little is known, however, about the underlying cues that trigger such responses and how the behavioural responses to conspecific cannibals differ from heterospecific predators. 2. This study tests which cues are used for the detection of conspecific predators in the larva of the dragonfly *Plathemis lydia* and how the behavioural response to cannibals differed from the response to heterospecific predators. 3. Individuals were exposed to chemical cues, visual cues, and a combination of both cues from conspecifics as well as no predator and heterospecific predator controls during which their activity and feeding rates were observed. 4. Individuals increased their activity, spatial movement and feeding behaviour in response to either visual or chemical cues from conspecific predators, which was opposite to responses displayed with cues from heterospecific predators. Interestingly, the responses to visual and chemical cues from conspecifics combined were weaker than to either cue in isolation and similar to the no cue control. 5. The results clearly indicate that individuals are able to use chemical and visual cues to detect even very subtle differences in phenotype of conspecific predators. 6. The opposite response in behaviour when exposed to conspecific cannibals vs. heterospecific predators suggests that the presence of cannibals will increase the mortality risk of small individuals due to heterospecific predation. This risk-enhancement is likely to have important consequences for the dynamics of predator – prey interactions.] Address: Volker H. W. 8076. Kadoya, T.; Washitani, I. (2007): An adaptive management scheme for wetland restoration incorporating participatory monitoring into scientific predictions using dragonflies as an indicator taxon. *Global Environmental Research* 11(2): 179-185. (in English) ["Here we propose an adaptive management scheme for wetland restoration using data collected by citizens to make scientific predictions. We assessed the potential advantages of such a scheme using a wetland restoration project conducted in a small floodplain area along the Matsu-ura River in Kyushu, Japan. For the case study, we compiled data provided by amateur naturalists on distribution patterns of dragonflies on the eco-regional scale, as well as ecological characteristics such as behaviour and habitat preferences. Based on this information, we predicted a species recovery trajectory at the wetland restoration site. By monitoring species recovery to test our prediction, we demonstrated that colonization by dragonfly species at the restored site could be predicted using species prevalence on the regional scale based on the nestedness rule. The data collected by the amateur naturalists were critical in making this prediction, which highlights the importance of citizen participation in the proposed scheme."] Address: Kadoya, T., Dept Ecosyst. 8077. Kim, K.g.; Jamg, S.K.; Park, D.W.; Hong, M.Y.; Oh, H.-H.; Kim, K.Y.; Hwang, J.S.; Han, Y.S.; Kim, I.K. (2007): Mitochondrial DNA sequence variation of the Tiny Dragonfly *Nannophya pygmaea* (Odonata; Libellul-

idae). *Int. J. Indust. Entomol.* 15(1): 47-58. (in English) ["*N. pygmaea* is one the smallest dragonflies in the world and listed as a second-degree endangered wild animal and plant in Korea. For the long-term conservation of such endangered species, an investigation on nation-wide genetic magnitude and nature of genetic diversity is required as a part of conservation strategy. We, thus, sequenced a portion of mitochondrial COI gene, corresponding to "DNA Barcode" region (658 bp) from 68 *N. pygmaea* individuals collected over six habitats in Korea. The sequence data were used to investigate genetic diversity within populations and species, geographic variation within species, phylogeographic relationship among populations, and phylogenetic relationship among haplotypes. Phylogenetic analysis and uncorrected pairwise distance estimate showed overall low genetic diversity within species. Regionally, populations in southern localities such as Gangjin and Gokseong in Jeollanamdo Province showed somewhat higher genetic diversity estimates than those of remaining regions in Korean peninsula. Although geographic populations of *N. pygmaea* were subdivided into 2 groups, distance- or region-based geographic partition was not observed." 8079. Martin, K. (2007): Chipmunks as predators of emerging Odonata. *Argia* 18(4): 12. (in English) ["During the summer of 2006, I observed four cases of *Gomphus vastus* predation by Eastern Chipmunk (*Tamias striatus*). All of the predation occurred on a sandy exposed beach located within the Turner's Pool area of the Connecticut River. The beach in this area is a wide (100 ft) sandy section, that lacks emergent vegetation and has only a few protruding logs. The beach area abuts a steeply forested slope, which provides ample cover for chipmunks. Predation was observed on 24 June 2006 between 8:00 and 8:40 AM, 3.7-3.9 m from the water's edge. As I sat at the edge of the study area, I observed several *G. vastus* nymphs emerging from the water, as they proceeded to crawl across the beach toward the bank, two chipmunks emerged from a small hole on the bank. The chipmunks ran down the hill and across to a large fallen log that partially extended over one side of the beach. As the first *G. vastus* neared the tip of the log, one of the chipmunks jumped down, pounced on the nymph, and carrying it in its teeth, ran up the bank and sat on a large rock. Another nymph neared the log, which the second chipmunk also grabbed and ate. While I was noting this behaviour, two more chipmunks emerged from opposite sides of the study area, and ran out onto the same log. Within a maximum period of five minutes, each of these chipmunks had also grabbed an emerging nymph. I did not observe any aggressive interactions between the four chipmunks. The chipmunks did not venture out onto the exposed section of the beach, but instead stayed near the fallen log, and the exposed roots that lined the

bank. Chipmunk predation of dragonfly nymphs may be a rare event, as during the 24 days (192 hours) of field-work conducted this season, these were the only such events that were observed." (Author)] Address: Martin, Kirsten, Environmental Studies, Antioch University New England, Keene, NH, USA. E-mail: Kirsten.Martin@antiochne.edu

8080. Mills, C. (2007): *Aphylla williamsoni* (Two-striped Forceptail) new for Arkansas. *Argia* 18(4): 34. (in English) [Okay Landing area of Millwood Lake in Howard County, Arkansas, USA 2-IX-2006] Address: Mills, C., Ogden AR 71853, USA. E-mail: cmills@arkansas.net

8081. Neiss, U.G. (2007): Estrutura da comunidade de microinvertebrados aquáticos associados a *Mauritia flexuosa* Linnaeus (Arecaceae). fitotelmata. na Amazônia Central, Brasil. Dissertação (mestrado)- INPA / UFAM. Manaus: X, 79 pp. (in Portuguese, with English summary) ["Adult *M. flexuosa* palms, known locally as buriti, have large individual axillae that can store substantial volumes of water (phytotelmata). The objectives of the present study were to compare the aquatic macroinvertebrate fauna associated with the axillae of palms occurring in groups and as isolated trees in order to verify the relationship between abiotic factors (volume of water, pH, electrical conductivity, dissolved oxygen and height above the ground) and the macroinvertebrates, in addition to inferring a trophic web for these organisms. A total of 60 axillae were sampled in May and June 2006. distributed over 17 rural and semi-urban locations in Manaus and President Figueiredo counties, Amazonas state, Brazil. A total of 31,135 individuals distributed over 19 macroinvertebrate taxa were collected. The families Chironomidae and Ceratopogonidae were the most abundant (32.2% and 29.6% respectively), followed by Oligochaeta (17.5%), Acarina (9.6%) and Culicidae [*Culex* (*Microculex*) *stonei* Lane & Whitman, 1943 (3.4%), *Culex* (*Mcx.*) *pleuristriatus* Lutz, 1903 (2%), *Culex* (*Mcx.*) *sp.1* (1.8%), *Culex* (*Culex*) *mollis* Dyar & Knab. 1906 (0.6%), *Wyeomyia* *sp.* (16 individuals) and *Toxorhynchites* (*Haemorrhoidalis*) *haemorrhoidalis* (Fabricius, 1794) (1 individual)]. For each axilla. the following averages (\pm SD) were calculated: individuals per axilla: 519 (\pm 348); volume of water: 1075 mL (\pm 972); temperature: 27.3 °C (\pm 1.4); pH: 5.6 (\pm 0.7); electrical conductivity: 25.2 μ S/cm (\pm 18.4) and dissolved oxygen: 7.3 mg/L (\pm 1.3). The most frequent taxa were *Culicoides* spp. and *Endotribelos* sp., both with 100% occurrence, followed by *Oligochaeta* (93.3%), *Acarina* (85%) and *Culex* (*Mcx.*) *stonei* (75%). The final multiple regression model relating macroinvertebrate abundance to the abiotic variables explained 25.3% of the variance ($F_{4,55}=4.66$; $p=0.0026$), volume being the only variable that was related to abundance ($p=0.007$). Multiple regression for species richness was not significant ($F_{4,55}=2.31$; $p=0.069$). The numbers of Culicidae and Odonata individuals showed significant positive relationships with water volume ($p=0.0009$ and $p=0.045$, respectively). The distribution of macroinvertebrates not differed between grouped and isolated palm trees (ANOSIM. $R=0.037$; $p=0.029$), the abundance of Odonata being influenced by the grouping of the trees (t-test, $p=0.048$). The presence of Odonata larvae (top predators in the ecosystem) appears not to influence the abundance of Culicidae larvae in the axillae of *M. flexuosa* (t-test, $p=0.382$). Analysis of the stomach content of Odonata representatives found in the buriti (Coe-

nagrionidae sp. and *Erythrodiplax* sp.) revealed Chironomidae, Ceratopogonidae and Culicidae as the most frequent prey. Diptera was the most frequent and abundant group, confirming the importance of this insect in communities associated with phytotelmatas. In comparison with other phytotelmata studies, the trophic web found in the *M. flexuosa* axillae is relatively complex, involving 20 taxa: the top predator of this web is represented by *Coenagrionidae* sp. and *Erythrodiplax* sp." 8090. Randel, C.J.; Aguirre, R.; Peterson, M.J.; Sly, N.J. (2007): Invertebrate abundance at Rio Grande Wild Turkey brood locations. Journal of Wildlife Management 71(7): 2417-2420. (in English) ["Abundance of Rio Grande wild turkeys (Meleagris gallopavo intermedia) has declined in the southeastern Edwards Plateau (EP) of Texas, USA, whereas abundance has remained stable in the northwestern EP. Invertebrates are a critical protein source for poult <6 weeks posthatch. We collected invertebrates at brood and paired locations in both the stable and declining regions. Our objective was to determine if differences in invertebrate abundance existed in regions typified by declining versus stable Rio Grande wild turkey abundance. We found no difference in invertebrate abundance between brood or paired locations within regions, but invertebrate abundance, whether measured as dry mass or frequency, was greater in the stable region. Decreased invertebrate abundance may have contributed to the decline in wild turkey abundance in the southeastern EP." (Authors) The study includes Odonata (at the order level) data of biomass and frequency of occurrence.] Address: Randel, C.J., Sapphos Environmental, Inc., Pasadena, CA 91105, USA. 8091. Rensburg, A.J. (2007): Aquatic and terrestrial vegetation influence lacustrine dragonfly (order Odonata) assemblages at multiple life stages. Ph.D., The University of Wisconsin - Madison, 127 pp. (in English) ["Understanding how animals respond to habitat structure is a fundamental objective in ecology, but is particularly challenging when the animals require distinct habitats for different life stages. Although the majority of animals have spatially segregated life stages, research on habitat associations has generally been restricted to only one of the life stages. The relative importance of aquatic and terrestrial habitat structure is not well known for the order Odonata. In northern Wisconsin (USA) lakes, housing development contributes to heterogeneity in riparian and littoral vegetation structure. I surveyed odonate larval assemblages at 41 sites across 17 lakes. Based on mixed-effects multiple regressions, model selection identified site-level littoral macrophyte abundance as a key driver of larval odonate species richness, and riparian wetland plant abundance as the best predictor for odonate density. Subsequent field experiments on larval predation and adult site selection helped explain these patterns. Additional surveys of the most abundant family (Gomphidae) at 22 lake sites indicated that local larval densities depend most on recruitment, which I estimated from adult densities during the previous year. Densities of emergent Gomphidae skins (exuviae) were most related to densities of the later-instar (second-year) larvae, further suggesting that larval survivorship and movement are less variable spatially than recruitment from the previous life stage. Field experiments conducted at two South African lakes demonstrated how riparian tree structures alter adult odonate abundances. Riparian shade reduced the abundance of odonates at these potential breeding sites. Perch structures, added to separate experimental plots,

supported locally higher adult abundances, but dragonflies were not sensitive to perch structure density or diversity. Thus shade is the critical habitat component that should be addressed for odonate conservation in South Africa. Collectively, this research describes the role of habitat structure during multiple life stages. Field experiments demonstrate that generalist predators are sensitive to vegetation structure. The results suggest that riparian habitat selection by animals with complex life cycles can influence aquatic communities." (Author)] Address: Remsburg, Alysa, Dept Zoology, Univ. 8100. Statzner, B.; Bonada, N.; Dolédec, S. (2007): Conservation of taxonomic and biological trait diversity of European stream macroinvertebrate communities: a case for a collective public database. *Biodivers. Conserv.* 16: 3609-3632. (in English) ["The use of databases for the conservation of biodiversity is increasing. During the last decade, such a database has been cre-

ated for European stream macroinvertebrates. Today, it includes 527 sites that are the least human-impacted representatives of many stream types across many European regions. It includes data on the abundance of 312 invertebrate genera, several environmental site characteristics, collection methods, bibliographic data sources, and 11 biological traits of the genera (e.g. size, life cycle, food and feeding habits, described in 61 categories). The database will be useful in addressing many topics that are potentially relevant to biodiversity conservation. To illustrate this potential, we provide examples of how the data could be exploited. First, we describe the frequency of some taxonomic and biological characteristics (e.g. richness and diversity of genera and traits) of the macroinvertebrate communities and assess how these characteristics are related (e.g. how trait richness increases with genus richness). Second, we describe the frequency of some characteristics of the genera and traits (e.g. occurrence frequency, abundance, dispersion index) and again assess how these characteristics are related (e.g. how occurrence increases with abundance). Finally, we suggest how the database could be developed into a collective, publicly accessible database that covers stream types and regions of Europe more comprehensively." During recent years quite a number of interesting species has been found. But on this day the main observations were Little bittern and Black woodpecker." (Author)] Address: not stated

8107. Vinogradova, E.B. (2007): 5. Diapause in aquatic insects, with emphasis on mosquitoes. Monographiae Biologicae 84: 83-113. (in English) ["In Odonata both egg and larval diapauses occur in different instars (Corbet, 1980). Embryonic diapause occurs in certain temperate species, notably *Aeshna*, *Sympetrum*, and *Lestes*. For instance, *Lestes* congener oviposits in dry stems, the eggs undergo a bit of embryogenesis in autumn and then enter diapause in winter, at which time they are resistant to both low temperature and desiccation. Hatching of larvae is observed only after wetting and exposure to temperatures of 5°C and higher (Sawchin & Gillott, 1974). Such a response may be augmented in some other species of *Lestes* by sensitivity to photoperiod. Larval diapause is the most common diapausing stage for dragonflies in the temperate zone. Larval growth rate is controlled by the interaction of responses to temperature and photoperiod such that morphological development within and between certain instars is arrested or accelerated at different times of year (Corbet, 1980). A relatively simple example of the mechanism of environmental regulation is provided by *L. eurinus* from North Carolina, USA, where the populations overwinter in three larval instars preceding the final one (Lutz, 1968). Over a wide temperature range larvae of these instars develop more rapidly under summer than under winter photoperiods. Such a response magnifies the seasonal change in growth rate due to temperature. More complex responses to temperature and photoperiod exist among certain other species from

North Carolina, South Ontario, Sweden, and England. Their common feature is that one or more late instars became unresponsive to a long photoperiod stimulus in late summer or early autumn and thus enter diapause. The larvae of some dragonflies may also diapause in a dried (anhydrobiotic) state (Van Damme & Dumont, 1999). In Brazil, one larva of *Pantala flavescens* survived drought at least a few months and after flooding successfully completed metamorphosis. It is argued that early larval tolerance to drought may be common in *Pantala* contributing its success in semiarid environments; possible other species in which a similar phenomenon occurs are also listed by Van Damme and Dumont (1999). In *Enallagma hageni* it has been shown experimentally (Ingram 1975) that termination of diapause can be caused by exposure to a low temperature, regardless of photoperiod, or to short photoperiod at a permissive temperature. A critical element in the seasonal regulation of many dragonflies at higher latitudes is the annual reversal of response to photoperiod among one or more late instars at, or sometimes before, the autumnal equinox. This reversal can induce the population to molt synchronously at that time and can also establish a latent sensitivity to spring photoperiod (Lutz 1974). In European *Leucorrhinia dubia*, which spends its last winter mainly in the final instar, analogous differential responses to photoperiod operate within the final instar and thus enhance the responses to photoperiod and the degree to which each of several developmental phases is synchronized within the larval population (Norling 1976). Such responses prevent autumnal emergence and reduce temporal variation among overwintering larvae that are due to emerge the next summer." (Author)] Address: Vinogradova, Elena, University of Experimental Entomology and Biocontrol, Zoological Institute of the Russian Academy of Science, University emb., 1, 199034, St. Petersburg, Russian Federation. 8108. Winterbourn, M.J.; Harding, J.S.; McIntosh, A.R. (2007): Response of the benthic fauna of an urban stream during six years of restoration. *New Zealand Natural Sciences* 32: 1-12. (in English) ["Okeover Stream flows through the University of Canterbury campus and has been subject to restoration since 1998. While initially spring-fed, its main source of flow is now aquifer water, which has been used for cooling university buildings. Water quality is generally good, but the low-gradient streambed includes substantial amounts of fine inorganic sediment and organic matter including deciduous tree leaves. Restoration activities include riparian plantings, channel shaping, substratum manipulations and additions, the construction of sediment traps and macrophyte management. Thirty aquatic invertebrate taxa (13-19 per year) have been recorded in annual surveys since 2000. *Paracalliope fluviatilis* (Amphipoda), Copepoda and Oligochaeta were most abundant in all years, whereas Mollusca and Trichoptera always made up <4% and <2% of individuals, respectively. Furthermore, cased caddisflies were found only in the two (of four) downstream reaches, whereas Copepoda were predominantly in the upper two reaches where flow was generally slower. Low annual MCI (69-84) and SQMCI (3.5-4.8) values indicated the fauna comprised mainly species that are tolerant of poor water quality or degraded habitat conditions. Our data indicate that the invertebrate fauna has yet to respond positively to the changes in physical habitat and riparian conditions made along Okeover Stream. The introduction of pulses of

poor quality water during heavy rainfalls, high levels of siltation, heavy metals in bed sediments, large accumulations of slowly decomposing leaves and an inadequate source of potential colonists may all contribute to the weak response of the invertebrate fauna to restoration activities." (Authors) *Xanthocnemis zealandica* is rare.] Address: Winterbourn, M.J., School of Biological Sciences, University of Canterbury, Private Bag 4800, Christchurch, New Zealand. (in English) ["The larval stage of *C. tokyoensis* is described for the first time from Korea. The larva can be distinguished from other known larvae of *Copera* by the absence of lateral setae on the abdominal segments and by the labial palpal lobe, which bears three setae. Line-drawings of key characters and discussion on Korean *Copera* are provided." (Author)] Address: Yum, Jin-Whoa, E-mail: lestes93@me.go.kr

8111. Zhang, W. (2007): Computer inference of network of ecological interactions from sampling data. *Environ. Monit. Assess.* 124: 253-261. (in English) ["Both direct and indirect ecological interactions may occur in an ecosystem with large numbers of taxa. Traditional food web technique is a popular tool to measure the quality and health of the environment. Much of works must be done before constructing a food web for an ecosystem especially with many taxa. This food web is generally specific for some ecological interactions and fixed for a set of given species. It is therefore not an effective method for dynamic and prompt assessment of environment. Ecological interactions and their interactive intensity may be detected by sampling biological taxa in the field and by detecting various between-taxa distances or similarities. Network may clearly exhibit the complex interactions among biological taxa. Statistic tests on various distance or similarity measures and computer designs are required to infer the network. We develop an algorithm and software to infer the network of direct or indirect ecological interactions in ecosystem. It is a prompt and effective tool in monitoring and assessment of the environment. A redundant network may be inferred and drawn by computer based on the statistic tests on sampling data or the pathway information given in HTML file. Dominant taxa may be found in the network. In total of 16 distance and similarity measures, including Euclidean distance, Manhattan distance, Pearson correlation, partial correlation, point correlation, linkage coefficients, Jaccard coefficient etc., are provided to detect taxa pairs with significant parametric or nonparametric similarities, based on randomization tests and ordinary statistic tests. Criteria to use distance and similarity measures are discussed." (Author) The

interaction network also includes Odonata.] Address: Zhang, W., Research Institute of Entomology and State Key Laboratory of Biocontrol, School of Life Sciences, Zhongshan Univ., Guangzhou 510275, P.R. China. E-mail: LS71@zsu.edu.cn; zhangwenjun@scientist.com

8113. Bambaradeniya, C.N.B.; Edirisinghe, J.P. (2008): Composition, structure and dynamics of arthropod communities in a rice agro-ecosystem. *Cey. J. Sci. (Bio. Sci.)* 37(1): 23-48. (in English) ["The study on terrestrial arthropod communities in rice agro-ecosystems was conducted in Bathalagoda, Sri Lanka. A total of 342 arthropod species was documented comprising 282 species of insects in 90 families and 17 orders and 60 species of arachnids in 14 families. Eight taxa new to Sri Lanka are reported. Majority of the insects documented were hymenopterans, dominated by bees and ants. Based on feeding habits, majority of the arthropods recorded were predators (149 species), dominated by spiders. However, in the rice field proper, abundance of phytophagous rice pests was higher than that of predators. Density fluctuations of predators and parasitoids were positively correlated. Species richness and diversity of terrestrial arthropods increased gradually with crop age, but declined following application of pesticides. Species diversity (H') of terrestrial arthropods during vegetative, reproductive and grain ripening stages and the fallow period were significantly different. Diversity of terrestrial arthropods in the field proper positively correlated with crop age and height of the rice plant, and in field bunds with the weed cover. Findings indicate that a stable relationship could be maintained between rice insect pests and their arthropod natural enemies through minimal biocide applications and manipulation of weed cover in the rice agroecosystem." (Authors) 19 odonate taxa, in most cases at the species level, are listed.] Address: Bambaradeniya, C.N.B., IUCN – The World Conservation Union, Asia Regional Office, Sri Lanka. (in English) ["The collection of the Natural History Museum "Dr. Nikola Nežlobinski" in Struga contains 23 dragonfly species, collected in the first half and in the middle of 20th century in the vicinity of city Struga on the shores of Ohrid Lake. *Somatochlora flavomaculata* is new for the fauna of Macedonia. Its occurrence in the Balkans and south-eastern Europe is outlined and a short zoogeographical discussion is provided. A list of 37 dragonfly species hereto recorded

at Ohrid Lake and its surroundings is compiled." (Authors)] Address: Bedjanic, M., Kolodvorska 21b, SI-2310 Slovenska Bistrica, Slovenia. E-mail: matjazbedjanic@yahoo.com

8115. Bobeldyk, A.M.; Lamberti, G.A. (2008): A decade after invasion: Evaluating the continuing effects of Rusty Crayfish on a Michigan river. *J. Great Lakes Res.* 34: 265-275. (in English) ["In 2004, we revisited a Michigan stream invaded by rusty crayfish (*Orconectes rusticus*) to determine if this species continued to expand its downstream range and negatively impact the stream food web. Compared to a 1992 study, we predicted that rusty crayfish would increase in density and downstream distribution from a small lake, resulting in further reduction of in-stream resources such as organic matter, benthic invertebrates, and periphyton. To determine current crayfish distributions and impacts, we conducted a longitudinal survey of crayfish abundance, ran a 28-d leaf breakdown experiment, and sampled benthic substrates. Leaf packs of sugar maple (*Acer saccharum*) leaves were placed at three sites with differing crayfish densities (high, intermediate, and none). Breakdown rates were compared across the three sites and for two treatments (closed leaf bags excluding crayfish and open bags allowing crayfish access). Benthic invertebrates were sampled from leaf bags and invertebrates and periphyton were sampled from cobbles. In contrast to 1992, we found that the maximum downstream distance of rusty crayfish declined from 4 km to less than 3 km downstream from the lake. Leaves in open bags decayed significantly faster ($k = 0.143$) than did leaves in closed bags at all sites ($k = 0.079$) ($p = 0.0005$). The site lacking crayfish had significantly higher densities of invertebrates compared to both high and intermediate crayfish density sites ($p = 0.005$). Although we found that rusty crayfish reduced standing stocks of leaves and invertebrates, we did not detect measurable changes in periphyton biomass. Therefore, rusty crayfish have not dispersed further downstream since 1992, but where present, these omnivores significantly reduce resource availability via the consumption of leaf material and benthic invertebrates." (Authors)] Address: Bobeldyk, Angela, Department of Biological Sciences, University of Notre Dame, Notre Dame, Indiana 46556-0369, USA. E-mail: bobeldyk.1@nd.edu

8116. Boulton, A.J.; Boyero, L. Covich, A.P.; Dobson, M.; Lake, S.; Pearson, R. (2008): Are tropical streams ecologically different from temperate streams? In: Dudgeon, D. (Ed): *Tropical Stream Ecology*. San Diego: Academic Press. ISBN: 978-0-12-088449-0: 257-284. (in English) ["If tropical streams differ ecologically from temperate ones, we must be cautious in our extrapolation of ecosystem models developed in temperate-zone streams. Similarly, approaches and techniques used routinely in management of temperate streams may not be applicable in the tropics. Despite considerable variability in geological history, flow regime and geomorphology, streams in the tropics typically receive higher insolation and more intense rainfall, with warmer water and often relatively predictable floods. For many groups of aquatic taxa, tropical streams also harbour higher biodiversity than their temperate equivalents. Nonetheless, there is little published evidence for consistent differences in food-web structure, productivity, organic-matter processing and nutrient dynamics, or responses to disturbance which would indicate that the term 'tropical' has special significance

when applied to stream ecology. Instead, ecological processes in tropical streams appear to be driven by the same variables that are important in temperate ones. For example, biotic responses to drought and flooding are similar to those in temperate streams while in-stream productivity is limited by the same factors: nutrients, shading, disturbance, and trophic structure. Shredders are reputed to be rare in many tropical streams but this also is the case in many southern temperate streams, implying that models of leaf breakdown developed in the north-temperate zone may not have the universal applicability often assumed. Biome comparisons among temperate and tropical streams are confounded by the immense inherent variability of streams within both these zones, and the wide range of climatic and hydrological conditions – even in the tropics. Valid extrapolation of models and management strategies may be less a matter of tropical versus temperate streams but, instead, of ensuring comparability at appropriate scales and fuller understanding of ecological mechanisms, plus recognition of the magnitude and complexity of spatial and temporal variation in stream ecosystems at all latitudes." 8119. Brooks, D.R.; Hoberg, E.P. (2008): Darwin's necessary misfit and the sloshing bucket: The evolutionary biology of emerging infectious diseases. *Evo. Edu. Outreach* 1: 2-9. (in English) ["Evolutionary studies suggest that the potential for rapid emergence of novel host-parasite associations is a "built-in feature" of the complex phenomenon that is Darwinian evolution. The current Emerging Infectious Disease (EID) crisis is thus a new manifestation of an old and repeating phenomenon. There is evidence that previous episodes of global climate change and ecological perturbation, broadly defined, throughout earth history have been associated with environmental disruptions that produce episodic bursts of new host-parasite associations, each of which would have been called an EID at the time of its first appearance. This perspective implies that there are many evolutionary accidents waiting to happen, requiring only the catalyst of climate change, species introductions, and the intrusion of humans into areas they have never inhabited before. [...] The trematode *Haematoloechus floedae* transmission dynamics, although specialized, are conservative across the genus, in each case involving a freshwater pulmonate snail, a dragonfly nymph, and a relatively large aquatic frog. Although most lung flukes are known from only a single snail species in natural infections, a number are capable of infecting a broader range of snails from the superfamily Lymnaeidae in the laboratory. The larvae, called cercariae, that emerge from the snail infect the second intermediate host, which, for all species studied to date is an anisopteran odonate (dragonflies). Members of the Lymnaeidae and the Anisoptera are widespread through-

out North American and Mesoamerica. Evolutionary conservatism in the physiology and ecology would allow the parasite to expand into novel territory; all that would be required is a species of lymnaeoid pond snail and a species of anisopteran dragonfly. Leopard frogs appear to be the ancestral frog hosts for *Haematoloechus* species. Within that historical context, however, *H. floedae* itself appears to have originated through a switch to bullfrogs, so the original host for *H. floedae* is bullfrogs. *Rana taylori* and *R. cf. forreri*, the hosts for *H. floedae* in Costa Rica, are leopard frogs. Parasite species can thus retain ancestral host utilization capabilities, even when they are not being used, which allows "new" associations to be formed through 'retrocolonization'." 8121. Campero, M.; De Block, M.; Ollevier, F.; Stoks, R. (2008): Metamorphosis offsets the link between larval stress, adult asymmetry and individual quality. *Functional Ecology* 22: 271-277. (in English) ["1. It is poorly understood which traits translate larval stressors into adult fitness in animals where larval and adult stages are separated by metamorphosis. Although fluctuating asymmetry (FA) is often assumed to do so, especially in insects the relationship between larval stress, adult FA and individual quality is often absent. One suggested hypothesis for this is the higher mortality of low quality (hence more asymmetric) animals during metamorphosis (i.e. developmental selection hypothesis). 2. Here we test this hypothesis and also propose and test an alternative hypothesis where metamorphosis is stressful but not lethal and increases FA of all animals up to a certain level (i.e. stressful metamorphosis hypothesis). 3. We manipulated larval stress (food stress and pesticide stress) and measured FA before and after metamorphosis in *Coenagrion puella*. Additionally, we assessed the relationship between FA and individual quality variables measured at metamorphosis (age, mass and two immune variables: phenoloxidase (PO) and haemocyte number). 4. Before metamorphosis, FA reflected the combination of food and pesticide stress and was negatively related with mass and both immune variables after metamorphosis. These patterns were, however, offset after metamorphosis. Low mortality, not linked to FA during metamorphosis, indicates that developmental selection cannot explain this. Instead, the strong increase in FA up to equal levels across treatments during metamorphosis supports the stressful metamorphosis hypothesis. 5. Taken together, the developmental stage in which FA is measured may critically determine the reliability of FA as an indicator of

stress and of individual quality in insects." (Authors)] Address: Campero, Melina, Unidad de Limnología y Recursos Acuáticos, Univ. Mayor de San Simón, Cochabamba, Bolivia. E-mail: melina.campero@gmail.com

8123. Chaput-Bardy, A.; Lemaire, C.; Picard, D.; Secondi, J. (2008): In-stream and overland dispersal across a river network influences gene flow in a freshwater insect, Calopteryx splendens. Molecular Ecology 17(5): 3496-3505. (in English) ["Gene flow in riverine species is constrained by the dendritic (branching) structure of the river network. Spatial genetic structure (SGS) of freshwater insects is particularly influenced by catchment characteristics and land use in the surroundings of the river. Gene flow also depends on the life cycle of organisms. Aquatic larvae mainly drift downstream whereas flying adults can disperse actively overland and along watercourses. In-stream movements can generate isolation by distance (IBD) at a local scale and differentiation between subcatchments. However, these patterns can be disrupted by overland dispersal. We studied SGS across the Loire River in C. splendens which is able to disperse along and between watercourses. Our sampling design allowed us to test for overland dispersal effects on genetic differentiation between watercourses. Amplified fragment length polymorphism markers revealed high genetic differentiation at the catchment scale but the genetic structure did not reflect the geographical structure of sampling sites. We observed IBD patterns when considering the distance following the watercourse but also the Euclidean distance, i.e. the shortest distance, between pairs of sites. Altogether, our results support the hypothesis of overland dispersal between watercourses. From a conservation perspective, attention should be paid to the actual pathways of gene flow across complex landscapes such as river networks." 8127. De Gennaro, D.; Rebagliati, P.J.; Mola, L.M. (2008): Fluorescent banding and meiotic behaviour in Erythrodiplax nigricans (Libellulidae) and Coryphaeschna perrensi (Aeschnidae) (Anisoptera, Odonata). Caryologia 61(1): 60-67. (in English) ["The species of Odonata are cytogenetically characterised by possessing holokinetic chromosomes, a post-reductional meiosis, an XX/XO (female/male) sex chromosome mechanism, m-chromosomes, and only one chiasma per bivalent. Chromosome studies were performed on males of E. nigricans and C. perrensi from Argentina. E. nigricans has n=12+XO and lacks m-chromosomes, while C. perrensi has 2n=27, n=13+XO, m-chromosomes and a large autosomal pair associated with the nucleolus. The meiotic behaviour of both species follows the general pattern of the order: the X chromosome is positively heteropycnotic during early prophase I; bivalents regularly show only one chiasma; all chromosomes migrate synchronously and almost parallel to the equatorial plane at anaphase I; at metaphase II the X chromosome is present in all the cells as a consequence of the post-reductional division, lies outside the metaphasic plate, and migrates asynchronously with the autosomes at anaphase II. In C. perrensi, the largest bivalent exhibits two chiasmata in a large proportion of cells, which is a very rare feature among dragonflies. Heterochromatin characterisation with DAPI-CMA banding reveals that C. perrensi does not show fluorescent banding, except for a CMA bright band at one telomeric region of the largest bivalent, associated with the NOR region; in E. nigricans, autosomes have small AT-rich telomeric blocks, except for the smallest pair, which exhibits conspicuous bands in both telomeric regions, one being GC-rich and the other AT-rich. Taking into account that the m-chromosomes have been found in other E. nigricans populations, their absence in the studied population may be due to the presence of such heterochromatic blocks." 8128. De Knijf, G. (2008): The season 2006 for dragonflies (Odonata) in Flanders: a review. Libellenvereniging Vlaanderen - nieuwsbrief 2(1): 9-13. (in Dutch, with English summary) ["Here we present the first results of the observations of dragonflies we received for the year 2006 for Flanders. A total of more than 6000 observations, the highest number ever, from 58 species were received. These were collected by 73 collaborators. All geographical regions and 40% of the total num-

ber of atlas squares (5x5 km UTM) were investigated. Three species, *Ischnura elegans*, *Anax imperator* and *Orthetrum cancellatum* were seen in more than 50% of the investigated squares. Remarkable was the still going on increase of *Calopteryx splendens* which was observed in 30% of the squares. Southern species as *Erythromma viridulum* and *Crocothemis erythraea* are getting quite common and are among the 20 most reported species in Flanders. Other southern species as *Lestes barbarus*, *Sympetrum fonscolombii*, both mentioned in more than 10% of the squares, and *Aeshna affinis*, *Anax parthenope* and *Orthetrum brunneum* were observed at several localities. The decline of some Red List species seems still to be going on. The number of localities for some of them, e.g. *Coenagrion lunulatum*, *Gomphus vulgatissimus*, *Sympetrum depressiusculum* and *Leucorrhinia rubicunda* has fallen to less than three. They can be considered as becoming extinct in Flanders in the near future if their decline continues." 8131. Durst, S.L.; Theimer, T.D.; Paxton, E.H.; Sogge, M.K. (2008): Age, habitat, and yearly variation in the diet of a generalist insectivore, the Southwestern Willow Flycatcher. *The Condor* 110(3): 514-525. (in English, with Spanish summary) ["Characterizing avian diet is complex, especially for generalist insectivores, as food resources can vary over space and time, and individuals of different sexes and ages may consume different food. We examined diet of a generalist insectivore, the Southwestern Willow Flycatcher (*Empidonax traillii* extimus), at Roosevelt Lake in central Arizona from 2000 to 2004, determined from 344 fecal samples. We found that five prey categories accounted for 70% of the proportional abundance in flycatcher diet: Hymenoptera, Diptera, Cicadellidac, Coleoptera and Formicidae, although the relative amounts of these and other taxa differed significantly among years. We detected no

differences in diet between sexes of adults, but adults and nestlings differed, with higher proportions of Hymenoptera in adult samples and more Diptera in nestling samples. Using a subset of samples, we compared flycatcher diet in habitat patches dominated by native cottonwood (*Populus fremontii*) and willow (*Salix gooddingii*), exotic salt cedar (*Tamarix ramosissima*), or a mix of these tree species. We found that prey groups varied significantly among habitats in only one year, 2002, with Araneae, Lepidoptera and Odonata significant indicators of native habitat, Cicadellidae and Hymenoptera significant indicators of exotic habitats, and Homoptera a significant indicator of mixed habitat. In 2002, a severe drought resulted in reduced prey base and near total reproductive failure, but we detected no major shift in the composition of adult diet during that year, suggesting that for generalists like the Southwestern Willow Flycatcher, overall insect abundance may be a more important driver of productivity than abundance of specific prey taxa." 8135. Fernandez, L.; Springer, M. (2008): El efecto del beneficiado del café sobre los insectos acuáticos en tres ríos del Valle Central (Alajuela) de Costa Rica. *Rev. Biol. Trop.* 56 (Suppl. 4): 237-256. (in Spanish, with English summary) ["The effect of coffee processing on aquatic insects in three rivers from the Central Valley (Alajuela) of Costa Rica: In Costa Rica one of the greatest sources of organic pollution in the rivers has been the residual material generated from the processing of coffee beans. In this study, the usefulness of aquatic insects as bioindicators is examined in order to measure the effect of spills of coffee processing plants into two rivers of the Central Valley. The study was conducted at three different coffee processing plants at the three most important moments of the harvest, at the beginning, the peak and at the end. On each of the three dates, biological samples were taken 50m up- and 50m down-stream from the point where the coffee processing plants discharge their liquid wastes. The following physical and chemical factors were also measured: DBO, DQO, pH, temperature, fats and oils, sedimentable solids, dissolved oxygen and the discharge of the river. Systematic samples of aquatic insects were taken in order to obtain relative abundance, taxa richness, diversity (Shannon-Wiener), similarity (Bray-Curtis) and biological index B.M.W.P.' (Biological Monitoring Working Party) adapted for Costa Rica. Physical-chemical results showed a decrease in the amount of dissolved oxygen and in the discharge of the rivers. In addition, in some cases very high values of DBO and DQO were reached as the season advanced; nevertheless, the majority of the measurements taken were within the limits established by the laws of Costa Rica. Populations of insects increased down stream as the season advanced, due mainly to an increase in the density of *Chironomus* larvae (Diptera) which became the dominant group. At the same time other pollution sensitive taxa diminished or disappeared. This was reflected by decreasing taxonomic richness and a low diversity index. Similarity between samples taken up and down stream was less than half (0,41), and comparing the

three main harvest moments, the highest point was very similar to the end of the harvest (0,81) and both were very different from the beginning of the harvest (0,26). According to the modified biological index BMWP, water quality diminished to category "strongly contaminated" at the highest point of the harvest. The results indicate that there is an important effect on the populations of aquatic insects caused by the period of harvest, which is not necessarily detected by the standard analysis required by law. Therefore we recommend that the fauna of aquatic macroinvertebrates should be included as a mandatory procedure in water quality testing, the capacity of the treatment plants should be evaluated, and the standard limits established by present laws in Costa Rica, should be critically analyzed." (Authors) Odonata (*Hetaerina*, *Argia*, *Brechmorhoga*, *Perithemis*, *Palaemnema*) are treated on the genus level.] Address: Fernández, L., Escuela de Biología, Universidad de Costa Rica, 2060 San Pedro, San José, Costa Rica. 8139. Heckman, C.W. (2008): *Encyclopedia of South American Aquatic Insects: Odonata -Zygoptera*. Springer-Verlag. ISBN: 9781402081750: VIII, 692 pp. (in English) ["Zygoptera completes the two volume work on the order Odonata in the *Encyclopedia of South American Aquatic Insects*. A brief review of the biology of the group includes illustrations of the main morphological features as well as explanations of alternative systems for naming the wing veins and other characteristics commonly used to distinguish the species. This will show the user of the identification keys in the volume the alternative names for the anatomical structures most frequently encountered in the literature. The sections on the morphology of the adults and larvae are followed by brief discussions of ecological and zoogeographical factors influencing the distribution of the

dragonflies and instructions on the various methods used to observe, collect, preserve, and examine specimens. Most of the book is devoted to keys that facilitate identification of both adults and those larvae which have already been described. For the first time, all of the available information needed to identify the adults of all recognized species inhabiting South America has been compiled from a large number of individual taxonomic works written in six languages during the past two centuries. Separate keys are provided to identify all larvae that have been positively identified and described prior to early 2007. In addition to the descriptions of the morphological features used to distinguish the species, the keys provide the known ranges listed by country and by states within Brazil, as well as the synonyms most likely to be encountered in the literature. The publications cited with the species names and in the keys can be found compiled in an extensive bibliography, informing the user where more extensive species descriptions and additional information about each species can be located. Although taxonomic revisions are deliberately avoided, suggestions for additional research and the opinions of experts concerning imminent taxonomic changes are provided where appropriate. To provide the user of the keys with maximum assistance in making reliable identifications, the book is richly illustrated with pen and ink drawings of thousands of individual morphological structures arranged in 767 figures. It is certain that many significant changes will occur in the systematics of South American damselflies in the future, and this book is meant to provide the impetus needed to accelerate the work of nomenclature and revision. Meanwhile, it will provide a comprehensive overview of the South American Zygoptera that has hitherto remained almost unobtainable to most South American scientists because of the great difficulties in obtaining the numerous publications from numerous countries in which the original descriptions of species and taxonomic revisions have appeared. It also provides student entomologists with a basic text for learning what they need to know to work effectively with the Zygoptera of South America and adjacent regions." (Publisher)]

8142. Herzon, I.; Helenius, J. (2008): Agricultural drainage ditches, their biological importance and func-

tioning. *Biological conservation* 141: 1171-1183. (in English) ["We reviewed studies on the biological state of agricultural drainage ditches in the temperate and boreal zones of the Northern Hemisphere. We looked at the relative importance of ditches for farmland biota as compared to that of other habitats, and assessed the degree to which biological communities of ditches contribute to the provisioning of ecosystem services. We evaluated impacts pertaining to replacement of open drains by subsurface drainage, removal of main ditches, rehabilitation of old drainage systems, and maintenance of ditches. Most ditches support species also common elsewhere. Whenever comprehensive surveys were conducted, ditches were shown to provide valuable wet vegetated noncropped habitats to both aquatic and terrestrial taxa, supply food resources lacking in otherwise dry and intensively managed cropland, and perform connectivity functions within a wider landscape. Regionally ditches were shown to harbour rare species or species not found presently in other farmland habitats. Some functions of drainage ditches, such as regulating water flow and nutrient retention, are likely to depend on the composition and structure of biological communities of ditches, though the issue remains poorly explored. The biggest threat to the quality of ditch networks as ecosystems is presented by a severe runoff from the fields, management in disregard of a habitat value of ditches, and removal of ditches." (Authors) The paper includes a passing note on the importance and ecological function of ditches in USA, but ignores completely e.g. the German publications on the highly significant ecological importance of ditches as habitat for the European protected by law species *Coenagrion mercuriale* and *C. ornatum*.] Address: Herzon, Irina, Dept of Applied Biology, University of Helsinki, Latokartanonkaari 5-7, 00014, Finland

8148. Kasangaki, A.; Chapman, L.J.; Balirwa, J. (2008): Land use and the ecology of benthic macroinvertebrate assemblages of high-altitude rainforest streams in Uganda. *Freshwater Biology* 53(4): 681-697. (in English) ["1. In sub-Saharan Africa, tropical forests are increasingly threatened by accelerating rates of forest conversion and degradation. In East Africa, the larger tracts of intact rainforest lie largely in protected areas surrounded by converted landscape. Thus, there is critical need to understand the functional links between large-scale land use and changes in river conditions, and the implications of park boundaries on catchment integrity. 2. The objective of this study was to use the mosaic of heavily converted land and pristine forest created by the protection of the high-altitude rainforest in Bwindi Impenetrable National Park, Uganda to explore effects of deforestation on aquatic systems and the value of forest in buffering effects of adjacent land conversion. A set of 16 sites was selected over four drainages to include four categories of deforestation: agricultural land, deforested upstream (of the park boundary), forest edge (park boundary) and forest. We predicted that forest buffer (downstream or on the edge) would moderate effects of deforestation. To address this prediction, we quantified relationships between disturbance level and both physicochemical characters and traits of the macroinvertebrate assemblages during six sampling periods (February 2003 and June 2004). 3. Results of both principal components analysis and cluster analyses indicated differences in limnological variables among deforestation categories. PC1 described a gradient from deforested sites with poor water quality to pristine forested sites with relatively good water quality. Agricultural sites and deforested upstream sites generally had the highest turbidity, total dissolved solids (TDS), and conductivity values and low transparency values. Forest sites and boundary site groups generally exhibited low turbidity, TDS, and conductivity values and high water transparency values. Sites also clustered according to deforestation categories; forest and forested edge sites formed a cluster independent of both agricultural land and deforested-upstream. 4. Water transparency, water temperature, and pH were the most important factors predicting benthic macroinvertebrate assemblages. Sensitive invertebrate families of Trichoptera, Ephemeroptera, Plecoptera, and Odonata dominated forested sites with high water transparency,

low water temperature, and low pH while the tolerant families of Ephemeroptera, Diptera, Hemiptera, and Coleoptera were abundant in agriculturally impacted sites with low water transparency, high water temperature, and high pH. 5. This study provides support for the importance of riparian buffers in moderating effects of deforestation. Forest and forested edge sites were more similar in both limnological and macroinvertebrate assemblage structure than sites within or downstream from agricultural lands. If the protected area cannot encompass the catchment, the use of rivers as park boundaries may help to maintain the biological integrity of the rivers by buffering one side of the watercourse." 8152. Lambeets, K.; Pellegrons, B. (2008): Estimating damselfly populations at the Hannecartbos (Koksijde). *Libellenvereniging Vlaanderen - nieuwsbrief* 2(1): 2-8. (in Dutch, with English summary) ["During a five day field survey in June 2007, population size and dispersal distance of *Coenagrion puella* and *Ischnura elegans* were estimated based on capture-mark-recapture (CMR) data. Beside it, all odonata species observed were listed. The study was performed in the Hannecartbos (Koksijde, Belgium), which is part of the Flemish nature reserve Ter Yde. In order to restore calcareous dune grasslands on a peaty, seepage-fed underground, the woodland was partly cleared in 2004. In general, 671 individuals spread over 13 species were observed. During the CMR study, a total of 631 individuals of *C. puella* (352) and *I. elegans* (279) were caught from which respectively 66 and 4 individuals were recaptured (total: 70). Population size was calculated by the Petersen estimate for closed populations and the Jolly-Seber

estimate for open populations. Both estimates were comparable for *C. puella*, but for *I. elegans* they differed remarkably due to low recapture numbers for this species. Dispersal distances were found to be quite similar for both species, with a maximum of 149.5m for *C. puella* and 104.5m for *I. elegans*. Furthermore, the Hannecartbos seems to provide suitable habitat conditions for rare species as *C. pulchellum* and *Libellula quadrimaculata*. This study indicates the high potential of both damselfly species for recolonizing suitable patches and their ability to build up persistent populations quite fast. Plausible factors confounding population size estimates as weather conditions and the lateral demarcation of the sample plots, however, may obfuscate the results. Also, maximum dispersal distances of both species may be larger since the survey was carried out along the banks of a small rivulet and did not account for other water bodies nearby. A standardized and more comprehensive experimental set-up would certainly increase the value of CMR-studies." (Authors)] Address: Lambrechts, K.; Onderzoeksgroep Terrestrische Ecologie (TEREC), Dep. 8154. Lin, Y.c. (2008): A survey of aquatic insects and biotic index in constructed wetlands. M.S. thesis, Department Graduate of Environmental Engineering and Science: 167pp. (in Chinese, with English summary) ["This study analysis the parameters of water quality and collected the aquatic insects in the Chna constructed wetland system, Gang-Wei constructed wetland system, Ke-Liao constructed wetland system, Er-Hang constructed wetland system, An-Shun constructed wetland system and Niao-Song wetland park since March 2006 to May 2008. We related aquatic insects sampling to water quality parameters in various constructed wetland system and investigated to establish the biotic index to assess constructed wetland water quality. The aquatic insects were collected regularly, and the monitoring parameters of water quality were recorded at the same time. In this research, we analyse the monitoring parameters of water quality including temperature, pH, conductivity, DO, BOD5, NH4-N and SS, and to calculate the river pollution index of a constructed wetland system. We counted the number and identified the species of the collected aquatic insects. We utilize the numbers and the species of the collected aquatic insects to calculate the biotic index, including the number of individual, Family-level biotic index, Richness index, Shannon-Weaver diversity index, Simpson's-

s diversity index and Evenness index. We wish to establish an ideal formula for the biotic index to assess the constructed wetland water quality. The results showed that the water quality and aquatic insects of the six constructed wetlands systems were significant difference. We compared the four water quality parameters that to calculate the river pollution index of the four regular sampling system, we found that the Gang-Wei system had high DO and low NH4-N value, Chna system had better BOD5 and SS value. The Gang-Wei system had the best environment quality overall. Chna system's aquatic insects recorded six orders, 15 family and 15 species, the number of individual per sampling area was 5044 / m². Gang-Wei system's aquatic insects recorded seven orders, 18 family and 19 species, the number of individual per sampling area was 14,998 / m². Ke-Liao system's aquatic insects recorded six orders, 8 family and 8 species, the number of individual per sampling area was 477 / m². An-Shun system's aquatic insects recorded five orders, 9 family and 9 species, the number of individual per sampling area was 544 / m². Niao-Song system's aquatic insects recorded five orders, 5 family and 5 species, the number of individual per sampling area was 111 / m². The correlation testing of the water quality parameters and the biotic index are significant difference, depending on the various characteristics of the constructed wetland system. The river pollution index (RPI) was used to evaluate the river water pollution levels. The river pollution index (RPI) of Gang-Wei system, Chna system, Ke-Liao system and Er-Hang system were progressive increase. The Family-level biotic index was to evaluate the water quality, the Gang-Wei system is better than the Chna system, and the Ke-Liao system is the worse. The higher Shannon-Weaver diversity index value represented the more species diversity and abundance. The Shannon-Weaver diversity index value of Gang-Wei system, Chna system, and Ke-Liao system were reduce progressively. Applied these methods to evaluate water quality had the same results. We were able to refer the current use of the biotic index to assess stream water quality methods, and to establish the biotic index to assess constructed wetland water quality. The potential biotic indexes were Family-level biotic index and Shannon-Weaver diversity index. These methods could assist chemical analysis to assess the whole water quality. The multiple gradually regression analysis was to establish an ideal formula for water quality parameters to estimate the Gleason index, Evenness index and Simpson's diversity index. The results were the same as the utility of river pollution index. It could reduce water quality parameters analysis project, and assess the overall water environment. Analyze the river pollution index (RPI) and the individuals of various orders correlation to establish the biological indicators. The result was that the Odonata, Hemiptera, Coleoptera and Ephemera were the candidate of the biological indicators in the constructed wetland system. It needed more large sample size and more detail aquatic insect classification to establish the more representative biological indicators. The constructed wetland was the breeding site of *Culex* and *Anopheles*. It has the potential to increase the local adult mosquito populations. These mosquitoes could be the vectors of pathogen or to disturb the neighbour of constructed wetland. It should improve the management of constructed wetland to reduce the public health problem." - 8159.** Mathuriau, C.; Thomas, A.G.B.; Chauvet, E. (2008): Seasonal dynamics of benthic detritus and associated macroinvertebrate communities in a neotropical stream. *Fundamental and Applied Limnology / Archiv für Hydrobiologie* 171(4): 323-333. (in English) ["The dynamics of benthic detritus and the structure, composition and functional feeding groups of associated macroinvertebrate communities were followed at biweekly intervals over one year in a 4th-order Andean stream located in a forested hill in SW Colombia. The density of macroinvertebrates and the number of taxa showed a similar bimodal annual pattern with highest values occurring from January to mid-March and from July to mid-October. The accumulated benthic detritus and the invertebrate abundance and community structure were apparently controlled by stream discharge. This was confirmed by a cluster analysis of invertebrate assemblages over the year where three groups of sampling dates emerged. The first group occurred during high discharges, the second one under intermediate hydrological conditions and the third coincided with low rainfall and low discharges. Numerically, collectors dominated, whereas shredders represented less than 5.3 % of the invertebrates. Unexpectedly, benthic detritus and collector densities were negatively correlated; however, no relation between benthic detritus and the abundance of shredders was found, which may suggest that benthic detritus consisting mainly of plant remains was not a limiting resource in this neotropical stream. Macroinvertebrates appear to have a minor role in the decomposition of plant matter which is consistent with previous observations from the same and other tropical streams. As a consequence, macroinvertebrate dynamics in this stream were more influenced by hydrological variations than by input of plant detritus." - 8160.** Maue, T.; Springer, M. (2008): Effect of methodology and sampling time on the taxa richness of aquatic macroinvertebrates and subsequent changes in the water quality index from three tropical rivers, Costa Rica. *Rev. Biol. Trop.* 56 (Suppl. 4): 257-271. (in English) ["Three rivers, one in Alajuela province and two in Puntarenas province in Costa Rica, were tested with two methods and different collecting times, in the rainy and dry season. The first method involved collecting of organic and inorganic material for a fixed time period (3, 5, 8, 10 min) with a strainer. This material was transferred to a plastic bowl containing 70% alcohol and aquatic macroinvertebrates were sorted out in the laboratory. With the second method the specimens were collected in the field directly out of the strainer for a total collecting time of 120 minutes and preserved immediately with 70% alcohol. In order to obtain species accumulation curves for this method, subsamples were taken every 15 minutes. The data analysis showed that the abundance and taxa richness was higher with the second method, and a higher number of genera could be found with increasing collecting time, but not necessarily a higher number of individuals. A difference in the number of individuals between rainy and dry season was observed. Species accumulation curves for samples taken with both methods showed that new genera and families were still being found after the maximum time of collection, no matter which season or river. Categories of water quality obtained from the BMWP-CR index varied greatly among sampling times and methods used. The second method always achieved a higher water quality than the longest sampling time (10 min)

in the first method. However, it still didn't reach the level obtained for all families found in both methods combined. Although the first method is the one officially used in most sampling protocols for biomonitoring in temperate zones, these results suggest that more extensive testing of adequate sampling time and methodology is still necessary for tropical rivers." (Authors) Taxa including Odonata are treated at the genus level.] Address: Maue, T., Hydrobiologie, Universität Essen-Duisburg, Essen, Germany. E-mail: tmaue@web.de

8164. Muscatello, J.R.; Belknap, A.M.; Janz, D.M. (2008): Accumulation of selenium in aquatic systems downstream of a uranium mining operation in northern Saskatchewan, Canada. *Environmental Pollution* 156:

387-393. (in English) ["The objective of this study was to investigate the accumulation of selenium in lakes downstream of a uranium mine operation in northern Saskatchewan, Canada. Selenium concentrations in sediment and biota were elevated in exposure areas even though water concentrations were low (<5 µg/L). [...] Detritivore and predator invertebrates (including 'Odonata') showed significant increases in selenium concentrations ($p < 0.05$) compared to filterer invertebrates, plankton and periphyton at both medium and high exposure sites. The overall pattern of selenium accumulation (from smallest to largest) was as follows: periphyton < plankton and filterer invertebrates < detritivore and predator invertebrates < small bodied fish (shiners) and predatory fish (juvenile pike). Selenium concentrations in the evaluated exposure areas were higher in fish, detritivore and predator invertebrates than filterer invertebrates, indicating the importance of sediments and detrital processes in selenium bioaccumulation. Filterer invertebrates feed on the particles suspended in the water column (e.g., plankton), but in contrast, other invertebrates rely on food sources closely related to detrital processes, suggesting a stronger association with sediments. [...] Biomagnification of selenium resulted in an approximately 1.5-6 fold increase in the selenium content between plankton, invertebrates and forage fish. However, no biomagnification was observed between forage fish and predatory fish. Selenium content in organisms from exposure areas exceeded the proposed 3-11 µg/g (dry weight) dietary toxicity threshold for fish, suggesting that the selenium released into these aquatic systems has the potential to bioaccumulate and reach levels that could impair fish reproduction." (Authors)] Address: Janz, D.M., Toxicology Centre, Univ. Saskatchewan, 44 Campus Drive, Saskatoon, SK Canada S7N 5B3. E-mail: david.janz@usask.ca

8165. Muschiol, D.; Traunspurger, W. (2008): Life at the extreme: meiofauna from three unexplored lakes in the caldera of the Cerro Azul volcano, Galápagos Islands, Ecuador. *Aquatic Ecology* 43(2): 235-248. (in English) ["On Isla Isabela, Galápagos Archipelago, 3 so far unexplored lakes were investigated in the caldera of Cerro Azul, one of the most active volcanoes in the world. The lakes face recurrent desiccation and eruption events and showed distinct differences in their water chemistry. Thirty cores from the upper 15 cm of sediment indicate distinct differences in the composition of meiobenthic communities between the lakes. In total, 27 different aquatic metazoan species could be distinguished. Numerically, rotifers dominated in two of the lakes, with mean densities up to 4.56 9 106 individuals m⁻² while the third lake was dominated by a gastrotrich of the genus *Chaetonotus* (0.67 9 106 individuals m⁻²). The largest lake harboured up to 14.4 9 106 nematodes m⁻², which is the highest nematode density thus far reported for a freshwater habitat. The lakes yielded few nematode species ($S = 7$, $N = 887$) and calculation of the Shannon-Wiener index (H_0) indicated an exceptionally low nematode diversity. The nematode community of one lake was clearly dominated by an undescribed suction-feeding *Mesodorylaimus* (59.6%), the community of the other lake by the epistrate feeder *Achromadora pseudomicoletzkyi* (89.3%), whereas the third lake surprisingly contained no nematodes. The benthic nematode biomasses for the two nematode-containing lakes differed by a factor 50. The food webs of the three lakes are presumed to have an exceptional simple structure." 8167. Ngai, J.T.; Kirby, K.R.; Gilbert, B.; Starzomski, B.M.; Pelletier, A.J.D.; Conner, J.C.R. (2008): The impact of land-use change on larval insect communities: Testing the role of habitat elements in conservation. Ecoscience 15(2): 160-168. (in English, with French summary) [Costa Rica; "Conservationists have proposed that maintaining key elements of the original land-cover type in modified landscapes may mitigate the detrimental effects of land-cover change on residual species. We tested this hypothesis for aquatic insect communities in tank-forming bromeliads in forested and non-forested habitats in Costa Rica. Bromeliad tanks hold much of the standing water in this region and therefore provide an important resource for insects with aquatic larval stages. We quantified the relative importance of land-use type and the bromeliad-specific "local" environment on the insect community, and also the effect of land-use type on this local environment. Insect species responded to both land-use type and the local environment, with these variables explaining a total of 36% of species densities. The local environment independently explained 19% of insect densities, while land-use type explained 17%, mainly through its modification of the local environment. Local environmental conditions were strongly correlated to land-use type ($r^2 = 0.64$), with non-forest habitat having a higher average temperature, a greater variation in temperature, and a lower density of bromeliads. Our results indicate that the land-use type in which bromeliads occur influences the relative densities of insects by altering the local environment of bromeliads. Therefore, maintaining bromeliads under land-use conversion will not necessarily maintain the bromeliad insect community of the original forested habitat." (Authors) *Mecistogaster ornata* was found more frequently in larger bromeliads in warmer, roadside areas.] Address: Ngai, Jacqueline, Biodiversity Research Centre, Dept Zool., Univ. of British Columbia, 6270 University Boulevard, Vancouver, British Columbia V6T 1Z4, Canada E-mail: ngai@zoology.ubc.ca

8168. Noikong, W.; Palarak, C. (2008): Diversity and nutritional values of edible aquatic insects in Ban Thi and Mueang Lamphun District, Lamphun Province. 32nd Congress on Science and Technology of Thailand (STT.32), 10 - 12 October 2006 at Queen Sirikit National Convention Center, Bangkok, Thailand "Science and Technology for Sufficiency Economy": 2 pp. (in English) ["During November 2004 to November 2005, samples of edible aquatic insects were collected from 6 sampling sites and 6 local markets. In addition, physical and chemical parameters of water quality were also determined. The result showed that total edible aquatic insects were 3 orders 10 families and 20 genera. Family Notonectidae represented as highest number of individual. According to the diversity index, Ban Jam, was found as the highest diversity (2.98) while Ban San Rim Ping, showed highest species richness (3.14). For nutritional

values analysis, family Hydrophilidae in order Coleoptera showed highest protein content, family Belostomatidae in order Hemiptera showed highest crude fat level whereas, highest level of carbohydrate, fiber and ash were belonged to family Gomphidae in order Odonata. The physical and chemical parameters analysis revealed that there were no significant different among sampling sites and water quality assessment resulting as mesotrophic – eutrophic status." 8173. Osadowski, Z.; Obolewski, K.; Strzelczak, A. (2008): Influence of anthropogenic factors on microhab-

itats inhabited by riverine hydrobionts – assessment with MRT method. *Ecological Questions* 10: 41-50. (in English) ["This study concerns the influence of urban area on vegetation and invertebrates inhabiting the Ślupia River (northern Poland). Altogether, 10 plant communities and 37 macrozoobenthos taxa were determined during four seasonal samplings (October 2005, January, April and August 2006). In order to reveal how the city of Ślupsk affects the vegetation and fauna, MRT (multivariate regression tree) models were created. On their basis the most important factors were determined from the following set of variables: season, water temperature, salinity, distance, water depth, bottom type, location in the river bed and degree of river bed transformations. Performed analyses showed that vegetation in the urban area was primarily influenced by distance (correlated with anthropogenic pressure), while for invertebrates season and temperature were the most important factors." 8175. Paz, A.; Moreno, P.; Rocha, L.; Callisto, M. (2008): Effectiveness of protected areas for the conservation of water quality and freshwater biodiversity in reference sub-basins in Das Velhas River. *Neotropical Biology and Conservation* 3(3): 149-158. (in Portuguese, with English summary) ["The creation of protected areas is one of the most important methods for the preservation of the biodiversity. It does not necessarily mean that the creation of these areas will guarantee the proper conservation of all biodiversity. It is necessary to evaluate the site, the protection capacity and the ecological status of this environment and if the management is effective. The proper conservation and management of rivers and the maintenance of their ecological integrity are essential to preserve the biodiversity and the health of freshwater ecosystems in Brazil. In this study, we assessed the effectiveness of six protected areas in maintaining the quality of freshwater habitats and in preserving the benthic assemblages in Das Velhas river watershed. Both abiotic and biotic analysis showed that the protected areas are effective in preserving the sampling stretches of Das Velhas watershed, due to the use control and the land occupation in the surrounding areas. The results suggest that, although the protected areas do not have the conservation of freshwater biodiversity as their priority, its effective management guaranteed the preservation of benthic communities in those rivers." (Authors) Odonata are treated at the family level.] Address: Paz, Aline, ICB, Depto. Biologia Geral, Lab. Ecologia de Bentos, UFMG, Caixa Postal 486, 31270-901, Belo Horizonte, MG, Brazil. 8179. Reinhardt, K. (2008): Der Beitrag von Eduard May (1905-1956) zur Libellenkunde (Odonata). *Libellula* 27(1/2): 89-110. (in German, with English summary) ["E. May worked on Fritz Ris's Odonata collection at the Senckenberg Museum in Frankfurt/Main between 1929 and 1931. This work led to most of his odonatological papers. Most of his original papers appear to be largely based on Friedrich Ris's unpublished manuscripts and notes and vary considerably in quality and novelty. E. May also published several reviews, most notably the Odonata part in the 'Fauna arctica' and the 'Tierwelt Deutschlands'. In the latter he covered the literature in depth, in particular ecological and behavioural observa-

tions for individual species, rather than the Odonata as a whole. As such he is among the founders of the 'Integrating Strand' sensu Corbet (1991) of German speaking odonatology although much of this work is based on earlier observations mainly by Wesenberg-Lund (1913) and Tillyard (1917). It remains unknown how E. May, who had published little on the Odonata, happened to become the contributor to such a prestigious reference series. Other odonatological works of E. May include a faunistic paper on Odonata collected in China, a paper on the classification of the Coenagrionidae and some field observations. None of these contributions are particularly original. His last paper on the Odonata was published in 1935. However, Odonata may have remained part of May's interest. As first evidenced here, in 1948 he stated that two publications on the Calopterygidae were in press and in preparation, both of which, however, never appeared in print." 8180. Robison, H.; McAllister, C.; Carlton, C.; Tucker, G. (2008): The Arkansas endemic biota: An update with additions and deletions. *Journal of the Arkansas Academy of Science* 62: 84-96. (in English) ["It has been over a decade since the publication of Robison & Allen (1995) that provided the definitive list of endemic flora and fauna of Arkansas. The present study brings up-to-date the endemic biota of the state. Since 1995, several new species have been described and new discoveries have been made, adding species to the state biota. Other species are deleted and new distributional information on other state endemics is presented. Specifically, 3 new plant species are added to the state list while 4 plant species are deleted. Sixteen new animal species/subspecies are added to the state list while numerous species are deleted. These changes bring to 110 (10 species of plants and 100 species/subspecies of animals) the total number of Arkansas state endemic plants and animals presently known, which represents a decrease by 7 species from the 117 species reported in 1995." *Cordulegaster talaria* Tennessee 2004 is an addition to the state list of endemics. "This new dragonfly was described from a first-order tributary of the Caddo River at Caddo Gap in Montgomery County. It was also reported from a site in Garland County and is considered endemic to the Ouachita Mountains of western Arkansas. Habitat of this new odonate is densely-shaded small seeps." 8182. Schuran, E. (2008): The impact of Deltamethrin on larval development of dragonflies (Odonata) of

the Okavango delta, Botswana. Diploma Thesis, Anhalt University (FH), Bernburg, Department 1, „Nature Conservation & Landscape Planning“ in cooperation with the Harry Oppenheimer Okavango Research Centre (HOORC), University of Botswana, Maun, Botswana: 39 pp. (in English, with German summary) ["Tsetse flies have long been a threat to the health of humans and their livestock in tropical and subtropical Africa. In the early 1940s, the first attempts to control or eradicate *Glossina morsitans centralis* were implemented in order to fight concealed pupae in the ground. Methods used were bush clearance, game destruction and ground spraying. The mid 1970s saw the dominance of aerial spraying with dieldrin and DDT above all other techniques. After a ten year break of aerial applications in the 1990s and a new outbreak of trypanosomiasis in 1999, deltamethrin, which is considered far less dangerous to the environment, was used in 2001/02 to fight the new outbreak. Tsetse fly control monitoring conducted between 2002 and 2005 did not detect any tsetse in the sprayed areas. However, it does appear that deltamethrin applications were responsible for a significant decrease in terrestrial and aquatic invertebrate abundance and shifted species composition within different habitats in the Okavango Delta. For a closer investigation of the affects caused by deltamethrin, fourteen artificial ponds were constructed at the ground of the Harry Oppenheimer Okavango Research Centre (HOORC) in May 2007. Half of these were treated with spraying campaigns of equivalent dose of deltamethrin after natural colonisation by freshwater invertebrates. The observation of subsequent effects focused primarily on Dragonflies (Odonata). During the research period was observed, that the abundance of invertebrate fauna decreased drastically in treated ponds. The emergence of Odonata stopped within these ponds almost entirely whereas Odonates in control ponds constantly flourished successful reproduction. This experiment was simultaneously conducted for Odonata larvae and *Bufo poweri* tadpoles under laboratory conditions. Applied was a concentration (30 µl) equivalent to the dose used in former spraying operations. Additionally the experiment was repeated with just half of the concentration. In both cases the results resembled and supported those obtained under field conditions. Odonata larvae died within 3 hours at a concentration of 15 µl and 30 µl; hence measurements of probably occurring delays in larval growth could not be measured. In accordance to results from the laboratory experiment the lethal dose is estimated below 15 µl. In accordance to the obtained results the significant increase in mortality of Odonata larvae and other fresh water invertebrates can not be denied. Hence, all further campaigns of aerial spraying should be handled carefully and with utmost concern. The impact of deltamethrin needs to be analyzed in a more controlled setting in order to achieve more concrete and generalizable results to avoid further endangerments of already threatened species and a loss in biodiversity." (Author)] Address: not stated

8183. Schweighofer, W. (2008): Syntopes Vorkommen von *Cordulegaster boltonii* und *C. heros* an einem Bach im westlichen Niederösterreich (Odonata: Cordulegastridae). *Libellula* 27(1/2): 1-32. (in German, with English summary) ["For the first time, co-occurrence of larval *C. boltonii* and *C. heros* was detected at three small streams in western Lower Austria. At one of these streams some aspects of this co-occurrence were investigated during 2006 and 2007. As no conspicuous

differences in larval microhabitat use could be found between the two species, an intensive mark-release-recapture study was conducted on male adults. This study revealed slight differences in patrolling activity patterns between the two species, both seasonally and daily. This was interpreted as a tendency to mutually avoid peaks in patrolling activity. At the stream studied, patrolling males of *C. boltonii* were much more frequent than those of *C. heros*. Furthermore, data on minimal lifespan and site fidelity of patrolling males was recorded. A few long-lived males visited the stream 35 days after having been marked. Some males displayed a tendency to frequent a certain stream section, but no males remained solely in one location. Only single individuals of a third Cordulegaster species, *C. bidentata*, were found at the study site." (Author)] Address: Schweighofer, W., Ötscherblick 10, A-3661 Artstetten, Austria. 8187. Serrano-Meneses, M.A.; Córdoba-Aguilar, A.; Azpilicueta-Amorín, M.; González-Soriano, E.; Székely, T. (2008): Sexual selection, sexual size dimorphism and Rensch's rule in Odonata. *Journal of Evolutionary Biology* 21: 1259-1273. (in English) ["Odonata exhibit a range of sexual size dimorphism (SSD) that includes species with male-biased (males > females) or female-biased SSD (males < females) and species exhibiting nonterritorial or territorial mating strategies. Here, we use phylogenetic comparative analyses to investigate the influence of sexual selection on SSD in both suborders: Anisoptera and Zygoptera. First, we show that damselflies have male-biased SSD, and exhibit an allometric relationship between body size and SSD, that is consistent with Rensch's rule. Second, SSD of dragonflies is not different from unit, and this suborder does

not exhibit Rensch's rule. Third, we test the influence of sexual selection on SSD using proxy variables of territorial mating strategy and male agility. Using generalized least squares to account for phylogenetic relationships between species, we show that male-biased SSD increases with territoriality in damselflies, but not in dragonflies. Finally, we show that nonagile territorial odonates exhibit male-biased SSD, whereas male agility is not related to SSD in nonterritorial odonates. These results suggest that sexual selection acting on male sizes influences SSD in Odonata. Taken together, our results, along with avian studies (bustards and shorebirds), suggest that male agility influences SSD, although this influence is modulated by territorial mating strategy and thus the likely advantage of being large. Other evolutionary processes, such as fecundity selection and viability selection, however, need further investigation." (in English) ["Alfalfa (*Medicago sativa* L.) is a superb forage, but it can be shelter by a complex of insect pests, natural enemies and pollinators. Alfalfa insect populations can vary greatly from field to field. Therefore, it is essential to check each alfalfa field frequently for the presence of insects. The survey of the insect fauna of alfalfa was carried out in different areas of Egypt like Ismailia, Suez, Swia Oasis and The New Valley. A high number of insects were collected from alfalfa fields. Different samples were collected during the season 2003, the insect faunal composition could be categorized to the following groups; pests, natural enemies and pollinators." (Authors) *Ischnura senegalensis* and *Crocothemis erythraea* are listed as common predators of pest insects.] Address: Mohamed A. Shebl, Department of Plant Protection, Faculty of Agriculture, Suez Canal University, Ismailia, Egypt

8189. Simaika, J.P. (2008): Conservation biogeography of South African dragonflies (Odonata). M.s. Thesis, Stellenbosch University, Department of Conservation Ecology and Entomology, Faculty of AgriSciences: XI + 71 pp. (in English) ["The great pressures on freshwaters require their conservationists and managers to develop methods to rapidly and accurately assess their condition. Dragonflies are excellent indicators of habitat integrity and are effective organisms for this purpose. However, assessment must be done at the correct spatial scale. My aim here is to optimize the spatial resolution at which species are mapped, using three different concepts and methods in freshwater invertebrate distribution mapping, with special emphasis on IUCN Red Listing. The first is the extent of occurrence (EOO) concept, using the minimum convex polygon, and the second, the area of occupancy (AOO) concept, using IUCN and quaternary catchments. The third approach uses a river layer to compare the suitability of grids as opposed to catchments in mapping. In this study I found that area estimation based on minimum convex polygons should not be encouraged for aquatic organisms. This study also suggests that the IUCN concept of area of occupancy (AOO) should be redefined simply as occurrence, referring to known point-locality presences

only and, if future data allow to known absences. The IUCN extent of occurrence (EOO), for aquatic species, should be defined as 'the sum of the smallest hydrological units identified of presently known, inferred or projected occurrences of a taxon, excluding cases of vagrancy, that are used to estimate the threat to a taxon'. A single hydrological unit is also the conservation or management unit. Currently, that unit is the quaternary catchment. Dragonflies have excellent potential as indicators of habitat integrity. For this purpose, my aim was to develop the Dragonfly Biotic Index (DBI) for South Africa and compare the DBI to another index, the Average Taxonomic Distinctness Index (AvTD), which was believed to have potential in assessments. The DBI and AvTD are correlated, which suggests that they could be used on a complementary basis to prioritize sites. The DBI is a low-cost, easy-to-use method and is already used for measuring habitat recovery. It has great potential for environmental assessment and monitoring freshwater biodiversity, especially as a complement to freshwater quality assessments that use macroinvertebrate scores. I thus recommend its integration into freshwater management and conservation schemes." 8193. Springer, M. (2008): Aquatic insect diversity of Costa Rica: state of knowledge. *Rev. Biol. Trop.* 56 (Suppl. 4): 273-295. (in English) ["Costa Rica hosts an extraordinarily high biodiversity and is among the best studied neotropical countries. Insects represent the most diverse group of organisms, not only in terrestrial but also in aquatic, especially freshwater, habitats. Among the most diverse aquatic insect orders are the Trichoptera, Diptera and Coleoptera; although Ephemeroptera can locally also be very abundant and diverse. In Costa Rica, the taxonomically best known orders of aquatic insects are Trichoptera, Odonata, and Plecoptera and within the Dipterans, groups of medical im-

portance have received special attention. The interest in aquatic insects has been constantly growing in Costa Rica over the past 10 years, but scientific publications are widely dispersed and often difficult to locate. Due to the importance of aquatic organisms in environmental impact studies and biomonitoring of freshwater habitats, there is an urgent need for comprehensive studies and publications that are locally available. In this sense, the present paper tries to give an overview on the state of knowledge and the literature published to date on the aquatic insects of Costa Rica, taking in account taxonomic, biological and ecological studies. [...] The country's Odonata fauna is very well known, especially the adults, but also, to some extent, the immatures. For the 268 species of Odonata existing in Costa Rica, a great amount of taxonomic works have been published (...), and the Costa Rican dragonfly fauna is considered to be the best known of all Latin-American countries (Ramírez et al. 2000). Despite this, only half of the species have their nymphal stages described and next to nothing is known about their behaviour, natural history, ecology and distribution (Ramírez 1996-1997, Ramírez et al. 2000.)] Address: Springer, Monika, Escuela de Biología, Universidad de Costa Rica, 2060 San Pedro de Montes de Oca, San José, Costa Rica. Biologie animala LIV:* 169-176. (in English, with Romanian summary) [Spatial and temporal distribution of benthic macroinvertebrates from the Ozana River was studied seasonally at 4 stations between autumn 2003 and summer 2004. As a result of the examination of 877 individuals collected 34 taxa were identified. The most diverse group were Ephemeroptera (8 taxa), Diptera (7 taxa), Gastropoda (5 taxa), and Plecoptera (4 taxa), whereas in terms of number of individuals dominant were Ephemeroptera (534 individuals), Trichoptera (121 individuals), and Diptera (93 individuals). The most abundant species was *Ecdyonurus* dis-

par (211 individuals), followed by *Paraleptophlebia submarginata* (125 individuals), and *Hydropsyche pellucidula* (120 individuals). Species assemblages of the macrobenthos and variations in ecological indices at stations with respect to seasons were determined and discussed." (Authors) Gomphus flavipes] Address: "Al. I. 8199. Takahashi, Y.; Watanabe, M. (2008): Male mate preference depending on mating experience in the damselfly, *Ischnura senegalensis* (Rambur) (Odonata: Coenagrionidae). *Japanese Journal of Entomology* N.S. 11(1): 13-17. (in Japanese, with English summary) ["Females of coenagrionid damselflies exhibit colour dimorphism, andromorph and gynomorph. Males seem to switch reversibly their mate choice to the morphs by prior experience of encounters with females. To clarify the effect of mating experience on male mate preference, binary choice experiments between the two female morphs in *Ischnura senegalensis* were conducted in the laboratory. Unexperienced males that had been reared separately from females after emergence showed fair selectivity, indicating that the innate male mate preference was not biased. Binary choice experiments for males that had been put into a small cage with a single female in the morning were also conducted both in the afternoon and in the following morning. In the former, males that mated with the female during the morning significantly preferred the same female morph, while males that did not mate due to the female rejection showed fair selectivity. In the latter, males that mated with female during the morning of previous day showed fair selectivity. These results indicate that the male mate preference changes depending on the prior mating experience, and the biased male preference disappears by the following morning." 8203. Viallanueva, R. (2008): Some notes on the dragonflies of Dinagat, northeast Mindanao, Philippines. *Echo* 2008: 2. (in English) [Verbatim: When arriving on Dinagat Island I travelled through the interior from Dinagat town to Albor-Libjo. The entire area from Dinagat to Albor was completely deforested and I saw only some areas with secondary growth, particularly in the mountain areas of Basilisa. Dragonfly habitats seen along the road included small ponds, wet rice field areas and creeks. Some small rivulets and trickles were present along some roadside cliffs. *Pantala flavescens* was often seen at roadsides and in open areas, *Macrodiplax cora* was also seen hovering at some ponds and pools along the road. While staying in the Albor District Hospital for 3 days I managed to explore few places in its vicinity. The area seems to be bare of forest specialist and only *Prodasineura integra* was noted near a small stream. Several opportunistic species like *Diplacodes trivialis*, *Neurothemis terminata* and *Orthetrum sabina* were the only Anisoptera encountered. I arrived in Loreto and stayed in Loreto District Hospital where I work as medical officer. I explored the surrounding waterways and managed to collect some specimens of *Teinobasis* sp. (nov?) in the nearby Nipa swamp were *Raphismia bispina* was also present. Aside from several widespread oriental species I managed to collect a *Gynacantha* sp female entering the hospital. During a short trip to a river near the entrance road to Chromico mining firm I saw *Euphaea amphicyana* and *Drepanosticta mylitta* and *Risicnemis appendiculata* were found at a shaded rivulet near the river. A trip to Paragua Forest reserve yielded two new records for the island: *Rhinagrion philippina* and *Teinobasis cf filamentum*. *Risicnemis prauesta* is the commonest species found in the area and was even found at some distance from the waterways. In total I visited seven sites thus far mostly within Loreto and a total of 29 species were recorded.] Address: Villanueva, R.J.T., D3C Gahol Apartment, Lopez Jaena St., Davao City, 8000 Philippines. - 8204.** Wang, X.-s.; Li, Y.; Shi, Y.-f. (2008): Effects of sandwich microstructures on mechanical behaviours of dragonfly wing vein. *Composites Science and Technology* 68: 186-192. (in English) ["Dragonfly wings, which consist mainly of the veins and membranes, are highly specialized flight organs adapted to cope with the individual flight behaviour of each dragonfly. Therefore, it is important and necessary from a bionic view to investigate how the microstructures affect their mechanical behaviours of elements. In this study, it is focused on effects of microstructure on mechanical characteristics of dragonfly wing vein. These results indicate that the microstructure of vein is a complex sandwich structure, which consists of chitin shell and protein/muscle with some fibrils. This sandwich structure can be subjected to the rather greater bending loading and torsional deformation based on the von Mises stress and flexural deformation analysis of finite element analysis (FEA). It assists us to understand and design the new high strength-to-weight ratio of composite materials or structure." - 8205.** Westermann, K. (2008): Auswirkungen von Hochwassern auf die Emergenzraten von Libellen an Fließgewässern des Oberrheinischen Tieflandes (Odonata). *Libellula* 27(1/2): 63-88. (in German, with English summary) ["Exuviae were collected systematically during several years at four running water sites in the southern Upper Rhine lowland plains. Different impacts of floods on the emergence of Odonata were documented: At two channels, over which the main flood discharge occurred, the emergence rates of all frequent species decreased to insignificant levels. In contrast, emergence rates drastically increased at a side channel, which featured little current during floods. At one stream, the emergence rates of some species recovered at the earliest after two years. In a mesotrophic channel considerable amounts of nutrients were accumulated during a flood, causing the macrophyte populations to almost entirely die off, so that Odonata larvae evidently migrated away in large numbers. Emergence was at most an exception during floods. A long-lasting flood delayed the emergence in the same year for several weeks. The specific flood characteristics of a running water site are crucial factors for both species composition and the abundance of Odonata. As reported from other organisms, the results confirmed that a 'catastrophic drift' may occur during floods, possibly leading to a substantial reduction of population sizes. The larvae of Odonata can survive in refugia like side channels, and recolonize watercourses with flood-depleted subpopulations from there. The canalization of most watercourses in Central Europe has destroyed many of these refugia or has reduced their effectiveness. Hence, securing and reconstructing refugia has become a key challenge for water management authorities when running waters are revitalized and measures for flood protection are taken. The conservation or recreation of a species-rich and abundant fauna in riverscapes cannot succeed otherwise." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany. - 8210.** Yu, X. (2008): Ovipositing of *Ischnura aurora*. *Echo* 2008: 2. (in English) [Verbatim: In the summer of 2006, I went to Yunnan, China for fieldwork. In a valley in Tengchong County I noticed a female *Ischnura aurora* ovipositing in the centre of a little pool on a stem of a kind of horsetail (*Equisetum* sp.). She moved slowly down along the stem into the water and stayed below the water for about two minutes. Suddenly, just like a missile launched from a submarine, she was ejected out of the water without leaving a ripple on the face of the pool and without any interruption she flew around and ceased at another stem nearby. All this happened in a split second and I am sure she came out off the water directly, so without crawling upward along the stem, as the position where she came out of the water was at a little distance from the stem of the plant. About one minute later, she tested the new stem with her ovipositor and went down into the water again. Four minutes later she used the same trick and came out of the water and flew away. I have observed the submerged oviposition behaviour of *Ischnura asiatica*, *Paracercion v-nigrum*, *Euphaea ochracea*, and some other species, but they never showed such an impressive style like this female *Ischnura aurora*.] Address: Xin Yu [yuxin@mail.nankai.edu.cn]

8213. Akira, M. (2009): Growth of several fish and dragonfly species in the drainage system of a consolidated paddy field. *Japanese Journal of Conservation Ecology* 14(1): 3-11. (in Japanese, with English summary) ["This study examined the growth of aquatic animals in the canal system constituting the main, lateral, and farm drains in a consolidated paddy field, with emphasis on canal structure and year-round water flow in the canals. A field survey at six sites, which involved three different canal levels, was carried out in Chikusei, Ibaraki Prefecture, Japan (36°21'N, 139°59'E). Sampling was conducted at monthly intervals from April 2001 to March 2002. Of the freshwater fish, young-of-the-year (YOY) *Zacco platypus* appeared in September, while YOY *Misgurnus anguillicaudatus* appeared in May. Last instars of *Calopteryx atrata* were collected only in June, suggesting emergence about this time, while those of *Orthetrum albistylum speciosum* were collected in May and July, suggesting a longer duration of emergence. Since populations of the four species decreased during the non-irrigation season when the wa-

ter level was low, I propose that a marsh be developed as a wintering site in the lower reaches of the canal system in consolidated paddy fields." (Author)] Address: not available

8214. Al-Houty, W. (2009): Insect biodiversity in Kuwait. *International Journal of Biodiversity and Conservation* 1(8): 251-257. (in English) ["Natural causes, together with the deliberate destruction of the environment with the objective of forcing political, military and means of civilization have resulted in great deterioration of the environment. The insect fauna of Kuwait has suffered from such destructions, resulting in some becoming extinct, while others are threatened with extinction from Kuwait desert, however, others still flourishing. This contribution records the status of the entomofauna in Kuwait prior to the Gulf War (from 1980 - 1990), and after the Gulf War (from 1992 - 2008), including the effects of new modern dwellings and severe draught. During the first period 474 species of insects were recorded from Kuwait (356 genera, 109 families, 19 orders) but the numbers of species increased to 492 (273 genera, 116 families, 19 orders) during the second period. The differences are caused by disappearance and re-appearance. This study will discuss the reasons for increase, disappearance and reappearance of insects in the desert ecosystem of Kuwait." (Author) 11 odonate taxa - without specification - and each prior and after the war are listed.] Address: Al-Houty, W., Department of Biological Sciences, Faculty of Science, University of Kuwait. 8217. Alvarez, G.; Nicieza, A.G. (2009): Differential success of prey escaping predators: Tadpole vulnerability or predator selection? *Copeia* 2009(3): 453-457. (in English) ["Species inhabiting habitats with different predators are expected to show divergent phenotypes for antipredator traits. Here, we used a predator-prey system of dragonfly larvae and tadpoles to determine if vulnerability to a common predator differs in species with contrasting antipredator strategies. We examined the vulnerability of tadpoles of *Rana temporaria* and *Bufo bufo* to predation by *Aeshna* larvae when the two species co-occur in the same arena. Our results demonstrated that tadpoles of *Bufo* were more vulnerable than tadpoles of *Rana* despite the observation that dragonfly larvae did not show initial preferences for either prey species. Differences in susceptibility to predation seem to be associated with their low performance in evasive responses. Most important, our data suggest that despite chemical protection that effectively prevented the consumption of *B. bufo* by *Aeshna* larvae, injured tadpoles that otherwise had survived are at a high risk of being cannibalized. This loss of survival advantage of a chemical defense is an indirect result of two antipredator responses: the effectiveness of the chemical defense itself and the immobility of refused tadpoles." (Authors)] Address: Álvarez, G, Depto de Biología de Organismos y Sistemas, Unidad de Ecología, Univ. de Oviedo, E-33006 Oviedo, Spain. E-mail: dalvarez@innova.uniovi.es.

8218. Andrew, R.J. (2009): Fine structure of the egg chorion in two anisopteran dragonflies from central India (Libellulidae). *Odonatologica* 38(4): 359-363. (in English) ["The fine structure of the egg chorion in *Brachydiplax sibirica* and *Orthetrum s. sabina*, is described using the scanning electron microscope. The unwetted eggs of *B. sibirica* are bluish-green and spindle-shaped while those of *O. s. sabina* are oval and light brown in colour. The egg chorion is distinctly divided into an outer exochorion and an inner tough endochorion. The exochorion expands into a thick, sticky, jelly-like structure in water during oviposition, whereas the endochorion remains unchanged. The endochorion is thin and smooth in *O. s. sabina*, but in *B. sibirica* the undersurface of the endochorion is pitted and rough. The apical

micropylar apparatus is composed of a sperm storage chamber (atrium) and a median projecting stalk, which possesses a pair of sub-terminal orifices. The atrium in *B. sibirica* is dome shaped with a tiny stalk whereas in *O. s. sabina* the micropylar apparatus is triangular with a longer stalk and a pair of almost apically placed orifices. Significant variations occur in the shape and size of the micropylar apparatus. The functional interrelationship of the micro morphological modifications in the chorionic structures is discussed." (Author)] Address: Andrew, R.J., Post-Graduate Department of Zoology, Hislop College, Nagpur 440 001, India. E-mail: rajuan-drew@yahoo.com

8220. Ardila-Garcia, A.M.; Gregory, T.R. (2009): An exploration of genome size diversity in dragonflies and damselflies (Insecta: Odonata). *Journal of Zoology* 278: 163-173. (in English) ["Like most insect orders, the Odonata remain poorly studied from the perspective of genome size. They exhibit several characteristics that make them desirable targets for analysis in this area, for example a large range in body size, differences in developmental rate, and distinct modes of flight – all of which are related to genome size in at least some animal taxa. The present study provides new genome size estimates and morphometric data for 100 species of odonates, covering about 1/5 of described North American diversity. Significant relationships are reported between genome size and body size (positive in dragonflies, negative in damselflies), and there is also indication that developmental rate and flight are related to genome size in these insects. Genome size is also positively correlated with chromosome number across the order. These findings contribute to an improved understanding of genome size evolution in insects, and raise several interesting questions for future research." 8221. Argyroudi, A.; Chatzinikolaou, Y.; Poirazidis, K.; Lazaridou, M. (2009): Do intermittent and ephemeral Mediterranean rivers belong to the same river type?. *Aquatic ecology* 43(2): 465-476. (in English) ["The benthic macroinvertebrate communities and ecological quality of eleven temporary rivers (seven intermittent and four ephemeral) in Dadia National Park, north-eastern Greece, were examined with respect to the degree of flow temporality. Sampling took place during the high flow season at both ephemeral and intermittent sites and during the low flow season only at the intermittent ones, which receded to pools. Despite the remarkable seasonal variation in both the hydrology and ecology of the intermittent rivers, the various metrics and indices as well as the multivariate analyses confirmed the clear distinction between the two river types (ephemeral and intermittent). Existing European quality indices do not sufficiently differentiate between ephemeral and intermittent river types, and thus cannot reliably discriminate the degree of natural variability from human induced stressors in temporary rivers." (Authors) Cluster A was composed of the low flow intermittent sites and characterized mostly by the Diptera family of Chironomidae

and the Odonata Platycnemydidae (40.62% and 21.99% contribution, respectively.)] Address: Argyroudi, A., School of Biology, Department of Zoology, Aristotle University of Thessaloniki, 54124 Thessaloniki, Greece. E-mail: anna.argyrou@gmail.com

8222. Asokan, S.; Samsoor Ali, A.M.; Manikannan, R. (2009): Diet of three insectivorous birds in Nagapattinam District, Tamil Nadu, India – a preliminary study. *Journal of Threatened Taxa* 1(6): 327-330. (in English) ["The dietary composition of the White-breasted Kingfisher *Halcyon smyrnensis*, the Small Bee-eater *Merops orientalis* and the Black Drongo *Dicrurus macrocercus* was studied between 2005 and 2006 in Nagapattinam District, Tamil Nadu, India by analyzing regurgitated pellets. The analysis revealed that the White-breasted Kingfisher preys mainly on arthropods (83.40%) and less on vertebrates; seven orders of insects were identified, with Coleoptera, Hemiptera, Hymenoptera and Orthoptera predominant. The small bee-eater diet is composed of Coleoptera (22.3%), Hymenoptera (20.8%), Hemiptera (14.1%), Orthoptera (12.6%), Odonata (10.7%), Lepidoptera (10.4%) and Diptera (8.6%). Beetles were also found to be the most frequent prey (23.7%) in the diet of black drongos, followed by Hemiptera (21.6%), Orthoptera (19.3%), Hymenoptera (14.4%), Lepidoptera (7.5%), Diptera (6.8%) and Odonata (6.0%)."] (Authors)] Address: Asokan, S., Ph.D. Research Scholar, Department of Zoology & Division of Wildlife Biology, A.V.C. College (Autonomous), Manampandal, Mayiladuthurai, Tamil Nadu 609305, India. E-mail: beeeasokan@yahoo.co.in

(in Turkish, with English summary) [The Odonata of Van Province, Turkey were investigated in 2003 and 2004. A total of 11 species including new provincial records (*Calopteryx splendens intermedia*, *Lestes barbarus*, *Aeshna affinis*, *Anax imperator* *Orthetrum anceps*, *Sympetrum meridionale*) were recorded.] Address: Özgökçe, M.S., Yüzüncü Yýl Üniversitesi, Ziraat Fakóltesi, Bitki Koruma Bölümü, VAN, Turkey. e-mail: msozgekce@yyu.edu.tr

8224. Ballengée, B.; Sessions, S.K. (2009): Explanation for missing limbs in deformed amphibians. *Journal of Experimental Zoology Part B: Molecular and Developmental Evolution* 312(7): 770-779. (in English) ["We present evidence that the most commonly found deformities in wild-caught amphibians, those featuring missing limbs and missing limb segments, may be the result of selective predation. Here we report that predatory dragonfly nymphs can severely injure and even fully amputate developing hind limbs of anuran tadpoles. Developmental responses of the injured/amputated tadpole limbs range from complete regeneration to no regeneration, with intermediate conditions represented by various idiosyncratic limb deformities, depending mainly on the developmental stage of the tadpole at the time of injury/amputation. These findings were reinforced by experimental amputations of anuran tadpole hind limbs that resulted in similar deformities. Our studies suggest that selective predation by dragonfly nymphs and other aquatic predators may play a significant role in the most common kinds of limb deformities found in natural populations of amphibians." (Authors)] Address: Sessions, S.K., Department of Biology, Hartwick College, Oneonta, New York, USA. E-mail: sessions@hartwick.edu

8225. Beckemeyer, R.J. (2009): First record of the dragonfly *Miathyria marcella* (Selys) for Kansas (Odonata: Anisoptera: Libellulidae). *Transactions of the Kansas Academy of Science* 112: 130-132. (in English) [USA, Sedgwick County, Kansas, Wichita State University Ninescah Field Station, 26-IX-2008, single specimen of a mature male *M. marcella*. "This occurrence is approximately 200 miles beyond the previously recorded range, a distance that does not seem likely to be due to an individual wandering about while feeding. Dragonflies are often displaced long distances by weather systems. Such a system was in place from 8 to 15 September, 2008, in the form of Hurricane Ike." 8226. Beckemeyer, R.J. (2009): Kinematics of a territorial defense maneuver by the dragonfly *Pachydiplax longipennis* (Odonata: Anisoptera: Libellulidae). *Transactions of the Kansas Academy of Science* 112(3/4): 169-180. (in English) ["A high speed (1000 frame/s) video segment, 0.367 seconds long, showing a territorial male *P. longipennis* dragonfly responding in the field to a challenge from a conspecific male, reveals that the defender used a high rate yaw-turn to position itself to drive off the challenger. In-phase flapping of the fore and hind wings was used during the yaw turn and in the following pursuit of the challenger. During the right yawing turn, the dragonfly flapped its right wings to a more negative stroke amplitude than its left wings on the first two downstrokes (1st downstroke: -65° right wing, -45° left wing; 2nd downstroke: -90° right wing, -50° left wing). Upstroke amplitudes were the same for both wings throughout the yaw turn. The 135° yaw turn was executed, in three wing beats (0.085 s) and in about 6/10ths of a body length of horizontal travel, at an average yaw rate of 1590%, and a peak turn rate of 3000%. This rapid yawing rotation was accompanied by a significant deceleration in flight path speed, which dropped from 30 to 7 body lengths per second (1.1 m/s to 0.3 m/s) as the dragonfly yawed through 90° in the first half of the yaw turn. The wingbeat frequency dropped from 41.7 Hz at the beginning of the yaw turn to 33.3 Hz at the end. The horizontal and vertical flight velocity components both reached zero near the completion of the yaw turn, during the upstroke portion of the third wing beat. Within 1/10th of a second after completing the yaw turn, the defender had reached speeds of 8 body lengths per second (0.3 m/s) upward and 14 body lengths per second (0.55 m/s) horizontally, and was accelerating along its flight path at approximately 150 body lengths per second² (5.5 m/s²) in its pursuit of the challenger." 8229. Bergmann, T.; Hadrys, H.; Breves, G.; Schierwater, B. (2009): Character-based DNA barcoding: a superior tool for species classification. *Berliner und Münchener Tierärztliche Wochenschrift* 122(11/12): 446-450. (in English, with German summary) ["In zoonosis research only correct assigned host-agent-vector associations can lead to success. If most biological species on Earth, from agent to host and from prokaryotes to vertebrates, are still undetected, the development of a reliable and universal diversity detection tool becomes a *conditio sine qua non*. In this context, in breathtaking speed, modern molecular-genetic techniques have become acknowledged tools for the classification of life forms at all taxonomic levels. While previous DNA-barcoding techniques were criticised for several reasons (Moritz and Cicero, 2004; Rubinoff et al. (2006a, b; Rubinoff, 2006; Rubinoff and Haines, 2006) a new approach, the so called CAOS-barcoding (Character Attribute Organisation System), avoids most of the weak points. Traditional DNA-barcoding approaches are based on distances, i.e. they use genetic distances and tree construction algorithms for the classification of species or lineages. The definition of limit values is enforced and prohibits a discrete or clear assignment. In comparison, the new character-based barcoding (CAOS-barcoding; DeSalle et al. 2005; DeSalle, 2006; Rach et al. 2008) works with discrete single characters and character combinations which permits a clear, unambiguous classification. In Hannover (Germany) we are optimising this system and developing a semiautomatic high-throughput procedure for hosts, agents and vectors being studied within the Zoonosis Centre of The „Stiftung Tierärztliche Hochschule Hannover“. Our primary research is concentrated on insects, the most successful and species-rich animal group on Earth (every fourth animal is a bug). One subgroup, the winged insects (Pterygota), represents the outstanding majority of all zoonosis relevant animal vectors." (Authors) The method is exemplified using *Crocothemis erythraea*, *Orthetrum chrysostigma* and *Anax imperator*.] Address: Bergmann, T., Institut für Tierökologie und Zellbiologie, Stiftung Tierärztliche Hochschule Hannover, Bünteweg 17d, 30559 Hannover, Germany. E-mail: tjard.bergmann@ecolevol.de

8230. Bhattarai, G.P.; Horner, J.D. (2009): The importance of pitcher size in prey capture in the carnivorous plant, *Sarracenia alata* Wood (Sarraceniaceae). *The American Midland Naturalist* 161(2): 264-272. (in English) ["Prey capture in pitcher plants has been found to be significantly dependent on pitcher size, but the ac-

tual importance of size is not clearly understood. We studied insect capture by the carnivorous plant *Sarracenia alata* and compared the rate of insect capture per unit capture area of plants with that of nonbiological models and traps. The total mass of insects captured was significantly positively related to capture area for both biological and nonbiological systems. However, the rate of insect capture was significantly greater for plants than for models and traps, which suggests a role of attractants in insect capture in pitcher plants. Odor from decaying insects was found to have a significant effect on insect capture on experimental attraction cups. Further study should focus on the nature of other attractants including nectar, UV reflectance and volatiles to determine their role in insect capture by pitcher plants. [...] Even though dragonflies are commonly observed perching on pitcher hoods, we have never observed one captured in hundreds of pitchers examined." (Authors)] Address: Horner, J.D., Department of Biology, Box 298930, Texas Christian University, Fort Worth, Texas 76129, USA. E-mail: J.Horner@tcu.edu

8231. Bjurström, L. (2009): Impacts of the non-native crayfish (*Pacifastacus leniusculus*) on littoral benthic invertebrate communities in Lake Päijänne. Master of Science Thesis, Department of Biological and Environmental Science, International Aquatic Masters Programme, University of Jyväskylä: 28 pp. + attachments. (in English, with Finnish summary) ["The introduced crayfish *P. leniusculus* is now a permanent resident in many of the large lakes in Finland, but the effects of this large omnivore on lake ecosystems are largely unknown. In general, it is thought that when crayfish abundance increases, species composition of benthic invertebrates may change towards species less vulnerable to predation by crayfish and the snail abundance is expected to decrease. However, indirect impacts of crayfish on benthic communities can also be expected. The impacts of *P. leniusculus* on littoral benthic invertebrate communities in large Lake Päijänne were therefore studied by comparing the benthic invertebrate assemblages of stony shores in lake areas with well established crayfish populations to those in areas without crayfish. The invertebrate community composition differed between the areas, and there was a clear reduction in species richness and abundance and of snail abundance in particular in the presence of signal crayfish. The crayfish sites were dominated by Chironomidae and Oligochaeta and small number of other invertebrate groups (including Odonata, Coenagrionidae, Corduliidae). The non-crayfish sites were dominated evenly by Chironomidae and Oligochaeta, Elmidae, Amphipods, Gastropoda and Trichoptera. [...] The invertebrate density was on average 44 % lower at areas with crayfish than without crayfish. [...] Significant negative relationships at the family level included [...] Coenagrionidae." (Author)] Address: Bjurström, Lotta; not stated

8232. Bonino, M.F.; Lescano, J.N.; Haro, J.G.; Leynaud, G.C. (2009): Diet of *Hydromedusa tectifera* (Tentaculata-Chelidae) in a mountain stream of Córdoba province, Argentina. *Amphibia-Reptilia* 30(4): 545-554. (in English) ["The diet of *H. tectifera* occurring in two mountain streams in the province of Córdoba is described through a comparative analysis of 154 individuals. Turtles were manually captured between August 2005 and August 2006 from streams at the localities of Tanti and Flor Serrana. Before being released, turtles were stomach-flushed, and sex and carapace length

were recorded. The stomach contents were observed under stereomicroscope; prey items were identified and classified according to size and volume. The importance of the different items was quantified using the Index of Relative Importance (IRI). Similarity in the diet between sexes and among size classes and seasons of an annual cycle was evaluated using the simplified Morisita index. Trophic breadth was estimated with the Shannon diversity index. Detrended Correspondence Analysis (DCA) was used to evaluate differences in the diet between categories (sex, size classes). Forty-seven food items belonging to the following taxa were identified: leeches, annelids, gastropods, arachnids, insects, and fishes. According to the IRI value, the most important items in the diet of *H. tectifera* were larvae of Trichoptera (IRI = 33.5), fishes (IRI = 30), and naiads of Odonata (IRI = 25.2). The relative importance of the items varied with size of turtles but not with sex. Size of prey consumed increased with increasing turtle size. A greater trophic breadth was observed in smaller individuals." (Authors)] Address: Leynaud, G.C., Centro de Zoología Aplicada. Facultad de Ciencias Exactas, Físicas y Naturales (Universidad Nacional de Córdoba), Rondeau 798, Casilla de Correo 122, Córdoba (5000), Argentina. Email: gleynaud@efn.uncor.edu

8233. Bowers, J. (2009): The Dragonflies of Lesbos. Promoline SA for the Friends of Green Lesbos, Mytilene, Lesbos. ISBN 978-960-930703-1: 92 pp. (in English) [The book starts with a brief discussion of dragonfly biology and ecology. Dragonfly habitats are listed with typical species. 42 species found on the island are briefly described and illustrated with a photograph. Neuroptera that may be confused with dragonflies are also illustrated. There is a gazeteer of the main dragonfly sites. The book finishes with a discussion of problems of dragonfly conservation. For more details on the Odonata of Lesbos, Greece, see: Lopau, W. (1995): Die Libellenfauna der Insel Lesbos. Libellen, Lurche, Kriechtiere. 8238. Brockhaus, T.; Hartmann, A. (2009): New records of *Epiophlebia laidlawi* Tillyard, 1921 in Bhutan with notes on its biology, ecology, distribution, zoogeography and threat status (Anisozygoptera: Epiophlebiidae). *Odonatologica* 38(3): 203-215. (in English) ["*E. laidlawi* larvae were found for the first time in Bhutan, collected in 5 streams in W and central parts of the country, at altitudes 2350-2885 m a.s.l. The habitats and larval development stages are described, and a brief overview is presented on the biology, ecology and known distribution in Bhutan, India and Nepal. The species inhabits fast running mountain streams in Himalayan broadleaf and subtropical pine forests at an altitude of 1300-2885 m a.s.l. The palaeobiogeographical history of the fossil Epiophlebiidae and Stenophlebiidae and of the 2 extant Epiophlebia species is discussed. *E. laidlawi* is a relict species, living in headwaters of pristine mountain forests. It is endangered because human influences, such as deforestation, provision of water power, erosion and other factors. The best protection would be ensured by the conservation of specific habitats in vast protected areas. This has at least partly been put into action in Nepal." (Authors)] Address: Brockhaus, T., An der Morgensonne 5, D-09387 Jahnsdorf, Germany. E-mail: T.Brockhaus@t-online.de

8239. Brooks, A.C.; Gaskell, P.N.; Maltby, L.L. (2009): Sublethal effects and predator-prey interactions: Implications for ecological risk assessment. *Environmental toxicology and chemistry* 28(11): 2449-2457. (in English) ["Ecological risk assessments tend to focus on contaminant effects on single species in isolation. However, additional effects from interactions between spe-

cies (e.g. predator-prey interactions) may also occur in natural systems. This study investigated the consequences of sublethal contaminant effects in prey on predator-prey interactions, particularly the interaction between prey behavioural changes and predation by predators with different hunting strategies. Ambush (*Ischnura elegans*) and active (*Notonecta glauca* (Heteroptera)) predator species were used in conjunction with three prey species (*Asellus aquaticus* (Crustacea, Isopoda), *Cloëon dipterum* (Ephemeroptera), and *Chironomus riparius* (Diptera)). Immobilised prey demonstrated the importance of prey behaviour for determining predation rates for both single and multiple prey species. *C. riparius* was less responsive following exposure to cadmium, becoming more vulnerable to attack by the active but not the ambush predator. There was also some evidence for reduced general activity in *C. dipterum* following cadmium exposure. Sublethal exposure of prey did not affect the prey choice of active predators, possibly due to prey behavioural changes being insufficient to influence their relative availabilities. However, cadmium exposure of prey did alter their susceptibility to ambush predators. There was a reduction in the proportion of *C. dipterum* and an increased proportion of *A. aquaticus* in the diet of ambush predators, possibly due to reduced activity in *C. dipterum* affecting their relative encounter rates with predators. Sublethal exposures can therefore result in reduced prey survival that would not be predicted by single species toxicity tests." (in English) ["Biological tiny structures have been observed on many kinds of surfaces such as lotus leaves, which have an effect on the colouration of *Morpho* butterflies and enhance the hydrophobicity of natural surfaces. We investigated the micro-scale and nano-scale structures on the wing surfaces of insects and found that the hierarchical multiple roughness structures help in enhancing the hydrophobicity. After examining 10 orders and 24 species of flying Pterygotan insects, we found that micro-scale and nano-scale structures typically exist on both the upper and lower wing surfaces of flying insects. The tiny structures such as denticle or setae on the insect wings enhance the hydrophobicity, thereby enabling the wings to be cleaned more easily. And the hydrophobic insect wings undergo a transition from Cassie to Wenzel states at pitch/size ratio of about 20. In order to examine the wetting characteristics on a rough surface, a biomimetic surface with micro-scale pillars is fabricated on a silicon wafer, which exhibits the same behaviours as the insect wing, with the Cassie-Wenzel transition occurring consistently around a pitch/width value of 20.2." (Authors) *Pantala flavescens* and *Orthetrum albistylum speciosum* have been studied.] Address: Byun, D., Department of Aerospace Information Engineering, Artificial Muscle Research Center, Konkuk University, Seoul 143-701, Republic of Korea. 8247. Carroll, T.M. (2009): Resource pulses and spatial subsidies in Ozark Karst Springs: Effects on community structure and food webs. Ph.D. Dissertation. University of Kansas: 162 pp. (in English) [Steury and Danforth Springs (37°21' N, 93°21' W; 37°24' N, 93°15' W) east of Springfield in the James River basin, Missouri, USA. "Spatial and temporal patterns of invertebrate community composition, biomass, functional diversity, foodweb dynamics, and foodweb complexity were examined in three Ozarks springs. Also examined was the effect of an experimental manipulation of algal production (function of light limitation) on foodweb pathways and complexity. Food source-consumer interactions were determined using carbon and nitrogen stable isotope and stoichiometric analyses. Biocomplexity and functional diversity increased temporally and spatially along the spring source-springbrook gradient likely due to variability in the composition and availability of food sources. Foodweb analyses indicated that the trophic base of the foodweb was autochthonous, shifting temporally towards a greater reliance on allochthonous resources. Spatial and temporal shifts in food availability and utilization were associated with corresponding increases in foodweb complexity. Isotope ratios, based on manipulation of algal production, indicated a shift toward more allochthonous-based pathways and increases in omnivory and foodweb complexity in manipulated (shaded) sections of the spring." (Author) The publication includes many notes on *Argia sedula*, represented in Danforth and Steury (coniferous and deciduous canopies, respectively). Young larvae of *A. sedula* feed on protozoans that colonize fine allochthonous detrital matter, and were prominent in springbrooks with heavy riparian growth of coniferous and deciduous trees.] Address: Carroll, Teresa Mae, <http://kuscholarworks.ku.edu/dspace/handle/1808/5571>

8251. Chakona, A.; Phiri, C.; Chinamaringa, T.; Muller, N. (2009): Changes in biota along a dry-land river in northwestern Zimbabwe: declines and improvements in river health related to land use. *Aquatic Ecology* 43(4): 1095-1106. (in English) ["Macroinvertebrates (including Odonata) were sampled from 15 sites along a dry-land river in northwestern Zimbabwe to assess biotic responses to land use changes along the course of the river. The headwater sites were protected by a riparian corridor of native forest, but this was replaced by intensive subsistence agriculture in the mid-reaches while the lower reaches were located within a protected wildlife area with diverse and wide riparian forests. Canonical correspondence analysis indicated that intensive agricultural activities within the mid-reaches caused severe degradation of the stream physical habitat through increased fine sediment deposition. This coincided with a significant decline in macroinvertebrate richness, diversity, and abundance at the agriculturally impacted mid-reach sites. The presence of wide riparian zones at the lower river sites resulted in significant improvements in stream physical habitat quality, and this was paralleled by significant recovery or reappearance of taxa that had disappeared from the mid-reaches. We suggest that restoration of the riparian vegetation within the mid-reaches of the Nyadza River would lead to improved physical habitat and biotic health of this dry-land river." 8252. Chaplin, G.I.; Valentine, J.F. (2009): Macroinvertebrate production in the submerged aquatic vegetation of the Mobile-Tensaw Delta: Effects of an exotic species at the base of an estuarine food web. *Estuaries and Coasts* 32(2): 319-332. (in English) ["This study, conducted in 1997, reports the first estimates of the im-

pacts of the proliferation of an exotic submerged aquatic vegetation (SAV) species (*Myriophyllum spicatum*) on macroinvertebrate production via comparisons with two co-occurring native SAV species (*Heteranthera dubia* and *Vallisneria spiralis*) in the tide-influenced Mobile-Tensaw Delta (located in the north-central Gulf of Mexico, 30°40' N, 87°55' W). Production of macroinvertebrates was greatest on *M. spicatum* and *H. dubia* and least on *V. americana*. The key determinant of these differences was a greater abundance of amphipods (*Gammarus mucronatus*) found on the leaves of *M. spicatum* and *H. dubia*. Macroinvertebrate production on *M. spicatum* was three times greater (>1 kg m⁻² year⁻¹) than on either of the native SAV species. No-choice palatability tests showed that these differences could not be attributed to differences in invertebrate grazing on these plants. Instead, it is probable that the high production within the structurally complex *M. spicatum* and *H. dubia* was the result of reduced predator foraging efficiency. If true, then the presence of this exotic species probably renders this elevated production inaccessible to most high-order predators." (Authors) Odonata are treated at the suborder level.] Address: Valentine, J.F., Department of Marine Science, University of South Alabama, Mobile, AL 36688, USA. Email: jvalentine@disl.org

8253. Chase, J.M.; Suhlman, R.S. (2009): Wetland isolation facilitates larval mosquito density through the reduction of predators. *Ecological Entomology* 34: 741-747. (in English) ["1. Wetlands harbour high biodiversity and offer important ecosystem services, but they are also a habitat for mosquito larvae (Diptera: Culicidae), which are important disease vectors. 2. Isolation among remnant, or newly created wetlands and ponds, and their consequent density in the landscape, is a key factor that can influence a variety of food web processes, including effects on mosquitoes which are important prey to many predators. 3. We assess the impact of habitat isolation on the density of pond-breeding mosquitoes (several *Anopheles* and *Culex* species) both directly and indirectly through the food web. 4. Results from structural equation modelling of survey data shows that larval mosquitoes are denser in ponds that are more isolated from one another, and that this result was primarily driven indirectly by a reduction of larval mosquito predators (e.g. predaceous insects and amphibians). Furthermore, results from a long-term mesocosm experiment factorially manipulating isolation and predator reduction show that the effect of isolation on mosquito density was eliminated when predators were experimentally reduced. 5. It is concluded that metacommunity processes, both directly and indirectly mediated through predators, can play an important role in the local abundance of wetland breeding mosquitoes and possibly the diseases they spread." (Authors) Mosquito predators are primarily insects in the orders Hemiptera, Odonata, and Coleoptera, as well as salamanders and newts. Their biomass was converted to dry-weight biomass using species-specific conversions.] Address: Chase, J.M., Dept of Biology and Tyson Research Center, Washington University in St. Louis, Saint Louis, MO 63130, USA. 8254. Chase, J.M.; Biro, E.G.; Ryberg, W.A.; Smith, K.G. (2009): Predators temper the relative importance of stochastic processes in the assembly of prey metacommunities. *Ecology Letters* 12(11): 1210-1218. (in English) [St Louis, Missouri, USA. "Communities as-

semble through a combination of stochastic processes, which can make environmentally similar communities divergent (high β -diversity), and deterministic processes, which can make environmentally similar communities convergent (low β -diversity). Top predators can influence both stochasticity (e.g. colonization and extinction events) and determinism (e.g. size of the realized species pool), in community assembly, and thus their net effect is unknown. We investigated how predatory fish influenced the scaling of prey diversity in ponds at local and regional spatial scales. While fish reduced both local and regional richness, their effects were markedly more intense at the regional scale. Underlying this result was that the presence of fish made localities within metacommunities more similar in their community composition (lower β -diversity), suggesting that fish enhance the deterministic, relative to the stochastic, components of community assembly. Thus, the presence of predators can alter fundamental mechanisms of community assembly and the scaling of diversity within metacommunities." (Authors) The following taxa are listed in the supporting material to the paper: *Aeshna canadensis*, *Epiaeschna heros*, *Tetragoneuria synosura*, *Erythemis simplicicollis*, *Libellula cyanea*, *L. incesta*, *L. pulchella*, *Pachydiplax longipennis*, *Pantala hymenaea*, *Perithemis tenera*, *Plathemis lydia*, *Sympetrum rubicundum*, *S. corruptum*, *Tramea lacerata*, *Archilestes grandis*, *Lestes disjunctus*, *Ischnura* sp., *Enallagma* sp. 1, *Enallagma* sp. 2, and *Argia* sp.] Address: Chase, J.M., Department of Biology and Tyson Research Center, Washington University in St. Louis, 1 Brookings Drive, St Louis, MO 63130, USA. (2009): Changes in the population structure and diet of the Chinese Stripe-Necked Turtle (*Mauremys sinensis*) inhabiting a disturbed river in northern Taiwan. *Zoological Studies* 48(1): 95-105. (in English) ["*Mauremys (Ocadia) sinensis* was investigated in the Keelung River, northern Taiwan, following severe habitat disturbances. "During a 2-yr levee construction and channel dredging project, the physical characteristics and riparian vegetation of the river were dramatically altered. Compared with results obtained prior to the disturbance, sex ratios were significantly skewed toward males, and the proportion of larger females significantly decreased both during and after project construction. Moreover, fewer small-sized juveniles were found following the construction disturbance. The diet of *M. sinensis* also changed, with plant materials assuming greater importance than they had prior to the disturbance. Furthermore, the mean volume of food ingested decreased both during and after the project. This tendency was more pronounced in females than males. Dietary overlap indices between the sexes during (0.591) and after (0.922) the project suggest that intraspecific food competition increased throughout the duration of the study." (Authors) Odonata contribute less than 0.1% to diet of the turtle.] Address: Chen, Tien-Hsi, Department of Life Science, National Taiwan Normal University, Taipei 116, Taiwan. - 8258.** Chin, K.S.; Taylor, P.D. (2009): Interactive effects of distance and matrix on the movements of a peatland dragonfly. *Ecography* 32(5): 715-722. (in English) ["We conducted a mark-release-recapture survey of *Leucorrhinia hudsonica* in each of two years (2002; 2003) in a harvested forest landscape in western Newfoundland, Canada. The odds of an individual male moving between peatlands was influenced by both the distance between peatlands and the type of intervening habitat (the matrix). Specifically, at meso scales (>700 m) there was a positive effect of the amount of cut matrix between peatlands on the odds of moving, but at fine scales (<700 m) there was the opposite effect; proportionally fewer individuals moved between peatlands. The odds of moving out of a peatland decreased as the surface area of water in the peatland increased. Multi-state mark-recapture models showed that the daily probability of a male moving between any two peatlands was 1.9% in 2002 and 6.9% in 2003 (n=1527 and 1280 marked individuals). The results suggest that additional empirical studies that directly measure patterns of movement with respect to landscape structure at multiple spatial scales in other taxa and situations are needed in order to uncover other possible non-linear changes in behaviour." - 8260.** Colding, J.; Lundberg, J.; Lundberg, S.; Andersson, E. (2009): Golf courses and wetland fauna. *Ecological Applications* 19(6): 1481-1491. (in English) ["Golf courses are often considered to be chemical-intensive ecosystems with negative impacts on fauna. Here we provide evidence that golf courses can contribute to the support and conservation of wetland fauna, i.e., amphibians and macroinvertebrates. Comparisons of amphibian occurrence, diversity of macroinvertebrates, and occurrence of species of conservation concern were made between permanent freshwater ponds surveyed on golf courses around Sweden's capital city, Stockholm, and off-course ponds in natureprotected areas and residential parklands. A total of 71 macroinvertebrate species were recorded in the field study, with no significant difference between golf course ponds and offcourse ponds at the species, genus, or family levels. A within-group similarities test showed that golf course ponds have a more homogenous species composition than ponds in natureprotected areas and ponds in residential parkland. Within the macroinvertebrate group, a total of 11 species of odonates were identified, with no difference detected between the categories of ponds, nor any spatial autocorrelation. [...] Among macroinvertebrates of conservation status, *Leucorrhinia pectoralis* was only detected in golf course ponds, and *Tricholeiochiton fagesi* (Trichoptera) was only found in one off-course pond. GIS results revealed that golf courses provide over a quarter of all available permanent, freshwater ponds in central greater Stockholm. We assert that golf courses have the potential to contribute to wetland fauna support, particularly in urban settings where they may significantly contribute to wetland creation. We propose a greater involvement of ecologists in the design of golf courses to further bolster this potential." - 8261.** Collier, K.J.; Hamer, M.; Chadderton, W.L. (2009): A new substrate for sampling deep river macroinvertebrates. *New Zealand Natural Sciences* 34: 49-61. (in English) ["We compared macroinvertebrate communities colonising multiplate samplers constructed from perspex or tempered hardboard (wood) with an alternative artificial substrate constructed from folded coconut fibre matting (coir) enclosed in nylon netting. Substrates were incubated for 62 days over January to March 2007 at six sites over 240 km along the Waikato River. The three substrates supported similar numbers of invertebrate taxa (27 - 29 taxa), but coir samples contained 71% of total invertebrate numbers from all substrates combined, compared with <17% for each type of multiplate sampler. Coir faunas were heavily dominated by the hydrobiid snail *Potamopyrgus* (84 % of numbers), and this taxon along with the amphipod *Paracalliope* comprised 58 - 66 % of invertebrates on both types of multiplate samplers. Analysis of a Bray-Curtis matrix suggested statistically significant differences in percent community composition between coir samplers and each type of multiplate sampler over the late summer study period. Densities per cm³ of Oligochaeta, Mollusca, and "other worms" (Platyhelminthes, Rhabdocoela, Nemertea and Hirudinea combined) were significantly higher in coir samples than one or both of the multiplate samplers. Results suggest coir samplers may provide a useful supplement to multiplate samplers for deep river invertebrate studies by collecting a different range of taxa, including those favouring cover and characteristic of depositional environments." (Authors) One specimen of *Hemicordulia* sp. was found in coir; *Xanthocnemis* sp. was represented in all substrates without significant differences.] Address: Collier, K.J., Environment Waikato, PO Box 4010, Hamilton, New Zealand. 8263. Cordoba-Aguilar, A. (2009): A female evolutionary response when survival is at risk: male harassment mediates early reallocation of resources to increase egg number and size. *Behavioral Ecology and Sociobiology* 63(5): 751-763. (in English) ["One unexplored area in sexual conflict studies is the female physiological costs and possible resource reallocation that accompany evolutionary costs due to male harassment. Using females of the damselfly *Hetaerina americana*, I first investigated whether male harassment affected female mating rate and survival and explored whether such effects induced a resource allocation from immunity (in the form of phenoloxidase activity) and muscular fat reserves to egg number and size. Using two seasons that differed in male harassment, it was found that the higher the male harassment, the fewer are the female matings and the lower is the female survival. These results were corroborated using an experimental approach in which a situation of high male harassment was induced. It was also found that when the first mating takes place and at high male harassment, females had more reduced phenoloxidase activity and fat reserves and tended to lay most of the eggs they produce in their lifetime and these were considerably large. However, at low male harassment, egg number and size were more equally produced across matings. Females under high male harassment seemed to suffer the survival costs but may show a plastic evolutionary response of reallocating resources to egg traits to maximize fitness." 8264. Córdoba-Aguilar, A.; Raihani, G.; Serrano-Meneses, M.A.; Contreras-Garduño, J. (2009): The lek mating system of *Hetaerina* damselflies (Insecta: Calopterygidae). *Behaviour* 146(2): 189-207. (in English) ["We investigated whether territorial males of *Hetaerina* damselflies show lekking behaviour using experimental techniques and observations: (i) we altered potential vegetation substrates to determine whether this affected the number of female visitations and matings; (ii) by removing territorial males and allowing other males to occupy the territory, we determined whether females changed their visitation and mating number; (iii) we observed whether vegetation substrates were present and used, and whether lighting conditions affected male territorial behaviour; (iv) we documented female pre- and post-copulatory behaviour to examine whether female choice occurred; and (v) we investigated whether male traits were linked to mating success. Our results revealed that (1) vegetation substrates were rarely found in territories and even when vegetation was present, it did not affect female visitation and mating number; (2)

males constantly moved to more illuminated places and females had little opportunity to exert choice due to harassment from males; (3) females oviposited outside territories; and (4) males with larger wing pigmentation and body size obtained a larger mating number because they were more likely to acquire a territory and/or displace other males while in tandem. This is the first documented evidence that odonate males display a lek mating system." 8265. Cordoba-Aguilar, A.; Serrano-Meneses, A.; Cordero-Rivera, A. (2009): Copulation duration in nonterritorial Odonate species lasts longer than in territorial species. *Ann. Entomol. Soc. Am.* 102(4): 694-701. (in English) ["We tested whether long copulation duration is more likely to have evolved in nonterritorial odonate species than in territorial species, given that nonterritorial males do not incur the costs of territory defense. A phylogenetic comparative method that controls for the phylogenetic nonindependence of species was used to compare copulation duration among 46 species of the two main odonate suborders (Anisoptera and Zygoptera). Copulation duration of nonterritorial anisopteran species was longer than for territorial dragonflies; however, this relationship was not found for Zygoptera. Long copulations in Anisoptera may be related to a male's ability to manipulate a female's stored sperm. It is suggested that constraints that prevent a territorial male from lengthening copulation do not seem to operate in Zygoptera. Other selective processes (i.e., cryptic female choice and/or sexual conflict) may also be important determinants of copulation duration in the Zygoptera. To our knowledge, this is the first exploration of the relation copulation duration and mating systems in insects.] Address: Cordoba-Aguilar, A., Centro de Investigaciones Biologicas, Universidad Autonoma del Estado de Hidalgo, Apdo. 8266. Cordoba-Aguilar, A. (2009): Seasonal variation in genital and body size, sperm displacement ability, female mating rate, and male harassment in two calopterygid damselflies (Odonata: Calopterygidae). *Biological Journal of the Linnean Society* 96(4): 815-829. (in English) ["Sperm competition is a pervasive force. One adaptation is the male ability to displace the rivals' sperm that females have stored from previous copulations. In the damselfly, *Calopteryx haemorrhoidalis asturica*, males with wider aedeagi displace more spermathecal sperm. The present study documents that the same mechanism operates in another damselfly, *Hetaerina americana*. However, this genital width in both species decreases along the season, but late-emerging females have more sperm displaced than early-emerging females. Because territorial males mated more and were larger in body and genital size than nonterritorial males, late-season females mated with considerably larger males with respect to female size and this produced higher sperm displacement. Assuming female benefits from storing sperm but that such benefit does not prevail if males displace sperm, it is predicted that, along the season, females will mate less and male harassment (in terms of male mating attempts and oviposition duration) will increase. These predictions were cor-

roborated. In *H. americana*, it was also tested whether spermathecal sperm became less viable along the season. The results obtained did not corroborate this. This is the first evidence indicating that season affects sperm displacement ability and female mating frequency due to changes in male body and genital size." 8270. Crick, K. (2009): Variations in key features of the final instar larvae and exuviae of the Azure Damsel-fly *Coenagrion puella* (Linnaeus). *J. Br. Dragonfly Society* 25(1): 16-26. (in English) ["A number of key features used for species identification of zygopteran final instar larvae and exuviae, published in the United Kingdom can be shown to have levels of variability exceeding the published limits. This paper seeks to record those variations as they apply to *Coenagrion puella*, based on the population contained within the Blackwater Valley catchment area located on the Hampshire/Berkshire border; outlining in detail specific variations found through close examination of 387 individuals. The features addressed include the species-specific characteristics of the caudal lamellae, the prementum and the post ocular region of the head; also some that are not found in current published keys, such as the setae on the labial palps and the lateral carinae on the second abdominal segment. The need to address a combination of key factors and to be aware of the areas of morphology where significant variations occur within species cannot be over emphasised." (Author) In fig. 5, the prementum of *C. puella* and *Ceriagrion tenellum* are transposed.] Address: Crick, K., 29 Village Way, Yateley, Hants, GU46 7SE, UK

8271. Czachorowski, S.; Czachorowski, P. (2009): New localities of *Nehalennia speciosa* (Charpentier, 1840) in the vicinity of Dobre Miasto (north-eastern Poland). *Odonatrix* 5(2): 45-47. (in Polish, with English summary) ["*N. speciosa* is one of the most endangered dragonfly species in Europe. In July 2008, two new localities were recorded. Adults were observed in shore vegetation of two water bodies near Dobre Miasto (north of Olsztyn, Masurian Lakeland), in the area planned to be included in the Natura 2000 network. Together with *N. speciosa* occurred: *Leucorrhinia albifrons*, *Aeshna grandis*, *Cordulia aenea*, *Erythromma najas*, *Coenagrion puella*, *Ischnura elegans*, *Lestes virens*, *Enallagma cyathigerum*." 8272. Daraż, B. (2009): Dragonflies (Odonata) of the Przemysl Foothills and adjacent areas along the San River. *Wiad. entomol.* 28(1): 5-32. (in Polish, with English summary) ["Studies were carried out at 36 localities in Pogórze Przemyskie (the Przemysl Foothills) and adjacent areas along the San River (SE Poland) in the years 2004-2007. 54 species of dragonflies (74% of the Polish dragonfly fauna) were recorded, among them: a) *Nehalennia speciosa* in a highly isolated population, currently situated at the southern border of the species distribution, b) *Crocothemis erythraea* at 5 localities, autochthonous at least at two of them, abundant at one site, and with a probable second generation, c) *Cordulegaster bidentata*, widespread at many localities, d) *Leucorrhinia albifrons* and *L. caudalis* at the southern

border of their distribution, the latter species being extremely rare at these latitudes, e) *L. pectoralis*, rare in southern Poland, f) several thermophilous species as e.g. *Aeshna affinis*, *Orthetrum brunneum*, *O. albistylum*, *Sympetrum meridionale*. The species composition of the odonate fauna and the occurrence of some species are commented on and discussed with reference to the geographical position of the area and the habitat spectrum. Conservation aspects are presented and assessed and some conservation measures are proposed." (Author)] Address: Daraz, B., ul. Kościelna 41, 35-505 Rzeszów; Poland. E-mail: bdaraz@poczta.onet.pl

8273. Dargent, T.; Bao, X.-q.; Grondel, S.; Le Brun, G.; Paquet, J.B.; Soyer, C.; Cattan, E. (2009): Micromachining of an SU-8 flapping-wing flying micro-electro-mechanical system. *J. Micromech. Microeng.* 19, 085028 (doi:10.1088/0960-1317/19/8/085028): 10 pp. (in English) ["This paper presents a feasibility step in the development of an ultra-small biomimetic flying machine. Advanced engineering technologies available for applications such as the micro-electro-mechanical system (MEMS) technologies are used. To achieve this goal, a flapping-wing flying MEMS concept and design inspired from insects is first described. Actuators and an actuation way for the control over the wing kinematics are proposed. The initial concepts are subsequently analyzed and presented using multi-body and finite element models. An overview of SU-8 photoresist structures and their functions in the future micro-robot insect is then presented. Consequently, micromachining enables the implementation of a flying MEMS. It is also demonstrated that the structure can be made at insect sizes and actuated at low power inputs. Moreover, the flapping frequency obtained is within the flapping frequency range of wings of many common insects of millimetric dimensions. Such prototypes are of interest as tools to artificially recreate and study insect flight with characteristics, similar to those of insects, that are able to produce lift and hover. Finally, if a micro-battery, wireless receivers, microcontrollers, sensors and actuators can all be fitted onto chips only a few millimeters square, with a mass in the order of milligrams, then we believe that an insect-size flying MEMS can be realized. All these requirements can now be achieved due to advanced engineering methods." (Authors) The publication includes references to Odonata.] Address: Cattan, E., Université Lille Nord de France, F-59000 Lille, France. E-mail: eric.cattan@univ-valenciennes.fr

8274. Darvizeh, M.; Darvizeh, A.; Rajabi, H.; Rezaei, A. (2009): Free vibration analysis of dragonfly wings using finite element method. *The International Journal of Multiphysics* 3(1): 101-110. (in English) ["In the present work, investigations on the microstructure and mechanical properties of the dragonfly wing are carried out and numerical modeling based on Finite Element Method (FEM) is developed to predict flight characteristics of dragonfly wings. Vibrational behaviour of wings type structures is immensely important in analysis, design and manufacturing of similar engineering structures. For this purpose natural frequencies and mode shapes are calculated. In addition, the kind of deformation in each mode shape evaluated and the ratio between numerical natural frequency and experimental natural frequency presented as damping ratio. The results obtained from present method are in good agreement with same experimental methods."] Address: Guilan University, Iran

8275. de Oliveira, D.E.; de Marco Júnior, P. (2009): Is there a trade-off between the melanin allocated to the immune system and to camouflage on larvae of the dragonfly *Micrathyrja catenata* Calvert, 1909 (Odonata: Libellulidae)? *Neotropical Biology and Conservation* 4 (3): 133-136. (in English, with Portuguese summary) ["In insects, the immune system responds to the presence of antigens involving them in melanin. However, the melanin is also allocated into the exoskeleton's pigmentation, used to camouflage. We aimed to test the existence of a trade-off between the allocation of melanin to the immune system and to camouflage on the larvae of *M. catenata*. We conducted the study in the "Reserva do km 41" (41 km' Reserve), 80 km distant from Manaus, Amazonas, Brazil. We implanted a nylon line into the abdomen of 30 larvae and observed if had or not deposition of melanin in the line. We counted the number of individuals who responded to implant depositing melanin and, later, we took photos of the larvae's heads and calculate gray intensity. We used a t-test for independent samples. 76% of larvae responded to treatment depositing melanin on the implants. There were no significant differences in the intensity of gray between the larvae that responded to the implants and those who did not responded. There is no trade-off to allocation of melanin for camouflage and for the immune system. This should happen because the immune system is not limited by the acquisition of resources or the camouflage's demand for melanin is not enough to influence the immune system." 8279. Dibble, E.D.; Thomaz, S.M. (2009): Use of fractal dimension to assess habitat complexity and its influence on dominant invertebrates inhabiting tropical and temperate macrophytes. *Journal of Freshwater Ecology* 24(1): 93-102. (in English) ["We evaluated the feasibility of using fractal geometry to measure the structural complexity innate to 11 species of temperate and tropical macrophytes. The efficacy of fractal dimension (D) as a surrogate of plant complexity was tested by using D values to predict the density of two dominant invertebrate taxa (Annelida and Odonata). Plants and invertebrates were collected from lagoons in the upper Parana River, Brazil, and from a lake in central Minnesota, USA. Fractal dimensions varied from 1.16 (SD=0.03) in *Potamogeton illinoensis* to 1.68 in *Najas conferta* (SD=0.07) and *Myriophyllum spicatum* (SD=0.02). Spatial scale did not affect D values, since the results obtained for pictures taken at 25 cm², 100 cm² and 600 cm² did not differ for five tropical species. Using the results of D recorded at 100 cm², a positive and significant relationship between plant complexity and Annelida and Odonata densities was observed. The biological significance of the positive correlations between D and invertebrate densities and the feasibility in calculating D make this method a potential candidate for measuring plant complexities at small scales."] (Authors)] Address: Dibble, E.D., Rm# 217, Thompson Hall, Department of Wildlife and Fisheries, Box 9690, Mississippi State, MS 39762-9690, USA. (2009): Patterns of phenotypic divergence in wing covariance structure of calopterygid damselflies. *Evolutionary Biology* 36(2): 214-224. (in English) ["Comparing species differences in covariance patterns of traits subject to divergent selection pressures can increase our understanding to the mechanisms of phenotypic divergence. Different species of calopterygid damselflies have diverged in the melanized wing patch of males. This trait serves multiple ecological functions and has behavioural consequences in terms of sexual selection, interspecific interactions, reproductive isolation. We compared the phenotypic variance-covariance matrices (P) of wing traits among nine populations of four European species of calopterygid

damselflies. We found modest divergence in covariance structure among populations of the same species, but strong divergence between species. Interestingly, the orientation of the first eigenvector of P (P max) differed more between closely related species than between distantly related species, although this pattern was absent when overall covariance structures were compared. We also found that distantly related species but geographically closer had converged towards a similar covariance structure. Finally, divergence in covariance structure was correlated with divergence in wing patch length, but not with other wing traits. This last finding suggests that divergent selection on wing patch length might have affected the stability of P. These results indicate that P might not only reflect ancestral developmental pathways but might also be influenced by current ecology." 8291. Fillinger, U.; Sombroek, H.; Majambere, S.; van Loon, E.; Takken, W.; Lindsay, S.W. (2009): Identifying the most productive breeding sites for malaria mosquitoes in The Gambia. *Malaria Journal* 2009, 8:62: 14 pp. (in English) ["Background: Ideally larval control activities should be targeted at sites that generate the most adult vectors, thereby reducing operational costs. Despite the plethora of potential mosquito breeding sites found in the floodplains of the Gambia River, about 150 km from its mouth, during the rainy season, only a small proportion are colonized by anophelines on any day. This study aimed to determine the characteristics of larval habitats most frequently and most densely populated by anopheline larvae and to estimate the numbers of adults produced in different habitats. Methods: A case-control design was used to identify characteristics of sites with or without mosquitoes. Sites were surveyed for their physical water properties and invertebrate fauna. The characteristics of 83 sites with anopheline larvae (cases) and 75 sites without (controls) were collected between June and November 2005. Weekly adult productivity was estimated with emergence traps in water-bodies commonly containing larvae. Results: The presence of anopheline larvae was associated with high invertebrate diversity (Odds Ratio, OR 11.69, 95% CI 5.61-24.34, $p < 0.001$), the presence of emergent vegetation (OR 2.83, 95% CI 1.35-5.95, $p = 0.006$), and algae (at borderline significance; OR 1.87, 95% CI 0.96-3.618, $p = 0.065$). The density of larvae was reduced in sites that were larger than 100 m in

perimeter (OR 0.151; 95% CI 0.060–0.381, $p < 0.001$), where water was tidal (OR 0.232; 95% CI 0.101–0.533, $p = 0.001$), vegetation shaded over 25% of the habitat (OR 0.352; 95% CI 0.136–0.911, $p = 0.031$) and water conductivity was above 2,000 $\mu\text{S}/\text{cm}$ (OR 0.458; 95% CI 0.220–0.990, $p = 0.048$). Pools produced the highest numbers of *Anopheles gambiae* adults compared with rice fields, floodwater areas close to the edge of the floodplain or close to the river, and stream fringes. Pools were characterized by high water temperature and turbidity, low conductivity, increased presence of algae, and absence of tidal water. Conclusion: There are few breeding sites that produce a high number of adult vectors in the middle reaches of the river in The Gambia, whereas those with low productivity are larger in area and can be found throughout the rainy season. Even though risk factors could be identified for the presence and density of larvae and productivity of habitats, the results indicate that anti-larval interventions in this area of The Gambia cannot be targeted in space or time during the rainy season." (Authors) Odonata are treated at the order level.] Address: Fillinger, Ulrike, Disease Control & Vector Biology Unit, London School of Hygiene & Tropical Medicine, Keppel Street, London, WC1E 7HT, UK. 8294. Flenner, I.; Olne, K.; Suhling, F.; Sahlén, G. (2009): Predator-induced spine length and exocuticle thickness in *Leucorrhinia dubia* (Insecta: Odonata): a simple physiological trade-off? *Ecological Entomology* 34: 735-740. (in English) ["1. Morphological defence structures evolve against predators but are costly to the individual, and are induced only when required. A well-

studied example is the development of longer abdominal spines in dragonfly larvae in the presence of fish. Numerous attempts to discover trade-offs between spine size and behaviour, development time or body size have, however, produced little evidence. 2. We considered a physiological trade-off. Spines consist of cuticle and using material to build longer structures may result in less material remaining elsewhere. We therefore measured exocuticle thickness at nine locations on *Leucorrhinia dubia* larvae from habitats with and without fish. 3. Our results show a significant effect of the interaction between fish presence and spine length on head and fore leg exocuticle thickness. Relative thickness increased with relative length of lateral spine 9 in the absence of fish, whereas no such relationship existed with fish. Hence, synthesis and secretion of cuticle material occur as a trade-off when larvae react to fish presence. 4. We assume the mechanism to be a selective synthesis of material with different responses in different parts of the larval body. These findings offer a new angle to the fish/spine trade off debate.] Address: Sahlén, G., Halmstad University, P.O. Box 823, 30118 Halmstad, Sweden. E-mail: goran.sahlen@hh.se

8295. Fliedner, H. (2009): Two remarkable observations from Puerto Rico. *Argia* 21(1): 8-9. (in English) [Lucia Beach east of Yabucoa, eastern coast of Puerto Rico, 4-XII-2008]: *Crocothemis servilia*, which is a new addition to the regional fauna, and *Erythrodiplax umbrata*. This male is "noteworthy because of the irregularity of its wing pattern. On the left forewing the dark band is missing totally, on the right one there is only an irregular dark mark near the anterior margin, and the dark bands on the hindwings are much lighter at the rear. This asymmetrical lack of pigment may be due to an anomaly in development." (Author)] Address: Fliedner, H., Louis-Seegelken Str., D-28717 Bremen, Germany. E-mail: H.Fliedner@t-online.de

8296. Florencio, M.; Serrano, L.; Gomez-Rodriguez, C.; Millan, A.; Dyaz-Paniagua, C. (2009): Inter- and intra-annual variations of macroinvertebrate assemblages are related to the hydroperiod in Mediterranean temporary ponds. *Hydrobiologia* 634: 167-183. (in English) ["Macroinvertebrate assemblages of 22 temporary ponds with different hydroperiod were sampled monthly during a dry year (2005–2006) and a wet year (2006–2007). Coleopteran and Heteropteran adults were most abundant at the end of the hydroperiod, while Coleopteran larvae, mainly Dytiscidae, were mostly recorded in spring. Macroinvertebrate assemblages differed between study years. The shorter hydroperiod of ponds in the dry year constrained the length of the aquatic period for macroinvertebrates, and three distinct wet phases of community composition could be distinguished: filling phase, aquatic phase and drying phase. In the wet year, with a longer pond hydroperiod, five phases could be identified, with the aquatic phase differentiated into winter, early spring and late spring phases. Dispersers such as *Anisops sardeus*, *Berosus guttalis* or *Anacaena lutescens* were typical during the filling phase and *Corixa affinis* or *Enochrus fuscipennis* during the drying phase. The ponds with intermediate hydroperiod showed a similar composition (mainly dispersers) at the beginning and end of their wet period; this is not being seen in early drying or long hydroperiod ponds. A general pattern was detected, with similar variation between both years, which may be associated with the life histories of the macroinvertebrate taxa re-

corded." (Authors) 16 odonate species are listed. Odonata and Heteroptera included the highest number of species and individuals during both years." (Authors)] Address: Florencio, Margarita, Donana Biological Station-CSIC, P.O. Box 1056, 41080 Seville, Spain. E-mail: margarita@ebd.csic.es

8297. Fraker, M.E. (2009): Predation risk assessment by green frog (*Rana clamitans*) tadpoles through chemical cues produced by multiple prey. *Behav. Ecol. Sociobiol.* 63: 1397-1402. (in English) ["Many prey assess predation risk through predator chemical cues. Numerous studies have shown that (1) prey sometimes respond to chemical cues produced by heterospecifics and (2) that many species are capable of associative learning. This study extends this research by focusing on predation risk assessment and antipredator behaviour in environments containing chemical cues produced by multiple prey species. The results show that *R. clamitans* tadpoles (1) assess risk from the chemical cue produced during predation by a heterospecific (gray tree frog, *Hyla versicolor*, tadpoles) and (2) can exhibit similarly strong behavioral responses to a mix of conspecific and heterospecific cues compared to conspecific cue alone, depending on their conditioning environment. I then discuss how the prey choice of the predators and the relative abundances of the prey species should influence the informational value of heterospecific cues." (Authors) The tadpole-odonate larvae interaction was tested using *Anax junius*.] Address: Fraker, M.E., Department of Ecology and Evolutionary Biology, University of Michigan, 830 North University, Ann Arbor, MI 48109-1048, USA. E-mail: mfraker@umich.edu

8298. Funk, A.; Reckendorfer, W.; Kucera-Hirzinger, V.; Raab, R.; Schiemer, F. (2009): Aquatic diversity in a former floodplain: Remediation in an urban context. *Ecological Engineering* 35(10): 1476-1484. (in English) ["The Lobau, a former floodplain area of the Danube River situated within the city limits of Vienna (Austria), was strongly affected by the river regulation in 1875. The reduced hydrological connectivity led to an increasing loss of aquatic habitats. A water enhancement scheme with a maximum water input of 0.5 m³ s⁻¹ was initiated in 2001. The present study assesses the effect of this scheme on biodiversity using three target species groups – aquatic molluscs, dragonflies and fish – following a common Before-After Control-Impact design (BACI). Dragonflies and molluscs were positively affected, reflecting the habitat alterations in the system. For fish, no significant impact was observed. The aim of the scheme has been achieved: increased habitat diversity and improved habitat conditions for the system's initial community and further rheophilic / rheotolerant species. Water enhancement schemes can be effective remediation measures and deserve further attention in the management of urban wetlands." (Authors)] Address: Raab, R., Tech. Büro für Biol., Quadenstr. 13, A-2232 Deutsch-Wagram, Austria. E-mail: rainer.raab@gmx.at

8299. Gaenzle Schilling, E.; Loftin, C.S.; Hury, A.D. (2009): Macroinvertebrates as indicators of fish absence in naturally fishless lakes. *Freshwater Biology* 54 (1): 181-202. (in English) ["1. Little is known about native communities in naturally fishless lakes in eastern North America, a region where fish stocking has led to a decline in these habitats. 2. Our study objectives were to: (i) characterise and compare macroinvertebrate

communities in fishless lakes found in two biophysical regions of Maine (U.S.A.): kettle lakes in the eastern lowlands and foothills and headwater lakes in the central and western mountains; (ii) identify unique attributes of fishless lake macroinvertebrate communities compared to lakes with fish and (iii) develop a method to efficiently identify fishless lakes when thorough fish surveys are not possible. 3. We quantified macroinvertebrate community structure in the two physiographic fishless lake types (n = 8 kettle lakes; n = 8 headwater lakes) with submerged light traps and sweep nets. We also compared fishless lake macroinvertebrate communities to those in fish-containing lakes (n = 18) of similar size, location and maximum depth. We used nonmetric multidimensional scaling to assess differences in community structure and t-tests for taxon-specific comparisons between lakes. 4. Few differences in macroinvertebrate communities between the two physiographic fishless lake types were apparent. Fishless and fish-containing lakes had numerous differences in macroinvertebrate community structure, abundance, taxonomic composition and species richness. Fish presence or absence was a stronger determinant of community structure in our study than differences in physical conditions relating to lake origin and physiography. 5. Communities in fishless lakes were more speciose and abundant than in fish-containing lakes, especially taxa that are large, active and free-swimming. Families differing in abundance and taxonomic composition included Notonectidae, Corixidae, Gyrinidae, Dytiscidae, Aeshnidae, Libellulidae and Chaoboridae. 6. We identified six taxa unique to fishless lakes that are robust indicators of fish absence: *Graphoderus liberus*, *Hesperocorixa* spp., *Dineutus* spp., *Chaoborus americanus*, *Notonecta insulata* and *Callicorixa* spp. These taxa are collected most effectively with submerged light traps. 7. Naturally fishless lakes warrant conservation, because they provide habitat for a unique suite of organisms that thrive in the absence of fish predation." 8302. Gorb, S.N.; Tynkkyne, K.; Kotiaho, J.S. (2009): Crystalline wax coverage of the imaginal cuticle in *Calopteryx splendens* (Odonata: Calopterygidae). *International Journal of Odonatology* 12(2): 205-221. (in English) ["In this study we use high resolution SEM to describe the diversity of wax crystals and their distribution on different morphological structures in male individuals of *C. splendens*. The entire cuticle surface of this damselfly, with the exception of ommatidia and ocelli, is covered with crystalline wax in dimensions from submicron to micron range. It is shown that shape – rod-like, plate like, filamentous, etc. –, size, and density of crystals vary on different surfaces and in individuals of different ages. Additionally, we demonstrate different types of damage to the crystalline wax layer: scratches, compressions, wear, and contamination. The primary function of the wax crystalline coverage in odonates is, presumably, reduction of surface wettability by water (superhydrophobicity). However, other functions are also discussed, especially in such specialized body areas as postero-ventral parts of male abdomen, the so called 'lantern'." 8305. Hannelly, E.C. (2009): The effects of introduced trout on native macroinvertebrates from lakes in the Trinity Alps Wilderness in northern California. Thesis, Faculty of Humboldt State University, Masters of Arts In Biology: IX, 61 pp. (in English) ["I examined differences in native macroinvertebrates among four lake management categories (fish stocked, temporary stocking suspension, fish removal lakes, and historically fishless lakes) and among three habitats (rock, organic/silt substrate, and emergent vegetation) from 16 different lake basins in a four-year study (2003-2006) in the Trinity Alps Wilderness in northeastern California. This study showed that introduced insectivorous fish reduce the diversity of native aquatic insects. Chironomid midges were more abundant and in greater proportion in fish lakes than in fishless lakes. Additionally, more taxa were sampled each subsequent year following fish removals and more taxa were sampled from Hidden Lake, a stocking suspension lake that did not maintain a fish population, than in the other three stocking suspension lakes that did sustain viable fish populations. The reduction in insect diversity due to fish was further exemplified in Hidden Lake alone, where more taxa were recorded each subsequent year of the study. *Libellula* was most common in fish stocked lakes. The life history and morphology of *Libellula* seems to give them an advantage over other invertebrate predators in fish lakes. Fish create top down effects that are illustrated by the apparent ability of *Libellula* to regulate other insect abundances and proportions. This study also demonstrated how large-bodied insects are more commonly found in complex habitats, which may be attributable to increased habitat availability and resources, to the invertebrates seeking refugia from insectivorous fish, or to a combination of both." ation of calopterygid damselflies has received considerable attention due to its role as an honest signal of male quality. We describe a quantitative analysis of this trait in two populations of *C. splendens* in England. One population, sampled close to the northern limit of its range in Northumberland, exhibited substantially smaller wing spots than a population sampled in Hampshire. Wing asymmetry (in terms of length and area) did not vary between the two populations, nor did it co-vary with the size of the wing spots. We propose that the decline in wing spot size is the result of variation in climate between the two sites. Such variation in immunocompetence could contribute to the determination of range margins in this species." (Authors)] Address: Thompson, D. 8308. Hassall, C.; Thompson, D.J.; Harvey, I.F. (2009): Variation in morphology between core and marginal populations of three British damselflies. *Aquatic Insects* 31(3): 187-197. (in English) ["As selective pressures are altered by the changing climate, species have been shown to shift their distributions. Here we investigate morphological variation in dispersal-related traits between core and marginal populations in three species of Odonata, a taxon that is known to be expanding polewards. We sampled individuals of (i) *Calopteryx splendens*, a species with a rapidly expanding range, (ii) *Erythromma najas*, a species with a slowly expanding range, and (iii) *Pyrrhosoma nymphula*, a species that does not exhibit a range margin in the UK (as a control). Only *C. splendens* exhibited consistent trends within two dispersal-related traits (wing:abdomen length ratio and aspect ratio). This result suggests that proximity to range margin alone does not account for variations in damselfly morphology, but that the rate of range expansion may also be important in determining variation." (Authors)] Address: Thompson, D.J., Population Biology Research Group, School of Biol. Sciences (Nicholson Building), Univ. of Liverpool, P.O. Box 147, Liverpool, L69 3BX, UK. 8312. Hoffmann, J. (2009): Summary catalogue of the Odonata of Peru - Kommentiertes Faksimile des Manuskripts von J. COWLEY, Cambridge, 20.05.1933 und aktuelle Liste der Odonaten Perus mit Fundortangaben sowie Historie zu Sammlern und Odonatologen in Peru. *International Dragonfly Fund Report* 16: 1-115. (in German, with English and Spanish summaries) ["In the entomological library of the Natural History Museum of Lima, Peru, a badly damaged manuscript, entitled 'Summary Catalogue of the Odonata of Peru' was discovered at the beginning of the 1990s. This manuscript had been kept there since 1933. Its author was stated as 'J. Cowley'. Whether indeed Cowley is the sole author of the whole text, cannot be asserted with certainty. However there are numerous indications that the manuscript was written in Cambridge, England. It seems certain that the list itself was written by Cowley, since many examples were given from his collection and the way the locations were cited. Presumably the manuscript was written together with the German veterinarian Paul Martin and his wife Margarita who lived in Lima. Martin was a very enthusiastic amateur lepidopterologist who had set up a network of butterfly collectors in Peru. Insects other than Lepidoptera were passed on by Martin to specialists, dragonflies apparently mainly to Cowley, who named a species in honour of Martin. The manuscript is of great value, since it is the first known and most complete list of Odonata with localities based on the state of knowledge of those days. Up to this time these records were scattered across few and also incomplete lists as part of taxonomic works or collection catalogues. On the basis of the state of knowledge and rules of nomenclature of his days (1933) Cowley named a total of 174 dragonfly species (synonymised 168 species) from 71 localities. Eleven years later Schmidt (1942) published a list of 173 Peruvian odonates, while 21 years later a catalogue with 165 species (synonymised 158 species) was published by Soukop in 1954. A comprehensive list of 252 species (synonymised to 243) was published by Racenis (1959) 26 years after Cowleys unpublished list. Since then there have been only a few complete lists. Currently and here presented, there are 481 species known from 238 localities, of which 87 were new species first described on the basis of type material from Peru. Up to the end of the 1960s material from commercial collectors and the trade with insects was the basis for most catalogues, with dragonflies being only a by-catch of butterfly collecting expeditions. Publications of lists from scientific expeditions on the other hand, were a rare event. The history of Odonatology in Peru is, therefore, largely connected to the history of research and collecting expeditions into the Amazon region for the greater

part of the 20th century. Up to the era of Cowley, expeditions into the collection regions of Peru took place mainly out of the east of the continent by way of the Amazon and its tributaries. The first of such odonatological evidences are by the famous Amazon researcher Henry Walter Bates, who also collected a large number of dragonflies between the years 1848 and 1859. With an increasing interest in the flora and fauna in their own country and with the founding of natural history institutions at the beginning of the 20th century in Lima, more and more expeditions were organised from Lima. Until the middle of the last century the majority of researchers and collectors active in Peru were still mainly Europeans. With the beginnings of the 70s of the last century, pure collecting expeditions became progressively less common. Odonata, collected during the last 20 years in Peru, mainly stem from research projects with a defined goal. A map of the locations until 2007 shows that more than 70% of the country is still unexplored as far as odonates are concerned. Thus the list of the 481 species more than likely does not reflect the actual inventory of dragonfly species and distribution of Peru. The register lists all the species which have definitely been recorded for the country and takes into account their present validity and comprehensible taxonomic relationships." 8314. Honkavaara, J.; Rantala, M.J.; Suhonen, J. (2009): Mating status, immune defence, and multi-parasite burden in the damselfly *Coenagrion armatum*. *Entomologia Experimentalis et Applicata* 132(2): 165-171. (in English) ["Immunity and reproductive effort are both physiologically costly and often a trade-off between these functions has been shown. In studies with damselflies, parasite load has been associated with fitness costs, such as reductions in mating success, male condition, and survival. Although each individual may be simultaneously infected by various parasite species, most studies have concentrated on the effects of a single parasite taxon. We examined natural ecto- and endoparasite infection levels in male *C. armatum* in relation to their mating status, fat reserves, and ability to further mount an immune response, measured as en-

capsulation of an experimentally introduced foreign object. Encapsulation response was lower for mated (paired) males than for single males and declined with increasing water mite abundance. Mated males had fewer water mites than single males. Male weight or fat reserves did not explain variation in encapsulation response. The number of gregarine gut parasites was not related to the level of encapsulation response and did not differ between mated and single males. However, there was a negative correlation between mite abundance and gregarine load. Our data suggest that current mite infection may compromise a male's resistance against further infections by pathogens and parasites, and there may be a trade-off between reproductive effort and encapsulation response in male *C. armatum*." (Authors)] Address: Honkavaara, J., Department of Biology, Section of Ecology, University of Turku, 20014 Turku, Finland. E-mail: johhon@utu.fi

8316. Horváth, G.; Kriska, G.; Malik, P.; Robertson, B. (2009): Polarized light pollution: a new kind of ecological photopollution. *Front. Ecol. Environ.* 7(6): 317-325. (in English) ["The alteration of natural cycles of light and dark by artificial light sources has deleterious impacts on animals and ecosystems. Many animals can also exploit a unique characteristic of light – its direction of polarization – as a source of information. We introduce the term "polarized light pollution" (PLP) to focus attention on the ecological consequences of light that has been polarized through interaction with human-made objects. Unnatural polarized light sources can trigger maladaptive behaviors in polarization-sensitive taxa and alter ecological interactions. PLP is an increasingly common byproduct of human technology, and mitigating its effects through selective use of building materials is a realistic solution. Our understanding of how most species use polarization vision is limited, but the capacity of PLP to drastically increase mortality and reproductive failure in animal populations suggests that PLP should become a focus for conservation biologists and resource managers alike." 8321. Iserbyt, A.; Bots, J.; Ting, J.J.; Jvostov, F.P.; Forbes, M.R.; Sherratt, T.N.; Van Gossum, H (2009): Multi-annual variation in female morph frequencies of the polymorphic damselfly, *Nehalennia irene*, at continental and regional scales. *Animal Biology* 59(3): 313-326. (in English) ["Female-limited polymorphism occurs in different animal taxa but is particularly abundant among species of damselflies, most likely as a consequence of selection to avoid excessive male harassment. Recent work *N. irene* indicated that within year spatial variation in female morph frequencies was limited in nearby populations (i.e. intra-regional scale), but large at a continental scale. As anticipated, some of the observed variation in morph frequency was correlated with variation in the estimated degree of male harassment towards female morphs, measured by male density and operational sex ratio. Here, we extended earlier work by quantifying variation in morph frequency over two to three years, allowing us to elucidate how morph frequencies vary temporally at both intra-regional and continental scales (data for 8 populations over three years and for 33 populations over two years, respectively). Annual variation in morph frequencies was relatively high at the intra-regional scale, but was never large enough to obscure the underlying spatial pattern at the continental scale. At both geographic scales, male density and operational sex ratio were highly variable between years. The estimated degree of male harassment correlated with variation in morph frequency within some regions, but not all. Together, the observed natural variation in female morph frequencies may be partly explained by variation in male harassment, but it appears that a complete understanding will require considering the role of other environmental factors." 8323. Iwata, S.; Watanabe, M. (2009): Spatial distribution and species composition of larval Odonata in the artificial reed community established as a habitat for *Mortonagrion hirosei* Asahina (Zygoptera: Coenagrionidae). *Odonatologica* 38(4): 307-319. (in English) ["Yearly changes in the odonate larval community were surveyed for 4 year after setting up an artificial reed community adjacent to the original habitat of *M. hirosei*, an endangered brackish water species. Only *M. hirosei* larvae were found in the original habitat during the survey period. In the first year of the established habitat, *Ischnura senegalensis* was the dominant species in the larval community. Although the abundance of *M. hirosei* larvae increased year by year, becoming the most abundant species after the second year, the species composition of the larval community of the established habitat was different between the West and East because of environmental factors, such as saline concentration and reed shoot density. *M. hirosei* larvae had expanded their distribution to the entire area of the established habitat in 2005, while the distribution of *I. senegalensis* had been restricted to several patchy areas in accordance with a decrease in their population. There was a negative relationship between the number of *M. hirosei* and *I. senegalensis* larvae. The prey-predator relationship and competitive relationship between the 2 species should have affected the population dynamics and distribution of *M. hirosei*. The odonate larval community and habitat environment that is optimal for *M. hirosei* conservation are discussed from the viewpoint of both biotic and abiotic factors.] Address: Iwata, S., Graduate School of Environmental Sciences, University of Tsukuba, Tsukuba, Ibaraki 305-8572, Japan. 8328. Junichi, T.; Motoharu, F.; Yoshitaka, T. (2009): Genetic diversity of the dragonfly *Libellula angelina* in the Okegayanuma area of Japan. *Japanese Journal of Conservation Ecology* 14(1): 73-79. (in Japanese, with English summary) ["The genetic diversity and differentiation among 60 individuals of the threatened dragonfly species *Libellula angelina* from three populations in the Okegayanuma area of Japan was determined using random amplified polymorphic DNA (RAPD) analysis. Twenty polymorphic loci were detected by 19 of the 80 RAPD primers examined, and 12 DNA types were determined (only four types were population specific). The diversity among and within the populations was lower; the mean gene diversity and gene differentiation values were 0.317 and 0.007, respectively. No significant between-population genetic differences were detected in the analysis of molecular variance (AMOVA). Of the ge-

netic divergence, 98.7% was attributable to population divergence and 1.3% to individual differences within a population. Cluster analysis indicated that most individuals from the three populations belonged to the same cluster. Our results provide data that could be used to elucidate genetic diversity in *L. angelina* populations, using RAPD analysis." (Authors)] Address: not available

8329. Kadoya, T.; Suda, S.; Washitani, I. (2009): Dragonfly crisis in Japan: A likely consequence of recent agricultural habitat degradation. *Biological Conservation* 142(9): 1899-1905. (in English) ["Many Japanese dragonfly species depend on habitat complexes maintained in rice paddy systems. We postulated that recent alterations to habitat complexes in paddy systems have had adverse effects on dragonfly populations, especially those 'once common species' that have come to depend primarily on paddy systems following losses of natural floodplain habitats. A high proportion of Japanese lentic dragonfly species depends on paddy fields or agricultural ponds that have been extensively degraded, while lotic species can often use both paddies and natural river systems. Thus we also postulated that lentic species are more susceptible to changes in agricultural habitats and are subject to higher extinction risks than lotic species. We aimed to extend previous work on estimating dragonfly extinction risk by developing mechanistic insights into the processes involved. Postulates were tested by analyzing relationships between (1) previous quantitative extinction risk assessments for dragonfly species and (2) species' ecological characteristics (i.e., distribution range and habitat type [lentic or lotic]). Lentic species were disproportionately represented among those with elevated extinction risk. Species with large distribution ranges were also subject to higher extinction risks than those with narrower ranges, reflecting a driving force acting at a national scale (i.e., intensive degradation of paddy systems)." 8330. Kaize, J.; Kalkman, V.J. (2009): Records of dragonflies from kabupaten Merauke, Papua, Indonesia collected in 2007 and 2008 (Odonata). *Suara Serangga Papua* 4(2): 40-45. (in English, with Indonesian summary) ["Odonata were collected in the period 9 July to 4 August 2007 and 4 to 16 June 2008 in the surroundings of Merauke, Papua province, Indonesia. In total 37 species were recorded during the fieldwork bringing the number of species known for the area to 42. It is estimated, that this is about half of the species present in the area. Of the 42 species recorded from the Merauke area 38 belong to the families of Coenagrionidae and Libellulidae. None of the genera endemic to New Guinea were recorded during the fieldwork and only one (*Hemicordulia silvarum* Ris, 1913) of the recorded species is endemic to New Guinea. The results seem to suggest that —compared to the central mountain range or the area in the north of New Guinea— the southern parts of New Guinea have an impoverished fauna. Further fieldwork in the area should be held in different seasons and should try to sample along running waters." 8331. Kalkman, V.J.; van Mastrigt, H.; Richards, S.J. (2009): First records of dragonflies (Odonata) from the

Foja Mountains, Papua Province, Indonesia. *Suara Serangga Papua* 4(1): 14-19. (in English, with Indonesian summary) ["A small collection of dragonflies obtained during two RAP biodiversity surveys to the Foja Mountains, organised by Conservation International with help of LIPI, Bogor, in 2005 and 2008 are brought on record. Twelve species were found at two sites below 100 m near Kwerba, a small village adjacent to the Mamberamo River. Thirteen species were recorded at 'Moss Camp' at 1650 m in the Foja Mountains. Of these *Hemicordulia ericetorum* was previously only known from the central mountain range while *Oreoeschna dictatrix* was only known from Lake Paniai and the Cyclops Mountains. It is likely that more genera and species now known only from the central mountain range occur in the Foja Mountains and probably also the Van Rees Mountains. However one species, *Argiolestes* spec. nov. is probably endemic to the Foja Mountains. Although this collection includes only a small fraction of the diversity likely to be present in the mountains it is nonetheless of interest as it represents the first records of dragonflies from the area." 8334. Kishida, O.; Trusseli, G.C.; Nishimura, K. (2009): Top-down effects on antagonistic inducible defense and offense. *Ecology* 90(5): 1217-1226. (in English) ["Antagonistic phenotypic plasticity may strongly influence trait evolution in tightly interacting predator-prey pairs as well as the role that trait plasticity plays in community dynamics. Most work on trait plasticity has focused on single predator-prey pairs, but prey must often contend with multiple predators in natural environments. Hence, a better understanding of the evolutionary and ecological significance of phenotypic plasticity requires experiments that examine how multiple predators shape prey trait plasticity. Here, using a simple food chain consisting of a top predator (dragonfly larvae, *Aeshna nigroflava*), an intermediate predator (salamander larvae, *Hynobius retardatus*), and frog (*Rana pirica*) tadpoles as prey, we show that the presence of dragonfly risk cues substantially modifies the intensity of antagonistic morphological plasticity in both amphibians. In the absence of dragonflies, tadpoles produced bulgier bodies in response to salamanders, and salamanders responded to this defense by enlarging their gape size. However, in the presence of dragonfly risk cues, the ex-

pression of both antagonistic traits was significantly reduced because tadpoles and salamanders produced phenotypes that are more effective against dragonfly predators. Thus, the reduced antagonism likely emerged, in part, because the benefits of antagonistic trait expression were outweighed by the potential cost of increased vulnerability to dragonfly predation. In addition, our results suggest that when all three species were present, salamander activity levels, which influence the amount of signals required to induce antagonistic traits, were more strongly affected by dragonfly risk cues than were tadpole activity levels. This species-specific difference in activity levels was likely responsible for the reduced tadpole mortality caused by salamanders in the presence vs. absence of dragonfly risk cues. Hence, dragonflies had a positive trait-mediated indirect effect on tadpoles by modifying both the morphological and behavioral traits of salamanders." 8337. Kobingi, N.; Raburu, P.O.; Masese, F.O.; Gichuki, J. (2009): Assessment of pollution impacts on the ecological integrity of the Kisian and Kisat rivers in Lake Victoria drainage basin, Kenya. *African Journal of Environmental Science and Technology* 3(4): 097-107. (in English) ["Macro-invertebrate assemblages were used as bioindicators to assess the ecological integrity of Rivers Kisat (influenced by urban development) and Kisian (influenced by agriculture) using community attributes and the Index of Biotic Integrity. Six stations, three per river, were selected to correspond to different impact types and intensities along the rivers. Physico-chemical parameters and nutrients were determined for each station on a monthly basis from November 2007 to April 2008. Two-way analysis of variance was used to compare water quality and nutrient parameters, and macro invertebrate community attributes between the two rivers, with the river and station as the main factors. Significant differences were accepted at 95% confidence level. There were inconsistencies in the variation of physico-chemical parameters along the two rivers.

However, River Kisat recorded higher values for all physico-chemical parameters considered, except pH and DO. Different indices and metrics representing the structural and functional organization of macro invertebrates were computed and evaluated for responsiveness to physico-chemical parameters and nutrient levels. Macro invertebrate diversity, richness and evenness values failed to delineate stations according to the different levels of degradation they were experiencing. However, the differences were captured by the index of biotic integrity, which separated stations into different classes of quality. River Kisat stations in urban areas scored lowest index values, less than 15 out of 25, while two river Kisat stations scored the highest value, more than 19. The index provided evidence of response to changes in ecosystem integrity exhibited by resident macro invertebrate assemblages to pollution arising from both point and nonpoint sources." (Authors) Aeshna sp. and Gomphus sp. are well represented in Kisian River, and only Aeshna sp. is very rare in Kisat River. As regrettably of often, taxonomic work was processed by using identification keys of non-African handbooks.] Address: Kobingi, Nyakeya, Kenya Marine & Fisheries Research Institute (KMFRI), P. O. Box 1881 Kisumu, Kenya. E-mail: kobnyakeya@yahoo.com.

8338. Koch, B.; Wildermuth, H.; Walter, T. (2009): Einfluss der Habitategenschaften auf das Verbreitungsmuster von *Coenagrion mercuriale* an einem renaturierten Fließgewässer im Schweizer Mittelland (Odonata: Coenagrionidae). *Libellula* 28(3/4): 139-158. (in German, with English summary) ["Only few and isolated populations of the Southern Damselfly exist in Switzerland and the species is considered as critically endangered. The recent discovery of a hitherto unknown population of *C. mercuriale* on a revitalized stream in the Canton of Zurich caused a study to be made on the size and the distribution pattern of the population along a heterogeneously structured 2.15 km-stretch. In summer 2007, the abundance of *C. mercuriale* was recorded at 215 sections and data on physical parameters were collected. The results of statistical analyses showed that the distribution pattern of *C. mercuriale* was significantly affected by the width of the watercourse, depth of the water, cover of the water vegetation, cover and width of the riparian vegetation and cover by trees higher than three metres. The composition of the riparian vegetation that could be classified into six different groups using a cluster analysis also exhibited an effect on the distribution. *Coenagrion mercuriale* preferred sites with relatively wide and deep water, luxuriant aquatic vegetation, wide intermittent but jaggy riparian vegetation and little cover by trees shading the water surface. Riparian vegetation that was mainly composed of *Carex* spp., *Lythrum salicaria* or *Phalaris arundinacea* was most densely colonized by *C. mercuriale*. In contrast, sections overgrown predominantly by *Filipendula ulmaria* and *Epilobium hirsutum* were generally avoided. Additionally, data on the local dragonfly fauna were collected and 14 streams in the neighbourhood of the study site were examined for their suitability for colonization by *C. mercuriale*. In total 21 Odonata species were recorded. Maintenance of the habitat by patchy clearance of dense riparian vegetation, aiming at the promotion of the local population, was conducted in the frame of a conservation programme in late 2007 and early 2008. Censuses carried out during the flying season 2008 showed that the measures adopted had a positive effect on *C. mercuriale*.] Address: Koch, Bärbel,

8340. Koskimäki, J.; Rantala, M.J.; Suhonen, J. (2009): Wandering males are smaller than territorial males in the damselfly *Calopteryx virgo* (L.) (Zygoptera: Calopterygidae). *Odonatologica* 38(2): 159-165. (in English) ["In territorial Odonata, adult males may use 2 mating tactics that may be genetically or environmentally determined: territoriality and non-territoriality. The non-territorial tactic has been sometimes found to include 2 additional males: sneaking and wandering. The non-territorial males, however, often have lower reproductive success than territorial males. Studies on various *Calopteryx* species have repeatedly shown that territorial and non-territorial behaviours are conditional mating tactics and that body size does not predict male resource-holding potential and territorial behaviour. Instead, the resource holding potential seems to depend on the amount of male fat resources. Here, both territorial and wandering *C. virgo* males were collected from a creek in central Finland. It was found that territorial males were larger and heavier than wandering males. The data show that the size of the individual may predict the reproductive tactic of some odonate males to a greater degree than previously thought." (Authors)] Address: Suhonen, J., Sect. 8345. Krilowicz, C. (2009): Congregating Odes. *Argia* 21(1): 8. (in English) [oas 25: Cape May, New Jersey, USA. "I then stopped and decided to look more closely for *S. ambiguum*. To my surprise I was surrounded by them. Earlier, I had unsuccessfully been searching in all the local ponds and surrounding fields for this species. My count for this area was 60 males and 8 females with four of those in a wheel. I am not 100% sure why all these bugs were here. The dominant activity was basking and mating. I did not make any observation of feeding behavior. I could only conclude that there was something unique about this site that attracted so many individuals. The date was 14 October 2008 and it happened to be a new late date for New Jersey. On 22 October 2008 I decided to look for *Aeshna umbrosa* in Atlantic County where it had not been recorded. I picked Makepeace Wildlife Management Area in Mayes Landing. While slowly driving down a deserted blacktop drive surrounded by overgrown pines a small bug hit my windshield. I stopped the car and jumped out. It was a *Lestes* congener and I was able to photograph and collect it. I decided to walk this section of road. By the time I finished my tally, I counted 50 male and 10 female *L.* congener and one *S. ambiguum* (late dates are fleeting). I never expected to see this spreadwing here, for it is an Atlantic County record and I had no idea where there was any standing water nearby. Only 100 yards away is a very large vernal pool which was completely dry. Again I did not observe any feeding behaviour and none were in a wheel. I wonder why they all decided to congregate here? May be just another location to pick a mate." (Author)] Address: Krilowicz, C., Haddonfield, NJ, USA. E-mail: chippop@verizon.net

8346. Kriska, G.; Bernath, B.; Farkas, R.; Horvath, G. (2009): Degrees of polarization of reflected light eliciting polarotaxis in dragonflies (Odonata), mayflies (Ephemeroptera) and tabanid flies (Tabanidae). *Journal of Insect Physiology* 55: 1167-1173. (in English) ["With few exceptions insects whose larvae develop in freshwater possess positive polarotaxis, i.e., are attracted to sources of horizontally polarized light, because they detect

water by means of the horizontal polarization of light reflected from the water surface. These insects can be deceived by artificial surfaces (e.g. oil lakes, asphalt roads, black plastic sheets, dark-coloured cars, black gravestones, dark glass surfaces, solar panels) reflecting highly and horizontally polarized light. Apart from the surface characteristics, the extent of such a 'polarized light pollution' depends on the illumination conditions, direction of view, and the threshold p^* of polarization sensitivity of a given aquatic insect species. p^* means the minimum degree of linear polarization p of reflected light that can elicit positive polarotaxis from a given insect species. Earlier there were no quantitative data on p^* in aquatic insects. The aim of this work is to provide such data. Using imaging polarimetry in the red, green and blue parts of the spectrum, in multiple-choice field experiments we measured the threshold p^* of ventral polarization sensitivity in mayflies, dragonflies and tabanid flies, the positive polarotaxis of which has been shown earlier. In the blue (450 nm) spectral range, for example, we obtained the following thresholds: dragonflies: *Enallagma cyathigerum* ($0\% < p^* 17\%$), *Ischnura elegans* ($17\% p^* 24\%$). Mayflies: *Baetis rhodani* ($32\% p^* 55\%$), *Ephemera danica*, *Epeorus silvicola*, *Rhithrogena semicolourata* ($55\% p^* 92\%$). Tabanids: *Tabanus bovinus*, *T. tergestinus* ($32\% p^* 55\%$), *T. maculicornis* ($55\% p^* 92\%$)." 8347. Kukulova-Peck, J. (2009): Carboniferous protodonatoid dragonfly nymphs and the synapomorphies of Odonoptera and Ephemeroptera (Insecta: Palaeoptera). *Palaeodiversity* 2: 169-198. (in English, with German summary) ["Three extremely rare fossil protodonatoid dragonfly nymphs are described from the middle Pennsylvanian (Moscowian) of Mazon Creek, Illinois: *Dragonympha srokai* n. gen., n. sp. (Meganisoptera), a large, nearly complete young nymph with an extended labial mask and uplifted wing pads; *Alanympa richardsoni* n. gen., n. sp. (Meganisoptera), a nymphal forewing with two articular plates attached to it; and *Carbonympha herdinai* n. gen., n. sp. (Eomeganisoptera), a detached nymphal forewing. Plesiomorphic states in *Dragonympha* n. gen. indicate homologies unresolved in modern Odonata. The segmented head bears 3rd tergum ventrally invaginated. The extended labial mask still shows limb segments. The prothorax bears a pair of winglets. The short wing pads are fully articulated, twisted, uplifted and streamlined with body. The mesothoracic anepisternum is placed between acrotergite and prescutum. The abdominal leglets form long, segmented, serial gill filaments. In the ontogenesis of modern dragonflies, the wing and articulation disc occurs just above subcoxal pleuron and far from tergum. Wing sclerites are arranged in eight rows protecting eight blood pathways running towards eight wing veins. The sistergroup of Odonoptera has not yet been convincingly resolved with computer cladistic approaches. Reasons are examined and discussed. More accurate, evolution-based character evaluations are shown with examples. The role of a correct model of the pan-arthropod limb and the origin of insect wings is discussed. Groundplan characters in dragonflies and mayflies are compared in their Paleozoic and modern states, their obscurity is clarified and complex synapomorphies are proposed. Palaeoptera is confirmed as a monophyletic group and the following sistergroup relationships are

suggested: Pterygota = Palaeoptera + Neoptera; Palaeoptera = Palaeodictyopteroidea + Hydropalaeoptera; Hydropalaeoptera = Odonoptera + Ephemeroptera." 8350. Larison, B. (2009): Impacts of environmental heterogeneity on alternative mating tactics in the threadtail damselfly. *Behavioral Ecology and Sociobiology* 63(4): 531-536. (in English) ["Environmental heterogeneity, including variation in the physical environment, may be key to understanding the evolution and maintenance of alternative mating tactics, but its influence is rarely examined. Males of the threadtail damselfly *Protoneura amatoria* reversibly use two alternative mating tactics (perching vs. hovering) and have previously been found to modulate their use of these tactics in response to variation in both light conditions and the density of ovipositing females. Here, I show that mating success payoffs of the two tactics are differentially influenced by these factors. The payoff of the perching tactic was greater than that of the hovering tactic under low light conditions and at low densities of ovipositing females. The payoff of the hovering tactic was greater under high light conditions and higher densities of ovipositing females. The differential success of the two mating tactics in response to light conditions is dis-

cussed in light of flight dynamics, vision, and predation." (Author)] Address: Larison, Brenda Dept Ecology & Evolutionary Biology, Univ. of California, Los Angeles, 621 Charles E. Young Drive So., Los Angeles, CA 90095, USA. E-mail: blarison@ucla.edu

8353. Lau, D.C.P.; Leung, K.M.Y.; Dudgeon, D. (2009): What does stable isotope analysis reveal about trophic relationships and the relative importance of allochthonous and autochthonous resources in tropical streams? A synthetic study from Hong Kong. *Freshwater Biology* 54: 127-141. (in English) ["1. Analysis of the stable isotope signatures of carbon (C) and nitrogen (N) of foods and consumers has led to some preliminary understanding of the relative importance of allochthonous and autochthonous resources in tropical streams. However, robust generalizations about the dynamics of food webs in these habitats, and their response to shading gradients or season, are still lacking. In addition, the feasibility of employing a baseline $\delta^{15}\text{N}$ value for estimating trophic positions (TPs) of consumers in small tropical streams has yet to be explored. 2. We analysed data on stable isotope signatures of food sources and aquatic consumers obtained from 14 studies carried out in small streams in monsoonal Hong Kong (22°30'N, 114°10'E) between 1996 and 2006. Emphasis was placed on determining the relative importance of leaf litter and autochthonous foods in supporting consumer biomass, and the extent to which trophic base and TP vary among streams and seasons. 3. Although allochthonous leaf litter was generally ^{13}C - and ^{15}N -depleted relative to autochthonous foods, there were marked isotopic shifts of food sources and consumers in response to season (dry versus wet) and stream shading. Consumer taxa were generally more ^{13}C - and ^{15}N -enriched in the unshaded streams, but seasonal effects were more variable. Despite these changes, there was consistent evidence that stream food webs were based on periphytic algae and/or cyanobacteria with leaf litter serving as a minor food. 4. Heptageniidae (Ephemeroptera), Tipulidae (Diptera), Elmidae (Coleoptera) and shrimps (Atyidae) were used as a baseline for calculating the TPs of other consumer taxa. The maximum TPs in shaded streams remained fairly constant between seasons (dry = 3.93; wet = 3.97), while those in unshaded streams were higher and showed seasonal fluctuations (dry = 5.13; wet = 4.39). 5. Although variations in consumer isotope signatures in response to season and shading gradients did not confound our interpretation of the stream food base, changes in consumer $\delta^{15}\text{N}$ did affect the calculation of consumer TPs. Misleading estimates of consumer TPs are likely if samples are collected from a narrow range of streams and/or during one season. Overestimation of

the TPs of specialist herbivores (e.g. fish grazers) is also possible when autochthonous resources are substantially more ¹⁵N-enriched than allochthonous foods." 8354. Le Viol, I.; Mocq, J.; Julliard, R.; Kerbiriou, C. (2009): The contribution of motorway stormwater retention ponds to the biodiversity of aquatic macroinvertebrates. *Biological Conservation* 142(12): 3163-3171. (in English) ["Biodiversity conservation does predominantly focus on protected natural areas, but has to consider also the usually Human-dominated matrix in which these natural areas are embedded. Here we study highway stormwater retention ponds, which may act as refuges for native flora and fauna and contribute to the maintenance of biodiversity in Human-dominated landscapes. However, the biodiversity supported by such artificial ponds has received little attention so far. Using standardised methods, we addressed the potential role of highway stormwater ponds as refuges by comparing aquatic macroinvertebrate communities (Coleoptera, Heteroptera, Odonata and Gastropoda) in highway stormwater ponds with ponds in the wider landscape. As expected from their pollutant retention function, highway ponds differed in abiotic conditions from surrounding ponds. However, they supported aquatic macroinvertebrate communities at least as rich and diverse at the family level as surrounding ponds and exhibited similar variability in family community composition and structure. The main difference we observed was a higher abundance of small and/or short-lived invertebrates in the highway ponds. These similar community compositions and structures suggest that highway ponds contribute to the biodiversity of the pond network at a regional scale. Thus, road practitioners should consider highway ponds not only for their hydrological and pollutant retaining purposes but also as a possibility to increase the role of highway verges as a refuge and, consequently, landscape connectivity. The management of these water bodies should recognise their potential for biodiversity especially in Human-dominated landscapes."(Authors)] Address: Le Viol, Isabelle, Muséum national d'Histoire naturelle, Conservation des espèces, restauration et suivi des populations, CERSP – UMR 7204 MNHN-CNRS-UPMC, 55 rue Buffon, 75005 Paris, France

8355. Lee, E.M.; Hong, M.Y.; Kim, M.I.; Kim, M.J.; Park, H.C.; Kim, K.Y.; Lee, I.H.; Bae, C.H.; Jin, B.R.; Kim, I. (2009): The complete mitogenome sequences of the palaeopteran insects *Ephemera orientalis* (Ephemeroptera: Ephemeridae) and *Davidius lunatus* (Odonata: Gomphidae). *Genome* 52(9): 810-817. (in English) ["Currently, the palaeopteran lineages (insect orders Ephemeroptera and Odonata) that have a problematic relationship with neopteran lineages are poorly represented by mitogenome sequences. In this study, we have determined the complete mitogenome of the oriental mayfly, *Ephemera orientalis*, and the dragonfly *Davidius lunatus*. The 16 463 bp mitogenome of *E. orientalis* and the 15 912 bp mitogenome of *D. lunatus* have many of the features typically detected in insect mitogenomes. Although the initiation codon for the *D. lunatus* COI gene is the typical ATA, *E. orientalis* is unusual in that no typical start codon was detected in the start region of

the COI gene. The A+T-rich regions of both mitogenomes have some unusual features. The *E. orientalis* A+T-rich region harbors two identical 55 bp sequences separated by 158 bp, and the *D. lunatus* A+T-rich region harbors a tandem repeat comprising two identical 261 bp copies and one partial copy of the repeat. Additionally, the A+T-rich regions of both mitogenomes harbour the stem-and-loop structures flanked by the conserved sequences "TA(A)TA" at the 5' end and "G(A)nT" at the 3' end, which have been suggested to be the signals involved in minor strand replication initiation. Furthermore, the *D. lunatus* A+T-rich region contains two tRNA-like structures with proper anticodon and cloverleaf structures." 8356. Lehmann, F.-O. (2009): 17. The limits of turning control in flying insects. In: Dario Floreano, Jean-Christophe Zufferey, Mandyam V. Srinivasan & Charlie Ellington (Eds.): *Flying Insects and Robots*. Springer Berlin Heidelberg. ISBN 978-3-540-89392-9 (Print): 231-246. (in English) ["This chapter provides insights into the turning flight of insects, considering this specific behaviour from experimental and numerical perspectives. The presented analyses emphasize the need for a comparative approach to flight control that links an insect's maneuverability with the physical properties of its body, the properties and response delays of the sensory organs, and the precision with which the muscular system controls the movements of the wings. In particular, the chapter focuses on the trade-off between lift production and the requirement to produce lateral forces during turning flight. Such information will be useful not only for a better understanding of the evolution and mechanics of insect flight but also for engineers who aim to improve the performance of the future generation of biomimetic micro-air vehicles." (in English) ["In Asia, insects have a long history of being a part of recreation and tourism activities, with some species such as rhinoceros beetles and dragonflies being raised as pets. While the role of insects in recreation and tourism (i.e. dragonfly gatherings, educational outings) is somewhat more modest in North America, Europe, and Australia, some of these activities are increasing in popularity. The availability of field guides, associations, and websites is helping to facilitate the growth of these leisure activities, and more specifically the viewing of Odonata. Participant observations and interviews were used to provide an empirical understanding of how one particular insect order - Odonata attracts participants to recreation and tourism activities, fosters interests, and creates controversies (e.g. collecting). A theoretical framework provided by naturework, an interpretivistic approach developed by Fine [(2003). *Morel tales: The culture of mushrooming*. University of Illinois Press.] is used to understand the philosophies involved in dragonflying. The conclusion highlights how new forms of recreation and tourism activities can promote greater awareness of insects." 8360. Linke, T.J. (2009): Flussjungfern am Niederrhein. Verbreitung und Habitatbindung. Diplomarbeit. Institut für Landschaftsökologie, Westfälische Wilhelms-Universität Münster: III, 44 pp, Anhänge. (in German, with English summary) ["Distribution and population density of clubtails at the lower Rhine over, are poorly investigated: only a few exuviae and adults of *Gomphus flavipes*, *G. vulgatissimus*, *Onychogomphus forcipatus* and *Ophiogomphus cecilia* were observed during the last decade. This study aims at investigating the local distribution and at identifying those environmental factors that determine habitat selection. Research was carried out at 30 study sites of 200 x 10 m size, between May 1st and August 31st 2008. Each site was sampled 10 times for exuviae. Additionally, structural parameters were ascertained. Exuviae of all four gomphids were found; however, numbers differed widely. Compared to other streams total abundances of all species were low. Most common species in the area were *G. flavipes* and *G. vulgatissimus* (4-5 exuviae/200 m waterside). At most sites, *G. flavipes* and *G. vulgatissimus* co-occurred. At five sites, exuviae of *O. forcipatus* occurred together with these two species. Exuviae abundances of *G. flavipes* showed positive correlation with the amount of fine sand fractions. A positive effect of sand and total riparian vegetation cover on the abundances of *G. vulgatissimus* was indicated. In sandy substrates *O. forcipatus* and *O. cecilia* are possibly replaced by *G. flavipes* and *G. vulgatissimus* due to hunting strategy and activity patterns. It is assumed, that low abundances of exuviae are caused by inappropriate and fragmented habitat structures, noticeable by the lack of fine substrate fractions. Additionally, hydromorphology, adjacent land use and shipping traffic may have a negative influence on the species." (Author)] Address: Linke, J., Schillerstr. 71, 48155 Münster, Germany

8363. Lorenzo-Carballa, M.O.; Cordero-Rivera, A. (2009): Thelytokous parthenogenesis in the damselfly *Ischnura hastata* (Odonata, Coenagrionidae): genetic mechanisms and lack of bacterial infection. *Heredity* 103: 377-384. (in English) ["Thelytokous parthenogenesis, the production of female-only offspring from unfertilized eggs, has been described in all the insect orders, but is a rare phenomenon in the Odonata. The only-known case of parthenogenesis in this group is the North American damselfly species *Ischnura hastata*, which has parthenogenetic populations in the Azores Islands. Here, we present for the first time the results of laboratory rearing, which showed parthenogenetic reproduction in the Azorean I. *hastata* populations. In an attempt to understand how parthenogenesis could have evolved in this species, we first determined the genetic mode of parthenogenesis by analysing the genotype of parthenogenetic females and their offspring at three polymorphic microsatellite loci. In addition, we used polymerase chain reaction amplification to test whether parthenogenesis in I. *hastata* could be bacterially induced. Our data indicate that thelytoky is achieved through an (at least functionally) apomictic mechanism and that parthenogenesis is not caused by endosymbionts. Finally, we discuss possible routes to parthenogenetic reproduction, as well as the evolutionary implications of this type of parthenogenesis." 8364. Lorenzo-Carballa, M.O.; Beatty, C.D.; Utzeri, C.; Vieira, V.; Cordero-Rivera, A. (2009): Parthenogenetic *Ischnura hastata* revisited: present status and notes on population ecology and behaviour (Odonata: Coenagrionidae). *International Journal of Odonatology* 12(2): 395-411, pl. VIII. (in English) ["Populations of *Ischnura*

hastata found in the Azores archipelago represent the only known example of parthenogenesis in the order Odonata. In this paper, we present results from field-work done on the islands of São Miguel, Pico, Santa Maria, and Graciosa, aimed at characterizing population ecology and habitat preferences of this species. Sampling of several ponds in the islands of São Miguel and Pico showed that *I. hastata* occurred in oligotrophic ponds, but was absent from all eutrophic ponds sampled, many of which have been impacted by cattle grazing and water extraction by humans. This suggests that parthenogenetic populations are highly sensitive to eutrophication, which may be different from suggested habitat preferences of sexual populations for this species. Mark-recapture studies showed *I. hastata* to occur in high densities in the studied populations. Although life expectancy of mature females was estimated at less than one week, their high fecundity and fertility could potentially explain the large number of individuals observed in some of the studied sites. Submerged oviposition seems to be a common behaviour, probably evolved as an adaptation to unfavourable climatic conditions and to avoid egg desiccation caused by water depletion. In summary, this work represents a first attempt to study the ecology and population biology of parthenogenetic populations of *I. hastata*, and may help us to understand the unique conditions under which these populations could have evolved and how to best insure their conservation." 8365. Lowe, C.D.; Harvey, I.F.; Watts, P.C.; Thompson, D.J. (2009): Reproductive timing and patterns of development the damselfly *Coenagrion puella* in the field. *Ecology* 90: 2202-2212. (in English) ["By a combination of detailed behavioural observations and molecular genetic approaches we have assessed development time, timing of first maturity, and the extent of genetic structure through the flying season in a wild population of *C. puella* in England. This work provides the first estimate of development time (egg to mature adult) in the field based on individual damselflies. Development time was significantly longer for females than males. In contrast to reported laboratory studies, there was no difference in development times between different female colour morphs. Development time ranged between 347 and 396 days and was negatively correlated with egg-laying date. As a result eggs laid early in one season reach adult maturity relatively late in the next; concurrently individuals developing from eggs laid late mature relatively early. We speculate that this pattern of development is a direct physiological response to seasonal environmental variation and results in reproductive synchrony within a population. Size, specifically hind wing length, declined with development time in males, but not in females. In one of the two years of the study there was evidence for weak clustering of related individuals during the reproductive season. This appeared to be the result of developmental synchronization within families: variance in timing of maturation was smaller in full-sib families than in half-sib families or randomly assigned unrelated groups." 8371. Magnusson, A.K.; Williams, D.D. (2009): Top-down control by insect predators in an intermittent pond – a field experiment. *Ann. Limnol. - Int. J. Lim.* 45: 131-143. (in English, with French summary) ["The role of predation in the regulation of freshwater communities is predicted to decrease along a habitat-duration gradient, from permanent to episodic waters. We tested the role of invertebrate predation in shaping the community structure in a fishless temperate intermittent pond with a three month long hydroperiod by comparing the community structure in two large field enclosures (4.2 m²) with added predators to two enclosures without added predators. The added predators reflected the density and composition of top predators in the pond and comprised weekly additions of dytiscid larvae (for three weeks) followed by weekly additions of odonate nymphs (for five weeks). Compared with the enclosure controls, the predator addition enclosures had fewer dipterans and crustaceans, higher concentrations of benthic ciliates and other protozoans, higher chlorophyll a and bacterial counts, and lower abundance of rotifers. Many treatment effects were temporally variable and this ap-

peared to be linked to predator identity, predator size, and prey availability. Compared with the surrounding pondwater, the enclosed areas had lower abundance of molluscs, ostracods and cladocerans but higher abundance of cyclopoids and higher concentrations of phytoplankton and ciliates. Despite high productivity and seasonally variable predator and prey assemblages, which likely buffered against strong top-down control, we conclude that the top-predators regulate the dipterans and zooplankton in this intermittent pond and that the effects propagated down through the food web to lower trophic levels." 8377. Martinez, N.; Küttel, M.; Weber, D. (2009): Deutliche Zunahme wildlebender Tierarten in der Schweiz seit 1900. Aussterbe- und Einwanderungsereignisse über 107 Jahre. *Naturschutz und Landschaftsplanung* 41(12): 375-381. (in German, with English summary) ["The number of species recorded on Red Lists in Central European countries is high and includes several species that already have disappeared. This suggests that the total species number is declining in these countries. However, besides disappearing species there are species immigrating into new areas, either due to human help or due to natural area expansion, as well as formerly extinct species that are remigrating. Regional extinction of some species therefore does not necessarily lead to a decrease in total species number. The study analysed the influence of extinction and of immigration on total species number in Switzerland for the last 107 years and for several taxonomic groups (mammals without bats, breeding birds, reptiles, amphibians, fish, cyclostomes, butterflies, grasshoppers and dragonflies). During this period total species number clearly increased (+19 species). This increase is mainly due to species that immigrated autonomously from other European countries. Most of them are wetland inhabitants." (Authors) As new to the Odonata fauna are listed *Erythromma lindenii* (1910), *Crocothemis erythraea* (1990), and *Orthetrum albistylum* (1990). Lost Odonata are *Coenagrion lunulatum* (2000), *C. ornatum* (1960), and *Onychogomphus uncutus* (1990).] Address: Martinez, N., Hintermann & Weber AG, Austr. 2a, CH-4153 Reinach, Switzerland. 8382. Meurgey, F. (2009): Redescription of *Argia concinna* (Rambur), with a description of *Argia telesfordi* spec. nov. from Grenada, West Indies (Zygoptera: Coenagrionidae). *Zootaxa* 2272: 54-62. (in English) ["*Argia telesfordi* sp. nov. a new species close to *Argia concinna*, is described from Grenada. Both species are illustrated and diagnosed. They can be distinguished by morphology of male tori, cerci and paraproct and female mesostigmal laminae. Their distribution is allopatric, with *Argia telesfordi* distributed on Grenada and *Argia concinna* known only from Guadeloupe and Dominica." (Author)] Address: Meurgey, F., Muséum d'Histoire Naturelle, 12, rue Voltaire, 44000 Nantes, France. E-mail: Francois.Meurgey@mairie-nantes.fr

8383. Meurgey, F. (2009): The Odonata of Grenada (Lesser Antilles). Survey report May 1 – 14 2009. L'Herminier Natural History Society. Odonata report # 1: 33 pp, app.. (in English) ["This report is based on the examination of 200 specimens, collected by two individuals. Although 23 specimen localities are included in this report, and although these localities occur in the totality of the six parishes of Grenada, the areal coverage of the island is uneven. The principal collecting localities have been in the north part of the island, and especially on St Andrews and St Marks parishes, along the east coast, in the central uplands of the island and in the most of waterfalls. There are very few collections from the south part of the island, and almost none from the south-west coast of the island. The most important locality, on the northeast coast of Grenada is the large swamp at Meadow Beach, at Conference Bay, where a

variety of habitats have been collected rather thoroughly. The most of the species are far more common here than elsewhere, and *Lestes tenuatus* and *Erythrodiplax fervida* has been recorded on Grenada only from this locality. Several waterfalls in the central upland region were collected repeatedly. These streams and small rivers are characteristically rocky, more or less swift, and have very limited emergent vegetation. They have limited odonata fauna, consisting mainly of *Argia concinna*, *Dythemis sterilis* and *Brechmorhoga praecox grenadensis*. From a biogeographical point of view, the dragonfly fauna of Grenada is clearly a mix between the Caribbean and the South American fauna, with three species originated from South America not shared with other islands, and one (*Argia concinna*) which is a Caribbean endemic. This first survey needs to be completed by further researches on the ecology and on the biology of species. The dragonfly fauna of Grenada could increase to 20-22 species." (Author)] Address: Meurgey, F., Muséum d'Histoire naturelle de Nantes, 12, rue Voltaire, F-44000 Nantes, France. E-mail: Francois.Meurgey@mairie-nantes.fr

8384. Michalczyk, M.; Buczyński, P.; Daraż, B. (2009): First data from the monitoring of population condition of Ornate Bluet *Coenagrion ornatum* (Selys, 1850) in the valley of Sieniocha river (Sniatycze, south-eastern Poland) *Wiaczeslaw. Odonatrix* 5(2): 33-44. (in Polish, with English summary) ["*Coenagrion ornatum* is a critically endangered dragonfly species in Poland known nowadays from only one site (three others given after 1990 extinguished). The authors discuss first data (2007–2008) coming from regular observations of the last known population discovered in 2007 r. in Sniatycze near Zamosc (50°38'–50°39'N, 23°32'E, UTM square: FB71). *C. ornatum* inhabits one of drainage ditches in the area of a spring fen of calcareous character (Fig. 1). *Molinietum caeruleae* and *Caricetum appropinquatae* are dominating in vegetation, in some places *Cladietum marisci* and *Schoenetum ferruginei*, associated with shallowly situated calcareous substratum, are also preserved. The described fen is systematically burnt-out together with surrounding meadows. The ditch with *C. ornatum* has no direct connection with springs. Its water is warmer, slightly impoverished in oxygen and more fertile than spring waters (Tab. 1). During the warmer winter in 2007 ice layer did not cover the whole water surface –it was present only in sides. In the cooler winter in 2008 layer reached the thickness of 5 cm and covered the whole water surface, however, the ditch were not frozen to the bottom. The ditch is shallow (a few cm), narrow (the width of water surface up to 1m, however, in many places only to 20–30 cm), the bottom is covered with muddy substrata. Current is slow, water transparent. The bottom is grown by *Berula erecta*: in varied density –from a single plant to compact clusters. In large part of the watercourse the expansion of *Phragmites communis* and *Carex appropinquata* is visible, banks are grown by single scrubby willows in some places. In the front part of the ditch water is covered by moss mats. Regular observations were conducted in the year 2007, from the moment of discovery of the site and through the whole year 2008. *C. ornatum* was noted during 11 controls (Tab. 2). Maximum number of individuals was 195, they inhabited the stretch of ditch with length of ca. 170 m –with *Berula erecta* the least choked by *Phragmites communis* and *Carex appropinquata*. The period of imaginal flight lasted from the last decade of May till the last decade of July (individuals

observed on 3 June were very numerous and partially mature therefore their emergence must have taken place several days earlier). It is a relevant supplement to the previous data from Poland. This corresponds with the data from Czech Republic and is similar to data from other countries of Central and Eastern Europe. The features of habitat correspond with these in literature. The fact that the species is resistant to ice layer seems to be important (however, water must be flowing just above the bottom). Two colour forms were distinguished within females: blue and green, within males – only blue one. Juvenile individuals of blue form were violet, green one – beige-brown. The base of eyes corresponded with colour forms. Three forms of abdominal pattern of males and two of females were described (Fig. 2). One of the forms of males (spot in form of goblet without a stem on the second segment) has been described for the first time. The following species coexisted with *C. ornatum* in the ditch (* autochthonic ones or probably autochthonic): *Lestes barbarus*, **L. sponsa*, *Ischnura elegans*, *I. pumilio*, **Enallagma cyathigerum*, **Coenagrion puella*, **C. pulchellum*, **Somatochlora flavomaculata*, *Libellula quadrimaculata*, *L. fulva*, **Orthetrum coerulescens*, *O. cancellatum*, *Sympetrum danae*, **S. sanguineum*, *S. vulgatum*. In neighbouring habitats (other ditches, peat excavations) there were also: *Calopteryx virgo*, **Sympecma paedisca*, *Pyrrhosoma nymphula*, **Aeshna juncea*, *Leucorrhinia albifrons*. The threat to the ornate bluet in Sniatycze is mainly the expansion of vegetation (reed and sedges). Moreover, water surface is covered with litter. In 2008, by the efforts of Nature Association of Zamosc, first protection activities were taken like mowing reeds in some places and removing reed and sedge litter from current to the banks of the watercourse. The aim of these activities is to redouble the length of the ditch with optimal conditions for the species. These actions will be continued and their results monitored. *C. ornatum* is the species proposed by Poland to the appendix II of Habitats Directive. On this account, as well as due to its legal protection and Red List status, this species should be encompassed by national program of inventarisation, monitoring and protection. In the meantime there are no funds for this purpose – at the same time money is available for researches of species important but not endangered in Poland to Nature 2000, like *Ophiogomphus cecilia* and *Leucorrhinia pectoralis*. The authors criticise this situation." (Authors)] Address: Michalczuk, M., Zamojskie Towarzystwo Przyrodnicze, ul. Szymonowica 19/6, 22-400 Zamość, Poland. E-mail: wiack@wp.pl

8385. Miszta, A.; Cuber, P. (2009): New localities of dragonflies (Odonata) endangered in Poland recorded in the years 2006–2008 in Silesian Province outside of protected areas. *Odonatrix* 5(2): 48-54. (in Polish, with English summary) ["In the area of districts: Chelm Śląski, Tarnowskie Góry, Ogrodzieniec and the city of Czechochowa, five new sites were found in 2006–2008, which occurred to be the breeding and development sites of endangered dragonfly species in Poland, such as: *Nehalennia speciosa*, *Somatochlora arctica*, *Cordulegaster boltonii*, *Aeshna subarctica elisabethae* and *A. juncea*. One of those sites, a sinkhole pond in Bledów near Chelm Śląski, is quite interesting for *N. speciosa*, *A. subarctica* and *A. juncea* were recorded all together. Another interesting site is in Pniowiec, where *S. arctica* and *C. boltonii* were found, which completed previous observations of the other dragonfly species in this site: *Brachytron pratense*. Because of their natural aspects

both sites are going to be included in the conservation system of Nature 2000 areas." (Authors)] Address: Miszta, Alicja, Centrum Dziedzictwa Przyrody Górnego Śląska, ul. Św. Huberta 35, 40-543 Katowice, Poland. E-mail: a.miszta@cdpigs.katowice.pl

8387. Montana, C.G.; Winemiller, K.O. (2009): Comparative feeding ecology and habitats use of *Crenicichla* species (Perciformes: Cichlidae) in a Venezuelan floodplain river. *Neotropical Ichthyology* 7(2): 267-274. (in English, with Spanish summary) ["Feeding behaviour and habitat use of two species of pike cichlids *Crenicichla lugubris* and *C. aff. wallacii* were studied in the río Cinaruco, a floodplain river in the Venezuelan llanos. We examined 309 individuals of *C. lugubris* and 270 individuals of *C. aff. wallacii* from both the main channel and lagoons throughout the falling-water phase of the annual hydrological cycle. [...] Analysis of stomach contents showed that larger specimens (> 100 mm SL) *C. lugubris* fed mostly on small fishes (e.g. characids, cichlids), but juveniles (< 100 mm SL) consumed mostly aquatic insects, fish scales, and shrimps. *Crenicichla aff. wallacii* fed on aquatic insects and other invertebrates associated with leaf litter substrates." (Authors) "Odonata" contributed up to app. 10% of the diet depending on the age class of the fish.] Address: Montaña, Carmen, Section of Ecology, Evolution and Systematic Biology, Dept Wildlife & Fisheries Sciences. Texas A&M University, College Station, TX 77843-2258, USA. E-mail: car1607@tamu.edu

8388. Moreira-Hara, S.S.; Zuanon, J.A.S.; Amadio, S.A. (2009): Feeding of *Pellona flavipinnis* (Clupeiformes, Pristigasteridae) in a Central Amazonian floodplain. *Iheringia, Sér. Zool.* 99(2): 153-157. (in English, with Portuguese summary) ["The feeding habits of *P. flavipinnis* at Catalão, a floodplain area on the Brazilian Central Amazon was studied. Data was obtained during three hydrological cycles, between September 1999 and September 2003. Diet composition, daily and seasonal variation in the feeding activity and the relationship between predator's size and its prey were analyzed. Almost 80% of the food consumed has autochthonous origin and diet was composed basically by insects and fish. Juvenile fish predominated in the stomach contents of all size classes but there was no significant relationship between predator's size and its prey. *P. flavipinnis* may be considered a carnivorous species which feeds mainly on juvenile (young-of-the-year) specimens of other fish. More intense feeding activity occurred at night and in the high water period." (Authors) "Odonata" accounted significantly to the diet of the fish species.] Address: Moreira-Hara, Sandra, Escola Superior Batista do Amazonas, Rua Leonor Telles, 278, Conj. Abílio Nery, Adrianópolis, Manaus, AM, Brazil. E-mail: sandrasocorromoreira@yahoo.com.br

8389. Moreno, P.; Franca, J.S.; Ferreira, W.R.; Paz, A.D.; Monteiro, I.M.; Callisto, M. (2009): Use of the

BEAST model for biomonitoring water quality in a neotropical basin. *Hydrobiologia* 630: 231-242. (in English) ["The use of predictive models in Neotropical basins is relatively new, and applying these models in large basins is hindered by the lack of ecological, geographical, and social-environmental knowledge. Despite these difficulties, we used data from the das Velhas River basin to apply the BEAST (Benthic Assessment of SedimenT) methodology to evaluate and classify the level of environmental degradation. Our two main objectives were to modify and implement the BEAST methodology for use in biomonitoring programs of Brazilian basins, and to test the hypothesis that a gradient of environmental degradation determines a gradient in the structure and composition of benthic macroinvertebrate assemblages. We evaluated 37 sites: 8 in the main river, 15 in the main tributaries with different impact levels, and 14 in tributaries with minimally disturbed conditions (MDC). The BEAST model allowed us to classify 16 test sites: two as natural, four as altered, three as highly altered, and seven as degraded. Our results indicated degradation of the das Velhas River basin near its urban areas. The BEAST model indicated that the pollution gradient found among the sites generated a gradient of the macroinvertebrate assemblages, corroborating the hypothesis." (Authors) Odonata are treated at the family level.] Address: Callisto, M., Laboratório de Ecologia de Bentos, Departamento de Biologia Geral, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, Av. Antônio Carlos 6627, Belo Horizonte, Minas Gerais, Brazil. E-mail: callistom@ufmg.br

8390. Msyani, E.K.; Lazaro, J.; Castor, O.N.; Chambegega, O.A. (2009): Seasonal inventory and status of flying insects, in Kihansi Gorge, Tanzania. *African Journal of Ecology* 47(3): 267-275. (in English) ["Sampling of flying insects in Kihansi Gorge was conducted in six micro-habitats namely Lower, Upper, Main, Mid-Gorge and Mhalala Spray Wetlands and adjacent forest. The four traps used were, malaise, pitfall, light and artificial substrate sampler, besides sweep netting and beating. In the wet season, 65,549 flying insects (65.13%) were recorded when compared to 35,633 flying insects (34.87%) in dry season. At its peak, 29,783 flying insects (29.15%) were recorded at the start of wet season (December 2004). The abundance value was significant ($\chi^2= 1794.98$, d.f.= 5, $P \leq 0.001$). The favourable weather condition at the beginning of the wet season might have triggered emergence of high numbers of winged insects like ants, to facilitate migration through dispersal and reproduction, and some aquatic insects (Plecoptera, Odonata and Trichoptera) moulted and entered into terrestrial life to raise terrestrial abundance. No association was recorded between abundance of flying insects and amphibians (Kihansi Spray Toad; *Nectophrynoides asperginis*), for Mid-Gorge and Main Spray Wetlands ($r = -0.71$, $n = 4$, $P = 0.147$ and $r = -0.69$, $n = 5$, $P = 0.201$) respectively." 8410. Peixoto, P.E.C.; De Marco Jr., P. (2009): No size or density effect on alternative mate-locating tactics in the tropical damselfly *Hetaerina rosea* males (Odonata: Calopterygidae). *Rev. Biol. Trop.* 57(1-2): 361-370. (in English, with Spanish summary) ["Males of *H. rosea* may defend mating sites along river margins (resident males) or, alternatively, wander among different areas presumably searching for mates (nonterritorial males). Although the occurrence of territorial and non-territorial males of *H. rosea* is very common in Brazil, studies examining which factors may be responsible for the adoption of alternative mate-locating tactics in this species are inexistent. We investigated the relationship between the adoption of these alternative mate-locating tactics by males of *H. rosea* and two possible causes: body weight and male abundance. We carried the study in three areas: sites 1, 2 and 3. Samples were monthly undertaken in sites 1 and 2 between September/2001 and August/2002 and in site 3 between May/1999 and January/2001. Using the scan method with fixed areas and mark-resighting techniques, we did not find any relationship between the proportion of nonterritorial males and male abundance per month on sites 2 ($n=6$) and 3 ($n=7$), indicating that the adoption of alternative mate-locating tactics is not affected by competition for territories. In the same way, nonterritorial and resident males showed similar body and thoracic weight measures ($n=30$ and $n=27$ for sites 2 and 3 respectively). Maybe the nonterritorial tactic is adopted by individuals searching for better territories or males that were evicted from their defended sites. The absence of relationship between weight and male territorial status is in accordance with other *Hetaerina* species. However, other traits not investigated here such as parasitic load, fat content and age may influence the adoption of different mate-ac-

quisition tactics in *H. rosea* males.] Address: Peixoto, P.E.C., Departamento de Zoologia, IB, UNICAMP, C.P.6109, CEP 13083-970, Campinas, São Paulo, Brasil. E-mail: popscardoso@yahoo.com.br

8413. Porst, G.; Irvine, K. (2009): Implications of the spatial variability of macroinvertebrate communities for monitoring of ephemeral lakes. An example from turloughs. *Hydrobiologia* 636(1): 421-438. (in English) ["Turloughs, ephemeral water bodies associated with karstified limestone, are an important habitat found in the West of Ireland. They are a priority habitat under the European Habitats Directive (92/43/EEC) and are groundwater-dependent habitats under the European Water Framework Directive (2000/60/EC; WFD). Sampling to meet the objectives of either Directive requires discrimination of inherent natural variation from anthropogenically induced disturbances and accounting for both spatial and seasonal patterns of biotic distribution. This study reports within. (submerged grassland) and between-habitat (submerged and emergent grassland) variability of macroinvertebrate (including *Lestes dryas*) communities in six turloughs. Two different habitat types were sampled from two turloughs in April 2007, and further assessment of spatial pattern in commonly found submerged grassland habitat was determined from four additional turloughs in spring 2008. While cluster analysis and non-metric multidimensional scaling identified differences in macroinvertebrate community structures between habitats in one out of two turloughs, congruence of invertebrate communities was, nevertheless, greater within than among turloughs. Within-habitat variability of macroinvertebrate communities across sampling locations of submerged grassland habitat was sufficiently low so that samples collected at any location of a turlough can provide a reliable metric of the macroinvertebrate community of a turlough as a whole. A standardized submerged grassland sampling approach for routine turlough sampling is recommended as a pressure response method to fulfil the requirements of the WFD. For a comprehensive conservation assessment, however, as demanded under the EC Habitats Directive, we suggest a multi-habitat sampling approach to obtain a thorough assessment of turlough

macroinvertebrate biodiversity." (Author)] Address: Porst, Gwendolin, Leibniz Institute of Freshwater Ecology and Inland Fisheries (IGB), Müggelseedamm 301, 12587 Berlin, Germany. E-mail: porst@igb-berlin.de

8414. Precigout, L.; Prud'Homme, E.; Jourde, P. (Coord.) (2009): *Libellules du Poitou-Charentes*. Poitou-Charentes Nature. ISBN: 978-2-918831-00-6: 256 pp. (in French) ["The fruit of 18 years of sampling and of the accumulated experience of more than 200 naturalists, this work treats the 73 species of dragonflies currently known in the Poitou-Charentes. Precise descriptions of the distribution, abundance, life cycle and conservation status of each species are presented. This detailed information is accompanied by graphs, distribution maps and by numerous photographs. More than a simple field guide, this is a book to read at home. It will please naturalists, fishermen and those who enjoy simply observing the natural world around them. It is a collective and associative work where each chapter reflects the different personalities of the contributors. To know, to respect, and to protect dragonflies - such are the principles which have led us to publish this work today. May it contribute to a better understanding and long term protection of these marvellous creatures which form an important part of our natural heritage." 8416. Pryke, J.S.; Samways, M.J. (2009): Conservation of the insect assemblages of the Cape Peninsula biodiversity hotspot. *Journal of Insect Conservation* 13(6): 627-641. (in English) ["The Cape Peninsula is an area of outstanding biological importance, not only for its high levels of floristic diversity and endemism, but also for its number of localised endemic invertebrates. Little is known of the spatial distribution of invertebrates across the Peninsula, or how best to conserve them. Sampling by visual searches assisted by aerial and aquatic hand-nets was undertaken throughout the Peninsula. The most important areas for insect diversity on the Peninsula, and associated environmental variables, were determined. The 'Peninsula effect' was also investigated. Nine Red Listed species and five new species for the Peninsula were recorded. This high number of Red Listed species (for those few groups that have been assessed) emphasises the biological importance of the Cape Peninsula. Table Mountain had the most Red Listed species, while Cape Point had many species not found in the other areas. Noordhoek Wetland is very important for aquatic Coleoptera. Small hills on the Peninsula are important for overall insect diversity. Elevation, slope, aspect, distance to water and vegetation structure were the most important environmental variables in determining the insect assemblages. The Peninsula effect appears to have no influence on these particular insect assemblages of the Cape Peninsula. The high number of new Peninsula records for well-known

taxonomic groups indicates that still little is known of the insect assemblages across the Peninsula. Nevertheless, areas of conservation priority identified in this study are Table Mountain (for Red Listed species), Noordhoek (for aquatic Coleoptera) and Cape Point and the small hills across the Peninsula (for their unique invertebrate assemblages). Conservation of a variety of elevations, including steep and flat areas, all aspects of mountains, as well as both the wet and dry areas, overall will contribute to the conservation of the insects." 8421. Reborá, M.; Piersanti, S.; Gaino, E. (2009): A comparative investigation of the antennal sensilla in adult Anisoptera. Odonatologica 38(4): 329-340. (in English) ["A fine structural overview of the flagellar sensilla of *Onychogomphus forcipatus*, *Aeshna cyanea*, *Somatochlora metallica*, and *Cordulegaster boltonii* revealed the presence of pits containing sensilla typically located on the latero-ventral side of the first flagellar segments in all four species. These sensilla are represented by coeloconic single-walled olfactory sensilla and deeply sunken sensilla styloconica (type-1 and type-2) sharing common features typical of thermo-hygroreceptors. Sensilla styloconica are located inside deep convoluted cavities. It is suggested that olfactory and thermo-hygroreceptive sensilla are the main sensilla on the antennae of all anisopteran families. The attribution of the coeloconic sensilla of dragonflies to single-walled olfactory sensilla (confirmed by the finding of pore tubules in *O. forcipatus*), together with their common occurrence in the suborder Anisoptera, are relevant for phylogenetic studies." (in German, with English summary) [The paper summarizes the development of the entomological collections at the Mainz Museum of Natural History / State Collection of Natural History of Rhineland-Palatinate, Germany. After the nearly complete destruction of the museum and its collections during the air raid on Mainz on February 27th, 1945, the rebuilding of the entomological collections started in the 1960's. The different phases of the rebuilding are described, introducing the volunteers, and important persons who worked for a long time in the entomological collections of the museum. In a second section the nowadays available collections and their collectors are presented. The most comprehensive inventory exists for the butterflies (Lepidoptera), true bugs (Heteroptera), wasps and bees (Hymenoptera), and beetles (Coleoptera). Concerning flies (Diptera) the museum has the largest individual collection based on the hoverflies (Syrphidae) from Franz Malec. Other insect orders are represented by small or very small collections or are lacking completely. Odonata are represented in five boxes, in most cases in poor labelling condition. Taxa are represented by records from Germany, Austria, Denmark, Norway, 10 specimens from Peru, and 44 specimens from Ruanda.] Address: Renker, C., Naturhistorisches Museum Mainz / Landessammlung für Naturkunde Rheinland-Pfalz, Reichklarastr. 10, 55116 Mainz, Germany. 8427. Riservato, E.; Boudot, J.-P.; Ferreira, S.; Jovice, M.; Kalkman, V.J.; Schneider, W.; Samraoui, B.; Cuttelod, A. (compilers) (2009): The status and distribution of dragonflies of the Mediterranean basin. Gland, Switzerland and Malaga, Spain: IUCN. ISBN: 978-2-

8317-1161-4: vii + 33 pp. (in English) [Executive Summary: Aim: This report contains a review of the conservation status of 165 Mediterranean species of dragonflies occurring in the Mediterranean basin, according to the IUCN regional Red Listing criteria. It identifies species that are threatened with extinction at regional level so that appropriate conservation action can be taken to improve their status. Scope: The geographical scope of this report is the Mediterranean region in terms of freshwater hydrosystems, defined by identifying all catchments of rivers flowing into the Mediterranean Sea as well as in the adjacent Atlantic waters of Spain, Portugal and Morocco. Status assessment: The status of all species was assessed using the IUCN Red List Criteria (IUCN 2001), which are the world's most widely accepted system for measuring extinction risk. All assessments followed the Guidelines for Application of IUCN Red List Criteria at Regional Levels (IUCN 2003). The assessments were peer-reviewed by other experts during a workshop and through correspondence with relevant experts. Results: Almost a fifth (19%) of the dragonfly species occurring in the Mediterranean region are threatened and a further 16% are Near Threatened. Four species (2%), *Agriocnemis exilis*, *Ceriatrigon glabrum*, *Rhyothemis semihyalina* and *Phyllomacromia africana* are listed as Regionally Extinct. Threatened dragonflies are found all over the Mediterranean region. However, some areas have a particular high concentration of threatened species: the most notable are the southern Balkans, northeastern Algeria and the Levant with the adjacent southern parts of Turkey. Fourteen percent of the species in the Mediterranean Basin are endemic, (9 of these are threatened and 5 Near threatened). This highlights the responsibility that the Mediterranean countries have to protect the global populations of these species. The highest number of endemics are found in the Maghreb and in the Levant whereas the smaller numbers are found in the southern Balkans, Crete and the Western Mediterranean. Dragonfly diversity is greatest in the northern parts of the region as both Mediterranean and more boreal species can be found in the same area. Italy has the highest number of species due to its particular shape allowing the presence of North African species in the south and alpine species in the north. Other species rich areas are found in France, the Balkans region, Greece, Tunisia and Turkey. Habitat destruction, degradation, pollution and mismanagement of water bodies are significant threats to dragonflies in the Mediterranean Basin. In recent years it has become clear that Climate Change will turn out to be one of the most important threats to dragonflies in the Mediterranean. Increased water demand together with a lower level of precipitation will result in the desiccation of brooks, a habitat on which many of the endemics are dependent. Conclusions: Threatened dragonflies in the Mediterranean Basin require urgent action to improve their status: While some species are already receiving some conservation attention thanks to international laws (e.g. the European Habitat Directive), others are not. The priorities identified in this study include addressing the threats, such as the destruction and degradation of freshwater habitats, and the need to improve monitoring, surveys and studies in some important areas of the Mediterranean Basin. Regional action is urgently needed: This report shows where the highest diversity, the highest level of endemism, and the highest portion of threatened dragonflies are found within the Mediterranean region. Based on this, five areas of high conser-

vation concern were selected (Maghreb, The Levant, Crete, Southern Balkans and Western Mediterranean). These areas are discussed separately, and for each one, conservation actions are prioritized. A sustained investment in the conservation and monitoring of species sites and landscapes is needed for all Mediterranean countries: To ensure that Mediterranean species are secure in the long term, this needs to be combined with the political will to integrate biodiversity conservation into all policy sectors.] Address: IUCN Centre for Mediterranean Cooperation, C/ Marie Curie 22, 29590 Campanillas, Malaga, Spain

8430. Romo-Beltrán, A.; Macías-Ordóñez, R.; Córdoba-Aguilar, A. (2009): Male dimorphism, territoriality and mating success in the tropical damselfly, *Paraphlebia zoe* Selys (Odonata: Megapodagrionidae). *Evolutionary Ecology* 23(5): 699-709. (in English) ["The tropical damselfly *Paraphlebia zoe* has two male morphs: a black-winged (BW) male which is associated with territorial defense of oviposition sites; and a hyaline-winged (HW) male similar in appearance to females, and, compared to the black morph, less frequently found defending territories. In a wild population of this species, we first assessed the relationship between phenotypic traits [male morph, size and territorial status (being territorial or non-territorial)], their role on mating success, and the degree to which a particular territory may contribute to male mating success. Second, to relate a physiological basis of being territorial we compared both morphs in terms of muscular fat reserves and thoracic muscle, two key traits related to territory defense ability. Males of both morphs defended territories although the BW males were more commonly found doing this. BW males were larger than HW males and size predicted being territorial but only within HW males (territorial males were larger) but not in BW males. Male mating success was related to territorial status (territorial males achieved a higher mating success), but not to morph or size. Furthermore, territory identity also explained mating success with some territories producing more matings than others. The BW morph stored more fat reserves which may explain why this morph was more likely to secure and defend a place than the HW morph. However, the HW morph showed higher relative muscle mass which we have interpreted as a flexible strategy to enable males to defend a territory. These results are distant to what has been found in another male dimorphic damselfly, *Mnais pruinosa*, where the advantage of the non-territorial morph relies on its longevity to compensate in mating benefits compared to the territorial morph." (2009): Geometric morphometric analysis of wing shape variation in ten European populations of *Calopteryx splendens* (Harris, 1782) (Zygoptera: Calopterygidae). *Odonatologica* 38(4): 341-357. (in English) ["The wings of 10 *C. splendens* populations were examined by landmark-based geometric morphometric analysis. Subspecific taxa in this group are currently based on wing spot size in males. Here, the variation in wing shape and size is evaluated, to test whether shape is different at a population level, and whether this has implications at a taxonomic level. It was found that Geometric Morphometrics successfully discriminates populations; overall wing shape significantly differed between populations but the results were only partly compatible with taxonomic studies based on wing spot size. Irrespective of wing spot, all populations showed differentiation in wing shape even though not in wing size; 4 groups were recognized based on wing shape: (1) Turkish1 population; (2) Spanish, Finnish, Russian and Turkish populations; (3) Italian, German and French populations; (4) Greek and Albanian populations. Ordination of the populations based on consensus data and cluster analysis phenogram confirmed such a pattern. The Spanish population (*C. xanthostoma*), did not show a strong identity, while the Turkish1 (*C. s. waterstoni*) was quite isolated. The Italian population (*C. s. caprai*) showed more relation to the French (*C. s. fairvei*) and German populations than to Albanian and Greek populations." (Authors)] Address: Dumont, H.J., Univ. 8433. Sánchez-Montoya, M.M.; Suárez, M.L.; Vidal-Abarca, M.R. (2009): Seasonal and interannual variability of macroinvertebrate reference communities and its influence on bioassessment in different Mediterranean stream types. *Fundamental and Applied Limnology / Archiv für Hydrobiologie*, Volume 174(4): 353-367. (in English) ["We investigated the seasonal changes in macroinvertebrate reference communities in four Mediterranean stream types (temporary, evaporite calcareous at medium altitude, siliceous headwaters at high altitude, and calcareous headwaters at medium and high altitudes) and the interannual changes in the two headwaters stream types in Spain. Eighty-eight seasonal reference sites distributed into 23 basins were sampled on three occasions (spring, summer and autumn of 2003), and 18 interannual reference sites distributed in 6 basins were sampled in the autumn of 2003, 2004 and 2005 to examine this temporal variability. Interannual reference sites were a subset of seasonal reference sites. The analysis of similarity (ANOSIM) performed on Bray-Curtis similarity distances, using presence-absence data, showed no seasonal or inter-

annual changes in the macroinvertebrate communities. The influence of seasonal and interannual variability was also tested in all the stream types using 18 macroinvertebrate metrics classified as richness, index, multi-metric index, tolerance/intolerance and diversity. ANOVAs showed no seasonal differences in any of the studied metrics for temporary and evaporite calcareous at medium altitude and most of the metrics in the two headwaters stream types. This suggests the suitability of using a single season approach for the biomonitoring purposes of these metrics. Conversely, the seasonal differences detected in the metrics related with EPT (Ephemeroptera, Plecoptera and Trichoptera) and OCH (Odonata, Coleoptera and Heteroptera) taxa in calcareous headwaters indicate possible differences in the relative presence of macrohabitats (riffles and pools) as a result of flow variation. No interannual changes were detected in any of the metrics except EPT/OCH in siliceous headwaters. However, the large variability in the annual rainfall in this study area suggests that this three-year study period may be too short to assess the effect of climatic variations on the ecological status assessment. In general, the lower temporal variability (measured as seasonal and interannual coefficients of variation) of the taxon richness metric (S) and the two studied indices (IBMWP and IASPT), compared with the other metrics, make them a priori robust indicators to assess ecological status in Mediterranean streams." The origin and possible migration route of the Finnish specimen is shortly discussed. (Asmus Schröter)] Address: not stated

8438. Schultz, T.D.; Fincke, O.M. (2009): Structural colours create a flashing cue for sexual recognition and male quality in a neotropical damselfly. *Functional Ecology* 173: 724-732. (in English) ["Structural colouration is common among animals that produce sexual displays involving motion or ultraviolet reflection. Different sources of colour may provide multicomponent signals that indicate the location, sex, and fitness of a potential mate or rival. We investigated the proximate basis and ultimate function of the wing colouration of the territorial damselfly *Megaloprepus caerulatus*, which produces a dynamic, high contrast display during flight. The wings of both sexes have blue and white bands, but the location of the white patches are sex specific. Wax filaments produce diffuse, white areas through broadband scattering of wavelengths between 300 and 700 nm. Blue bands reflect wavelengths between 300 and 500 nm (max = 398 nm) and shift in hue with viewing angle, the result of thin layer interference produced by layers of cuticle and pigment within the wing membrane. Both wing bands strongly reflect UV wavelengths. Both the iridescent UV-blue and white wing patches provide high contrast against the vegetation in forest light gaps where mating occurs. Moreover, the iridescent signal oscillates during flight. Angle-dependent UV-blue iridescence is periodically extinguished during each wing beat cycle, in contrast to the white areas, which remain bright. Males distinguish potential mates from rivals by the presence of a female's white wing tip. Blackening the white wing bands of males and adding white wing tips to resemble a female elicits a sexual rather than aggressive response from males. Conversely, blackening the white wing tips of females reduces sexual responses. The proportional area of the white wing bands of males is indicative of wing symmetry, correlated with body size, and in turn, territory residency suggesting that it may serve as a signal of male condition during intra- and intersexual interactions. We propose that the flashing iridescent UV-blue wing bands provide a beacon to potential mates across forest light gaps, whereas the white patches serve in mate recognition and may indicate male quality or territorial status. Our study identifies a unique combination of interference and broadband reflectors that provide a dynamic multicomponent signal." A(authors)] Address: Fincke, O.M., Dept Zool., Univ. 8441. Shang, J.K.; Combes, S.A.; Finio, B.M.; Wood, R.J. (2009): Artificial insect wings of diverse morphology for flapping-wing micro air vehicles. *Bioinspiration & Biomimetics* 4: 6 pp. (in English) ["The development of flapping-wing micro air vehicles (MAVs) demands a systematic exploration of the available design space to identify ways in which the unsteady mechanisms governing flapping-wing flight can best be utilized for producing optimal thrust or maneuverability. Mimicking the wing kinematics of biological flight requires examining the potential effects of wing morphology on flight performance, as wings may be specially adapted for flapping flight. For example, insect wings passively deform during flight, leading to instantaneous and potentially unpredictable changes in aerodynamic behaviour. Previous studies have postulated various explanations for insect wing complexity, but there lacks a systematic approach for experimentally examining the functional significance of components of wing morphology, and for determining whether or not natural design principles can or should be used for MAVs. In this work, a novel fabrication process to create centimeter-scale wings of great complexity is introduced; via this process, a wing can be fabricated with a large range of desired mechanical and geometric characteristics. We demonstrate the versatility of the process through the creation of planar, insect-like wings with biomimetic venation patterns that approximate the mechanical properties of their natural counterparts under static loads. This process will provide a platform for studies investigating the effects of wing morphology on flight dynamics, which may lead to the design of highly maneuverable and efficient MAVs and insight into the functional morphology of natural

wings." (Authors) The paper includes references to dragonfly wings.] Address: Wood, R.J., School of Engineering & Applied Sciences, Harvard Univ., Cambridge, MA 02138, USA. E-mail: rjwood@seas.harvard.edu

8442. Sharma, R.C.; Arambam, R.; Sharma, R. (2009): Surveying macroinvertebrate diversity in the Tons river, Doon Valley, India. *Environmentalist* 29: 241-254. (in English) ["A survey of macro-invertebrates and their monthly variations occupying the Tons river in Doon Valley was conducted from August 2003 – July 2004. Macroinvertebrate collections and water samples were taken from three sampling stations every month during the period of study. All the hydrological attributes were measured monthly for 1 year. The present study showed that the water velocity, hydromedian depth, turbidity and dissolved oxygen and nature and size of the bottom substrates do play a major role in determining the macroinvertebrate diversity of Tons river. The ecological relevance of the measured hydrological attributes was investigated by comparing their degree of correlation with invertebrate density and diversity. The Shannon–Wiener index (H0) of macroinvertebrates was found to be highest (3.60) during spring season (February and March) and lowest (2.59) during monsoon season (July and August). The high values of diversity index of macro-invertebrates at all the three sampling sites indicate diverse macroinvertebrate communities in the Tons river in Doon Valley, India." (Authors) The following taxa are listed in table 2: Agrion, Ceriagrion cerinorubellum, Ischnura, and Ophiogomphus.] Address: Sharma, R.C., Department of Environmental Sciences, H.N.B. 8444. Slos, S.; De Meester, L.; Stoks, R. (2009): Food level and sex shape predator-induced physiological stress: immune defence and antioxidant defence. *Oecologia* 161: 461-467. (in English) ["Despite the potential impact on prey fitness and predator–prey interactions, most studies of predation risk ignore physiological responses and their dependence upon food level and sex. Therefore, we reared male and female larvae of the damselfly *Lestes viridis* under predator stress (dragonfly larvae) at high and low food levels, and sub-

sequently scored for important variables of insect immune defence (i.e. phenoloxidase) and antioxidant defence [i.e. superoxide dismutase, and catalase (CAT)]. Under predation risk, larvae did not decrease growth rate or immune defence, and only slightly reduced food intake in the high food treatment, probably because of time stress, i.e. little time available to complete the larval development. However, larvae facing predator stress did show an upregulation of antioxidant enzymes. This upregulation was dependent upon food level for CAT and both food level and sex for SOD, consistent with energetic constraints and sex differences in the link between longevity and adult fitness. Our results illustrate that predator stress can influence life history, behavioural and physiological responses differentially and in a context-dependent way. This implies that non-consumptive physiological effects of predators on their prey show independent yet similar complexities in behavioural and life history response variables. In general, our results advocate that mechanistic studies on predator–prey interactions may benefit from including physiological variables." 8446. Song, H.; Bucheli, S.R. (2009): Comparison of phylogenetic signal between male genitalia and non-genital characters in insect systematics. *Cladistics* 25: 1-13. (in English) ["It is generally accepted that male genitalia evolve more rapidly and divergently relative to non-genital traits due to sexual selection, but there is little quantitative comparison of the pattern of evolution between these character sets. Moreover, despite the fact that genitalia are still among the most widely used characters in insect systematics, there is an idea that the rate of evolution is too rapid for genital characters to be useful in forming clades. Based on standard measures of fit used in cladistic analyses, we compare levels of homoplasy and synapomorphy between genital and non-genital characters of published data sets and demonstrate that phylogenetic signal between these two character sets is statistically similar. This pattern is found consistently across different insect orders (- the genus *Enallagma* represents the Odonata -) at different taxonomic hierarchical levels. We argue that the fact that male genitalia are under sexual selection and thus diverge rapidly does not necessarily equate with the lack of phylogenetic signal, because characters that evolve by descent with modification make appropriate characters for a phylogenetic analysis, regardless of the rate of evolution. We conclude that male genitalia are a composite character consisting of different components diverging separately, which make them ideal characters for phylogenetic analyses, providing information for resolving varying levels of hierarchy." 8447. Spaccesi, F.; Rodrigues Capitulo, A. (2009): Benthic invertebrate assemblage in Samborombón River (Argentina, S. America), a brackish plain river. *Aquatic Ecology* 43(4): 1011-1022. (in English) ["The

spatial and temporal differences in the structure and composition of benthic invertebrates were studied at three sites of the Samborombón River, which is an important tributary of the Río de la Plata Estuary (Argentina), having a low slope and brackish drainage. Biological samples were taken during each season. Physico-chemical variables were measured to determine their association in the benthic fauna distribution. Site 1, in the headstream, was characterized by freshwater Pampean organisms; site 2 showed the highest density, taxa diversity, and richness; brackish species, e.g., *Laonereis culveri*, were found here. Site 3, close to the Samborombón Bay, was characterized by an unstable taxonomic composition that is strongly influenced by the estuary. The lowest density and taxonomic diversity of organisms were registered and distinguished by estuarine species. The multivariate method (redundancy analysis) showed the benthic groups having an important spatial variability, superimposed on the temporal variability, associated with the salinity gradient of the river." 8449. Stavenga, D.G. (2009): 15. Surface colours of insects: Wings and eyes. In: Gorb, S.N. (Ed): *Functional surfaces in biology. Little structures with big effects. Volume 1.* Verlag Springer Netherlands. ISBN 978-1-4020-6696-2 (Print): 285-306. (in English) [On pages 288-289 Odonata are treated: "14.3 Damselfly Wing colours: The wings of damselflies are thin chitinous structures with mechanically strong veins, bordering membranous cells. Damselfly wings are usually rather colourless, although often adorned with some black spots. A few species have colourful wings, however A notable example is the damselfly *Neurobasis chinensis*, where the membranous structure in the cells of the hindwings feature beautiful multilayers, causing blue-green iridescent wings (Vukusic et al.. 2004). Remarkably, the mature males of another Asian damselfly, *Calopteryx japonica*, also display iridescent wings, but here the multilayers are exclusively in the wing veins. They provide the wings with a blue-green sheen (Fig. 14.3). Measurements of the reflectance of immature and mature males and females show that the reflectance is generally rather low (Fig. 14.4a-d), but the mature male wings have a noticeable reflectance peak in the blue (Fig. 14.4d). The wing transmittance varies strongly with age and sex. The transmittance spectra of the wings of immature and mature females indicate that the wings contain some melanin pigment (Fig. 14.4e, 0, so that the wings have a rather inconspicuous, brownish colouration. The wing transmittance of the immature males is much lower than that of the females (Fig. 14.4g), due to a higher concentration of melanin, and this concentration increases sharply with age (Fig. 14.4h). The deposition of melanin in the wing cells and the vein multilayers causes a dark background upon which the iridescence of the mature males, although not very intense, still clearly stands out. Behavioral observations show that the resulting striking blue colour of the mature

males plays an important role in the sexual recognition and discrimination of immature and mature animals (Hariyuma et al.. 2005)." 8454. Suhling, F.; Martens, A.; Leipelt, K.-G.; Schütte, K.; Hoppe-Dominik B. (2009): Libellen Braunschweigs – Verbreitungsmuster und Bestandstrends der Libellenfauna einer Großstadt (Odonata). *Braunschweiger Naturkundliche Schriften* 8(2): 449-476. (in German, with English summary) ["In the period from 1980 to 2009, 51 odonate species were recorded in the area of Braunschweig, Lower Saxony, Germany. With a data base of 4405 records from 180 localities and a relatively continuous field work in that period, distribution patterns as well as long-term trends in the occurrence of species were analysed. For several species distinct trends of decline or increase could be detected and related to local habitat variation and general population trends. 30 of the recorded species were categorised as more or less frequent, 13 as rare and eight species were only recorded as single specimens. *Sympetrum pedemontanum*, *Coenagrion pulchellum*, *Ischnura pumilio* and especially *Sympetrum danae* showed a decline, whereas *Sympecma fusca*, *Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Orthetrum brunneum* and *O. coerulescens* became more frequent during that period. The diversity of the dragonfly fauna of Braunschweig can be explained by the presence of pond systems in the urban periphery and by the presence of two rivers and their floodplain remnants: both habitat types were improved by restauration and conservation measures, i.e. construction of small ponds and sympathetic river management, respectively." (2009): Macroarthropod species richness and conservation priorities in *Stratiotes aloides* (L.) lakes. *Journal of Insect Conservation* 13(4): 413-419. (in English) ["Species with narrow ranges and specialised traits are most at risk, and the extinction wave is further enhanced by coextinctions. We studied the conservation value and indicator potential of *Stratiotes aloides*, an aquatic macrophyte that has declined considerably in Europe. Our purpose was to determine whether *S. aloides* could be used as an indicator of a valuable habitat in terms of macroarthropod diversity and species richness. The potential occurrence of an internationally endangered *Stratiotes*-habitat specialist, the dragonfly *Aeshna viridis*, can increase the conservation value of plant colonies. *S. aloides* beds harboured diverse macroarthropod fauna often containing species of conservation concern, including *A. viridis*. *Stratiotes* is a potential indicator of a valuable habitat, and its indicator value is enhanced by the easy identification of the species. However, its use as an indicator of a defined macroarthropod community is limited because no particular community type is connected to it. We suggest that protecting *Stratiotes* simultaneously conserves valuable arthropod fauna, including *A. viridis*." 8456. Swillen, I.; De Block, M.; Stokks, R. (2009): Morphological and physiological sexual selection targets in a territorial damselfly. *Ecological Entomology* 34(6): 677-683. (in English) ["1. Several morphological and physiological traits may shape fitness through the same performance measure. In such cases, differentiating between a scenario of many-to-one mapping, where phenotypic traits independently shape fitness leading to functional redundancy, and a scenario where traits strongly covary among each other and fitness, is needed. 2. A multivariate approach was used, including morphological and physiological traits related to flight ability, a crucial performance measure in flying insects, to identify independent correlates of short-term mating success (mated versus unmated males) in the territorial damselfly *Lestes viridis*. 3. Males with higher flight muscle mass, higher relative thorax mass, and more symmetrical hindwings, all traits presumably linked to manoeuvrability, were more likely to be mated. Unexpectedly, although relative thorax mass is often used as a proxy for flight muscle mass, both traits were selected for independently. Mated males had a higher thorax fat content than unmated males, possibly because of enhanced flight endurance. 4. The finding of several independent targets of sexual selection linked to flight ability is consistent with a scenario of many-to-one mapping between phenotype and performance. Identifying such a scenario is important, because it may clarify situations where animals may show suboptimal values for some phenotypic traits shaping a performance measure, while still having high performance and fitness. We argue in the discussion that the functional approach of sexual selection provides a potent tool for examining unresolved issues in both sexual selection theory, as well as life-history theory." 8457. Takahashi, Y.; Watanabe, M. (2009): Diurnal changes and frequency dependence in male mating preference for female morphs in the damselfly *Ischnura senegalensis* (Rambur) (Odonata: Coenagrionidae). *Entomological Science* 12(3): 219-226. (in English) ["*I. senegalensis* females exhibit colour dimorphism, consisting of an andromorph and a gynomorph, which might be maintained under a frequency-dependent process of mating harassment by mate-searching males. Males change their mating preference for female morph depending on prior copulation experience. Binary choice experiments between two female morphs were carried out in four local populations in the early morning (07.00–09.00 hours) and the afternoon (12.00–14.00 hours), times which mark the onset and the end of diurnal mating activity, respectively. According to the line census along the water's edge, the proportion of andromorphs in the female population varied from 21 to 67% throughout the survey period for four local populations. Males showed non-biased preference for female morphs in the early morning in each local population, while they chose the common morph in the afternoon. Male mating preference for female morphs was positively correlated to the proportion of female morphs in the population. If the selective mating attacks on the common female morphs inhibit their foraging and/or oviposition behaviour, frequency-dependent male mating attacks might provide a selective force for maintaining the female colour dimorphism in *I. senegalensis*." 8461. Teuscher, M.; Brändle, M.; Traxel, V.; Brandl, R. (2009): Allometry between leg and body length of in-

sects: lack of support for the size-grain hypothesis. *Ecological Entomology* 34(6): 718-724. (in English) ["The size-grain hypothesis (Kaspari & Weiser, 1999) states that (1) as organisms decrease in size, they perceive their environment as being more rugose; (2) long legs allow organisms to step over obstacles but hinder them from entering small gaps; and (3) as the size of an organism decreases, the benefits of long legs begin to be outweighed by the costs of construction. Natural selection should therefore favour proportionally longer legs in larger organisms, thereby leading to a positive allometry between leg and body length (scaling exponent $b > 1$). Here we compare the scaling exponent of leg-to-body length relationships among insects that walk, walk and fly, and predominantly fly. We measured the lengths of the hind tibia, hind femur, and body length of each species. The taxa varied considerably in the scaling exponent b . In seven out of ten groups (Formicidae, Isoptera, Carabidae, Pentatomidae, Apidae, Lepidoptera, Odonata adult), b was significantly greater than one. However, there was no gradual decrease in b from walking to walking/flying to flying insects. The results of the present study provide no support for the size-grain hypothesis. We propose that leg length is not only affected by the rugosity of the environment, but also by (1) functional adaptations, (2) phylogeny, (3) lifestyle, (4) the type of insect development (hemimetabolism or holometabolism), and (5) constraints of gas exchange." (2009): Wetland creation in agricultural landscapes: Biodiversity benefits on local and regional scales. *Biological Conservation* 142: 964-973. (in English) ["Wetland creation aiming at a simultaneous increase in nutrient retention and species diversity in agricultural landscapes has recently become applied as a catchment-scale compensation measure for past wetland losses. Here, we evaluate if, and to what extent, dual-purpose wetlands benefit local and regional diversity of agricultural landscapes. We analysed composition and a , b , and c diversity of aquatic macroinvertebrate assemblages among dual-purpose wetlands in an agricultural region in southwest Sweden in relation to local (water quality, wetland morphology, succession stage, proximity to other aquatic habitats) and landscape parameters (regional connectivity, wetland density). Diversity of mature agricultural ponds was used as a standard to evaluate the value of dual-purpose wetlands. Dual-purpose wetlands sustained a , b , and c diversity similar to that of natural lentic water bodies in agricultural landscapes in the region and elsewhere. Over 80% of the overall species richness was attributed to b diversity, and each created wetland contributed to overall species accumulation. Ecosystem parameters explained 19% of the compositional variation among assemblages, but were only marginally related to diversity. Wetland density promoted a and c diversity, while spatial heterogeneity (b) remained equally high, independent of wetland density. Our results indicate that catchment-scale wetland creation for simultaneous retention and diversity purposes benefits the biodiversity of agricultural landscapes, particularly if the density of aquatic habitats is increased by at least 30%." (Authors) Odonata belong to the most diverse insect orders in man-made water bodies.] Address: Sah-

8463. Ting, J.T.; Bots, J.; Pérez Jvostov, F.; van Gossum, H.; Sherratt, T.N. (2009): Effects of extreme variation in female morph frequencies on the mating behaviour of male damselflies. *Behavioral Ecology and Sociobiology* 64(2): 225-236. (in English) ["Female-limited polymorphism is often attributed to selection to avoid excessive male mating attempts. It is encountered in various taxonomic groups, but is particularly common in damselflies, where one female morph (andromorph) typically resembles the conspecific male in colour pattern, while the other(s) (gynomorph(s)) do not. Two sets of theories have been proposed to explain the phenomenon in damselflies, which can be classified as the learned mate recognition (LMR) and male mimicry (MM) hypotheses. To test predictions of these hypotheses, we evaluated the rate of male sexual response towards female morphs and conspecific males in *Nehalennia irene*. The LMR hypothesis predicts that males should respond sexually to andromorphs at greater rates in populations containing a higher relative frequency of andromorphs. The MM hypothesis predicts that males respond more often sexually to both andromorphs and males as the ratio of andromorphs to males increases. While LMR predicts that the rate of mating attempts towards gynomorphs should vary, the MM predicts that it should be relatively fixed. On experimentally presenting live specimens to focal males in five different populations with extreme variation in female morph frequencies, we observed that as the andromorph frequency and ratio of andromorphs to males increased, the proportion of male mating attempts increased on both andromorphs and males, whereas it decreased on gynomorphs. While the simplest form of the MM hypothesis is rejected, the results support specific predictions of both hypotheses and suggest that future studies should not treat these hypotheses as mutually exclusive." 8464. Toivanen, T.; Rantala, M.J.; Suhonen, J. (2009): Influence of alternative mating tactics on predation risk in the damselfly *Calopteryx virgo*. *Can. Jour. Zool.* 87: 684-688. (in English, with French summary) ["Alternative mating tactics are a widespread feature in insects. A typical form of alternative mating behaviour is being a sneaker in the vicinity of a territorial male. Such nonterritorial males have lower mating success, but they may benefit from lower energetic costs and decreased predation risk. In this study, we examined whether nonterritorial male damselflies *C. virgo* are subject to lower predation risk than territorial males. To distinguish predation from other sources of mortality, we used models. The experiment consisted of dried male damselflies settled into the typical perching positions of territorial and nonterritorial males. Also the spatiotemporal patterns of predation risk were studied. The survival of nonterritorial male models was consistently higher than that of territorial male models, which can be attributed to different predation risk. Survival of the models was lower in the presence of avian predators and in large populations. Survival rates were affected by habitat type but did not change during the season. We conclude that nonterritorial male damselflies are less vulnerable to predation and that there may be a

trade-off which could potentially make the fitness of sneakers equal to that of territorial males." (Author)] Address: Suhonen, J., Secti. Ecology, Dept Biology, Univ. Turku, 20014 Turku, Finland. E-mail: juksuh@utu.fi

Ein Streiflicht zur Berücksichtigung der relevanten Rechtsnormen in der Praxis. *Naturschutz und Landschaftsplanung* 41(3): 78-82. (in German, with English summary) ["Species Protection and Environmental Liability in Watercourse Maintenance – Consideration of relevant legal norms'. Measures in the context of watercourse maintenance may seriously impair protected species. Some examples are given, including strictly protected species of the European Habitats Directive (92/43/EEC). It is necessary to pay attention to the regulations of the German Federal Nature Conservation Act (BNatSchG) on species protection as well as

to those of the Environmental Damage Act (USchadG) on environmental liability. Currently this seems to be insufficiently known or is not taken seriously enough. Concerning measures planned in the framework of watercourse maintenance firstly at least a rough estimation of their effects is necessary. If highly endangered species could be affected a more detailed assessment should be done. Both the estimation and the assessment aim to clarify (a) which particularly sensitive and protected species are affected, (b) which possibilities for prevention or reduction of negative impacts respectively a careful management are given, (c) if nevertheless legal prohibitions are touched, (d) if a legal exemption is necessary and even possible under the specific circumstances (reasons for the planned measures, lack of satisfactory alternative solutions, conservation status of the populations), (e) if and which additional measures could be necessary in this context." 8470. Tun-Lin, W.; Lenhart, A.; Nam, V.S.; Rebolgar-Tellez, E.; Morrison, A.C.; Barbazan, P.; Cote, M.; Midega, J.; Sanchez, F.; Manrique-Saide, P.; Kroeger, A.; Nathan, M.B.; Meheus, F.; Petzold, M. (2009): Reducing costs and operational constraints of dengue vector control by targeting productive breeding places: a multi-country non-inferiority cluster randomized trial. *Tropical Medicine and International Health* 14(9): 1143-1153. (in English) ["Objectives: To test the non-inferiority hypothesis that a vector control approach targeting only the most productive water container types gives the same or greater reduction of the vector population as a non-targeted approach in different ecological settings and to analyse whether the targeted intervention is less costly. Methods: Cluster randomized trial in eight study sites (Venezuela, Mexico, Peru, Kenya, Thailand, Myanmar, Vietnam, Philippines), with each study area divided into 18-20 clusters (sectors or neighbourhoods) of approximately 50-100 households each. Using a baseline pupal-demographic survey, the most productive container types were identified which produced $\geq 55\%$ of all *Ae. aegypti* pupae. Clusters were then paired based on similar pupae per person indices. One cluster from each pair was randomly allocated to receive the targeted vector control intervention; the other received the 'blanket' (nontargeted) intervention attempting to reach all water holding containers. Results: The pupal-demographic baseline survey showed a large variation of productive container types across all study sites. In four sites the vector control interventions in both study arms were insecticidal and in the other four sites, non-insecticidal (environmental management and/or biological control methods). Both approaches were associated with a reduction of outcome indicators in the targeted and non-targeted intervention arm of the six study sites where the follow up study was conducted (PPI, Pupae per Person Index and BI, Breteau Index). Targeted interventions were as effective as non-targeted ones in terms of PPI. The direct costs per house reached were lower in targeted intervention clusters than in non-targeted intervention clusters with only one exception, where the targeted intervention was delivered through staff-intensive social mobilization. Conclusions: Targeting only the most productive water container types (roughly half of all water holding container types) was

as effective in lowering entomological indices as targeting all water holding containers at lower implementation costs. Further research is required to establish the most efficacious method or combination of methods for targeted dengue vector interventions." (Authors) In Myanmar, the study included dragonflies to reduce *Ae. aegypti*, and is in combination with sweeps and fishes as predators of *Aedes* the most effective method to reduce *Ae. aegypti* as well as community participation in controlling and maintaining water containers.] Address: Tun-Lin, W., Dept Medical Research, Yangon, Myanmar

8472. Tynkkynen, K.; Raatikainen, K.J.; Häkklä, M.; Haukilehto, E.; Kotiaho, J.S. (2009): Alternative reproductive tactics and the propensity of hybridization. *J. evol. biol.* 22: 2512-2518. (in English) ["One explanation for hybridization between species is the fitness benefits it occasionally confers to the hybridizing individuals. This explanation is possible in species that have evolved alternative male reproductive tactics: individuals with inferior tactics might be more prone to hybridization provided it increases their reproductive success and fitness. Here we experimentally tested whether the propensity of hybridization in the wild depends on male reproductive tactic in *Calopteryx splendens* damselflies. Counter to our expectation, it was males adopting the superior reproductive tactic (territoriality) that had greatest propensity to hybridize than males adopting the inferior tactics (sneakers and floaters). Moreover, among the territorial males, the most ornamented males had greatest propensity to hybridize whereas the pattern was reversed in the sneaker males. Our results suggest that there is fluctuating selection on male mate discrimination against heterospecific females depending on both ornament size and the male's reproductive tactic." 8473. Tyrrell, M.; Emary, C.; Piper, M. (2009): The Beautiful Demoiselle *Calopteryx virgo* (Linnaeus) in Northamptonshire: eastwards expansion & habitats. *J. Br. Dragonfly Soc.* 25(2): 100-106. (in English) ["Northamptonshire is at the eastern limit of the range of *C. virgo* in the Midlands of England, making this population of regional importance. *C. virgo* is included as a Key County species according to key sites criteria (French & Smallshire, 2008). Historically, *C. virgo* in Northamptonshire has been limited to two river systems, the Rivers Tove and Cherwell, with its range showing few signs of expanding. However, since 2003, it has undergone a significant range expansion and is now recorded on six river systems, adding the Great Ouse near Brackley, the Leam, the Avon and the Nene to the list. While increased recording in the County over this time period will have undoubtedly contributed new records, this is mainly infilling, and a genuine expansion has been noted into new previously well recorded areas. This paper discusses this expansion using a series of dated distribution maps, and reviews the river habitats of all

river systems with possible expansion corridors discussed." (Authors) Address: Tyrrell, M., 8 Warwick Close, Raunds, Northamptonshire, NN9 6JH, UK

8474. Uzenbaev, S.D.; Lyabzina, S.N. (2009): An experimental study of the effects of spider venom on animals. *Entomological Review* 89(4): 479-486. (in English) ["The effects of venom of spiders from the families Pisauridae, Argyronetidae, and Araneidae on different animals (worms, molluscs, arthropods, fishes, and mammals) were studied. The animals of different classes varied in their sensitivity to spider venom. The animals that can be a potential prey were the most sensitive. The venom of spider females was more efficient than that of males. The spiders were found to be able to kill five victims in sequence; the most effective action of venom was on the first two ones. The venom regenerates in 1.5–2 hours." (Authors) In case of the two odonata taxa studied, the results are as follows: Sensitivity of *Lestes sponsa* larvae to venom of terrestrial *Araneus bituberculatus* (7.4 h before death); *A. diadematus* (1.5 h before death); Sensitivity of *Lestes sponsa* larvae to venom of aquatic *Argyroneta aquatica* (12.4 h \pm 2.3 before death); *Dolomedes fimbriatus* (14.3 h \pm 4.2 before death); Sensitivity of *Aeshna juncea* larvae to venom of aquatic *Argyroneta aquatica* (17.7 h \pm 5.6 before death); *Dolomedes fimbriatus* (44.8 h \pm 4.2 before death)] Address: Uzenbaev, S.D., Petrozavodsk State University, Petrozavodsk, 185910 Russia. 8476. Veber, T.; Kotta, J.; Lauringson, V.; Kotta, I. (2009): Influence of the local abiotic environment, weather and regional nutrient loading on macrobenthic invertebrate feeding groups in a shallow brackish water ecosystem. *Oceanology* 51(4): 541-559. (in English) ["This study evaluated the extent to which depth, sediment type, exposure to waves and coastal slope inclination modulate the relationships between regional nutrient loading, weather patterns and the species composition and dominance structure of macrobenthic invertebrate feeding groups in a brackish water ecosystem of the Baltic Sea. Irrespective of feeding function, the species composition and dominance structure of benthic invertebrate communities were determined by local abiotic variables such as exposure, depth and sediment type. Regional weather variables (average southerly winds, salinity, water temperature, ice conditions) either separately or interactively contributed to the variability of benthic invertebrates. Nutrient loading had significant effects on benthic invertebrates only in interactions with local abiotic or regional weather variables. Herbivores, deposit feeders and suspension feeders exhibited a stronger response to the studied environmental variables than carnivores. All this suggests that (1) the dynamic coastal habitats studied in this work are not very sensitive to shifts in nutrient loading and (2) local abiotic conditions and weather patterns largely define the ob-

served biotic patterns. We believe that the benthic invertebrate time series will only be a better reflection of the nutrient loading signal if more years covering extreme events are included." (2009): Can comprehensive background knowledge be incorporated into substitution models to improve phylogenetic analyses? A case study on major arthropod relationships. *BMC Evolutionary Biology* 2009, 9:119: 19 pp. (in English) ["Background: Whenever different data sets arrive at conflicting phylogenetic hypotheses, only testable causal explanations of sources of errors in at least one of the data sets allow us to critically choose among the conflicting hypotheses of relationships. The large (28S) and small (18S) subunit rRNAs are among the most popular markers for studies of deep phylogenies. However, some nodes supported by this data are suspected of being artifacts caused by peculiarities of the evolution of these molecules. Arthropod phylogeny is an especially controversial subject dotted with conflicting hypotheses which are dependent on data set and method of reconstruction. We assume that phylogenetic analyses based on these genes can be improved further i) by enlarging the taxon sample and ii) employing more realistic models of sequence evolution incorporating nonstationary substitution processes and iii) considering covariation and pairing of sites in rRNA-genes.

Results: We analyzed a large set of arthropod sequences, applied new tools for quality control of data prior to tree reconstruction, and increased the biological realism of substitution models. Although the split-decomposition network indicated a high noise content in the data set, our measures were able to both improve the analyses and give causal explanations for some incongruities mentioned from analyses of rRNA sequences. However, misleading effects did not completely disappear." (Authors)] Address: Björn M von Reumont, Molecular Lab, Zoologisches Forschungsmuseum A. Koenig, Bonn, Germany. E-mail: bmv@arcor.de

8485. Walker, I. (2009): Emergence of aquatic insects and spider abundance in the Balbina Reservoir (Presidente Figueiredo, Amazonas, Brazil) during the phase of declining eutrophication. *Acta Limnol. Bras.* 21(2): 199-207. (in English, with Portuguese summary) ["Aim: Between April 1991 and December 1994 the patterns of insect emergence were assessed by a total of 422 emergence traps that were set for 24 hours periods on the water surface of the riparian zones of two islands in the Balbina Lake; Methods: These collections were accompanied by observations of spider densities along the shrubby forest margins of the islands. Furthermore, to characterize the lake ecosystem, casual observations on Odonata and spider abundance within the inundated forest with dead, emergent trees were recorded, and some of the species were identified; Results: Insect emergence did not decline during the 4 years of collection, and the Chironomidae and Chaoboridae were dominant throughout, adding up to 70-90% of the catches. There is some indication of seasonal cycles, and the specific pattern of Ephemeroptera emergence is demonstrated in more detail; Conclusions: It appears that production of aquatic insects in the Balbina Reservoir, while still in its eutrophic phase, is lower than along the Tarumã- Mirim, an undisturbed Central Amazonian forest stream of nutrient-poor, acid water. [...] A total of 37 counts made during these excursions resulted in a mean estimate of 40-55 adult Odonata/ha of inundated dead forest, and there was no consistent trend of change of abundance during the seven- year period of observation. On a single occasion no Odonata were seen (20 July/94, 8:30 hours, Ilha das Aranhãs), and it may be that this is due to the relatively early hour of the day, because the highest number recorded from this area was 306/ha, between 14:00-16:00 hours (28 November/95). This interpretation is favored by the observation that on May 2nd 1993, 37% of emergent tree tops were occupied by Odonata at 9:00 in the morning, as against 68% at midday on the same day in the same place (near the Ilha das Aranhãs). Excessive densities

were recorded in July/97 when approaching the Serra do Chocador: 5-15 individuals per 100 m², which amounts to 500-1500/ha. Extension of the 100 m² values to hectares, however, may not be realistic, because naiads may accumulate locally for emergence; for example, on March/94, 41 Odonata-exuviae were counted within 1 m² of aquatic macrophytes that floated between the dead trees near the Serra do Chocador. Although adult Odonata were not specified when motoring to the research sites, the abundance of *Brachymesia herbida* in the emergent dead forest of the reservoir between the dam and the research islands was noted during the whole period of the project." (Author) In tab. 4 the following taxa are listed: *B. herbida*, *Erythemis hematogaster*, *Erythemis vesiculosa*, *Orthemis ferruginea* (?), *Perithemis lais*, *Ischnura fluviatilis*, and *Protoneura* sp.] Address: Walker, I., Coordenação de Pesquisa em Ecologia – CPEC, Instituto Nacional de Pesquisa da Amazônia – INPA, Av. André Araújo, 2936, Aleixo, CP 478, CEP 69011-970, Manaus, AM, Brazil. E-mail: iwalker@inpa.gov.br

8486. Walker, I. (2009): Omnivory and resource - sharing in nutrient - deficient Rio Negro waters: Stabilization of biodiversity? *Acta Amazonica* 39(3): 617-626. (in English, with Portuguese summary) [*Ischnura* spec. and *Aeschnosoma* spec. "are essentially insectivores, [...] any other prey type is sporadic. The only exception is oligochaete capture by *Aeschnosoma*. The Anisoptera occupy niches within the litter layers, and thus, have access to the small oligochaetes that colonize the surface of litter leaves, while the Zygoptera usually occupy surfaces near the open water, where oligochaetes are less frequent. The prevalent prey of both Odonata species are Ephemeroptera and Chironomidae, presumably because these are the most frequent and ubiquitous insect larvae in these benthic habitats (Walker 1994, 1998). Algae ingestion is questionable, because small algae may accidentally enter the ventricle in the course of prey capture. Rather surprising are fish vertebrae within an Odonata ventricle, yet, the smallest fish species of the litter habitat is a tiny gobby *Microphylipnus*, with a standard length of 1,2cm. This fish, therefore, is within the range of the normal prey of larger anisopteran larvae, furthermore, there are the larvae and juveniles of other small litter-colonizing fish species, which may serve as prey. On the whole it appears that both Odonata species, [...] accept any animal prey within the range of their perception and size that allows for successful capture and ingestion. Thus, even if algae- feeding is excluded, they are omnivores in the sense that they feed on various trophic levels, considering that larger insect larvae (Ephemeroptera, Trichoptera) feed on algae, microcrustacea and chironomids (Walker 1987)." (Author)] Address: Walker, Ilse, Instituto Nacional de Pesquisas da Amazônia (INPA), Coordenação de Pesquisas em Ecologia (CPEC), Caixa Postal 478, 69011-970, Manaus (AM), Brazil. 8487. Ware, J.L.; Simaika, J.P.; Samways, M.J. (2009): Biogeography and divergence time estimation of the relict Cape dragonfly genus *Syncordulia*: global significance and implications for conservation. *Zootaxa* 2216: 22-36. (in English) ["*Syncordulia* (Libelluloidea) inhabits mostly cool mountainous streams in the Cape Floristic Region of South Africa. It is found at low densities in geographically restricted areas. *Syncordulia* is endemic to South Africa and, until recently, only two spe-

cies were known, *S. venator* and *S. gracilis*, both considered Vulnerable by the World Conservation Union (IUCN). Two new species, *S. serendipator* and *S. legator*, were described from previously unrecognized museum specimens and new field collections. Here we corroborate the validity of these two new species using multiple genes and propose intergeneric relationships within *Syncordulia*. Molecular data from two independent gene fragments (nuclear 28S and ribosomal and cytochrome oxidase subunit I mitochondrial data) were sequenced and/or downloaded from GenBank for 7 libelluloid families, including 12 *Syncordulia* specimens (2 *Syncordulia gracilis*, 4 *S. serendipator*, 2 *S. legator* and 4 *S. venator*). The lower libelluloid group GSI (sensu Ware et al. 2007), a diverse group of non-corduliine taxa, is strongly supported as monophyletic. *Syncordulia* is well supported by both methods of phylogenetic analyses as a monophyletic group deeply nested within the GSI clade. A DIVA biogeographical analysis suggests that the ancestor to the genus *Syncordulia* may have arisen consequent to the break-up of Gondwana (>120 Mya). Divergence time estimates suggest that *Syncordulia* diverged well after the breakup of Gondwana, approximately 60 million years ago (Mya), which coincides with the divergence of several Cape fynbos taxa, between 86 – 60 Mya. DIVA analyses suggest that the present distributions of *Syncordulia* may be the result of dispersal events. We relate these phylogenetic data to the historical biogeography of the genus and to the importance of conservation action." 8488. Watts, P.C. (2009): Characteristics of microsatellite loci in Odonata. *International Journal of Odonatology* 12(2): 275-286. (in English) ["Microsatellite loci have become the genetic markers of choice for population-level molecular ecological studies. However, microsatellite loci had been isolated for comparatively few species of odonate until the past five years. This review summarises the main characteristics – expected heterozygosity and microsatellite length – of 116 microsatellite loci that have been isolated from the genomes of 11 odonate species and discusses potential problems associated with using microsatellite loci to study odonate biology. It is clear that odonates are characterised by relatively short microsatellites, typically less than 10 core motifs, that demonstrate a high level of heterozygote deficits. Some reasons why some odonate species have particularly low levels of gene diversity are discussed also." (Author)] Address: Watts, P.C., School of Biol. Sc., Biosciences Building, Univ. Liverpool, Crown Str., L69 7ZB, Liverpool, UK. E-mail: phill@liv.ac.uk

8490. Wichard, W.; Gröhn, C.; Sereuszus, F. (2009): Aquatic Insects in Baltic Amber - Wasserinsekten im Baltischen Bernstein. Verlag Kessel. ISBN: 978-3-941300-10-1: 336 pp. (in Bilingual text (English/German)) ["At first sight the embedment of aquatic insects in Baltic amber seems to be contradictory, as the insects live in water and amber originated from resin of

extinct trees that grew in a Fennoscandian montane forest approximately 40–50 million years ago. About 25% of all animals found in amber are aquatic insects. The larvae of these amphibious forms lived in water whereas adults were frequently terrestrial and capable of flying. The Tertiary “amber forest” apparently contained a great amount of lentic waters, flood plains and flowing waters. The resin was washed out of dead wood and streams and rivers transported it to the sea where it became fossilized into amber. Without water, the genesis of amber would be impossible. The high number of aquatic insects in amber is connected with the process of its fossilization. As if in a complex “paleontological jigsaw puzzle” amber inclusions are combined together so that the whole mosaic of the nature of 40–50 million years ago can be reconstructed.” (Authors) Odonata are treated on pages 19-29.] Address: www.verlagkessel.de.

8491. Wildermuth, H.; Küry, D. (2009): Libellen schützen, Libellen fördern. Leitfaden für die Naturschutzpraxis. Beiträge zum Naturschutz in der Schweiz 31: 88 pp. (in German; French) [This is a manual on protection and conservation of Odonata including the management of their habitats in Switzerland.] Address: Schweizerische Arbeitsgemeinschaft Libellenschutz, SAGLS, Life Sciences AG, Greifengasse 7, CH-4058 Basel, Switzerland

8492. Willigalla, C.; Fartmann, T. (2009): Die Libellenfauna der Regenrückhaltebecken der Stadt Mainz (Odonata). Libellula 28(3/4): 117-137. (in German, with English summary) [“Between 2006 and 2008, 32 species of Odonata were recorded at twelve rain-storage ponds (RSP) in Mainz. This is 84 % of the total Odonata fauna of the city area of Mainz, which comprises 38 species in total. Twenty-two of the observed species were classified as indigenous. On average, we found between six and nine species per RSP. Therefore, beside park ponds, RSP serve as a second important habitat for dragonflies and damselflies in urban areas. The diversity of Odonata depended on pond size and the position of the ponds in different city zones. In the suburbs more species were found than in the city centre. In damselflies the abundance was negatively correlated with the density of buildings in the surroundings (up to 200 m around the ponds). Where building cover exceeded 40 %, damselfly abundances were very low. The spatial distance between the RSP was the main driver of similarity among Odonata assemblages of the RSP. Due to the warm urban climate in cities RSP generally favour Mediterranean species. However, the macroclimate had a stronger impact on community composition in cities. The Odonata fauna of the RSP of Mainz was very similar to those of the cities of Münster and Osnabrück. The main reason for this seems to be that the majority of species occurring in RSP are widespread and common species that are typical of eutrophic ponds. We assume that in Germany about 35 Odonata species are able to colonize RSP in cities. Enallagma cyathigerum, Erythromma viridulum, Aeshna affinis, A. mixta, Libellula depressa and Orthetrum cancellatum act as regional character species.] Address: Willigalla, C., Am Großen Sand 22, D-55124 Mainz, Germany. 8494. Winkler, C.; Neumann, H.; Drews, A. (2009): Verbreitung und Ökologie von *Coenagrion armatum* am südwestlichen Arealrand in Schleswig-Holstein (Odonata: Coenagrionidae). Libellula 28(1/2): 1-24. (in German, with English summary) [“Distribution and ecology of *C. armatum* on the southwestern fringe of its area in Schleswig-Holstein, Germany — The last systematical surveys of *C. armatum* in Schleswig-Holstein (SH) had been conducted during the 1960s and 1970s. The last population was detected in 1982. In order to record the present distribution of *C. armatum* in SH a countrywide survey was carried out between 24-IV and 5-VI-2008. Based on former records, 137 standing waters in 37 sites were investigated. Imagines of *C. armatum* were found at 18 waters, which were situated in 12 sites. All these sites were located in the northern part of SH. More than ten imagines were detected at eight waters, whereas more than 100 imagines were recorded from a shallow lake and a peat digging hole. Tandems were found at 13 waters and ovipositions at four of these localities. Only one pair was seen in wheel position. *C. armatum* populated mesotrophic waterbodies from 0.01 to 4.7 ha with shallow water zones. Most waters were regarded as perennial. All known occurrences were restricted to moor- and heathland. The soft rush *Juncus effusus* occurred, at least partially, as riparian vegetation on all colonised waters. Stocks of soft rush offered perches and were used by *C. armatum* for hiding and mating. Broken stems of soft rush on the water surface were even used for oviposition. The flying period of *C. armatum* extended at least from 6-V to 30-V-2008.” (Authors)] Address: Winkler, C., Bahnhofstr. 25, 24582 Bordesholm, Germany. E-mail: chr.winkler@email.de

8505. Zhao, Y.; Tong J.; Sun J.; Chen D.; Zhang, J. (2009): Property tests of nanoindentation on membranous wings of dragonflies. *Journal of Agricultural Mechanization Research* 11: 26-29. (in Chinese, with English summary) ["The nano-mechanical behaviour of dragonfly membranous wings was investigated with a nano-indenter. The holding time and the loading rate were selected 20s and 53µN/s by the method of test optimization. In nano-indentation experiment, 6 indentation measurements were done in an area of 0.075mm × 0.01mm and then took the mean value as the nano-mechanical parameter of this position. It was shown that the maximums of the reduced modulus and the hardness of the living dragonfly *Anax parthenope julius* Brauer and *Pantala flavescens* Fabricius are about at position of 0.7L of their wings, where L is the total length of their wings. The maximums of the reduced modulus and the hardness of the dragonfly *Sympetrum striolatum* are at position of 0.5L of its wing, where L is the total length of the wing. The reduced modulus and the hardness of *A. parthenope julius* are maximum on the corresponding parts among the three dragonflies, related to the large somatotype."] (Authors)] Address: Zhao, Y., The College of Mechanical and Power Engineering, Henan Polytechnic University, Jiaozuo 454000, China

8506. Zherikhin, V.V.; Sukacheva, I.D.; Rasnitsyn, A.P. (2009): Arthropods in contemporary and some fossil resins. *Paleontological Journal* 43(9): 987-1005. (in English) ["More than 4800 arthropod inclusions were isolated and identified from resin of various contemporary conifer trees in various parts of northern Eurasia. Their composition is compared with that in representat-

ive collections of Baltic and Rovno ambers (Upper Eocene) and with that in Dominican amber (Lower Miocene). The original composition of inclusions of Dominican amber is reconstructed for the first time using a procedure intended to reduce the effect of human bias. Taphonomical characteristics of resins and their effects on the composition of inclusions are studied. The actual paleontological approach reveals a trend towards a decrease in the relative abundance of arboreal springtails and nematoceran dipterans and an increase in that of the true bugs, beetles, lepidopterans, and hymenopterans (especially ants) between the Eocene and the present. Relative abundances of spiders and mites show no clear trend. The available data on other arthropods are still insufficient for elucidating evolutionary trends. Surprisingly, a small contemporary sample from Taimyr (N. Siberia) was inexplicably more similar to the Eocene amber than to other contemporary resins. No other significant differences in composition of inclusions, compared across different conifer genera or geographic areas, have been revealed. A more detailed comparison between contemporary and fossil hymenopteran and beetle inclusions reveals correlations with both age (= evolutionary change) and geography. The absolute dominance of ants, particularly Formicinae and Myrmicinae, and, among solitary hymenopterans, Ichneumonidae, Braconidae, and Pteromalidae, and a corresponding decline in the abundance of Scelionidae and Dolichoderinae in contemporary resins compared to amber reflect evolutionary changes. In contrast, the overwhelming abundance of Formicinae and consistent occurrence of sawflies in contemporary resins of northern Eurasia appear to be explained by geography. The Eocene assemblages of beetle inclusions are characterized by a wider and more variable set of dominant families, in sharp contrast to contemporary resins, which are uniformly dominated by Curculionidae, Chrysomelidae, and Staphylinidae. Additional analyses are needed to explain this difference." (Authors)] Address: V. V. 8507. Allen, K.A.; Thompson, D.J. (2010): Movement characteristics of the Scarce Blue-tailed Damselfly, *Ischnura pumilio*. *Insect Conservation and Diversity* 3(1): 5-14. (in English) ["1. *I. pumilio*, is threatened in the UK and exists in small, transient colonies. Consequently, little is known about its dispersal characteristics. This study investigates movement in two contrasting habitats with the aim of informing conservation management on a landscape scale. 2. Mark-release-recapture studies were performed at an established colony in the New Forest and a smaller population in the Red River valley in southern England. A total of 2304 individuals was marked. 3. *I. pumilio* was found to be exceptionally sedentary. Mean gross lifetime movement was 56 m and 43% of individuals moved <50 m in their lifetime. Movements over 150 m were very rare. Maximum lifetime movement was 1165 m. As such, *I. pumilio* is the most sedentary odonate studied in the UK to date. 4. Movement was inversely density dependent, which has important conservation implications if individuals attempt to emigrate from small populations be-

cause of low density. The presence of parasitic mites (*Hydryphantes* sp.) significantly increased movement distance. 5. *I. pumilio* had a low dispersal probability compared to other damselflies. As the smallest British odonate, this is in keeping with the relationship between size and dispersal found across taxa. 6. *I. pumilio* has been regarded as a 'wandering opportunist' due to its tendency to appear in locations far from known sites. However, this study suggests that long range movement rarely occurs from prime habitat that is maintained in an early successional stage. This has implications for the conservation of the species in the UK." (Author)] Address: Allen, Katherine, School Biol. Sc., University of Liverpool, Liverpool, UK. E-mail: kaallen@liv.ac.uk

8508. Anderson, C.N.; Grether, G.F. (2010): Inter-specific aggression and character displacement of competitor recognition in *Hetaerina* damselflies. *Proc. R. Soc. B* 277: 549-555. (in English) ["In zones of sympatry between closely related species, species recognition errors in a competitive context can cause character displacement in agonistic signals and competitor recognition functions, just as species recognition errors in a mating context can cause character displacement in mating signals and mate recognition. These two processes are difficult to distinguish because the same traits can serve as both agonistic and mating signals. One solution is to test for sympatric shifts in recognition functions. We studied competitor recognition in *Hetaerina* damselflies by challenging territory holders with live tethered conspecific and heterospecific intruders. Heterospecific intruders elicited less aggression than conspecific intruders in species pairs with dissimilar wing colouration (*H. occisa*/*H. titia*, *H. americana*/*H. titia*) but not in species pairs with similar wing colouration (*H. occisa*/*H. cruentata*, *H. americana*/*H. cruentata*). Natural variation in the area of black wing pigmentation on *H. titia* intruders correlated negatively with heterospecific aggression. To directly examine the role of wing colouration, we blackened the wings of *H. occisa* or *H. americana* intruders and measured responses of conspecific territory holders. This treatment reduced territorial aggression at multiple sites where *H. titia* is present, but not at allopatric sites. These results provide strong evidence for agonistic character displacement." (Authors) The experiments reported here were carried out in June–August 2006, May–July 2007 and April–May 2008 at 10 sites in Texas, USA and Mexico.] Address: Grether, G.F., Dept Ecology & Evolutionary Biol., Univ. 8511. Bots, J.; de Bruyn, L.; Snijkers, T.; van den Branden, B.; van Gossum, H. (2010): Exposure to perfluorooctane sulfonic acid (PFOS) adversely affects the life-cycle of the damselfly *Enallagma cyathigerum*. *Environmental Pollution* 158(3): 901-905. (in English) ["We evaluated whether life-time exposure to PFOS affects egg development, hatching, larval development, survival, metamorphosis and body mass of *Enallagma cyathigerum* (Insecta: Odonata). Eggs and larvae were exposed to five concentrations ranging from 0 to 10 000 µg/L. Our results show reduced egg hatching success, slower larval development, greater larval mortality, and decreased metamorphosis success with increasing PFOS concentration. PFOS had no effect on egg developmental time and hatching or on mass of adults. Eggs were the least sensitive stage (NOEC = 10 000 µg/L). Larval NOEC values were 1000 times smaller (10 µg/L). Successful metamorphosis was the most sensitive response trait studied (NOEC < 10 µg/L). The NOEC value suggests that *E. cyathigerum* is amongst the most sensitive freshwater organisms tested. NOEC for metamorphosis is less than 10-times greater than the ordinary reported environmental concentrations in freshwater, but is more than 200-times smaller than the greatest concentrations measured after accidental releases. Long-term laboratory exposure to perfluorooctane sulfonic acid reduces survival and interferes with metamorphosis of *Enallagma cyathigerum* (Insecta: Odonata)." 8513. Buffagni, A.; Erba, S.; Armanini, D.G. (2010): The lentic-lotic character of Mediterranean rivers and its importance to aquatic invertebrate communities. *Aquatic Sciences* 72(1): 45-60. (in English) ["Hydromorphological features are crucial in structuring habitats for freshwater organisms. The quantification of these variables is often performed through accurate measuring or detailed estimation, but their assessment is not always feasible for river management purposes. Economic and time constraints often lead to difficulty in creating simple summaries of collected data for practical use. The Lentic-lotic River Descriptor (LRD) was developed to identify the character of a river site in terms of local hydraulic conditions. Information about the presence of flow types, channel substrates, in-stream vegetation, organic debris and artificial features is included in its calculation. The main aim of this paper is to investigate whether the lentic-lotic character of a river site, as summarized with the LRD descriptor, is relevant to aquatic invertebrate communities in nearly natural river sites. Invertebrate data were collected with multi-habitat, proportional sampling and hydromorphological information was gained by applying the CARAVAGGIO method (river habitat survey technique) in the field. The dataset was generated from High or Good ecological status river sites located in Mediterranean areas of Italy. Correspondence Analysis was performed to relate the invertebrate community structure to a set of catchment-scale, reach-scale and chemical environmental variables. The results of the multivariate analysis indicate that LRD provides a persuasive explanation of the most important axis of variation in benthic data. This paper also presents the optimal LRD range for a set of invertebrate taxa, accompanied by a short discussion of their potential use in conservation issues." 8514. Davis, J.M.; Rosemond, A.D.; Eggert, S.L.; Cross, W.F.; Wallace, J.B. (2010): Long-term nutrient enrichment decouples predator and prey production. *PNAS* 107(1): 121-126. (in English) ["Increased nutrient mobilization by human activities represents one of the greatest threats to global ecosystems, but its effects on ecosystem productivity can differ depending on food web structure. When this structure facilitates efficient

energy transfers to higher trophic levels, evidence from previous large-scale enrichments suggests that nutrients can stimulate the production of multiple trophic levels. Here we report results from a 5-year continuous nutrient enrichment of a forested stream that increased primary consumer production, but not predator production. Because of strong positive correlations between predator and prey production (evidence of highly efficient trophic transfers) under reference conditions, we originally predicted that nutrient enrichment would stimulate energy flow to higher trophic levels. However, enrichment decoupled this strong positive correlation and produced a nonlinear relationship between predator and prey production. By increasing the dominance of large-bodied predator-resistant prey, nutrient enrichment truncated energy flow to predators and reduced food web efficiency. This unexpected decline in food web efficiency indicates that nutrient enrichment, a ubiquitous threat to aquatic ecosystems, may have unforeseen and unpredictable effects on ecosystem structure and productivity." (Author) The paper includes data on *Cordulegaster* and *Lanthus*.] Address: Davis, J.M., Odum School of Ecology, University of Georgia, Athens, GA 30602, USA. E-mail: jmdavis@isu.edu.

8515. Dumont, H.J.; Vierstraete, A.; Vanfleteren, J.R. (2010): A molecular phylogeny of the Odonata (Insecta). *Systematic Entomology* 35: 6-18. (in English) ["We estimated the phylogeny of the order Odonata, based on sequences of the nuclear ribosomal genes 5.8 S, 18S, and ITS1 and 2. An 18S-only analysis resolved deep relationships well: the order Odonata, as well as suborders Zygoptera and Epiprocta (Anisoptera + Epiophlebia), emerged as monophyletic. Some other deep clades resolved well, but support for more recently diverged clades was generally weak. A second, simultaneous, analysis of the 5.8S and 18S genes with the intergenic spacers ITS1 and 2 resolved some recent branches better, but appeared less reliable for deep clades with, for example, suborder Anisoptera emerging as paraphyletic and Epiophlebia superstes recovered as an Anisopteran, embedded within aeshnoid-like anisopterans and sister to the cordulegastrids. Most existing family levels in the Anisoptera were confirmed as monophyletic clades in both analyses. However, within the corduliids that form a major monophyletic clade with the Libellulidae, several subclades were recovered, of which at least Macromiidae and Oxygastridae are accepted at the family level. In the Zygoptera, the situation is complex. The lestid-like family groups (here called Lestomorpha) emerged as sister taxon to all other zygopterans, with Hemiphlebia sister to all other lestomorphs. Platystictidae formed a second monophylum, subordinated to lestomorphs. At the next level, some traditional clades were confirmed, but the tropical families Megapodagrionidae and Amphipterygidae were recovered as strongly polyphyletic, and tended to nest within the clade Caloptera, rendering it polyphyletic. Platycnemididae were also non-monophyletic, with several representatives of uncertain placement. Coenagrionids were diphyetic. True Platycnemididae and non-American Protoneurids are closely related, but their relationship to the other zygopterans remains obscure and needs more study. New World protoneurids appeared relatively unrelated to old world + Australian protoneurids. Several recent taxonomic changes at the genus level, based on morphology, were confirmed, but other morphology-based taxonomies have misclassified taxa considered currently as Megapodagrionidae, Pla-

tycnemididae and Amphipterygidae and have underestimated the number of family-level clades." (Authors)] Address: Dumont, H.J., Department of Biology, Ghent University, Ledeganckstraat, 35, B-9000 Ghent, Belgium. E-mail: Henri.Dumont@ugent.be

8516. Eberhard, W.G. (2010): Evolution of genitalia: theories, evidence, and new directions. *Genetica* 138: 5-18. (in English) ["Many hypotheses have been proposed to explain why male intromittent genitalia consistently tend to diverge more rapidly than other body traits of the same individuals in a wide range of animal taxa. Currently the two most popular involve sexual selection: sexually antagonistic coevolution (SAC) and cryptic female choice (CFC). A review of the most extensive attempts to discriminate between these two hypotheses indicates that SAC is not likely to have played a major role in explaining this pattern of genital evolution. Promising lines for future, more direct tests of CFC include experimental modification of male genital form and female sensory abilities, analysis of possible male-female dialogues during copulation, and direct observations of genital behaviour." (Author) References on Odonata are made.] Address: Eberhard, W.G., Smithsonian Tropical Research Institute, and Escuela de Biología, Universidad de Costa Rica, Ciudad Universitaria, San Pedro, Costa Rica. 8517. Flenner, I.; Richter, O.; Suhling, F. (2010): Rising temperature and latitudinal development in dragonfly populations. *Freshwater biology* 55: 397-410. (in English) ["1. For modelling the future ecological responses to climate change, data on individual species and on variation within and between populations from different latitudes are required. 2. We examined life cycle regulation and growth responses to temperature in Mediterranean and temperate populations of a widespread European odonate, *Orthetrum cancellatum*. In an experiment, offspring from individual females from different parts of the range were kept separately to elucidate differences between families. 3. The experiment was run outdoors at 52°N at a natural photoperiod for almost a year. We used four temperature regimes, ambient (i.e. following local air temperature) and ambient temperature increased by 2, 4 and 6°C, to mimic future temperature rise. A mathematical model was used to categorise the type of seasonal regulation and estimate parameters of the temperature response curve. 4. Growth rate varied significantly with temperature sum, survival and geographic origin, as well as with family. Offspring of all females from the temperate part of the range had a life cycle with a 12 h day-length threshold necessary to induce diapause (i.e. diapause was induced once day length fell below 12 h). By contrast, Mediterranean families had a 10 h threshold or had an unregulated life cycle allowing winter growth. The temperature response did not significantly differ between populations, but varied between families with a greater variation in the optimum temperature for growth in the Mediterranean population. 5. The variation in seasonal regulation leads to a diversity in voltinism patterns within species, ranging from bivoltine to semivoltine along a latitudinal gradient. Given that the type of seasonal regulation is genetically fixed, rising temperatures will not allow faster than univoltine development in temperate populations. We discuss the consequences of our results in the light of rising temperature in central Europe." (Authors)] Address: Flenner, Ida, Ecology & Environmental

8518. González-Tokman, D.-M.; Córdoba-Aguilar, A. (2010): Survival after experimental manipulation in the territorial damselfly *Hetaerina titia* (Odonata: Calopterygidae): more ornamented males are not more pathogen resistant. *Journal of Ethology* 28(1): 29-33. (in English) ["It has been hypothesized that sexual ornaments communicate pathogen resistance ability. We experimentally explored the relationship between the expression of a male ornamental trait (wing pigmentation) of *H. titia* and survival after a bacterial challenge. We infected males with *Serratia marcescens* (a Gram-negative bacteria typical of insects) and compared survival against a group infected with dead bacteria and a noninfected group. Wing pigmentation was entered as a predictor of survival in this comparison. Our study indicated that wing pigmentation was not a good predictor of immune ability against bacteria. This result contradicts previous findings in the same and other calopterygid species in which wing pigmentation intensity inversely correlated with gregarine infection levels. It also contradicts the general idea that ornaments are honest indicators of pathogen defense." 8519. Heiser, M.; Schmitt, T. (2010): Do different dispersal capacities influence the biogeography of the western Palearctic dragonflies (Odonata)? *Biological Journal of the Linnean Society* 99(1): 177-195. (in English) ["The biogeography of the western Palearctic has been intensively studied for more than a century. Recent advances in genetics have allowed the testing of old theories based on distribution patterns, although these analyses are obviously restricted to a reduced number of specific genetic data sets. On the other hand, an increased knowledge on the distributions of species and advances in computer capacities have allowed more detailed biogeographical analyses based on species presence/absence. In the present study, we selected the Odonata as the study group. For all 162 species native to the western Palearctic, we compiled their respective presence or absence in 97 predefined biogeographical regions. Using cluster analyses and principal component analyses, both based on Jaccard similarity coefficients, we analysed the differentiation among these regions and species. In subsequent analyses, the data set was reduced to the Zygoptera, Anisoptera, and the western Palearctic endemics. All analyses consistently showed different faunal regions and faunal elements. In particular, the (1) western and (2) eastern Mediterranean; (3) Central and (4) Northern Europe; and (5) the British Isles were invariably found in all cases. Although the two major Mediterranean regions were characterized by several endemic faunal elements, Northern Europe and the British Isles lacked such elements, but were characterized by faunal compositions strongly deviating from the rest of the western Palearctic region. Moderate differences between Zygoptera and Anisoptera existed, with the latter more clearly redrawing the Mediterranean refuge areas, whereas the former reflected to a greater extent the postglacial expansion patterns from these regions. In general, our findings underline the old biogeographical

theories, but refine especially our understanding of the Atlanto- and Ponto-Mediterranean region. Central Europe, comprising the area with the highest species numbers of our whole study region, unravels as a crossroad of postglacial immigrations, but might also represent a region of in situ glacial survival." 8520. Kefford, B.J.; Zalizniak, L.; Dunlop, J.E.; Nugegoda, D.; Choy, S.C. (2010): How are macroinvertebrates of slow flowing lotic systems directly affected by suspended and deposited sediments? *Environmental Pollution* 158(2): 543-550. (in English) ["The effects of suspended and deposited sediments on the macroinvertebrates are well documented in upland streams but not in slower flowing lowland rivers. Using species found in lowland lotic environments, we experimentally evaluate mechanisms for sediments to affect macroinvertebrates, and in one experiment whether salinity alters the effect of suspended sediments. Suspended kaolin clay reduced feeding of *Ischnura heterosticta* at high turbidity (1000–1500 NTU) but had no effects on feeding of *Hemianax papuensis* and *Micronecta australiensis* (Hemiptera: Corixidae). In freshwater (0.1 $\mu\text{S}/\text{cm}$), survival of *Ischnura aurora* was poor in clear water, but improved with suspended kaolin. Growth and feeding of *I. aurora* were unaffected by suspended sediments and salinity. Burial (1–5 mm) of eggs with kaolin or sand reduced hatching in *Physa acuta* (Gastropoda: Physidae), *Gyraulus tasmanica* (Gastropoda: Planorbidae) and *Chironomus cloacalis* (Diptera: Chironomidae). Settling sediments may pose greater risk to lowland lotic invertebrates than suspended sediments." 8521. Koperski, P. (2010): Diversity of macrobenthos in lowland streams: ecological determinants and taxonomic specificity. *J. Limnol.* 69(1): 1-14. (in English) ["The present study contains the results of an investigation of the relationships between the environmental variables and the taxonomic diversity of common and important groups of benthic macrofauna: Chironomidae, Ephemeroptera, Odonata, Hirudinea and Gastropoda, collected from various types of bottom substrate in seven lowland streams of north-eastern Poland. Four metrics were used to express the diversity of the studied taxa in each sample as the examples of its four different aspects: species richness, rarity, Shannon-Weaver's diversity index and Pielou evenness index. The values of total species richness and Shannon-Weaver index were rarified by functional extrapolation with Michaelis-Menten asymptotic function chosen as a richness estimator. There are high differences in taxonomic diversity of benthic animals between the studied streams. The results of estimation of total species richness and total species diversity are mainly affected by the diversity of the taxon richest in species – larval Chironomidae and, to a lesser extent, Hirudinea. The total taxonomic diversity significantly correlates with the status of riparian vegetation and with the isolation of the sampling site, while the relationship with other environmental parameters, i.e. pollution and seasonality, is not significant. The diversity of Gastropoda and Hirudinea is significantly affected by pollution (positively), water depth and season-

ality; whereas the diversity of Ephemeroptera and Chironomidae by the state of riparian vegetation, and that of Odonata by stream width and isolation of the site. The study presents and discusses reduced diversity of certain higher taxa as a result of a reduction in pollution loading to a stream with simultaneous unchanged values of the total diversity." (Authors)] Address: Koperski, P., Dept Hydrobiol., Univ. Warsaw, Banacha 2, 02-097 Warszawa, Poland. E-mail: p.t.koperski@uw.edu.pl

8522. Marques Couceiro, S.R.; Hamada, N.; Forsberg, B.R.; Padovesi-Fonseca, C. (2010): Effects of anthropogenic silt on aquatic macroinvertebrates and abiotic variables in streams in the Brazilian Amazon. *Journal of Soils and Sediments* 10(1): 89-103. (in English) ["Purpose: While environmental risks associated with petroleum extraction such as oil spills or leaks are relatively well known, little attention has been given to the impacts of silt. The increase in petroleum exploitation in Amazonia has resulted in sediment input to aquatic systems, with impacts on their biodiversity. Here we use a combination of field measurements and statistical analyses to evaluate the impacts of anthropogenic silt derived from the construction of roads, borrow pits, and wells during the terrestrial development of gas and oil, on macroinvertebrate communities in streams of the Urucu Petroleum Province in the Central Brazilian Amazon. Material and methods: Ten impacted and nine non-impacted streams were sampled in January, April, and November of 2007. Macroinvertebrates were sampled along a 100-m continuous reach in each stream at 10-m intervals using a dip net. Abiotic variables including, a siltation index (SI), suspended inorganic sediment (SIS), sediment colour index (SCI), suspended organic sediment (SOS), pH, electrical conductivity, dissolved oxygen, temperature, water velocity, channel width, and depth, were measured at three equidistant points in each stream (~30-m intervals). Results and discussion: SI did not differ between impacted and undisturbed streams. SIS was higher and SCI lower (more reddish) in impacted than in non-impacted streams. SCI had a positive and SIS a negative effect on both macroinvertebrate richness and density. SIS and SCI also influenced macrophyte taxonomic composition. In impacted streams, taxonomic richness and density were 1.5 times lower than in non-impacted streams. No taxon was significantly associated with impacted streams. SIS was positively correlated with SOS and electrical conductivity while SCI was negatively correlated with SOS, electrical conductivity, and pH. The lack of difference in SI between impacted and non-impacted streams suggests that anthropogenic sediment does not accumulate on stream beds. The reddish colour of SIS in impacted streams reflects terrestrial erosion and indicates the rapid flow of suspended sediments through these reaches, impacting macroinvertebrate richness, density, and species composition. Conclusions: Anthropogenic suspended silt has had a significant negative impact on aquatic macroinvertebrate diversity and density in streams in the Urucu Petroleum Province. Soil conservation measures are needed to reduce silt inputs and restore these streams to their natural condition. Additional studies are also needed to investigate the dynamics of sediments in the impacted streams." (Authors) Odonata are treated at the genus level.] Address: Marques Couceiro, Sheyla Regina, Instituto Nacional de Pesquisas da Amazônia/Coordenação de Pesquisas em Entomologia, Av. 8523. Muscatello, J.R.; Janz, D.M. (2010): Selenium accumulation in aquatic biota downstream of a uranium mining and milling operation. *Science of the total environment* 407(4): 1318-1325. (in English) ["Uranium mining and milling operations have the potential to release trace elements such as arsenic, molybdenum, nickel, selenium and uranium and ions (e.g., sulfate, ammonium) into the receiving aquatic ecosystem. The major implication of elevated environmental selenium is its propensity to accumulate in the aquatic food chain, potentially impairing fish reproduction. The objective of this study was to investigate the accumulation of selenium in the major compartments of aquatic ecosystems (lakes) upstream and downstream of a uranium mine in northern Saskatchewan, Canada. Selenium concentrations in aquatic biota were elevated in the exposure lake although water and sediment concentrations were low (0.43 µg/L and 0.54 µg/g dry weight, respectively). Biomagnification of selenium resulted in approximately 1.5 to 6 fold increase in the selenium concentration between plankton, invertebrates and fish. However, no biomagnification was observed between forage and predatory fish. Although some aquatic biota (e.g., forage fish) exceeded the lower limit of the proposed 3 to 11 µg/g (dry weight) dietary toxicity threshold for fish, no adverse effects of selenium could be identified in this aquatic system. Continued environmental monitoring is recommended to avoid potential selenium impacts. [...] Selenium concentrations in Diptera, Trichoptera and Odonata were significantly ($p < 0.05$) greater in the exposure site than the reference site. In addition, there were significant ($p < 0.05$) increases in the concentrations of Co and Mn in Gastropoda, Odonata and Hirudinea between sites. The concentration of As was greater for Odonata collected from exposure site compared to the reference site ($p < 0.05$). In contrast, other concentrations of trace elements in Diptera (Ba, copper [Cu], Mn, Ni and zinc [Zn]), Trichoptera (Ba and V), Gastropoda (Cr, Fe and V) and Odonata (Cd, Cu and Sr) collected from the exposure site were significantly less ($p < 0.05$) than the reference site." 8526. Reinhardt, K. (2010): Natural selection and genital variation: a role for the environment, parasites and sperm ageing? *Genetica* 138: 119-127. (in English) ["Male genitalia are more variable between species (and populations) than other organs, and are more morphologically complex in polygamous compared to monogamous species. Therefore, sexual selection has been put forward as the major explanation of genital variation and complexity, in particular cryptic female choice for male copulatory courtship. As cryptic female choice is based on differences between males it is somewhat paradoxical that there is such low within-species variation in male genitalia that they are a prime morphological identification character for animal species. Processes other than sexual selection may also lead to genitalia variation but they have recently become neglected. Here I focus on pleiotropy and natural selection and provide examples how they link genitalia morphology with genital environments. Pleiotropy appears to be important because most studies that specifically tested for pleiotropic effects on genital morphology found them. Natural selection likely favours certain genital morphology over others in various environments, as well as by reducing re-infection with sexually transmitted diseases or reducing the likelihood of fertilisation with aged sperm. Both pleiotropy and natural selection differ locally and between species so may contribute to local variation in genitalia and sometimes variation between monogamous and polygamous species. Furthermore, the multitude of genital environments will lead to a multitude of genital functions via natural selection and pleiotropy, and may also contribute to explaining the complexity of genitalia." (Authors) References to Odonata are made.] Address: Reinhardt, K., Dept Animal and Plant Sciences, University of Sheffield, Sheffield S10 2TN, UK. E-mail: K.Reinhardt@sheffield.ac.uk

8527. Starzomski, B.M.; Suen, D.; Srivastava, D.S. (2010): Predation and facilitation determine chironomid emergence in a bromeliad-insect food web. *Ecological Entomology* 35: 53-60. (in English) ["1. Ecological theory has focused on negative interactions, such as competition and predation, to explain species' effects on one another. This study demonstrates the importance of considering both positive and negative interactions in explaining how species influence abundances at the local scale. 2. Two experiments were conducted using the aquatic insect food web in Costa Rican bromeliad phytotelmata. Manipulations contrasted the strength of predation between trophic levels versus facilitation within a trophic level on the emergence of detritivore chironomids. 3. Predation had a strong negative effect on chironomids, reducing emergences by 81% overall. Most predation was as a result of the top predator, *Mecistogaster modesta*; the intermediate predator, a tany-podine chironomid, had little effect. In the absence of predators, shredder and scraper detritivores (tipulid and scirtid larvae) increased the emergence rate of chironomid larvae by 86%. The mechanism of facilitation was likely the processing, by tipulids and scirtids, of intact detritus into fine particles that the detritivore chironomids consume or use to build protective cases. 4. This study is among the first demonstrations of a pro-

cessing chain in a multispecies context, and in bromeliad-insect food webs. Our finding that top-down effects are of similar magnitude to facilitative effects suggests that the relative importance of processing chains in nature will depend on food web context." 8528. Takahashi, Y.; Watanabe, M. (2010): Female reproductive success is affected by selective male harassment in the damselfly *Ischnura senegalensis*. *Animal Behaviour* 79: 211-216. (in English) ["In animals without any courtship behaviour, persistent mating attempts by males are frequently observed. Male harassment affects female reproductive success in the laboratory, but few studies have evaluated the costs of male harassment in the wild. In *I. senegalensis*, females exhibit colour dimorphism (andromorph and gynomorph), and the morph frequency varies between local populations. In two populations where gynomorphs were common, we found that males harassed more gynomorphs than andromorphs throughout their daily foraging and oviposition activity period. Gynomorphs excreted less faeces than andromorphs, indicating that preferential harassment of gynomorphs decreased their food intake. Gynomorphs also produced fewer eggs than andromorphs. As a result, gynomorphs laid 35% fewer eggs per day than andromorphs, suggesting that male harassment decreased their reproductive success." 8530. Both, C. (1997): Career-decisions of Calopteryx-species. *Brachytron* 1(1): 11-15. (in Dutch, with English summary) ["Males of *Calopteryx splendens* and *C. virgo* sometimes engage in long, escalated fights. This paper addresses the question why these damselflies spend so much time and energy in those fights. By individually marking males from both species we showed that about three quarters of the marked individuals was restricted to a particular site. These males were frequently involved in short disputes with bordering males, suggesting that the males defended territories. Males not restricted to a particular site hardly got engaged in these border disputes, suggesting that these males were non-territorial. Only one escalated fight was observed in which a marked territorial male was displaced by a non-territorial individual after more than 30 minutes continuous fighting. Territorial males attracted females by a flight display, sometimes including a part in which males entered the stream and floated some distance downstream. Non-territorial males chased females in a pursuit flight. The territorial strategy is far more rewarding in *Calopteryx* damselflies, resulting in 1000 times more eggs fertilized per day than males without territories (Plaistow & Siva-Jothy, 1996). The escalated fights seem to be a way of getting the preferred mating option." (Author)] Address: Both, C., Droevendaalsesteeg 57, 6708 PB Wageningen. The Netherlands. E-mail: Both@cto.nioo.knaw.nl

8531. Habraken, J.M.; Crombaghs, B.H. (1997): Discovery of a larva of *Gomphus flavipes* along the Waal. *Brachytron* 1(1): 3-5. (in Dutch, with English summary) ["On the 5th of June 1996 a living larva of *G. flavipes* was found in the residue of the cooling-water filters of the EPON power station at Nijmegen. This was the first record of the species in The Netherlands since 1902. Pollution and canalization of rivers have caused its extinction in most of western Europe. It was recently re-discovered along some German rivers. The cooling-water is extracted from a canal connecting the rivers Waal (Rhine) and Maas (Meuse) which originate in Germany and France respectively. It seems probable that larval drift, due to high-water in recent winters, explains this remarkable discovery. The Rhine is the most

likely source, there being a number of barriers in the canal from the other side. The importance of the regeneration of riverine habitats for the possible return of populations of *G. flavipes* to The Netherlands is stressed." 8533. Pritchard, G.; Kortello, A. (1997): Roosting, perching, and habitat selection in *Argia vivida* Hagen and *Amphiagrion abbreviatum* (Selys) (Odonata: Coenagrionidae), two damselflies inhabiting geothermal springs. *Canadian Entomologist* 129(4): 733-743. (in English, with French summary) ["Although *A. abbreviatum* and *A. vivida* often occur at the same geothermally heated springs in western Canada and the United States, they differ markedly in their abundance at any particular site. There is no relationship between crude data on water temperature, conductivity, or aquatic vegetation and the relative abundance of the two species, but there is a striking correlation with presence or absence of trees. The absence of *A. abbreviatum* from heavily treed areas is associated with the paucity of suitable daytime perching sites, and there may be competitive pressure exerted by *A. vivida* for the perching sites that are available. *A. vivida* does not live at open sites because it requires trees for night-time roosts. *A. vivida* roosted higher than *A. abbreviatum* in cages and held the body at a greater angle from the cage wall. The roosting posture of *A. vivida* is probably related to interception of solar radiation in the morning, and the body positions of

both species possibly provide defence against predation." (Authors)] Address: Pritchard, G., Div. Ecol. Dept Biol. Sci., Univ. Calgary, Calgary, AB, T2N 1N4, Canada. E-mail: gpritcha@ucalgary.ca

8534. Strausfeld, N.J.; Hansen, L.; Li, Y.; Gomez, R.S.; Ito, K. (1998): Evolution, discovery, and interpretations of arthropod mushroom bodies. *Learning & Memory* 5: 11-37. (in English) ["Mushroom bodies are prominent neuropils found in annelids and in all arthropod groups except crustaceans. First explicitly identified in 1850, the mushroom bodies differ in size and complexity between taxa, as well as between different castes of a single species of social insect. These differences led some early biologists to suggest that the mushroom bodies endow an arthropod with intelligence or the ability to execute voluntary actions, as opposed to innate behaviors. Recent physiological studies and mutant analyses have led to divergent interpretations. One interpretation is that the mushroom bodies conditionally relay to higher protocerebral centers information about sensory stimuli and the context in which they occur. Another interpretation is that they play a central role in learning and memory. Anatomical studies suggest that arthropod mushroom bodies are predominately associated with olfactory pathways except in phylogenetically basal insects. The prominent olfactory input to the mushroom body calyces in more recent insect orders is an acquired character. An overview of the history of research on the mushroom bodies, as well as comparative and evolutionary considerations, provides a conceptual framework for discussing the roles of these neuropils. [...] Thysanura, Ephemeroptera, and Odonata are probably all primarily anosmic (lacking a sense of smell) with respect to airborne odors. [...] A crucial feature is that these apterygotes, as well as palaeopteran insects, all lack the glomerular antennal lobes typical of Neoptera whose ancestors first appeared in the Late Carboniferous. Another important feature of the mushroom bodies of primitive anosmic insects is that they lack calyces. However, their neuropils derive from thousands (in odonates, hundreds of thousands) of globuli cells that provide cell body fibers forming a thin pedunculus, which, anteriorly, gives rise to elaborately subdivided and swollen lobes. [...] Judging from their modern representatives, the mushroom body lobes of these earliest insects thus seem to serve mainly mechano- and optosensory integration rather than olfaction." As example of anosmic insects (Odonata), *Argia* sp. is used. "In some species, the calyx is divided into inner, middle, and outer components vertical, medial, frontal, and recurrent lobes (in some species, lobe subdivisions represent inner, middle, and outer calyces)." 8536. Kiauta, B.; Kiauta, M. (1999): A note on dragonfly response during the 98,3% solar eclipse of 11 August 1999 in the Netherlands (Odonata). *Opusc. zool. flumin.* 172: 1-6. (in English) ["An analysis of odonate behaviour at a locality near Utrecht, combined with the available evidence from India and France, seems to indicate it is the rapid reduction of light intensity during a solar eclipse rather than a relatively minor drop in the ambient temperature that triggers the behavioural response. The latter is similar to the behaviour preceding oncoming heavy weather." (Authors)] Address: Kiauta, B., P.O. Box 256, NL-3720 AG Bilthoven, The Netherlands. E-mail: mb.kiauta@12move.nl

8537. Wirth, T.; Le Guellec, R.; Veuille, M. (1999): Directional substitution and evolution of nucleotide content in the Cytochrome Oxidase II gene in earwigs (Dermapteran Insects). *Mol. Biol. Evol.* 16(12): 1645-1653. (in English) ["The cytochrome oxidase subunit II (COII) gene was sequenced for six dermapteran species. The nucleotide composition of this gene is biased in most animals. While the CG content of other insect orders is low (mean, 27.6%; range, 19.5%–33.1%), species from the *Forficula* genus showed unusually high values (mean, 42.4%; range, 37.3%–44.1%), mostly due to high CG frequencies at third codon positions: the mean CG content at these positions was around 45% (range, 43.9%–46.9%) for *Forficula*, compared with only 13.3% for other insects. This effect was so strong that in one species, *Forficula lesnei*, there was no significant difference between the frequencies of the four bases. During evolution, this loss of bias has involved a significant increase in the synonymous substitution rate and an increase of transitions over transversions compared with other insects. A strong directionality of substitutions has favored T->C and A->G changes. This phenomenon was also observed between two conspecific populations of *Forficula auricularia*. A species from a closely related genus, *Anechura bipunctata*, was intermediate between *Forficula* and other insects for these parameters, while two remotely related dermapteran species, *Labidura riparia* and *Euborellia moesta*, were similar to other insects. These results suggest that the evolution of *Forficula* DNA content has been both rapid and recent." (Authors) *Symptetrum striolatum* was used as outgroup representative in phylogenetic analysis.] Address: Wirth, T., Laboratoire d'Ecologie and Ecole Pratique des Hautes Etudes, Paris 6 University, Paris, France

8538. Batzer, D.P.; Pusateri, C.R.; Vetter, R. (2000): Impacts of fish predation on marsh invertebrates: direct and indirect effects. *Wetlands* 20(2): 307-312. (in Eng-

lish) ["We excluded predatory fish from a marsh weedbed to evaluate experimentally their impact on invertebrate prey. Gut analyses of wetland fish, including pumpkinseed sunfish (*Lepomis gibbosus*), brown bullhead (*Ictalurus nebulosus*), black crappie (*Pomoxis nigromaculatus*), and common carp (*Cyprinus carpio*), revealed that large numbers of midge larvae (Diptera: Chironomidae) were consumed. However, our exclusion of these predatory fish from study habitats did not result in midge population increases. On the contrary, fewer epiphytic midges occurred where predatory fish had been excluded ($P = 0.0043$). Populations of midge competitors (especially Planorbidae and Physidae) and invertebrate midge predators (especially Corixidae and Glossiphoniidae) were suppressed directly by fish, and midges that co-existed with fish apparently benefitted indirectly from those interactions. For epiphytic midge larvae, the negative direct influence of fish predation was strong, but positive indirect effects apparently were even more powerful. [...] When all of the potential invertebrate predators of non-tanypod midges were pooled (odonates, hemipterans, leeches, tanypod midges), more occurred in habitats where fish were excluded, but in this case, no interaction existed between predator taxa and fish treatment" (Authors)] Address: Batzer, D.P., Department of Entomology, University of Georgia, Athens, Georgia, USA 30602.

8539. Birge, W.J.; Price, D.J.; Shaw, J.R.; Spromberg, J.A.; Wigginton, A.J.; Hogstrand, C. (2000): Metal body burden and biological sensors as ecological indicators. *Environmental Toxicology and Chemistry* 19(4): 1199-1212. (in English) [Big Bayou Creek, Kentucky, USA; "Metal body burden (BB) was analyzed in three groups of organisms evaluated as sentinel monitors of metal exposure. The study site was a lotic system of moderate gradient that received effluent outfalls from an uranium enrichment plant. Metal BBs (e.g., Ag, Cd, Cr, Cu) increased in the order Cheumatopsyche spp. (caddisfly), *Campostoma anomalum* (central stoneroller minnow), and *Stenonema* spp. (mayfly). This was consistent with their classifications as metal-tolerant, moderately tolerant, and sensitive taxa, respectively. The Ag, Cd, and Cu BBs in stoneroller minnows from upstream, effluent-receiving, and downstream stations correlated strongly with macroinvertebrate bioassessment (BA) scores, numbers of taxa, and the Ephemeroptera, Plecoptera, Trichoptera indices. Proportional differences in metal BBs in the minnow were used to derive metal multipliers that were applied to total recoverable metal concentrations to calculate bioavailable metal. The bioavailable metal fractions correlated with BA scores and numbers of taxa. When five metals (i.e., Ag, Cd, Cu, Cr, Pb) were included in an additive model, results also correlated with BA scores ($r = -0.93$) and numbers of taxa ($r = -0.86$). Metal BB in minnows was a strong indicator of ecological impact and provided a means of determining bioavailable metals. Also, we describe the development of the metal biosensor, which incorporates a reconstructed fish gill epithelium, the primary target of metal exposure. This *in vitro* biosensor should directly quantify bioreactive metals that cross the epithelium and react with a genetically engineered intracellular detector. This biosensor complements biotic ligand models based on surface binding of metals to gill epithelia." (Authors) Density of Odonata in appendix 1 is documented at the family level.] Address: Birge, W.J., School of Biological Sciences, University of Kentucky,

8541. Termaat, T. (2000): Survey of new riverine habitat of *Gomphus flavipes* in The Netherlands in 1999. *Brachytron* 4(1): 13-17. (in Dutch, with English summary) ["After the rediscovery of *G. flavipes* in The Netherlands in 1996, the species was recorded in 1998 in eight 1x1 km-squares along the river Waal near Nijmegen in the eastern part of The Netherlands. Extensive research in 1999 displayed the species presence at many new locations of *G. flavipes* along the rivers Waal, Nedernjn, Nieuwe Merwede and Beneden Merwede. One wandering male was found near Goirte outside the species normal riverine habitat, at short distance of the Belgian border. An overview is presented of all new locations, many reaching well westwards. In addition, all locations where the species appeared to be absent despite searching are presented also. Possible reasons for absence of *G. flavipes* along the river Lek are discussed, just as the possibilities for the species presence along other river systems." (Author)] Address: Termaat, T., Rijnsteeg 8-10a, 6708 PP Wageningen, The Netherlands

8542. Euliss, N.H.; Mushet, D.M.; Johnson, D.H. (2001): Use of macroinvertebrates to identify cultivated wetlands in the prairie pothole region. *Wetlands* 21(2): 223-231. (in English) ["We evaluated the use of macroinvertebrates (in most cases at order or family level, and including Odonata larvae) as a potential tool to identify dry and intensively farmed temporary and seasonal wetlands in the Prairie Pothole Region. The techniques we designed and evaluated used the dried remains of invertebrates or their egg banks in soils as indicators of wetlands. For both the dried remains of invertebrates and their egg banks, we weighted each taxon according to its affinity for wetlands or uplands. Our study clearly demonstrated that shells, exoskeletons, head capsules, eggs, and other remains of macroinvertebrates can be used to identify wetlands, even when they are dry, intensively farmed, and difficult to identify as wetlands using standard criteria (i.e., hydrology, hydrophytic vegetation, and hydric soils). Although both dried remains and egg banks identified wetlands, the combination was more useful, especially for identifying drained or filled wetlands. We also evaluated the use of coarse taxonomic groupings to stimulate use of the technique by nonspecialists and obtained satisfactory results in most situations." 8549. Dudley, R. (2002): Mechanisms and implications of animal flight maneuverability. *Integr. Comp. Biol.* 42: 135-140. (in English) ["Accelerations and directional changes of flying animals derive from interactions between aerodynamic force production and the inertial resistance of the body to translation and rotation. Anatomical and allometric features of body design thus mediate the rapidity of aerial maneuvers. Both translational and rotational responsiveness of the body to applied force decrease with increased total mass. For flying vertebrates, contributions of the relatively heavy wings to whole-body rotational inertia are substantial, whereas the relatively light wings of many insect taxa suggest that rotational inertia is dominated by the contributions of body segments. In some circumstances, inertial features of wing design may be as significant as are their aerodynamic properties in influencing the rapidity of body rotations. Stability in flight requires force and moment balances that are usually attained via bilateral symmetry in wingbeat kinematics, whereas body roll and yaw derive from bilaterally asymmetric movements of both axial and appendicular structures. In many flying vertebrates, use of the tail facilitates the generation of aerodynamic torques and substantially enhances quickness of body rotation. Geometrical constraints on wingbeat kinematics may limit total force production and thus accelerational capacity in certain behavioural circumstances. Unitary limits to animal flight performance and maneuverability are unlikely, however, given varied and context-specific interactions among anatomical, biomechanical, and energetic features of design." 8553. Sherwood, G.D.; Kovacs, J.; Hontela, A.; Rasmussen, J.B. (2002): Simplified food webs lead to energetic bottlenecks in polluted lakes. *Can. J. Fish. Aquat. Sci.* 59: 1-5. (in English, with French summary) [Quebec, Canada; "Very little is known about the consequence of human activities on the flow of energy through natural ecosystems. Here, we present a trophic-based approach to describing energy relationships in pollutant-disturbed lakes, emphasizing the importance of prey diversity in maintaining energy transfer to growing fish. Both diet and community analysis indicated that the food web leading to yellow perch (*Perca flavescens*) in metal-polluted lakes was extremely simplified compared with reference lakes. Through the application of an in situ marker for fish activity costs (muscle lactate dehydrogenase activity) and through bioenergetic modelling, we show how this has severe consequences on the efficiency of energy transfer to perch from their prey; premature energetic bottlenecks (zero conversion efficiency) occur when successively larger prey types are not available to growing perch. These observations provide a much needed ecological and physiological framework for assessing how energy transfer can be affected in polluted systems. Our approach need not be limited therein but should be applicable to any aquatic system where food web structure is variable and (or) disrupted." (Authors) The analysis includes Odonata, but without further details.] Address: Sherwood, G.D., Department of Biology, McGill University, 1205 Dr. Penfield, Montreal, QC H3A 1B1, Canada. 8554. Taketo, A. (2002): Transition of odonate fauna in the artificial ponds in Yuhidera, Kanazawa: situation in the 9th year. *Tombo* 45(1/4): 33-35. (in Japanese, with English summary) ["The Odonate fauna in artificial ponds at Yuhidera sanctuary on the 9th year is reported. Two rare species, *Polycanthagyna melanictera* and *Aeschnophlebia anisoptera* emerged and are new records in 2001. A teneral male of *Sympetrum pedemontanum elatum* was caught, for the first time in this area. Except for such species as *Libellula quadrimaculata asahinai*, *Anax parthenope julius* and *Pseudothemis zonata*, yield of dragonflies as revealed by exuviae collection decreased markedly. Nine zygopteran species appeared in this area and, larval density of Zygoptera was considerably higher than that of Anisoptera. Unexpectedly, *Micropterus salmoides*, a kind of voracious foreign sunfish, had been illicitly released into one of the pond. In November, the pond was drained to remove the sunfish thoroughly. Examination of digestive tract of the fish demonstrated remains of *P. zonata* larvae." (Author)] Address: Taketo, A., 1-19, Ishibiki 1-chome, Kanazawa City, 920, Japan

8555. Van der Weide, M. (2002): 'De Nederlandse Libellen', about the results and the future. *Brachytron* 6(2): 56-59. (in Dutch, with English summary) ["This article provides an anthology of the recently published book 'De Nederlandse Libellen'. It ends with targets for further field research. The main aim of the book is the presentation of the distribution of the seventy species recorded in The Netherlands. The distribution is given in three periods (before 1950, 1950-1989 and 1990-1997). Striking changes in distribution are for example visible in *Erythromma viridulum*, *Sympecma fusca*, *Gomphus flavipes* and *G. vulgatissimus*. The balance in the drag-

onfly fauna in the last 100 year is as follows: five species have disappeared. 20 have decreased. 23 are more or less stable and 17 have increased. Species of fens, brooks and rivers show the highest decreases. Morphology, life history and behaviour of dragonflies in relation to their environment is also described in the book. However, with the publication of this atlas, knowledge of dragonflies in The Netherlands is not complete. For the future the challenges are monitoring of the dragonfly populations, further distribution surveys and research on behaviour, ecology and the effects of nature management." 8557. Brothers, D.J.; Rasnitsyn, A.P. (2003): Diversity of Hymenoptera and other insects in the Late Cretaceous (Turonian) deposits at Orapa, Botswana: a preliminary review. *African Entomology* 11(2): 221-226. (in English) ["The kimberlitic eruption that formed the crater at Orapa occurred about 91 Mya, and its fossiliferous sediments were deposited shortly thereafter. The pieces of rock from Orapa which contain insect fossils, approximately 2000 currently housed in the Bernard Price Institute of Palaeontology at the University of the Witwatersrand and about 220 in the National Museum of Botswana in Gaborone, were screened for Hymenoptera, and all arthropods on the 68 pieces so selected were identified to the lowest level possible. After adjusting for the prior selection of Hymenoptera, the ordinal composition of the arthropods was calculated. The major components, based on number of specimens, are: Coleoptera (29 %), Homoptera (18 %), Blattodea (17 %), Diptera (13 %), Thysanoptera (7 %), and Hymenoptera and Orthoptera (6 % each)." (Authors) 1 specimen of the 641 studied insects belonged to the Odonata.] Address: Brothers, D.J., School of Botany and Zoology, University of Natal Pietermaritzburg, Private Bag X01, Scottsville, 3209 South Africa

8558. Harp, G.L.; Harp, P.A. (2003): Dragonflies (Odonata) of the Ouachita National Forest. *Journal of the Arkansas Academy of Science* 57: 68-75. (in English) [USA; "The Ouachita National Forest (ONF) was established in 1907 and encompasses 1.8 million acres (728,450 ha) in Arkansas and Oklahoma, almost entirely within the Ouachita Mountains Natural Division. The adult dragonfly species richness, seasonal and spatial distribution, and relative abundance were surveyed during 2002. Fifty four collections were made at 43 sites during 10-19 May (20 collections), 10-22 July (19 collections) and 9-17 September (15 collections). Literature records were searched, as well as records from pertinent museums and individuals. Eighty-three species are reported here for the ONF, 77 of which were collected during 2002. *Nehalennia integricollis* is newly reported for Arkansas, as are several species for the six Arkansas and two Oklahoma counties that encompass the ONF. The species richness results from a diversity of aquatic habitats, particularly within the

Caddo Ranger District. Plastic species (e.g. *Plathemis lydia*) typically are widely distributed and have long flight seasons. More specialized species (e.g. *Ophiogomphus westfalli*) often are quite restricted in both distribution and flight season. Maintenance of good water quality in all aquatic habitat types will ensure species richness for dragonflies and the invertebrates upon which they feed." (Authors)] Address: Harp, G., Dept of Biological Sciences, Arkansas State Univ., State University, AR 72467, USA. E-mail: glharp@astate.edu

8572. Bernard, R. (2005): Buffer protection zones for *Nehalennia speciosa* – a vision, law and problems. *Odonatrix* 1(2): 21-24. (in Polish, with English summary) ["Buffer protection zones in the range up to 100 m around localities with *N. speciosa*, proposed by the

author, were legally implemented in Poland in 2004 by the Ministry of Environment, with the aim to prevent deforestation, changes in hydrological conditions and any other impact on the species habitat. So far, conservation measures of this type have been used in Poland mainly for birds. The vital role of forests as buffer zones for *N. speciosa* is evident. To a large extent they influence hydrochemical conditions and through them the composition and texture of vegetation, extremely important for the species. They also contribute to the stabilization of the hydrological conditions and serve as windshields. In the article, the necessity of implementation of the protection zones is substantiated considering a deep regress of this very endangered species. The legal status quo is described, some of its imperfections are explained, and a list of bans is enclosed. The expected problems related to designation of individual localities and outlining the range of their protection zones are considered in the context of continuous disputes with forest administration bodies." (Author)] Address: Bernard, R., Department of General Zoology, Adam Mickiewicz University, Umultowska 89, PL-61-702 Poznań, Poland; E-mail: bernard@amu.edu.pl

8573. Brown, G. (2005): *Celithemis verna* in New York. *Argia* 17(3): 21-22. (in English) [Several specimens were recorded at Long Island in summer 2005. "It is, to my knowledge, the first record of this southern species for New York, and the first record north of New Jersey."] Address: not stated

8574. Buczyński, P.; Tończyk, G. (2005): New regulation pertaining to the list of the animal species being under protection. *Odonatrix* 1(1): 3-5. (in Polish, with English summary) ["The new regulation about species protection of animals encompasses 15 dragonfly species: *Sympecma paedisca*, *Coenagrion armatum*, *C. ornatum*, *Nehalennia speciosa*, *Gomphus flavipes*, *Ophiogomphus cecilia*, *Aeshna caerulea*, *A. subarctica*, *A. viridis*, *Cordulegaster boltonii*, *Somatochlora alpestris*, *S. arctica*, *Leucorrhinia albifrons*, *L. caudalis* and *L. pectoralis*. Additionally, for *N. speciosa* 100 m yearlong protection zone was introduced, covering its breeding and regularly inhabiting areas. In the paper the history of constructing the list of dragonflies under protection was also presented. They were provided for the first time in the regulation from 1995 in which only 7 species were involved. The next regulation (2001) encompassed 11 species, and the newest (2004) – 15 ones. It seems that after almost 10 years of efforts and mistakes, the composition of protected dragonflies has been competently fixed. It covers: non-threatened species or little threatened ones (their protection is associated with the ratification of the Bern Convention by Poland in 1995 as well as the acceptance of the EU-Habitat Directive in 2004) and really endangered (of the highest threat categories on the Red List of Threatened Animals in Poland). The authors analyse the practical dimension of species protection. Its up-to-date very restrictive legal construction derives from vertebrate and vascular plant protection. It can hinder the conducting of scientific research and cause conflicts with forest services." (Authors)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska Univ., Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

8575. Buczyński, P. (2005): Why *Odonatrix*? *Odonatrix* 1(1): 1. (in Polish, with English summary) [*Odonatrix* is the bulletin of the Odonatological Section of the Pol-

ish Entomological Society (PTE). It is launched twice a year, in January and July, and presents information on recent events of the section as well as Polish and world-wide odonatology, announcements and discussions of scientific conferences, comments on odonological literature, short reviews and popular scientific texts as well as faunistic notes. The bulletin is also available as a PDF-file in the Internet. It is written in Polish, with English abstracts.] Address: Buczyński, P., Dept Zool., Maria Curie-Skłodowska Univ., Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

8582. Butler, R.G.; deMaynadier, P.G.; Tomlinson, M.; Robbins, H.; Long, P.; Marenberg, A. (2005): Northeast range extension and observations of atypical "sash" of *Enallagma laterale* (New England Bluet) in Maine. *Argia* 17(3): 23-25. (in English) [*Enallagma laterale* (New England Bluet) is a globally rare damselfly species (G3 or vulnerable) that has been documented in eastern Pennsylvania, northern New Jersey, southeastern New York, Connecticut, Rhode Island, Massachusetts, southeastern New Hampshire, and in southwestern and coastal Maine, the northern extreme of its range. Previously the northern-most known location for this species was Tilton Pond in Fayette, Maine (Kennebec City: N 44.4563°, W 70.0722°), and the eastern-most site was Pitcher Pond in Lincolnville, Maine (Waldo City: N44.3361°, W 69.0498°). In Downeast, Maine on 16 June 2004, a new breeding location for *E. laterale* was discovered at Otter Pond in T24 MD BPP, ME (Washington City: N44.8244°, W 67.9324°). Approximately 105 km from the nearest known site to the southwest, this population currently represents the extreme northeastern known limit to the distribution of *E. laterale* in North America. The habitat is described, and the morphology of the terminal abdominal segments is discussed.] Address: deMaynadier, P.G., Endangered Species Group, Maine, Maine Department of Inland Fisheries and Wildlife, 650 State Street, Bangor, Maine 04401, USA. 8585. Cios, S. (2005): Trout preying on adult dragonflies. *Odonatrix* 1(1): 5-7. (in Polish, with English summary) ["In the stomach of a brown trout caught on 22.06.2001 in Lake Valkeisjarvi near Oulu (Finland) the author found 14 males of *Cordulia aenea* and 2 males of *Enallagma cyathigerum*. The fish fed close to the water surface, without jumping out of the water. The large number of adults in the diet and the fact that they

were solely males, results from falling on the water surface of victims of combats between territorial males. The author discusses also literature data on the proportion of sexes in adult Odonata and on the role of imagines as food of fish." (Author)] Address: Cios, S., ul. Stryjeńskich 6/4, 02-791 Warszawa, Poland. E-mail: tanislaw.cios@msz.gov.pl

8586. Cios, S. (2005): Further accounts of fish preying on adult Odonata. *Odonatrix* 1(2): 24-25. (in Polish, with English summary) ["... In the first case the angler observed big chub (*Leuciscus cephalus*) jumping out of the water (River Gwda in Poland) trying to catch male adults of *Calopteryx* perching on vegetation overhanging the water. He didn't see any successful attacks, but in the stomachs of caught fish he found some of these damselflies. The second account also concerns male adults of *Calopteryx*. In River Dosse near Berlin another angler has seen brown trout jump out of the water, in an effort to catch the males. This angler has also once found an adult of *Anax imperator* in the stomach of a brown trout caught in the River Nuthe near Berlin. The last account is taken from an angler's article published in Internet. The angler has seen brown trout in the River Lozoya (Castilia in Spain) jump out of the water, trying to catch damselflies (probably females of *Calopteryx haemorrhoidalis*) perching on vegetation overhanging the water." (Author)] Address: Cios, S., ul. Stryjeńskich 6/4, 02-791 Warszawa, Poland. E-mail: stanislaw.cios@msz.gov.pl

8590. Geiger, W.; Alcorlo, P.; Baltanas, A.; Montes, C. (2005): Impact of an introduced Crustacean on the trophic webs of Mediterranean wetlands. *Biological Invasions* 7: 49-73. (in English) ["Based on a review and our own data, we present an overview of the ecological impacts on the trophic web of Mediterranean wetlands by an introduced Decapod Crustacean, the red swamp crayfish (*Procambarus clarkii*). *P. clarkii* lacks efficient dispersal mechanisms but is very well adapted to the ecological conditions of Mediterranean wetlands (fluctuating hydroperiods with regular intervals of drought). As an opportunistic, omnivorous species, which adapts its ecology and life history characteristics, such as timing and size at reproduction to changing environmental conditions, it became readily established in most of the Mediterranean wetland environments. High reproductive output, short development time and a flexible feeding strategy are responsible for its success as an invader. Like most crayfish, it occupies a keystone position in the trophic web of the invaded system and interacts strongly with various trophic levels. It efficiently grazes on macrophytes and is one of the main factors, besides the impact of flamingos, cattle and introduced fish, of the change of many water bodies from a macrophyte dominated, clear water equilibrium to a phytoplankton driven turbid water balance. Juveniles feed on protein rich animal food with the corresponding impact on the macroinvertebrate community in competition with other crayfish or fish species. At the same time, it serves as a prey for mammals, birds and fish. Due to its predatory and grazing activity, it efficiently canalises energy pathways reducing food web complexity and structure. Feeding also on detritus it opens, especially in marshlands, the detritic food chain to higher trophic levels which results in an increase of crayfish predators. As a vector of diseases, it has a severe impact on the preservation and reintroduction of native crayfish. *P. clarkii* accumulates heavy metals and other pollutants in its organs and body tissues and transmits them to higher trophic levels. Due to the long history of its presence, the complex interactions it established within the invaded ecosystems and the socio-economic benefits it provides to humans, prevention and control seem the most promising management measures to reduce the negative impact of this crayfish species." (Authors) Odonata rarely were represented in crayfish traps.] Address: Geiger, W., Departamento de Ecología, Universidad Autónoma de Madrid, 28049 Madrid, Spain. E-mail: walter.geiger@uam.es

8593. Larsen, R. (2005): Navajo word for dragonfly. *Argia* 17(3): 41. (in English) ["Robert Larsen recently circulated a list of Odonata from the Navajo Nation homeland. In this he reveals that on the Navajo homeland ("Dine'Tah"), odonates are called "Tani-l'ai".] Address: not stated

8594. Lee, Y.-F.; Mccracken, G.F. (2005): Dietary variation of Brazilian Free-tailed bats links to migratory populations of pest insects. *Journal of Mammalogy* 86(1): 67-76. (in English) ["We examined food habits of Brazilian free-tailed bats (*Tadarida brasiliensis*) at 3 colonies in central Texas over 3 summers. Fecal samples collected from 1,550 bats contained remains of 12 orders and 35 families of insects, documenting the most diverse diet ever reported in insect-eating bats. Daily and seasonal patterns of insect consumption were similar at the 3 sites and closely correlated to patterns of emergence, migration, and availability of adult populations of corn earworms *Helicoverpa zea* and fall armyworms *Spodoptera frugiperda*, both species of noctuid moths and major crop pests. The percentage of feces volume comprised by moth remains increased from 14.8% \pm 2.1 SE (range: 6.3–43.7%) to 43.0% \pm 7.1 (range: 1.7–73.5%) in samples collected at midnight versus dawn on days when large influxes of migratory moths arrived in Texas in early morning, following their massive emergence from northern Mexico. Daily patterns diminished later in the season, after moth populations became established in local crops and were available in large numbers throughout night. Moth consumption decreased in both evening and dawn feeding periods when crops senesced and moth populations declined. These and other data suggest that crop pests comprise a substantial portion of the bats' diet and that bats provide valuable natural pest control services." (Authors) Odonata represented 0.2% to the diet items of *T. brasiliensis*.] Address: Lee, Y.-F., Dept Life Sciences & Inst. Biodiversity, National Cheng Kung Univ., Tainan 701, Taiwan

8595. Matthews, J.H. (2005): Long-distance migration and emergence patterns in *Anax junius*: review of work to date. *Argia* 17(3): 29-30. (in English) [The author refers current knowledge on the bimodal emergence pattern in *A. junius* (residents/overwintering population in late spring/summer, while migrants emergence in later summer/autumn), records of (rare) overwintering larvae at the northern range limit of the species distribu-

tion (in Canada), and migration events of the species. He outlines his own attempts to get additional information on the migration system of *A. junius* (running dissertation).] Address: Matthews, J.H., USGS/Oregon State University, 541/738-0386, USA. E-mail: johoma@gmail.com

(in English) [USA; Paris Mountain State Park: 22 species; Jones Gap State Park: 17 species.] Address: Worthen, W.B., Dept Biology, Furman Univ., Greenville, SC 29613, USA. E-mail: worthen@furman.edu

2006

8612. Albertoni, E.F.; Palma-Silva, C. (2006): Macroinvertebrates associated with floating macrophytes in urban channels (Balneário Cassino, Rio Grande, RS, Brazil). *Neotropical Biology and Conservation* 11(2): 90-100. (in Portuguese, with English summary) ["The Bal-

neario Cassino is located at south coastal plain of Rio Grande do Sul State. It has channels to pluvial running in all of its extension, with dense stands of floating macrophytes. The aim of this study was to characterize macroinvertebrates associated with these macrophytes, which were sampled in five sampling points (P1 *Pistia stratiotes*; P2 *Spirodela intermedia*; P3 *Eichhornia crassipes*; P4 *Salvinia minima* and P5 *Eichhornia crassipes*), monthly, with a net (500 μ m mesh size) in triplicates, between March 2000 and February 2001. The macrophytes were washed on 500 μ m mesh size sieve, the retained material preserved in 80 % alcohol and then separated at stereomicroscope. The plants were dried (60°C) to obtain the dry weight. At each point dissolved oxygen, temperature, pH and electric conductivity, and nutrient (P and N) concentrations were measured. The associated community was assessed with taxa abundance and occurrence, and calculated the Shannon-Wiener diversity index and homogeneity (Jf, Pielou). The Dice-Sorensen similarity among plants was estimated. *Eichhornia crassipes* (P5) had the highest relative density (116,723.61 org. 100g DW⁻¹) and the higher taxa number (46). In all plant species Chironomidae (Diptera), Oligochaeta and Copepoda predominated in abundance and density. The associated community showed high similarity among macrophyte species, with significant difference in Hf ($p < 0.05$), varying between 2.51 (*E. crassipes* P3 in spring) and 0.98 (*S. minima* P4 in summer). Low concentration of dissolved oxygen (between 1.4 and 7.6 mg.L⁻¹) and high nutrient concentration (total-P between 0.01 and 4.81 mg.L⁻¹, and total-N between 0.35 and 14.94 mg.L⁻¹) suggesting an eutrophication process in these channels, mainly during summer months, when increased population and domestic sewage contribution to this systems. This process is reflected by macroinvertebrate community, by the predominant groups, and indicates the deterioration of water quality of these channels." (Authors) Odonata are treated at the family level.] Address: Albertoni, E.F.; Laboratório de Ecologia e Limnologia, Depto de Ciências Morfobiológicas, Fundação Universidade Federal do Rio Grande (FURG), Avenida Itália, km 8, Caixa Postal 474, Rio Grande, RS, 96.201-900, Brasil. 8619. Braccia, A.; Voshell, J.R. (2006): Benthic macroinvertebrate fauna in small streams used by cattle in the Blue Ridge Mountains, Virginia. *Northeastern Naturalist* 13(2): 269-286. (in English) ["Cattle production is a common land use, and the adverse effects of cattle grazing on stream habitat and macroinvertebrates has been well documented. The purpose of our study was to provide a list of taxa that can be expected to occur in small streams impacted by cattle in the southern Blue Ridge Mountains and to demonstrate how taxon-specific natural history information can be used to gain insight about benthic habitat condition. We identified 97 benthic macroinvertebrate taxa (including *Cordulegaster*, *Gomphus*, *Lanthus*, and *Stylogomphus albistylus*) from five cattle-impacted streams that differed in cattle grazing intensity. Our findings suggest that some macroinvertebrate taxa can sustain low levels of cattle grazing and that sedimentation is a major stressor to the macroinvertebrate fauna." (Authors)] Address: Braccia, Amy, Department of Entomology. Blacksburg, Virginia, USA; E-Mail rvoshell@vt.edu

- 8630.** Casey, R.E.; Simon, J.A.; Atueyi, S.; Snodgrass, J.W.; Karouna-Renier N.; Sparling, D.W. (2006): Temporal trends of trace metals in sediment and invertebrates from stormwater management ponds. *Water Air Soil Pollution* 178: 69-77. (in English) ["Stormwater ponds are an increasingly common feature in urban landscapes. Because these ponds retain runoff and particulate-bound contaminants from impervious surfaces, organisms inhabiting stormwater ponds may be exposed to elevated metal levels in sediments. This study evaluated temporal changes in sediment and macroinvertebrate Cu, Pb and Zn over an eleven-year period with specific attention to land use in pond watersheds. Sediment and invertebrate metal levels were quantified using atomic absorption spectrophotometry (1993 samples) or inductively coupled plasma mass spectrometry (2003–2004 samples). Sediment trace element levels did not significantly change from 1993 to 2003-2004 with the exception of Zn in ponds receiving runoff from highways, which increased from a mean of 32 mg kg⁻¹ in 1993 to 344 mg kg⁻¹ in 2003–2004. Sediment Pb and Cu generally remained below published threshold effects concentrations (TEC) except for two instances of elevated Cu in 2003–2004. Zn remained below the TEC in 1993 but exceeded the TEC in six ponds in 2003–2004. Trace metal body burdens varied among invertebrate groups, and to a lesser extent among land uses, but in both cases this variation was a function of year. In general, trace element body burdens were more similar among invertebrate groups or land use or both during 2003–2004 when compared to levels in 1993. Our results suggest sediment and invertebrate trace metal levels are at steady state in these stormwater management ponds and that risk to organisms in-

habiting these ponds does not vary as a function of pond age. [...] In general, Cu, Pb and Zn levels were lowest among odonates, composite samples and molluscs, respectively." (Authors) Address: Casey, R.E., Department of Chemistry, Towson University, 8000 York Rd., Towson, MD 21252-0001, USA. E-mail: racasey@towson.edu

8641. Hung, K.-y.; Lin, Y.-s.; Severinghaus, L.L. (2006): Comparison of three common methods for studying the diet of nestlings in two *Accipiter* species. *Zoological Studies* 45(2): 234-243. (in English) ["Food provisioning to 4 *Accipiter virgatus* nests and 2 *A. trivirgatus* nests was monitored during 1998 and 2000 in Yangmingshan National Park, Taipei, Taiwan. We made direct observations of prey deliveries and collected prey remains and pellets throughout the breeding seasons in order to compare the effectiveness and efficiency of the different diet analysis methods for these 2 raptor species. The method of using prey remains worked best for *A. virgatus* for all measurements, producing 45.23% of all prey items found, 45.23% of all prey items identified to prey taxa, and 38.87% of all prey items identified to species. The observation method worked best for *A. trivirgatus*, providing 41.05% of all prey items and 18.95% of prey items identified to species, but the proportion of prey items identified to prey taxa was highest using the pellet method (37.37%). Time efficiency was consistently the highest for the prey remains method in *A. virgatus*. In contrast, for *A. trivirgatus*, the pellet method was most efficient for assessing the number of prey items delivered and the number identified to prey taxa, but the prey remains method worked best for

identifying prey to species. Combining the prey remains and pellet methods increased the prey taxa identified to 81.63% for *A. virgatus* and 58.95% for *A. trivirgatus*. Although the value of direct observation has been stressed by many researchers, its effectiveness varied between these 2 species studied in Taiwan." (Authors) *A. virgatus* preyed upon *Anotogaster sieboldii*.] Address: Severinghaus, Lucia Lin, Research Center for Biodiversity, Academia Sinica, Taipei, Taiwan 11528, R.O.C. - 8655.** Schneider, T. (2006): Die Libellenfauna an der Schmalen Sinn vor und nach Einbürgerung des Bibers (*Castor fiber albicus*). Beiträge zur Naturkunde in Ost-hessen 43: 61-74. (in German, with English summary) ["The odonata fauna of the trout region brook „Schmale Sinn" in the secondary chain of mountains in the south-east of Hessen (Central Germany) is poorly investigated. The introduction of the beaver at the end of the 80th in the last century resulted in changes in the environment with the creation of beaver ponds in this region. The analysis of the Odonata fauna in this region over a long period prior and after the introduction of the beaver revealed an increase of species from 19 before to 26 after the establishing of a stable beaver population. Not all of the changes of the Odonata fauna in this period were due to the creation of ponds by the beavers. The disappearance of one specie (*Orthetrum coerulescens*) was already established several years before the beaver was introduced. From 8 species new in the region, 2 (*Gomphus pulchellus*, *Aeshna mixta*) appeared at the same time at the beaver pond and at several other biotopes of the region. The introduction of the beaver in the trout region brook „Schmale Sinn" had no negative effects on the autochthonous Odonata fauna, in contrary the spectrum and abundance of species increased." (Author)] Address: Schneider, T., Arnold-Knoblach-Ring 76, 14109 Berlin/Wannsee, Germany. E-mail: karin.thomas.schneider@gmx.de

- 8664.** Wasscher, M.T. (2006): Van NLO tot NVL, 35 jaar georganiseerde libellenstudie in Nederland. *Brachytron* 9(1/2): 21-32. ["Before 1970 some people in The Netherlands were studying dragonflies, but there was no higher organisation with newsletters and/or meetings. Since the start of the NLO on 7 March 1970, three periods of 'official' dragonfly activity can be recognised. These periods were separated by intervals of lesser activity, where no meetings were organised and few, if any, official newsletters were published. In those intervening periods, there were always youth federation members studying dragonflies, and those dragonfly lovers would then start the next period of official dragonfly study in The Netherlands. The first period commenced with the formation of the NLO during 1970, under the leadership of Bastiaan Kiauta. This period ended with the foundation of the international SIO in 1974. The second period lasted from 1979 to 1992 and was started by Marian Verdonk, with Marcel Wasscher gradually taking over her tasks. The final period, which is still on-going, started in 1994, though already in 1992 youth federation members of the NJN had started a 'Dragonfly Project' which would result in increased interest in dragonflies in The Netherlands. In 1997 both the NLO and the Dragonfly Project merged into a new

dragonfly organisation, the NVL. In 2002 the Dutch Atlas was published, a milestone in dragonfly study in The Netherlands. Over the last decade, dragonflies have become an important group for nature study and nature management. This is illustrated by an official Red List, two field guides in Dutch, 22 regional and provincial study groups and over 400 members of the NVL, some of whom are also professional dragonfly workers." 8668. Besprozvannykh, V.V. (2007): Life cycle of the trematode *Halipegus japonicus* (Halipegidae) in Primorskiy Krai (Russia). *Vestnik Zoologii* 41(1): 23-28, 95. (in Russian with English and Ukrainian summaries) [*H. japonicus* Yamaguti, 1936 involves the fresh water snails *Helicorbis suffunensis* and *Polypylis semiglobosa* as first intermediate hosts, ostracode crustaceans as second and larvae of the dragonflies *Cordulia* and *Aeshna* as third intermediate host. A possibility of involvement of the fish species *Percottus glehni* and *Pseudobagrus fulvidraco* into the life cycle of the trematode is shown; the parasite is localized in the fish esophagus on its early stages.] Address: Besprozvannykh, V.V., Biologo-pochvennyi institut DVO RAN, prosp. 100-let Vladivostoky, 159, Vladivostok, 690022, Russia

8669. Boyce, W.M.; Lawler, S.P.; Schultz, J.M.; McCauley, S.J.; Kimsey, L.S.; Niemela, M.K.; Nielsen, C.F.; Reisen, W.K. (2007): Nontarget effects of the mosquito adulticide pyrethrin applied aerially during a West Nile virus outbreak in an urban California environment. *J. Am. Mosq. Control. Assoc.* 23: 335-339. (in English) ["In August 2006, a pyrethrin insecticide synergized with piperonyl butoxide (EverGreen Crop Protection EC 60-6, McLaughlin Gormley King Company, Golden Valley, MN) was sprayed in ultralow volumes over the city of Davis, CA, by the Sacramento-Yolo Mosquito and Vector Control District to control mosquitoes transmitting West Nile virus. Concurrently, we evaluated the impact of the insecticide on nontarget arthropods by 1) comparing mortality of treatment and control groups of sentinel arthropods, and 2) measuring the diversity and abundance of dead arthropods found on treatment and control tarps placed on the ground. We found no effect of spraying on nontarget sentinel species including dragonflies (*Sympetrum corruptum*), spiders (*Argiope aurantia*), butterflies (*Colias eurytheme*), and honeybees (*Apis mellifera*). In contrast, significantly higher diversity and numbers of nontarget arthropods were found on ground tarps placed in sprayed versus unsprayed areas. All of the dead nontarget species were small-bodied arthropods as opposed to the large-bodied sentinels that were not affected. The mortality of sentinel mosquitoes placed at the same sites as the nontarget sentinels and ground tarps ranged from 0% to 100%. Dead mosquitoes were not found on the ground tarps. We conclude that aerial spraying with pyrethrins had no impact on the large-bodied arthropods placed in the spray zone, but did have a measurable impact on a wide range of small-bodied organisms." (Authors)] Address: Boyce, W.M., Wildlife Health Center, University of California, One Shields Avenue, Davis, CA 95616, USA

8670. Buczyński, P. (2007): Dragonflies (Odonata) of the valley of the River Bug between Gołębie and Włodawa. *Nowy Pam. Fizjogr., Warszawa* 5(1-2): 3-26. (in Polish, with English summary) [The article presents faunistic and ecological data on the Odonata of the middle part of the River Bug valley (Poland) gathered during long-term studies in the years 1993-2005 (mainly 2000-2003), in the vicinity of 24 localities, and resulting in records of 52 dragonfly species (71% of the Polish dragonfly fauna).] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

8671. Kefford, B.J.; Salter, J.; Clay, C.; Dunlop, J.E.; Nugegoda, D. (2007): Freshwater invertebrates' response to gradients of salinity and turbidity: using pref-

erence as a rapid sub-lethal test. *Australasian journal of ecotoxicology* 13: 131-142. (in English) ["This study investigates the use of a sub-lethal rapid toxicity testing method that allows animals to move within a concentration gradient in an attempt to measure a sub-lethal response of preference to inhabit a particular contaminant concentration. We describe a testing apparatus and trial its use in assessing the preferences of selected riverine invertebrates (collected from Victoria, Australia) for two common river contaminants, salinity and turbidity [simulated by suspended fine sediment (standardised clay, kaolin)]. For salinity preference experiments, the testing apparatus was found to be unsuitable for use with small macroinvertebrates due to the need to use vigorous aeration to mix the test solution in order to prevent horizontal stratification. However, aerated salinity preference tests were successful using the freshwater shrimp *Paratya australiensis* (Decapoda: Atyidae), and indicated their preference for salinity <17.6-18.8 μ S/cm. This observed preference for low salinity was unchanged by acclimation to salinity of 0.1, 10 or 20 μ S/cm prior to testing. A dispersion of suspended particulates was used for turbidity preference experiments, and so vigorous aeration was unnecessary. When used in this way the test apparatus was found to be suitable for testing all stream macroinvertebrates tested (nine species including *Ischnura aurora* and *I. heterosticta*) and one microinvertebrate. One test species, *Micronecta annae* (Hemiptera: Corixidae), was observed to prefer relatively high turbidity (>200 NTU) but only when collected from one of two locations. Another species, *Austrochiltonia subtenuis* (Amphipoda: Hyalellidae), showed weak evidence for a preference for lower turbidity (<200 NTU). It is unknown whether the lack of turbidity preference shown for the other seven species is because turbidity is not directly harmful or whether they are not able to detect and/or avoid certain turbidity levels. When preference experiments find that most species show no preference to a specific contaminant, then another approach will be needed to establish their sensitivity." (Authors) *Ischnura aurora* appeared unsuitable for preference testing in the device. Their movement was restricted by air bubbles and the lack of suitable substrate for them to attach. *Ischnura heterosticta* was observed across the spectrum of turbidity levels examined.] Address: Kefford, B., Biotechnology & Environmental Biology, School of Applied Sciences, RMIT University, PO Box 71, Bundoora, Victoria 3083, Australia. E-mail: ben.kefford@rmit.edu.au

8672. Silva F.J.; Callisto, M. (2007): Benthic macroinvertebrates collection: a tool for the knowledge of freshwater biodiversity. *Neotropical Biology and Conservation* 2(1): 3-10. (in Portuguese, with English summary) ["Zoological collections can be considered important registries of freshwater biodiversity for academical and research activities. The objective of this study was to organize a database of the diversity of benthic indicators of water quality collected in many freshwater ecosystems. The Benthic Macroinvertebrates Reference Collection of the Laboratory Ecology of Benthos, Institute of Biological Sciences, Federal University of Minas Gerais was created in 1997. This collection comprises 16,500 registers from different lotic and lentic ecosystems in Brazil and other countries. The taxa (with one or more organisms) are preserved in tubes, glasses, and wardrobes. In the tomb notebooks are registered: the taxonomical identification, origin, collection method, number of individuals, sample number and field obser-

ations. Besides the maintenance of the Reference Collection, a database is being constructed with the benthic biodiversity information. Up to this moment, the database has almost 71,000 registers preserved in 6,000 tubes and in 174 glasses. The incorporation of new organisms to the Collection is of c. 7,100.00 (+ 7,471.67) organisms per year. The aquatic insects are the main abundant and taxonomic diverse in the Collection. Diptera, Ephemeroptera, and Trichoptera were the most numerical important groups, with respectively 37.9%, 16.7%, and 14.5%. Among the Dipterans, Chironomidae comprises 59 genera. This Reference Collection represents an important tool for knowledge of benthic biodiversity in lotic and lentic ecosystems, allowing later taxonomical identification, and the development of population dynamics and community structure studies, due to the increase deposit of knew material. Moreover, it is of paramount importance to guarantee future taxonomical, biogeographical, phylogenetical and ecological studies, using this material." (Authors) Odonata are treated at the family level.] Address: Callisto, M., Univ. Federal de Minas Gerais, Instituto de Ciências Biológicas, Departamento de Biologia Geral, Laboratório de Ecologia de Bentos. CP. 486, CEP. 30.970-201, Belo Horizonte, MG, Brasil. E-mail: callisto@icb.ufmg.br

8673. Verdonschot, R.C.M.; Groenendijk, D.; Bouwman, J.H. (2007): Dragonflies on shallow soft-water lakes in Noord-Brabant; a first attempt for a synecological analysis of the Dutch national dragonfly database. *Brachytron* 10(2): 185-193. (in Dutch, with English summary) ["Shallow soft-water lakes are one of the most Odonata rich habitats in the Netherlands. Different types of shallow soft-water lake ecosystems are distinguished to test whether the Odonata species composition of those waters reflect this classification. A comparison was made of observations of adults at 13 shallow soft-water lakes. In the province of Noord-Brabant, which is situated on sandy soils in the southern part of the Netherlands, information about the species composition was gathered using the database of Odonata observations of the Netherlands, considering the period 1990-2003, the months may-august. TWINSPAN was used to analyse the species composition data. Because observations from the database are used, there is a lot of uncertainty regarding investigated area, search time, number of individuals. Therefore, only present/absent data were used. Despite this drastic transformation, the analysis shows that the species composition of shallow soft-water lakes fed by rain water differs from lakes which are fed by both rain water and buffered ground water. The lakes fed by buffered ground water were characterised by *Aeshna grandis*, *A. mixta*, *A. cyanea*, *Erythromma najas*, *Brachytron pratensis* and *Cordulia aenea*. The lakes fed by rainwater were characterised by *Lestes dryas* and *Libellula depressa*." (Authors)] Address: Bouwman, J., De Vlinderstichting, Postbus 506, 6700 AM Wageningen, The Netherlands. E-mail: jaap.bouwman@vlinderstichting.nl

8674. Waldhauser, M.; Waldhauserova, I. (2007): Interesting findings of dragonflies (Odonata) in the Liberec Region. *Sborník Severočeského Muzea, Přírodní Vědy*, 25: 39-48. (in Czech, with English summary) [Records of the following species from the Liberec Region, Czech Republic are presented: *Aeshna affinis*, *A. caerulea*, *Brachytron pratense*, *Sympetrum depressiculum*, *S. fonscolombii*, *S. meridionale*, *S. pedemontanum*, *Somatochlora alpestris*, *S. arctica*, *Cordulegaster*

bidentata, *Ophiogomphus cecilia*, *Gomphus vulgatis-simus*, *Leucorrhinia albifrons*, and *L. pectoralis*.] Address: Waldhauser, M., Petrovice 136, 471 25 Jablonné v Podještědí, Czech Republic.

8675. Wang, Y.-n.; Leong, R.; Tian, P.-t.; Chan, M.-h.; Liu, S.W.; Chang, C.-s. (2007): Using biological investigation to evaluate the landslide rebuilt at experimental forest of NTU. *Journal of Experimental Forest of the National Taiwan University* 21(4): 307-319. (in Chinese, with English summary) [We collected 143 landslide rebuilt cases that were restored between 2001 and 2002 at Experimental Forest of National Taiwan University to evaluate the restoring effectiveness by using biological investigation. Important vegetation index (IVI), birds diversity index (BDI), and aquatic insect community parameters index (AICPI) were applied for biological investigation. Our data showed that major vegetation in landslide rebuilt are *Miscanthus floridulus*, *Arundo formosana*, *Trema orientalis*. The performance of silviculture of *Acacia confusa* and *Alnus formosana* silvicultures were better than *Zelkova serrata*. BDI at BeSer creek watershed was better than Chenyolan creek. However, BDI was not different with different technics and construction situation, while BDI could be differed with the size of landslide area. We collected 26 families and 32 taxa aquatic insects, mainly in Ephemeroptera and Trichoptera. Aquatic insect diversity was 1.94 – 2.03, and evenness was 0.63 – 0.69. Water quality assessed by aquatic insects biotic index was at good scale for most landslide rebuilt cases, except site 1 at fine scale." (Authors) *Euphaea formosa* was recorded at two sites.] Address: E-mail: cannon@exfo.ntu.edu.tw

(2008): Invasive species threats to native aquatic insect biodiversity and conservation measures in Hawai'i and French Polynesia. *Journal of Insect Conservation* 12(3-4): 415-428. (in English) ["Impacts of invasive species, and of attempts to control them, on the aquatic invertebrate fauna of Hawaii and French Polynesia are reviewed and discussed, as a foundation for determining conservation need. Aquatic insects are poorly documented in the region, with many species undescribed, so that practical conservation must be pursued with highly incomplete basic taxonomic knowledge. The establishment of at least one dedicated reserve for aquatic invertebrates is recommended for each high island in an archipelago, as an aid to safeguarding local endemic species, and other recommendations include increased monitoring for new alien species (particularly of fish), planning for removal of alien species from selected water bodies where alien species are less likely to recolonize, effective protection of key sites with high biodiversity value, and securing sites for future restoration and translocation or rare and endangered species." (Author) Many references to Odonata are made.] Address: Englund, R.A., J. Linsley Gressitt Center for Entomological Research, Bishop

8679. Harp, G.; Harp, P.; McCord, S. (2008): Aquatic macroinvertebrates collected from thirty-two Missouri Ozark streams. *Journal of the Arkansas Academy of Science* 62: 61-74. (in English) ["A previously reported study of the distribution and status of an endemic dragonfly in Missouri, USA emphasized data collected by aerial netting and examination of specimens housed in the Wilbur Enns Museum of Entomology. Dip net samples were also taken, however, to find naiads of the target species at sites where adults might not have been found and to determine whether there were associated species. Forty-one collections were made in 32 Ozark streams between mid-May and early June 1999-2000." (Authors) Odonata represent 64 of the 372 taxa identified, in most cases identified at the species level, in some cases at the genus level. The taxa are listed locality wise.] Address: Harp, G., Department of Biological Sciences, Arkansas State University, State University, AR 72467, USA. E-mail: glharp@astate.edu

8680. Kaynas, B.Y.; Gürkan, B. (2008): Species richness and abundance of insects during post-fire succession of a *Pinus brutia* forest in Mediterranean region. *Polish Journal of Ecology* 56(1): 165-172. (in English) ["In the Marmaris National Park (located on the Mediterranean coast of SW Turkey) mostly covered with *Pinus brutia* forests, four sites were selected to study the post-fire successional trends in vegetation and insect communities. The sites represented: 1, 5, and 21 years after fire as well as control site (more than 45 years after fire). On the study plots (0.5 ha) the insects were collected with the sweep net swung along three transects each of 100 m length, in monthly intervals between August 2000 and September 2001. The number of plant species decreased from 41 to 32 along succession, as well as the number of stage-specific species but the mean height of vegetation increased with successional stage. The abundance and species richness of herbivorous insects decreased along succession as well as two main herbivore groups – xylophagous and sap-feeders. However, no major changes were found between the sites in terms of abundance or species richness of predators. This decrease in herbivorous forms may be a result of changes in the plant architecture and vegetation structure between post-fire successional stages." (Authors) Odonata are treated at the order level.] Address: Kaynas, B.Y., Hacettepe University, Faculty of Science, Biology Department 06800 Beytepe-Ankara, Turkey. E-mail: bkaynas@hacettepe.edu.tr

8681. Ketelaar, R.; Bouwman, J. (2008): A reconstruction of the dragonfly and butterfly fauna of the Koningsven (Odonata, Lepidoptera). *Nederlandse faunistische mededelingen* 29: 5-20. (in Dutch, with English summary) ["The Koningsven ('Kings peat') is a former peat moor in the eastern part of the Netherlands. It

was almost completely reclaimed in the first half of the twentieth century, leaving only a tiny bit of 7 hectare of wetland. The area has a reputation as former habitat of rare and threatened plant species. Old publications show its enormous natural value. Recently, plans have been developed to renaturalise the area and restore the Koningsven. For a better understanding of the natural history of the area, a reconstruction of the former fauna of dragonflies and butterflies was based on records in literature and faunistic databases. It is shown that the Koningsven was a very important biodiversity hot spot for dragonflies and, to a lesser degree, butterflies. Dragonflies like *Nehalennia speciosa*, *Coenagrion hastulatum*, *Leucorrhinia caudalis* and *L. pectoralis* are nowadays rare, threatened or even extinct in the Netherlands and northwestern Europe. [...] At present it is likely that nowhere in northwestern Europe a similar habitat and species composition can be found. The planned renaturalisation will hopefully contribute to at least a partial recovery of this extraordinary fauna." (Authors)] Address: R. 8684. McCauley, S.J.; Davis, C.J.; Werner, E.E. (2008): Predator induction of spine length in larval *Leucorrhinia intacta* (Odonata). Evolutionary Ecology Research 10: 435-447. (in English) ["Questions: Do larvae of a dragonfly with a broad habitat distribution have longer abdominal spines when they co-exist with fish, and are these differences the result of phenotypic plasticity? Hypothesis: Phenotypic plasticity will result in larvae having longer spines when they are exposed to cues from predatory fish. Organism: Larvae of *L. intacta* (Research site: Natural ponds and cattle tanks on the E.S. George Reserve in southeast Michigan. Methods: We compared the morphology of larvae collected from two natural ponds before and after a drought resulted in the extirpation of fish from one pond. We also compared spine morphology of larvae reared in an experiment where they were either exposed to caged fish or empty cages. Finally, we use a phylogeny for this genus to begin reconstructing the evolutionary history of plasticity and spine morphology within *Leucorrhinia*. Results: Larvae collected from ponds with fish present had longer spines than larvae collected from ponds without

fish. In the experiment, exposure to fish resulted in longer spines for some but not all of the spines measured. These results indicate that at least some of the variation in spine length is the result of plasticity. *L. intacta* is not a sister species to a European *Leucorrhinia* in which similar plasticity has been found. Mapping plasticity on to the phylogeny of this genus indicates that either plasticity is ancestral to the two major clades of this genus or that it has arisen independently twice." 8685. Miyaguchi, H.; Katsuura, M.; Yamamoto, R.; Hirabayashi, T.; Ban, S.; Toda, T.; Yamamoto, H. (2008): Aquatic invertebrate fauna in Tohorogawa mire, eastern Hokkaido. Japanese Journal of Limnology 69: 143-153. (in Japanese, with English summary) [Japan; "To clarify the characteristics of the aquatic invertebrate fauna in Tohorogawa mire, we collected aquatic invertebrates from peat soils, peat-excitation pools and the Tohorogawa River, in May 2005 and June 2006. As a result, 83 taxa of aquatic invertebrates were found in the study site. Northern species included [...] *Libellula quadrimaculata asahinai*, [...], while southern species were [...] *Orthetrum albistylum speciosum* [...]. The proportion [sic: only three taxa are documented!] of northern species of Odonata and Coleoptera in Tohorogawa mire was similar to that found in other mires in eastern Hokkaido. This indicates that Tohorogawa mire allows the inhabitation of northern species at the same level as the other mires in eastern Hokkaido. The northern species were distributed in peat-excitation pools where the water temperature is comparatively low, while the southern species were found in peat soil where the water temperature is relatively high. Therefore, it is concluded that the significant spatial difference in water temperature is a major factor allowing the coexistence of northern and southern aquatic invertebrates in Tohorogawa mire." 8686. Mrosovsky, N.; Godfrey, M.H. (2008): The path from grey literature to Red Lists. Endang. Species Res. 6: 185-191. (in English) ["This paper concerns the process by which Red List designations are decided and supported; it does not concern whether the past or present Red List categorizations are correct. We argue that, contrary to statements extolling the scientific and authoritative nature of the Red List, the reality for some species falls far short of these ideals. The prominent role played by the grey literature is an important factor in these problems. We use the case of the hawksbill turtle *Eretmochelys imbricata* as an example of the problems with relying on unavailable grey literature, but similar problems apply to various taxa classified in the Red List." (Author) The case of *Pseudagrion newtoni* is briefly outlined: Occurrence of grey literature (including personal communications) in selected Red List (RL) assessments (retrieved from the IUCN Red List website (www.redlist.org)) show, that 8 of the 9 citations are based on published information.] Address: Mrosovsky, N., Department of Ecology and Evolutionary Biology, University of Toronto, 25 Harbord Street, M5S 3G5 Toronto, Ontario, Canada. - 8690.** Srygley, R.B.; Dudley, R. (2008): Optimal strategies for insects migrating in the flight boundary layer: mechanisms and consequences. *Integrative and Comparative Biology* 48(1): 119-133. (in English) ["Directed aerial displacement requires that a volant organism's airspeed exceeds ambient wind speed. For biologically relevant altitudes, wind speed increases exponentially with increased height above the ground. Thus, dispersal of most insects is influenced by atmospheric conditions. However, insects that fly close to the Earth's surface displace within the flight boundary layer where insect airspeeds are relatively high. Over the past 17 years, we have studied boundary-layer insects by following individuals as they migrate across the Caribbean Sea and the Panama Canal. Although most migrants evade either drought or cold, nymphalid and pierid butterflies migrate across Panama near the onset of the rainy season. Dragonflies of the genus *Pantala* migrate in October concurrently with frontal weather systems. Migrating the furthest and thereby being the most difficult to study, the diurnal moth *Urania fulgens* migrates between Central and South America. Migratory butterflies and dragonflies are capable of directed movement towards a preferred compass direction in variable winds, whereas the moths drift with winds over water. Butterflies orient using both global and local cues. Consistent with optimal migration theory, butterflies and dragonflies adjust their flight speeds in ways that maximize migratory distance travelled per unit fuel, whereas the moths do not. Moreover, only butterflies adjust their flight speed in relation to endogenous fat reserves. It is likely that these insects use optic flow to gauge their speed and drift, and thus must migrate where sufficient detail in the Earth's surface is visible to them. The abilities of butterflies and dragonflies to adjust their airspeed over water indicate sophisticated control and guidance systems pertaining to migration."] (Authors)] Address: Srygley, R.B., USDA-Agricultural Research Service, 1500 N. - 8691.** Stewart, T.W.; Downing, J.A. (2008): Macroinvertebrate communities and environmental conditions in recently constructed wetlands. *Wetlands* 28(1): 141-150. (in English) [Iowa, USA; "We quantified macroinvertebrate community characteristics in nine temporary or permanent wetlands, and related these to environmental conditions. Macroinvertebrates inhabiting the water column and shallow sediment (42-cm depth) were sampled 20 months after wetland construction in June 2005. A total of 29 taxa were collected, and macroinvertebrate communities varied among wetlands. Total macroinvertebrate biomass (mean 6 SE 5 16.44 6 4.72 g AFDW/m³) and densities (mean 6 SE 5 372,096 6 124,972 individuals/m³) were positively related to coarse particulate organic matter abundance (living and nonliving plant matter; CPOM) and negatively related to turbidity. Density of ecologically sensitive EOT (Ephemeroptera, Odonata, Trichoptera) taxa was also positively related to CPOM and negatively related to turbidity. Total taxa richness was negatively related to turbidity, and percent of total macroinvertebrate density consisting of EOT (% EOT) was positively related to CPOM. These relationships were greatly influenced by 10 dominant taxa (nematodes, physid snails, mites, small squaregill mayflies, narrowwinged damselflies, biting midges, non-biting midges, ostracods, cladocerans, and cyclopoid copepods) that were positively associated with CPOM and negatively related to turbidity. Two wetlands inhabited by common carp (*Cyprinus carpio*) appeared to be in the poorest condition. These wetlands had the lowest macroinvertebrate biomass and densities and highest turbidity. Additionally, although net uptake of total nitrogen (TN) occurred in these high-turbidity wetlands, NH₃ concentrations were two-fold higher in outflow than inflow. Net uptake of total phosphorus (TP) occurred only in wetlands with low turbidity, high CPOM abundance, and high macroinvertebrate abundance and diversity. To enhance macroinvertebrate abundance and diversity and ecological functions (e.g., nutrient removal) in newly constructed wetlands, management efforts should be directed toward increasing plant abundance and reducing turbidity.] Address: Stewart, T.W., Dept of Natural Resource Ecology & Management, Iowa State Univ. 8693. Tafangenyasha, C.; Dube, L.T. (2008): Evaluation of the usefulness of the South African scoring systems in savanna rivers. *Tropical and Subtropical Agroecosystems* 8: 135-144. (in English, with Spanish summary) ["The usefulness of the South African Scoring Systems (SASS) in a savanna river was studied for an array of lowveld streams. The streams were also characterised using standard chemical methods from August 2004 to May 2005 to complement biological monitoring methods. Nutrients such as total nitrogen, nitrate nitrogen and total phosphates did not show differences ($p>0.05$) between the wet and dry seasons. The SASS and ASPT scores were different ($p<0.05$) between dry and wet season at test sites but not between the dry and wet season at control sites. Site, media and site x media interaction had a significant effect on SASS scores and only site showed significant difference in ASPT scores. Multiple comparison tests using paired t-tests with Bonferoni adjustment showed site effect ($p<0.05$) on total nitrogen, ammoniacal nitrogen, ASPT scores and SASS scores. Media effect showed difference ($p<0.05$) on total nitrogen, nitrate nitrogen and SASS scores. The effect of season was significant ($p<0.05$) on total nitrogen and total phosphate. In this study, nutrient data show that water quality is dynamic and the nutrients change with season because of real changes in nutrient concentrations. The results indicate that SASS indices provide a better measure of water quality since they integrate seasonal influences on changes in water bodies than chemical data that reflect conditions at the time the water samples were taken. The study of seasonal effects on nutrients and water quality has the potential to develop our conceptual understanding of the impact of discharges on the fluvial ecology for an environment that is naturally challenging for organisms, given the temporal variation in river flow, temperature and suspended solids." 8696. Anderson, A.L.; Brown, W.D. (2009): Plasticity of hatching in Green Frogs (*Rana clamitans*) to both egg and tadpole predators. *Herpetologica* 65(2): 207-213. (in English) ["We examined whether embryos of *R. clamitans* would adaptively alter hatching times in the presence of both egg predators (the crayfish *Procambarus nigrocinctus*) and tadpole predators (the dragon nymph *Anax junius*). Under laboratory conditions, we exposed eggs with developing embryos to four experimental treatments that varied in the type of caged predator: egg predator only, tadpole predator only, both predators together, or no predator. As predicted, the presence of an egg predator caused a significant reduction in time to hatching. However, contrary to our prediction, eggs also hatched sooner in the presence of a tadpole predator. Moreover, there was no significant interaction between the effects of the two predators and thus no evidence that *R. clamitans* embryos can distinguish between predator types. We also found significantly lower hatching success in the presence of an egg predator, despite the fact that the predator did not have direct contact with the eggs. These results suggest adaptive early and delayed hatching do not co-occur in this species with this particular predator regime." (Authors)] Address: William D. (in English) ["We present the first cladistic analysis of *Argia* species, focusing on those occurring in North America north of Mexico. Our analysis is based on mitochondrial 16S rDNA and morphological characters of both sexes of adults and immatures. We reexamine classical work on *Argia* taxonomy and phylogeny. Our results agree considerably with previous hypotheses based morphology in an absence of phylogenetic analysis, and thus our work represents and independent test of these previous hypotheses. *Argia* is recovered as monophyletic. The clade composed of *A. funcki* plus *A. lugens* is basal among the species studied here. The species *A. fumipennis*, including the three subspecies, appears to be a paraphyletic assemblage, and thus may warrant being considered separate species as originally described. The feasibility of producing a thorough phylogenetic analysis of the entire genus using multiple sources of data is discussed." 8711. Dijkstra, K.D.B.; Matushkina, N. (2009): Kindred spirits: "Brachythemis leucosticta", Africa's most familiar dragonfly, consists of two species (Odonata: Libellulidae). *International Journal of Odonatology* 12(2): 237-256. (in English) ["Brachythemis leucosticta was found to include two morphotypes, which we consider to represent separate species. Males are separable by the ventral structure of S8 and often differ in the colour of the venation and genital lobe. Females are as yet not reliably distinguishable. Examination of 1,154 males demonstrated that both species are widespread: the true *B. leucosticta* occupies most of tropical Africa and Madagascar, while *B. impartita* (comb. nov.; corrected spelling - neotype P: Ngaoundaba Ranch, Cameroon; in RMNH) ranges north and south of the Sahara, and extends into Eurasia. The two overlap from The Gambia to Ethiopia and south at least to Lake Victoria. The presence of wing bands was scored for all examined males and 970 females. Banded females are frequent in sub-Saharan populations of *B. impartita*, but virtually absent in *B. leucosticta* and northern *B. impartita*. *B. impartita* males become banded shortly after emergence, but *B. leucosticta* becomes so more gradually. Larval morphology and ecology require further study, but some ecological and seasonal segregation may occur in areas of overlap. Of two larval forms described from Uganda, the 'mud form' may pertain to *B. leucosticta*, and the 'sand form' to *B. impartita*." (Authors)] Address: Dijkstra, K.D., Curator of invertebrates, National Zoological Collection of Suriname, University of Suriname, P.O. Box 9212, Paramaribo, Suriname. 8712. DiLeo, C.; Deng, X. (2009): Design of and experiments on a dragonfly-inspired robot. *Advanced Robotics* 23(7-8): 1003-1021. (in English) ["This paper describes the design of dragonfly-inspired robots. Dragonflies demonstrate unique and superior flight performance compared with most other insect species. They are equipped with two pairs of independently controlled wings. The high level of dexterity in wing motion of the dragonfly allows it to hover, fly fast forward, make turns rapidly, fly sideways and even glide. A dragonfly-inspired robot that could effectively mimic those kinematics would potentially exhibit superior flight performance compared with existing designs of insect robots. In this paper, we introduce two generations of robotic dragonfly prototypes developed to implement simplified dragonfly kinematics. Preliminary experiments on kinematics and aerodynamic force measurements of the prototypes are also presented." (Authors)] Address: Deng, X., Dept of Mechanical Engineering, Univ. 8718. Dyatlova, E.S. (2009): Dragonflies (Insecta, Odonata) of the southwestern Ukraine: biodiversity, ecology and conservation. Thesis for a degree of Candidate of Biological Sciences (Ph. D. (Biology)) by speciality 03.00.16 – ecology. Odessa National - Mechnikov University, MES of Ukraine. – Odesa. Autoreferat: 22 pp. (in Ukrainian, with English summary) ["The recent odonate fauna is described. In the study area (Odesa, Mykolaiv and Kherson provinces) 48 species of dragonflies were recorded, belonging to 21 genera and 8 families. Two species and one subspecies (*Sympetrum pedemontanum*, *Coenagrion scitulum* and *Orthetrum coerulescens anceps*) were recorded for the first time in southwestern Ukraine. The fauna of Zmeiny Island in the Black Sea and National Park "Nizhnednestrovsky" in the lower Dniestr river were almost unstudied before our investigations. Two Zygoptera species (*Ischnura elegans* and *Coenagrion pulchellum*) were chosen as model objects for population studies. Age and sex structures of populations and the ratio of female morphs were investigated. Morphometry analysis, fecundity and parasite infestation were studied in two *I. elegans* "infuscans" and "andromorph" female morphs. Based on criteria we have developed, six important dragonfly areas (IDA) were identified. Three IDA are of particular importance: the Danube delta, Dniestr and Dniepr rivers." (Author)] Address: Dyatlova, Elena

8720. Ferreras-Romero, M.; Márquez-Rodríguez, J.; Ruiz-García, A. (2009): Implications of anthropogenic disturbance factors on the Odonata assemblage in a Mediterranean fluvial system: River Guadiamar, southern Iberian Peninsula. *International Journal of Odonatology* 12(2): 413-428. (in English) ["During a period of nine years, from 2000 to 2008, two consecutive studies - one focusing on observations of adult Odonata, the other on collection of larvae - were carried out in the basin of the Guadiamar River in the southwestern Iberian Peninsula. In addition to monitoring Odonata, several environmental variables were assessed, including an index based on macroinvertebrate communities (IBMWP). In April 1998, this river system suffered from an accidental release of a large mass of toxic mining waste, which exterminated macroinvertebrates in the middle and lower parts and floodplain. Several years later, dragonfly communities in these areas were similar to those of unaffected upper reaches. Communities of sites less affected by general human impact were dominated by semivoltine anisopterans. In contrast, headwaters and river reaches where riparian forest had been destroyed many years ago and seasonality of river discharge was boosted by landscape management harboured chiefly uni- or bivoltine species, regardless whether a site had been affected by mining waste or not. Species assemblage was especially poor in lower river reaches that experienced permanent, diffuse urban and agricultural pollution. A few parti-voltine species were recorded, but only in habitats with a high IBMWP index. It seems that over the long term, Odonata respond more to land use and catchment management than other groups included in the IBMWP index." 8721. Fraker, M.E. (2009): Perceptual limits to predation risk assessment in green frog (*Rana clamitans*) tadpoles. *Behaviour* 146(8): 1025-1036. (in English) ["Many prey assess predation risk through information sources that decline in reliability over time (i.e., the information sources indicate a wider range of potential predation risk levels over time until they provide no information about the current predation risk). However, prey may lack the perceptual ability to accurately assess the reliability of ageing information sources. Here, evidence is provided that suggests that *R. clamitans* tadpoles are unable to assess the age of the chemical cue of predatory larval *Anax junius* upon exposure to

cue up to 48 h old (but can at 72 h). As a result, tadpoles may overestimate the level of risk when they encounter aged *Anax* chemical cue, resulting in a disproportionately strong behavioural response. In general, the results suggest that the predation risk assessment of prey depends not only on the objective characteristics of the information source, but also on the perceptual limitations of the prey. Prey may lack the context to accurately assess information sources and may consequently misestimate the actual level of predation risk." 8728. Hilfert-Rüppell, D.; Rüppell, G. (2009): Males do not catch up with females in pursuing flight in Calo-

pteryx splendens (Odonata: Calopterygidae). International Journal of Odonatology 12(2): 195-203. (in English) ["In high densities males of Calopteryx splendens showed alternative reproductive behaviour at the river Oker in northern Germany. One of several tactics was to pursue females. Pursuing flight was filmed in summer 2006 in slow motion. Frame by frame analysis showed that males fly in irregular flight patterns: they showed different lengths of wing beat phases in comparison to females which fly more steadily. Females had significantly lower wing beat frequencies than males. The flight patterns of males depended on their position to other pursuing males and to the pursued female. The possible causes of these flight differences are discussed." (Authors)] Address: Hilfert-Rüppell, Dagmar, Zool. Inst. TU Braunschweig, Fasanenstr. 3, D-38092 Braunschweig, Germany. 8732. Hong, S.J. (2009): Surface ultrastructure of *Plagiorchis muris* growth and developmental stages in rats, the final host. Parasitol. Res. 105(4): 1077-1083. (in English) ["In the excysted metacercaria, the whole fluke surface was covered with peg-shaped tegumental spines. Ciliated sensory papillae (type I) were concentrated around the oral sucker, and non-ciliated sensory papillae (type II) were aligned on the lip of oral and ventral suckers. Several type II papillae were aligned laterally with linear symmetry between the oral and ventral suckers. In juvenile flukes, cytoplasmic processes were band-shaped on the anterior half of the body surface and velvety on the posterior half. In adult flukes, cytoplasmic processes were differentiated into velvety processes, and densities of tegumental spines were reduced on the posterior half of the body. Flukes grew to be elongated and leaf-like as adults and retained a surface ultrastructure that was similar to that of juveniles in terms of the distribution of tegumental spines and sen-

sory papillae. From the above results, the authors suppose that the marked differentiation of cytoplasmic processes and the reduced density of tegumental spines observed on the posterior half of the body surface are closely related to the development of reproductive organs therein. [...] *Sympetrum eroticum* were caught in the rice paddies of Yongho-myon, Koseong-gun, Gyeongsangnam-do, Korea during June and July 1994. They were crushed with a mortar and pestle and digested within artificial gastric juice at 37°C for 1 h. After washing with phosphate-buffered physiological saline (PBS), *P. muris* metacercariae were collected from particulates under a dissecting microscope." (Author)] Address: Hong, S.J., Department of Medical Environmental Biology, Chung-Ang University College of Medicine, Tongjak-gu, Seoul 156-756, South Korea. E-mail: hongsj@cau.ac.kr

8733. Iserbyt, A.; van Gossum, H. (2009): Unexpected absence of behavioural differences between female damselfly colour morphs. Animal Behaviour 78(6): 1463-1469. (in English) ["Males are often selected for higher mating rates than females. As a consequence of this sexual conflict, unreceptive females may suffer fitness costs from excessive male sexual harassment. In a variety of vertebrate and invertebrate species, multiple female morphs coexist in natural populations which have been observed to differ in body colour, in behaviour and also in the amount of male harassment received. However, the degree of harassment on a female morph may depend on the frequency and density of males and female morphs in the population. We quantified harassment rate and subsequent refusal behaviour of males and female morphs of the polymorphic damselfly *Nehalennia irene*. Unexpectedly and contrary to previous work, female morphs received similar amounts of male harassment and showed mostly the same behaviour. We discuss why differences in morph behaviours may be lacking and how this compares to contemporary explanations for the maintenance and evolution of female-limited polymorphisms." (Authors)] Address: Iserbyt, A., Evolutionary Ecology Group, University of Antwerp, Groenenborgerlaan 171, B-2020 Antwerp, Belgium. E-mail: arne.iserbyt@ua.ac.be

8734. Iwasaki, H.; Suda, D.; Watanabe, M. (2009): Foraging activity of *Sympetrum infuscatum* (Selys) adults living in Satoyama Forest gaps (Odonata: Libellulidae). Jpn. J. Appl. Entomol. Zool. 53: 165-171. (in Japanese, with English summary) ["Adult *S. infuscatum* live in the forest gaps throughout their life except when visiting rice paddy fields for oviposition. They prey on small flying insects in the forest gaps, using sit-and-wait tactics. They perch on the tips of branches or grass all day and take off when a small flying insect comes into sight. In the present study, the foraging behaviour of *S. infuscatum* in the forest gaps was observed. The perching height was high in the morning and evening and low around noon. The diurnal change in the perching height corresponded to the abundance of flying small insects. The mean daily frequency of foraging flights was 251 for females and 182 for males, and the mean actual number of insects captured was 109 and 89, respectively. A total of 2,935,300 small flying insects were preyed on by *S. infuscatum* adults during one day in the Satoyama forest gaps." 8751. Ohba, S. (2009): Feeding habits of the diving beetle larvae, *Cybister brevis* Aubé (Coleoptera: Dytiscidae) in Japanese wetlands. *Appl. Entomol. Zool.* 44 (3): 447-453. (in English) ["A number of descriptive reports suggest that *Cybister* larvae feed on tadpoles, fish, and aquatic insects; however, no quantitative study on their feeding habits has been reported. In order to elucidate the feeding ecology of *C. brevis* larvae, field observations and laboratory experiments were carried out. In the field, all *C. brevis* larvae fed on invertebrates, such as insects and isopoda, but did not eat vertebrates, such as fish and anuran larvae. A rearing experiment demonstrated that all *C. brevis* larvae provided with tadpoles died. Larvae provided with Odonata nymphs - [Small damselfly nymphs (Platycnemididae: *Copera* spp. and *Lestes* spp., <15 mm), medium damselfly nymphs (same species, 15-20 mm), and large dragonfly nymphs (Libellulidae: *Orthetrum albistylum speciosum*, *Sympetrum frequens*, *S. infuscatum*; Aeshnidae: *Planaeschna milnei*, and *Anax parthenope parthenope*, 20-30 mm) were provided as food to 1st, 2nd, and 3rd instars, respectively.] - had a longer total body length than larvae reared with a mixture of tadpoles and Odonata nymphs. In addition, larvae of *C. brevis* could search for and eat motionless Odonata nymphs, but all larvae died from starvation when they were supplied with motionless tadpoles. These results suggested that *C. brevis* larvae mainly preyed upon invertebrate animals and did not eat vertebrate animals, such as tadpoles and fish." 8752. Orr, A.G. (2009): Reproductive behaviour of *Libellago semiopaca* on a Bornean rainforest stream (Odonata: Chlorocyphidae). *International Journal of Odonatology* 12(2): 157-180. (in English) ["The repro-

ductive behaviour of *L. semiopaca* was studied on a swift-flowing shallow forest stream in Brunei. Females oviposited just below the water-line, commonly in groups, only on large, firm-textured, semi-submerged logs, usually guarded by males. Both sexes were very sedentary. Suitable sites, with good illumination and deep deposits of fine gravel and leaf mulch in dead water immediately behind the log were scarce. When stream levels were high, no oviposition sites were available. When possible, females generally oviposited every day, arriving between 10:00 and 15:00 h, and usually remaining on site for at least two hours. Males arrived earlier, between 09:00 and 13:00 h, and established small territories along the log. Females apparently began reproductive activity only when all oocytes were mature, and the egg load diminished daily as eggs were laid. Most matings occurred before 12:00 h with early-arriving females. Females mated every 2-3 days, probably to replenish sperm supplies. Male density was at its highest after 11:00 h and males shared territories, spending much of their time flying in low intensity confronting contests. Removal of males from a site, just as it was becoming available by falling water levels, resulted in little use of the site by females. Pinning decoy dead females at a good oviposition site failed to attract females if males had been removed. It is suggested that the prolonged male agonistic display attracts females to the site, and possibly commits them to future matings with the territory holders." 8755. Phillips, I.D.; Vinebrooke, R.D.; Turner, M.A. (2009): Experimental reintroduction of the crayfish species *Orconectes virilis* into formerly acidified Lake 302S (Experimental Lakes Area, Canada). *Canadian Journal of Fisheries and Aquatic Sciences* 66(11): 1892-1902. (in English, with French summary) ["Reintroduction of functionally important species is considered a key strategy for restoring damaged ecosystems. However, the sudden reappearance of an extirpated species may have adverse ecological impacts, degrading ecosystem services. Therefore, we experimentally reintroduced *O. virilis* [...] to determine its effect on the littoral food web following a 17-year absence. In June 2004, a single-factor experimental design consisting of two treatment levels (crayfish-less control versus 1.8 introduced crayfish-m⁻²) was replicated five times for a total of 10 littoral cages (4m²). *O. virilis* significantly ($P < 0.05$) suppres-

sed the total biomass of other benthic invertebrates by 70% primarily because of declines in larval damselflies and midges. In addition, crayfish reduced periphytic biomass by 90% ($P < 0.001$). Stable isotopic analyses of the mesocosm food webs further indicated that *O. virilis* likely functioned as an omnivore, exerting direct and possibly indirect effects on other invertebrates and periphyton. Our findings highlight how the reintroduction of *O. virilis* must be balanced with adequate fish predation to prevent this species from becoming an invader and negatively affecting the productive capacity of boreal lakes. [...] Crayfish treatments had contrasting species-specific effects on odonates. *O. virilis* enclosures contained significantly less biomass of the most abundant odonate, *Aeshna* sp. However, crayfish significantly increased the population density of this anisopteran (RM-ANOVA, $F = 4.37$, $P = 0.04$). In contrast, crayfish significantly increased total zygopteran biomass, consisting primarily of *Enallagma* sp.. [...] *O. virilis* strongly suppressed the total abundance of the *Aeshna* sp. by negatively affecting larger individuals belonging to this genus. However, densities of *Aeshna* sp. were significantly elevated in the enclosures relative to the crayfishless controls because of the increase in small individuals. Similarly, the smaller zygopteran genus *Enallagma* sp. was also more abundant in the presence of crayfish. Therefore, we suggest that size-selective predation by crayfish on larger odonates, or possibly their active avoidance of this large predator, released smaller odonates from competition and cannibalism." 8756. Purse, B.V.; Thompson, D.J. (2009): Oviposition site selection by *Coenagrion mercuriale* (Odonata: Coenagrionidae). *International Journal of Odonatology* 12(2): 257-273. (in English) ["The aim of the study was to determine oviposition site selection in the endangered damselfly *Coenagrion mercuriale* in its UK stronghold and to determine hatching success of eggs. This was achieved by watching the behaviour of marked pairs from the onset of copulation to the end of oviposition and recording the number and duration of oviposition attempts and the plants oviposited in during the pairing. Pairs were either freely observed along a stream or placed in pre-placed cages within the stream. Stems into which oviposition had been observed were collected after four weeks and the fate of deposited eggs was determined. Pairs typically oviposited in several stems during multiple oviposition bouts, but usually in just one plant species. Mean total duration of oviposition behaviour was 671 s but ranged from 244 to 1,471 s. Mean number of eggs laid was 91 and ranged from 23 to 337. The female submerged completely in 15% of ovipositions. Mean egg deposition rate was 14 eggs per min but there was considerable variation. There was a significant positive relationship between total duration of oviposition in a stem and number of eggs laid in that stem. None of the habitat variables measured was a good predictor of duration of oviposition or number of eggs laid. Mean mortality of eggs was 14% at the time of collection and there was asynchronous development. *Hypericum elodes* was used significantly more than expected from its frequency in the environment and *Eleocharis palustris*, *Molinia caerulea* and *Myrica gale* significantly less." 8762. Saha, N.; Aditya, G.; Saha, G.K. (2009): Habitat complexity reduces prey vulnerability: An experimental analysis using aquatic insect predators and immature dipteran prey. *Journal of Asia-Pacific Entomology* 12(4): 233-239. (in English) ["The effects of alternative prey and structural complexity of habitat on the selection of mosquito larvae by aquatic insect predators were evaluated in the laboratory. The water bugs *Anisops bouvieri*, *Diplonychus* (= *Sphaerodema*) *rusticus*, and *D.*

annulatus, and the odonate nymphs, *Ceriagrion coromandelianum* and *Brachydiplax chalybea chalybea*, selected mosquito larvae based on their abundance relative to chironomid larvae and on the levels of habitat complexity. The effect of one prey species on the other was asymmetrical, as indicated through prey selectivity values. Compared to open habitat, the presence of macrophytes reduced the vulnerability of mosquito larvae while the effect was reverse in the presence of sediments. When both sediment and macrophytes were present in habitats, all the predators except *D. annulatus* consumed more mosquito larvae than chironomid larvae. The clearance rate, an indicator of predatory efficiency, varied among the predator species and habitat types. The results suggest that the outcome of the interactions between insect predators and mosquito immatures was context-dependent and that it was mediated by the presence of alternative trophic species and the habitat complexity." 8766. Schoeppner, N.M.; Relyea, R.A. (2009): Phenotypic plasticity in response to fine-grained environmental variation in predation. *Functional Ecology* 23: 587-594. (in English) [1. In nature, organisms experience environmental variability at coarse-grained (inter-generational) and fine-grained (intra-generational) scales and a common response to environmental variation is phenotypic plasticity. The emphasis of most empirical

work on plasticity has been on examining coarse-grained variation with the goal of understanding the costs and benefits of plastic responses in response to a particular environment. 2. In this study, we investigated the effects of fine-grained variation in predation on the inducible defences of larval wood frogs (*Rana sylvatica*) by widely altering the density and feeding schedule of caged predators (*Dytiscus* spp.) while holding average predation constant. 3. We found that predator cues induced change in tadpole behaviour, morphology, and mass. Surprisingly, however, temporal variation in predation did not cause the tadpoles to alter their activity (compared to a constant predation treatment) or mass. Temporal variation in predation did alter tadpole tail depth, but only when experiencing our most extreme variation treatment in which the predators were fed once every 8 days. Under these conditions, the predator-induced tadpole tail was less extreme compared to environments containing constant predation. 4. While a number of previous studies have examined behavioural responses of prey to temporal variation in predation risk without holding average predation constant, this appears to be the first test of temporal variation per se. As in previous studies of organism responses to temporal variation in resources, our results suggest that fine-grained environmental variability can affect the expression of phenotypically plastic traits, but our tadpoles appear to be generally unresponsive to this finegrained variation for many of their traits." 8767. Schoeppner, N.M.; Relyea, R.A. (2009): When should prey respond to consumed heterospecifics? Testing hypotheses of perceived risk. *Copeia* 2009(1): 190-194. (in English) ["In aquatic systems, a long-standing question is why chemical cues from some diets consumed by a predator induce strong anti-predator responses in prey while other diets induce weak or no responses. We performed an experiment to determine if strong prey responses to particular predator diets are due to prey being closely related to the predator's diet (i.e., phylogenetic relatedness) or due to prey coexisting with the predator's diet and thereby sharing a risk of predation. We compared the behaviour of Gray Treefrog tadpoles (*Hyla versicolor*) to cues from a dragonfly nymph (*Anax junius*) that consumed either conspecific Gray Treefrogs, one of six diets that commonly coexist with Gray Treefrogs (spanning a wide range of phylogenetic relatedness), or one diet that is closely related to Gray Treefrogs but has an allopatric range that has not overlapped for at least 20,000 yrs. We found that tadpoles could discriminate among the diets and that the magnitude of behavioural response supported the hypothesis of diet phylogenetic relatedness and refuted the hypothesis of diet coexistence." 8769. Smith, G.R.; Boyd, A.; Dayer, C.B.; Ogle, M.E.; Terlecky, A.J. (2009): Responses of grey treefrog and American toad tadpoles to the presence of cues from multiple predators. *The Herpetological Journal* 19(2): 79-83. (in English) ["Prey may often need to confront and integrate cues from multiple predators simultaneously. We examined the effects of the cues of two potential predators, mosquitofish and odonates, individually and in combination, on the behaviour of two species of anuran tadpoles, grey treefrog (*Hyla versicolor*) and American toad (*Bufo americanus*). Mosquitofish cues alone reduced the activity of tadpoles of *H. versicolor*, but had no effect on activity of the tadpoles of *B. americanus*. Odonate cues had no independent effects on the behaviour of *B. americanus* or *H. versicolor*. The behaviour of neither species was affected differently by the simultaneous exposure to mosquitofish and odonate cues compared to the independent effects of each predator cue. Habitat use was not affected by any cues or combination of cues in either species. Our results suggest that grey treefrog tadpoles and American toad tadpoles do not respond to the combination of cues from multiple predators any differently than would be expected from their exposure to each cue independently. Our results also demonstrate that the behavioural response of tadpoles to predator cues can be variable among species of prey, as well as among species of predator." 8770. Sodhi, N.S.; Wilcove, D.S.; Subaraj, R.; Yong, D.-I.; Lee, T.-m.; Bernard, H.; Lim, S.L.H. (2009): Insect extinctions on a small denuded Bornean island. *Biodiversity and Conservation* 19(2): 485-490. (in English) ["We report odonate and butterfly extinctions on Pulau Mengalum (Sabah) between 1928 and 2007. Pulau Mengalum has lost all of its closed-canopy forest; 55.5% of the odonates and 40% of the butterflies present in 1928 have likely been extirpated. Fourteen and five species of odonates and butterflies found by us were new records for the island, respectively. It is unclear if newly recorded species were missed by previous surveyors in 1928 or if they have colonized the island after that time. While our study indicates that deforestation is a serious threat to tropical insects, it remains unclear if deforested areas provide opportunities for new colonists. [...] Mengalum has likely lost five (55.5%) of nine odonates since 1928 (*Archibasis melanocyana*, *Camacinia gigantea*, *Gynacantha dohrni*, *Lestes praemorsa*, and *Raphismia bispina*). Our last survey in October did not add any species to the previously recorded odonates suggesting that our sampling was adequate. [...] We recorded 14 new odonates in 2007 (*Archibasis viola*, *Agriocnemis femina*, *A. pygmaea*, *Brachydiplax chalybea*, *Diplacodes trivialis*, *Isch-*

nura senegalensis, *Lathrecista asiatica*, *Macrodiplax cora*, *Mortagrion falcatum*, *Orthetrum sabina*, *Pantala flavescens*, *Pseudagrion microcephalum*, *Rhyothemis phyllis*, and *Tramea transmarina*). One of these new records (*A. viola*) is a forest species." 8771. Stefanović, K.S.; Nikolić, V.P.; Tubić, B.P.; Tomović, J.M.; Atanacković, A.D.; Simić, V.M.; Paunović, M.M. (2009): Aquatic macroinvertebrates of the Jablanica river, Serbia. *Arch. Biol. Sci., Belgrade* 61(4): 787-794. (in English, with Serbian summary) [*Gomphus vulgatissimus* was the only dragonfly sampled during 2005 and 2006 at four sampling sites along the Jablanica River, a right-hand tributary of the Kolubara River.] Address: Stefanovic, Katarina, Siniša Stankovic Institute for Biological Research, 11060 Belgrade, Serbia

8772. Steiner, U.K.; Van Buskirk, J. (2009): Predator-induced changes in metabolism cannot explain the growth/predation risk tradeoff. *PLoS ONE* 4(7): e6160., doi:10.1371/journal.pone.0006160: 4 pp. (in English) ["Defence against predators is usually accompanied by declining rates of growth or development. The classical growth/predation risk tradeoff assumes reduced activity as the cause of these declines. However, in many cases these costs cannot be explained by reduced foraging effort or enhanced allocation to defensive structures under predation risk. Here, we tested for a physiological origin of defence costs by measuring oxygen consumption in tadpoles (*Rana temporaria*) exposed to predation risk (final instar dragonfly larva (*Aeshna cyanea*) over short and long periods of time. The short term reaction was an increase in oxygen consumption, consistent with the "fight-or-flight" response observed in many organisms. The long term reaction showed the opposite pattern: tadpoles reduced oxygen consumption after three weeks exposure to predators, which would act to reduce the growth cost of predator defence. The results point to an instantaneous and reversible stress response to predation risk. This suggests that the tradeoff between avoiding predators and growing rapidly is not caused by changes in metabolic rate, and must be sought in other behavioural or physiological processes." 8773. Suhling, F.; Martens, A.; Marais, E. (2009): How to enter a desert - patterns of Odonata colonisation of arid Namibia (Odonata). *International Journal of Odonatology* 12(2): 287-308.. (in English) ["With a total of 75 species the odonate diversity in the Namibian desert is surprisingly high. Based on their distribution characteristics, invasion patterns, and breeding success, there are six well-defined categories of Odonata: widespread species - (1) permanently living in the desert, and desert biased, (2) permanently living in the desert, but not desert-biased; (3) entering the desert seasonally; (4) entering from neighbouring tropical or temperate regions, whose populations may breed in the desert sometimes or locally. Category (5) consists of species with highly localised breeding populations in the desert, which are widely isolated from potential source populations. The last category (6) consists of species restricted to allochthonous perennial rivers. We discuss these patterns from a geographical and a temporal perspective. On the one hand, there have been

different spatial directions from where species have entered deserts. On the other hand, Odonate distribution patterns in the deserts have a palaeoclimatic as well as a present time perspective, the latter with seasonal and annual fluctuations and a strong influx from neighbouring biomes. The discovery of a desert-bias in several species suggests that odonates could be well adapted to desert conditions or, in other words, some species of odonates may be promoted by arid conditions." 8775. Szállassy, N.; Szabó, Z.D.; Nagy, B.H. (2009): Survival of dragonfly *Libellula fulva* males according to their mating status: a four year study. *Entomologica romanica* 14: 13-18. (in English, with Romanian summary) ["During four seasons (2000-2003), a closed *L. fulva* population was studied along a creek in Eastern Hungary. The movement of marked and solitary males was observed with binoculars and it was recorded along a 350 meter natural section of the Kutas-channel. Our aim was to analyse the recapture and survival rate of two male groups of *L. fulva* by using mark-recapture models. The model-selection showed that the recapture rate of mated males was higher than of solitary ones. Survival rate of mating males was also higher in every year than the survival of the solitary individuals. This result suggest, that even if it is costly for males to occupy and defend a territory, finding, guarding and mating a female, the successful males have still a higher survival rate." 8776. Takahara, T.; Yamaoka, R. (2009): Temporal and spatial effects of predator chemical and visual cues on the behavioral responses of *Rana japonica* tadpoles. *Current Herpetology* 28(1): 19-25. (in English) ["A laboratory experiment was conducted to evaluate temporal and spatial effects of predator chemicals and visual stimuli on the behavioural responses of the *Rana japonica* tadpoles. Nymphs of *Anax parthenope julius* were used as the predator model. Tadpoles exhibited defensive responses by reducing tail movement time associated with their activity when exposed to chemicals from the nymphs. These responses tended to be quicker and stronger as distance from the nymphs decreased. Tadpoles exposed to visual stimuli from the nymphs also exhibited similar but weaker behavioural responses. Our results suggest that in a short distance encounter defensive responses of the *R. japonica* tadpole are induced more quickly by chemical cues of the predator than by its visual cues. For the tadpole, detecting the dragonfly nymph by chemical cues may function as a trigger for effective predator-avoidance strategy in tadpole-dragonfly nymph interactions." (Authors)] Address:

8782. Wildermuth, H. (2009): Season and temperature dependent location of mating territories in *Somatochlora flavomaculata* in a heterogeneous environment (Odonata: Corduliidae). *International Journal of Odonatology* 12(2): 181-193. (in English) ["In a heterogeneous environment, males of *S. flavomaculata* regularly occupy site-fixed locations away from water, adjacent to vertical landscape elements, and to a lesser extent, also at water, i.e. at oviposition sites. Territories both over land and over water are typically patrolled by continuous site-fixed flights. These places serve as rendezvous sites where copulation is initiated. The results of a sevenyear study in a heterogeneous mire habitat of Central Europe with scattered oviposition sites demonstrated that the rendezvous sites changed over the flight season in both location and quality. At the beginning of the reproduction period territories were established almost exclusively over land. Subsequently, there was a significant shift from sites over land to sites over water, and towards the end of the flight season virtually all territories were situated over water. Areas with overgrown puddles were also attractive for establishing territories, even at the beginning of the flight season. When the puddles desiccated during hot and dry spells in the first half of the reproduction period, these sites were no longer used as rendezvous sites. However, no shift towards territories over water was observed in this situation. Small-scale transfer of territories was also related to ambient temperatures. Below 28°C all males patrolled in full sunshine, but when temperatures rose they shifted their patrol sites gradually to the shade, presumably for thermoregulatory reasons. It appears that the mate search strategy of *S. flavomaculata* is characterised by extensive phenotypic plasticity with respect to time and space." 8783. Willkommen, J. (2009): The tergal and pleural wing base sclerites – homologous within the basal branches of Pterygota? *Aquatic Insects* 31(Supplement 1): 443-457. (in English) ["The Ephemeroptera are usually regarded as the sister group of the remaining Pterygota. Their wing base sclerites and pterothoracic musculature are compared with that of other basal pterygote lineages. It is shown that most elements of the neopteran wing base are also present in Ephemeroptera and Odonata. The wing base in the ground plan of Pterygota is presumably composed of three axillaries and a proximal median plate. The first axillary is provided with two muscles. The third axillary is equipped with one short muscle in the ground plan of Pterygota. A second muscle, which inserts at the third axillary and originates from the episternum, is most likely an autapomorphic character of Neoptera. The results imply that the wing base of Plecoptera is close to the pterygote ground plan. It is assumed that the wing bases of Ephemeroptera and Odonata are secondarily stiffened. The so-called basalare and its associated muscles in Ephemeroptera and Odonata are probably not homologous to the basalare and respective muscles in Neoptera. Though the wing bases of both Ephemeroptera and Odonata show similar modifications their specialisations may have evolved independently from each

other." (Author)] Address: Willkommen, Jana, Staatliches Museum für Naturkunde, Abt. Entomologie, Rosenstein 1, D-70191 Stuttgart, Germany. E-mail: willkommen.smns@naturkundemuseum-bw.de

8786. Abbott, J.K.; Svensson, E.I. (2010): Morph-specific variation in intersexual genetic correlations in an intra-specific mimicry system. *Evolutionary Ecology Research* 12: 105-118. (in English) ["Background: Positive intersexual genetic correlations are typically viewed as constraining the evolution of sexual dimorphism, when traits are subject to sexually antagonistic selection. Our study species, *Ischnura elegans*, has a female-limited colour polymorphism with three female colour morphs (males are monomorphic), one of which is considered to be a male mimic. Questions: Are there morph-specific differences in the magnitude of intersexual genetic correlations in *I. elegans*? Specifically, do male-mimic (Androchrome) females have higher intersexual genetic correlations for morphological traits than non-mimic (Infuscans) females? Methods: We collected copulating pairs in the field and raised offspring from these pairs in the laboratory. We measured five morphological traits in both parent and offspring generations and investigated their heritabilities and genetic correlations. Results: We found a negative overall relationship between the degree of sexual dimorphism for a trait and its intersexual genetic correlation. But the magnitude and direction of intersexual genetic correlations depended on the female morph. As expected, male mimic (Androchrome) females had higher intersexual genetic correlations. In addition, the genetic correlations between the morphs were in all cases significantly lower than unity. Male mimic (Androchrome) females had higher mother–son covariances

than the non-mimic (*Infuscans*) morph, and this difference is the proximate explanation for the difference in intersexual genetic correlations between the morphs." 8787. Aletsee, M. (2010): Classification of dystrophic ponds by means of the TWINSPAN algorithm for an ecological characterisation of the Odonata habitats in the Hohe Venn / Hautes Fagnes (Germany/Belgium). *Brachytron* 12(1/2): 50-59. (in English, with Dutch and German summaries) ["the Hohe Venn contains a large number of mired *palsa*. Regarding the Odonata, there are two types of reproduction habitats, the ones with a central, open water body (shallow pool, *Kolk*) and the ones with at most times a shallow, temporary water body (shallow, *Schlenke*). Huge parts of the fens in this area were destroyed by afforestation and intensive draining (Kamp, 1962). At the beginning of the 1990s, some *palsa* were restored by filling up the drains with clay (Paulissen, 1997). This paper compares a descriptive morphologic-genetic classification of the habitats of Odonata with a classification using the TWINSPAN algorithm. We discuss in particular the potential of recolonisation of the restored *palsa*. Some characteristic and very rare species like *Aeshna subarctica* and *Somatochlora arctica* could not be found in the recently developed habitats, while others such as *Coenagrion hastulatum* and more euryoecious species, i.e. those that tolerate very different environmental conditions, have successfully established themselves." 8788. Arscott, D.B.; Larned, S.; Scarsbrook, M.R.; Lambert, P. (2010): Aquatic invertebrate community structure along an intermittence gradient: Selwyn River, New Zealand. *Journal of the North American Benthological Society* 29(2): 530-545. (in English) ["Changes in community structure and life-history traits of benthic invertebrates were examined along a longitudinal intermittence gradient in an alluvial river. The gradient was characterized with modeled and measured hydrologic, chemical, and physical environmental variables. The invertebrates were collected in the Selwyn River, southeastern New Zealand, at multiple sites in each of 4 river sections with distinct hydrological conditions (perennial-losing, ephemeral, intermittent, perennial-gaining). Values of hydrological metrics for each site were generated with an empirical model developed for the Selwyn River. The metrics included 4 that characterized intermittent flow (flow permanence, flow duration, drying frequency, distance to nearest perennial site). Most invertebrate richness and density metrics were significantly higher in the perennial-losing and perennial-gaining sections than in the ephemeral and intermittent sections. A principle components analysis (PCA) separated invertebrate samples from the 4 sections along 2 primary factors. Nine of 13 hydrological metrics, including the 4 intermittence metrics, were correlated with the PCA site scores. Linear regressions indicated that most taxon-richness metrics and some density metrics were related to flow permanence, flow duration, or both. Based on the regression analysis, we predicted that 1.9 taxa/m² are added with each 10% increase in flow permanence, and 0.5 taxa/m² are added with each 10-d increase in flow duration. Results from a nested-

ness analysis indicated that communities at ephemeral and intermittent sites were nested subsets of the communities at perennial sites, and the nesting order of sites was related to both flow permanence and flow duration. Assemblages of taxa with particular life-history traits (life span, fecundity, maximum size, and voltinism) varied linearly with flow permanence and flow duration. The variation in invertebrate communities along the Selwyn River was primarily the result of progressive removal of desiccationsensitive taxa with increasing intermittence, not to selection for desiccation-resistant specialists. Quantitative intermittence–ecology relationships are needed to predict the consequences of future changes in flow intermittence, but such relationships are rare. The univariate relationships reported in our study contribute to a small but growing array of intermittence–ecology relationships." (Author) In data analysis, Odonata are treated as "other insects".] Address: David B. Arscott, D.B., Stroud Water Research Center, 970 Spencer Rd, Avondale, Pennsylvania 19311 USA. 8794. Bowerman, J.; Johnson, P.T.J.; Bowerman, T. (2010): Sublethal predators and their injured prey: linking aquatic predators and severe limb abnormalities in amphibians. *Ecology* 91(1): 242-251. (in English) ["While many predators completely consume their prey, others feed only on blood or tissue without killing the prey, sometimes causing ecologically significant levels of injury. We investigated the importance of sublethal predator attacks in driving an emerging issue of conservation importance: missing-limb deformities in amphibians. We combined long-term field data and manipulative experiments to evaluate the role of sublethal predation in causing abnormalities in two regions of central Oregon, USA. Since 1988, western toads (*Bufo boreas*) in Lake Aspen have exhibited abnormalities dominated by partially missing limbs and digits at annual frequencies from <1% to 35%. On Broken Top volcano, we found comparable types and frequencies of abnormalities in Cascades frogs (*Rana cascadae*). Field sampling and observational data implicated two aquatic predators in these abnormality phenomena: introduced sticklebacks (*Gasterosteus aculeatus*) at Lake Aspen and cordulid dragonfly larvae (*Somatochlora albicincta*) at Broken Top. In experiments, these predators produced limb abnormalities identical to those observed in the respective regions. At Lake Aspen, in situ predator exclosures effectively eliminated abnormalities in toads, while comparisons among years with low and high stickleback abundance and between wetlands with and without sticklebacks reinforced the link between fish and amphibian abnormalities. Neither trematode parasite infection nor pesticide contamination could explain observed abnormalities. Our results suggest that predators are an important explanation for missing-limb abnormalities and highlight the ecological significance of sublethal predation in nature." 8796. Bried, J.T.; Mazzacano, C.A. (2010): National review of state wildlife action plans for Odonata species of greatest conservation need. *Insect Conservation and Diversity* 3(2): 61-71. (in English) ["1. The overarching goal of United States wildlife action plans is to prevent wildlife from becoming endangered or declining to levels where recovery becomes unlikely. Effective plan implementation depends on establishing Species of Greatest Conservation Need (SGCN), defined as wildlife species with small or declining populations or other characteristics that make them vulnerable. 2. Although nearly two-thirds of distinct Odonata species known from the U.S. (441 species as of 2005) were appointed as SGCN, over half the states neglected to assign dragonfly SGCN, damselfly SGCN, or both. Western and southern states listed proportionately fewer Odonate SGCN than states of the Great Lakes, Mid-Atlantic, and New England regions, apparently reflecting geographic patterns of legal authority, available information, and involvement by Odonata specialists. 3. Greater consultation of Odonata specialists is encouraged in any revision of state wildlife action plans, along with increased: (i) use of existing conservation lists, (ii) inferences from field guides and major faunal synopses, (iii) recognition of patterns of endemism, and (iv) application of empirical species distribution modelling. 4. Legal and management restrictions aside, insects and other invertebrates are often neglected in mainstream conservation efforts because they are perceived as understudied. It is erroneous to assume 'not enough information' exists for well-studied microfauna such as Odonata and doing so further undermines the conservation of less conspicuous and charismatic taxa." 8799. Chaput-Bardy, A.; Gregoire, A.; Baguette, M.; Pagano, A.; Secondi, J. (2010): Condition and phenotype-dependent dispersal in a damselfly, *Calopteryx splendens*. *PLoS ONE* 5(5): e10694. doi: 10.1371/journal.pone.0010694: 7 pp. (in English) ["Individual dispersal decisions may be affected by the internal state of the individual and the external information of its current environment. Here we estimated the influence of dispersal on survival and investigated if individual phenotype (sex and wing length) and environmental condition (conspecific density and sex-ratio) affected dispersal decisions in *C. splendens*. As suspected from the litera-

ture, we showed that the proportion of dispersing individuals was higher in females than in males. We also found negative-density dependent dispersal in both sexes and influence of sex-ratio on dispersal. Individuals moved less when sex-ratio was male biased. These results are consistent with a lek mating system where males aggregate in a place and hold mating territories. Contrary to our expectations, neither dispersal nor survival was affected by wing length. Nevertheless, mean adult survival was about 8% lower in dispersing individuals than in residents. This might reflect a mortality cost due to dispersal." (Authors)] Address: Chaput-Bardy, Audrey, 1 Laboratoire d'Etudes Environnementales des Systèmes Anthropisés, Univ. d'Angers, Angers, France. 8800. Chase, J.M.; Burgett, A.A.; Biro, E.G. (2010): Habitat isolation moderates the strength of top-down control in experimental pond food webs. *Ecology* 91(3): 637-643. (in English) ["Habitat isolation is well known to alter patterns of species' abundance, richness, and the ratios of predators : prey. Less clear, however, is how isolation alters interactions within food webs. Here, we present the results from an experiment performed in artificial ponds (mesocosms) manipulating habitat isolation crossed with a predator reduction treatment to disentangle how isolation mediates the top-down effect of predators. The strength of the trophic cascade, from predators, through herbivores, to producers, was considerably stronger in connected than in isolated habitats. We further found that the overall richness of both predator and herbivore species declined strongly with isolation. Experimental predator reductions suggest that the mechanism underlying the herbivore response was likely mediated by a keystone predator effect; when predators were reduced, herbivore richness was lower, and there was no discernible effect of isolation on herbivore richness. Finally, we found that the composition of predators in more isolated habitats consisted of species that were smaller and likely less effective predators than species that persisted in less isolated habitats. In all, our experiment showed that habitat isolation can alter the structure of communities by a combination of direct effects of the species in question, as well as effects mediated through their interactions in the food web." (Authors) The study includes Odonata.] Address: Chase, J.M., Department of Biology and Tyson Research Center, Washington University in Saint Louis, Saint Louis, Missouri 63130 USA

8802. Cobbaert, D.; Bayley, S.E.; Greter, J.-L. (2010): Effects of a top invertebrate predator (*Dytiscus alaskanus*; Coleoptera: Dytiscidae) on fishless pond ecosystems. *Hydrobiologia* 644(1): 103-114. (in English) ["We investigated the predatory effects of *D. alaskanus*, a large predaceous diving beetle, on the biomass, species composition and diversity of fishless pond communities. The effects were tested using presence and absence treatments of *D. alaskanus* in 24 mesocosms

distributed among six ponds. We sampled phytoplankton, zooplankton and macroinvertebrates every two weeks for a six week period. Periphyton was sampled from the mesocosm walls on the final day. Total macroinvertebrate biomass decreased in the presence of dytiscids while species richness was not affected. Macroinvertebrate predators, snails and *Gammarus lacustris* decreased in the dytiscid treatments. Laboratory feeding experiments confirmed feeding preferences consistent with the mesocosm results. Periphyton biomass was six times greater in the dytiscid enclosures, concomitant with the decreased grazing by gastropods and other invertebrate primary consumers indicating a benthic trophic cascade. Top-down effects of dytiscids on other predatory invertebrates led to increased total zooplankton biomass, largely due to increased abundances of large and small cladocerans. Zooplankton species richness increased in the dytiscid enclosures. Inconsistent with trophic cascade theory, phytoplankton did not respond to top-down effects of *D. alaskanus* within the study period. Overall, the results show *D. alaskanus* predation caused trophic effects via two distinct food chains, a dytiscid–snail–periphyton trophic cascade, and a dytiscid–predatory macroinvertebrates–zooplankton partial trophic cascade." (Authors) *D. alaskanus* preferred prey was large mobile predaceous macroinvertebrates including Corixidae, Zygoptera and Chaoborus.] Address: Cobbaert, Danielle, Department of Biological Sciences, University of Alberta, Edmonton, AB, T6G 2E9, Canada. 8804. Combes, S.A.; Crall, J.D.; Mukherjee, S. (2010): Dynamics of animal movement in an ecological context: dragonfly wing damage reduces flight performance and predation success. *Biology letters* 6(3): 426-429. (in English) ["Much of our understanding of the control and dynamics of animal movement derives from controlled laboratory experiments. While many aspects of animal movement can be probed only in these settings, a more complete understanding of animal locomotion may be gained by linking experiments on relatively simple motions in the laboratory to studies of more complex behaviours in natural settings. To demonstrate the utility of this approach, we examined the effects of wing damage on dragonfly flight performance in both a laboratory drop–escape response and the more natural context of aerial predation. The laboratory experiment shows that hindwing area loss reduces vertical acceleration and average flight velocity, and the predation experiment demonstrates that this type of wing damage results in a significant decline in capture success. Taken together, these results suggest that wing damage may take a serious toll on wild dragonflies, potentially reducing both reproductive success and survival." 8808. Crumrine, P.W. (2010): Size-structured cannibalism between top predators promotes the survival of intermediate predators in an intraguild predation system. *J. N. Am. Benthol. Soc.* 29(2): 636-646. (in English) ["Individuals in most natural populations of predators vary in size, and size differences among individuals often result in cannibalism. Cannibalism is an extremely common phenomenon in the animal kingdom, particularly among generalist predators that engage in intraguild predation (IGP). However, few studies have specifically addressed the effects of cannibalism on IGP.

The aim of my study was to investigate how trophic and behavioural interactions between 2 size classes of an intraguild (IG) predator influenced the survival and behaviour of IG prey and a shared prey resource. I tested for these effects with larval odonates by exposing a shared prey resource (*Ischnura verticalis*) to the presence or absence of IG prey (*Pachydiplax longipennis*) and 2 size classes of IG predators (small or large *Anax junius*) in a 2 3 2 3 2 factorial design. Mortality rates of the shared resource in all single-predator treatments were significantly greater than in nonpredator controls, and risk reduction was observed when the shared resource was exposed to combinations of predators. The significant negative effect of large *A. junius* on *P. longipennis* survival and activity level was greater than that of small *A. junius*. Cannibalism occurred between large and small *A. junius* in size-structured IG predator treatments, and the effects of the size classes were not additive for the survival of IG prey. Cannibalism was not solely responsible for risk reduction in IG prey, and reduced activity level of small *A. junius* in the presence of larger conspecifics probably had a positive influence on *P. longipennis* survival. My results demonstrate that cannibalism among IG predators can influence the survival of IG prey and might contribute to coexistence among predators in systems with strong IGP." 8810. Damm, S.; Dijkstra, K.D.; Hadrys, H. (2010): Red drifters and dark residents: The phylogeny and ecology of a Plio-Pleistocene dragonfly radiation reflects Africa's changing environment (Odonata, Libellulidae, Trithemis). *Molecular Phylogenetics and Evolution* 54: 870-882. (in English) ["In the last few million years, tropical Africa has experienced pronounced climatic shifts with progressive aridification. Such changes must have had a great impact on freshwater biota, such as Odonata. With about forty species, *Trithemis* dominates dragonfly communities across Africa, from rainpools to streams, deserts to rainforests, and lowlands to highlands. Red-bodied species tend to favour exposed, standing and often temporary waters, have strong dispersal capacities, and some of the largest geographic ranges in the genus. Those in cooler habitats, like forest streams, are generally dark-bodied and more seden-

tary. We combined molecular analyses of ND1, 16S, and ITS (ITS1, 5.8S, and ITS2) with morphological, ecological, and geographical data for 81% of known *Trithemis* species, including three Asian and two Madagascan endemics. Using molecular clock analyses, the genus's origin was estimated 6–9 Mya, with multiple lineages arising suddenly around 4 Mya. Open stagnant habitats were inferred to be ancestral and the rise of *Trithemis* may have coincided with savannah-expansion in the late Miocene. The adaptation of red species to more ephemeral conditions leads to large ranges and limited radiation within those lineages. By contrast, 3 clades of dark species radiated in the Plio-Pleistocene, each within distinct ecological confines: (1) lowland streams, (2) highland streams, and (3) swampy habitats on alternating sides of the Congo-Zambezi watershed divide; together giving rise to the majority of species diversity in the genus. During *Trithemis* evolution, multiple shifts from open to more forested habitats and from standing to running waters occurred. Allopatry by habitat fragmentation may be the dominant force in speciation, but possibly genetic divergence across habitat gradients was also involved. The study demonstrates the importance of combining ecological and phylogenetic data to understand the origin of biological diversity under great environmental change." (Authors)] Address: Dijkstra, K.D., Curator of invertebrates, National Zoological Collection of Suriname, University of Suriname, P.O. Box 9212, Paramaribo, Suriname. 8811. De Paiva Silva, D.; De Marco, P.; Resende, C.D. (2010): Adult odonate abundance and community assemblage measures as indicators of stream ecological integrity: A case study. *Ecological Indicators* 10(3): 744-752. (in English) ["Water resources demand constant conservation actions due to several problems (e.g. riparian vegetation cut-off, construction of dams, acidification, sewage and pesticide spills) that degrade the aquatic systems worldwide and affect its physico-chemical parameters and habitat characteristics. Odonata is a potential group of organisms that could indicate these habitat alterations once they have aquatic and terrestrial life forms. In this study, we tested the use of adult odonate individual species and community assemblage measures to evaluate the effect of riparian vegetation cut-off and sewage discharges. The study was performed at Turvo Sujo River, in Viçosa, Southern Brazil. We selected twelve sites, six of them were upstream and six were downstream the city. Species abundance and species richness estimates of adult odonates were performed on sunny days during summer and winter. We analyzed the goodness-of-fit of the species abundances to geometric and lognormal series. We also measured the Habitat Physical Integrity Score (HPIS), pasture and forest proportions and physico-chemical water parameters at each site. Only few species were abundant in up- and downstream regions. Abundance of *Argia modesta* was higher at the upstream ($t = 3.188$; $df = 17$; $p = 0.005$) than at the downstream region and this species is a potential habitat bioindicator organisms. Species richness was statistically different only in the wet season and species-abundance relations at the two regions fitted well to both geometric and lognormal series. The lack of riparian vegetation indicates a loss of habitat integrity and heterogeneity at Turvo Sujo River basin, which was mainly dominated by lake-dwelling odonate species. Low species richness differences are caused by spe-

cies pool biases toward those ones capable to survive at degraded ecosystems, suggesting that the effects of water parameters are much less important than a landscape dominated by pastures and practically without forests. We suggest the use of species-abundance models (like geometric and lognormal series) to determine the degree of impacts over a given community once they are simple models and can show intrinsic processes structuring communities." 8816. Dube, T.; Makaka, C.; Sibanda, Z. (2010): An assessment of the effect of industrial and sewage effluent on aquatic invertebrates: A case study of a southern urban stream, Zimbabwe. *Journal of Sustainable Development* 3(2): 210-214. (in English) ["The impact of industrial effluent discharged in Mazai stream was assessed through physical-chemical parameters and also by bio-monitoring of benthic macro-invertebrates. Samples were collected at three sites, one before the effluent discharge point into the stream (site 3) and two sites which were located downstream after the dis-

charge points (sites 1 and 2). High levels of chemical pollutants were recorded at sites 1 and 2 (ZINWA red category) whereas site 3 (reference site) consisted of relatively clean water (ZINWA blue category). This was confirmed by the biological evaluation process. The SASS4 scores at sites 1 and 2 indicated a deterioration of water quality while site 3 there was good water quality with high species diversity. Detrended correspondence analysis (DCA) showed that pollution sensitive taxa such as Hemiptera, Trichoptera, Coleoptera and Odonata were dominant at site 3 whilst the other sites were dominated by pollution tolerant species such as Chironomids. Continuous discharge of effluent could lead to extreme degradation of Mazai stream hence loss of biodiversity of macro-invertebrates." 8818. Duxbury, C.; Holland, J.; Pluchino, M. (2010): Experimental evaluation of the impacts of the invasive catfish *Hoplosternum littorale* (Hancock, 1828) on aquatic macroinvertebrates. *Aquatic Invasions* 5(1): 97-102. (in English) [*H. littorale* is a callichthyid catfish native to South America. It was first recorded in Florida in 1995. It has now dispersed throughout much of Florida. It is thought that this fish has had little or no impacts to native fish. However, it is unknown if the introduction of this fish can cause other ecological impacts, such as alteration of aquatic invertebrates assemblages. We conducted a cage experiment to evaluate the effects of the hoplo catfish on macroinvertebrates. Results showed that macroinvertebrate abundance and taxa on artificial substrates (MAS) were reduced by 31 and 50% in the fish treatments, respectively. The entire macroinvertebrate assemblage structure was significantly different between fish and no-fish treatments. This difference was driven primarily by reductions in amphipods, and chironomids. Macroinvertebrates were also identified from fish stomachs and these were compared to assemblages on the MAS. We found a smaller subset of taxa in the stomachs, as compared to the MAS. These results suggest that this fish could alter the macroinvertebrate assemblage structure. This could have implications for environmental monitoring programs that use macroinvertebrates to assess water quality." (Authors) Relative abundance of Odonata found on the artificial substrates in fish and no-fish treatments (n=10, each) did not differ significantly. No Odonata were found in the stomach contents of caged fish.] Address: Duxbury, C., Walt Disney Imagineering, Research & Development, 1365 Ave. of The Stars, Lake Buena Vista, Florida, USA. 8820. Ellenrieder, N. von (2010): Odonata biodiversity of the Argentine Chaco biome. *International Journal of Odonatology* 13(1): 1-25. (in English, with Spanish summary) ["Odonates of small temporary pools, marshes, large permanent ponds, oxbow lakes, dams, and perennial rivers were sampled in the semiarid Chaco biome of NW Argentina between September 2007 and December 2008. Information from 35 localities yielded 60 species; presence/absence information of species was recorded in a spatial-relational database. Alpha, beta, and gamma diversity and total species richness expected for the area were estimated, and structure of Chaco odonate assemblages was preliminarily analyzed using nonmetric multidimensional scaling (NMS) ordination. Species composition was found to be related to both habitat type and longitudinal sector. Some species that might be indicative of habitat type were identified. — In order to analyze the distribution and biogeography of the odonates of the Chaco biome in Argentina, collections and literature were also examined, adding 58 localities (93 total) and 28 species (88 total). Odonate diversity of the Chaco was compared with that of neighboring Yungas and Paranense biomes by means of percent complementarity and cluster analysis, which showed Chaco odonate composition to be slightly more similar to that of the Yungas than to the Paranense biome, and W and E Chaco sectors to be more similar between them than with either of the two neighboring biomes. Most odonate species found in the Chaco are vagile and more widely distributed in the Neotropical region, with only four potential endemics." (Authors)] Address: Ellenrieder, Natalia von, California State Collection of Arthropods, Cdfa, 3294 Meadowview Road, Sacramento, CA 95832. Email: natalia.ellenrieder@gmail.com

8821. Fenoglio, S.; Bo, T.; Cammarata, M.; Malacarne, G.; Del Frate, G. (2010): Contribution of macro- and micro-consumers to the decomposition of fish carcasses in low-order streams: an experimental study. *Hydrobiologia* 637: 219-228. (in English) ["Vertebrate carrions, in particular fish, can provide a significant source of organic matter to lotic systems. Most studies related to animal matter degradation have been

undertaken in Western North America, where entire lotic networks depend on large masses of anadromous salmonids, but less is known of other aquatic environments. In this study, the decomposition process of trout was analyzed in a Northern Italian stream, investigating the different importance of macro (invertebrates)—and micro (fungi)—consumers. Trout carcasses exhibited an exponential mass loss over time and attracted a rich community of microbic and invertebrate colonists. Final values for fish decay were significantly affected by the presence of macroconsumers; nevertheless, the role of macroinvertebrates seems to be not as predominant as in other ecological systems. Our study indicates that in lotic environments, which lack specialized necrophagous or sarcophagous invertebrate taxa equivalent to those found in terrestrial environments (such as maggots or carrion beetles), micro-consumers play a main role in fish carcasses decomposition." (Authors) *Calopteryx splendens* was absent in the river bed; its relative abundance from macroinvertebrates on fish carcasses counts 0,5%.] Address: Fenoglio, S., Dept of Environmental & Life Sciences, University of Piemonte Orientale, Via Teresa Michel, 11, 15121 Alessandria, Italy. 8822. Fulan, J.A.; Almeida, S.C. (2010): Effect of the spatial heterogeneity on the predation of *Scinax fuscovarius* and *Physalaemus cuvieri* tadpoles by Odonata larvae. *Acta Scientiarum. Biological Sciences*, Maringá 32(2): 121-124. (in English, with Portuguese summary) ["The objective of this work was to analyze the effect of predation by Odonata naiads (*Micrathyrina* sp.) on two amphibian species with distinct habits – benthic and mid-water – and to verify whether the presence and architecture of macrophytes can mediate this interaction. All tadpoles and Odonata larvae were captured in a temporary pond. Sixteen tanks were used for three different treatments: *Pistia*, *Salvinia* and no macrophytes. Ten tadpoles of each species and two Odonata larvae were placed in each tank. The survival of tadpoles according to treatments was assessed through analysis of repeated measures. We concluded that the survival of *P. cuvieri* and *S. fuscovarius* tadpoles was not affected by the presence and architecture of the macrophytes (*Pistia* and *Salvinia*) or by their behaviour." Lestes species (*L. rectangularis*, *L. unguiculatus*, *L. congener*) in dependence of water table and water temperature. Water temperature arised to app. 33°C; no larval mortality could be observed.] Address: Gregoire, J., 5373 Fitzgerald Rd., Burdett, NY 14818, USA. E-mail: khmo@empacc.net

8825. Groenendijk, D.; Bouwman, J.H. (2010): Occurrence and conservation of *Somatochlora arctica* in the Netherlands. *Brachytron* 12(1/2): 18-24. (in English, with Dutch and German summaries) ["*S. arctica* is one of the least known and rarest dragonflies of northwest Europe. As one of the most characteristic species of raised bog, its decline is paralleled by the diminishing quantity and quality of this habitat type. Since the publication of the Species Protection Plan in 2005, seven populations are known to be present in the Netherlands. Locating the breeding grounds and understanding the adult's behaviour were given priority. Small pools, about a metre deep and largely covered with *Sphagnum* moss, were frequented by both males and females. Females were seen ovipositing, and larvae in various stages and empty skins were found. These pools have been targeted for measures on the short term; depending on the local situation, managers are given advice either on how to protect them or how to dig new ones. On the long term, the existence of such pools needs to be included into plans for the restoration of the bog, ensuring suitable breeding grounds for this rare and beautiful species. Moreover, as most populations are located in border areas, cross-border protection is urgently needed." 8830. Jara, F.G.; Perotti, M.G. (2010): Risk of predation and behavioural response in three anuran species: influence of tadpole size and predator type. *Hydrobiologia* 644: 313-324. (in English) ["Many species alter their activity, microhabitat use, morphology and life history in response to predators. Predation risk is related to predator size and palatability of prey among others factors. We analyzed the predation risk of three species of tadpoles that occur in norwestern Patagonia, Argentina: *Pleurodema thaul*, *Pleurodema bufoninum* and *Rhinella spinulosa*. We sampled aquatic insect predators in 18 ponds to determine predator-tadpole assemblage in the study area. In laboratory conditions, we analysed the predation rate imposed by each predator on each tadpole species at different tadpole sizes. Finally, we tested whether tadpoles alter their activity in the presence of chemical and visual cues from predators. Small *P. thaul* and *P. bufoninum* tadpoles were the most vulnerable prey species, while small *R. spinulosa* tadpoles were only consumed by water bugs. Dragonflies and water bugs were the most dangerous tadpole predators. Small *P. thaul* tadpoles reduced their activity when they were exposed to all predators, while large tadpoles only reduced the activity in the presence of large predators (dragonfly larvae and water bugs). Small *P. bufoninum* tadpoles reduced the activity when they were exposed to beetle larvae and dragonfly larvae, while large tadpoles only reduced activity when they were exposed to larger predators (water bugs and dragonfly larvae). *R. spinulosa* tadpoles were the less sensitive to presence of predators, only larger tadpoles responded significantly to dragonfly larvae by reducing their activity. We conclude that behavioural responses of these anuran species were predator-specific and related to the risk

imposed by each predator." (Authors)] Address: Jara, F.G., Laboratorio de Fotobiología-INIBIOMA (CONICET), Centro Regional Universitario Bariloche, Universidad Nacional del Comahue, Quintral 1250, 8400 San Carlos de Bariloche, Rio Negro, Argentina. E-mail: fjara@crub.uncoma.edu.ar

8831. Karube, H.; Moriya, H.; Hayashi, F. (2010): Distribution of calopterygid damselflies of the genus *Mnais* in Kanagawa prefecture and its adjacent areas, central Japan. *Bull. Kanagawa prefect. Mus. (Nat. Sci.)* 39: 25-34. (in Japanese, with English summary) ["Two closely related species of *Mnais* damselflies. *M. pruinosa* and *M. costalis* are known in Kanagawa Prefecture. The previous studies of DNA sequences of the ITS1 region suggested that another group of *Mnais* is also distributed there. In this study, we sequenced 223-bp of ITS1 of 543 *Mnais* damselflies collected across Kanagawa Prefecture and its adjacent Shizuoka, Yamanashi, Tokyo, and Saitama Prefectures. Morphological measurements were also made for 404 male adult specimens. Obtained sequences consisted of three types, each corresponding to *M. pruinosa*, *M. costalis*, and another one. The last group was distributed in the central part of the studied region, being surrounded by either species, and had intermediate morphologies between the two species. Thus, this group seems to be a hybrid swarm derived from isolation of the past hybrid individuals of the two species. We discuss the possible geographic events in the past that affected the distribution patterns of them." (Authors)] Address: Karube, H., Kanagawa Prefect. Mus. Nat. - 8834.** Kim, D.G.; Yum, J.W.; Yoon, T.J.; Bae, Y.J. (2010): Life history of an endangered dragonfly, *Nannophya pygmaea* Rambur, in Korea (Anisoptera: Libellulidae). *Odonatologica* 39(1): 39-46. (in English) ["Aspects of the *N. pygmaea* life history, an endangered species in Korea, were studied at an abandoned paddy field in Mungyeong, Gyeongsangbuk-do, Korea. The larvae were sampled quantitatively at monthly intervals (every 2 weeks during the emergence period) from June 2006 to July 2007 and the adults were counted via a line-transect method. Based on the analyses of larval body length distribution, degree days (DD), and emergence time, the species is considered univoltine with an emergence period from mid-May to early August. The estimated sum of the thermal amount, effective to larval development during the study period, was 2468 DD. The relationship between the larval head width and wingsheath width, which is coincident with the temperature fluctuation pattern, shows that the population harbors at least 4 size groups (cohorts) in a generation." (2010): Movement and habitat selection by *Argia vivida* (Hagen) (Odonata, Coenagrionidae) in fuel-modified forest. *Journal of Insect Conservation* 14(2): 133-140. (in English) ["Fuel management for wildfire protection is becoming increasingly common in the wildland-urban interface and may have conservation implications for species with restricted distributions and limited dispersal abilities. To evaluate the impact of forest fuel management on the damselfly *A. vivida* at the northern margin of its range, we examined terrestrial movements and habitat associations using Capture-Mark-Recapture and point count techniques. We found that habitats away from the springs were particularly important for *A. vivida* females. Most damselflies travelled at least 50 m between capture and recapture and patches of cleared forest up to this size did not pose a barrier to movement. Although *A. vivida* typically roosts in trees at night, cleared fuel treatment areas were preferred over unmodified or thinned forest as daytime basking and foraging sites. Preferred sites were also characterized by heterogeneous canopy closure, i.e., a clearing adjacent to unmodified forest with a closed canopy. We speculate that this behaviour derives from the species' thermoregulation requirements; the use of sunspots for thermal basking during the day and the use of forest cover at night to slow the radiant loss of heat. Our findings demonstrate the scale of movements that define available habitat and the importance of both daytime and night time habitat requirements in considering terrestrial foraging and movement corridors. Consequently, conservation efforts for this species in fuel management areas should focus on maintaining unmodified stands of dense trees in association with cleared patches of appropriate dimension, rather than a uniformly thinned forest." - 8838.** Kraus, J.M. (2010): Diet shift of lentic dragonfly larvae in response to reduced terrestrial prey subsidies. *Journal of the North American Benthological Society* 29(2): 602-613. (in English) ["Inputs of terrestrial plant detritus and nutrients play an important role in aquatic food webs, but the importance of terrestrial prey inputs in determining aquatic predator distribution and abundance has been appreciated only recently. I examined the numerical, biomass, and diet responses of a common predator, dragonfly larvae, to experimental reduction of terrestrial arthropod input into ponds. I distributed paired enclosures ($n = 7$), one with a screen between the land and water (reduced subsidy) and one without a screen (ambient subsidy), near the shoreline of 2 small fishless ponds and sampled each month during the growing season in the southern Appalachian Mountains, Virginia (USA). Screens between water and land reduced the number of terrestrial arthropods that fell into screened enclosures relative to the number that fell into unscreened enclosures and open reference plots by 36%. The $\delta^{13}C$ isotopic signatures of dragonfly larvae shifted towards those of aquatic prey in reduced-subsidy enclosures, a result suggesting that dragonflies consumed fewer terrestrial prey when fewer were available (ambient subsidy: 30%, reduced subsidy: 19% of diet). Overall abundance and biomass of dragonfly larvae did not change in response to reduced terrestrial arthropod inputs, despite the fact that enclosures permitted immigration/emigration. These results suggest that terrestrial arthropods can provide resources to aquatic predators in lentic systems, but that their effects on abundance and distribution might be subtle and confounded by in situ factors." (Author) The most common dragonflies emerging from the ponds during the experiment were *Libellula lydia*, *L. pulchella*, *Somatochlora elongata*, *Cordulia shurtleffi*, *Aeshna umbrosa*, and *Sympetrum rubicundulum*.] Address: Kraus, Johanna, Trani Center for Life Sciences, Dept of Biology, Virginia Commonwealth Univ., 1000 West Cary Street, Richmond, Virginia 23284-2012 USA. (in Polish, with English summary) [On 11-VII-2007, a male *C. boltonii* was recorded near Lubienia (UTM EB15), Poland. "The nearest known locality is situated in the Suchedniowsko-Oblęgorski Landscape Park, where the species was recorded in 1981. After the year 2005 found in the vicinity of Suchedniowsko-Oblęgorski Landscape Park and in the Świętokrzyskie (Holy Cross) Mountains. The extent of *C. boltonii* in Poland includes northwestern, midwestern and southern part of the country, and only one locality known from the North-East. The species seemed to be nearly extinct in the Upper Silesia region, however, it has recently been rediscovered in this area. The species is protected by law in Poland and in the

national Red List 2002 it was qualified for the category VU – (vulnerable). However, new data have shown the more favourable conservation status of the species than it had previously been assessed. Therefore, *C. boltonii* has been deleted from the Polish Red List." (Authors)] Address: Kutera, M., Rudka 30, 27–415 Kunów. Poland. E-mail: marcin.kutera@poczta.onet.pl

8840. Lavilla, I.; Rodrigueza-Linares, G.; Garrido, J.; Bendicho, C. (2010): A biogeochemical approach to understanding the accumulation patterns of trace elements in three species of dragonfly larvae: evaluation as biomonitors. *J. Environ. Monit.* 12: 724-730. (in English) ["The accumulation patterns of different trace elements (As, Cd, Cr, Cu, Fe, Mn, Ni, Pb and Zn) were studied in three species of dragonfly larvae (*Cordulegaster boltoni*, *Boyeria irene* and *Onychogomphus uncatas*). Additionally these species were assessed as potential biomonitors in a lotic ecosystem (Louro River, Spain). Element concentrations were determined by inductively coupled plasma optical emission spectrometry (ICP-OES) in both dragonfly larvae and river sediments. The surface of the larvae was observed and analyzed with scanning electron microscopy (SEM). A desorption test was used to establish the percentage of element adsorbed into the exoskeleton. Field biomonitoring studies were made considering the first part of the river as a control area in relation to the second part, which was severely polluted by industrial and domestic activities. Upon application of principal component analysis (PCA), two different element groups were found in relation to element bioaccumulation. Cu, Cd and Zn were mainly associated with the inner part of the larvae. As, Cr, Fe, Mn, Ni and Zn were found on the outer body parts, related with deposition of oxyhydroxides in the hydrocycle. SEM revealed a layer of inorganic particles, similar in composition to fine bed sediments. Significant relations between the element content of this group and that of sediments at the sampling site were found. Differences in bioaccumulation for each of the three species, except for As, were observed. Dragonfly larvae revealed their ability to reflect environmental concentrations of As in freshwater media." 8841. Lehmann, F.-O. (2010): Wing-wake interaction reduces power consumption in insect tandem wings. In: G.K. Taylor, M.S. Triantafyllou & C. Tropea (eds.): *Animal Locomotion*. Springer Verlag. Berlin Heidelberg. ISBN 978-3-642-11632-2: 203-213. (in English) ["Insects are capable of a remarkable diversity of flight techniques. Dragonflies, in particular, are notable for their powerful aerial manoeuvres and endurance during prey catching or territory flights. While most insects such as flies, bees and wasps either reduced their hind wings or mechanically coupled fore and hind wings, dragonflies have maintained two independent-controlled pairs of wings throughout their evolution. An extraordinary feature of dragonfly wing kinematics is wing phasing, the shift in flapping phase between the fore and hind wing periods. Wing phasing has previously been associated with an increase in thrust production, readiness for manoeuvrability and hunting performance. Recent studies have shown that wing phasing in tandem wings produces a twofold modulation in hind wing lift, but slightly reduces the maximum combined lift of

fore and hind wings, compared to two wings flapping in isolation. Despite this disadvantage, however, wing phasing is effective in improving aerodynamic efficiency during flight by the removal of kinetic energy from the wake. Computational analyses demonstrate that this increase in flight efficiency may save up to 22% aerodynamic power expenditure compared to insects flapping only two wings. In terms of engineering, energetic benefits in four-wing flapping are of substantial interest in the field of biomimetic aircraft design, because the performance of man-made air vehicles is often limited by high-power expenditure rather than by lift production. This manuscript provides a summary on power expenditures and aerodynamic efficiency in flapping tandem wings by investigating wing phasing in a dynamically scaled robotic model of a hovering dragonfly." 8845. Locklin, J.L.; Vodopich, D.S. (2010): Patterns of gregarine parasitism in dragonflies: host, habitat, and seasonality. *Parasitology Research* 107(1): 75-87. (in

English) ["Gregarines are ubiquitous protozoan parasites that infect arthropods worldwide. More than 1,600 gregarine species have been described, but only a small percentage of invertebrates have been surveyed for these apicomplexan parasites. Adult dragonfly populations were surveyed for gregarines at two reservoirs in Texas, USA for 2 years. Gregarine prevalence and intensity were compared intraspecifically between host genders and reservoirs, among wing loads, and through time. Of the 29 dragonfly species collected, 41% hosted gregarines. Nine of these dragonfly species were previously undocumented as hosts. Among the commonly collected hosts, prevalence ranged from 18 to 52%. Parasites were aggregated among hosts and had a median intensity of five parasites per host. Gregarines were found only in hosts exceeding a minimum wing load, indicating that gregarines are likely not transferred from the naiad to adult during emergence. Prevalence and intensity increased during both years, suggesting that gregarine oocyst viability parallels increasing host population densities and may be short-lived. Prevalence and intensity also differed between dragonfly populations at two reservoirs. Regression analyses revealed that host species, host gender, month, and year were significant explanatory variables related to gregarine prevalence and intensity. Abundant information on odonate distributions, diversity, and mating activities makes dragonfly-gregarine systems excellent avenues for ecological, evolutionary, and parasitological research. Our results emphasize the importance of considering season, hosts, and habitat when studying gregarine-dragonfly ecology." 8846. Lumbra, L. (2010): Wildlife, Plants and Natural Communities News. Natural Heritage Harmonies Winter 2010: 4-6. (in English) [Vermont, USA; Statewide surveys have been completed to identify Odonata that live in peatland habitats and large rivers. Information from this project has greatly increased our knowledge of both common and rare members of the odonate family. Twenty-seven species of greatest conservation need (SGCN) were targeted in these habitats, of which 20 were observed. Three additional SGCN were encountered during the course of field work. One new species for the state, *Enallagma durum* was also observed. Efforts included at least 54 sites on 23 rivers and 28 peatland sites. Overall, the project has resulted in the discovery of new sites for many of Vermont's Odonata SGCN. This project has allowed us, for the first time, to assign status ranks to all of Vermont's Odonata, which number over 140 species.] Address: Vermont Fish & Wildlife Department, 103 South Main Street, 10 South Waterbury, VT 05671-0501, USA

8847. Mantel, S.K.; Muller, N.W.J.; Hughes, D.A. (2010): Ecological impacts of small dams on South African rivers Part 2: Biotic response – abundance and composition of macroinvertebrate communities. *Water SA* 36(3): 361-370. (in English) ["This paper investigates the cumulative impacts of small dams on invertebrate communities in 2 regions of South Africa – the Western Cape and Mpumalanga. Previous research found reduced discharge, increased total dissolved salts, and a decrease in average score per taxon (ASPT; collected using SASS4 methods) at sites with high density of small dams in their catchment. These

changes in ASPT are investigated using the invertebrate abundance data available in the River Health Programme. Multivariate analyses found differences in invertebrate communities in rivers with high densities of small dams in their catchment in foothill-gravel streams (in both Western Cape and Mpumalanga) and in foothill-cobble streams (in Western Cape only). Opportunistic taxa that are tolerant of pollution, and capable of exploiting various habitats, and those that prefer slower currents increased in numbers, while other taxa that are sensitive to pollution and disturbance declined in numbers. Some regional differences were noted possibly reflecting climatic differences between the regions. Since the results of this study are correlative, it highlights the need for a systematic (by sites and seasons) and detailed (at species level) collection of data to verify the results of cumulative effects of small dams. This can further the development of a framework for small-dam construction and management that will limit their impact on river catchments. ... the average abundance for the taxa contributing to 90% of the dissimilarity in the invertebrate communities between sites with low and high small-dam density for the 3 group comparisons where ANOSIM found significant differences. In general, the abundance of taxa with low SASS4 scores (signifying species that are less sensitive to pollution and disturbance, and primarily belonging to Turbellaria, Mollusca and Heteroptera) increased, and those with high SASS4 score (i.e. more sensitive species, mostly Odonata, Trichoptera and some Ephemeroptera) declined." (Authors) Odonata are treated at the family level.] Address: Mantel, S.K., Unilever Centre for Environmental Water Quality – Institute for Water Research (UCEWQ-IWR), Rhodes University, PO Box 94, Grahamstown, South Africa. Martin, K.H. (2010): The transition zone: Impact of riverbanks on emergent dragonfly nymphs. Implications for riverbank restoration and management. Ph.D. thesis, Antioch University, Antioch New England: Environmental Studies: IV, 104 pp. (in English) ["The use of riprap in the restoration and stabilization of riverine landscapes is an issue of concern for many ecologists. While current methods of bank stabilization, especially those involving the placement of rocks (riprap) along the waterline, are effective in controlling erosion their presence changes habitat components (slope, substrate composition, near-shore river velocity) at the river-land interface. The additional impacts of river current, water temperature, soil composition, slope, and water level fluctuation, may further imperil emerging nymphs. The purpose of this research is to document the effects of riprap, location (upriver or downriver of hydroelectric intake/outtake facilities), water level fluctuation, river velocity, air temperature, water temperature, substrate temperature, and soil composition on the distance traveled to eclosure site by *G. vastus* and *S. spiniceps*, and the density of *S. spiniceps*, *G. vastus*, *N. yamaskanensis*, *D. spinosus*, *O. rupinsulensis*, *M. illinoensis*, and *E. priniceps*. Knowledge of the conservation status of these species is fairly limited, although *S. spiniceps* (threatened), *G. vastus* (species of special concern), and *N. yamaskanensis* (species of special concern) are all currently listed on the Massachusetts Endangered Species list. Species density was determined through exuviae collection, and emergence distance was recorded from the edge of the waterline to the site of attached exuviae. Results of the study indicate that nymphal response to the observed abiotic

features varies both with location and species. The presence of riprap had no significant effect on densities of *S. spiniceps*, *G. vastus*, *N. yamaskanensis*, *D. spinosus*, *O. rupinsulensis*, *M. illinoiensis*, and *E. princeps*, but did significantly reduce the distance traveled from the waterline by both *G. vastus* and *S. spiniceps*." 8848. McCauley, S. (2010): Body size and social dominance influence breeding dispersal in male *Pachydiplax longipennis* (Odonata). *Ecological Entomology* 35 (3): 377-385. (in English) ["1. Dispersal behaviour can be affected by an individual's phenotype, by the environmental or social context they experience, and by interactions between these factors. Differential dispersal propensities between individuals may also be an important modifier of functional connectivity between populations. To assess how a key trait, body size, affected both social interactions and dispersal behaviour, this study examined the relationship between body size, antagonistic interactions, and breeding dispersal in male *P. longipennis* across a seasonal decline in adult body size. 2. During a seasonal peak in male body size in this study, dispersers were smaller than non-dispersers. Later in the season, the body size of dispersers and non-dispersers did not differ. 3. Focal observations found that body size was related to competitive dominance, large males engaged in aggressive chases more often and smaller males were more frequently pursued. 4. These results indicate that when large males were present, small males were more likely to disperse suggesting that dispersal is a tactic adopted by social subordinates in this context. If breeding dispersal is typically undertaken by subordinate males, functional connectivity between populations may be less than estimated from absolute dispersal rates." 8849. McCauley, S.J.; Brodin, T.; Hammond, J. (2010): Foraging rates of larval dragonfly colonists are positively related to habitat isolation: Results from a landscape-level experiment. *American Naturalist* 175 (3): E66-E73. (in English) ["There is increasing evidence of intraspecific variation in dispersal behaviour. Individual differences in dispersal behaviour may be correlated with other traits that determine the impact individuals have on patches they colonize. We established habitat patches—artificial pools—across a landscape, and these pools were naturally colonized by dragonfly larvae. Larvae were collected from pools at different levels of isolation and held under common lab conditions for 5 months. We then compared larval foraging rates. Foraging rate was positively related to habitat isolation, and colonists from the most isolated artificial pools had significantly higher foraging rates than individuals from the least isolated pools. Our results indicate that spatial patterns in colonist behaviour can develop across a landscape independent of species-level dispersal limitation. This finding suggests that studies of community structure across space should include an assessment of the distribution of phenotypes as well as species-level dispersal limitation patterns." 8852. Moreno, J.L.; Angeler, D.G.; De las Heras, J. (2010): Seasonal dynamics of macroinvertebrate communities in a semiarid saline spring stream with contrasting environmental conditions. *Aquatic Ecology* 44: 177-193. (in English) ["Semiarid saline streams are rare aquatic ecosystem types. Their constituent biota is expected to have adapted evolutionarily to strong hydrological variability and salinity stress; however, their ecology is not well known. In this study, we quantify the seasonal changes in the structure of the macroinvertebrate community in the Reventón Rambla (southeastern Spain), a permanent saline spring stream which is included in a drainage system consisting of ephemeral dry channels (so-called "ramblas"). Seasonal patterns of community structure were studied in two reaches with contrasting environmental regimes using univariate and multivariate statistics. The upstream site showed more stable environmental conditions than the downstream site, and both sites also differed with regard to species richness, and structural and functional group attributes. On a seasonal basis, community dissimilarity was high during periods when both sites were isolated during summer droughts but dissimilarity decreased when both sites were connected through surface flow. Furthermore, the communities tended to show cyclical trajectories in multivariate ordination space. Rather than being related to salinity stress, these patterns seemed to track the hydrological disturbance regime of this rambla system. Spates tended to disrupt communities, while signs of recovery were evident during low-flow periods. Results suggest that salinity fluctuation does not pose a severe abiotic constraint to these adapted macroinvertebrate communities. Their

suits of functional properties provide them with the necessary traits to recover quickly from natural disturbance. While human-caused salinization of streams severely impacts communities eventually reducing their recovery potential, our results suggest that communities in natural saline streams may show similar responses to hydrological disturbance as communities from non-saline streams. [...] The biomass of Diptera and Odonata was significantly higher in the upstream reach, and Ephemeroptera and Heteroptera in the downstream reach. The biomass of Mollusca, Hydrachnidia, Diptera, Odonata, Ephemeroptera, Coleoptera and Heteroptera showed a marked increase in the spring-summer period. The highest value of average dissimilarity between upstream and downstream sites was recorded in summer (78.17%), when communities were more independent as a result of isolation of both reaches. When both sites were connected by high flows (e.g. autumn), the structure of upstream and downstream communities was more similar, showing a lower dissimilarity value. The main dissimilarities between upstream and downstream sites in community structure, measured as biomass differences, were shown by Mollusca [...] and Odonata (*Orthetrum brunneum* at upstream)." 8854. Nagel, L.; Robb, T.; Forbes, M.R. (2010): Inter-annual variation in prevalence and intensity of mite parasitism relates to appearance and expression of damselfly resistance. *BMC Ecology* 2010, 10:5: (in English) ["Background: Insects can resist parasites using the costly process of melanotic encapsulation. This form of physiological resistance has been studied under laboratory conditions, but the abiotic and biotic factors affecting resistance in natural insect populations are not well understood. Mite parasitism of damselflies was studied in a temperate damselfly population over seven seasons to determine if melanotic encapsulation of mite feeding tubes was related to degree of parasitism, host sex, host size, emergence timing, duration of the emergence period, and average daily air temperature. Results: Although parasite prevalence in newly emerged damselflies was >77% each year, hosts did not resist mites in the early years of study. Resistance began the year that there was a dramatic increase in the number of mites on newly emerged damselflies. Resistance continued to be correlated with mite prevalence and intensity throughout the seven-year study. However, the percentage of hosts resisting only ranged from 0-13% among years and resistance was not sex-biased and was not correlated with host size. Resistance also was not correlated with air temperature or with timing or duration of damselfly emergence. Conclusions: Resis-

tance in host damselflies was weakly and variably expressed over the study period. Factors such as temperature, which have been identified in laboratory studies as contributing to resistance by similar hosts, can be irrelevant in natural populations. This lack of temperature effect may be due to the narrow range in temperatures observed at host emergence among years. Degree of mite parasitism predicted both the appearance and continued expression of resistance among parasitized damselflies." 8857. Ohiokhioya, T.; Imoobe, T.; Ohiozebau, E. (2010): Pollution status of a tropical forest river using aquatic insects as indicators. *African Journal of Ecology* 48(1): 232-238. (in English, with French summary) ["Aquatic insects inhabiting Okhuo River, in a tropical forest near Benin City, Southern Nigerian, were studied between January and December 2006 to determine the taxa composition, diversity, EPT index, relative proportions of the various groups and hence the pollution level of the waterbody. Three stations were selected and sampled monthly using the kick sampling technique. A total of 3235 individual aquatic insects belonging to 24 taxa distributed among 23 genera in six orders were collected. The insect orders occurred in the following order of dominance: Ephemeroptera > Odonata > Coleoptera > Diptera > Plecoptera > Tricoptera. Based on the diverse composition of the community dominated by organisms intolerant of organic enrichment, and the

high diversity and EPT index, water quality in Okhuo River is not significantly degraded. Community composition varies seasonally, with a trend toward a declining proportion during the rainy season and increasing proportions during the dry season. Aquatic insect composition in Okhuo River compares favourably with those in similar, relatively undisturbed forest streams and rivers in Nigeria, but the diversity and proportional distribution of taxa vary considerably between streams." (in English) [Maui, Hawaii, this winter (9–15 December 2009); visiting known as prospective localities for *Megalagrion* species, no *Megalagrion* specimens could be traced. „We saw crayfish and *Gambusia* (both introduced) at a number of the stream crossings, and my understanding was that both of them, as well as other fish species introduced in the lower reaches of many of the streams, could have adverse effects on *Megalagrion* populations. I wonder if they have increased and/or spread farther since Jerrell was there in 1993.“] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dpaulson@ups.edu

8863. Pinto, A.P.; Carvalho, A.L. (2010): A new species of *Lauromacromia* (Odonata: Corduliidae) from Southeastern Brazil, with a cladistic analysis of the genus and comments on Neotropical dragonfly biogeography. *Zootaxa* 2425: 45-68. (in English) ["*Lauromacromia melanica* sp. nov. from Conceição da Barra municipality, Espírito Santo State, Brazil, is described and illustrated based on two males (both in MNRJ nº 135). The new species is similar to *L. pinguaba* differing from it mainly by the absence of pale spots on S3–6 and by the ellipsoid shape of metepisternal pale stripe. A key for males of all species of the genus is provided. A cladistic analysis encompassing 43 external morphological male characters carried out in two distinct procedures, the first with all characters unordered and the second with two or three state characters ordered. The unordered analysis generated only one most-parsimonious tree (66 steps of length, CI = 0.69, RI = 0.62). The hypothesis of monophyly of *Lauromacromia* is supported and includes three groups, one formed by the Atlantic Forest species (*L. melanica* sp. nov. + *L. pinguaba*), and another by the Cerrado species (*L. flaviae* + (*L. bedei* + *L. luismoojeni*)), and *L. dubitalis*, positioned in polytomy with these two groups. The ordered analysis also generated only one most-parsimonious tree (68 steps of length, CI = 0.70, RI = 0.67), which maintained the monophyly of *Lauromacromia* but *L. dubitalis* positioned basally as sister-group to the Atlantic Forest + Cerrado species groups. The geographic distribution of *Lauromacromia* is updated with a new record of *L. luismoojeni* based on one adult male (Brazil: Mato Grosso do Sul State) and probable first Brazilian records for *L. dubitalis* (Amazonas and Pará States) based on two larvae. A vicariance hypothesis is proposed to explain spatial evolution of *Lauromacromia*, and based on current biogeographical classifications we consider *Gomphomacromia* and *Rialla* apart from Neotropical biota. Some aspects of biology and ecology of *Lauromacromia* are also discussed." (Authors)] Address: Pinto, A.P., Programa de Pós-graduação em Ciências Biológicas (Zoologia) IB - USP, Museu de Zoologia, Universidade de São Paulo, Av. Nazaré 481, Ipiranga 04263-000, São Paulo, SP, Brazil. E-mail: odonata_angelo@hotmail.com

8864. Popova, O.N.; Smirnova, Yu.A. (2010): Community of aquatic insects in forest-steppe lakes of Baraba (South of West Siberia). *Contemporary Prob-*

lems of Ecology 3(1): 50-54. (in English) ["The studies were performed from 2004 to 2006 (mid-May-late October) on drainage Lake Fadikha, a typical water body with reed beds in the Barabinsk region of the Baraba forest-steppe zone in the south of West Siberia." At the lake and adjacent areas, 41 species of dragonflies (imagos) were identified. Samples taken from the lake contained larvae of 18 Odonata species. A checklist of the species is omitted in the paper. Some results are discussed as follows: In the sublittoral, 14 species (8 Anisoptera and 6 Zygoptera), and in the reed border, also 14 species (9 Anisoptera and 5 Zygoptera) were found. In the sublittoral, *Lestes sponsa*, *Aeshna serrata*, *Leucorrhinia dubia*, and *Sympetrum danae* were absent. "The absence of *Lestes sponsa* in the sublittoral zone is not surprising since this species prefers shallow, saline, and heavily silted or overgrown water bodies. The absence of the other three species may be occasional [...]. In reeds (*Phragmites australis* reed beds), *Enallagma cyathigerum*, *Erythromma najas*, *Anax parthenope*, and *Somatochlora flavomaculata* are absent. [...] Ten species, characterized by wide environmental valence, appeared to be common for the sublittoral and reeds: *Sympecma paedisca*, *Coenagrion armatum*, *C. lunulatum*, and *C. pulchellum*, and *Leucorrhinia pectoralis*, *L. rubicunda*, *Libellula quadrimaculata*, *Sympetrum flaveolum*, *S. sanguineum*, and *S. vulgatum*. A comparison of the number of dragonfly larvae in the studied biotopes showed that Odonata are 3.3 times more abundant in reeds than in the sublittoral, and of them Anisoptera were 1.7 times and Zygoptera 3.6 times more abundant in reeds than in the sublittoral. The ratio of the numbers of Anisoptera and Zygoptera is 1 : 6.4 in the sublittoral and 1 : 13.5 in reeds. Most likely, these ratios are not quite realistic. This large difference between Anisoptera and Zygoptera in the number of larvae is likely due to the specific distribution of representatives of each of the suborders in the water environment. Anisoptera larvae, unlike Zygoptera larvae, appear to show aggregated distribution more often than random; therefore they are rare and less abundant in samples. Generally, the number of Anisoptera larvae in a water body should not be much smaller than that of Zygoptera larvae because counts of imagos provide evidence for approximately equal proportions of these suborders in nature." 8866. Pryke, J.S.; Samways, M.J. (2010): Significant variables for the conservation of mountain invertebrates. *J. Insect Conserv.* 14: 247-256. (in English) [Conserving biodiversity on mountains holds particular challenges, with topographic species beta diversity being high. In turn, conserving mountain biodiversity in the heart of a biodiversity hotspot, with intense urbanization on its lower slopes, poses further challenges. We investigate here an iconic mountain at the southern tip of Africa, which is under multiple human pressures, while receiving much conservation attention. We sought here some general principles to guide conservation management of this and other similar mountains. Our focal organisms were surface-active invertebrates, as they are abundant, diverse, and environmentally sensitive at point localities. We show that vegetation structure and elevation were the most important environmental variables determining this diversity. Type of fynbos vegetation, proximity of forest to a river, aspect, and abundance of the alien Argentine ant *Linepithema humile*, had no significant influence. Suburban woodland species richness and abundance had a non-significant difference to that of natural forest. Fynbos had high species beta diversity of invertebrates, suggesting that large areas of this dominant vegetation type should be conserved. However, many specialist and highly local endemic species were in forest, highlighting the irreplaceability of forest habitats. Such a mountain, with its complex topography, requires total protection, as there is no room for loss of any part of the mountain. We emphasize that, while the upper slope and summit are well protected, the lower slopes are in need of urgent attention, a situation which mirrors that in Europe." (Authors) Reference is made to *Orthetrum rubens* which has not been recorded on the Cape Peninsula since the holotype was collected in 1927.] Address: Samways, M.J., Dept Entomol. & Nematol., Univ. More than 70% of Odonata were caught at mercury, and app. 30% at black light sources. None was attracted by ultra violet light sources. The absolute numbers of Odonata are not stated.] Address: Ramamurthy, V.V., Division of Entomology, Indian Agricultural Research Institute, New Delhi-110012, India

8868. Reels, G. (2010): Report on field surveys of dragonflies in Hainan, China, and preparation of a field guide to the Odonata of the island. *International Dragonfly Fund - Report* 24: 1-60. (in English) [Four Kadoorie Farm & Botanic Garden (KFBG, Hong Kong)

field surveys were joined in order to gather information for a field guide on Hainan Odonata focused primarily on nature reserves, with some sampling of unprotected upland and lowland habitats. The locations visited were dictated by KFBG, in close collaboration with local officials, and comprised sites in southern, central and eastern parts of the island. The results of the study are detailed and species list are presented locality-wise. A checklist of 160 Odonata of Hainan is presented, but additional material from other region of the Island and current studies not yet finished are known. The total number of Hainan Odonata taxa should be 170, and it is to expect that this number will be exceeded by intensifying research activities. The paper contains personally written reports and little stories, and is furnished with wonderful pictures of Odonata species and landscape impressions.] Address: Reels, G., H-3-30 Fairview Park, Yuen Long, Hong Kong. 8869. Resende, D.C. (2010): Residence advantage in heterospecific territorial disputes of Erythrodiplax braueri species (Odonata, Libellulidae). *Revista Brasileira de Entomologia* 54(1): 110-114. (in English, with Portuguese summary) [Área de Proteção Ambiental (APA) São José, Minas Gerais, Brazil; "Territories are the outcome of interactions determining where and how long individuals settle. To odonate species, aggressive disputes are not so common since the outcome can be predetermined by advantages such as residency, age, and body size. However, it is possible to predict that at heterospecific disputes, larger body-sized or more aggressive species have some profits overcoming these individual advantages, generating patterns of species hierarchy. Here, I studied the aggressiveness of five Erythrodiplax species (*E. famula*, *E. fusca*, *E. latimaculata*, *E. media*, *E. pallida*) during territorial disputes and verified if larger body-sized species are more aggressive than smaller ones or if the residence advantage prevails on the heterospecific disputes. Larger species were not more aggressive than smaller ones and winners of intra- and interspecific territorial disputes were defined mainly by the residence. So, the residence advantage between heterospecific opponents appears to prevail over any other asymmetry among these species. This pattern may occur because, despite the territorial behaviour in dragonfly males, heterospecific disputes may not increment male reproductive success because it may not increase their access to females." (Author)] Address: Resende, D.C., Laboratório de Bioinformática e Evolução, Departamento de Biologia Geral, Universidade Federal de Viçosa, 36570-000, Viçosa-MG, Brasil. E-mail: dcresende@ig.com.br

8870. Sadeghi, S.; Kyndt, T.; Dumont, H.J. (2010): Genetic diversity, population structure and taxonomy of *Calopteryx splendens* (Odonata: Calopterygidae): An AFLP analysis. *Eur. J. Entomol.* 107(2): 137-146. ["*Calopteryx splendens* is a widely distributed palaeartic damselfly with a remarkably uniform morphology. Variation in the size and shape of the pigmented spot on the wing is the main diagnostic character used to discriminate subspecies across its huge geographic range. Here, AFLP analysis was used to assess the genetic structure and diversity of nine populations representing 3 putative subspecies and evaluate the pigment spot as a taxonomic marker. Genetic diversity was high, with the number of polymorphic loci per population ranging from 141 to 280 out of a total of 333 variable sites

(42.3–84.1%) and Nei's gene diversity from 0.160 to 0.283 (overall 0.299). Overall population genetic differentiation ($F_{ST} = 0.2766$) suggests limited gene flow and adaptation to local environments. Restricted gene flow and genetic differentiation among populations are supported by significant F_{ST} estimates. High levels of gene flow ($N_m > 1$) were only recorded among three Asian populations (Russia – Kazakhstan – Turkey). The patterns of genotypic diversity suggest that a given wing spot size and shape may arise from the hybridization of a limited number, possibly not more than four, ancestral gene pools in different ways and at different times. Clearly, the sample analyzed was not sufficient to capture all of the complex history of *C. splendens*, but sufficient to indicate the taxa *ancilla*, *waterstoni*, and *orientalis* possibly represent three of the four ancestral gene pools, and originated in western Asia. The origin of the fourth, *xanthostoma*, is the western Mediterranean." 8871. Samejima, Y.; Tsubaki, Y. (2010): Body temperature and body size affect flight performance in a damselfly. *Behav. Ecol. Sociobiol.* 64: 685-692. (in English) ["Flight performance is undoubtedly an important factor for behavioural success in flying insects. Though it is well-known that the flight performance is influenced by body temperature and body size, the relative importance of these factors is not well-understood. We performed laboratory experiments using the male-polymorphic damselfly *Mnais costalis* with larger territorial males and smaller nonterritorial males in a population. We analyzed the effects of body temperature and body size, measured as the thoracic temperature and left hind-wing length, respectively, on two indices of flight performance: maximum lifting force and size-corrected lifting force. The latter is an index of acceleration that is related to aerial agility. The results showed that higher body temperature produced both larger maximum lifting force and larger size-corrected lifting force. In contrast, while larger size produced a larger maximum lifting force, it produced a lower size-corrected lifting force. The results of field measurements showed that territorial males had variable thoracic temperatures depending on the insolation in their territories. In contrast, nonterritorial males had less variable and generally higher thoracic temperatures than territorial males as they are mostly found in sunny spots. Until now, the influence of body temperature on behavioural performance has remained unclear although considerable studies have suggested such influence. We showed, here, for the first time, combined effects of body size and body temperature on flight performance. We also showed that body temperature was influenced by the mating strategies of a damselfly. These findings provide new insights into the cost and benefits of territorial behaviour in ectothermic animals." 8872. Sanchez-Herrera, M.; Realpe, E. (2010): Population structure of *Polythore procera* at a Colombian stream (Odonata: Polythoridae). *International Journal of Odonatology* 13(1): 27-37. (in English, with Spanish summary) ["We studied a population of *Polythore procera* along a stream in the Colombian eastern Andean foothills. Mark and recapture samples were made dur-

ing January to April 2006, covering both dry and wet seasons. We determined population size, daily survival probability, and longevity during the entire period and compared them with precipitation data. Age and sex proportions along two different sectors of the stream were also analyzed, and notes about their ecology and habitat were taken. Our data suggest this species has a high daily survival probability in comparison with those of other odonates. Males are highly territorial, and exhibit low dispersal capacity. We also conclude that population dynamics of *P. procerus* can be affected by an extrinsic factor such as seasonality." 8873. Śniegula, S.; Johansson, F. (2010): Photoperiod affects compensating developmental rate across latitudes in the damselfly *Lestes sponsa*. *Ecological Entomology* 35(2): 149-157. (in English) ["1. Although there is a great deal of theoretical and empirical data about the life history responses of time constraints in organisms, little is known about the latitude-compensating mechanism that enables northern populations' developmental rates to compensate for latitude. To investigate the importance of photoperiod on development, offspring of the obligatory univoltine damselfly *Lestes sponsa* from two populations at different latitudes (53°N and 63°N) were raised in a common laboratory environment at both northern and southern photoperiods that corresponded to the sites of collection. 2. Egg development time was shorter under northern photoperiod regimes for both populations. However, the northern latitude population showed a higher phenotypic plasticity response to photoperiod compared with the southern latitude population, suggesting a genetic difference in egg development time in response to photoperiod. 3. Larvae from both latitudes expressed shorter larval development time and faster growth rates under northern photoperiod regimes. There was no difference in phenotypic plastic response between northern and southern latitude populations with regard to development time. 4. Data on field collected adults showed that adult sizes decreased with an increase in latitude. This adult size difference was a genetically fixed trait, as the same size difference between populations was also found when larvae were reared in the laboratory. 5. The results suggest phenotypic plasticity responses in life history traits to photoperiod, but also genetic differences between north and south latitude populations in response to photoperiod, which indicates the presence of a latitudinal compensating mechanism that is triggered by a photoperiod." 8877. Tom, K.R.; Newman, M.C.; Schmerfeld, J. (2010): Modeling mercury biomagnification (South River, Virginia, USA) to inform river management decision making. *Environmental Toxicology and Chemistry* 29(4): 1013-1020. (in English) ["Mercury trophic transfer in the South River (VA, USA) was modeled to guide river remediation decision making. Sixteen different biota types were collected at six sites within 23 river miles. Mercury biomagnification was modeled using a general biomagnification model based on 15N and distance from the historic mercury release. Methylmercury trophic transfer was clearer than that for total Hg and, therefore, was used to build the predictive model (r^2 prediction = 0.76). The methylmercury biomagnification factors were similar among sites, but model intercept did increase with distance down river. Minimum Akaike's Information Criterion Estimation (MAICE) justified the incorporation of distance in the model. A model with a very similar biomagnification factor to the South

River (95% confidence intervals [CI] = 0.38-0.52) was produced for a second contaminated Virginia river, the North Fork Holston River (95% CI = 0.41-0.55). Percent of total Hg that was methylmercury increased monotonically with trophic position. Trophic models based on ^{15}N were adequate for predicting changes in mercury concentrations in edible fish under different remediation scenarios." (Authors) Test organisms include "Gomphidae" and "Zygoptera".] Address: Newman, M., College of William and Mary - VIMS, Gloucester Point, Virginia 23062, USA. E-mail: newman@vims.edu

8879. Villanueva, R.J.T. (2010): Dragonflies of Polillo Island, Philippines. *International Dragonfly Fund - Report* 23: 1-24. (in English) [Polillo is a small group of islands east of central Luzon made up of four main islands and several islets. Odonata were recorded and voucher specimens collected between April 16 and April 27 2009. Sixty-two species of 14 families and 41 genera were found. An additional two unidentified Aeshnidae were seen. Two of the 17 previously recorded species were not found. An observed *Anax* could not be determined and it was uncertain whether it was the previously recorded *A. guttatus* or represented an additional island record. The *Gynacantha* material could not be compared at the moment with the previously recorded species. Forty-seven of the recorded species are new to the island and one species is new to the Philippines. Furthermore, five of the recorded species (*Sulcosticta*, *Amphicnemis*, *Teinobasis*, *Heliogomphus*) are new or possible new to science. An additional four of the recorded species (*Drepanosticta*, *Amphicnemis*, *Teinobasis*, *Rhinocypha*) shows variation from known species or need more material for better comparison and some of them may even represent an additional species new to science. The first male of *Idionyx salva* was found. *Drepanosticta* sp. n. without naming is described. *Teinobasis martinschorri* nov. sp. is described after three males (holotype male: Tamulaya, Polillo, Polillo Island. April 25, 2009. RJTV leg., to be deposited in RMNH; paratype: 2 males in the authors collection). A female of *Gomphidia kirschii* is described in detail.] Address: Villanueva, R.J.T., 1 D3C Gahol Apartment, Lopez Jaena St., Davao City, 8000 Philippines. E-mail: rjtvillanueva@gmail.com

8880. Vries, H.H. de (2010): Species Protection Plan for *Aeshna viridis*. *Brachytron* 12(1/2): 25-31. (in English, with Dutch and German summaries) ["*A. viridis* was the first dragonfly in the Netherlands to have its own national species protection plan. This was published in 2001 by the Ministry of Agriculture, Nature and Fisheries, aiming to initiate several conservation activities. As *A. viridis* is strongly associated with *Stratiotes aloides*, this plant plays an important role in the strategies adopted for protection and communication. The protection plan led to a number of projects in several

provinces, including the compilation of distribution maps, communication about good management and starting nature restoration. Backed up with European legislation, the need for protection of this species has come to the attention of a much wider audience. Therefore, it can be expected that this plan will continue to have an effect long after the projects it gave rise to have ended." 8882. Wedmann, S.; Poschmann, M.; Hörschemeyer, T. (2010): Fossil insects from the Late Oligocene Enspel Lagerstätte and their palaeobiogeographic and palaeoclimatic significance. *Palaeobio. Palaeoenv.* 90: 49-58. (in English) ["Fossil insects can provide unique insights into evolutionary history, and their study has become increasingly important in recent decades. In this paper, we give an overview of the insect taphocoenosis from the upper Oligocene Enspel Lagerstätte (Rheinland-Pfalz, Germany) and discuss taphonomic similarities with other localities. Among the fossil insects identified, terrestrial groups are highly dominant, with march flies (*Bibionidae*) and weevils (*Curculionidae*) being the most common groups; aquatic insects are rare. We provide a detailed survey of the represented taxa, including new records of a predaceous diving beetle (*Dytiscidae*), a soldier beetle (*Cantharidae*) and mayfly larvae (*Ephemeroptera*). Updated information on the ants (*Formicidae*) and reticulated beetles (*Cupediidae*) is reported. The palaeoclimatic and palaeobiogeographic inferences that can be drawn from the represented groups are discussed. Studies on the insects from Enspel indicate a warm temperate climate. Several records document that the distribution of many insect groups in the Oligocene was distinctly wider than it is today. [...] While only one adult damselfly (*Odonata*: *Zygoptera*) has been found in Enspel, several dragonflies (*Odonata*: *Anisoptera*) have been recorded, comprising both larvae and remains of the adults (Wedmann 2000) (Fig. 6). Most fossils belong to the darners (*Aeshnidae*), but the morphological diversity seen among the larvae (Fig. 6a-c) suggests the presence of further, hitherto undetermined dragonfly families. Several fossils of adult specimens belong to the species *Oligaeschna jungi* Piton and Theobald, 1939 (Fig. 6d), previously recorded from the upper Oligocene locality Puy-de-Mur (Auvergne, France) (Piton and Theobald 1939). A leaf with characteristic marks of damselfly eggsets has also been found (Poschmann and Wedmann 2005)." 8883. Wesner, J.S. (2010): Aquatic predation alters a terrestrial prey subsidy. *Ecology* 91(5): 1435-1444. (in English) ["Organisms with complex life histories (CLH) often cross habitat or ecosystem boundaries as they develop from larvae to adults, coupling energy flow bet-

ween ecosystems as both prey (bottom-up) and consumers (top-down). Predation effects on one stage of this life cycle can therefore cascade across ecosystems, magnifying the impact of local predation. The majority of predation studies have assessed effects only on a local level, within the habitat of the predator. I used large outdoor stream mesocosms to test the hypothesis that predation in an aquatic habitat alters the magnitude and trophic structure of a prey assemblage in a terrestrial habitat. I also tested how a consumer in the terrestrial habitat (web-weaving spiders) responded to these changes in prey export. Two fish species were the predators (red shiner, *Cyprinella lutrensis* and orangethroat darter, *Etheostoma spectabile*) in an experiment with three treatments: both fish species monocultures plus a fishless control. Fish predation reduced aquatic insect emergence biomass by 50% compared to the fishless control and altered the trophic structure of the emergent community, reducing emerging insect predator biomass by 50%, but had no effect on other insect trophic groups. Spiders captured only insects that were unaffected by fish predation (mostly chironomids) and therefore did not respond numerically to overall changes in insect abundance or biomass. Patterns of insect emergence were largely driven by a strong negative relationship between fish and a predatory dragonfly (*Pantala flavescens*). The results of this experiment show that predation in one habitat can have strong effects on the biomass and trophic structure of subsidies entering adjacent habitats, resulting in contrasting predictions for the role of these subsidies in recipient food webs. In the absence of fish, aquatic habitats produced terrestrial insect communities with higher biomass (bottom-up potential) and a higher proportion of predators (top-down potential) than when fish were present." (Author)] Address: Wesner, J.S., Biological Station and Department of Zoology, University of Oklahoma, Norman, Oklahoma 73019 USA

8886. Wittwer, T.; Sahlen, G.; Suhling, F. (2010): Does one community shape the other? Dragonflies and fish in Swedish lakes. *Insect Conservation and Diversity* 3(2): 124-133. (in English) ["1. Freshwater communities are often structured by predation. In permanent lentic freshwater habitats dragonfly larvae are major predators which, in return, suffer predation by fish. Antipreda-

tor traits vary between the dragonfly species, and the dragonfly communities are therefore shaped by the presence of fish. But fish communities vary, and as different fish species affect dragonflies in different ways, the species composition of the fish community may affect the composition of the dragonfly community. 2. We sampled dragonfly larvae in 24 lakes with a known fish stock in south-western Sweden, and explored the impact of fish as well as vegetation structure on dragonfly communities by means of multivariate analyses. 3. We found that the presence of four fish species affected the community structure of dragonflies. The impact strength depended mainly on the abundance of *Perca fluviatilis*, with which most dragonfly species were negatively correlated. Many dragonfly species were also positively correlated with the occurrence of at least one fish species, which may reflect similar habitat requirements or imply indirect positive effects of these fish species. 4. Of the 24 recorded dragonfly species, four did not occur in lakes dominated by *P. fluviatilis*, whereas only one species was lacking in lakes dominated by *Rutilus rutilus*. The dragonfly species diversity was higher in *R. rutilus* lakes than in *P. fluviatilis* lakes. 5. Our results suggest that the fish species composition is a major determinant of the dragonfly community, which in turn will influence the lower trophic levels." (Authors)] Address: Wittwer, T., Department of Earth and Ecosystem Sciences, Lund University, Sölvegatan 12, SE-223 62 Lund, Sweden. E-mail: torben.wittwer@nateko.lu.se

8887. Zhang, H. (2010): The Superfamily Calopterygoidea in South China: taxonomy and distribution. Progress Report for 2009 surveys. *International Dragonfly Fund - Report 26*: 1-36. (in English) [Three families in the superfamily Calopterygoidea occur in China, viz. the Calopterygidae, Chlorocyphidae and Euphaeidae. They include numerous species that are distributed widely across South China, mainly in streams and upland running waters at moderate altitudes. To date, our knowledge of Chinese species has remained inadequate: the taxonomy of some genera is unresolved and no attempt has been made to map the distribution of the various species and genera. This project is therefore aimed at providing taxonomic (including on larval morphology), biological, and distributional information on the superfamily in South China. In 2009, two series of surveys were conducted to Southwest China-Guizhou and Yunnan Provinces. 1. Odonata recorded from Xiangzhigou, Guizhou Province: A total of 51 species were found in Xiangzhigou area, belonging to 11 families. Many of the species recorded here are rather rare in South China, such as *Anaciaeschna martini*, *Cephalaeschna needhami*, *Cephalaeschna obversa*, *Planaeschna maolanensis*, *Polycanthagyna melanictera*, *Chlorogomphus papilio*, *Watanabeopetalia usignata*. 2. Odonata from Yunnan: A total of 82 species in 12 families were recorded from Xiangshuangbanna, Yunnan Province. Four species are new to the fauna of China, and 9 species have not been identified." 8892. Vinebrooke, R.D.; Turner, M.A.; Kidd, K.A.; Hann, B.J.; Schindler, D.W. (2001): Truncated foodweb effects of omnivorous minnows in a recovering acidified lake. J. N. Am. Benthol. Soc. 20(4): 629-642. (in English) ["Cyprinids (*Margariscus margarita*, *Phoxinus* spp., *Pimephales promelas*) have resumed reproduction in a boreal headwater lake (Lake 302S, Experimental Lakes Area, northwestern Ontario) that is recovering from experimental acidification. Concomitant changes to the littoral food web suggested that these omnivorous minnows suppressed the development of green algal mats, termed metaphyton. We tested this hypothesis by conducting an experiment using minnow enclosures, minnow exclosures, and open control plots in the shallow littoral zone of Lake 302S. Minnows significantly suppressed zooplankton biomass, and altered community composition by disproportionately reducing large daphnids and chydorids. Epiphytic chironomids were also significantly less abundant in the presence of minnows. Minnows had a significant time-dependent, negative effect on benthic invertebrate biomass and community composition because chironomids and anisopterans were suppressed during the second half of the 6-wk experiment. However, minnows did not reduce the abundance of the dominant primary producer, namely metaphyton. Stable isotope analyses revealed that minnows did not suppress metaphyton because these algae were not the primary C source for the food web. Instead, our findings suggest that the littoral food web depended mainly on sedimentary C, which resulted in the foodweb effect of minnows being truncated at the level of invertebrates. Therefore, metaphyton appears to be regulated primarily by abiotic factors (e.g., availability of dissolved inorganic C) and not herbivory in recovering acidified lake." 8896. Labandeira, C.C. (2002): Paleobiology of predators, parasitoids, and parasites: Death and accommodation in the fossil record of continental invertebrates. In: Kowalewski, M., and P.H. Kelley, (eds.), 2002. *The Fossil Record of Predation*. Paleontological Society Papers 8: 211-249. (in English) ["Carnivory is the consumption of one animal by another animal; among invertebrates in terrestrial and freshwater ecosystems this type of feeding can take three forms: predation, parasitoidism, and parasitism. Differences among these three functional modes involve (i) whether the duration of feeding on the prey item is quick or there is an accommodation, coevolutionary or otherwise, between the carnivore and the host prey; (ii) whether the prey or host is killed; (Hi) whether single or multiple prey or host items are consumed during the carnivore's lifespan, and (iv) the relative sizes of the carnivore and its prey or host. Uniformitarian and nonuniformitarian evidence directly relating to the history of carnivory can be found in exceptionally preserved deposits from the mid-Paleozoic to the Recent, but such evidence is relatively rare because carnivores are the least represented trophic group in ecosystems. Six types of paleobiological data provide evidence for carnivory: taxonomic affiliation, fossil structural and functional attributes, organismic damage, gut contents, coprolites, and indications of mechanisms for predator avoidance. Only 12 invertebrate phyla have become carnivorous in the continental realm. Six are lophotrochozoans (*Acanthocephala*, *Rotifera*, *Platyhelminthes*, *Nemertinea*, *Mollusca*, and *Annelida*) and six are ecdysozoans (Ne-

matoda, *Nematomorpha*, *Tardigrada*, *Onychophora*, *Pentastoma*, and *Arthropoda*). Most of these groups have poor continental fossil records, but the two most diverse - nematodes and arthropods - have comparatively good representation. The record of arthropods documents (i) the presence of predators among primary producers, herbivores, and decomposers in early terrestrial ecosystems; (ii) the addition later in the fossil record of the more accommodationist strategies of parasitoids and parasites interacting with animal hosts; (Hi) the occurrence of simpler food-web structures in terrestrial ecosystems prior to parasitoid and parasite diversification; and (iv) a role for mass extinction in the degradation of food-web structure that ultimately affected carnivory. Future research should explore how different modes of carnivory have brought about changes in ecosystem structure through time. Despite numerous caveats and uncertainties, trace fossils left by predators on skeletons of their prey remain one of the most promising research directions in paleoecology and evolutionary paleobiology." (Author) The paper includes many references to Odonata.] Address: Labandeira, C., Department of Paleobiology, National Museum of Natural History, Smithsonian Institution, Washington, DC 20560-0121 and Department of Entomology, University of Maryland, College Park, Maryland 20742 USA. 8917. Orr, R.L. (2004): Notes on the 2004 impact of the 17-Year Periodical Cicada on Potomac River dragonflies. *Argia* 16(3): 11-12. (in English) ["Every 17 years during May and June, three species of Magicicada emerge together in phenomenal numbers. These large heavy 25 – 50 mm red-eyed Homoptera dominate the landscape for about a month. Their numbers are truly impressive with up to 1.5 million per acre; but densities of a few tens, to hundreds, of thousands per acre are more the norm. Predators (mainly birds, mammals, reptiles etc.) become so focused on the cicadas that they tend to ignore other types of prey items. During mass emergences of *Gomphus vastus*, mortality rates in 2002 and 2003 at some sites along the Potomac climbed in excess of 50% (the wings of the emerging

specimens were scatted along the shore line). During May and June of 2004 (with mass emergence of cicadas), two very obvious differences were noted when compared to the same period in 2002 and 2003 (without mass emergence of cicadas). First, dragonfly wings were noticeably absent in 2004. It was obvious that few predators wanted to eat dragonflies when they had a belly full of cicadas! „The emerging dragonflies were having a banner year, with negligible predation thanks to the cicadas. Second, the number of dead adult dragonflies found in June 2004 was far in excess of the numbers found in previous years. The reason for this is not that more dragonflies were dying but that they were not being eaten by scavengers. Again, why eat a dying or dead dragonfly when there are lots of dead and dying cicadas to eat?“ „Did the dragonflies feed on the adult cicadas? It may be surprising, but I would say, generally not. It was likely a size thing. I observed *Hagenius brevistylus*, *Epiaeschna heros*, and *Anax junius* successfully take them out of the air and onto the ground but it always ended in the buzzing cicada getting away.“] Address: Orr, R.L., 5215 Durham Road East, Columbia, MD 21044-4444, USA. 8929. Daigle, J.J. (2005): A super Bowl Weekend or The Hunt for Red October: Part II. *Argia* 17(1): 10. (in English) [Feb. 2005, Big Pine Key, Florida, USA. Report on a few catches of *Orthemis* sp., *Tramea* sp. and potential species to trace later in the season.] Address: Daigle, J., 2166 Kimberley Lane, Tallahassee, FL 32311, USA. E-mail: jdaigle@nettally.com

8930. de Maynadier, P.; Hudson, J. (2005): First national records for Canada Whiteface (*Leucorrhinia patricia*) in the USA. *Argia* 17(1): 5-6. (in English) [18-VI-2003, *L. patricia* was collected for the first time in the USA in Maine (Somerset Co.), and the second record was realised on 23-VI-2003 in Alaska (Southeast Fairbanks Borough). Habitats and co-occurring Odonata species are documented.]

8931. Donnelly, N. (2005): Is there life after acetone? A "cool" method for preserving odonates. *Argia* 17(1): 18. (in English) [In cases acetone to proceed specimens is not available in field trips, the author proposes the following treatment: „I have found what seems to be an easier, and more satisfactory method. First, I thoroughly dry the specimen. My method is truly "cool": instead of heat I use a desiccant. My desiccant of choice is 4-angstrom synthetic zeolite, which generally goes under the commercial name "molecular sieve". It is non-toxic, and is also handy for drying your wallet when it falls in the river. It lowers the partial pressure of water to a lower value even than silica gel, which is itself far superior to cobalt-doped calcium sulfate ("Drierite"). The desiccant can be reused essentially infinitely by cooking it in the oven at about 300 degrees F. When you return from the trip with your crispy specimens, then a good soak in acetone will degrease them."] Address: Donnelly, T., 2091 Partridge Lane, Binghamton, NY 13903, USA. E-mail: tdonnel@binghamton.edu

Sci., University of Texas, Austin TX 78712, USA. E-mail: jcabbott@mail.utexas.edu

8933. Hogsden, K.L.; Vinebrooke, R.D. (2005): Environmental predictors of benthic consumers and autotrophic communities along a recovery gradient. *Can. J. Fish. Aquat. Sci.* 62: 2226-2239. (in English, with French summary) ["Ecological theory predicts that biological factors replace abiotic regulation of community structure during recovery from ecosystem stress. We examined relationships between benthic autotroph (epilithic periphyton) and consumer communities, and environmental variables, along a gradient of six recovering acidified lakes to identify the best explanatory variables of community structure. Dissolved organic carbon, pH, and total dissolved phosphorus were important predictors of autotrophic biomass, while total dissolved phosphorus was the only significant factor explaining variation in consumer biomass. Abiotic factors (e.g., dissolved organic carbon, pH) were also significant predictors of autotrophic and consumer community composition. Autotrophic biomass was significantly greater in recovering lakes owing to an increased abundance of attached filamentous green algae. However, consumer biomass did not differ significantly between severely stressed and recovering lakes because of a compensatory shift from numerous small tolerant omnivores to fewer large-bodied sensitive grazers. Lack of a significant relationship between autotrophic and consumer biomass along with stable isotopic evidence of few primary consumers suggested that grazing pressure was weak, especially in the stressed lakes. The persistent importance of abiotic factors to autotrophic and consumer communities suggested that ecosystem recovery remained incomplete in these lakes." (Authors) Odonata are treated at the family level.] Address: Hogsden, Kristy, Freshwater Biodiversity, Laboratory, Dept of Biological Sciences, University of Alberta, Edmonton, AB T6G 2E9, Canada. E-mail: khogsden@gmail.com).

8934. Hunt, P. (2005): Additional notes on the Odonata of the Cayman Islands. *Argia* 17(1): 16. (in English) [Twelve species of Odonata were recorded between 8 – 12 April 2004, two of these were not previously recorded from the Cayman Islands: *Coryphaeschna adnexa* and *Micrathyria aequalis*.] Address: Hunt, Pamela, Audubon Society of New Hampshire, 3 Silk Farm Road, Concord, NH 03301, USA. E-mail: phunt@nhaudubon.org

8935. Johnson, P.G. (2005): Odonata survey of Pinnacles National Monument, California. *Argia* 17(1): 4. (in English) [38 Odonata species were recorded between 2001 and 2003. No details are dealt with. Records of *Lestes stultus* and *Erpetogomphus compositus* represent considerable range extensions, and *Anax walsinghami* is distributed very disjunctly in California.

Predation of *Cordulegaster dorsalis* by red-legged frogs is outlined. Noteworthy is the observation of reptile predation on Odonata: „I watched a Western fence lizard flinging itself into the air repeatedly at coenagrionids, like a dog leaping after a Frisbee.“] Address: not stated

8936. Landmann, A. (2005): Rote Listen und Föderalismus im deutschsprachigen Raum: Entwicklung, Bestand, fachliche und praktische Probleme. *Naturschutz und Biologische Vielfalt* 18: 167-185. (in German, with English summary) ["More than 2000 Red Lists (RL) have been published in German-speaking countries during the last thirty years. Many of these RL only refer to political subunits (federal countries, provinces, districts, cities) and often to only small areas. After giving a general review of numbers and history of such regional-level RL (RRL) in Switzerland, Austria, Germany, Liechtenstein and the South Tyrol (Alto Adige, Italy), the paper mainly deals with specific scientific problems of RRL which tend to increase with decreasing reference areas (eg. problems connected with metapopulation biology, biogeography) and with tendencies reducing the practicability of RRL for nature conservation activities (e. g. inflation with insufficiently known invertebrate taxa or with biological units below species level). For several scientific and practical reasons, I think that in many cases the IUCN-guidelines for RL at regional-levels are not adequately applicable for RRL at small scales. As such RRL are mostly dedicated to serve as instruments for regional nature conservation, different and more region-specific criteria and threat descriptors might be more useful than for national and international RL. Moreover, I doubt, that the comparability between RRL is improved by just simply adopting standardised criteria and categories." (Authors) The analysis includes Red Lists referring to Odonata.] Address: Landmann, A., Institut für Zoologie der Universität Innsbruck, Technikerstr. 25, A-6020 Innsbruck, Austria. E-mail: Armin.Landmann@uibk.ac.at

8937. Laswell, J. (2005): Curtis "Curt" Williams. *Argia* 17(1): 2. (in English) [Obituary: 5-IX-1917 – 19-II-2005] Address: not stated

8943. Xu, Q.-h. (2005): A new species of the genus *Aciagrion* Selys from Fujian, China (Odonata: Coenagrionidae). *Entomological Journal of East China* 14(4): 301-302. (in Chinese, with English summary) [*Aciagrion huaanensis* sp. nov. is described. The new species is similar to *A. olympicum*, but different from the latter by "(1) the blue markings on head limited only to frons, postocular spots and the stripe linking the latter, (2) two small brown spots at the median area of postclypeus, (3) the scape, pedicel and flagellum of antenna with different colour respectively, (4) dorsal base of segment 3—7 narrowly ringed with pale blue, and (5) dorsal markings of segments 8—9 on basal 4/5 and basal half respectively, not as *A. olympicum* which has bifurcate markings on segments 8 and elongate triangle-shaped markings on segment 9." Measurements (mm): female: Abd. + app. 28 mm, hindwing 20 mm. Holotype: female: Huaan County, Fujian Province, China (24°49'N 117°45'E), 2005-09-22, coll. XU Qi-han; the type specimen is deposited in Zhangzhou Education College, Fujian, China.] Address: XU Qi-han, Zhangzhou Education College, Zhangzhou, Fujian 363000, China

2006

8944. Abellan, P.; Sanchez-Fernandez, D.; Millan, A.; Botella, F.; Sanchez-Zapata, J.A.; Gimenez, A. (2006): Irrigation pools as macroinvertebrate habitat in a semi-arid agricultural landscape (SE Spain). *Journal of Arid Environments* 67: 255-269. (in English) ["The intensification of agriculture has resulted in the loss of many aquatic ecosystems in southern Europe. Despite this, the construction of irrigation pools and reservoirs to retain the water necessary for intensive cultivation may also provide new habitats for macroinvertebrates. The biotic and abiotic attributes of 40 such reservoirs in south-eastern Spain were studied to determine the presence of macroinvertebrates, and to discover if there is such a thing as an optimal design of an artificial pond for maximizing macroinvertebrate richness. A total of 72 macroinvertebrate taxa belonging to 38 families were recorded from the pools examined. Pools constructed with low-density polyethylene covered with sand and stones contained a significantly greater species richness, abundance and diversity of macroinvertebrates than those constructed with high-density plastic materials. The treatment with algicide, and the presence of emergent and submerged vegetation, accounted for most of the deviance when modelling species richness by means of logistic regression." (Authors) The following Odonata taxa are listed: *Coenagrion*, *Ischnura*, *Libellula*, *Orthetrum*, *Crocothemis erythraea*, *Diplacodes lefebvrei*, *Sympetrum*, and *Anax*.] Address: (P. Abellán, P., Departamento de Ecología e Hidrología,

Universidad de Murcia, Campus de Espinardo, 30100 Murcia, Spain. E-mail: pabellan@um.es

Verbreitungsatlas der Libellen (Odonata) im Freistaat Thüringen. *Naturschutzreport* 22, Jena. *Odonatrix* 2(2): 47-48. (in Polish, with English summary) [Review of a German regional fauna on Odonata.] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

8947. Buczyński, P.; Daraż, B. (2006): Interesting records of *Leucorrhinia caudalis* in secondary habitats. *Odonatrix* 2(1): 9-12. (in Polish, with English summary) ["Breeding populations of *L. caudalis* were found in the years 2000-2005 in a sand pit in Zarzeka (CE Poland) and in fish ponds in Pawłokoma (SE Poland). The localities are interesting complements to the knowledge about the distribution of the species at the southern border of its compact range. The importance of fish ponds and surface rock excavations as secondary habitats is stressed. The water bodies are especially essential in areas that are poor of optimal habitats (well preserved glacial lakes and oxbow lakes) or where the habitats are destroyed. Some clues on the conservation activities (interference in succession of water body, limitation of an intensive fish culture, restrictions on fishing) are given." (Authors)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

8948. Buczyński, P.; Tończyk, G.; Daraż, B.; Dyatlova, E.; Michalczyk, W.; Miszta, A.; Szymański, J.; Szpala, B.; Tondys, J. (2006): Dragonflies collected during the 3rd National Symposium of Odonatology of the Polish Entomological Society (Zwierzyniec, September 15-17, 2006). *Odonatrix* 2(suppl. 1): 1-12. (in Polish, with English summary) ["15 localities in SE Poland were visited within the frame-work of a field workshop that was conducted during the 3rd National Symposium of Odonatology of the Polish Entomological Society. These localities represented the following habitats: streams, rivers, fish ponds, sand pits, fens, and transitional peat bogs. 40 dragonfly species were recorded, of which the following ones were the most interesting for faunistic, zoogeographical and sociological reasons: *Sympecma paedisca*, *Ophiogomphus cecilia*, *Aeshna juncea*, *A. subarctica elisabethae*, *A. viridis*, *Somatochlora arctica*, *Sympetrum depressiusculum*, *S. meridionale*, *S. striolatum*, *Leucorrhinia pectoralis*. Peat bogs were regarded as the most important habitats that hold strong populations of many endangered species. The numerous occurrence of Mediterranean species was also discussed." (Authors)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

- 8949.** Buczyński, P. (2006): Notes on the occurrence of *Aeshna affinis* Vander L. in the Lublin region. *Odonatrix* 2(2): 33-36. (in Polish, with English summary) ["Fifteen new localities of *Aeshna affinis* are given from the Lublin district (SE Poland). Data about the occurrence of the species in this region is compiled and discussed. *A. affinis* has been recorded more frequently, especially in the last years. Clear abatement towards the north and strong preferences for river valleys (81% of localities) as well as warm and shallow waters (95%) were observed. The occurrence of this species mainly in river valleys can be associated with the using them as migration tracks. The main track is probably the River Bug valley (>50% of localities)."] (Author)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com
- 8950.** Cios, S. (2006): References to Odonata in Polish literature from the 18th and 19th centuries. *Odonatrix* 2(1): 12-17. (in Polish, with English summary) ["Presented are the oldest currently known references to Odonata in Polish literature (well known entomological papers from the second part of the 19th century are omitted). The first one is in KLUK (1780), who mentioned the species after Linnaeus. KLUK (1780), CZEMPIŃSKI (1789), JAROCKI (1807) and MORAWSKI (1880) reported massive flights of these insects in May. Of particular interest is the terminology. It seems that there was no single common name of these insects. Three old local ones are known – babka, lalka and strzałka. KLUK (1780) and many later authors used the name panna, a translation of demoiselle and Wasserjungfern. CZEMPIŃSKI (1789) was the first author to record the name wazka, currently referring to Odonata. He could have introduced it as an equivalent of libella. However, in Polish there was a verb ważyć, which referred to flying birds and insects. The relatively small number of references to Odonata may be due to poor knowledge of these insects in the past. The common people often confused them with locusts and probably even with butterflies."] (Author)] Address: Cios, S., ul. Stryjeńskich 6/4, 02-791 Warszawa, Poland. E-mail: stanislaw.cios@msz.gov.pl

- 8963.** Hogsden, K.L.; Vinebrooke, R.D. (2006): Benthic grazing and functional compensation in stressed and recovered lakes. Can. J. Fish. Aquat. Sci. 63: 1999-2010. (in English, with French summary) ["During ecosystem recovery, grazing pressure is expected to increase as larger herbivores become reestablished. Alternatively, grazing pressure may remain unchanged during recovery as large consumers replace and functionally compensate for more abundant populations of smaller, tolerant herbivores. We tested these hypotheses by conducting a 90-day experiment in which three size categories of benthic consumers were excluded from producers in three chemically stressed and three recovered lakes. Our findings showed that consumers did not significantly affect producer biomass in either type of lake. However, exposure to larger and more abundant grazers did induce a physiognomic shift towards less edible producers in the recovered lakes. In comparison, recovered lakes contained significantly greater producer biomass and diversity. Comparison of the observed subtle effects of consumers and pronounced negative impact of ecosystem stress on benthic producers suggest that they can compensate for natural disturbances (e.g., grazing), but not for the other multiple stressors associated with anthropogenic acidification of the Killarney lakes." (Authors) Odonata are treated at the family level.] Address: Hogsden, Kristy, Freshwater Biodiversity, Laboratory, Department of Biological Sciences, University of Alberta, Edmonton, AB T6G 2E9, Canada. 8971. Lockwood, M.T. (2006): Una primera aproximació a la riquesa específica dels odonats al Parc Natural de la Zona Volcànica de la Garrotxa. Butlletí de la Institució Catalana d'Història Natural 73 (2005): 71-83. (in Spanish, with English summary) ["A total of 35 species of odonata (dragonflies and damselflies) were recorded from the Natural Park of the Volcanic Zone of La Garrotxa (NE Iberian Peninsula; PNZVG) in 2002 and 2003, of which 27 were observed at Els Estanys de Can Jordà. Three factors were considered in explaining this species-richness. First, the PNZVG is located at a confluence of biogeographical regions, a fact which ensures that there is great variety in the habitat type in the natural park and therefore in the Odonata that fly there. Secondly, the habitat surrounding the wetlands in the natural park is very varied and satisfies the ecological needs of a great variety of species. Lastly, the wetlands themselves in the PNZVG are very varied, and have good water quality. At the end we comment that only by understanding the reasons for such great species-richness can habitat be managed for Odonata in the PNZVG and elsewhere." 8974. Nakada, A. (2006): An observation of heterogeneric copulation between *Deielia phaon* (Selys, 1883) male and *Orthetrum albistylum speciosum* (Uhler, 1853) female. Tombo 48: 23-24. (in Japanese) [Japan] Address: not stated in English

8975. Naraoka, H. (2006): Four continental *Sympetrum* dragonflies (Libellulidae) collected in Aomori Prefecture, northern Honshu, Japan, in 2005. Tombo 48: 33-34. (in Japanese, with English summary) ["*Sympetrum depressiusculum*, *S. cordulegaster*, *S. vulgatum imitans* and *S. f.flaveolum* were collected from Aomori Prefecture in autumn of 2005. The former three species are well-known migrants from Continental Eurasia. *S. f. flaveolum* is new to Honshu, and is considered to have migrated from Eurasia continent or Hokkaido. A female, instead of males, of *S. vulgatum imitans* was recorded for the first from Japan." (Authors)] Address: Naraoka, H., 36-71 Fukunoda, Kitatsugaru, Aomori 0383661, Japan

8976. Rowe, R.J. (2006): Patterns and processes in freshwater systems: the social dimension. *New Zealand Natural Sciences* 31: 59-71. (in English) ["Social interactions within species present an under-appreciated complicating factor in freshwater ecology. Such processes can markedly alter distribution patterns. Odonata are an important group of animals in freshwater systems and have the capacity, under some circumstances, to exclude other organisms (invertebrate and vertebrate) from otherwise suitable habitats. Within the Odonata stylised agonistic behaviours are widespread in larvae of Zygoptera and have important consequences for both the ecology of the species concerned and for the impact of zygopteran larvae within ecosystems. In this paper the diversity of agonistic displays within the Zygoptera is reviewed. On phylogenetic grounds, supported by fossil dates, zygopteran display systems are very ancient (~ 150-200 My). Given the obvious costs in energy, increased exposure to predators, and the real risk of damage during interactions, agonistic behaviours must have considerable adaptive significance. Investigations of the processes involved in social interactions, and how they generate the patterns that are more generally recorded, will probably require

a return to large aquarium studies, or to in situ examination of microhabitats using underwater observatories." (Author)] Address: Rowe, R.J., School of Marine and Tropical Biology, James Cook University, Townsville 4811, Australia. E-mail: richard.rowe@jcu.edu.au

8977. Sahlén, G. (2006): Specialists vs. generalists among dragonflies - the importance of forest environments in the formation of diverse species pools. In: Rivera, A.C. (Ed). 2006. Forests and Dragonflies. 4th WDA Symposium of Odonatology, Pontevedra, Spain, July 2005. Pensoft Series Faunistica 61: 153-179. (in English) ["In Scandinavia more Odonate species occur in forested environments than in agricultural areas. Some authors attribute the high number of forest species to extensive river and wetland networks. But because there are also fewer species in some agricultural areas with numerous wetlands, there must be another explanation-It is known that forestry practices affect species composition. Remove the trees, the environment changes and some species disappear. The time elapsed after logging affects species survival. While undisturbed forest habitats support the greatest number of species, partivoltine species decrease during the first 5-10 years after disturbance, partivoltine species are not affected - in fact the univoltine species present here are also part of the species pool of agricultural areas; they are true generalists. A discriminant analysis comparing the species composition of lakes in different seral stages during forest regrowth gave more than 90% separation between the stages. Moreover, an even better separation was achieved when the investigation was combined with an analysis of (semi)aquatic plant communities along the shoreline, or when dragonfly density was taken into account. Plants and odonates are interconnected; the insects respond to the habitat's form and structure rather than to water chemistry (e.g. acidity or nutrient levels) or other ecological parameters. Forestry thus affects the very structures needed for survival. What kind of structures are we dealing with? A classification of species according to habitat preferences in a comparison between agricultural and forested areas showed that, in treeless habitats there were fewer specialists as well as generalists in constructed wetlands compared to older ponds and lakes. The latter habitats however, had fewer species than were present in the adjacent forested lakes. An investigation of constructed wetlands under 10 years of ago showed that, those close to forest habitats (over small clumps of trees) had, on average, more than twice as many breeding species than those in more open areas. Trees are obviously important to Odonata species, at least during some stage of their life. All species would probably survive in the waters of open areas, yet certain species do not survive unless a forest habitat occurs at a moderate distance from their breeding waters. Larval as well as adult habitat is relevant: egg-laying substrates must be included. Forests thus seem to possess what agricultural areas do not the maintenance of a high diversity of Odonata within a landscape depends on several seral stages and many different wetlands, surrounded by a diverse matrix of plants, including trees. All this adds up to one general rule: forests harbour specialists, while open landscapes are the playgrounds of generalists." (in German) [29-VI-2005 near Winterthur, Switzerland, a male *Anax imperator* was observed catching a bee (*Apis mellifera*). Starting to devour its prey, a few seconds later some small Diptera occupied the caput of the *Anax* and tried to get something from the dragonfly's prey. The Diptera stayed as long on the head of the *Anax* as long as it fed on its prey (5 min.), and then disappeared as secretly as they had arrived. The Diptera could not be identified, but looks similar to *Desmometopa*.] Address: Schneider, B., Wolfbühlstrasse 34a, CH-8408 Winterthur, Switzerland. E-mail: b.schneider@libellen.li

8981. Śniegula, S. (2006): The adventure with *Soma-tochlora sahlbergi* Trybom, 1889. *Odonatrix* 2(2): 36-39. (in Polish, with English summary) ["At the beginning of July 2004, I reached a decision to challenge myself and bike 4,5 thousand km one way in order to search for the population of *S. sahlbergi*. This happened in gorgeous regions of north-western Canada. The adventure started in Calgary (51°N) and ended in Inuvik (68° N). The search for treeline emerald started from the 28th day of my trip, from a place where a paved road transfers to a gravel road called Dempster Highway. The gravel highway stretches from 64°N to Inuvik. It runs through subarctic tundra and is underlain by permafrost. The investigation took place on meso- and oligotrophic ponds, peat bogs and along creeks. The weather conditions and the date were adequate to see flying *S. sahlbergi*, but investigations usually ended by observations of another Odonata, mostly from families *Aeshna* and *Enallagma*. On August 2nd, while checking a small (8 x 4m) and approximately 1,3m deep peat bog located on the North slope of the Ogilvie Mountains range, a single male of *S. sahlbergi* was noticed. In addition to *Sphagnum* moss and lichens, the pond was surrounded also by single sedges and in a farther distance by low spruce trees and shrubby birch. The male was patrolling open water, sometimes crisscrossing the pond over the water surface. The observations lasted 15 minutes, until tree-line emerald left the pond and flew to the evergreen forest. *S. sahlbergi* is a far north dragonfly. It requires deep, cold water that is surrounded by moss but not necessary *Sphagnum*. Because of the severe climate, the right habitats are hard to check by scientists. Currently, it is hard to say

how big is the whole population and in what degree this species is endangered. It should be noticed that treeline emerald would be probably a good indicator for environmental changes caused by global warming and in North Norway additionally, by acid rains." - 8992.** Bernard, R.; Kosterin, O. (2007): Odonatological impressions from the Vasyugan Plain, Western Siberia. *Odonatrix* 3(2): 50-58. (in Polish, with English summary) ["Between 12 and 23 July 2006, dragonflies of selected localities in the Vasyugan Plain, West Siberia, were studied during an expedition by Rafal Bernard and Oleg Kosterin. The article presents personal impressions of the first author from this expedition, partly based on the odonatological results. Our investigations were focused on the largest in the world complex of Sphagnum bogs and fens and on rivers flowing between them. Additionally, small anthropogenic water bodies were also visited. In total, 34 odonate species were recorded. An important result of our expedition is the picture of the summer aspect of the odonate fauna in these mostly primeval and remote boggy areas, with the flourishing complex of peat-moss bog species and an interesting species composition of the fauna of rivers. *Nehalennia speciosa* (the main aim of our expedition) and *Aeshna subarctica*, both species poorly known and considered to be rare in Siberia, appeared to be omnipresent in pools of Sphagnum peat bogs. The latter species and two other aeshnids occurring there, *A. crenata* and *A. juncea* were well-segregated in aspects of space, weather and behaviour. It is also noteworthy that one member of the mentioned complex of species, *Coenagrion johanssoni*, abundant in primary habitats - small bog water bodies, is completely missing in large oxbows and man-made larger ponds. This absence seems to be related to their higher trophic and inappropriate or too poor vegetation. One mystery of peat-moss complexes remained undisclosed: the breeding places of generally very abundant foraging *Somatochlora arctica*. In rivers, the records of western *Gomphus vulgatissimus* and eastern *Shaogomphus postocularis* broadened significantly their known ranges to the north. What is more, the former species, earlier almost unknown in Siberia, turned out to be widely distributed and fairly abundant in the studied area, and the latter one was for the first time found west of the Ob' River. From zoogeographical point of view records of *Lestes virens*, *Coenagrion puella*, *Coenagrion pulchellum*, *Leucorrhinia albifrons*, *Leucorrhinia pectoralis* and *Sympetrum sanguineum* were also interesting as they were situated at the hitherto known northern range limits of these species or to the north of them. The expedition did not bring taxonomic surprises but an interesting high percentage of androchrome females of *Calopteryx splendens* and dark-winged *Somatochlora* individuals, especially noteworthy in *Somatochlora flavomaculata*, were recorded." - 8993.** Bried, J.T.; Hunt, P.; Worthen, W.B. (2007): How often and how long? Studying temporal survey design for adult odonates. *Argia* 18(4): 8-11. (in English) ["This study is not about trying to find an optimum survey design, as decisions regarding sampling frequency and survey length will depend on the project objectives, the level of accuracy required, and the human resources available. Instead, our mission is to offer a set of guidelines and options built upon rigorous data that will facilitate prudent decisions about temporal survey design in any projects using adult odonates." (Authors)] Address: Worthen, W.B., Dept Biol., Furman University, Greenville, SC29613 USA. E-mail: worthen@furman.edu
- 8994.** Buczyński, P. (2007): Polish and dedicated to Poland odonatological papers. 5. The second half of the year 2006. *Odonatrix* 3(2): 62-64. (in Polish, with English summary) [The author presents a list of Polish and dedicated to Poland odonatological papers that were published in the second half of the year 2006. In the reported time period, 24 papers appeared, and 2 Ph.D. theses and 1 expertise were written. Some additions to the year 2005 were given too. The list does not contain the papers published in *Odonatrix* - they are listed in a separate index at the end of an ever volume.] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com
- 8995.** Buczyński, P. (2007): Odonatological conferences in the year 2007. *Odonatrix* 3(1): 29. (in Polish, with English summary) [Announcements and brief information on the coming conferences of GdO in Dresden, Germany, and WDA in Namibia.] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com
- 8996.** Buczyński, P. (2007): New records of *Erythromma viridulum* (Charpentier, 1840) on the edge of its distribution area in the northern Poland. *Odonatrix* 3(1): 15-18. (in Polish, with English summary) ["The author gives four localities of *E. viridulum* situated in the northern Poland at Polish-Russian borderline, outside the up-to-date-known area of its occurrence. *E. viridulum* has been in the stage of expansion towards the north in last two decades, likewise in other countries of western and central Europe. The changes of climate and eutrophication of surface waters are crucial factors of this state. It is clear that next records of this species outside its range are expected. The neighbourhood of the localities given in the paper to Kaliningrad District (NW part of Lake Głębockie - only 2.2 km) points out that this species might occur in its area." (Author)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com
- 8997.** Buczyński, P. (2007): Dragonflies in the Net. Part 2. Germany. *Odonatrix* 3(1): 30-32. E-mail: pawbucz@gmail.com
- 8998.** Cios, S (2007): Odonata as food of fish. *Odonatrix* 3(1): 1-8. (in Polish, with English summary) ["Presented is data on the occurrence of Odonata in fish stomachs in certain waters in Poland, Finland, Italy and France. In general Odonata are a rare item in fish stomachs (they constitute less than 1% of the organisms eaten). In Poland the main Odonata eaten by salmonids are *Calopteryx*, *P. pennipes* and gomphids, almost exclusively in highland and lowland running waters. In the material from Finland there is a striking lack of Zygoptera. The material from Italy, though small, indicates a similar role of lotic and lentic species. In general high water favours consumption of Odonata larvae by salmonids in running waters, by increasing their availability to fish (higher catastrophic drift). In the case of perch it seems that the consumption increases during low water level. In the material adults played a negligible role." (Author)] Address: Cios, S., ul. Stry-

jeńskich 6/4, 02-791 Warszawa, Poland. E-mail: tani-slav.cios@msz.gov.pl

8999. Cotrel, N.; Rouillier, P.; Boissinot, A. (2007): Atlas commenté des Odonates des Deux-Sèvres. Nature entre Deux-Sèvres 1: 56-76. (in French) [Deux-Sèvres is a Department in the region Poitou-Charentes situated in the west of France. A total of 59 species is briefly introduced and records of the species are mapped.] Address: Deux-Sèvres Nature Environnement, 7 rue Crémeau, 79000 NIORT, France. E-mail: contact@dsne.org

9000. Curtean-Babduc, A. (2007): Contributions to the study of Cibin river Odonata larvae communities. Brukenthal. Acta Musei 3: 117-124. (in English, with Romanian summary) [Romania; between 1997 - 2001, and in 2005 nine sampling stations (S1 - S9) - localized along Cibin River, starting at 16 km downstream the springs to the confluence with the Olt River - were sampled for their Odonata fauna. Eight species: *Calopteryx virgo* (S3, S4, S5, S6), *C. splendens* (S1), *Lestes dryas* (S1), *Gomphus vulgatissimus* (S2, S3, S9), *Ophiogomphus cecilia* (S2, S3), *Cordulegaster boltonii* (S1, S2), *Cordulegaster bidentata* (S2, S3), and *Leucorrhinia pectoralis* (S6, S7, S9) were recorded.] Address: Curtean-Babduc, Angela, „Lucian Blaga” University, Faculty of Sciences, Ecology and Environmental Protection Department, Oituz Street, no. 31, Sibiu, Sibiu County, Ro - 550337, Romania. E-mail: angela.banaduc@ulbsibiu.ro

9001. Dapkus, D. (2007): Protected species of insects in conservation areas of central Lithuania recorded in 2007. New and rare for Lithuania insect species 19: 5-9. (in English, with Lithuanian summary) [Lithuania; records of *Leucorrhinia pectoralis* and *Ophiogomphus cecilia* are documented.] Address: Dapkus, D., Dept of Zoology, Vilnius Pedagogical University, Studentu 39, LT-08106 Vilnius, Lithuania. 9011. Michalczuk, W. (2007): Ornate damselfly *Coenagrion ornatum* (Sélys, 1850) found in the Wołyńska Upland (south-eastern Poland). Odonatrix 3(2): 40-42. (in Polish, with English summary) ["The paper is a preliminary report about the population of *C. ornatum* re-

corded 20 km east-south-east of Zamość (50°39'N, 23°32' E, the Wołyńska Upland, south-eastern Poland). Numerous imagines of *C. ornatum* were observed on 15 May, 2007 in the valley of the River Sieniocha at the outlet canal of the spring peat bog of carbonate character. *Enallagma cyathigerum*, *Somatochlora flavomaculata* and *Libellula fulva* were co-occurring species. *C. ornatum* has been observed for the first time since 1992 and it has been the first record in south-eastern Poland since over 60 years. In the near future more detailed analyses of the recorded population as well as the habitat and its monitoring are planned." (Author)] Address: Michalczuk, M., Zamojskie Towarzystwo Przyrodnicze, ul. Szymonowica 19/6, 22-400 Zamość, Poland. E-mail: wiack@wp.pl

9012. Miszta, A.; Dolný, A. (2007): Localities of protected and rare dragonfly species in the Silesian woiwodship found out of water and peat bog nature reserves in the years 2003-2005. *Odonatrix* 3(1): 9-14. (in Polish, with English summary) [A survey of dragonflies at 13 localities in the Silesian woiwodship but situated outside the area of nature reserves was made. 15 dragonfly species belonging to protected or rare animal species occurred. Only one of the sites seems to be safe from human activities or natural succession. The remaining ones need continuous monitoring, some of them should be actively protected." (Authors)] Address: Miszta, Alicja, Centrum Dziedzictwa Przyrody Górnego Śląska, ul. Św. Huberta 35, 40-543 Katowice, Poland. E-mail: a.miszta@cdpgs.katowice.pl

9013. Miszta, A.; Boroń, M.; Cuber, P.; Dolný, A. (2007): The occurrence of *Aeshna affinis* Vander Linden, 1820 and *Crocothemis erythraea* (BRULLÉ, 1832) in sinkhole ponds in the Silesian voivodeship in 2006 (Odonata: Aeshnidae, Libellulidae). *Odonatrix* 3(2): 42-46. (in Polish, with English summary) [A study "of dragonflies on man-made reservoirs of the Silesian Region took place, in 2006 there were recorded numerous males and less numerous females of *A. affinis*. Single individuals have been reported in 1939 in Gwozdziany and in 1966 in Ustron. Since its last record *A. affinis* has been noted again in 2005 in an old river bed of the River Odra River in Lasaki. It has been recorded on seven new sites in the next year. Most of those new sites were small sinkhole ponds created by coal-mining. What is more *A. affinis* was recorded on a few natural sites too. While on natural sites there were 2 - 4 specimens recorded, on anthropogenic water bodies there were usually about 20 individuals. Creating tandems indicated making attempts to inhabit anthropogenic water bodies by this species. There was another quite rare and stenothermic species - *C. erythraea* recorded on two sites together with *A. affinis*. This species has been observed since 2002 in Oder River Valley, near the southern border of Silesian Region with Czech Republic. Nevertheless it was recorded for the first time in sinkhole ponds in 2006." (Authors)] Address: Miszta, Alicja, Centrum Dziedzictwa Przyrody Górnego Śląska, ul. Św. Huberta 35, 40-543 Katowice, Poland. E-mail: a.miszta@cdpgs.katowice.pl

9019. Schielke, E.; Costantini, C.; Carchini, G.; Sagnon, F.; Powell, J.; Caccone, A. (2007): Short report: Development of a molecular assay to detect predation on *Anopheles gambiae* complex larval stages. *Am. J. Trop. Med. Hyg.* 77(3): 464-466. (in English) ["We developed a molecular assay to detect predation on *Anopheles gambiae* sensu lato (s.l.) mosquitoes. This intergenic spacer ribosomal DNA polymerase chain reaction assay and restriction enzyme analysis uses *An. gambiae*-specific primers to detect mosquito DNA in the DNA extracts from whole invertebrate predators, which enables identification of species (*An. gambiae* s.s. versus *An. arabiensis*) and molecular forms (M versus S in *An. gambiae* s.s.). We show that *An. gambiae* s.l. DNA can be detected after ingestion by members of the families Lestidae after four hours, Libellulidae after six hours, and Notonectidae (order Hemiptera) after 24 hours. This method is an improvement over previously published methods because of ease of execution and increased time of detection after ingestion." (Authors)] Address: Powell, P., Dept Ecol. Evol. Biol., Yale Univ., PO Box 208106, New Haven, CT 06520-8106, USA. E-mail: jeffrey.powell@yale.edu

9020. Sibley, F.C.; Daigle, J.J. (2007): Florida Keys—September/October 2006 or where's Wilma? *Argia* 18(4): 17-19. (in English) [Hurricane affected ponds and species composition of habitats. The results of a pre-

hurricane (Oct. 2005) and the post-hurricane (Oct. 2006) samples are documented and discussed.] Address: Sibley, F.C., The Conservation Agency, 6 Swinburne St. Jamestown, RI 02835, USA. E-mail: fcsibley@empacc.net

9021. Śniegula, S. (2007): The Odonata of the Täfteån (Västerbotten, Province, Sweden). *Odonatrix* 3(2): 47-49. (in Polish, with English summary) ["This article contains data on Odonata species recorded on July 16th, 2006 in two localities at the Täfteån River. *Calopteryx virgo* and *Cordulegaster boltonii* represent typical lotic species and were recorded in locality 1. *Pyrrhosoma nymphula* was previously recorded in 5 localities in the Västerbotten Province. It seems that these are the most northern localities of the species, whose larvae prefer slow flowing and productive rivers. The author recorded *P. nymphula* in locality 2. Two widespread in Sweden *Aeshna* species are usually found in meso- and dystrophic lakes. Both were recorded exclusively in locality 2. *Somatochlora metallica* was a dominant dragonfly in two studied localities. In the Västerbotten Province larvae of this species are found in variety of aquatic habitats." (Author)] Address: Śniegula, S., Rakowo 32, 78-445 Lubowo, Poland. E-mail: ssniegula81@interia.pl

9022. Tończyk, G. (2007): Moreover than dragonfly impressions from field studies at northern Mazowsze. *Odonatrix* 3(1): 19-21. (in Polish, with English summary) ["Report on nature impressions from the expedition to the northern Mazowsze in the frames of "Atlas of the distribution of the dragonflies (Odonata) of Poland" project. The studies covered 124 study sites and resulted in recording 55 dragonfly species. However, the studied area was strongly transformed - especially this referred to small water courses. Melioration and pollution were probably the main reasons why *Calopteryx virgo* was found as a very rare species. *Erythromma viridulum*, *Lestes barbarus*, *Aeshna juncea*, *A. subarctica elisabethae*, *A. viridis*, *Orthetrum albistylum* and *O. brunneum* were the most interesting species recorded during studies." (Author)] Address: Tończyk, G., Zakład Limnologii i Ekologii Bezkręgowców, Katedra Zoologii Bezkręgowców i Hydrobiologii Uniwersytetu Łódzkiego, ul. Banacha 12716, PL-90-237 Łódź, Poland. 9026. Wendzonka, J. (2007): Second record of *Crocothemis erythraea* (Brullé, 1832) in Western Poland with remarks on its distribution and ecology (Odonata: Libellulidae). *Odonatrix* 3(2): 33-39. (in Polish, with English summary) [*C. erythraea* was observed in a pond near the village Gostyń Stary, 51° 54' N, 16° 57' E, by Gostyn, 65 km S of Poznań, Poland.] Address: Wendzonka, J., ul. Graniczna 17, 63-800 Gostyń, Poland. E-mail: wendzonka@wp.pl

9027. Zięba, P.; Buczyński, P. (2007): Green Hawker *Aeshna viridis* caught in light traps. *Odonatrix* 3(1): 26-28. (in Polish, with English summary) ["Adults of *A. viridis* were collected in light traps in the valley of the river Narewka in Białowieża village, NE Poland (2006-07-22, 1 female at mercurial lamp and 2006-07-23, 3 females and 1 male at arc-lamp). All specimens were caught on ca 21.40. The collected individuals were sitting frontally to the lamp so that their body axes were forwardly directed to the source of light. The authors discuss the known cases of light-trapped dragonflies, especially in the zone of temperate climate and in Europe. This phenomenon can be the result of spontaneous activity of dragonflies or their arousal to activity by strong light. Up-to-date observations have shown that there are two possible explanations: in particular cases the first or the second mechanism was involved. For the observations from Białowieża more possible is the second one: *A. viridis* was multiply found in the valley of the Narewka River, also at the sites where light traps were provided. It seems that many cases of dragonflies attracted to the light source are overlooked for odonatologists do not use the method and other entomologists who set light traps are not interested in dragonflies or underestimate such observations. So for gathering more data on the subject the cooperation of odonatologists and specialists of other insect groups is needed." 9028. Bernard, R.; Daraż, B. (2008): State and habitat of a peripheral and isolated population of *Nehalennia speciosa* (Charpentier, 1840) in southeastern Poland (Odonata: Coenagrionidae). *Odonatrix* 4(1): 12-19. (in Polish, with English summary) ["The peripheral population of *N. speciosa*, discovered in 2004 in the nature reserve "Broduszurki", SE Poland (49°49' N, 22°21' E; UTM EA91), is the southernmost remaining population of the species in E Europe and E part of Central Europe. The Broduszurki population represents the same Evolutionary Significant Unit (ESU) as other Polish populations of the species and could be included into the same Management Unit (MU). However, a slightly greater genetic distance and genetic differentiation against all other studied populations, combined with the current state of strong isolation (the nearest species locality 90 km distant), might justify treating this population as a separate MU. This population, occupying ca 0.06 ha, is medium-sized (max > 400 imagines per control and min 1500 in the flight period) and dynamic, recently increasing and colonizing new patches of the habitat, but also tightly attached to selected small areas. The local high density was mirrored in a high mortality in spiders' webs (e.g. 36 individuals/14 webs or 35/15). The habitat of *N. speciosa* is secondary: several-dozen-year old peat excavation pools in different stages of succession, surrounded by low peaty pine forest. *N. speciosa* occurred in two subpopulations (pools) and four habitat patches. It was related mostly to the rich in water habitat with *Carex rostrata*, *Sphagnum* sp., *Warnstorfia fluitans*, and admixtures of *Juncus effusus* and *Molinia caerulea*, resembling the "rostrata" habitats known from several other localities in E Poland and Europe. However, the species occurrence in one patch based mostly on *Molinia caerulea* is exceptional, known only from Lower Saxony, where one locality even highly resembles the Broduszurki one. The habitat in this patch is spatially separated between the larval one (*Warnstorfia fluitans* "soup" in water) and that one for imagines - land tussocks of *M. caerulea* explored by the species up to 5 m from the water. Dry leaves of *Molinia*, hanging into water and used for the emergence were a passage between these two microhabitats. However, the use of such an untypical habitat is possible only due to a specific combination of conditions, such as the occurrence of *M. caerulea* under the canopy of trees protecting from excessive insolation and stronger winds. As *N. speciosa* was not observed in other seemingly similar places nearby for no apparent reason, it seems that some of these conditions have remained unrecognised." - 9037.** Gamboa, M.; Reyes, R.; Arrivillaga, J. (2008): Macroinvertebrados bentónicos como bioindicadores de salud ambiental. *Boletín de malariología y salud ambiental XLVIII(2)*: 109-120. (in Spanish, with English summary) [Benthic macroinvertebrates as bioindicators of environmental health: The fluvial system has been under strong human pressure, due to a lack of urban planning, which has triggered a potentially dangerous potable water problem for human consumption and irrigation. These changes in the quality of the fluvial systems have promoted important microclimatic changes, within the niche of special aquatic fauna, macroinvertebrates, that have a susceptible population dynamics to habitat disturbances. For sustainable development it is necessary to consider aquatic atmosphere conservation and to propose an adequate management plan, which includes bioindicators as a potential tool, to evaluate the perturbation grade and monitor the fluvial system within the water conservation plan. A bioindicador is defined as a set of species, with specific requirements in relation to physical or chemical variables, so that the significant changes of these variables indicates for the species that the system is perturbed and the species are close to tolerance limits. The assemblages of macroinvertebrates are the best bioindicators of contaminated water, because they are very abundant, are present in all the fresh water ecosystems, easy to collect and monitoring is low cost. The taxa to consider for environmental quality are: Ephemeroptera, Trichoptera, Plecoptera, Diptera, Odonata and Coleoptera. In this work we suggest the use of these aquatic macroin-

vertebrates as biological bioindicators, and their utility as biotic indices to estimate the tolerance of benthos to the polluting agents (BMWP, IBMW, BMWQ, IBF, EPT, the percentage of scrapers and the abundance of Chironomidae) as well as the functional response of these organisms to the polluting agents. Increasing studies of biomarkers leads to a better understanding of how fresh water is affected by a pollutant.] Address: Gamboa, Maribet, Depto de Estudios Ambientales, Laboratorio de Genética de Poblaciones, Ecología Molecular de Insectos, Departamento de Biología de Organismos, Universidad Simón Bolívar, Caracas 89000, Venezuela. ["*O. coerulescens* is a rare dragonfly in Poland and the data of its distribution is still insufficient (DD category in the Red List of Poland). In 2007, adults of this species were observed at two sites in the Lubuskie district (western Poland). In a meadow at a small ditch near Wicina (UTM: WT03) two females were recorded. At Lake Głębokie near Proszów (VT83) a single male was observed." (Author)] Address: Rychła, Anna, ul. Osiedlowa 12, Ploty, PO-66-016 Czerwiensk, Poland. E-Mail: rychlan@op.pl

9048. Shcherbakov, D.E. (2008): Madygen, Triassic Lagerstätte number one, before and after Sharov. *Alavesia* 2: 113-124. (in English) ["The insect fauna of the world's richest Triassic fossil locality, Madygen (Ladinian–Carnian of Kyrgyzstan) is reviewed; other groups of animals and plants recorded from the locality are also listed. The research history, fossil preservation and paleoenvironment of the Madygen Formation are briefly discussed. The site was discovered in 1933, and the better part of fossils was collected from the outcrop richest in insects, Dzhayloucho, during five expeditions headed by Alexander Sharov, who discovered there and described two peculiar gliding reptiles that made Madygen worldwide known. The entomofauna includes 20 orders (including the earliest Hymenoptera and early Diptera) and nearly 100 families. The insect assemblage is numerically dominated by Coleoptera, Blattodea, and Auchenorrhyncha. In Dzhayloucho, subdominants are Mecoptera, Orthoptera, and Protorthoptera. The largest insects belong to Titanoptera, the order established by Sharov and the most diverse in Madygen. Amphibiotic insects are rare and represented almost exclusively by adults. In some outcrops phyllopod *Kazacharthra* are common. The paleoenvironment may be reconstructed as an intermontane river valley in seasonally arid climate, with mineralized oxbow lakes and ephemeral ponds on the floodplain. ... Turning to the entirely amphibiotic orders, we find the Odonata the most abundant (about 100 specimens, all adults), and nearly as diverse in Madygen (10 families with 30 species) as in the Jurassic of Karatau or Solnhofen. This rich fauna is dominated by stalk-winged forms analogous to modern damselflies, and appears more archaic than those of Ipswich or Molteno (Pritykina 1981). Most groups are Triassic endemics: *Triadophlebiidae* (1/3), *Paurophlebiidae* (5/11), *Zygophlebiidae* (4/4), *Mitophlebiidae* (1/1), *Xamenophlebiidae* (1/1), *Batkeniidae* (1/1). Other families either are Permian relicts as the *Triadotypidae* s.l. (1/1) and *Kennedyidae* (1/2), or survived into the Jurassic as the *Protomyrmeleontidae* (2/4) and *Triassolestidae* (2/2)."] (Author)] Address: Shcherbakov, D.E., Paleontological Institute, Russian Academy of Sciences, Profsoyuznaya 123, Moscow 117647, Russia. 9056. Abbott, J.C. (2009): Odonata (Dragonflies and Damselflies). In: Gene E. Likens (Ed.): *Encyclopedia of Inland Waters*. Elsevier Ltd. ISBN: 978-0-12-370626-3: 394-404. (in English) ["Odonata [...] inspire a wide range of emotions ranging from fear to admiration. They are a beneficial group of insects whose primary prey items, as both larvae and adults, include biting flies such as mosquitoes (Culicidae), black flies (Simuliidae), and horse and deer flies (Tabanidae). They also represent important components in the food webs of freshwater systems. Odonata are paleopterous, exopterygote insects whose closest relatives are the Ephemeroptera. The larvae are longer-lived than the adults and have evolved numerous adaptations to the freshwater aquatic environment resulting in pronounced differences in form across taxonomic groups. The adults occupy a conspicuous presence in the air, especially around ponds. The group is largely found in warmer areas, with over 75% of its species occurring in tropical regions. Some species, such as *Anax junius*, are known to migrate and are capable of travelling from Canada to Veracruz, Mexico, though our understanding of exactly what triggers these events, when they occur, and which members in the population are migrating, still remains a mystery." (Author) The article gives information on: Paleontology, Systematics, Characterization and Morphology, Biology, Life Cycle and Metamorphosis, Egg stage, Larval stage, Larval Habitats, Emergence, Dispersal and Maturation, Recognition and Courtship, Mating, Mate Guarding Behaviour, Thermoregulation, Conservation, Further Reading, Glossary.] Address: Abbott, J.C., University of Texas at Austin, Austin, TX, USA

(2009): 6th Polish Symposium of Odonatology of the Polish Entomological Society "Polish odonatology in the past, present time and future", Poznan and environs, October 23-25, 2009. First announcement. *Odonatrix* 5(1): 16-17. (in Polish, with English summary) [Announcement: "6th Polish Odonatological Symposium will be focused on the first book on the dragonflies of Poland, "Atlas of the distribution of dragonflies in Poland". The Atlas is scheduled to be published in September 2009. This is an opportunity to sum up past and present achievements of Polish odonatology and the conservation status of the Polish odonate fauna. Workshops, informal discussions and presentations, and a field trip are also planned. If you are interested in the participation, please, contact Dr. Rafal Bernard (Adam Mickiewicz University in Poznań, Department of General Zoology, Umultowska 89, PO-61-614 Poznań, e-mail: rbernard@amu.edu.pl) (Author)] Address: Bernard, R., Dept of General Zoology, Adam Mickiewicz Univ., Umultowska 89, PL-61-702 Poznań, Poland; E-mail: bernard@amu.edu.pl

9059. Ballesteros, T.M.; Torres-Mejia, M.; Ramírez-Pinilla, M.P. (2009): How does diet influence the reproductive seasonality of tropical freshwater fish? A case study of a characin in a tropical mountain river. *Neotropical Ichthyology* 7(4): 693-700. (in English, with Portuguese summary) ["Seasonal breeding of tropical freshwater fish may be synchronized with periods of high food consumption. We explored this hypothesis by studying the relationship between diet and reproductive activity of *Creagrutus guanes* (Teleostei, Characidae). Our results showed that *C. guanes* had a generalist and omnivorous diet dominated by aquatic insects (mainly Diptera larvae) and seeds. *Creagrutus guanes* did not show intersexual or ontogenetic variation in diet. Peaks

of feeding activity during rainy months were not synchronized with breeding in dry months. Our results do not support the hypothesis that the reproductive season has to be synchronized with high food consumption. We discussed the hypothesis fat reserves may be an important factor for the desynchronization of peaks of feeding and reproduction as explanation of seasonal breeding of this species." (Authors) The 'Index of Relative Importance' for Odonata as diet is very low.] Address: Ballesteros, Tania M., Laboratorio de Biología Reproductiva de Vertebrados, Universidad Industrial de Santander, A.A. 678, Bucaramanga, Colombia. 9060. Benazzouz, B.; Mouna, M.; Amezian, M.; Bensusan, K.; Perez, C.; Cortes, J. (2009): Assessment and conservation of the dragonflies and damselflies (Insecta: Odonata) at the marshes of Smir. Bulletin de l'Institut Scientifique, Rabat, section Sciences de la Vie 31(2): 79-84. (in English, with French summary) ["Wetlands are characterized by their high biodiversity. However, these habitats are very vulnerable and are often altered by human activity, which often includes drainage. Many wetlands have disappeared and this trend will continue until ecological awareness increases. The Smir marshes are presently targeted by the tourism industry. Knowledge of the Odonata of the marshes is important because these insects are useful indicators of habitat quality. Therefore, an inventory of Odonata living in the Smir marshes was carried out over thirteen months, demonstrating the importance of this area in terms of biodiversity. The status of the species collected is examined in order to promote the protection of the marshes and their living organisms. The biogeography of these insects is also considered so as to assess their origin." (Authors) With the exception of *Sympecma fusca*, *Anaciaeschna isosceles*, and *Aeshna mixta*, the odonate species recorded are widely distributed in northern Africa. The following species are listed: *Ischnura graellsii*, *Sympecma fusca*, *A. mixta*, *A. isosceles*, *Anax ephippiger*, *A. imperator*, *A. parthenope*, *Crocothemis erythraea*, *Diplacodes lefebvrei*, *Orthetrum chrysostigma*, *O. cancellatum*, *O. trinacria*, *Sympetrum striolatum*, *S. fonscolombii*, *S. meridionale*] Address: Benazzouz, B., Université Ibn Tofail, Faculté des Sciences, Laboratoire Génétique & Physiologie Neuroendocrinienne, B.P.133, 14000-Kénitra, Maroc. 9061. Bhattarai, S.; Chaudhary, R.P.; Taylor, R.S.L. (2009): Ethno-medicinal plants used by the people of Nawalparasi District, Central Nepal. Our Nature 7: 82-99. (in English) ["Despite new advances in modern medicine, the cultural use of plant in traditional medicine continues from ancient time to this day all over the world. The present research seeks to explore ethnomedicinal plants used by the local people of Nawalparasi district for primary healthcare. Local healers were interviewed regarding the detail uses of plants. When convenient a jungle or forest walk was also conducted, accompanying local healers for plant collection and detailed information gathering. A rich and unique diversity of 94 ethnomedicinal plant species belonging to 49 families under 86 genera were documented. In Nawalparasi, the expense of modern medical treatment combined with the poor economic status of indigenous people and a strong belief in the traditional medicine and traditional medical practitioners are the main reasons for the persistence of the traditional healing sys-

tem. In addition, we have also documented a lack of continuation and flow of indigenous knowledge from the elders to the younger generation. Youth tend to be attracted by the wave of modernization and do not appreciate the importance of conservation of traditional knowledge. The use of plants in Nawalparasi is an old tradition and the exploration of such unique cultures should be completed thoroughly so that the oral traditions are not lost forever. Immediate conservation and management approaches of valuable medicinal plants with the involvement of local indigenous people of Nawalparasi district will encourage the sustainable conservation of both biological and cultural diversity. ... 69. *Plumeria rubra* L. (Apocynaceae), V 2586. 'Galaini' (N). (b) About 100 g stem bark is mixed with 100 g of jag-gery and approximately 100 g of dead dragonflies and cooked. This is then taken twice a day to try to prevent rabies infection after someone is bitten by a mad dog. It is taken until the patient recovers, which the healers stated does happen." 9062. Boroń, M.; Mirosławski, J. (2009): Using insects (damselflies: *Azur damselfly* - *Coenagrion puella*) as biomarkers of environmental pollution. Fresenius environmental bulletin 18(7a): 1219-1225 [Czech Republik, Poland; "The phenomenon of bioaccumulation in damselflies was used to assess the metal pollution in the natural environment and indirectly but consequently, to estimate the risks for humans. *C. puella* was collected in polluted regions of Silesia and the control site – Wigry National Park. Flame atomic absorption spectrophotometer was used to estimate the concentration of chosen heavy metals: Cd, Cr, Cu, Fe, Mn, Ni, Pb, and Zn. The analysis indicated a general correlation between metal concentration in damselflies and in chosen elements of environment. It has been stated that azure damselflies can be used as biomarkers of environmental pollution for iron, lead and zinc, also manganese and nickel to an average degree. However, there is an insignificant correlation in case of cadmium and copper. Chromium was not present in the samples." 9065. Buczyński, P.; Karasek, T.; Kowalak, E.; Kowalak, J.; Oder, T. (2009): Contribution to the knowledge of dragonflies (Odonata) of the Roztocze Upland. *Odonatrix* 5(1): 1-6. (in Polish, with English summary) ["The paper presents the results of studies conducted in Roztocze Upland (SE Poland) during the camp of Student Scientific Circle of Biologists of Maria Curie-Skłodowska University in July 2008. At 27 study sites, of which 13 were situated in the Roztoczanski National Park, 37 dragonfly species were found (51% of the national fauna). The most interesting were: *Sympecma paedisca*, *Nehalennia speciosa*, *Gomphus vulgatissimus* and *Ophiogomphus cecilia*. 9 species have been recorded for the first time from the Roztoczanski National Park, which elongated the list of well-known species to the number of 47. The study site of *Nehalennia speciosa* (Borowina near Józefów, *Caricetum lasiocarpae* on the edges of the water body between dunes) has been known for over 10 years. New data confirms the subsistence of the population and even the decrease in numbers: at least >1.000 specimens, juvenile imagines and development behaviour were observed. At the same time, the disappearance of the other population of *N. speciosa* was found - on a transitional peat-bog near the village Hamernia (last data from 2002). Perhaps the same refers to the population of *Somatochlora arctica* on a transitional peat-bog near the village Tarnowola (last data from 2003). Other examples of vanishing of peat-bog species on Roztocze due to drying out of habitats are also given. Perhaps we are witnessing the start of regress of this ecologic group which has not been endangered up till now. Data about Gomphidae has been analyzed by their rarity in the discussed region which is surprising for Roztocze is rich in rivers with suitable habitat structure and satisfactory water quality. The authors give two possible explanations responsible for these conditions: forest basin of the rivers (which results in shading and low pH among others) as well as strong fish stocking of Roztocze rivers by trout by Polish Angling Association." (authors)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

9066. Buczyński, P.; Bernard, R.; Pietrzak, L. (2009): Dragonflies (Odonata) of selected dystrophic water bodies in the vicinity of Złocieniec (north-western Poland). *Chrońmy Przyrodę Ojczystą* 65(5): 353-364. (in Polish, with English summary) ["Studies of the odonate fauna (mostly larvae and exuviae, additionally imagines) were carried out between 1999 and 2001 at 3 localities in the environs of Złocieniec ("Czarnówek" No. 1, "Gronowo" No. 2, "Krosino" No. 3). All the water bodies represent acidic habitats typical of the Pomeranian Lake Districts (NW Poland): an oligohumic, very poor in nutrients, and extremely clearwater pool surrounded by a broad Sphagnum bog (No. 3); a mesohumic lake and small pools situated in a Sphagnum bog channel (No. 1a – pools, 1b – lake); a polyhumic, kettle lake with brownish water, bounded only with a few-metre-wide Sphagnum zone (No. 2). 27 species were recorded, i.e. 37% of the odonate fauna of Poland. Most of them were autochthonous, several – probably autochthonous, and one certainly allochthonous species. Number of species was the poorest in small, less diversified pools "hanging" in Sphagnum mats, and (among greater water bodies) in oligohumic, crystal lake No. 3. Species composition was mostly typical of the habitats, predominated by tyrphobiontic (*Leucorrhinia dubia*, *Aeshna sub-*

arctica elisabethae) and tyrphophilic (e.g. *L. rubicunda*, *L. albifrons*, *Lestes virens*, *Coenagrion hastulatum*, *Nehalennia speciosa*) species. This was confirmed by high values of the Biocenosis Natality Index (especially in its quantitative aspect). In this context, the occurrence of *Erythromma viridulum* (with reproductive behaviour) was rather surprising. It suggests its misidentification of the microhabitat – an occupied specific patch of floating Sphagnum at locality No. 1 was physiologically very similar to favourable *Ceratophyllum demersum*. The autochthonous large population of *Lestes viridis* at locality No. 1 and a regular occurrence of *Coenagrion lunulatum* were also noteworthy. However, the large population of *N. speciosa* (critical species in Europe, EN in the Polish Red list, NT in the Global Red list) in *Carex limosa* belt at locality No. 2 was certainly the most valuable element, qualifying this site for legal protection with the use of a buffer protection zone." (Authors)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

9067. Buczyński, P. (2009): Red list of dragonflies (Odonata) of the Lublin Region (Eastern Poland). Second edition: 2009. *Odonatrix* 5(1): 25-29. (in Polish, with English summary) ["The author presents the new red list of dragonflies of the Lublin Region, 10 years after publishing the previous edition (Buczyński 1999). The list includes 10 species: 4 species of high risk categories (VU-CR) and 6 of low risk categories (LC, NT). The most endangered are: *Coenagrion ornatum* (CR), *Cordulegaster boltonii* (CR), *Coenagrion armatum* (EN) and *Nehalennia speciosa* (EN). The scale of threats of dragonflies of the Lublin Region is smaller than in the whole Poland (Bernard et al. 2002) or in the Łódź Region (central Poland) (Tończyk, Szymański 2006). Seriously endangered are the faunas of small running waters and Sphagnum peat bogs. For the protection of dragonflies in Poland, particularly important are populations of *Coenagrion armatum* (9 in total) as well as one of 3-4 populations of *C. ornatum* known nowadays in the country which is large and stable." (Author)] Address: Buczyński, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

9068. Canobbio, S.; Mezzanotte, V.; Sanfilippo, U.; Benvenuto, F. (2009): Effect of multiple stressors on water quality and macroinvertebrate assemblages in an effluent-dominated stream. *Water Air Soil Pollution* 198: 359-371. (in English) ["Lura stream flows in the populated and industrialized conurbation North of Milan, Italy. The area suffers a sprawling urbanization which is leading to major alterations in water quality, hydrology and morphology of streams. These water bodies are known as effluent-dominated streams, because most of the baseflow is given by Wastewater Treatment Plant (WWTP) discharges. In this paper, a 5 year long assessment of Lura stream is presented and the collected data is discussed to understand overall ecological quality. Multivariate analysis carried out on macroinvertebrate assemblages and environmental variables suggests that invertebrate communities suffer severe alteration both upstream and downstream WWTP discharges. Results indicate that the high polluting loads coming from WWTP discharges affect seriously the stream water quality, but the most important cause of impairment are pulse perturbations related to the modified hydrology, causing droughts and flash floods, and to the spills

of untreated sewage from overflows during rain events." (Authors) *Onychogomphus* sp., *Crocothemis* sp. and *Orthetrum* sp. are listed from the Lura stream.] Address: Canobbio, S., Dipartimento di Scienze dell'Ambiente e del Territorio, Università degli Studi di Milano-Bicocca, Piazza della Scienza 1, 20126 Milan, Italy. This species is closely related to *P. attenuatus* Bates in Selys, 1886.] Address: Couroy, Y., 271 rue de l'Armée de l'Est, 70110 Villersexel, France

9075. Daraž, B. (2009): New data on dragonflies (Odonata) of northeasternmost Bulgaria. *Odonatrix* 5(2): 55-64. (in Polish, with English summary) ["During the summer trip to north-eastern coasts of Bulgaria, the fauna of dragonflies was studied at 12 study sites between the 2nd and 12th of July 2008. The studies covered the area between the Romanian border and the River Kamchia, mostly within the villages of Shabla, Kavarna, Balchik and Dobrich. In the northern part, temporary running waters prevail. Thus, studies were concentrated in a narrow zone along the coasts of the Black Sea where permanent waters occur, both running and standing. In the southern part of the studied area the network of permanent flowing waters is more dense and present in the depth of the land. 24 dragonfly species, have been recorded in the studied area, which comprises 35% of 68 species known in Bulgaria. The most interesting were the records of: *Cordulegaster insignis*, *Cordulegaster picta* and *Lestes macrostigma*, moreover, *Caliaeschna microstigma* is also worth mentioning. *C. insignis* has been known from 13 published localities and a few unpublished records found recently. Its occurrence is practically restricted to the eastern part of the country and a few sites situated along the Danube River. Two new study sites partly covered a gap in the north-eastern part of the country. This suggests a wider and more continuous occurrence of the species range in eastern Bulgaria. The range of *C. picta* in Bulgaria encompasses a narrow belt along the coast of the Black Sea. Four new study sites found by the author have a bit extended this belt in its northern part, in the basin of the River Batova. These study sites are presently the northernmost known localities in the

whole range of the species. *C. picta* has been found in general in small fast-flowing streams with a stony bottom, totally or to a large degree shaded by trees. Numerous patrolling males have been observed (often in a high density), as well as females ovipositing in shallow sandy areas along the stream banks. Larvae were found among stones while exuviae - among roots and dry vegetation near banks. Four study sites of *L. macrostigma* have been recorded so far from Bulgaria. The 5th site, given in this paper, was known previously from 2006, however, it was not published. This study site has a similar coastal situation to three study sites adjacent to the Burgas Gulf. However, it is located much more to the north. Very numerous local population, estimated to over 10000 of specimens, results from optimal habitat conditions: the low depth and high temperature of brackish water, and the abundant occurrence of *Bolboschoenus maritimus* and *Scirpus* sp. swamps. *C. microstigma* was recorded in Bulgaria in the southern, central and eastern part of the country. In the east, it was known from the coasts of the Black Sea to Kavarna. The author's studies provided 6 sites of this species, one of them was situated 25 km to the north-east of Kavarna. The last record is presently northernmost locality of *C. microstigma* in the eastern Balkans. Two recorded species - *L. macrostigma* and *C. ornatum* belong to critical species in Europe. Four species were proposed to the Bulgarian Red List of dragonflies: *C. insignis* (CR), *L. macrostigma* (CR), *C. microstigma* (VU), *C. picta* (VU). New records combined with the literature data seem to show that the species mentioned above are not threatened in Bulgaria to such degree." (Author)] Address: Daraż, B., ul. 9076. Delasalle, J.-F. (2009): Contribution à la connaissance d'un Zygoptère récemment décrit de Guyane française: *Neoneura angelensis* Juillerat, 2007 (Odonata: Zygoptera: Protoneuridae). *Martinia* 25(4): 149-152. (in French, with English summary) [The paper presents new observations of *N. angelensis* in French Guyana with a description of the biotope and the observation of the reproduction of that Protoneuridae.] Address: Delasalle, J.-F., Domaine de Chantraigne 30 rue Jules Lardière BP 70225 F-80800 Corbie, France. E-mail: jf.delasalle@aliceadsl.fr

9077. Dolata, P.T.; Stawicki, A.; Żuk, T. (2009): New records of the Scarlet Dragonfly *Crocothemis erythraea* (Brullé, 1832) in the South Wielkopolska region (SW Poland) and some remarks about its detecting and the participation of amateurs in odonatology. *Odonatrix* 5 (1): 13-16. (in Polish, with English summary) ["Two new localities (within 35 km) of the Scarlet Dragonfly were recorded on the clay pits in the South Wielkopolska region: 1) Odolanów (Ostrów Wielkopolski district, 51°35' N, 17°39' E, UTM: XT81): one male on 28th May 2007; 2) Kotlin (Jarocin district, 51°54' N, 17°40' E, UTM: XT85): one male on 23rd June 2007. Those records were made 4-48 km from localities detected by Zurawlew (2009) in Pleszew district (Fig. 1) and support his opinion about high importance of clay pits for this species. Both records came from Kartoteka Przyrodnicza Południowej Wielkopolski (Nature Database of the South Wielkopolska), the "citizen science" scheme, led by local group of the Polish Society for the Protection of Birds. The wider co-operation of the odonatologists with such groups and schemes is proposed in the article." (Authors)] Address: Żuk, T., Południowewiel-

kopolska Grupa OTOPI, ul. Wrocławska 60 A/7, 63-400 Ostrów Wielkopolski, Poland. E-mail: tomasz.zuk@post.pl

9078. Dommange, J.L.; Guilmet, M. (2009): Odonates nouveaux pour le département de l'Aveyron. *Martinia* 25(3): 102. (in French) [France; *Sympetrum meridionale*, VII-2009, le Rougier de Camarès (commune de Montlaur) & lac du causse de Villeneuve (commune de Martiel); *Somatochlora arctica*, V-2009, commune de Laguiole, Aubrac. La découverte d'exuvies et d'individus émergents (24 et 30 mai 2009); *Calopteryx haemorrhoidalis*, 2005 and 2006, Dourdou de Camarès (commune de Montlaur) & 2008, Lot (communes de Balaguier-d'Olt).] Address: Guilmet, Martine, 51, cité Cardaillac, F-12000 Rodez, France

9079. Doucet, G. (2009): Suivi de l'émergence d'*Oxygastra curtisii* (Dale, 1834) et de *Gomphus graslinii* Rambur, 1842 sur un étang du centre de la Dordogne (Odonata: Anisoptera: Corduliidae, Gomphidae). *Martinia* 25(4): 157-164. (in French, with English summary) ["Following the discovery of *O. curtisii* and *G. graslinii* exuviae in a pond located in the center of Dordogne department, France during early June 2008, the author decided to study the emergence of both species in order to increase the knowledge of their phenology and abundance in this particular breeding biotope. Exuviae collection highlighted not only that both species had great population size but also that several other species which are encountered in this pond are rather relevant of running waters."] Address: Doucet, G., 74 me de la Colonie, F-75 013 Paris, France. E-mail: guillaume.doucet@yahoo.fr

9080. Dufour, C. (2009): Nouvelle preuve de reproduction d'*Onychogomphus* f. *forcipatus* (Linnaeus, 1758) dans le Lac de Neuchâtel, Suisse (Odonata, Gomphidae). *Ento Helvetica* 2: 23-31. (in French, with English and German summaries) [*O. forcipatus* reproduces again in the Lake of Neuchâtel, Switzerland "along a highly artificial bank, after many decades without any observations of either larvae or exuvia. This return is probably linked to the great improvement of the quality of the water which is the result of efforts developed over more than 40 years. A particularly rapid imaginal moult is described and illustrated." (Author)] Address: Dufour, C., Muséum d'histoire naturelle, rue des Terreaux 14, CTI-2000 Neuchâtel, Switzerland. E-mail: Christophe.Dufour@unine.ch

9081. Duprez, B. (2009): Étude des exuvies d'*Aeshna cyanea* (Millier, 1764) dans une mare de ferme en Limousin (Corrèze) (Odonata, Anisoptera, Aeshnidae). *Martinia* 25(3): 129-130. (in French, with English summary) ["Based on three sampling sessions of *A. cyanea* exuviae, the author presents the corresponding chronology, sex-ratio and measurements." (Author)] Address: Duprez, B., 43 avenue Alexandre de Serbie, F-51100 Reims, France

9082. Eid, E.; Katbeh-Bader, A.; Al-Otoom, M.; Othmaii, Y. (2009): Contribution to the Entomofauna of Dibeen Forest Reserve in Jordan. *Centre for Entomological Studies Ankara - Cesa News* 49: 19-41. (in English) ["A baseline insect survey of the Dibeen Forest Reserve was conducted from 26th of March till the 5th of May, 2006. Pitfall traps, light traps and butterfly nets were used for collecting. The collected specimens were preserved in the University of Jordan Insect Museum and Dibeen Forest Reserve. A total of 122 insect spe-

cies in 11 orders and 42 families were identified. Nine of these species were recorded for the first time from Jordan. Available biological and or ecological data, distribution and relevant remarks about each species are given. Rare, common, pest species, and species that can be used in ecological studies are discussed." (Authors) Only two Odonata species - *Orthetrum chrysostigma*, *Trithemis arteriosa* - were recorded.] Address: Katbeh-Bader, A. Department of Plant Protection, Faculty of Agriculture, University of Jordan, Amman 11942, Jordan. Email: Ahmadvk@ju.edu.jo

9083. Faucheux, M.J. (2009): Sensilles antennaires de l'imago de *Brachythemis leucosticta* (Burmeister, 1839) (Odonata, Anisoptera, Libellulidae). *Martinia* 25 (1): 40-48. (in French, with English summary) ["The sensory complement of the adult antenna of *B. leucosticta* is studied using scanning electron microscopy. The scape and the pedicel bear aporous sensilla chaetica: those located at the following joints (head-scape, scape-pedicel, pedicel-flagellum) are proprioceptors which monitor the movements of these segments in relation to each other; the other sensilla chaetica are tactile mechanoreceptors. The sensillum campaniformium of the pedicel controls the movements of flagellum. The two first flagellomères possess two types of multiporous sensilla coeloconica whose hygroreceptive function is assumed, and a third type of sensillum coeloconicum with unknown function." (Author)] Address: Faucheux, M.J., Lab. d'Endocrinologie des Insectes Sociaux, Fac. Sciences et Techniques, 2 rue de la Houssinière, B.P. 92208, F-44322 Nantes Cedex

9084. Faucheux, M.J.; Meurgey, F. (2009): Les sensilles antennaires d'une larve fousseuse, *Ophiogomphus cecilia* (Geoffroy in Fourcroy, 1785) (Odonata, Anisoptera, Gomphidae). *Martinia* 25(2): 85-92. (in French, with English summary) ["The flattened antenna of the burrower larva of *Ophiogomphus cecilia* bears five types or subtypes of mechanoreceptive sensilla: club-shaped sensilla, thorny sensilla chaetica, sensilla filiformia of subtypes short, long, thorny. The variety of the sensilla filiformia suggests that the reception of the vibrations is carried out subtly. The dorsal surface of antenna is covered with club-shaped sensilla whose presence is related to the burrowing behaviour of the larva; they are probably current receptors that also detect the presence and position of prey. They are described for the first time on the larval antennae of Odonata. Thorny sensilla chaetica are tactile. The proprioceptors which monitor the relative position of antennal segments in other species are not here observed." (Authors)] Address: Faucheux, M.J., Laboratoire d'Endocrinologie des Insectes Sociaux, Faculté des Sciences et Techniques, 2 rue de la Houssinière, B.P. 92208, F-44322 Nantes Cedex 3, France

9085. Feldwieser, G. (2009): Blutsauger auf den Flügeln der Braunen Mosaikjungfer (*Aeshna grandis*) - erster Fund der Gnitz Forcipomyia paludis (Diptera: Ceratopogonidae) auf Libellen in Baden-Württemberg, mercuriale 9: 31-32. (in German) [Bad Wurzach, Baden-Württemberg, Germany; photographic evidence of a ceratopogonid *Forcipomyia paludis* sucking on the wings of *A. grandis*.] Address: Feldwieser, G., Gönningerstr. 27, D-72793 Pfullingen, Germany

viae at the tip of *Typha latifolia*.] Address: Feldwieser, G., Gönningerstr. 27, D-72793 Pfullingen, Germany

9087. Feldwieser, G. (2009): Blaugrüne Mosaikjungfer (*Aeshna cyanea*) fällt ins Wasser und einem Gelbrandkäfer (Coleoptera: Dytiscidae) zum Opfer. *mercuriale* 9: 39. (in German) [Reutlingen, Baden-Württemberg, Germany; photographic documentation of an *A. cyanea* male accidentally fallen into water and caught by water tension. *Dysticus marginatus* preyed upon the dragonfly immediately, starting to devour it at the caput.] Address: Feldwieser, G., Gönningerstr. 27, D-72793 Pfullingen, Germany

9088. Franz, N.M.; Vanegas, S.Z.Y. (2009): The university of Puerto Rico at Mayagüez insect collection – then and now. *Entomological news* 120(4): 457-464. (in English) ["The origin, historical trajectory, and present status of the insect collection of the University of Puerto Rico at Mayagüez (collection coden: UPRM) are reviewed. The collection initiated in the mid 1920s and has grown relatively continuously thanks to efforts by several outstanding entomologists working at UPRM. As of 2007, the collection includes more than 130,000 objects (individual specimens, slides, or vials) pertaining to 25 hexapod orders (Odonata: 840 specimens). The numbers of collection objects per order are listed. The geographic emphasis is on Puerto Rico and surrounding islands. The auchenorrhynchos Hemiptera, Collembola, and Coleoptera are particularly well represented. The collection is in a process of reorganization and is available for specimen loans and related collaborative activities." (Authors)] Address: Franz, N.M., Dept Biol., P. O. Box 9012, Univ. of Puerto Rico, Mayagüez, Puerto Rico 00681 USA. E-mail: franz@uprm.edu

9089. Gaenzle Schilling, E.; Loftin, C.S.; Huryn, A.D. (2009): Effects of introduced fish on macroinvertebrate communities in historically fishless headwater and kettle lakes. *Biological Conservation* 142(12): 3030-3038. (in English) ["Widespread fish introductions have led to a worldwide decline in the number of fishless lakes and their associated communities. Studies assessing effects of fish stocking on native communities in historically fishless lakes have been limited to high-elevation headwater lakes stocked with non-native trout. Little is known about the effect of fish stocking in historically fishless and hydrologically isolated lowland kettle lakes. We compared the effects of introduced fish on macroinvertebrate communities in kettle lakes stocked with centrarchids, salmonids, and cyprinids, and headwater lakes stocked with brook trout (*Salvelinus fontinalis*) in Maine, USA. Fish had significant effects on macroinvertebrate community structure in both lake types, with reduced species richness and abundances of taxa characteristic of fishless lakes. The effects of introduced fish were more pronounced in headwater lakes despite a less diverse fish assemblage than in kettle lakes. We attribute this to abundant submerged vegetation providing refuge from fish predation and reduced stocking frequency in kettle lakes. We assessed effects of stocking duration on macroinvertebrates in a subset of headwater lakes with known dates of trout introduction. Species richness and abundance of most taxa declined within 3 years following trout introduction; however, richness and abundance were least in lakes with long stocking histories (40 years). Macroinvertebrates previously identified as fishless bioindicators were absent from all stocked lakes, indicating that trout rapidly eliminate these sensitive taxa. Conservation of this his-

torically undervalued ecosystem requires protecting remaining fishless lakes and recovering those that have been stocked. [...] The odonates *Aeshna eremita* and *Leucorrhinia* spp. were more abundant in fishless than stocked headwater lakes. No odonates differed in abundance or percent occurrence between stocked and fishless kettle lakes." (Authors)] Address: Gaenzle Schilling, Emily, Department of Wildlife Ecology, University of Maine, 5755 Nutting Hall, Orono, ME 04469-5755, USA. E-mail: emily.schilling@umit.maine.edu

9090. Gilard, B.; Vrignaud, S. (2009): Redécouverte de *Coenagrion ornatum* (Selys in Selys et Hagen, 1850) dans le département de l'Allier (Région Auvergne), 20 ans après une première donnée (Odonata, Zygoptera, Coenagrionidae). *Martinia* 25(3): 95-101. (in French, with English summary) ["*C. ornatum* has been rediscovered in Allier department (Auvergne Region, France) during 2005 and 2006 investigations, twenty years after its first observation in the area. Among important populations of *C. mercuriale*, those of *C. ornatum* were found in pastures. They were very localized and sensitive to overgrazing." (Authors)] Address: Gilard, B., 3, lotissement de la Croix des Frères, rue du Mont Mouchet, F-43100 Brioude, France

9091. Grand, D.; Billaud, F. (2009): Les Odonates du marais temporaire de Morlin (Communes de Montagny et de Taluyers) (Département du Rhône). *Martinia* 25(1): 15-24. (in French, with English summary) ["*Lestes dryas* has been recently discovered in Morlin temporary pond and is thus the 62nd species of Rhône department, France. A low deep ditch borders the 3 ha pond which is mainly composed by a submerged meadow with shrubs and trees. This meadow dries out from early summer to autumn, sometimes winter, except for a pool measuring only a few squared meters; such a milieu is rare in the department. Thirty three Odonata species can be encountered. Among them a significant part is represented by typical temporary pools species such as *Lestes barbarus*, *L. virens*, *Aeshna affinis*, *Sympetrum meridionale* and *S. sanguineum* but also by *Chalcolestes viridis* and *Sympetma fusca* that can stand the drying of the pool during summer but are rather permanent pool species. Considering those seven species, lots of adults emerge from the water and *L. barbarus* and *S. sanguineum* do so especially early (respectively on the 8th and 15th of May). Other conspicuous dragonflies fly around the pool: *Ischnura pumilio*, *Coenagrion scitulum*, *Anax parthenope*, *Sympetrum fonscolombii*; *Leucorrhinia pectoralis* do so occasionally. Finally, the author underlines that Morlin temporary pool is threatened by a highway project." (Author)] Address: Grand, D., Impasse de la Voûte, F-69270 St. Romain-au-Mont d'or, France. (in German) [Thuringia, Germany; documentation of a record in early summer 2008 without further data details of the regionally rare *B. pratense*.] Address: Grosser, N., Fakultät LGF, Fachrichtung Landschaftsarchitektur Fachhochschule Erfurt University of Applied Sciences Leipziger Strasse 77 99085 Erfurt, Germany

9093. Guerbaa, K. (2009): Restauration de milieux favorables à *Coenagrion mercuriale* (Charpentier, 1840) sur la Réserve Naturelle Nationale de la Tourbière des Dauges (Saint-Léger-la-Montagne, Haute-Vienne). *Martinia* 25(3): 131-32. (in French, with English summary) ["The author presents a management approach of *C. mercuriale* based on a traditional agricultural technique. It consists in creating or restoring drains using a tractor equipped with a channel digger. The advantages of this technique are highlighted." (Author)] Address: Guerbaa, K., CREN Limousin, Sauvagnac, F-87340 Saint-Léger-la-Montagne, France

9094. Hennequin, E.; Lolive, N. (2009): Synthèse des connaissances des Odonates du Pays de Tulle (Département de la Corrèze). *Martinia* 25(1): 25-27. (in French, with English summary) [France; data were gathered by field investigations and literature, resulting in 50 Odonata species of which 17 are in the Limousin Red List. Only a few are briefly discussed, but the complete checklist is omitted.] Address: Hennequin, E., Société Limousine d'Odonatologie, 11 rue Jauvion, F-87000 Limoges assoslo@wanadoo.fr

9095. Hennequin, E. (2009): Découverte d'une nouvelle population de *Leucorrhinia dubia* (Vander Linden, 1825) dans le département de la Corrèze (Limousin) (Odonata, Anisoptera, Libellulidae). *Martinia* 25(3): 116. (in French) [France; 28-V-2008] Address: Hennequin, E., Conservatoire Régional des Espaces Naturels du Limousin, 6 ruelle du Theil, F-87510 Saint-Gence, France

9096. Hennige, K. (2009): Odonate Sightings April 1 to August 31 2009. *The Blue Bill* 56(3): 105-107. (in English) [76 species are listed according their first sighting in 2009. The report includes records in the Kingston Checklist area and Charleston Lake & Menzel Provincial Parks, Ontario, Canada. Cool weather delayed the appearance of many species by one to two weeks, and numbers for some common species were lower than in past years. A new species was added to the Checklist when 3 *Somatochlora walshi* were seen along Roblin Road, 3km east of the Menzel Gate. This species was also seen in at least three more locations just outside the Kingston Checklist area and at least 15 were seen at Menzel. *Somatochlora kennedyi* and *S. willamsoni* also were found at Menzel Centennial Provincial Park. Even more surprising was the discovery of 1 male and several female of the very rare and scattered distributed *Williamsonia fletcheri*, also at Menzel Centennial. Other highlights include the second record of *Sympetrum costiferum*, third and fourth records of *Epiaeschna heros*, also on Charleston Lake, 3km from the 2007 location, a new population of *Enallagma antennatum* along Millhaven Creek, and 3 records of the rare *Gomphaeschna furcillata*.] Address: Hennige, K. E-mail: khennige@sympatico.ca

9097. Hope, P. (2009): New records of *Leucorrhinia pectoralis* in Turkey (Odonata: Libellulidae). *Libellula* 28(1/2): 93-96. (in English, with German summary) ["In June 2008, a male *L. pectoralis* was observed perched on a waterside plant beside a canal, in an area known as Koca Calis, situated on the Mediterranean coast near Fethiye, Mugla province, Turkey. In the same month, another male *L. pectoralis* was photographed at Koycegiz, 80 km to the west of Fethiye. These two sightings extend the previously known range of *L. pectoralis* 200 km further south to the Mediterranean

coast." (Author)] Address: Hope, P., 2 English Bridge Court, Wyle Cop, Shrewsbury, Shropshire, SY1 1XH, United Kingdom. E-mail: paulhope99@googlemail.com

9098. Ingley, S.J. (2009): Life on the fly: Ecology and evolution of the helicopter damselflies (Odonata: Pseudostigmatidae). University of Florida, Dept of Wildlife Ecology & Conservation, CALS Honors Program: 32 pp. (in English) [Helicopter damselflies form a relatively small, yet dynamic group of endangered odonates (including the largest extant odonate, *Megaloprepus caeruleus*, with a wingspan of ~190 mm). This highly specialized group is found in primary-growth rainforest (Central and South America; one East African species) where they oviposit exclusively in phytotelmata and are specialist foragers on orb weaver spiders which are plucked from their web. Pseudostigmatids exhibit unique wing structure within Zygoptera, and within Pseudostigmatidae both broad and narrow wing forms exist. Oviposition, spider feeding, and wing form evolution are examined for the first time within an evolutionary context using modern phylogenetic methods of tree reconstruction and character optimization. Phylogenetic analyses (Bayesian and Parsimony) were performed on a data set composed of 60 morphological characters and ~3.4kb of sequence data (Mitochondrial loci: 12S, 16S, COII; Nuclear loci: 28S, H3). Findings include monophyletic Pseudostigmatidae, *Coryphagrion grandis* (East African species) as the sister group to all Neotropical genera, and *Pericnemis* as sister to Pseudostigmatidae. The genera *Mecistogaster* and *Pseudostigma* are monophyletic while *Microstigma* forms a monophyletic group with *Megaloprepus*. Oviposition in phytotelmata likely evolved multiple times within Zygoptera, and spider feeding evolved from a single origin. There are two separate origins of narrow wings within Pseudostigmatidae. These findings provide new insight into Pseudostigmatid evolution that can be used to generate awareness of the threatened status of Helicopter damselflies.] Address: Ingley, S.J. E-mail: sjingley@gmail.com

9099. Juillerat, L., Monnerat, C. (2009): Odonata in southern Morocco, with first records of *Orthetrum ransonnetii* and *Sympetrum sinaiticum* (Odonata: Libellulidae). *Libellula* 28(1/2): 97-115. (in English, with French and German summaries) ["On several field trips between 2001 and 2008 to southern Morocco, 26 odonate species were recorded in 24 localities. *O. ransonnetii* and *S. sinaiticum* were recorded for the first time in April 2003 and April 2007 respectively. Both are new for the Moroccan fauna, increasing the number of odonate species for this country to 61." (Authors)]

9100. Kovacs, T.; Ambrus, A.; Olajos, P.; Szilagyi, G. (2009): Records of Ephemeroptera and Odonata from the Biebrza National Park, Poland. *Folia historico naturalia musei Matraensis* 33: 87-96. (in English) [This paper provides data on 20 Ephemeroptera and 42 Odonata species from the Biebrza National Park, Poland, including many species protected by European law.] Address: Kovács, T., Mátra Museum, H-3200 Gyöngyös, Kossuth Lajos u. 40, Hungary. 9101. Krieger, M. (2009): Frühe Heidelibelle *Sympetrum fonscolombii* (Selys 1843) in Rotenburg/Fulda um das Jahr 1880. *Libellen in Hessen* 2: 62. (in German) [A male of *S. fonscolombii* was traced in the collection of the Natural History Museum Kassel, caught by Heinrich

Eisenach prior 1886 in Rotenburg/Fulda, Hessen, Germany. This seems to be one of the oldest records known from Germany.] Address: Krieger, M., Fuldablick 20, 36199 Rotenburg a.d. Fulda, Germany

9102. Krieg-Jacquier, R.; Deliry, C. (2009): Observations récentes de *Leucorrhinia albifrons* (Burmeister, 1839) dans le département de l'Ain (Odonata, Anisoptera, Libellulidae). *Martinia* 25(3): 119-127. (in French, with English summary) ["At the beginning of summer 2006, a new site of *L. albifrons* has been discovered in Bugey (Jura mountain, Ain department, France). Because of the big size of the population, its nearness to other populations and the discovery of another big population in the northern part of Isère department in 2007, the species seems likely to disperse in montane regions." (Authors)] Address: Deliry, C., Villa D, 2 rue de la Forge, F-38200 Villette de Vienne, France

9103. Lambert, J.-L. (2009): A propos du statut de *Leucorrhinia caudalis* (Charpentier, 1840) et *Leucorrhinia albifrons* (Burmeister, 1839) dans le bassin du Drugeon (département du Doubs) (Odonata, Anisoptera, Libellulidae). *Martinia* 25(1): 3-13. (in French, with English summary) ["*L. caudalis* and *L. albifrons* have been recently rediscovered in the hydrographical basin of Drugeon river (Doubs department, France) by roughly 840 meters asl. The author demonstrates their autochthony and reminds that *L. pectoralis* and *L. dubia* are also native from this area. He wonders about historical data regarding the status of *L. caudalis* at this altitude. Several species mainly encountered in the plain have been recently observed in this middle high mountain area, especially in Remoray's lake natural reserve. Hence their strongly suspected nativity could be established." (Author)] Address: Lambert, J.-L., Office National de l'Eau et des Milieux Aquatiques, Service Départemental de la Marne, F-51520 La Veuve, France. E-mail: sd51@onema.fr

9104. Lambret, P.; Cohez, D.; Janczak, A. (2009): *Lestes macrostigma* (Eversmann, 1836) en Camargue et en Crau (Département des Bouches-du-Rhône) (Odonata, Zygoptera, Lestidae). *Martinia* 25(2): 51-65. (in French, with English summary) [France; "*L. macrostigma* is a patchily spread species. It is not legally protected, either in Europe or in France, despite its conservation status. This paper reviews the previous and recent investigations (i.e. before and from 1998 onwards) in Camargue and in Crau. Its abundance can experience great variations from to year and the species can even eclipse from a site during some time. Nonetheless those eclipses are not irreversible. Our data show that its biology and ecology are still poorly known. Numerous human activities threaten the preferred habitats of the species and therefore increase its weakness. Hence, it seems necessary (i) to lead further investigations in the area and (ii) to monitor and to study already known populations and (iii) to protect this endangered species at the European scale." (Authors)] Address: Lambret, P., Marais du Vigueirat, 13104 Mas Thibert, France. E-mail: philambret@hotmail.com

9105. Lambret, P.; Boudot, J.-P. (2009): *Nesciothemis farinosa* (Förster, 1898) et *Orthetrum ransonnetii* (Brauer, 1865) nouveaux pour l'Arabie Saoudite et autres observations d'Odonates sur les reliefs côtiers de la Mer Rouge. *Martinia* 25(4): 153-155. (in French, with English summary) [*Nesciothemis farinosa* and *Orthetrum ransonnetii* have been recently identified from pho-

tographs taken in Saudi Arabia in 2002; both are new to the country. Additional records include *Ceragrion glabrum*, *Pseudagrion hamoni*, *Anax ephippiger*, *Paragomphus sinaiticus*, *Orthetrum chrysostigma*, *Pantala flavescens*, *Trithemis arteriosa*, and *T. kirbyi*.] Address: Lambret, P., Marais du Vigueirat, F-13104 Mas Thibert, France. E-mail: philambret@hotmail.com

9106. Lolive, N. (2009): *Cordulegaster bidentata* Selys, 1843 dans le département du Cantal: état des connaissances (Odonata, Anisoptera, Cordulegastriidae). *Martinia* 25(2): 73-78. (in French, with English summary) [*C. bidentata* seemed to be a quite rare species in the Cantal department, France prior 2005. To improve knowledge on the distribution of that species the Odonatological Society of Limousin region developed a method to detect larvae of *C. bidentata*. Conducting this method lead to a significant increase of new localities for the species. Thus, the new data gathered thereby show that this species is well represented in the department.] Address: Lolive, N., 35 avenue de la République, F-1 5000 Aurillac, France

9107. Machado, A.B.M. (2009): *Tukanobasis* gen. nov. with the descriptions of *T. corbeti* sp. nov. from the Amazonian region of Brazil (Odonata: Coenagrionidae). *International Journal of Odonatology* 12(2): 331-336. (in English) ["A new coenagrionid genus, *Tukanobasis*, is described for *T. corbeti* sp. nov. found in a flooded forest in the Amazonian region of Brazil (holotype: Brazil, Amazonas State, Taraqua [3°27'15"S, 62°51'05"W, 35 m], viii 1964, in ABMM). The new genus is characterized by the presence of an apical brown spot on Hw of mature males, a ventral thoracic tubercle, long paraprocts, two large pleural yellow stripes, and a short CuA. Its affinities are uncertain." (Author)] Address: Machado, A.B.M., Departamento de Zoologia, Inst. Cienc. 9110. Mauersberger, R. (2009): Nimmt *Leucorrhinia caudalis* im Nordosten Deutschlands rezent zu? (Odonata: Libellulidae). *Libellula* 28(1/2): 69-84. (in German, with English summary) ["Evidence is given that *L. caudalis* became more numerous and widespread in the lake region of northern Brandenburg and Mecklenburg-Vorpommern, Germany, during the last ten years. In the years 1992 to 1996 0.4 % of all dragonfly records referred to *L. caudalis*, whereas 1.4 % of records referred to this species in the period from 2004 to 2008. Between 2001 and 2008, the constancy of *L. caudalis* at the monitoring sites of 16 lakes increased from 19 to 53 %. During the same period, the average annual abundance at all monitoring sites rose from 0.3 to 4.7 exuviae per 10 m shoreline. Altogether 48 sites in Brandenburg and 14 in Mecklenburg-Vorpommern were recorded where *L. caudalis* was newly detected from 2004 to 2008. Global warming is assumed as a probable cause for this increase." (Author)] Address: Mauersberger, R., Prenzlauer Allee 66, 17268 Templin, Germany. E-mail: rue.mau@web.de

9111. McLachlan-Troup, T.A.; Dickman, C.R.; Grant, T.R. (2009): Diet and dietary selectivity of the platypus in relation to season, sex and macroinvertebrate assemblages. *Journal of Zoology* 280(3): 237-246. (in English) ["The diet of the platypus *Ornithorhynchus anatinus* was studied by examination of material collected from the cheek pouches of animals captured while foraging in streams in Kangaroo Valley, NSW, Australia. Platypuses consumed benthic invertebrates from 55 families in 16 orders, with virtually no prey being derived from the terrestrial environment. We also sampled invertebrates in pool, riffle and stream edge habitats to identify where prey were obtained. Invertebrates in the diet were most similar to those collected along stream edges and in pools compared with the faster-flowing riffles, suggesting that platypuses focused their foraging activities largely in these deeper water habitats. Although there was no seasonality in the assemblage structure of macroinvertebrates, the diet of platypuses varied between seasons, notably between winter and summer, suggesting that some dietary selectivity is seasonal. Dietary differences between the sexes were not detected. Overall, our results suggest that some dietary selection occurs in the platypus with respect to both foraging habitat and season. Seasonal selectivity may reflect different metabolic demands on platypuses at different times of the year. In contrast, habitat selectivity may reflect difficulty of prey access and risk of prey escape in fast-flowing riffles, higher energy costs and risk of predation associated with exploiting this habitat, and prey avoidance responses that are more rapid in the shallow riffles than in the deeper water pools and stream edges. These alternatives await evaluation by future research." (Authors)] Macroinvertebrate taxa found most frequently in cheek pouch samples from platypuses (n=50 samples)

included Gomphidae with 34 %.] Address: McLachlan-Troup, Tanya, Inst. Wildlife Res., School of Biological Sciences, A08, University of Sydney, Sydney, NSW 2006, Australia. E-mail: mclachlan.troup@gmail.com

9113. Michel, M.J.; Adams, M.M. (2009): Differential effects of structural complexity on predator foraging behavior. *Behavioral Ecology* 20(2): 313-317. (in English) ["The choice of predator foraging mode has important consequences for ecological communities. Foraging mode designations are often made on the basis of predator activity, yet activity can be affected by various environmental stimuli independent of changes in foraging mode. Structural complexity can reduce predator activity by either interfering with predator vision and mobility or as part of a foraging mode shift. We examined the effects of simulated aquatic vegetation on multiple behaviours of 2 aquatic insect predators to distinguish between these 2 possible outcomes. Larvae of the diving water beetle (*Dytiscus* spp.) shifted from an active predator in treatments without structure to a sit-and-pursue (SAP) predator in treatments containing structure, as indicated by a decrease in activity and prey encounter rates and an increase in probability of capture. This trade-off between encounter rates and probability of capture resulted in an equal number of prey captures among the treatments. Dragonfly nymphs (*Anax junius*) remained SAP predators in both treatments, although interference from the simulated vegetation significantly reduced activity. Structure also slightly decreased the number of aeshnid prey captures. Physiological attributes of the predators, such as mode of respiration and method of prey detection, seemed to influence foraging behaviour. This study emphasizes the benefits of measuring multiple predator behaviours when classifying predators to particular foraging modes." 9115. Mühle, L.; Rohe, L.; Flenner, I.; Suhling, F. (2009): Atmungsverhalten von *Orthetrum cancellatum*-Larven: Einfluss der aktuellen Temperatur und der Aufzuchtbedingungen (Odonata: Libellulidae). *Libellula* 28 (1/2): 59-68. (in German, with English summary) ["The intensity of respiration of larval Anisoptera can be determined by observing the frequency of abdominal movements. We used this to study the influence of the current temperature on the larval respiration of *O. cancellatum*. We assumed that (1) the breathing rate of the larvae increases with rising temperature and that (2) the response to the current temperature depends on the rearing conditions. The larvae were kept for nine

months under four different rearing conditions. The egg clutches originated from two countries in different climate zones, from southern France in the Mediterranean area and from northern Germany in the temperate zone. Our experiment revealed that the ventilation rate increased with increasing temperature. This was more pronounced with higher rearing temperatures than the larvae experienced. We interpreted this as a habituation effect. The size of the larvae influenced the ventilation rate as well. On the other hand, the genetic and geographic origin of the larvae had no significant effect." (Authors)] Address: Suhling F., Inst. Geoökologie, TU Braunschweig, Langer Kamp 19c, D-38102 Braunschweig, Germany. E-mail: f.suhling@tu-bs.de

9116. Ohba, S. (2009): Ontogenetic dietary shift in the larvae of *Cybister japonicus* (Coleoptera: Dytiscidae) in Japanese rice fields. *Environmental Entomology* 38(3): 856-860. (in English) ["No quantitative study on the feeding habits of *C. japonicus* larvae has been reported. In this study, field observations and rearing experiments were carried out to show the feeding ecology of *C. japonicus* larvae. Unlike previous commentaries, the first- and second-instar larvae of *C. japonicus* preyed on insects, mainly Odonata nymphs (*Orthetrum* spp. and *Sympetrum* spp.) and *Notonecta triguttata*, irrespective of prey availability, but did not eat vertebrates such as tadpoles and fish in the field. On the contrary, the third-instar larvae fed on both insects and vertebrates. Rearing experiments showed that the number of Odonata nymphs consumed was significantly more than the number of tadpoles consumed by the first and second instars but third-instar larvae ate both the Odonata nymphs and tadpoles in the tadpole-Odonata nymph mixture experiment. The total body lengths of *C. japonicus* new adults in the Odonata nymph and tadpole-Odonata nymph mixture treatments were statistically equal. These results suggested that the first- and second-instar larvae of *C. japonicus* prey mainly on insects and do not eat vertebrate animals (insectivore), whereas the third-instar larvae fed on both insects and vertebrates (generalist)." (Author)] Address: Ohba, S., Dept of Vector Ecology & Environment, Institute of Tropical Medicine, Nagasaki University, Sakamoto, Nagasaki 852-8523, Japan. E-mail: oobug@hotmail.com

9117. Olthoff, M.; Schmidt, E. (2009): Die Libellen (Insecta, Odonata) des Truppenübungsplatzes Haltern-Borkenberge (Kreis Coesfeld und Recklinghausen). *Abhandlungen aus dem Westfälischen Museum für Naturkunde* 71(3): 223-262. (in German, with English summary) ["Between 2004 and 2008, the dragonfly fauna of the Haltern-Borkenberge Training Area, a hilly sand area with little bogs (approx. 1.800 ha) southwest of the city of Münster in the Westphalian Bight, was recorded. Water-filled ruts and two oligotrophic ponds were investigated in the intensively used opened parts of the training area, while two small bogs (Habichtsmoor, Heimingshofmoor) were examined in the woody south of Borkenberge. Two bogs in the north of the training area (Gagelbruch, Suskenbrocksmoor) were examined very intensively, while the little stream Sandbach was only investigated at random. Altogether, 44 species of dragonflies were recorded. Three more species were documented between 1990 and 2002, which sums up to 47 in total, i.e. almost two thirds of the North Rhine-Westphalian species (64% of 73 species). The water-filled ruts that developed from the military training represent important biotopes for pioneer species (*Ischnura pu-*

milio, *Platetrum depressum*). The oligotrophic ponds in the open area accommodate remarkable populations of *Lestes virens* and *Leucorrhinia rubicunda*. The woody bogs in the south of the training area (Habichtsmoor, Heimingshofmoor) are relatively poor in species (21 species), though very important for specific acid water dragonflies (e.g. *Ceriagrion tenellum*, *Somatochlora arctica*, *Leucorrhinia dubia*, *L. rubicunda*). The two bogs in the northern part of the training area are species-rich (30 species in Suskenbrocksmoor, 41 species in Gagelbruch). The low density of acid water dragonflies and the breakdown of species since 2002 (*S. arctica* in both bogs, in addition *Brachytron pratense*, *Coenagrion lunulatum*, *C. hastulatum* in Gagelbruch) can be regarded as an indication of unfavourable water conditions. The stream Sandbach at the northern borderline of the training area is habitat for running-water dragonflies (*Calopteryx splendens*, *C. virgo*, *Gomphus vulgatissimus*). After 1990, a large population of *Orthetrum coerulescens* was discovered in a nutrient-poor ditch in Gagelbruch. Its core population is supposedly located in an outflow of a flooded quarry which was set up in the 1980s. The flooded quarry and the outflow have got mediterranean thermic conditions caused by ground water. All species found in Borkenberge are categorized in ecological groups and discussed in detail." 9118. Oosterhout, M.P. van; van der Velde, G.; Gaigher, I.G. (2009): High altitude mountain streams as a possible refuge habitat for the catfish *Amphilius uranoscopus*. *Environ. Biol. Fish.* 84: 109-120. (in English) ["*Amphilius uranoscopus* is [...] restricted to rivers and streams in east, southern and central Africa. It is likely to be displaced due to both competition and predation by exotic trout and other introduced fish. In high altitude mountain streams it can be the only species occurring, which means that this habitat may act as a refuge for this species. [...] The abiotic environment, population structure, behaviour and feeding biology of *Amphilius uranoscopus* were studied in a small, high-altitude perennial tributary of the Limpopo River in the Soutpansberg mountain range, Limpopo Province, South Africa, during 2005–2006. Here *A. uranoscopus* showed nocturnal behaviour. It used dark hollow crevices in rapids as shelters during the daytime. The rapids are characterized by a high flow rate, high dissolved oxygen content and coarse riverbed substrate consisting mainly of boulders without fallen leaves. In contrast to the adults, juveniles found shelter among the fallen leaves in pools. At night, *A. uranoscopus* moved out of the rapids into the open water of the pools. The main food of *A. uranoscopus* consisted of macroinvertebrates, mainly Trichoptera larvae." (Authors) The diet also includes a few Odonata ('Zygoptera', 'Anisoptera', 'Gomphidae')] Address: Gaigher, I.G., Lajuma Environmental Research Centre, P.O. Box 522, Makhado 0920, South Africa. 9124. Radwell, A.J.; Camp, N.B. (2009): Comparing chemiluminescent and LED light for trapping water mites and aquatic insects. *Southeastern Naturalist* 8(4): 733-738. (in English) ["This research compared the effectiveness of red, yellow, green, and blue chemiluminescent candles and white light from an LED source in capturing water mites and aquatic insects in a macrophyte bed of a small reservoir. We sought to compare the abundance of organisms captured and to determine whether specific taxa showed a preference for certain colours. A total of 2974 organisms in 19 taxa were collected including 7 water mite genera and 12 other invertebrate taxa. The abundance of Hydrachnida (water mites) in the traps was greater than all other taxa combined. The dominant insect taxa collected were Ephemeroptera and Odonata. No statistically significant inter-taxon preferences for colour were found, but overall there was a greater attraction to yellow, green, or white light than to red and blue light. Since white light from the reusable LED source performed as well as yellow or green disposable chemiluminescent candles that are typically used in aquatic traps, submersible LED flashlights could be considered a suitable alternative" (Authors)] Address: Radwell, Andrea, 34 Sunrise Place, Cabot, AR 72023, USA. 9135. Śniegula, S.; Gołąb, M.J. (2009): The dragonflies (Odonata) of peat bog water bodies in the vicinity of Borne Sulinowo (West and South Pomeranian Lakeland District). *Wiad. entomol.* 28(1): 33-41. (in Polish, with English summary) [Poland; "Five localities in the vicinity of the town of Borne Sulinowo, northwestern Poland, were studied in two seasons: 2005 and 2006. The investigated habitats included small dystrophic (sublocality 1a, localities 2 and 3) and eutrophic (sublocality 1b, 4 and 5) forest lakes surrounded by Sphagnum mats. Thirty-six species of dragonflies were recorded at all the localities. Among them there were two species (*Aeshna subarctica* and *Leucorrhinia dubia*) that represented dragonflies restricted to bogs (tyrphobionts), and three species (*A. juncea*, *Somatochlora flavomaculata* and *Sympetrum danae*) that were characteristic of bogs but not confined to them (tyrphophiles). The composition of dragonfly species at locality 1 (fish-free sublocality 1a and fishstocked sublocality 1b) showed that introducing fish into peat-bogs may have drastic effects on dragonflies sensitive to habitat changes. Locality 5 had a very interesting species composition that included the Mediterranean dragonflies *Anax imperator*, *A. parthenope*, and a coexisting numerous population of northern species *L. albifrons*. It must be stressed that four reported dragonflies: *Sympecma paedisca*, *A. subarctica*, *L. albifrons* and *L. pectoralis* are protected by law in Poland and three species are placed on the Polish Red list: *A. juncea*, *A. subarctica* and *L. albifrons*. The data enclosed in this paper confirm that the environs of Borne Sulinowo comprise a large number of valuable aquatic habitats that are important in sustaining the populations of stenotopic dragonflies." 9136. Sonnenburg, F.; Böhm, K.; Haßel, C. (2009): Libellenfauna der Ohligser Heide. *Jber. Naturwiss. Ver. Wuppertal* 61: 101-124. (in German, with English summary) ["The dragonfly fauna of Ohligser Heide (Germany, North Rhine-Westphalia, Solingen) is well known because of field studies conducted by the Biolo-

gische Station Mittlere Wupper and further odonatologists, and based on data analysis of published papers. This enables us to record changes in the dragonfly fauna since 1984 and before. Over the whole period 40 species were recorded in total, 27 of them with established populations and four of them colonizing at least periodically in the study area. The number of established species has been increasing continuously, which is a result of successful re-creation of wetland habitats. Many of the dragonfly species found are regionally rare. Nine species show a more or less high affinity for bog or heath habitats. The study area is of major importance for dragonfly protection not only locally but also on wider scale." 9137. St John, M.A. (2009): The benthic invertebrate community of lakes previously impaired by mining-related acidification near Wawa, Ontario. M.S. Thesis, Graduate Department of Zoology, University of Toronto: VII, 75pp. (in English) ["Iron mining began in Wawa, Ontario in the late 1800s and ceased in 1998. The sintering process of iron pyrite produced sulfur dioxide which led to the acidification of nearby lakes. Benthic macroinvertebrate samples were collected from lakes along a gradient of historical impairment in Wawa to examine the extent to which the benthos of the lakes would separate along the historical impairment gradient. The results show that the lakes are not separated along a gradient of impairment, and acid-intolerant taxa were collected in previously acidified lakes. There was no ameliorative intervention to combat the historical acidification and the observed recovery of water chemistry and benthos is entirely due to natural ecosystem processes. The two sampling methods (littoral kick sampling using a D-net and Hester-Dendy substrates) used to sample the benthos in these lakes can lead to substantial differences in the taxa collected." (Author) Odonata are treated at the genus level.] Address: St John, Margaretha Ann, Graduate Department of Zoology, University of Toronto, Canada

(2009): Recovery of benthic invertebrate communities from acidification in Killarney Park lakes. *Environmental Monitoring and Assessment* 166(1-4): 293-302. (in English) ["Using a reference-condition comparison, recovery of benthic invertebrate communities from acidification was assessed in three lakes in Killarney Wilderness Park approximately 40–60 km from the massive metal smelters in Sudbury, Canada. Test site analyses (TSAs) were used to compare the park lakes to 20 reference lakes near Dorset Ontario, 200 km to the east. An extension of a previous survey (1997–2001) of two sensitive mayfly species (*Stenonema femoratum* and *S. interpunctatum*) was conducted in one of the lakes. TSA results indicate that the three Killarney lakes remain significantly different from reference condition due primarily to higher abundances of a few acid-tolerant families and the presence of some less abundant sensitive families. Colo-

nization rates differ greatly between the two mayfly species presumably because of competition for available habitat. Overall, this study suggests that early colonizers will gain an advantage to out-compete subsequent arrivals, and these competitive interactions will delay the return of communities to reference condition. ... George Lake was found to be the most different from reference, and this is largely because of the presence of Gammaridae, Cordulegastridae, and Glossosomatidae." 9143. van Buskirk, J. (2009): Natural variation in morphology of larval amphibians: Phenotypic plasticity in nature? *Ecological Monographs* 79(4): 681-705. (in English) ["Phenotypic plasticity has been studied intensively in experimental settings but infrequently in nature, and therefore the relevance of experimental findings is poorly known. This is especially true for morphological plasticity in amphibian larvae induced by predators and competitors. This paper describes a seven-year survey of head and tail shape in eight species of anuran and newt larvae in northern Switzerland, involving 6824 individual larvae and 59 ponds. I tested relationships between geometric measures of size and shape and five habitat gradients: pond permanence, cover by forest canopy and aquatic vegetation, and the densities of predators and competitors. Responses to competitors and predators were often similar to those reported in

experiments. High competitor density was associated with small size and a large head in newt larvae, a long or deep head/body in anuran larvae, and a short or shallow tail in newts and some tadpoles. High predator density was correlated with a deep tail fin and tail muscle in many species. In anurans, the change in shape between low- and high-predator ponds in nature closely paralleled the plastic response to nonlethal predators in mesocosm experiments. The survey revealed many previously undescribed relationships between morphology and the other habitat features. Several species had relatively large tails in ponds that were shaded or thickly vegetated. Associations between year-to-year changes in shape and habitat within ponds implicated phenotypic plasticity rather than genetic population divergence, at least in anurans. These results inspire confidence in the relevance of experiments and highlight many new patterns that will merit further study. [...] Common predators were aeshnid dragonfly larvae (*Aeshna cyanea* and *Anax imperator*), larval dytiscid beetles (especially *Dytiscus marginalis* and *Hydaticus* spp.), four species of adult *Triturus* newts, adult backswimmers (Hemiptera: *Notonecta glauca*), and larval libellid and corduliid dragonflies." 9148. Wildermuth, H. (2009): Förderung der Libellenfauna kleiner Moorgräben durch einfache Naturschutzmaßnahmen (Odonata). *Libellula* 28(1/2): 31-48. (in German, with English summary) ["In a nature reserve near Zürich, Switzerland, the overgrown drains with an overall length of 370 m were revitalized in 1.5 ha of recently cleared fenland. In order to promote the odonate fauna and other aquatic organisms, several controllable weirs had been installed successively, thus preventing or protracting desiccation of the drains during hot periods with low or no precipitation. Habitat maintenance by a rotational strategy of clearing the ditches should allow the dragonflies to colonize the water bodies permanently. Extensive monitoring during three years revealed positive results throughout. In total 22 species were recorded, nine of them with regular reproduction. *Orthetrum coerulescens*, *Pyrrhosoma nymphula* and *Coenagrion puella* turned out to be the most abundant species and were found at all sections. *Cordulegaster boltonii* preferred the rare, short stretches with visible running water, and *Somatochlora flavomaculata* colonised sites with stagnant water, submerged vegetation and peat mud. Due to the retention of the water by weirs, the drains never dried up completely, which allowed the larvae to survive during longer lasting hot and dry periods. After clearing of largely overgrown sections in autumn, no emergence of dragonflies was noted in the subsequent season at these sites as the larvae had obviously been eliminated with the excavated material. However, the cleared sections were immediately colonised by reproductively active adults, e.g. by *O. coerulescens*; by the following spring larvae in different stadia were found there, together with other species. The results substantiate the hypothesis that the dragonfly fauna of the small fen ditches was considerably promoted by simple measures of habitat restoration and maintenance." 9149. Wright, I.A.; Burgin, S. (2009): Comparison of sewage and coal-mine wastes on stream macroinvertebrates within an otherwise clean upland catchment, southeastern Australia. *Water Air Soil Pollution* 204:

227-241. (in English) ["Macroinvertebrates have been widely used in freshwater ecosystems as surrogates to assess the impacts of waste discharges and water pollution. However, often interpretations have been made on the impact of one pollutant in the presence of others that may provide an unidentified additive effective or otherwise confound the results. There have been few opportunities to study the impact of pollutants without such potentially confounding effects. We studied macroinvertebrates using a replicated kick sampling technique and identified to the family level to assess and compare the effects of zinc-rich coal-mine waste and organic pollution from treated sewage on an otherwise clean upland stream network within a world heritage area. We used multivariate analysis of macroinvertebrate assemblages from polluted and clean sites to measure and compare the effect of each waste impact to community structure. We also calculated three widely used biotic indices (Ephemeroptera, Plecoptera and Trichoptera (EPT) family richness, family richness, and abundance) and found that the EPT index was the only one to respond to both pollution types. Macroinvertebrate abundance was an important attribute of the study, with each source of pollution having a contrasting effect on total abundance. It also helped us to measure the relative response of families to each pollutant. There was an initial significant modification of macroinvertebrate assemblages below the outflow of each of the pollutants, followed by different degrees of recovery downstream." (Authors) Taxa including Odonata: Aeshnidae and Gomphidae are treated at the family level.] Address: Wright, I.A., College of Health and Science, Univ. of Western Sydney, Locked Bag 1797, South Penrith Distribution Centre, 1797 Sydney, NSW, Australia. 9150. Xiao, T.; Ang, H. (2009): Numerical study of unusual phase relationships and aerodynamic interaction between forewing and hindwing of dragonfly Model. *Acta Aeronautica et Astronautica Sinica* 30(7): 1165-1175. (in Chinese, with English summary) ["Dragonflies have the ability to control the aerodynamic forces for flight by modulating the phase relationship between their forewings and hindwings. In this article, unsteady flows of a dragonfly model in hovering (advance ratio $J = 0$) and in forward flight with medium-speed ($J = 0.3$) are simulated by solving unsteady Navier-Stokes (N2S) equations on dynamic overset unstructured grids. At each advance ratio, 13 phases from 0° to 360° with intervals of 30° each are considered. The variation of aerodynamic force and power with phase as well as the aerodynamic perturbation between the forewing and hindwing are studied. It is found that the period average vertical force and power varies in a "U" shape as a function of the phase. The vertical force generated by the model is enough to balance the weight, and the data for aerodynamic power also agree with the statistical data of real dragonflies. In the wide phase region of 90° to 270° , aerodynamic interaction between the wings is relatively strong and stable. The vertical force and power is relatively small and stay roughly constant. All these results may be useful for explaining the unusual phase relationships between the wings of dragonflies." 9155. Zhao, H.-x.; Zhong, Z. (2009): Research advance in mechanics of dragonfly wings. *Chinese quarterly of mechanics* 30(3): 389-404. (in Chinese, with English summary) ["The study shows that Odonata are supremely versatile, maneuverable fliers in nature because of the special constructions of their wings. The pterostigma and nodus can balance the fore- and hind-wings and eliminate the wings tremor. Four types of wing model are generally used: the conceptual model, physical model, simple analytical model and numerical analysis

model. The first three models are simplified ones, though the numerical model can modify as three dimensional numerical simulation, but ignore the materials composition of the wings. The flight mechanism of dragonfly and the mechanical characteristics of its wings were described, and pointed out that the influence of the unsteady flow must be taken into account when analyzing the flight mechanism of dragonfly. The measuring method of elastic modulus, hardness and bending stiffness of the wings were introduced. It shows that the spanwise EI scales with the cube of span length, whereas the chordwise EI scales with the square of chord length. A prospect of mechanism of dragonfly and its wings was proposed." (Authors)] Address: Zhao, H.-x., School of Aerospace Engineering and Applied Mechanics, Tongji Univ. Shanghai 200092, China

9156. Żurawlew, P. (2009): Occurrence and records of breeding behaviour of Scarlet Dragonfly *Crocothemis erythraea* (Brullé, 1832) (Odonata: Libellulidae) in the Pleszew Poviát (south-eastern Great Poland). *Odonatrix* 5(1): 18-21. (in Polish, with English summary) [In 2007 and 2008, "over 60 study sites were controlled against the occurrence of Odonata. 45 species were recorded within (61,6% of the dragonfly fauna in Poland). *C. erythraea* was recorded at four study sites (all of them were clay excavations): 1) Kwileń (51°59'N, 17°51'E, UTM: XT96), in 2007 - 4 observations 1 male, and in 2008 it was noted during 9 controls: the highest numbers 10 VI - ca. 15 males, 3 VII and 31 VII - each ca. 10 males, additionally, 10 VI a pair in copula was observed, and next, 1 female laying eggs in *Batrachium* sp.; 2) Kowalew (51°53'N, 17°43'E, UTM: XT85), 1 male observed 11 VI 2008; 3) Nowa Wies (51°52'N, 17°46'E, UTM: XT95), 1 male recorded on 18 VI 2008; 4) Lenartowice (51°55'N, 17°48'E, UTM: XT95), 2 males patrolling and territorial noted on 25 VI 2008. In Poland the stable populations of the Scarlet Dragonfly have been found so far in the valley of the Upper Vistula River and in Przemysl Upland. Clay excavations are the environments that play very important role in the existence of many dragonfly species. This refers not only to the Pleszew Poviát but also to the whole south-eastern Great Poland (Wielkopolska)." (Author)] Address: Żurawlew, P., Kwileń 67A, 63-313 Chocz, Poland. E-mail: grusleo@wp.pl

9157. Andrew, R.J. (2010): Mortality during emergence of *Pantala flavescens* Fabricius in central India (Anisoptera: Libellulidae). *Odonatologica* 39(1): 57-62. (in English) ["Mortality during emergence was studied at an open drain in the city of Nagpur (central India). The total mortality rate (MR) was 10.92% (n = 686). Failure to moult (incomplete emergence state, MR = 4.8%) and failure to expand abdomen and harden wings for flight (complete emergence state, MR = 6.12%) were the two major reasons of mortality. The emerging dragonflies failed to moult and were found dead in the following conditions: cuticle of the thorax split and head and thorax of the pharate partly out of the exuviae (MR = 2.04%), head, thorax and wings out but the entire abdomen trapped in the exuviae (MR = 2.76%). After complete moulting some pharates were found floating, dead or completely exhausted in the water body. Some of the dead pharates had a curved telescopic abdomen

and crumpled (MR = 0.44%), or stretched wings (MR = 2.33%), while others exhibited a straight, expanded abdomen and stretched overlapping (MR = 1.75%) or stretched spread wings (MR = 1.60%). Death due to overcrowding and predation was negligible. Statistical analysis revealed that mortality is independent of stage of emergence ($P = 0.25$). (Author)] Address: Andrew, R.J., Dept of Zoology, Hislop College, Civil lines, Nagpur-440 001, India. E-mail: rajuanrew@yahoo.com

9158. Andrew, R.J.; Patankar, N. (2010): The process of moulting during female emergence of the dragonfly *Pantala flavescens* (Fabricius) (Anisoptera: Libellulidae). *Odonatologica* 39(2): 141-148. (in English) ["The chain of events occurring during emergence in *P. flavescens* is described in detail. The moulting process is divided into 3 stages. The larva climbs out of the water a few hours after sunset. If disturbed while climbing, it exhibits thanatosis i.e. death feigning and crab-like side-ways crawling. It stops at a suitable vertical emergent support. Manipulation from vertical to horizontal of this support stops commencement of ecdysis. 1 Stage I starts from the moment the larva finds a suitable site for moulting. Soon, it starts shuddering, quivering and shaking its body in a synchronized pattern. The imago inside the exuviae exerts pressure on the thoracic tergites until the cuticle splits. This stage varies from 8 to 20 min and occupies 16% of the moulting period. 1 During stage II, the head and thorax of the imago emerge out of the split thoracic cuticle. The imago exhibits an antero-posterior humping movement and the body hangs out downwards with folded legs. The half suspended, upturned imago starts 'breathing' heavily. Unfolding of the legs and movements of the packed wings takes place in a characteristic manner. The imago turns upwards, grips the head of the exuviae and jerks out the remaining terminal portion of the abdomen from the exuviae. This stage takes 18 to 35 min and occupies 31% of the moulting time. Pigmentation of the head region is completed during this stage. 1 In stage III, the imago is released from the exuviae, it starts hardening its cuticle and extending the wings. The imago moves a few inches above the exuviae. The abdomen is pale green and curved upwards. The wings expand but are opaque. Simultaneously, pigmentation of the body starts around the thoracic region and the terminal tip of the abdomen. Within 10-14 min the whole body of the imago develops a species-specific teneral pattern of colouration. Meanwhile, the expanding wings unfold and separate out and the teneral adult is ready for flight. This stage takes 40-55 min and occupies 53% of the total moulting period. Observations on incomplete metamorphosis indicate that gravitational force is responsible for uniform wing expansion." (Authors)] Address: Andrew, R.J., Dept of Zoology, Hislop College, Civil lines, Nagpur-440 001, India. E-mail: rajuanrew@yahoo.com

9159. Baker, R.A. (2010): Robert John Tillyard (1881-1937) F.R.S. - an account of his life and legacy with special reference to odonatology. *J. Br. Dragonfly Society* 26(1): 1-9. (in English) ["R. J. Tillyard had a short but remarkable life into which he packed so much scientific work. Trained as a mathematician at Cambridge, he soon left England for Australia to teach at the grammar school in Sydney before embarking on a career in scientific research and then scientific administration in Australia and New Zealand. However his first love was in natural history and in particular dragon-

flies. He published about 180 scientific papers; also five books, his best known being "The Biology of Dragonflies". He was elected a Fellow of the Royal Society in 1925." (Author)] Address: Baker, R.A., Faculty of Biological Sciences, University of Leeds, Leeds LS2 9JT, UK

9160. Bernard, R.; Schmitt, T. (2010): Genetic poverty of an extremely specialized wetland species, *Nehalennia speciosa*: implications for conservation (Odonata: Coenagrionidae). *Bulletin of Entomological Research* 100(4): 405-413. (in English) ["Oligo- and mesotrophic wetlands, such as bogs, fens and swamps, have become more and more restricted in Europe, and wetland species related to them have increasingly been threatened. Due to increasing habitat fragmentation, the exchange of individuals of these species among sites and, as a consequence, gene flow has been reduced or even eliminated. Therefore, we analysed the genetic structure of 11 populations of an endangered stenotopic damselfly, *Nehalennia speciosa* (Odonata: Coenagrionidae), in Poland and Lithuania by means of allozyme electrophoresis of 14 gene loci. The overall genetic diversity of all populations was low (A: 1.32; H: 2.6%; Ptot: 29.2%), and no significant differences were observed among the different groupings of populations (degree of fragmentation, habitat type and size, population size). The genetic differentiation among populations was also low (FST: 2.0%) and no regional groups were detected. A low degree of isolation by distance was observed for genetic distances. Taking into account these results, the conservation effort for this species should be focused on large local populations and not necessarily on metapopulation structures. Furthermore, *N. speciosa* could be (re-)introduced in extinct patches and seemingly suitable localities. Genetically, such relocations should be feasible due to the generally high genetic homogeneity of populations." (Authors)] Address: Bernard, R., Dept of General Zoology, Adam Mickiewicz University, Umultowska 89, PL-61-702 Poznań, Poland; E-mail: rbernard@main.amu.edu.pl

9161. Bernard, R.; Daraž, B. (2010): Relict occurrence of East Palaearctic dragonflies in northern European Russia, with first records of *Coenagrion glaciale* in Europe (Odonata: Coenagrionidae). *International Journal of Odonatology* 13(1): 39-62, pl. 1. (in English) ["The East Palaearctic *C. glaciale* and *C. hylas* are characterized by a current disjunct distribution. New data from northern European Russia significantly modify the earlier known pattern of their distribution. The first European records of *C. glaciale* and a new record of *C. hylas* west of the Urals are reported from the environs of Pinega village (Arkhangelsk oblast, Pinega region). Distribution ranges of these two species are analysed in light of their palaeogeography. These postglacial relicts in Europe are representatives of a cold-stenothermal fauna that probably colonized the continent during the late Pleistocene and early Holocene in the period of the maximum spread of birch and pine. During the Atlantic period they withdrew far to the East remaining probably only as isolates in the Urals and in Europe. However, the new records suggest that the European remains of the early Holocene distribution may be more numerous and extensive than previously believed and are concentrated especially in the almost unexplored northeast. The survival of *C. glaciale* and *C. hylas* in the presumptive isolate of their distribution range in the Pinega region is probably a consequence of a specific combination of severe climate and habitat and microclimatic

conditions, largely influenced by karst. The habitat conditions at 'Pinega' localities are analysed in the context of the species' requirements. Additionally, biogeographically important findings of the North and Central Asian *Aeshna serrata* are recorded. This species was previously assumed to occur in Europe only as an isolate around the Baltic Sea, but the new records suggest that it has a much more extensive but fragmented distribution in the European north and northeast." (Authors)] Address: Bernard, R., Dept General Zool., Adam Mickiewicz University, Umultowska 89, PL-61-702 Poznań, Poland; E-mail: rbernard@main.amu.edu.pl

9162. Bernard, R.; Kosterin, O.E. (2010): Biogeographical and ecological description of the odonata of eastern Vasyugan Plain, west Siberia, Russia. *Odonatologica* 39(1): 1-28. (in English) ["Results of the studies of odonate fauna, carried out in July 2006 in the odonatologically almost unexplored Vasyugan Plain, are presented. The studies concentrated in the northern and northeastern parts of the largest bog in the world, the Vasyugan Bog, and its surroundings. Large primeval complexes of Sphagnum bogs and fens and other accompanying habitats, man-made as well, were studied. 25 localities are briefly described and the occurrence of 35 recorded spp. is commented. Due to almost total absence of typically East Palaearctic species (only *Shaogomphus postocularis* found), the aspect of the Odonata fauna in the studied area is similar to a certain degree to that known from central and eastern Europe, but with some differences in the species composition, abundance of many species and their habitat preferences. In *Coenagrion puella*, *C. pulchellum*, *Enallagma risi*, *Nehalennia speciosa*, *Gomphus vulgatissimus*, *Shaogomphus postocularis*, *Somatochlora flavomaculata*, *Leucorrhinia albifrons*, and *L. pectoralis*, the northern limit of their distribution appears further N than it was previously known. This suggests that the actual northern range limit of some of these species in W Siberia does not descend as sharply to the S as it was expected. The first known site of *S. postocularis* W of the Ob' river and on a perfect plain is also worth noticing. Among the most remarkable discoveries was the regular, area-wide occurrence of several previously poorly known in Siberia species, such as *N. speciosa*, *Aeshna subarctica*, *G. vulgatissimus* and *S. flavomaculata*. Taxonomically interesting is the coexistence, in the studied area but not at the same localities, of two taxa considered as subspecies or separate species, *E. c. cyathigerum* and *E. (c.?) risi*. The fact of clear spatial separation and at most a minimum degree of intergrading (if any) of these 2 taxa suggests their full species status which would agree with morphological and recent molecular data. The regular and not rare presence of 2 androchrome *Calopteryx splendens* / forms and females with the wings coloured to the tips, as well as the occurrence of brownish wing 'smoking' of many / *S. flavomaculata* and *S. arctica* are peculiar features of the Vasyugan Odonata aspect. The male segregation in the 'triangle' of peat bog aeshnids, *Aeshna crenata*, *A. juncea* and *A. subarctica*, is described and discussed. Between *A. juncea* and *A. subarctica* it was very advanced, partially spatial and partially weather/temporal, between *A. crenata* and *A. subarctica* almost complete, spatial, and between *A. crenata* and *A. juncea* advanced, weather/temporal. These observations confirm the dominant position of *A. crenata* over the water table, and also suggest the lack of *crenata*-dominance off the water table. The reliability of adult diagnostic features, more

and less commonly used to distinguish between *A. subarctica* and *A. juncea*, is discussed." (Authors)] Address: Kosterin, O.E., Institute of Cytology & Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. E-mail: kosterin@bionet.nsc.ru

9163. Brodman, R.; Newman, W.D.; Laurie, K.; Osterfeld, S.; Lenzo, N. (2010): Interaction of an aquatic herbicide and predatory salamander density on wetland communities. *Journal of Herpetology* 44(1): 69-82 (in English) ["Pesticides can be important conservation tool, but they could have unintended impacts on amphibians. The commercial glyphosate-based herbicide Accord is approved for use in wetlands and ponds because it is designed to be safer to aquatic wildlife than other herbicide formulations (e.g., Roundup or Atrazine); however, field experiments are needed to determine whether there are direct, indirect, or sublethal effects on amphibians or effects on wetland community structure. We conducted a replicated field experiment in constructed ponds to test for both the effects of Accord and predator (Tiger Salamanders, *Ambystoma tigrinum*) density on amphibians and aquatic invertebrates. Herbicide treatment had significant density-dependent effects on Tiger Salamander growth, development, and survival. The survival of anurans and aquatic invertebrates was also affected by herbicide treatment and predator density. At certain Tiger Salamander densities, the community structure was altered such that some species became more common with herbicide treatment, whereas others became less common. Behaviour assays of salamander larvae suggest that herbicide treatment alters predator-prey relationships in the experimental pond communities. These results suggest that competition and predation may mediate indirect effects of this herbicide on the aquatic fauna. We conclude that exposure to Accord poses less of a risk to the ecology of amphibians than do other formulations of glyphosate-based herbicides. ... The abundance of benthic worms (*Turbellaria* and *Oligochaeta*) and pelagic insects (*Anisoptera*, *Zygoptera*, *Corixidae*, *Notonectidae*, *Belostomatidae*, *Gyrinidae*, *Dytiscidae*, *Chaoboridae*) were not significantly affected by herbicide treatment. ... Tiger Salamander larvae from herbicide treated ponds ate significantly fewer chironomid midges and *Bufo* tadpoles but significantly more damselflies than larvae from control ponds." 9164. Bwong, B.A.; Measey, G.J. (2010): Diet composition of *Xenopus borealis* in Taita Hills: effects of habitat and predator size. *African Journal of Ecology* 48(2): 299-303. (in English, with French summary) [Kenya; "Frogs in the genus *Xenopus* are ubiquitous in sub-Saharan Africa, yet very little is recorded on their ecology. They are commonly found in anthropogenically disturbed habitats, but how do these compare to conspecifics from natural habitats? The diet of *Xenopus borealis* from three different sites in Taita Hills, Kenya was established based on a sample of 77 (54 females and 23 males) specimens from two disturbed and one pristine sites. *Xenopus borealis* from all the sites was found to be a dietary generalist, feeding predominantly on invertebrates. A total of twelve invertebrate orders both terrestrial and aquatic were recorded in addition to amphibian eggs, tadpoles and fish. Frogs from the

pristine forest were smaller and had ingested more terrestrial prey items than frogs in the disturbed open habitat ponds. The stomach content (both by mass and quantity) was independent of body size. The results suggest that *X. borealis* is an opportunistic generalist predator which may be constrained by food availability in its natural habitat. However, disturbed habitats provide abundant food items which are enough to significantly increase the mean size of the population." (Authors) Odonata were recorded from all three habitats sampled.] Address: Bwong, B.A., Herpetology Section, National Museums of Kenya, PO Box 40658-00100, Nairobi, Kenya: E-mail: bebwong@yahoo.com

9165. Catarino, M.F.; Zuanon, J. (2010): Feeding ecology of the leaf fish *Monocirrhus polyacanthus* (Perciformes: Polycentridae) in a terra firme stream in the Brazilian Amazon. *Neotropical Ichthyology* 8(1): 183-186. (in English, with Portuguese summary) ["*M. polyacanthus* is a remarkable leaf-mimicking fish that inhabits streams, lake and river margins along the Amazon basin. Despite its obvious predatory habits and being frequently present in the international aquarium trade, little is known about its diet under natural conditions. We examined 35 specimens of leaf fish (28.5-82.0 mm SL), of which 19 had food the stomach. Thirty-three preys were found in the stomach contents, 19 of which were measured (2.0-33.0 mm total length). Up to five preys were found in the stomach contents of a single leaf fish specimen. The diet of the leaf fish was constituted by fish (63.15% FO, n = 12) and invertebrates (36.3% FO, n = 4); fish and invertebrate preys occurred together in three stomachs (15.8% FO). Of the 33 prey found in the stomachs, 21 were fish and 12 invertebrates. Among the consumed preyfishes, Characiformes and Perciformes represented 76.1% and 14.2% respectively. Characidae was the most commonly recorded prey family, followed by Lebiasinidae. Invertebrates were represented by shrimps (Decapoda) and insects (Coleoptera, Hymenoptera, Ephemeroptera and Odonata). There was a positive relation between the size of the leaf fish specimens and of its consumed preys. The combination of leaf fish's visually effective body camouflage and the reduced activity of the characids at crepuscular hours probably allow the capture of such fast moving preys. The coiled position of the fishes found in the stomach of *M. polyacanthus* possibly allowed the accommodation of more than one prey simultaneously, which seems to be important for predators that consume proportionally large preys that are captured only occasionally." Dragonfly Society* 26(1): 10-28. (in English) ["The identification of exuviae of the *C. pulchellum* can be determined in the majority

of cases by examination of the caudal lamellae and the setae on the prementum. These can however, be highly variable and some specimens are similar to *C. puella* and pose difficulties for separation. A combination of characters when used in a score matrix will aid identification of borderline specimens." (Author)] Address: Cham, S., 24 Bedford Avenue. Silsoe, Bedfordshire, MK45 4ER, UK

9168. Choong, C.Y.; Orr, A.G. (2010): The larva of *Podolestes orientalis* from West Malaysia, with notes on its habitat and biology (Odonata: Megapodagrionidae). *International Journal of Odonatology* 13(1): 109-117, pl. IV. (in English) ["The larva of the south-east Asian *P. orientalis*, is described and figured. Specimens were collected from shallow forest pools lined with large dead leaves in secondary lowland forest. Final and earlier stadium larvae were found concentrated around the edges of pools in very shallow water. Larvae sometimes perched in exposed situations, just below the water surface, with abdomen upturned and caudal lamellae splayed outward to expose the broad respiratory surfaces. This represents the first account of the immature stages for this south-east Asian genus. The caudal lamellae are very broad and flattened, inserted horizontally, suggesting a close relationship between the genus *Podolestes* and Australian region megapodagrionids." 9171. Covaciu-Marcov, S.D.; Cicirt-Lucaciu, A.; Mitrea, I.; Sas, I.; Caus, A.V.; Cupsa, D. (2010): Feeding of three syntopic newt species (*Triturus cristatus*, *Mesotriton alpestris* and *Lissotriton vulgaris*) from Western Romania. *North-Western Journal of Zoology* 6(1): 95-108. (in English) ["The feeding of three newt species from western Romania is different in the aquatic period regarding both the composition and the time needed. Thus, *Mesotriton alpestris* spends shorter time in the water compared to *Triturus cristatus* and *Lissotriton vulgaris*, having the weakest feeding habit in this environment. This is probably a consequence of its relationship with mountainous and harsher climate areas that

shortens its aquatic environment period, which also affects the species in a lower altitude habitat. The difference in the food of the three species results from their different sizes and hunting territories. *L. vulgaris* mainly hunts near puddle banks, in areas with lower and warmer water and the other two species hunt near the bottom, in the deeper areas. The crested newts have the longest aquatic period and the highest affiliation for hunting in this habitat. This species consumes larger sized preys while the common newts consume numerous reduced sized preys, having an intensive feeding and high food diversity. Meanwhile, differences between the food ingested by male and female individuals are not significant in any newt species." (Authors) Odonata don't play an important role as food of nets.] Address: Covaciu-Marcov, S.D., University of Oradea, Faculty of Sciences, Department of Biology, 1 Universitatii str., Oradea - 410387, Romania. 9173. De Knijf, G.; Termaat, T. (2010): *Sympetum meridionale* in Belgium and The Netherlands. Identification, distribution and status in North-western Europe. *Brachytron* 13(1/2): 4-18. (in Dutch, with English summary) ["Since 2000 sightings of *S. meridionale* have become frequent in Belgium and The Netherlands. First records came from Belgium, soon followed by observations in The Netherlands. *S. meridionale* is difficult to identify among other *Sympetum* species. notable *S. striolatum* and *S. vulgatum* with which it often co-occurs. *S. meridionale* shows a lot of variation in coloration depending on age and sex. In general it can be distinguished by the paucity of black markings. Fully coloured imagines can be recognised by their rather pale coloration. It is advisable that several characters are checked for correct identification. In the 19th century, the species was only observed once in The Netherlands (Friesland). More records are available from Belgium, mostly from Selys, but its former status remains unclear. It is plausible that the species could reproduce then, but only sporadically and not over a longer time period. Records from the 20th century are very scarce. There is one observation in 1906 in a large peat bog area at 700 m altitude in Belgium and one in The Netherlands in 1994. Since 2000, 26 records are available from 15 localities in Belgium, nearly all from the northern part. *S. meridionale* could reproduce successfully at least on three localities: in 2000 in Harchies (Henegouwen), in 2003 in Kallo (port of Antwerp) and in 2006 and 2007 in Ekeren (north of Antwerp). Only two records are available from the Netherlands for the period 2000-2005. Since 2006 the species has been observed at no less than 35 localities. At one locality (Vooroes Duin, Zuid-Holland) it was able to reproduce from 2006 to 2008. This recent increase in records has also been noted in several other regions or countries in North-western Europe. For the French regions Picardie and Nord-Pas-de-Calais, no records from before 2000 are available. Since then, several records are known. *S. meridionale* could reproduce en masse at water reservoirs in the region Champagne-Ardenne. No populations are present in the Lorraine region, but the species

has been noted at several localities, especially in the valley of the Moselle. The only record for Luxembourg is from 1993 and also originated from this river valley. The last records in the UK already date back from 1948, when the species was noted on the Channel Islands. This might reflect a lack of experience of English odonatologists with the species. In Germany, the species has always been limited to Baden-Württemberg and Bavaria. In more northern regions like North Rhine-Westphalia, the species was first observed in 2000. It has been observed since 2006 in most of the German federal states and reproduction has been recorded at several localities. We suppose that the recent increase of records of *S. meridionale* in Belgium and The Netherlands is primarily due to climate change. As so, it follows the recent increase of several other southern species, like *Crocothemis erythraea*, in Northern Europe. Specimens of *S. meridionale* have been observed in Belgium and The Netherlands at a broad spectrum of habitats, ranging from heathlands to forest edges, peat bogs, dune waters and garden ponds. All localities where reproduction could be observed can be characterised by the presence of relatively small, shallow and very thermophilic water bodies, which partly dry out in summer. Well developed emergent vegetation is present at the shore. Imagines of *S. meridionale* can be observed in Belgium and The Netherlands from mid June to early September. The species has only one generation per year in Belgium and the Netherlands." (Authors)] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. 9176. Dudgeon, D.; Cheung, F.K.W.; Mantel, S.K. (2010): Foodweb structure in small streams: do we need different models for the tropics?. *J. N. Am. Benthol. Soc.* 29(2): 395-412. (in English) ["Prevailing notions of foodweb structure and trophic relations in fresh waters are based on research undertaken in a limited range of latitudes or habitat types. This limitation had led to the general view that stream food webs are detritus-based with short food chains and simple interactions that often are dominated by a few key species. We used gut-content analyses and stable-isotope signatures to characterize feeding relationships and foodweb attributes of benthic communities in riffles in 2 forest streams in Hong Kong. We compared them with existing data on foodweb structure from pools in 1 of the streams and data from the literature. The 2 approaches to dietary analyses yielded complementary results,

providing confidence that trophic relations and foodweb structure were adequately characterized. Food webs in both streams were remarkably similar regardless of habitat (riffle vs pool). Consumers in both streams depended primarily on autochthonous resources, as has been reported from some other tropical streams, and food chains were short although connectance was higher than has been recorded previously for stream food webs. Very few omnivores were found, and omnivory was even rarer than is typical of temperate streams, although it is common in other tropical streams and rivers. No evidence was found for dominance by a few common macroconsumer species, as observed elsewhere in the tropics. The apparently high levels of autochthony in tropical running waters imply that models of ecosystem functioning for northern temperate streams are inadequate for describing tropical systems. However, marked differences in the degree of omnivory and dominance of tropical stream food webs by macroconsumers is evidence that characterization of trophic interactions and stream ecosystem functioning cannot be captured by a simple tropical vs temperate dichotomy. Successful management of these systems will depend upon development of conceptual models that reflect the diversity of food webs within and between regions." (Authors) A single odonate, *Euphaea decorata* (Euphaeidae), was well represented in significant numbers in samples from both streams (Appendix 1).] Address: Dudgeon, D., School Biological Sciences, Division of Ecology & Biodiversity, University of Hong Kong, Hong Kong. 9177. Felix, Z.I.; Wang, Y.; Schweitzer, C.J. (2010): Effects of experimental canopy manipulation on amphibian egg deposition. *Journal of Wildlife Management* 74(3): 496-503. (in English) ["Although effects of forest management on amphibians are relatively well studied, few studies have examined how these practices affect egg deposition by adults, which can impact population recruitment. We quantified the effects of 4 canopy tree-retention treatments on amphibian oviposition patterns in clusters of 60-L aquatic mesocosms located in each treatment. We also related aquatic and terrestrial biophysical parameters in treatment plots to oviposition patterns. Cope's gray treefrogs (*Hyla chrysoscelis*) deposited more egg masses in clear-cut and 25–50% tree-retention treatments than in controls. In contrast, mountain chorus frogs (*Pseudacris brachyphona*) deposited more egg masses in unharvested control and 75% retention treatments than in clear-cut or 25–50% retention treatments. Spotted salamanders (*Ambystoma maculatum*) only deposited eggs in 75% retention treatments and controls. The number of egg masses deposited by mountain chorus frogs was positively related to canopy cover and negatively related to water temperature, pH, and dissolved oxygen, whereas we noted the opposite relationships for Cope's gray treefrogs. We did not detect a relationship between the number of egg masses deposited by any species and the distance of mesocosms to either the nearest mature closed-canopy forest or to the nearest natural amphibian breeding pool. The impacts of the silvicultural treatments we studied were species-specific and depended on the amount of trees removed. In areas where protection of spotted salamander and mountain chorus frog breeding habitat is a priority, we recommend harvests retain at least 75% of the canopy. Our results also suggest that retention of 25–50% of canopy trees surrounding amphibian breeding pools has little conservation benefit.

[...] We observed larval dragonflies at least once in 17% of 25–50% and 75% retention treatment arrays, and in 33% of clear-cut arrays. Other studies have reported increased prevalence of dragonflies in open- versus closed-canopy pools (McCauley 2005, Hocking and Semlitsch 2008). Increased abundance of larval dragonflies in clear-cuts compared to mature forest habitats had little effect on survival of gray treefrog tadpoles in Missouri (Hocking and Semlitsch 2008). It is unlikely that higher prevalence of dragonfly larvae in open-canopy treatments affected mountain chorus frog and spotted salamander oviposition because these amphibian species breed prior to dragonflies and we dewatered all pools between years." 9178. Ferland-Raymond, B.; March, R.E.; Metcalfe, C.D.; Murray, D.L. (2010): Prey detection of aquatic predators: Assessing the identity of chemical cues eliciting prey behavioral plasticity. *Biochemical Systematics and Ecology* 38(2): 169-177. (in English) ["Chemical cues transmitted through the environment are thought to underlie many prey responses to predation risk, but despite the known ecological and evolutionary significance of such cues, their basic composition are poorly understood. Using anuran tadpoles (prey) and dragonfly larvae (predators), we identified chemical cues associated with predation risk via solid phase extraction and mass spectrometry of the extracts. We found that dragonfly larvae predators consistently produced a negative ion, m/z 501.3, when they fed on bullfrog (*Rana catesbeiana*) and mink frog (*Rana septentrionalis*) tadpoles, but this ion was absent when dragonflies were fasted or fed invertebrate prey. When tadpole behavioral responses to dragonfly chemical cues were examined, tadpoles reduced their activity, particularly in response to dragonflies feeding on tadpoles. Furthermore, a negative correlation was noted between the level of tadpole activity and the concentration of the m/z 501.3 compound in dragonfly feeding trials, indicating that this ion was possibly responsible for tadpole anti-predator behaviour." 9180. Fraker, M.E.; Hu, F.; Cuddapah, V.; McCollum, A.; Relyea, R.A. (2010): Characterization of an alarm pheromone secreted by amphibian tadpoles that induces behavioral inhibition and suppression of the neuroendocrine stress axis. *Hormones and Behavior* 55(4): 520-529. (in English) ["Many species assess predation risk through chemical cues, but the tissue source, chemical nature, and mechanisms of production or action of these cues are often unknown. Amphibian tadpoles show rapid and sustained behavioral inhibition when exposed to chemical cues of predation. Here we show that an alarm pheromone is produced by rapid tadpole skin cells, is released into the medium via an active secretory process upon predator attack (*Anax junius*), and signals predator presence to conspecifics. The pheromone is composed of two components with distinct biophysical properties that must be combined to elicit the behavioural response. In addition to the behavioural response, exposure to the alarm pheromone caused rapid and strong suppression of the hypothalamo-pituitary-adrenal (HPA) axis, as evidenced by a time and dose-dependent decrease in whole body corticosterone content. Reversing the decline in endogenous corticosterone caused by exposure to the alarm pheromone through addition of corticosterone to the aquarium water (50 nM) partially blocked the anti-predator behaviour, suggesting that the suppression of the HPA axis promotes the expression and maintenance

ce of a behaviorally quiescent state. To our knowledge this is the first evidence for aquatic vertebrate prey actively secreting an alarm pheromone in response to predator attack. We also provide a neuroendocrine mechanism by which the behavioural inhibition caused by exposure to the alarm pheromone is maintained until the threat subsides." 9181. Giannatos, G.; Karypidou, A.; Legakis, A.; Polymeni, R. (2010): Golden jackal (*Canis aureus* L.) diet in Southern Greece. *Mammalian Biology - Zeitschrift für Säugetierkunde* 75(3): 227-232. (in English) ["The diet of jackals was studied in the Mediterranean lowlands of Fokida and Samos island, Greece, by analyzing 127 scats collected between January 2002 and May 2003. Across all seasons frequencies of food items show that the most common items were mammals (frequency 42.7%, biomass 69.8%) and birds (12.0%, biomass 27.7%). Although the frequencies of plant material (27.3%) and insects (18.0%) were quite high, their biomass contribution was low (1.7%, 0.8% respectively). Most of the biomass consumed composed of mammals of domestic livestock origin (55.9%) which were presumably scavenged. This reveals the importance of this food item to the opportunistic jackals in wildlife-poor ecosystems like the anthropogenic Mediterranean lowlands. The occurrence of small mammals in the scats was very low while very few traces of grass and human refuse (such as leftovers of meals, plastic, pieces of paper etc.) were found in the diet of jackals. Furthermore, the findings support the opportunistic nature of a species capable to exploit any easily available food source." (Authors) 3 items from a total of 45 insects represent Odonata.] Address: Giannatos, G., Section of Zoology – Marine Biology, Department of Biology, University of Athens, Panepistimioupolis GR-15784, Athens, Greece. 9185. Hassall, C.; Lowe, C.D.; Harvey, I.F.; Watts, P.C.; Thompson, D.J. (2010): Phenology determines seasonal variation in ectoparasite loads in a natural insect population. *Ecological Entomology* 35(4): 514-522. (in English) ["1. The extent to which individuals are parasitised is a function of exposure to parasites and the immune response, which in ectotherms may be associated with temperature. 2. We test the hypothesis that seasonal variation in ectoparasite burden is driven by temperature using an extensive mark-release-recapture study of adult *Coenagrion puella* as a model system. Mite counts were taken both at capture and on a subset of subsequent recaptures over two entire, consecutive breeding seasons. 3. Emergence date was the most significant factor in determining individual differences in mite burden, and mean counts for individuals emerging on the same days showed strong unimodal relationships with time of season. Subsequent recounting of mites on a subset of individuals showed that patterns of loss of mites were similar between seasons. 4. While temperature did not significantly affect mite burdens within seasons and ectoparasite prevalence was very similar across the two seasons, intensity of infection and rate of mite gain in unparasitised individuals were significantly higher in the cooler season. 5. We demonstrate that, while temperature may modulate the invertebrate immune response, this modulation does not manifest in variations in mite burdens in natural populations." 9186. Holuša, O.; Holuša, J. (2010): "Accompanying" behaviour of *Brachythemis leucosticta* (Burmeister in Europe (Anisoptera: Libellulidae). *Odonatologica* 39(1): 63-70. (in English) ["At a location in southern Spain (nr Vejer de la Frontera, Rio Barbate valley, Andalusia), observations were made on a local population of ca 40 *B. leucosticta* individuals, a species known for its inclination to accompany large mammals (the test subject was a human). The goal of the tests was to ascertain how far they are willing to accompany a large mammal, whether the size of the group has an influence on the distance for accompanying the subject and whether the accompaniment differs between sexes. Accompanying a person was recorded in 53 cases, involving 41 male and 83 female dragonflies. They generally flew at a height of 10-50 cm above the ground in front of the moving person, distributed in a semicircle with a radius of 1-2 m (the maximum observed group size was 11 dragonflies). Group size did not influence

the flight range of the last individual or the detachment of the first individual from the group, as the dragonflies broke away at random. The average distance of accompaniment by females (38.4 m) was further than that by males (23.9 m). The maximum path of accompaniment was 89 m for males and 111 m for females. After detaching from the person, the dragonflies returned to the shade. Only rarely did females settle on open pasture, and then just for a brief period. In 3 cases (i.e. 1.6%), hunting of prey stirred up from the pasture by the person was observed." (Authors) According Dijkstra & Matushkina (2009): Kindred spirits: "Brachythemis leucosticta", Africa's most familiar dragonfly, consists of two species (Odonata: Libellulidae). International Journal of Odonatology 12(2): 237-256 the behaviour described should correspond to *B. impartita*.] Address: Holuša, J., Department of Forest Protection and Game Management, Faculty of Forestry and Wood Sciences, Czech University of Life Sciences, Kamyčká 1176, CZ-16521 Prague 6-Suchbát, Czech Republic. 9187. Hossie, T.J.; Murray, D.L. (2010): You can't run but you can hide: refuge use in frog tadpoles elicits density-dependent predation by dragonfly larvae. *Oecologia* 163(2): 395-404. (in English) ["The potential role of prey refuges in stabilizing predator-prey interactions is of longstanding interest to ecologists, but mechanisms underlying a sigmoidal predator functional response remain to be fully elucidated. Authors have disagreed on whether the stabilizing effect of prey refuges is driven by prey- versus predator-centric mechanisms, but to date few studies have married predator and prey behavioural observations to distinguish between these possibilities. We used a dragonfly [*Anax junius*] nymph-tadpole system to study the effect of a structural refuge (leaf litter) on the predator's functional response, and paired this with behavioural observations of both predator and prey. Our study confirmed that hyperbolic (type II) functional responses were characteristic of foraging predators when structural cover was low or absent, whereas the functional response was sigmoidal (type III) when prey were provided with sufficient refuge. Prey activity and refuge use were density independent across cover treatments, thereby eliminating a prey-centric mechanism as being the genesis for density-dependent predation. In contrast, the predator's pursuit length, capture success, and handling time were altered by the amount of structure implying that observed shifts in density-dependent predation likely were related to predator hunting efficiency. Our study advances current theory by revealing that despite fixed-proportion refuge use by prey, presence of a prey refuge can induce density-dependent predation through its effect on predator hunting strategy. Ultimately, responses of predator foraging decisions in response to changes in prey availability and search efficiency may be more important in producing density-dependent predation than the form of prey refuge use." (Authors)] Address: Hossie, T.J., Environmental & Life Sciences Graduate Program and Department of Biology, Trent University, 1600 West Bank Dr., Peterborough, ON, K9J 7B8, Canada. 9190. Johansson, F.; Sniegula, S.; Brodin, T. (2010): Emergence patterns and latitudinal adaptations in development time of Odonata in north Sweden and Poland. *Odonatologica* 39(2): 97-106. (in English) ["Using exuviae, data are presented on emergence dates of dragonflies from northern Sweden and northwestern Poland. The 17 species sampled in Sweden showed considerable overlap in emergence periods. In Sweden, *Leucorrhinia rubicunda* was the first species to emerge (May 31) and *Sympetrum danae* the last (July 19). A comparison of first dates of emergence of species in Sweden and Poland showed a difference between 9 and 30 days, with all Polish species emerging first. Compared to spring species, summer species and obligate univoltine summer species showed less difference in first date of emergence between Swedish and Polish populations. In a laboratory experiment *Leucorrhinia dubia* was reared from both regions from the egg to final instar larva under northern Swedish and northwestern Polish photoperiods. Swedish larvae developed faster under a northern Swedish photoperiod compared to a northwestern Polish photoperiod. However, no such difference in development was found for northwestern Polish larvae. This suggests that there are genetic differences between both populations in response to photoperiod. The results are discussed in the context of compensation of larval development of northern populations in relation to photoperiod." (Authors)] Address: Johansson, F., Dept of Ecology & Environmental Science, Animal Ecology Group, Umea University, 90187 Umea, Sweden. E-mail: frank.johansson@eg.umu.se

9191. Jovic, M.; Gligorovic, B.; Stankovic, M. (2010): Review of faunistical data on Odonata in Bosnia & Herzegovina. *Acta entomologica serbica* 15(1): 7-27. (in English, with Serbian summary) ["This paper deals with faunistical data and taxonomic notes on Odonata in Bosnia and Herzegovina. A database containing all available published, previously unpublished, and new data was made in order to create a review of the current knowledge of the country's Odonata fauna and point out the priorities in future investigations. 57 Odonata species are listed as resident species in Bosnia and Herzegovina. Of that number, exact data on the occurrence of 6 species (*Lestes parvidens*, *L. macrostigma*, *Erythromma viridulum*, *Aeshna grandis*, *Lindenia tetraphylla* and *Somatochlora flavomaculata*) are presented and discussed here for the first time." 9194. Kalkman, V.J.; Boudot, J.-P.; Bernard, R.; Conze, K.J.; De Knijf, G.; Dyatlova, E.; Ferreira, S.; Jovic, M.; Ott, J.; Riservato, E.; Sahlén, G. (2010): European Red List of Dragonflies. Luxembourg: Publications Office of the European Union. ISBN 978-92-79-14153-9: vii + 28pp. (in English) ["Aim: The European Red List is a review of the conservation status of ca. 6,000 European species (dragonflies, butterflies, freshwater fishes, reptiles, amphibians, mammals and selected groups of beetles, molluscs, and vascular plants) according to the IUCN regional Red Listing guidelines. It identifies species that are threatened by extinction at the regional level – so that appropriate conservation action can be taken to improve their status. This Red List publication summarises the results concerning the European dragonflies. Scope: All dragonfly species native to Europe are included, except those confined to northern Caucasus. The geographic scope is continent-wide, extending from Iceland in the west to the Urals in the east, and from Franz Josef Land in the north to the Mediterranean and the Canary Islands in the south. The Caucasian region is not included. Red List assessments were made at two regional levels: for geographical Europe, and for the 27 current Member States of the European Union. Status assessment: The status of all species was assessed using the IUCN Red List Criteria (IUCN 2001). This is the world's most widely accepted system for measuring extinction risk. All assessments followed the Guidelines for Application of IUCN Red List Criteria at Regional Levels (IUCN 2003). Preliminary regional assessments were made by Jean-Pierre Boudot and Vincent Kalkman. These assessments were then evaluated by Rafal Bernard, Klaus-Jürgen Conze, Geert De Knijf, Elena Dyatlova, Sónia Ferreira, Miloš Jovic, Jürgen Ott, Elisa Riservato and Göran Sahlén during a

workshop held in Faro, Portugal and through correspondence with relevant experts. The assessments are available on the European Red List website and internet platform: <http://ec.europa.eu/environment/nature/conservation/species/redlist> and <http://www.iucnredlist.org/europe>. Dragonflies in Europe: Dragonflies are colourful, relatively large, and well-known insects. Their larvae live in freshwater habitats such as lakes, bogs, seepages, rivers and springs. Dragonflies occur almost everywhere in Europe, but the highest species diversity is found in the southern half, with the highest numbers in parts of southern France, the footland of the Alps and parts of the Balkan Peninsula. Europe holds 138 species, only three of which are not found in the 27 member states of the EU. Five species were regarded as Not Applicable, as they have no stable populations in Europe. Two species (*Cordulegaster helladica* and *Onychogomphus forcipatus*) have three subspecies each, the taxonomy and distribution of which are sufficiently well-known to make them eligible for an assessment. Thus, a total of 137 species and subspecies were assessed. Eighteen of the European species are endemic to Europe (i.e. they are not found anywhere else in the world). Fourteen are endemic to the EU27. Sixteen of the 18 endemics are either confined to islands, to the Balkan Peninsula or (at least mainly) to the Iberian Peninsula and France. Results: Approximately one out of seven (15%) European dragonflies are threatened in Europe, with a similar proportion being threatened at the EU level. An additional 11% are considered Near Threatened. By comparison, 23% of the amphibians, 19% of the reptiles, 15% of the mammals, 13% of the birds, 11% of the saproxylic beetles and 9% of the butterflies in Europe are threatened (Temple & Cox 2009, Cox & Temple 2009, Temple & Terry 2007, BirdLife International 2004, Nieto & Alexander 2010, Van Swaay et al. 2010). No other groups have so far been comprehensively assessed at the European level. About a quarter (24%) of the European dragonflies have declining populations, ten percent are increasing and roughly half of the species are stable. For the remaining 12%, the available information is too limited to define any population trends. Most of the threatened species are confined to parts of southern Europe. Currently, the main threat to European dragonflies is desiccation of their habitats due to the increasingly hot and dry summers combined with intensified water extraction for drinking and irrigation. Other important threats to species living in running waters are water pollution and the construction of dams and reservoirs. Conclusion and recommendations: This report shows where the highest levels of diversity and endemism, and the greatest proportion of threatened dragonflies are found within the European region. Using these parameters, three key areas for dragonfly conservation in Europe have become evident: the southern Balkan Peninsula, Crete and the Iberian Peninsula. Certain measures are urgent: *A freshwater action plan is needed for Crete. *Species action plans should be made for the most threatened species on the southern Balkan Peninsula, especially for *Pyrrhosoma elisabethae*, *Cordulegaster helladica* ssp. and *Somatochlora borisi*, as these taxa are endemic to Europe. *Large scale and multi-taxa conservation plans for river systems are needed in order to establish a balance between agriculture, development and nature conservation, especially on the Iberian Peninsula, in southern France, Greece and parts of Italy. *Better management practices for fish ponds and rice fields would also have

valuable conservation effects without increasing the long term costs. *Development of a sustainable network of local experts and volunteers is needed to facilitate the conservation and monitoring of dragonfly species and habitats.] Address: Kalkman, V.J., European Invertebrate Survey - Nederland, p/a Nationaal Natuurhistorisch Museum - naturalis, Postbus 9517, 2300 RA Leiden, The Netherlands. E-mail: kalkman@naturalis.nl

9195. Kalkman, V.J.; Choong, C.Y.; Orr, A.G.; Schütte, K. (2010): Remarks on the taxonomy of Megapodagrionidae with emphasis on the larval gills (Odonata). *International Journal of Odonatology* 13(1): 119-135. (in English) ["A list of genera presently included in Megapodagrionidae and Pseudolestidae is provided, together with information on species for which the larva has been described. Based on the shape of the gills, the genera for which the larva is known can be arranged into four groups: (1) species with inflated sack-like gills with a terminal filament; (2) species with flat vertical gills; (3) species in which the outer gills in life form a tube folded around the median gill; (4) species with flat horizontal gills. The possible monophyly of these groups is discussed. It is noted that horizontal gills are not found in any other family of Zygoptera. Within the Megapodagrionidae the genera with horizontal gills are, with the exception of Dimeragrion, the only ones lacking setae on the shaft of the genital ligula. On the basis of these two characters it is suggested that this group is monophyletic." 9196. Karlsson, M.; Sahlén, G.; Koch, K. (2010): Continuous and stepwise oocyte production in Libellulidae (Anisoptera). *Odonatologica* 39(2): 107-119. (in English) ["Compared to other insect groups, libellulids have a rather high mean number of ovarioles. In addition, the mean ovariole diameter differs greatly between and within species. In general, 2 different types of ovariole arrangement exist: (1) all developing oocytes mature and equal in size; in some species without, and in others with, surrounding connective tissue and (2) oocytes displaying gradual maturation, with only the outermost ovarioles mature. These differences have ecological consequences: the first arrangement occurs in species that have stepwise egg production. These species will lay one or more clutches, after which an interclutch interval of ovariole regrowth follows. Species with the second arrangement have continuous egg production and are able to lay at least some eggs all the time, reducing the length of interclutch intervals. However, no direct connection between mate-guarding strategies and ovariole arrangements can be seen. Nevertheless, it is believed that the process of ovariole maturation differs between these groups. It is concluded that ovary morphology in libellulids may exhibit evolutionary fixed traits, although the whole picture still remains complex. The ovariole arrangement may have a crucial impact on the reproductive ecology of the species." 9197. Kishida, O.; Trussell, G.C.; Mougi, A.; Nishimura, K. (2010): Evolutionary ecology of inducible morphological plasticity in predator-prey interaction: toward the practical links with population ecology. *Population*

Ecology 52(1): 37-46. (in English) ["The outcome of species interactions is often strongly influenced by variation in the functional traits of the individuals participating. A rather large body of work demonstrates that inducible morphological plasticity in predators and prey can both influence and be influenced by species interaction strength, with important consequences for individual fitness. Much of the past research in this area has focused on the ecological and evolutionary significance of trait plasticity by studying single predator-prey pairs and testing the performance of individuals having induced and noninduced phenotypes. This research has thus been critical in improving our understanding of the adaptive value of trait plasticity and its widespread occurrence across species and community types. More recently, researchers have expanded this foundation by examining how the complexity of organismal design and community-level properties can shape plasticity in functional traits. In addition, researchers have begun to merge evolutionary and ecological perspectives by linking trait plasticity to community dynamics, with particular attention on trait-mediated indirect interactions. Here, we review recent studies on inducible morphological plasticity in predators and their prey with an emphasis on internal and external constraints and how the nature of predator-prey interactions influences the expression of inducible phenotypes. In particular, we focus on multiple-trait plasticity, flexibility and modification of inducible plasticity, and reciprocal plasticity between predator and prey. Based on our arguments on these issues, we propose future research directions that should better integrate evolutionary and population studies and thus improve our understanding of the role of phenotypic plasticity in predator-prey population and community dynamics." (2010): Aquatic macroinvertebrate assemblages associated with root masses of water hyacinths, *Eichhornia crassipes* (Mart.) Solms-Laubach, 1883 (Commelinales: Pontederiaceae) in Taabo Lake, Ivory Coast. *Journal of Natural History* 44 (5&6): 257-278. (in English) ["We examined aquatic macroinvertebrates associated with *Eichhornia crassipes* roots at five sampling sites in Taabo Lake. An average density of 1644 individuals (ind.)/m² was recorded. In total, 68 macroinvertebrate taxa belonging to 34 families and 14 orders were identified. Among these, Insecta was predominant (77.94%). The highest densities were recorded at Taabo cit during both rainy and dry seasons. Taxon diversity differences were not observed among all stations according to a Kruskal-Wallis test. High densities of predators were recorded. Next most prevalent in the trophic structure were detritivores. Indicator taxa analysis, using the Indval method, showed that stations upstream of the lake were characterized by eight taxa, while 11 appeared as indicators of the station near the dyke. Predators and herbivores dominated within those indicators. Sites near bays were distinguished by 18 indicator taxa with a predominance of predators and detritivores. Conductivity, NH₄⁺, temperature, PO₄³⁻, turbidity and dissolved oxygen were parameters that strongly influenced the macroinvertebrate community. ... Five orders (Coleoptera, Diptera, Heteroptera, Odonata and Ephemer-

optera) dominated within Insecta, which represented qualitatively 77.94% of macroinvertebrate assemblages. Table 4 shows the diversity of these macroinvertebrates at the five stations." 9199. Kownacki, A. (2010): Benthic macroinvertebrates from waters of the Tatra National Park – present state, threats, protection. Benthic fauna of Polish national parks. ISBN 978-83-62298-09-9: 54-60. (in Polish, with English summary) ["738 species of benthic macroinvertebrates were found so far in the Tatra National Park waters. Many of them living above the timber line are not found in Poland except the Tatra Mts. Among them only 2 species and probably additional 2 taxa are recognized as endemic. Tatra waters are generally not altered by the human activity. The effect on benthic macroinvertebrate are observed only below the inflow of sewage from shelter house. Other factors such as introduction of fish into high mountain lakes, acid rains and climatic changes little effect on fauna. Nevertheless *Branchinecta paludosa polonica* disappeared in the Polish part of Tatra." (Author) The paper includes remarks on *Cordulegaster boltonii*, *Somatochlora alpestris*, and *S. arctica*.] Address: Kownacki, A., Institute of Nature Conservation PAS, al. 9200. Lacerda, C.H.F.; Hayashi, C.; Soares, C.M.; GFernandes, C.E.B. (2010): Influence of aquatic plants on the predation of *Piaractus mesopotamicus* larvae by *Pantala flavescens*. *Acta Scientiarum. Biological Sciences*, Maringá, 32(2): 147-151. (in English, with Portuguese summary) ["The experiment aimed to study the influence of the aquatic plants *E. najas*, *P. stratiotes* and *S. auriculata* on the predation of *P. mesopotamicus* larvae by *P. flavescens*. One hundred and twenty larvae of *P. mesopotamicus* and 24 larvae of *P. flavescens* were placed in 24 aquariums with capacity of 12 L, with one Odonate per aquarium. Treatments were different regarding the species of aquatic plants *E. najas*, *S. auriculata* and *P. stratiotes*, with one control treatment without aquatic plants. One aquarium (12 L) containing one Odonate and 30 *P. mesopotamicus* larvae was considered one experimental unit. After 18 hours, the Odonates were removed from the aquariums and fish larvae left (alive) were counted in each experimental unit. The survival rate of *P. mesopotamicus* larvae in the treatment without aquatic plants (control) was significantly lower than in the treatment with *E. najas*. However, the survival rates in the aquariums with floating aquatic plants did not differ from the control. The morphological characteristics of *E. najas* promoted higher structural complexity in the environment, offering more protection to the fish larvae, and increasing their survival. We concluded that the presence of the submerged aquatic plant *E. najas* promoted the reduction of predation of *P. mesopotamicus* larvae by *Pantala flavescens*." 9205. Mendoza, G. de; Catalan, J. (2010): Lake macroinvertebrates and the altitudinal environmental gradient in the Pyrenees. *Hydrobiologia* 648: 51-72. (in English) ["The distribution of different macroinvertebrate (including 'Aeshna' and 'Enallagma') groups inhabiting the littoral zone of 82 mountain lakes in the Pyrenees was investigated in relation to the altitudinal environmental gradient. For each lake, altitude, longitude and latitude, together with 28 environmental variables, relating to chemical and physical characteristics and to lake general productivity, were considered. Using Principal Component Analysis (PCA) we showed that the altitudinal environmental gradient (i.e. altitude and altituderelated variables) represented the largest gradient of environmental variability. We found that incidence was related to altitude in about 50% of macroinvertebrate groups, most relationships being inverse, and also that the number of macroinvertebrate groups found per lake was better described by a second-order polynomial function than by simple linear regression. However, this relationship was linear for a subset of high-altitude lakes above 2,500 m a.s.l., suggesting an ecological threshold around this altitude. Redundancy Analyses (RDAs) showed the importance of environmental factors varying with altitude for the distribution of macroin-

vertebrate groups. Organic matter, salmonid presence, fine substrate dominance, macrophyte coverage, temperature and altitude by itself were, in this order, the most relevant factors. Partial RDAs showed that different combinations of these variables contributed to the explanation of the distribution of each group. However, the variable that uniquely explained most variability differed from group to group. We conclude that the altitudinal gradient is a multi-faceted ecological factor, which impinges on each group by means of some specific environmental variable(s) that are particularly relevant for the life history of that group." 9215. Rada, B.; Puljas, S. (2010): Do Karst rivers "deserve" their own biotic index? A ten years study on macrozoobenthos in Croatia. *International Journal of Speleology* 39(2): 137-147. (in English) ["In this study we present the results of a ten year survey of the aquatic macroinvertebrate fauna along four karst rivers: Jadro, Žrnovnica, Grab and Ruda, all of them situated in the Middle Dalmatia region of Croatia, in an attempt to construct the Iliric Biotic Index, which will be more applicable for the water quality analysis than the most frequently applied biotic index in Croatia, the Italian Modification of Extended Biotic Index. The rivers geologically belong to the Dinaric karst, unique geological phenomena in Europe. Benthic macroinvertebrates were collected along each river at 15 sites by standard methods of sampling along with several physicochemical parameters, including: temperature, dissolved oxygen, carbon dioxide, alkalinity, hardness and pH. Univariate and multivariate techniques revealed differences in the macroinvertebrate community structure as well as in physicochemical parameters between the Karst rivers and continental rivers. Based on those differences, the Iliric Biotic Index was proposed as the standard of karst river water quality in Croatia in accordance with the EU Water Framework Directive. Differences between the Iliric Biotic Index and the most commonly used biotic indices in the European Community and the USA (The Biological Monitoring Working Party (B.M.W.P.) scores, i.e. Extended Biotic Index, Indice Biotique, Family Biotic Index) suggest that karst rivers need a new biotic index." (Authors) In a table records of the benthic fauna of the karst rivers made during the period of investigation (1994-2004) are compiled. The list includes - without further details - *Anax imperator*, *Cordulegaster boltonii*, and *Calopteryx virgo*.] Address: Rada, B., University of Split, Faculty of Science, Department of Biology, Teslina 12/III, 21000 Split, Croatia. 9218. Regier, J.C.; Shultz, J.W.; Zwick, A.; Hussey, A.; Ball, B.; Wetzer, R.; Martin, J.W.; Cunningham, C.W. (2010): Arthropod relationships revealed by phylogenomic analysis of nuclear protein-coding sequences. *Nature* 463 (7284): 1079-1083. (in English) ["The remarkable antiquity, diversity and ecological significance of arthropods have inspired numerous attempts to resolve their deep phylogenetic history, but the results of two decades of intensive molecular phylogenetics have been mixed. The discovery that terrestrial insects (Hexapoda) are more closely related to aquatic Crustacea than to the terrestrial centipedes and millipedes (Myriapoda) was an early, if exceptional, success. More typically, analyses based on limited samples of taxa and genes have generated results that are inconsistent, weakly supported and highly sensitive to analytical conditions. Here we present strongly supported results from likelihood, Bayesian and parsimony analyses of over 41 kilobases of aligned DNA sequence from 62 single-copy nuclear protein-coding genes from 75 arthropod species. These species represent every major arthropod lineage, plus five species of tardigrades and onychophorans as outgroups. Our results strongly support Pancrustacea (Hexapoda plus Crustacea) but also strongly favour the traditional morphology-based Mandibulata (Myriapoda plus Pancrustacea) over the molecule-based Paradoxopoda (Myriapoda plus Chelicerata). In addition to Hexapoda, Pancrustacea includes three major extant lineages of 'crustaceans', each spanning a significant range of morphological disparity. These are Oligostraca (ostracods, mystacocarids, branchiurans and pentastomids), Vericrustacea (malacostracans, thecostracans, copepods and branchiopods) and Xenocarida (cephalocarids and remipedes). Finally, within Pancrustacea we identify Xenocarida as the long-sought sister group to the Hexapoda, a result confirming that 'crustaceans' are not monophyletic. These results provide a statistically well-supported phylogenetic framework for the largest animal phylum and represent a step towards ending the often-heated, century-long debate on arthropod relationships." (Authors) The analysis includes "*Ischnura*" and "*Libellula*".] Address: Wetzer, Regina, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA.

- 9219.** Roland, H.-J.; Roland, U. (2010): New records of Odonata on a birding trip to Cambodia 12th-26th February 2010. *Agrion* 14(2): 30-33. (in English) ["On a guided birding trip to various places in Cambodia, over 500 pictures of Odonata were taken. 24 Anisoptera and 8 Zygoptera species could be identified. Among these only one was without photo evidence, *Pseudothemis jorina*. One *Neurothemis* species had to be left unidentified. The following species have not been recorded for Cambodia before: *Aethriamanta aethra*, *A. brevipennis*, *A. gracilis*, *Brachydiplax farinosa* and *Rhyothemis triangularis*. This fact can be partially explained by the low number of observers of Odonata in Cambodia. Most of the species are rather common in neighbouring countries." - 9220.** Samways, M.J.; Sharratt, N.J. (2010): Recovery of endemic dragonflies after removal of invasive alien trees. *Conservation Biology* 24(1): 267-277. (in English) ["Because dragonflies are very sensitive to alien trees, we assessed their response to large-scale restoration of riparian corridors. We compared three types of disturbance regime—alien invaded, cleared of alien vegetation, and natural vegetation (control)—and recorded data on 22 environmental variables. The most significant variables in determining dragonfly assemblages were percentage of bank cover and tree canopy cover, which indicates the importance of vegetation architecture for these dragonflies. This finding suggests that it is important to restore appropriate marginal vegetation and sunlight conditions. Recovery of dragonfly assemblages after the clearing of alien trees was substantial. Species richness and abundance at restored sites matched those at control sites. Dragonfly assemblage patterns reflected vegetation succession. Thus, initially eurytopic, widespread species were the main beneficiaries of the removal of alien trees, and stenotopic, endemic species appeared after indigenous vegetation recovered over time. Important indicator species were the two national endemics (*Allocnemis leucosticta* and *Pseudagrion furcigerum*), which, along with vegetation type, can be used to monitor return of overall integrity of riparian ecology and to make management decisions. Endemic species as a whole responded positively to restoration, which suggests that indigenous vegetation recovery has major benefits for irreplaceable and widespread generalist species." (in English) ["Silks play a crucial role in the survival and reproduction of many insects. Labial glands, Malpighian tubules, and a variety of dermal glands have evolved to produce these silks. The glands synthesize silk proteins, which become semicrystalline when formed into fibers. Although each silk contains one dominant crystalline structure, the range of molecular structures that can form silk fibers is greater than any other structural protein group. On the basis of silk gland type, silk protein molecular structure, and the phylogenetic relationship of silk-producing species, we grouped insect silks into 23 distinct categories, each likely to represent an independent evolutionary event. Despite having diverse functions and fundamentally different protein structures, these silks typically have high levels of protein crystallinity and similar amino acid compositions. The substantial crystalline content confers extraordinary mechanical properties and stability to silk and appears to be required for production of fine protein fibers." (2010): Diurnal changes in male mate preference to female dimorphism in *Ischnura senegalensis* (Rambur) (Zygoptera: Coenagrionidae). *Odonatologica* 39(2): 159-162. (in English) ["*I. senegalensis* females exhibit colour dimorphism as andromorphs and gynomorphs, to which males seem to switch their mate preference according to prior copulation experience. In the field where andromorphs were dominant, the binary choice experiments were conducted both in the early morning, which marks the onset of daily copulation activity, and in the afternoon, which marks the end of the copulation activity. During

the former period, males showed fair selectivity, while they preferred the andromorphs in the afternoon, suggesting that male mate preference to each female morph switched in relation to copulation experience; i.e. the mating attempts of males were biased to the dominant female morph. Mating attempts in the afternoon were considered to inhibit female oviposition behaviour, resulting in a decrease of her reproductive success. Therefore, biased male mate choice toward the dominant morph in the afternoon might be a selective force to maintain the female colour dimorphism." (2010): Mating experience affecting male discrimination between sexes and female morphs in *Ischnura senegalensis* (Rambur) (Zygoptera: Coenagrionidae). *Odonatologica* 39(1): 47-56. (in English) ["*Ischnura senegalensis* females exhibit colour dimorphism, appearing as andromorphs and gynomorphs. Binary choice experiments between sexes and morphs were conducted in the laboratory. Virgin males reared separately from females showed no preference between sexes or between morphs, suggesting that virgin males were unable to recognize potential mates and had no innate mating preference for a particular female morph. After enclosure with a single female in a small cage, males that had experienced copulation significantly preferred the same female morph with which they had copulated, while males that failed to copulate with the female showed no preference. The males that had experienced copulation significantly preferred females over males. Therefore, ability of males to discriminate between sexes and morphs was confirmed by their copulation experience." (Authors)] Address: Watanabe, M., Grad. 9227. Takahashi, Y.; Watanabe, M. (2010): Morph-specific fecundity and egg size in the female-dimorphic damselfly *Ischnura senegalensis*. *Zoological Science* 27: 325-329. (in English) ["Females of coenagrionid damselflies exhibit colour dimorphism, consisting of an andromorph and a gynomorph. This study compared reproductive traits between the female morphs in both fieldcaptured and laboratory-reared females of the female-dimorphic *I. senegalensis*. No difference was found in the onset of egg development between the morphs. The andromorphs developed significantly smaller mature eggs and had significantly more immature eggs than the gynomorphs. These results suggest that the andromorphs are r-strategists (high fecundity with small eggs), whereas the gynomorphs are K-strategists (low fecundity with large eggs). Fecundity and egg size might determine the quantity and quality of the offspring, respectively, indicating that morph-specific reproductive traits would contribute to the overall fitness of each female morph, and consequently be key factors affecting morph frequency in a population." 9228. Taylor, A.N. (2010): Impacts of cadmium contamination and fish presence on wetland invertebrate communities: An application of population measures and multi-metric tests. *Ecological Indicators* 10(6): 1206-1212. (in English) ["Wetlands are extensively used in heavy metal bioremediation, and it is important to know how biota are impacted by such toxins. I examined invertebrate communities in six experimental wetland ponds in Ithaca, NY, USA to assess the effects of residual cadmium. Three ponds had been treated with cadmium in 1983, and still had average levels of 3.6 mg/kg in the sediment in 2001. Also, two of the cadmium ponds and one non-cadmium pond had predatory fish populations. I quantified the variable effects on invertebrate communities using non-parametric statistics, CCA (canonical correspondence analysis), and three published multi-metric tests ([Burton et al., 1999], [Apfelbeck, 2001] and [Helgen and Gernes, 2001]). Cadmium effects could not be seen in ponds with fish because invertebrate abundance in these ponds was low. In ponds without fish, cadmium appeared to have significant influence on invertebrate abundance, but not on diversity. None of the multi-metric tests detected a cadmium impact. This study suggests that trophic interactions between fish and invertebrates should be considered in wetland index development and implementation." (Author) Odonata are treated at the genus level. No effects of cadmium on Odonata seem to exist.] Address: Office of Surface Mining, 1645 S. 101 East Avenue, Suite 145, Tulsa, OK 74128, USA. E-mail: ataylor@osmre.gov

9234. Yates, A.G.; Bailey, R.C. (2010): Covarying patterns of macroinvertebrate and fish assemblages along natural and human activity gradients: implications for bioassessment. *Hydrobiologia* 637(1): 87-100. (in English) ["Bioassessment is based upon the premise that biological assemblages have predictable relationships with the surrounding natural and human environments. As the nature of these relationships can vary from region to region, it is important that environment-biota relationships be established prior to the initiation of any bioassessment program. In this study, multivariate analysis was used to establish how fish and benthic macroinvertebrate (BMI) assemblages in southwestern Ontario streams vary across natural and human activity gradients. The use of canonical correspondence analysis allowed us to determine that changes in community composition of both fish and BMI are strongly correlated with variation in the extent of human activity. The primary source of variation in community composition across activity gradients appeared to reflect a shift from intolerant to tolerant taxa as the extent of human activity increased. Habitat and feeding traits, for BMI and fish respectively, accounted for a secondary source of variation primarily attributable to differences in the extent of human activity at the reach scale. However, variation in human activity, especially at the basin scale, covaried with the dominant natural gradient of surface geology, making interpretation of the results difficult. Implications for bioassessment studies are discussed." (Authors) Odonata are treated at the family level.] Address: Yates, A.G., Department of Biology, The University of Western Ontario, 1151 Richmond St. N., London, ON, N6A 5B7, Canada. (in Chinese, with English summary) ["Total mercury contents of cicadae bodies, wings and exuviae were studied in Huludao City to discuss mercury distribution characteristics in cicadae and to reveal the environmental mercury accumulation effects in the long life-cycle insects through comparing cicadae with other insect species. The average mercury contents of cicadae bodies were 2.64 mg·kg⁻¹ and much higher than those in the contrast sites (1.00 mg·kg⁻¹ on average) in Huludao City. Mercury contents were found in the order of cicadae bodies > wings (0.98 mg·kg⁻¹ on average) > exuviae (0.50 mg·kg⁻¹ on average). Sex differences of mercury contents and body weights of cicadae were significantly great. The females had larger body weights (1.11 g on average) and lower mercury contents (1.34 mg·kg⁻¹ on average) than the males (body weight: 0.54 g on average; mercury contents: 3.38 mg·kg⁻¹ on average), respectively. Mercury contents of cicadae's bodies varied greatly with sample sites, mercury contents of wings changed little. No significant correlation was found between mercury contents of soil and cicadae bodies. Mercury contents of cicadae were lower than those of dragonflies, higher than those of other insects with shorter life-cycle periods and it reflected the accumulation effects of environmental mercury in the long life-cycle insects such as cicadae." (2010): The EU Habitats Directive and the German Natura 2000 network of protected areas as tool for implementing the conservation of relict species. In: Habel, J.C. & T. Assmann (Hrsg.): *Relict Species: Phylogeography and Conservation Biology*. Verlag Springer Berlin Heidelberg. ISBN 978-3-540-92161-5: 323-340. (in English) ["This study analyses whether the Natura 2000 network of Sites of Community Importance (SCIs) is able to protect relict species in the taxonomic groups of higher plants, molluscs, dragonflies and damselflies as well as butterflies (only Rhopalocera) in Germany. Altogether, a total of 157 species from all groups are identified as relict species in Germany. 14 of these are included in Annexes II, IV or V of the Habitats Directive. Most glacial relicts are well covered by an indirect protection regime of the European Union (EU) Habitats Directive as they occur in 46 of Annex I habitat types, and their occurrences are to a large extent covered by Natura 2000 sites (SCIs). For a few relict species and certain relict plant communities a gap remains in the EU protection regime, which can be filled by a national protection regime, for example, in nature reserves. The best way to protect local relict species is to include them in special management plans for their conservation." (Authors)] Address: Zimmermann, M., Inst. 9245. Chambers, D.B.; Messinger, T. (2001): Benthic invertebrate communities and their responses to selected environmental factors in the Kanawha River Basin, West Virginia, Virginia, and North Carolina. U.S. Department of the Interior, U.S. Geological Survey, Water-Resources Investigations Report 01-4021, National Water-Quality Assessment Program, Charleston, West Virginia 2001: VII, 52 pp. (in English) ["The effects of selected environmental factors on the composition and structure of benthic invertebrate communities in the Kanawha River Basin of West Virginia, Virginia and North Carolina were investigated in 1997 and 1998. Environmental factors investigated include physiography, land-use pattern, streamwater chemistry, streambed-sediment chemistry, and habitat characteristics. Land-use patterns investigated include coal mining, agriculture, and low intensity rural-residential patterns, at four main stem and seven tributary sites throughout the basin. Of the 37 sites sampled, basin size and physiography most strongly affected benthic invertebrate-community structure. Land-use practices also affected invertebrate community structure in these basins. The basins that differed most from the minimally affected reference condition were those basins in which coal mining was the dominant nonforest land use, as determined by comparing invertebrate-community metric values among sites. Basins in which agriculture was important were more similar to the reference condition. The effect of coal mining upon benthic invertebrate communities was further studied at 29 sites and the relations among invertebrate communities and the selected environmental factors of land use, streamwater chemistry, streambed-sediment chemistry, and habitat characteristics analyzed. Division of coal-mining synoptic-survey sites based on invertebrate-community composition resulted in two groups—one with more than an average production of 9,000 tons of coal per square mile per year since 1980, and one with lesser or no recent coal production. The group with significant recent coal production showed higher levels of community impairment than the group with little or no recent coal production. Median particle size of streambed sediment, and specific conductance and sulfate concentration of streamwater were most strongly correlated with effects on invertebrate communities. These characteristics were related to mining intensity, as measured by thousands of tons of coal produced per square mile of drainage area." (Authors) The study includes data on *Ophiogomphus* sp., *Boyeria grafiana*, *Macromia taeniolata* (low tolerance against pollution), and *Argia* sp.

(high tolerance against pollution).] Address: Chambers, D.B., U.S. Geological Survey, Branch of Information Services, Box 25286, Denver, CO 80225-0286, USA

9251. Schlüter, M.; Welt, M. (2002): The dragonfly: a more effective genetic biomarker of pollution. Poster 78-04. presented at the 12th Annual Meeting of the Society of Environmental Toxicology and Chemistry Europe,

Vienna (Austria), 12-16 May 2002: (in English) ["Currently, there are limited insect biomarkers with field applications, even though insects play key roles in most terrestrial and freshwater ecosystems. Most pollutants and toxicants occur at the highest concentrations in the soil or aquatic sediment due to solubility and settling; however most current biomarker species spend little or no time in these areas. The development of a biomarker species that resides a significant portion of its life span in the sediment may be a more sensitive indicator of environmental health and stability. Dragonflies are an excellent example of an insect species whose larvae spends one or more years in the aquatic sediment. The main goal of the following study is to investigate the potential of the dragonfly as a new biomarker species of pollution. Dragonflies show a high level of genetic diversity as measured by allozymes (protein phenotypes) and by DNA fingerprinting. Allozyme allele frequencies were examined to determine if these characteristics were related to environmental quality. Population genetic structure (allele frequencies) of several populations of a common dragonfly species, *Erythemis simplicicollis*, were compared and contrasted. Populations were sampled from "polluted" sites (e.g. heavy metals, petroleum) and "clean" sites. Differences in allele frequencies were detected in the populations. These differences may be related to the toxicants present in the environment. DNA fingerprinting (RAPD markers) was able to identify individuals as well as separate populations. Allozyme data show that selection for specific phenotypes are related to environmental pollution. This was illustrated by comparisons of allozyme phenograms to genomic population phenograms. These differences suggest that the phenotypic (allozyme) data from dragonflies may serve as an effective biomarker of environmental health." (Authors)] Address: Schlüter, M., Dept Biol., Xavier Univ., 1 Drexel Dr., New Orleans, LA 70125-1098. USA

9252. Watanabe, M.; Mimura, Y.; Higashi, T. (2002): Ecological studies on habitat establishment for threatened brackish water damselfly, *Mortonagrion hirosei*: microclimate of the habitat. Annual Report of the interdiscipl. Res. Inst. environ. Sci. 21: 47-58. (in Japanese, with English summary) ["The spatial distribution for perching sites of the endangered brackish water damselfly, *Mortonagrion hirosei*, was restricted about 20cm above the water surface in a small reed community of an estuary in the warm-temperate zone of Japan. The flight season was from late May to early August. The peak estimated daily number of the damselfly adults was about 1000, that is 2 adults per square meter in the habitat. There was a dense reed community, 440 shoot per square meter, that is, the distance between shoots is 5cm. Relative light intensity at the 20cm above the water surface in the reed community was about 10%. Although there was no difference between ambient and inside temperature of reed community, the wind velocity inside the reed community was apparently lower than that outside the community. Therefore, the micro-environment of the damselfly habitat was comparable to that of forest floor. The closed habitat made by a lot of shoot of the reed may inhibit the other odonate species to enter inside of the reed community. Consequently, the floor of the reed community was considered to be a suitable micro-habitat of the brackish water damselfly." kuba, Ibaraki 305-8572, Japan. E-mail: watanabe@kankyo.envr.tsukuba.ac.jp

9253. Zuellig, R.E.; Kondratieff, B.C.; Rhodes, H.A. (2002): Benthos recovery after an episodic sediment release into a Colorado rocky mountain river. Western North American Naturalist 62(1): 69-72. (in English) [During late September 1996, approximately 7000 m³ of clay- to gravel-sized sediment was flushed from Halligan Reservoir, Larimer County, Colorado, into the North Fork Cache la Poudre River during dam inspections. Approximately 9.6 km of this river was partially or completely affected by this episodic sediment release. Pools up to 3.2 km downstream from the dam lost 50% of their volume. Hess samples taken from October 1996 to September 1997, 100 m downstream from the dam (site 1) and 3.2 km downstream (site 2), revealed effects of sediment on recovery patterns of benthic communities. A 2-way ANOVA was used to determine significant interactions using site and date as main factors. Pairwise differences were then compared using least squares means to determine significant dates within and between sites. Ten days after the sediment release, both density and taxa richness at site 1 (55 organisms per m², 5 taxa) were significantly lower ($P < 0.05$) than site 2 (1156 organisms per m², 25 taxa). These differences remained until June when species richness and densities increased. Plecoptera and Trichoptera colonized from June to September after being eliminated at site 1 and reduced at site 2. No permanently flowing tributaries exist within the study area; therefore, passive downstream drift from such inputs apparently did not influence recovery. Increased densities of taxa such as Baetidae, Hydroptilidae, Hydropsychidae, Chironomidae, Simuliidae, and Oligochaeta occurred plausibly by rapid reproduction. Based on pre-event data, community function completely changed at site 2 from a scraper community to one dominated by collector-gatherers." (Authors) Odonata are represented in very small numbers by "Zygoptera" and *Ophiogomphus severus*.] Address: Zuellig, R.E., Colorado State University, Dept of Bioagricultural Sciences and Pest Management, Fort Collins, CO 80523

9262. Bree, D. (2004): Significant Odonate observations from Petroglyphs Provincial Park and Area in 2002. Ontario Odonata 4: 33-37. (in English) ["Updates to the checklist of the Odonata found at Petroglyphs Provincial Park during field studies in 2002 are presented. Documented are eleven new species for the park's list bringing the total to 71. Included are two uncommonly encountered species, *Cordulegaster obliqua* and *Enallagma aspersum*, which are also new for Peterborough County, and two provincially rare species, *Lestes eurinus* and *Williamsonia fletcheri*. Two of the other new species for the park, *Erythemis simplicicollis* and *Celithemis eponina* suggest the possibility of a northern range expansion of southern species. Additional documentation of breeding evidence for species in and near the park is presented, including the provincially rare *Progomphus obscurus* and the uncommon *Neurocordulia yamaskanensis*. New late and early flight dates for Peterborough County are also included." (Author)] Address: Bree, D., Box 123, Bloomfield, Ontario K0K 1G0, Canada. E-mail: dbree@post.kosone.com

9263. Catling, P.M.; Jones, C.D.; Pratt, P. (2004): Ontario Odonata projects; News and comments; Recent literature; Index to species in the year 2002 summary table. Ontario Odonata 4: 194-216. (in English) [10 even running studies are compiled; NEWS AND COMMENTS: 1. *Williamsonia lintneri* has been found in a number of localities in Michigan and likely occurs in Ontario. Articles about its occurrence in Michigan may be found in *Williamsonia*, an excellent publication of the

Michigan Odonate Survey (<http://insects.umrnz.lsa.urnich.edu/michodo/mos.htm> 1, michodo@urnich.edu. 2. Could Citrine Forktails (*Ischnura hastata*) be expanding north, or have they just been overlooked? There are a number of recent records in the Great Lakes region. See Craves, J. and D. O'Brien. 2003. Update on two 2002 State Records. *Williamsonia* 7(3,4): 6-7. 3. Mike May and Phil Corbet have outlined a question about the northern occurrences of *Anax junius* and their note is worth reading: May, M. and P. Corbet. 2003. Gathering useful information about the seasonal ecology of *Anax junius*. *Argia* (the news journal of the dragonfly society of America) 15(2): 15-16. See also an article about overwintering *Anax junius* in this volume. 4. Although the resource guide may not be reprinted, it is anticipated that the first volume of a three volume guide to the Dragonflies of Ontario by P. M. Catling will be available late in 2004. The first advertisements will likely appear in "Ontario Insects." 5. Mystery species: The following species (historically known from Ontario) have not been recorded during the detailed survey of Odonata in Ontario over the past four years: *Aeshna mutata*, *A. subarctica*, *Anax longipes*, *Celithemis fasciata*, *Coenagrion angulatum*, *Gomphus ventricosus*, *Leucorrhinia borealis*, *Somatochlora ensigera*, *S. hudsonica*, *Stylurus plagiatu*s, *Sympetrum ambiguu*m. 6. Status of Canadian Dragonflies. The National General Status Working Group, which is composed of biologists from each of the Canadian provinces and territories and three federal agencies whose mandate includes wildlife, met in Ottawa on November 22, 2003 to finalize assessments of the general status of 209 dragonfly species in Canada. Ensuring human actions don't drive species extinct in Canada means knowing the status of species across the length and breadth of the nation - which species are secure for now, which to keep an eye on, and which need to be formally assessed and perhaps protected. The most recent effort on dragonflies provides an overview of their status in Canada. It brings the results of Provincial, Territorial, and Federal monitoring efforts onto a single platform for the first time. This effort was conducted under the auspices of the National Accord for the Protection of Species at Risk. The results and interpretation of these assessments will be available on the Wild Species Web site <http://www.wildspecies.ca> as part of Wild Species 2005, the second of the General Status of Species in Canada reports. For more information, contact wild.species@ec.gc.ca (From Lisa Twolan and Jim Duncan, January 23, 2004)." (Authors)] Address: Catling, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. Catanoiu (Eds): Studies and research in Vanatori Neamt Natural Park. 1: 28-35. (in English, with Romanian summary) [At present, 11 Odonata species have been recorded until now. The relative small number of species found results from an inappropriate period of the year in which the samples have been collected.] Address: Mancu, C.O., Acad. Remus Radulet 13, bl. 119, ap. 7, Timisoara 300281, Timis County, Romania. E-mail: cosminovidiu@yahoo.com

9279. Moiseenko, T.I. (2005): Effects of acidification on aquatic ecosystems. Russian Journal of Ecology 36(2): 110-119. (in English) ["Effects of acidification on aquatic ecosystems are analyzed on the basis of an analytical synopsis of relevant data. Major active agents influencing aquatic organisms and main trends in the reorganization of microbial, phyto- and zooplanktonic, benthic, and fish communities in an acidified environment are described. A generalized concept of changes in ecosystems caused by acid precipitation and accompanying factors is formulated. These changes include the reduction of biodiversity of all structural elements due to the disappearance of species sensitive to acidification, modification of trophic structure, and decrease of fish stock." (Author) The study includes references to a few studies with information on acidification impacts on Odonata, but provides no original data. Translated from *Ekologiya*, No. 2, 2005, pp. 110-119] Address: Moiseenko, T.I., Institute of Water Problems, Russian Academy of Sciences, ul. Gubkina 3, Moscow, 119991 Russia

9281. Paoletti M.G.; Dufour, D.L. (2005): Edible invertebrates among Amazonian indians: A critical review of disappearing knowledge. Paoletti M.G. (ed.) 2005. Ecological Implications of Minilivestock. Potential of Insects, Rodents, Frogs and Snails Science Publishers, Enfield N.H., USA 648 pp: 293-342. (in English) ["For the indigenous populations of Amazonia, invertebrates constitute an important component of the diet. Information on entomophagy for 39 ethnic groups (and three other post-Columbian settlers) or about 21.4% of the 182 groups known in the Amazon Basin is presented here,

but utilization of this non-conventional food resource is surely much more widespread. A database is given of all the information available for each ethnic group regarding the species included in the diet, scientific and the ethno name if known, stage of life cycle consumed, manner of preparation and, when known, host plant. This database lists 209 scientifically identified species (including seven Odonata taxa identified at the species resp. genus level). Information on an additional 426 species and ethno names, with an insecure link to Linnean taxonomy suggest that local knowledge is very extensive. The database represents not only an easy-to-consult resource, but also a support for further research. Caterpillars, termites, leafcutter ants, bees, wasps, and Coleoptera seem to be the more collected items, together with a few aquatic ones. The most intensively collected are those dependent on forest leaves and litter, representing in general the higher biomass, so much work needs to be done for other groups, including caterpillars, aquatic insects, grasshoppers, snails, and spiders. Knowledge of the relations between indigenous populations and ecosystems is indeed the base for the preservation of natural and cultural biodiversity. We are at the beginning of a survey that has to be expanded." (Authors)] Address: Paoletti M.G., Dept of Biology, Padova University, Via U. Bassi 58/b, Padova, Italy. my Kuwait visit ("May 2006") gave me, quite unexpectedly, my first encounter with the Arabian lobetail (*Lindenia tetraphylla*), Arabia's largest perching dragonfly. Also present were many of the smaller, hovering desert darter (*Selysiotthemis nigra*). Both of these species were probably migrating into the area in response to the recent rains, as they have long been recognised to do." (Author)] Address: Feulner, G., c/o Dubai Natural History Group, PO Box 9234, Dubai, United Arab Emirates

9290. Feulner, G. (2006): Diverse Dragonflies. *Gazelle, Dubai* 21(5): 6-7. (in English) [Oman; "In March I visited a minor wadi in the Mahdhah area where, at the mountain front, a small settlement exists and a series of bedrock pools have been "improved" for human and agricultural use. Just above this area, at a 10m long natural pond that had not existed when I visited the site two years before, I found 12 species of dragonflies – an impressive number given that only about 24 species have been identified from the UAE and neighbouring northern Oman. My mid-morning visit gave me an opportunity to watch how all of these "similar but different" organisms divided up the available pond habitat among them." (Author) The following species are briefly discussed: *Ischnura evansi*, *Arabicnemia caerulea*, *Arabineura khalidi*, *Trithemis arteriosa*, *T. kirbyi*, *T. annulata*, *Paragomphus sinaiticus*, *Crocothemis erythraea*, *Diplacodes lefebvrei*, *Orthetrum sabina*, *O. chrysostigma*, *Anax imperator*] Address: Feulner, G., c/o Dubai Natural History Group, PO Box 9234, Dubai, UAE

9291. Feulner, G. (2006): Dragonfly migration. *Gazelle, Dubai* 21(3): 4. (in English) ["*Hemianax ephippiger* was once again on its characteristic January migration in January 2006. Or rather, since this phenomenon is not known with certainty to be a directional one, perhaps it should be called a peregrination. In any case, large numbers were observed at mid-month among low hills in the Wadi Shawkah area. In previous years, in January swarms could be found intermittently over much of the mountain areas, including even the very tip of the Musandam Peninsula. Gary Feulner would be interested to know if others have noticed this year's 'migration.' The Vagrant Emperor is a relatively large dragonfly and generally patrols at a height of more than a meter above the ground, seldom perching. Both males and females appear basically olive green in flight, although the male may show accents of blue. [If high-swarmling dragonflies seem slightly reddish, you are probably seeing the Globe Skimmer (*Pantala flavescens*), a strong migrant which often appears after localized showers.] Address: Feulner, G., Dubai Nat. Hist. Gr., P.O. Box 9234, Dubai, UAE

9292. Jensen, P.D. (2006): Ecological impact of selenium and mercury on two insect food chains. PhD Dissertation, University of California, Riverside, CA, USA. 139 pp. (in English) [The author evaluated the effects of Se and/or methyl-mercury (MeHg) on consumption rates of *Sympetrum corruptum* when fed *Culex quinquefasciatus* (Diptera: Culicidae). He found that *S. corruptum* in Se treatment solutions consumed significantly more mosquito larvae per day than controls; however, predators eating prey contaminated with Se + MeHg consumed significantly fewer prey per day. Predators' consuming more in Se-treated water with non-treated prey was attributed to the mosquito larvae experiencing a reduction in avoidance behaviour. Predators' consuming less in the Se + MeHg treatments was attributed to treatments making the prey unpalatable or suppressing

the predator's appetite.] Address: Jensen, P.D., Department of Entomology, University of California, Riverside, 92521 California, USA

9299. Semwal, N.; Akolkar, P. (2006): Water quality assessment of sacred Himalayan rivers of Uttaranchal. *Current Science* 91(4): 486-496. (in English) ["Mass bathing in sacred water bodies is an age-old ritual in India. Organized outdoor bathing is an important in situ utilization of water bodies, which demands water quality requirements for drinking as well as bathing purposes. Apart from this, the Himalayan rivers have a great potential for hydroelectric power generation due to altitudinal variations. The present study deals with water quality assessment of rivers in Uttaranchal, in view of their religious importance and ecological sustainability. Based on bio-monitoring assessment, biological water quality criteria have been evolved for rivers of Uttaranchal, indicating various beneficial uses of water quality and their respective levels of characteristics. Out of 60 stretches of 19 rivers, 41 stretches indicated clean water quality of Class 'A', five stretches were slightly polluted (class 'B'), six were moderately polluted (class 'C'), one stretch was highly polluted (class 'D') and there were altogether seven severely polluted (class 'E') stretches. The physico-chemical water quality in most of the rivers of Uttaranchal remained unchanged except of total dissolved solids, which ranged from 90.23 to 121.33 mg/l, total suspended solids varying from 126.5 to 236.5 mg/l and total alkalinity of 37.0 to 96.0 mg/l. Religious places have contributed significant levels of sulphates to water quality (1.66 to 20.0 mg/l). Traces of iron, zinc and copper metals in water and sediments have been observed in clean water quality stretches. Agricultural practices on the river bank may have considerable impact on contribution of pesticide residues such as total Endosulfan, Dieldrin and DDT. Open defecation is the most common activity on river banks, which has significant contribution towards the aesthetic water quality of rivers." (Authors) Odonata are treated at the family level.] Address: Semwal, N., Central Pollution Control Board (Ministry of Environment & Forests, Govt of India), Parivesh Bhawan, East Arjun Nagar, Delhi 110 032, India. - 9304.** Cordoba-Aguilar, A.; Leshner-Trevino, A.C.; Anderson, C.N. (2007): Sexual selection in *Hetaerina titia* males: a possible key species to understand the evolution of pigmentation in calopterygid damselflies (Odonata: Zygoptera). *Behaviour* 144(8): 931-952. (in English) ["*H. titia* males bear wing pigmentation patterns similar to *Hetaerina* and *Calopteryx* (a derived sister genus of *Hetaerina*) species: black (typical of *Calopteryx*) and red (typical of *Hetaerina*). Sexual selection has operated on red (via male-male competition) and black (via male-male competition and female choice) in *Hetaerina* and *Calopteryx*, respectively. We investigated sexual behaviour and pigmentation in *H. titia* to understand their evolution in both genera using *H. titia* as a possible evolutionary transitional stage. Similar to *Calopteryx*, the black pigmentation correlated with five male quality aspects: defending a territory, survival, immune ability, parasite resistance and fat reserves. We hypothesize that black pigmentation, but not red, may be used to signal energetic condition when males compete for a territory. The red pigmentation, despite indicating male quality in *Hetaerina* species, did not correlate with quality but showed a positive relation with parasite burden. These results suggest that the red lost its function which was gained by the black pigmentation, possibly via intrasexual competition, in the absence of female choice (as *H. titia* does not show male pre-copulatory courtship as in *Calopteryx*, during which females choose males based on black pigmentation). It is unknown why the red pigmentation was retained." (Authors)] Address: Cordoba-Aguilar, A., Centro de Investigaciones Biológicas, Univ. Autónoma del Estado de Hidalgo, Apdo. 9310. Feulner, G. (2007): Dragonflies at the Beach. *Gazelle, Dubai* 22(2): 5. (in English) ["When I first came to the UAE, I was surprised to find the occasional dragonfly deep within sand desert regions such as Liwa. Later I learned that two kinds, both relatively large, can often be found in the deserts of the UAE, although sadly from the point of view of study they are "hawkers" that tend to remain in flight continuously and seldom settle. One is the globe skimmer, *Pantala flavescens*, a pan-tropical dragonfly that is a strong migrant and often one of the first to show up in a "dry" area (desert, wadi or mountain) after rain. In January a lone female specimen patrolled very close to us as we sat in the shade of the car near midday among large dunes in the Umm Az-Zamool area. This is a medium size dragonfly that is often identifiable by the slightly "dipped" posture of its abdomen in flight. Females are a yellowish green; males may be more orange or reddish, with a bright yellow face. The other is the larger Vagrant Emperor, *Hemianax ephippiger*, also yellowish green, but with hints of blue in the male, which seems often to migrate in January and February. Most of the Emperor dragonflies in the collection at EAD (formerly ERWDA) in Abu Dhabi are of this species. In confirmation of prior experience, I have recently seen this species in the Huqf area of Oman (patrolling outside a roadside restaurant) and in Umm Az-Zamool (patrolling the landscaped surroundings of a guardhouse). I was able to confirm the identification of the Umm Az-Zamool species because one flew into the lantern in the archeologists' field camp there. It was swatted and dispatched by one of the workmen, but preserved for science and brought back to civilisation by former DNHG member John Martin, a member of the archeological team. Like the Globe Skimmer, the Vagrant Emperor is a strong migrant and

can be found throughout the UAE, not just in deserts. In mid-February, travelling home by taxi from a delightful tour of Bur Dubai's Temple Alley, I saw two individuals patrolling different patches of roadside landscaping within urban Dubai." (Author)] Address: Feulner, G., c/o Dubai Natural History Group, PO Box 9234, Dubai, UAE

9311. Feulner, G. (2007): Dragonflies at the Beach. *Gazelle, Dubai* 22(10): 6-7. (in English) [United Arab Emirates; "In early September of this year, on a visit to Hulaylah Island north of Rams, RAK, ... I encountered *P. flavescens* almost everywhere on the barrier island, despite the decidedly overgrazed and partly 'developed' landscape. We saw them swarming high in the air near large mesquite trees; around goat and camel pens; patrolling a partially fenced area that excluded camels (but not goats) and therefore had retained a low ground cover of the bristly *Heliotropium kotschy*; over more or less barren, overgrazed sand near a shallow lagoon with flamingoes (where the dragonflies seemed to seek out our vehicles as an intruder into their familiar surroundings; and even along the length of the 1 km jetty at the mouth of the inlet.) We found them active from 7 am until we ourselves departed at nearly noon." (Author)] Address: Feulner, G., c/o Dubai Natural History Group, PO Box 9234, Dubai, UAE

9314. Greenway, M.; Polson, C. (2007): Protecting aquatic ecosystem health: are water quality objectives realistic? Case studies from Queensland, Australia. *NOVATECH 2007*: 1747-1754. (in English, with French summary) ["Many regulatory authorities set water quality objectives or thresholds based on nutrient concentrations to safeguard aquatic ecosystem health. But do these criteria adequately assess the biological and ecological status? Our research has been focussing on the performance of constructed wetlands for water quality improvement and ecosystem health. In this paper we present data on macroinvertebrate species richness from two wastewater treatment wetlands and two stormwater treatment wetlands. Despite nutrient concentrations exceeding water quality objectives all four wetlands supported a diverse assemblage of macroinvertebrates, including sensitive taxa. From our study we concluded that water quality objectives may be too stringent and that aquatic plants are more important for macroinvertebrate richness. Thus, constructed wetlands are effective for both water quality improvement and aquatic biodiversity." (Authors) Taxa, including Odonata, are treated at the order level.] Address: Greenway, Margaret, School of Engineering, Griffith

(in French, with English summary) [Prior 2002, only 18 records of *C. bidentata* were available in Limousin (Corrèze and Haute-Vienne departments), France. In order to improve the knowledge about this species, an efficient method for searching larvae operating with a landing net was proposed. Within three years, this method led to the discovery of the species at ten additional sites.] Address: Guerbaa, K., Société Limousine d'Odonatologie, 11, rue Jauvion, F-87000 Limoges, France

9322. Manger, R. (2007): An unusual hibernator - *Sympecma paedisca*. *Vlinders* 1/2007: 4-6. (in Dutch, with English summary) ["In the Netherlands, there are two damselflies that hibernate as adult, *S. fusca* and *S. paedisca*. Both species are on the Red List; *S. paedisca* is critically endangered. Recent research on heathland in Drenthe into the hibernation and survival of *S. paedisca* has brought new facts to light. Being nondescript brown in colour, it is well camouflaged in its winter biotope. The adults can be found deep in grass tussocks in cold weather, but may fly when it is sunny. During hibernation, they stay put. Only half of the winter population survives. They do not reproduce here, despite water in the vicinity. In spring, they suddenly disappear. Wing marking at the reproduction sites showed that adults are able to fly large distances of up to 20 km. Eggs are laid in mid-April on dead vegetation, especially *Typha latifolia* and *Phragmites australis*, in lowland marshes. Perhaps these damselflies show migratory behaviour, spending eight or nine months on land and then flying in search of suitable waters to reproduce." (Authors)] Address: Manger, R., Stoepveldsingel 55, 9403 SM Assen. The Netherlands. E-mail: rmanger@planet.nl

9323. Matushkina, N.A. (2007): The morpho-functional adaptations in Lestidae (Odonata, Zygoptera) to the oviposition into plant substrates of different stiffness. Questions of aquatic entomology of Russia and adjacent lands: Materials of the Third All-Russia Symposium on Amphibiotic and Aquatic Insects. Voronezh State University. ISBN 978-5-9273-1169-9: 177-183. (in Russian, with English summary) ["Several morpho-functional peculiarities of ovipositors in five lestids species, *Sympecma paedisca*, *Lestes virens*, *L. sponsa*, *L. barbarus*, and *Chalcolestes parvidens*, are listed, in part on the basis of this author's earlier studies. Some of the found modalities of the ovipositor's skeletal musculature and the insect's oviposition behaviour were considered as possible adaptations to oviposition into plants of different stiffness. The problems and methodology of such complex research, as well as the phylogenetic significance of some obtained results, are briefly discussed." (2007): Effects of pesticides on community structure and ecosystem functions in agricultural streams of three biogeographical regions in Europe. *Science of the Total Environment* 382: 272-285. (in English) ["There is a paucity of large-scale field investigations on the effects of organic toxicants on stream macroinvertebrate community structure and ecosystem functions. We investigated a total of 29 streams in two study areas of France and Finland for pesticide exposure, invertebrates and leaf-litter breakdown. To link pesticide exposure and community composition we applied the trait-based Species At Risk (SPEAR) indicator system. In the French region, pesticide stress was associated with a decrease in the relative abundance and number of sensitive species in the communities. The presence of undisturbed upstream reaches partly compensated the effects of pesticide contamination. Functional effects of pesticides were identified by a 2.5-fold reduction of the leaf-litter breakdown rate that was closely correlated with the structural changes in the contaminated streams. No effects of pesticides were observed in Finnish streams since contamination with pesticides was very low. In a follow-up analysis, the SPEAR approach successfully discriminated between reference and contaminated sites across different biogeographical regions, also including results of a previous field study in North Germany. Furthermore, change of the community structure was detectable at a concentration range as low as 1/100 to 1/1000 the acute 48 h-LC50 of *Daphnia magna*. Our findings demonstrate that pesticides may influence the structure and function of lotic ecosystems and that the SPEAR approach can be used as a powerful tool in biomonitoring over large spatial scales." - 9346.** Breton, F. (2008): Phénomènes migratoires chez *Sympetrum fonscolombii* (Selys, 1840) dans les Alpes du Sud (Odonata, Anisoptera, Libellulidae). *Martinia* 24(4): 113-128. (in French, with Italian and English summary) [The paper compiles older observations on migration of *S. fonscolombii* across the European Alps (and the Pyrenees). More systematic observations were made between 2003 and 2007 along the southwestern Alps situated along the border between Italy and France, analysing 38 records of - in most cases - southwards directed late summer-autumn migrations. "These irregular migrations, which could concern several millions of individuals, seem to be initiated by massive emergences in the Italian region of Piémont, starting at the end of July. The most observed direction is toward north-west and south, sometimes toward west and south-west. The environmental conditions which release these migrations are debated." (Authors)] Address: Breton, F., Parc national du Mercantour, Franc. E-mail: francois.breton@espaces-naturels.fr
- 9347.** Collen, B., Ram, M., Dewhurst, N., Clausnitzer, V., Kalkman, V., Cumberlidge, N. and Baillie, J.E.M. (2008): Broadening the coverage of biodiversity assessments. In: J.-C. Vié, C. Hilton-Taylor and S.N. Stuart (eds). *The 2008 Review of The IUCN Red List of Threatened Species*. IUCN Gland, Switzerland. 9 pp. (in English) [Verbatim: "Box 4: Threats to dragonflies and damselflies: a. Restricted range - damselflies: The Pemba Featherleg *Platycnemis pembipes*, a fragile black and white damselfly was first discovered in 2001 on the island of Pemba off the Tanzanian coast. Remarkably its nearest relatives occur on Madagascar, separated by 1,000 km of ocean. Although the species might have reached Pemba aided by strong monsoon winds, recent studies suggest it may be the survivor of an ancient African fauna that is now largely confined to Madagascar. The species only inhabits the single stream flowing through Pemba's last remnant of forest and is listed as Critically Endangered. The Pemba Featherleg shares this fate with two other East African damselflies of unknown origin. *Amanipodagrion gilliesi* (Critically Endangered) survives on a single stream in Tanzania's Usambara Mountains. It shares no similarities with any other known species. Equally unique is *Oreocnemis phoenix* (Critically Endangered), named for its bright red males. Streams on the high plateau of Mount Mulanje in Malawi, known aptly as 'the island in the sky' and a mere 24 km across, are its only known habitat. The plateau is made up of bauxite deposits: mining these would significantly impact the habitat. b. Climate change impact on the Ancient Greenling *Hemiphlebia mirabilis*: The Australian endemic damselfly *Hemiphlebia mirabilis* (Endangered), the Ancient Greenling, is notable for its apparent archaic characters, its male mating displays and its biogeography. Originally thought to have been a Victorian endemic, the species was subsequently found in northeastern Tasmania and then on Flinders Island.

This suggests that the species would have occupied the Bassian Ridge when it was exposed during glacial times and this may have been a dispersal route at some time. The species is cryptic within its reed habitat except when the males in particular display by waving their expanded, white anal appendages. The species breeds in open, sedge marshes with a low water level and seems to be capable of recolonizing habitats when they have become dry, probably surviving in the egg stage. In recent times, however, dry spells are longer and more frequent due to climate change and they pose a severe threat to this already rare species. The Ancient Greenling is not the only Australian dragonfly to be affected by climate change and it seems likely that dry spells will become a major driver for decline in the near future." 9348. COSEWIC/COSEPAC; Harris, A.; Foster, R. (2008): COSEWIC. 2008. COSEWIC assessment and status report on the Rapids Clubtail *Gomphus quadricolor* in Canada. Committee on the Status of Endangered Wildlife in Canada. Ottawa (www.sararegistry.gc.ca/status/statuse.cfm). ISBN 978-0-662-48813-2: vi + 35 pp. (in English) ["Species information: *Gomphus* (*Gomphus*) *quadricolor* Walsh 1863, Rapids Clubtail, is a member of the family Gomphidae, the clubtail dragonflies. It is a small dragonfly, with a wingspan of 25-27 mm and a contrasting pattern of brownish-black and yellowish-green stripes on the thorax. The abdomen is slender, but in males is expanded slightly at the tip. Distribution: The range of *Gomphus quadricolor* includes Ontario and 25 states in the northeastern and northcentral U.S. The global maximum extent of occurrence encompasses about 1.7 million km². In Canada, it was historically known from four sites in southern and eastern Ontario, but is extant at only two sites. Its extent of occurrence in Canada is about 1570 km² and its area of occupancy is approximately 26 km². Habitat: Larvae live in muddy pools in clear, cool streams. Adult males perch on rocks in rapids. Adult females inhabit forests on the riverbanks, moving to the rapids when ready to mate. Biology: Adult *Gomphus quadricolor* fly between early June and early July in Ontario and live about three to four weeks. Mating takes place over the river and females deposit eggs on the water surface over rapids. Eggs or recently hatched larvae are carried downstream to pools. Larvae spend most of their time buried just below the surface of the sediment in the bottom of the pool, breathing through the tip of the abdomen raised above the sediments. The duration of the larval stage of *Gomphus quadricolor* is unknown, but is probably two or more years. Before the final moult, larvae crawl onto vegetation on the edge of the stream. Newly emerged adults disperse inland to avoid predation until the exoskeleton hardens and they are able to fly swiftly." 9350. Cremona, F.; Planas, D.; Lucotte, M. (2008): Biomass and composition of macroinvertebrate communities associated with different types of macrophyte architectures and habitats in a large fluvial lake. *Fundamental and Applied Limnology - Archiv für Hydrobiologie* 171/2: 119-130. (in English) ["The influence of macrophyte habitat and architecture on macroinvertebrate biomass, abundance, and richness was investigated in Lake St. Pierre, a large fluvial lake of the St. Lawrence River (Quebec, Canada). A lake-wide estimate of macroinvertebrate biomass associated with different macrophyte habitats was also calculated in order to assess the quantitative effects of vegetation changes on macroinvertebrate communities. For two years during the ice-free period, phytophilous macroinvertebrates were sampled in macrophyte beds comprising more than ten species of plants and three habitats (emergent, floating-leaved, submerged), and in three submerged macrophyte architectures based on plant morphology (simple, intermediate, and complex). Invertebrate sub-samples were classified into four functional groups (detritivore, grazer, crawling predator - including not further specified Odonata -, diving predator). Biomass and density of invertebrates were expressed per unit of plant dry weight. The main findings are that macroinvertebrate biomass, abundance and richness were significantly greater in submerged than in emergent and floating-leaved habitats. However, macrophytes with a complex architecture did not host significantly greater macroinvertebrate biomass than plants with a simpler architecture. This could be related to substrate preferences of herbivores (mostly Gastropoda) toward the tape grass *Vallisneria americana*. Differences in macroinvertebrate abundance and biomass were found between the two years associated with variations in the river water level. During the year with average water level, total macroinvertebrate biomass was 16 % greater than in the year with a lower water level. We conclude that a reduction in the water level of Lake St. Pierre, predicted to occur with climate change, could lead to a decrease in benthos biomass which constitutes a crucial food source for fish."
